$\lvert q^{-1}(w)\rvert$	1	2	3	4	5	6
$\#\{w\}$	132	66	18	3	6	18

and

seed weight	144	288	432	576	864	1008	1440	1944	2088
$\#\{w\}$	120	54	18	9	15	6	3	12	6.

For the three words distinguished by the reader, one obtains

	μ_{468}	μ_{seed}
π	5/468	7/729
e	1/468	1/729
φ	1/468	1/729.

Proof. Invariance under the symmetric group assigns equal masses to all points of E_{468}; normalization fixes them at $1/468$. The formula for the pushforward measure follows by summing over each fiber. The same argument applied to the seed set yields the second measure. The histograms are obtained by exhaustive enumeration of the finite catalogue of 468 emissions and 243 words; their sums verify

$$132 + 66 + 18 + 3 + 6 + 18 = 243,$$

$$132 + 2 \cdot 66 + 3 \cdot 18 + 4 \cdot 3 + 5 \cdot 6 + 6 \cdot 18 = 468$$

and the sum total of the weights is 104 976. □

The nonuniformity of the pushforward measure is a finite theorem: distinct words have different numbers of realizations. Conversely, no normalizable uniform probability exists on all of $\mathbb{R}$, and these measures do not intrinsically order all the reals. The word for π belongs to one of the six fibers of size five and weight 1008; it is not the unique maximum of either histogram. Its proved singularity arises from the composite structure of its five regions, from its oriented partition $3 + 2$, and from its subsequent compatibilities, not from declaring an absolute probability on the continuum a priori.

53.11 Selector orbital finite preceding the Archimedean reader

The preceding measures reveal multiplicities, but an isolated six-trit word still depends on an orientation. The catalog has an internal symmetry that allows unoriented classes to be selected first and a representative to be fixed afterward. Write a word as $abc \mid def$ and define

$$r(abc \mid def) = cab \mid efd, \qquad s(abc \mid def) = def \mid abc.$$

These permutations also act on the six coordinates of the datum U_6. In the complete catalog, they satisfy

$$r^3 = 1, \qquad s^2 = 1, \qquad srs = r^{-1},$$

and hence they generate an action denoted by D_3^{cat}. The action uses the fixed TRIT labeling

$$\Psi(U_6) = (-U_6 \bmod 3)$$

and the published partition of the six coordinates into two triads.

For a word w, let $f(w) = |q^{-1}(w)|$ be the number of emissions, $m(w)$ its seed mass, and

$$\nu(w) = (n_0(w), n_1(w), n_2(w))$$

its ordered census of trits. Also let $d(e)$ be the additive diagonal class of an emission and $o(e) \in \{\mathrm{ES}, \mathrm{NO}\}$ its published orientation.

Theorem 53.14 (Internal orbital selection of the three words)**.** *The action D_3^{cat} preserves the set of* 468 *emissions, the projection $q : E_{468} \to W_{243}$, and the seed multiplicity. Its action on W_{243} has exactly* 43 *orbits:* 38 *of size six and five of size three. The following uniqueness statements hold within that quotient.*

1. *There exists a unique orbit $\mathcal{O}_\pi$ of size six such that, for every $w \in \mathcal{O}_\pi$,*

$$f(w) = 5, \qquad m(w) = 1008, \qquad \{m(e) : e \in q^{-1}(w)\} = \{432, 144, 144, 144, 144\}.$$

   It is

$$\mathcal{O}_\pi = \{001112, 010211, 100121, 112001, 121100, 211010\},$$

   and all its words have census $\nu = (2, 3, 1)$.

2. *Consider the orbits of size six whose words have a single emission, of multiplicity* 144*, and whose joint diagonal support is $\{0, 3, 6\}$. There are exactly six. Among them there is a unique orbit with the same census $(2, 3, 1)$ of $\mathcal{O}_\pi$:*

$$\mathcal{O}_e = \{011120, 012110, 101201, 110012, 120011, 201101\}.$$

3. *In the same sector there exists a unique balanced orbit, that is, with $\nu = (2, 2, 2)$:*

$$\mathcal{O}_\varphi = \{002112, 020211, 112002, 121200, 200121, 211020\}.$$

   Finally, the guiding clause

$$\exists e \in q^{-1}(w) : \qquad d(e) = 6, \qquad o(e) = \mathrm{ES} \tag{53.7}$$

select a single representative from each orbit and produces, respectively,

$$\boxed{010211, \qquad 201101, \qquad 121200.}$$

Proof. The group relations are verified directly as identities of permutations of six coordinates. Enumeration of the 468 rows verifies that r and s send every U_6 to another row of the catalogue with the same multiplicity, and that ternary projection commutes with both actions. Therefore, the orbits can be computed on the 243 words without losing the fibers.

The exhaustive partition gives the size histogram.

$$38 \cdot 6 + 5 \cdot 3 = 243.$$

Filtering those 43 orbits by the first predicate leaves exactly one; filtering by singleton fiber, minimum multiplicity, and diagonal support $\{0, 3, 6\}$ leaves six. The census $(2, 3, 1)$ leaves a single orbit in the first case, and the balanced census $(2, 2, 2)$ leaves a single orbit in the second. Finally, the search for a lift with $d = 6$ and orientation ES leaves one word in each of the three orbits. All filtrations are performed on structural descriptors of the catalogue before consulting the decimal reader. □

The predicates of the theorem may be combined into a selection invariant. For an orbit $\mathcal{O}$, we define its *orbital profile*

$$\Sigma_{\mathrm{cat}}(O) = \big(|O|,\ f,\ m,\ \mathcal{M}_{\mathrm{fib}},\ \mathcal{D},\ \nu\big),$$

where f is the fibre size, m the seed mass, $\mathcal{M}_{\mathrm{fib}}$ the multiset of multiplicities of their lifts, $\mathcal{D}$ the diagonal support when used, and ν the trit census. The three distinguished classes occupy different positions in this invariant space:

O	$\lvert O\rvert$	f	m	$\mathcal{M}_{\mathrm{fib}}$	$(\mathcal{D}, \nu)$
O_π	6	5	1008	$\{432, 144, 144, 144, 144\}$	$(-, (2, 3, 1))$
O_e	6	1	144	$\{144\}$	$(\{0, 3, 6\}, (2, 3, 1))$
O_φ	6	1	144	$\{144\}$	$(\{0, 3, 6\}, (2, 2, 2))$.

The demonstrated singularity does not mean that these numbers receive an absolute probability over $\mathbb{R}$. It means that, within the finite universe produced by the emitter and before evaluating digits, their classes are separable by internal invariants and that the class of π has a regional fiber of a different type. This is the mathematical formulation of a structural priority in HMT.

The negative control is informative. If the diagonal support $\{0, 3, 6\}$ is omitted, there exist four balanced singleton orbits and O_φ ceases to be unique. Before the gauge is fixed, each orbit admits six possible orientations. Once it is fixed, the word of π preserves three positive lifts of U_6, rather than a single region. Thus, the theorem selects the oriented word while respecting the geometric multiplicity of the five regions.

The non-uniformity is reinforced when passing to orbits:

	emissions	seeds
O_π	5/78	14/243
O_e	1/78	2/243
O_φ	1/78	2/243.

These quotients remain masses in the finite catalog, not probabilities assigned to the evaluated real numbers.

The causal advance is precise. The three words cease to be named inputs: they are recovered from the symmetry and finite invariants of APP–TPK, relative to the action D_3^{cat}, the TRIT labeling, the distribution $3+3$, and the orienting gauge equation (53.7). The proof uses neither L_0, L_1, decimal digits, α, CODATA, nor the dodecaphasic state. The absolute uniqueness of that action among all possible automorphisms, the deduction of the gauge rather than its declaration, the canonicity of the reader L_0/L_1 independently of the target value, and the coinductive emission of the infinite expansions remain subsequent claims.

53.12 Position of π, e, φ and α in the classification

The theorem 53.1 explains why any decimal prefix can be re-emitted from a 3-adic state: the raw capacity is universal. Therefore, the mere back-and-forth operation on a tape selects no constant. The distinctive content of the published construction lies in the objects preceding and following that re-emission:

1. the finite fibers and the five distinct regions of π;
2. the typed Archimedean reader that associates words, cylinders, and blocks;
3. the dodecafase signed and the closure reversible

$$U_{12}^{\mathrm{sgn}} \longleftrightarrow K \longleftrightarrow (D_3K, D_4K, Q) \longleftrightarrow \alpha_{\mathrm{HMT}};$$

4. the contrast criteria that distinguish an equivalence of charts from a selector preceding evaluation.

The twelve published decimal triples of π, e, φ are exact finite coordinates of the enriched reader. The printed string of thirty-six digits is the rational dodecaphasic projection $\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}})$:

$$\frac{729735256928380099728510547238066 3}{10^{36}}.$$

The exact identity in this window is

$$\alpha_{12} := \pi_{12}(\alpha_{\mathrm{HMT}}) = \frac{729735256928380099728510547238066 3}{10^{36}}.$$

The compatible recurrence at arbitrary depth constructs the infinite section

$$\alpha_{\mathrm{HMT}} := \varprojlim_{N} A^{(N)},$$

and each rational window is an exact projection of that same object. The kernel $E_{21/22}$ constructs, in another chart, the finite simple positive root α_E; the graded transport of the TPK extends that kernel into a compatible family whose limit root is α_B. If $\alpha_A := \varprojlim_N \rho_N(\alpha_{12})$, the truncation squares of the two families commute and determine the same surviving cylinder at each depth. The exact two-way theorem therefore establishes

$$\boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}.$$

The equality of $\mathrm{Tr}_9(\alpha_E^{-1})$ and $\mathrm{Tr}_9(\alpha_{12}^{-1})$ is the first finite certificate of that identity; it neither defines it, limits its scope nor selects the extensions. The typed projection keeps the coinductive section, its rational window and the analytic root distinct without separating their identity in the limit.

The square root of -1 belongs to another chart. In the section 3.5, one constructs

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1), \qquad \iota^2 = -1,$$

and the Witt matrix is proved to realize that quadratic structure. This is an exact finite algebraic extension, not a visible category of real expansions.

53.13 Previous chart, inductive survival, and construction of the global boundary

The following controls are falsifiers of the preceding finite results:

1. that two states distinct modulo 3^T emit the same word of T blocks, or that there is a word without a preimage;
2. failure of the explicit inverse of equation (53.2);
3. that a rational number should appear whose canonical expansion is not eventually periodic, or an irrational number whose expansion is periodic;
4. that a finite deterministic emitter produces a tape that is not eventually periodic;
5. that the catalog censuses do not sum to 468, 243, and 104 976, or that the measures of the three words do not agree with the enumeration.

The raw Hensel chart

$$\mathbb{Z}_3^6 \longrightarrow [0, 1]$$

is continuous and surjective; upon adjoining the integer part, its raw atlas covers $\mathbb{R}$. This exact result does not imply that every raw fiber contains a representative that survives the additional filters. The published finite windows and the named readers of π, e, φ are verified within HMT, relative to their seeds, regions, orientations, and enriched rules.

The positional representation of a number records a sequence of symbols, but does not necessarily preserve the state determining its continuation. Triadic Modular Holography distinguishes the two levels. Nonadic phase indicates the position of a reading within the nine-step cycle; the enriched state additionally

preserves orientation, Euclidean quotient, carry transport, and boundary condition. Return of the phase does not therefore imply return of the state.

Let S be a space of enriched states, let $T : S \to S$ be a transition, and let

$$g : S \longrightarrow \mathbb{Z}/9\mathbb{Z}$$

the phase, with $g(Ts) = g(s) + 1$. For a basis $b \geq 2$, a reader $d : S \to \{0, \dots, b-1\}$ produces

$$x(s) = \sum_{n \geq 0} \frac{d(T^n s)}{b^{n+1}}.$$

When a value admits the two usual positional expansions, we adopt the canonical representation that does not end in a constant tail $b - 1$. This convention distinguishes an ambiguity of notation from multiplicity proper to HMT, which arises from distinct enriched sections having the same evaluation. The nonadic return operator is the restriction

$$M = T^9 : g^{-1}(r) \longrightarrow g^{-1}(r).$$

The difference between $T^9 s = s$ and $g(T^9 s) = g(s)$ formalizes the distinction between periodicity and monodromy.

The transition of the enriched state of TPK may be given by a relation rather than a function. In that case, the preceding notation applies to the shift on the space of infinite histories or to a deterministic realization whose state has been enlarged with the information necessary to fix the continuation; it is not presupposed that a visible block has a unique successor.

Definition 53.15 (HMT Number and Arithmetic Presentation)**.** An HMT number is solely a compatible section $\boldsymbol{x}$ of the inverse system of surviving states. Given a positional reader L whose domain contains $\boldsymbol{x}$, the pair $(\boldsymbol{x}, L)$ is a presentation or measurement of the number. The Archimedean value published by that presentation is the singleton intersection of the associated cylinders when their diameters tend to zero. Two sections with the same value are not identified before applying the Archimedean quotient.

Definition 53.16 (Visible and enriched periodicities)**.** The output is eventually periodic when there exist $N \geq 0$ and $p > 0$ such that

$$d(T^{n+p} s) = d(T^n s), \qquad n \geq N.$$

The state is eventually periodic when

$$T^{N+p} s = T^N s.$$

The second condition implies the first. The converse requires that the reader separate the tails of the orbit under consideration, that is, that

$$\big(d(T^{n+k} s)\big)_{k \geq 0} = \big(d(T^{m+k} s)\big)_{k \geq 0} \quad \Longrightarrow \quad T^n s = T^m s.$$

Theorem 53.17 (Classification by phase return)**.** *Let $s \in S$.*

1. *If the orbit of s reaches a state whose future output is constantly null, then $x(s)$ has a terminating expansion and is rational.*
2. *If the state is eventually periodic, then the output is eventually periodic and $x(s) \in \mathbb{Q}$.*
3. *If the reader separates the tails of the orbit and the orbit of s is not eventually periodic, then the output is not eventually periodic and $x(s) \notin \mathbb{Q}$.*
4. *Nonperiodicity does not distinguish between algebraic irrationality and transcendence. This distinction requires a polynomial certificate or an additional transcendence theorem.*

Proof. The first two parts are the classical characterization of the rationals through terminating or eventually periodic positional expansions. In the third, eventual periodicity of the output would produce two identical tails. The separation hypothesis would then identify the corresponding states, contradicting the nonperiodicity of the orbit. The fourth part follows from the existence of algebraic and transcendental irrationals with expansions that are not eventually periodic. □

Corollary 53.18 (Nonadic Monodromy and Aperiodicity)**.** *Suppose that the phase returns every nine steps, that the return orbit*

$$\{M^k s : k \geq 0\}, \qquad M = T^9,$$

is not eventually periodic and the reader separates the tails. Then the output is not eventually periodic, and the number produced is irrational. In this case, phase periodicity coexists with an aperiodic evolution of the enriched state.

The hypothesis cannot be replaced by a single inequality $M(s) \neq s$, nor by a finite number of distinct returns. Relative to the initial state, the declared transition and reader, the current window certifies nine phase returns with change of state; it proves finite monodromy, but not by itself the aperiodicity of the entire orbit.

53.14 Classification of constants by genealogical antecedent, generating operation, and codomain

The HMT classification separates properties that the ordinary representation brings together under a single value:

Class	Structural condition
Definitive	The output reaches a null tail.
Rational periodic	The output is eventually periodic.
Rational monodromy	The output is periodic, but the enriched state traverses a nontrivial fibre that the visible reader forgets.
Irracional coinductivo	The output is not eventually periodic and the cylinders determine a unique value.
Recurrente local	A finite word contains returns or squares, without this imposing periodicity on the suffix.
Algebraic	The value satisfies a nonzero polynomial with integral coefficients; the route must be accompanied by that certificate.
Transcendent	The value satisfies no nonzero integer polynomial; the classification requires a transcendence theorem.
Distinguido HMT	The section satisfies a frozen structural predicate of fiber, boundary, survival, or symmetry; it is a class transverse to the preceding ones.

Thus, HMT does not alter the correct arithmetic definitions of rationality, algebraicity, and transcendence. It refines them by adding the genealogy of the state, phase monodromy, and the multiplicity of the fibers that Archimedean evaluation had forgotten.

In particular, φ is algebraic because it satisfies $X^2 - X - 1 = 0$, whereas the transcendence of e and π follows from classical external theorems. These properties are compatible with the three sections being distinguished by HMT. The dodecaphasic closure later constructs the exact rational projection $\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}})$, and the compatible prolongation constructs the coinductive section α_{HMT}, in section 30.14; neither is used in this taxonomy as an input or published here as a second residence. The kernel $E_{21/22}$ produces a distinct analytic root, whose agreement with the integer route is proved in the codomain of Tr_9. Section, rational projection, analytic root, reader and value thus retain their own types.

Finally, an "infinitesimal direction" requires its own typing. For a finite reader r_m, two distinct sections in the same fiber of r_m define a difference that is invisible at depth m, although active in a subsequent prolongation. They do not thereby constitute a nonzero infinitesimal real. If two sections coincide under every faithful truncation of the inverse system, they are the same section. A genuine arithmetic infinitesimal would require the construction of an ordered or valued non-Archimedean extension and proof that the HMT operations descend to it.

53.15 Number as a compatible section: arithmetic classification, Archimedean evaluation, and genealogy

The numerical classification of HMT preserves the ordinary arithmetic species and adds a coordinate that positional evaluation discards: the genealogy of the section that publishes the value. The result is a joint classification. The first axis answers which number is obtained; the second records by which compatible sequence of states, returns, carries, and closures it is obtained. This distinction makes it possible to formulate within a single language integers, rational expansions, irrationals, the imaginary unit, regularizations, and spectral constants without identifying objects that only share a scalar.

53.15.1 Archimedean evaluation separates the section from its value

Let

$$X_\infty^{\mathrm{surv}} = \varprojlim_n X_n^{\mathrm{surv}}$$

an inverse system of surviving states with its restriction maps. A compatible section is a family $\boldsymbol{x} = (x_n)_{n\geq 0}$ satisfying $\rho_{n+1,n}(x_{n+1}) = x_n$ at every depth. A positional reader L assigns a cylinder $I_n(\boldsymbol{x}; L)$ to each prefix. When the cylinders are compatible, their diameters converge to zero and the convention for endpoints is fixed canonically, one defines

$$\mathrm{Val}_L(\boldsymbol{x}) := \text{the point of } \bigcap_{n\geq 0} \overline{I_n(\boldsymbol{x}; L)}. \tag{53.8}$$

Definition 53.19 (Number, presentation and value in HMT)**.** An *HMT number* is a compatible section $\boldsymbol{x} \in X_\infty^{\mathrm{surv}}$. The pair $(\boldsymbol{x}, L)$ is a *presentation* of the number, and $\mathrm{Val}_L(\boldsymbol{x})$ is the value published by that presentation. The fibre

$$\mathrm{Val}_L^{-1}(r)$$

preserves the genealogies that the Archimedean quotient represents by the same value r.

The capacity of the chart and selection of a section are distinct typed results. The theorem 53.5 constructs a continuous surjective map

$$P_{\mathrm{raw}} : \mathbb{Z}_3^6 \longrightarrow [0, 1],$$

and the corollary 53.6 globalizes it to

$$\widehat{P}_{\mathrm{raw}} : \mathbb{Z} \times \mathbb{Z}_3^6 \longrightarrow \mathbb{R}.$$

These maps prove the complete representational capacity of the raw chart. The survival predicate and the readers that distinguish π, e, φ select, within that capacity, the corresponding structural genealogies.

53.15.2 Termination and periodicity determine rationality

For the expansion canonica in basis mil

$$x = \sum_{n \geq 1} \frac{b_n}{1000^n}, \qquad b_n \in \{0, \dots, 999\},$$

one adopts the convention that eliminates the duplication produced by an eventually constant tail of blocks 999. The theorem 53.7 then provides the following exact classification.

Theorem 53.20 (Visible classification in the cubic decimal chart)**.** *Let $x = a/q \in [0, 1)$ be an irreducible fraction when x is rational. Then:*

1. *the expansion terminates if and only if $q \mid 1000^N$ for some N, an equivalence restricting the prime factors of q to 2 and 5;*
2. *the expansion is eventually periodic if and only if $x \in \mathbb{Q}$;*
3. *the expansion is not eventually periodic if and only if $x \in \mathbb{R} \setminus \mathbb{Q}$.*

Algebraicity and transcendence constitute a second axis: a real number is algebraic if it is a zero of a nonzero polynomial in $\mathbb{Q}[X]$, and is transcendental if it is a zero of none.

Proof. An expansion of length N has a denominator dividing 1000^N, and the converse is obtained by expressing a/q with that denominator. For a rational number, successive division has a finite set of remainders: a zero remainder produces termination, and repetition of a remainder produces periodicity. A periodic tail is, conversely, a rational geometric series. The polynomial classification is independent of the positional base. □

The enriched dynamics also distinguishes output periodicity from state periodicity. If T transports the state and d publishes a block, the conditions

$$d(T^{n+p}s) = d(T^n s), \qquad T^{n+p}s = T^n s$$

define, respectively, visible-phase return and state return. The second implies the first. The inverse implication requires the reader to separate the tails of the orbit, according to theorem 53.17. Therefore, a periodic nonadic phase nonadic periodic can transport a nonperiodic memory periodic.

Table 53.1: Joint taxonomy of the published value and the enriched state.

Class	Condition on the value	Genealogical condition or required proof
Integer	Element of $\mathbb{Z}$.	Finite and unique balanced ternary word; sign and magnitude remain typed.
Decimal finito	A rational number whose reduced denominator divides some power of 1000.	The output reaches a null tail.
Rational periodic	Expansion that is eventually periodic.	An eventually periodic state suffices; a periodic output may preserve an additional internal fibre.
Rational monodromic	Same rational value as the previous row.	The output returns while the enriched state traverses a fiber that the visible reader forgets.

Class	Condition on the value	Genealogical condition or required proof
Irracional coinductivo	Expansion that is not eventually periodic.	An infinite family of compatible cylinders fixes a unique value; global aperiodicity requires a proof over the entire orbit, not a finite window.
Algebraic	Root of a polynomial no zero of $\mathbb{Q}[X]$.	The polynomial is appended and its vanishing is verified.
Transcendent	Real external to the closure algebraic of $\mathbb{Q}$.	A transcendence theorem is appended; decimal nonperiodicity by itself only proves irrationality.
Distinguido HMT	Any of the preceding arithmetic classes.	The section satisfies a frozen fiber, boundary, survival, symmetry, or closure predicate.

This table locates on different axes two questions that must be answered separately. Ordinary classification determines the properties of the value; the HMT reader determines the structural chain generating the section. For example,

$$\varphi^2 - \varphi - 1 = 0$$

classifies φ as an algebraic irrational, whereas the transcendence of e and π belongs to external classical theorems. All three may simultaneously be sections distinguished by different HMT predicates. Their printed truncations of one thousand or ten thousand digits are finite rationals that demonstrate the calculated prefixes of a prolongable output; they do not replace the infinite object they represent.

The dodecaphase closure defines, in turn, the finite rational projection

$$\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}}) = \frac{729735256928380099728510547238 0663}{10^{36}}. \tag{53.9}$$

This projection is exact and rational. The object $\alpha_{\mathrm{HMT}} = \varprojlim_N A^{(N)}$ is the infinite section constructed by the compatible recurrence; its rational truncations do not replace it. The structural derivation of the limit and the classification of each finite projection are complementary statements.

53.15.3 The balanced ternary chart represents the integers bijectively

Let

$$\mathscr{W}_{\mathrm{bal}} = \{\varnothing\} \cup \{a_1 \cdots a_m : a_j \in \{-1, 0, +1\},\ a_1 \neq 0\}$$

and define

$$b(\varnothing) = 0, \qquad b(wa) = 3b(w) + a.$$

The theorem 53.3 demonstrates that

$$b : \mathscr{W}_{\mathrm{bal}} \xrightarrow{\sim} \mathbb{Z} \tag{53.10}$$

is a bijection. The final trit is the unique representative of the class modulo three, and the quotient $(n - a)/3$ strictly reduces the absolute value until zero is reached. The first nonzero trit fixes the sign. This chart is a representation that is exact and arithmetic; the membership of a word in a surviving section additionally incorporates the conditions of route, orientation, and boundary.

For $n > 0$, the coordinates

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad \kappa_9(n) = \frac{n - \rho_9(n)}{9}$$

realize the decomposition $n = 9\kappa_9(n) + \rho_9(n)$. The phase $\rho_9 \in \{1, \dots, 9\}$ publishes the zero residue class as 9, and κ_9 preserves the number of turns. With the sign $\varepsilon \in \{-1, +1\}$,

$$n \longleftrightarrow \big(\varepsilon, \kappa_9(|n|), \rho_9(|n|)\big)$$

is bijective on $\mathbb{Z} \setminus \{0\}$; zero remains the base point. The visible-phase return $9 \to 1$ is thus a phase transition with memory advance, not an identification of consecutive integers.

53.15.4 Finite complex structure induced by the Witt endomorphism $J^2 = -I_6$

The ordinary imaginary unit is the element $i \in \mathbb{C}$ satisfying $i^2 = -1$; it is algebraic of degree two over $\mathbb{R}$ and over $\mathbb{Q}$. The HMT realization belongs to a different finite domain. If C_P is the Paley conference matrix and $J = A_W$ its reduction modulo three in $\mathrm{End}_{\mathbb{F}_3}(\mathbb{F}_3^6)$, then

$$\boxed{J^2 = 2I_6 = -I_6.} \tag{53.11}$$

Since $X^2 + 1$ is irreducible over $\mathbb{F}_3[X]$, the extension

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1)$$

separates the eigenspaces of J associated with $\pm\iota$. The result, proved in chapter 32, endows the ternary module with a finite complex structure and organizes two conjugate orientations. Its force is *internally exact, proved using the declared Paley–Witt matrix*; the comparison with $\mathbb{C}$ preserves the distinction between the two fields.

53.15.5 6 operators realize the rational $-1/12$ on distinct domains

Zeta regularization assigns to the sequence of positive integers the finite part obtained by meromorphic continuation:

$$\sum_{n\geq 1}^{[\zeta]} n := \zeta(-1) = -\frac{1}{12}. \tag{53.12}$$

The superscript $[\zeta]$ forms part of the type of the expression. The ordinary partial sum satisfies $\sum_{n=1}^{N} n = N(N+1)/2$ and grows without bound; therefore (53.12) is a regularized value, not the limit of those partial sums.

HMT additionally contains six exact algebraic realizations of the same rational number. Scalar coincidence permits their comparison; each object retains its domain, map, and normalization.

Table 53.2: Typed realizations of $-1/12$.

Domain	Map and evaluation	Conclusion and normalization
Marked hexad–octad incidence	$F_6 \hookrightarrow F_8$, with $\lvert F_6\rvert = 90$, $\lvert F_8\rvert = 120$, and $(90 - 120)/(24\binom{6}{2}) = -1/12$.	Exact combinatorial defect for the declared normalization.

Domain	Map and evaluation	Conclusion and normalization
Dodecaphase periodicities	To step of 30° produce $$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3}, \\ = -\frac{1}{12}.$$	Exact oriented difference of periods.
Gram Operator	For $K_{60,81} = \operatorname{diag}(0, 12)$, the pseudoinverse on the nonzero range is $1/12$; the negative orientation publishes $-1/12$.	Exact operator identity on the non-vanishing component.
Second scale difference	The calculo produce $C(L) = 8/81$ and the extractor declarado $R(L) = -(27/32)C(L) = -1/12$.	Exact after fixing the normalization factor $-27/32$; that factor is an explicit primitive.
Modular quotient eta	$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12} \\ \times \prod_{n\geq 1}(1 + q^n + q^{2n})^{-1}.$$	exponent modular exact, procedente of $1/24 - 3/24$.
Projectors of the twelve-phase cycle	For $D_r = I - S^r$, $$\tau(\Pi_{\ker D_3} - \Pi_{\ker D_4}) = \frac{3-4}{12}, \\ = -\frac{1}{12}.$$	Exact transverse defect between steps three and four.

The six realizations are proved in chapter 33. Zeta regularization, the incidence defect, the pseudoinverse, the scale extractor, the eta quotient, and the trace of projectors are different maps. An identification of their domains would require an additional intertwiner. Likewise, the term $+1/12$ of the Glaisher–Kinkelin formula belongs to the regularization of the hyperfactorial and retains that distinct type.

53.15.6 Multiplicative decomposition of primes as irreducible modes of the TPK

An ordinary prime is an integer $p > 1$ whose factorizations $p = ab$, with $a, b \in \mathbb{N}$, necessarily contain a unit. The reduced coproduct

$$\Delta_{\times}^{\mathrm{red}} e_n = \sum_{\substack{ab=n \\ a,b>1}} e_a \otimes e_b$$

turns that definition into a spectral selector. According to theorem 27.21, the positive operator

$$N_{\times}^{\mathrm{red}} = (\overline{\Delta_{\times}^{\mathrm{red}}})^{*}\overline{\Delta_{\times}^{\mathrm{red}}}$$

satisfies $N_{\times}^{\mathrm{red}} e_n = d_{\mathrm{red}}(n) e_n$, and its kernel, after removing e_1, selects exactly the primes. The multiplicative intertwiner transports the same selector to the native product of APP. This selector is the spectral projection onto $\ker N_{\times}^{\mathrm{red}} \ominus \mathbb{C}e_1$, which coincides exactly with the subspace generated by the primes and does not depend on recognizing decimal lists.

Unique factorization additionally provides the Fock realization

$$U_F : \Gamma_s(\ell^2(\mathbb{P})) \xrightarrow{\sim} \ell^2(\mathbb{N}_{\geq 1}), \qquad U_F \, d\Gamma(H_{\mathbb{P}}) \, U_F^* = \log Q,$$

where $H_{\mathbb{P}} e_p = (\log p) e_p$. Each prime is a multiplicatively irreducible mode; a composite integer is a finite occupation of those modes.

For n coprime to 10, its decimal clock is the multiplicative order

$$\tau_n = \operatorname{ord}_n(10).$$

If p is primo y $p \notin \{2, 3, 5\}$, the equation (53.13) demonstrates

$$\tau_p \mid p - 1, \qquad M_p := \frac{10^{\tau_p} - 1}{p} \in \mathbb{N}, \qquad M_p \equiv 0 \pmod 9. \tag{53.13}$$

For a compound,

$$\operatorname{ord}_n(10) = \operatorname{lcm}_{p^a \| n} \operatorname{ord}_{p^a}(10).$$

Therefore, the composite clock synchronizes prime-power clocks, whereas a prime supplies an irreducible component. The nonadic congruence (53.13) describes phase closure; the primality selector resides in the reduced coproduct. Separation of these two functions prevents selective capacity from being attributed to the decimal period by itself.

53.15.7 Each constant is associated with its extraction operator

The cycles of order 3^m, the limit of their heat traces, and the theta–Mellin transform construct the functional

$$\mathcal{Z}_3(s) = \frac{\displaystyle\int_0^{\infty} \Theta_+(x) x^{s/2-1} \, \mathrm{d}x}{\pi^{-s/2}\Gamma(s/2)} = \zeta(s), \qquad \Re s > 1. \tag{53.14}$$

Theta inversion meromorphically extends the functional. The residual partition

$$\zeta(s) = Z_0(s) + Z_1(s) + Z_2(s)$$

separates aggregate, scale, and orientation. A single operatorial source admits several extraction maps—finite part, Laurent coefficient, evaluation, regularized derivative, or character—; coincidence of the source does not identify the resulting constants.

Table 53.3: Definition, extraction map, and mathematical scope of the complementary numerical constants.

Object	Standard definition	Map and mathematical reference	Conclusion and condition
Euler–Mascheroni γ	For $H_N = \sum_{n \leq N} n^{-1}$, $\gamma = \lim_{N\to\infty}(H_N - \log N)$, equivalente to the parte finite of ζ in $s = 1$.	If $C_r = \mathrm{FP}_{s=1} Z_r(s)$, then $\gamma = C_0 + C_1 + C_2$, by (27.9).	Exact identity of the residual functional demonstrated with the declared operator and normalization.
Stieltjes constants γ_n	If $\zeta(1+z) - z^{-1} = \sum_{n\geq 0} a_n z^n$, they are defined by $\gamma_n = (-1)^n n! a_n$.	The residual coefficients $c_{r,n}$ satisfy $\gamma_n = (-1)^n n! \sum_r c_{r,n}$ and $L^{(n)}(1, \chi_{-3})/n! = c_{1,n} - c_{2,n}$: this is the coefficientwise decomposition of (41.11) by the three residue classes of (27.9).	Exact decomposition; numerical extractions verify the coefficients, not their definition.
Apéry $\zeta(3)$	Value of the Riemann zeta function at $s = 3$.	$\mathcal{Z}_3(3) = \zeta(3)$, with prefixes bounded by rational intervals; its spectral residence within the graded tower is fixed at equations (43.1) y (43.2).	Exact evaluation of the functional; its irrationality follows from the classic theorem of Apery [3].

Object	Standard definition	Map and mathematical reference	Conclusion and condition
Glaisher–Kinkelin A_{GK}	Regularized Growth Constant of the Hyperfactorial.	$A_{\mathrm{GK}} = \exp(1/12 - \mathcal{Z}_3'(-1))$, by equations (43.1) y (43.2).	Exact regularized derivative; $1/12$ belongs to this hyperfactorial normalization.
Euler–Kronecker constant $\gamma_{F_{-3}}$	Logarithmic finite part of the Dedekind zeta function of the field $F_{-3} = \mathbb{Q}(\sqrt{-3})$.	The residual character χ_{-3} selects the field and produces $\gamma_{F_{-3}} = \gamma + L'(1, \chi_{-3})/L(1, \chi_{-3})$, through (42.2).	Exact identity; the choice of field comes from the character modulo three.
Meissel–Mertens B_1	For $S_P(x) = \sum_{p \le x} p^{-1}$, $B_1 = \lim_{x\to\infty}(S_P(x) - \log\log x)$.	It is the finite part of the truncated prime trace over the one-particle sector of the Fock Hamiltonian, by (42.4); the selector of prime modes is fixed before regularization is performed.	Exact operatorial representation once the prime modes have been fixed; the selector of irreducibles precedes it.
Feigenbaum $(\delta, \alpha_{\mathrm{F}})$	Universal scaling constants of the renormalization fixed point for the quadratic period-doubling cascade.	The family dodecafasica declarada produce to level eight $\delta_8^{\mathscr{B}}(0) = 4.66921218915\ldots$ and $\alpha_8^{\mathscr{B}}(0) = 2.50296847988\ldots$, by section 45.6.	Exact finite calculation up to $n = 8$; convergence to the universal fixed point requires proving convergence of the renormalization operator. α_{F} and α_{HMT} are distinct objects.
Catalan G	$G = L(2, \chi_{-4}) = \sum_{n\ge 0}(-1)^n/(2n+1)^2$.	The natural reader is the odd character modulo four evaluated at 2, by equation (41.6).	Exact classical identity with localized operator; it is not an output of the residual functional modulo three.
Khinchin K	Almost-sure geometric mean of the digits of the continued fraction for the Gauss system.	The reader is the ergodic mean of $\log a_1$ for $T(x) = x^{-1} - \lfloor x^{-1} \rfloor$ and its invariant measure, by equation (44.2).	Incorporated classical ergodic theorem; it requires dynamics distinct from the triadic spectral tower.

The table establishes a reading rule: a constant is defined by its object, its operator, and its extraction map, not by the appearance of a decimal prefix in a catalogue. Euler–Mascheroni and Stieltjes belong to finite parts and Laurent jets; Apery, to an evaluation; Glaisher–Kinkelin, to a regularized derivative; Euler–Kronecker, to the character of the field; Meissel–Mertens, to a prime trace; Feigenbaum, to a finite dynamical family; Catalan and Khinchin, to distinct neighboring operators.

53.15.8 Domains, premises, and necessary conditions of the genealogical classification of the number

The arithmetic definitions of integer, rational, irrational, algebraic, and transcendental are standard. The balanced ternary chart, the separation between section and value, the native selector of irreducibles, the Paley–Witt root of minus one, the six realizations of $-1/12$, and the spectral readers are deduced from the maps cited in each subsection. This section gathers them without introducing an additional constant or numerical selector.

The force of each assertion is determined by its map:

1. the indicated bijections, matrix identities, coproducts, traces, and evaluations are exact on their declared domains;

2. the transcendence of e and π, the irrationality of $\zeta(3)$ and Khinchin's ergodic theorem are classical theorems incorporated for purposes of control or classification;
3. the Feigenbaum approximants establish the computed branch and depth; universality requires the renormalization operator and its convergence theorem;
4. equality of two scalars from different domains authorizes a comparison and requires an intertwiner to identify the complete objects;
5. a decimal truncation proves the computed prefix, whereas the arithmetic class of the infinite value requires, as appropriate, a polynomial equation or a theorem of irrationality or transcendence.

Under these rules, the HMT ontology of number acquires a precise formulation: the Archimedean value is the published coordinate; the compatible section preserves the chain that generates it; the operator determines which property is read; and its hypotheses determine exactly which conclusion follows.

53.16 Genealogical closure of the concept of number: compatibility, memory, and Archimedean evaluation

The number theory developed in HMT culminates in a distinction of types that governs the subsequent transition to Dimensional Mechanics. A *digit* is a visible coordinate of a finite state; a *value* is the Archimedean image published by a reader; an *HMT number* is the complete compatible genealogy that preserves, together with its prefixes, orientation, quotient, carry, boundary, and memory. The fiber of a value gathers the distinct genealogies that publish that same scalar.

This construction extends ordinary arithmetic classification. Integer, rational, irrational, algebraic, and transcendental continue to denote properties of the value. HMT incorporates a second axis: the manner in which a section is prolonged, returns, preserves memory, and reaches a stable evaluation. The closure of Parts I–III fixes both axes and the map relating them.

53.16.1 Digit, section, value and symmetry

Let

$$\mathcal{S}_0^{\mathrm{surv}} \xleftarrow{\rho_{1,0}} \mathcal{S}_1^{\mathrm{surv}} \xleftarrow{\rho_{2,1}} \cdots$$

the inverse system of surviving states, where each restriction preserves the typed TPK data belonging to the preceding level, and let

$$\mathcal{S}_\infty^{\mathrm{surv}} := \varprojlim_n \mathcal{S}_n^{\mathrm{surv}}.$$

Definition 53.21 (Ciphers)**.** Having fixed a positional reader L, the digit or block visible at depth n is

$$d_{L,n}(x_n) := \pi_{L,n}^{\mathrm{vis}}(x_n).$$

It is the coordinate published by the finite presentation x_n; the fiber of $\pi_{L,n}^{\mathrm{vis}}$ preserves the states sharing that coordinate.

Definition 53.22 (HMT Number and Presentation)**.** An HMT number is to compatible section

$$\boldsymbol{x} = (x_n)_{n\geq 0} \in \mathcal{S}_\infty^{\mathrm{surv}}, \qquad \rho_{n+1,n}(x_{n+1}) = x_n.$$

The pair $(\boldsymbol{x}, L)$ is a presentation of the number. The section preserves the complete history; the reader declares which coordinates of that history are published.

Definition 53.23 (Archimedean value)**.** Suppose that L assigns to each x_n a compact cylinder $I_{L,n}(\boldsymbol{x}) \subset \mathbb{R}$, with

$$I_{L,n+1}(\boldsymbol{x}) \subseteq I_{L,n}(\boldsymbol{x}), \qquad \operatorname{diam} I_{L,n}(\boldsymbol{x}) \longrightarrow 0.$$

The value published by the presentation is

$$\mathrm{Val}_L(\boldsymbol{x}) := \text{the unique element of } \bigcap_{n\geq 0} I_{L,n}(\boldsymbol{x}).$$

Proposition 53.24 (Existence and uniqueness of the evaluation)**.** *The preceding hypotheses determine a map*

$$\mathrm{Val}_L : \mathcal{S}_\infty^{\mathrm{surv}} \longrightarrow \mathbb{R}.$$

Each fibre $\mathrm{Val}_L^{-1}(r)$ *preserves the genealogies that the Archimedean evaluation represents by the same value* r*.*

Proof. The finite intersection property of the nested family of compact sets guarantees a nonempty intersection. Two distinct points would have a positive distance bounded by every diameter, contradicting the convergence of the latter to zero. □

Definition 53.25 (Genealogical symmetry)**.** A symmetry of the HMT number system is a family of bijections $g = (g_n)_{n\geq 0}$ that preserves survival and types, and satisfies

$$\rho_{n+1,n} \circ g_{n+1} = g_n \circ \rho_{n+1,n} \qquad (n \geq 0).$$

The action

$$g_\infty(\boldsymbol{x}) := (g_n x_n)_{n\geq 0}$$

is an automorphism of the inverse limit. A genealogical invariant is a function constant on its orbits.

Symmetry is thus characterized as a transformation compatible at every depth. This notion renders decimal publication, exceptional incidence, and subsequent spectral realization comparable while preserving the proper type of each output.

53.16.2 Evolutionary Conservation of Unity

For $n \geq 1$, let

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad \kappa_9(n) = \frac{n - \rho_9(n)}{9}. \tag{53.15}$$

Then

$$n = 9\kappa_9(n) + \rho_9(n), \qquad \rho_9(n) \in \{1, \ldots, 9\}.$$

The coordinate ρ_9 publishes the nonadic phase and represents the null class through 9; κ_9 records the number of circuits. The digital root publishes the phase. Reduction modulo nine accompanied by its quotient publishes phase and memory.

The associated helical realization is

$$\mathcal{H}_9(n) := \left(\cos\frac{2\pi(\rho_9(n)-1)}{9}, \sin\frac{2\pi(\rho_9(n)-1)}{9}, \kappa_9(n) + \frac{\rho_9(n)-1}{9}\right). \tag{53.16}$$

Proposition 53.26 (Phase return and memory advance)**.** *The realization* (53.16) *satisfies*

$$\mathcal{H}_9(n+9) = \mathcal{H}_9(n) + (0, 0, 1).$$

The visible return $9 \to 1$ *closes the phase and increments the state memory by one.*

Proof. The identities $\rho_9(n+9) = \rho_9(n)$ and $\kappa_9(n+9) = \kappa_9(n) + 1$ fix the circular coordinates and increase the height exactly. □

This identity formulates evolutionary conservation: unity returns as phase, and the new state transports the preceding closure as memory. The cubic completion realizes the same law in three dimensions:

$$10^3 = (9+1)^3 = 9^3 + 3 \cdot 9^2 + 3 \cdot 9 + 1 = 729 + 243 + 27 + 1 = 729 + 271. \tag{53.17}$$

The interior has 729 states; 243 + 27 constitutes the punctured corona; the apex +1 completes the base-one-thousand unit. The identity 729 + 270 = 999 describes the state immediately preceding closure, and 729 + 271 = 1000 describes the completion. The law

$$10^d = (9+1)^d = \sum_{r=0}^{d} \binom{d}{r} 9^{d-r}$$

transports the same unit between dimensions and preserves the genealogy of its strata.

53.16.3 Visible syntax and semantics of prolongation

A local signature describes the current form of a branch. Its survival semantics is the system of prolongations it can support. For $x_n \in \mathcal{S}_n^{\mathrm{surv}}$, define

$$\mathrm{Ext}_m(x_n) := \{x_m \in \mathcal{S}_m^{\mathrm{surv}} : \rho_{m,n}(x_m) = x_n\}, \qquad m \geq n.$$

Two states that satisfy

$$d_{L,n}(x_n) = d_{L,n}(y_n)$$

may possess different extension trees. In the finite witness $60 \to 81$, two branches with the same visible signature possess, respectively, zero and twelve prolongations. The witness establishes that future continuity adds information to the local output. The HMT number incorporates that continuity as part of the object.

Coinduction is expressed through the compatibility of all prefixes. Blocks of one thousand or ten thousand digits are truncated publications of a uniformly prolongable rule. Numerical generation reaches any requested depth; the lift to the enriched state also preserves the hypotheses of existence, uniqueness, and compatibility of its fibers.

53.16.4 Arithmetic classification and genealogical classification

In a basis $b \geq 2$, the canonical presentation of a real number separates the following visible classes:

1. an integer belongs to $\mathbb{Z}$ and admits a finite balanced-ternary word;
2. a rational number has a finite or eventually periodic expansion;
3. an irrational number has an expansion that is not eventually periodic;
4. an algebraic number is a root of a nonzero polynomial in $\mathbb{Q}[X]$;
5. a transcendental number belongs to the complement of the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$.

Periodicity distinguishes rational from irrational numbers; the polynomial equation distinguishes algebraic from transcendental numbers. These are different axes. For example, φ is algebraic irrational because $\varphi^2 - \varphi - 1 = 0$; the transcendence of e and π follows from classical theorems; an HMT genealogy additionally distinguishes the propagation, closure, and self-scaling functions that realize those values.

The same separation governs $e + \pi$. The sum of the two presentations defines a composite object and publishes

$$\mathrm{Val}(e) + \mathrm{Val}(\pi) = e + \pi.$$

Its arithmetic class is a question in its own right. The HMT construction determines the map that forms the composite and preserves the two genealogies involved.

53.16.5 Factorization of the genealogical closure of the number through Euler's operational system

The classical Euler equation belongs to a unique quadratic family. Let J_σ be a generator satisfying

$$J_\sigma^2 = \sigma I, \qquad \sigma \in \{-1, 0, +1\}.$$

The separation of even and odd powers provides

$$\exp(tJ_\sigma) = C_\sigma(t)I + S_\sigma(t)J_\sigma, \tag{53.18}$$

with the exact realizations

$$\begin{aligned} J_{-1}^2 = -I \quad &: \quad \exp(tJ_{-1}) = \cos t\, I + \sin t\, J_{-1}, \\ J_0^2 = 0 \quad &: \quad \exp(tJ_0) = I + tJ_0, \\ J_{+1}^2 = I \quad &: \quad \exp(tJ_{+1}) = \cosh t\, I + \sinh t\, J_{+1}. \end{aligned}$$

Elliptic, parabolic, and hyperbolic are three regimes of a single operator exponential. The tritic classification determines the geometry of the evolution.

The hyperbolic branch contains the Fibonacci self-scale. For

$$F = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad A = F^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix},$$

we have $\det A = 1$, $\operatorname{tr} A = 3$, and

$$\eta = \operatorname{arcosh} \frac{3}{2} = 2 \log \varphi.$$

Therefore, there exists $J_h^2 = I$ such that

$$A = \exp(\eta J_h), \qquad A^n = \cosh(n\eta)I + \sinh(n\eta)J_h. \tag{53.19}$$

The relation $\varphi^2 = \varphi + 1$ expresses two readings of the same process: local additive recurrence and spectral multiplicative scaling. This compatibility provides the elementary model of the double sum–product evaluation that APP formalizes on their common support.

53.16.6 Typed Unification of Circular, Complex, and Hyperbolic Geometries

The initial geometric motivation of HMT can be formulated exactly as a common architecture of support, boundary, and generators. The complex plane $\mathbb{C}$ contains the unit circle

$$S^1 = \{e^{\mathrm{i}\theta} : \theta \in \mathbb{R}\},$$

which constitutes the elliptic realization of (53.18). The upper half-plane $\mathbb{H} = \{w \in \mathbb{C} : \operatorname{Im} w > 0\}$ is transported to the hyperbolic disc by means of the Cayley transformation

$$C(w) = \frac{w - \mathrm{i}}{w + \mathrm{i}}, \qquad C : \mathbb{H} \xrightarrow{\sim} \mathbb{D}, \qquad \mathbb{D} = \{z \in \mathbb{C} : |z| < 1\}.$$

The ideal boundary of $\mathbb{D}$ is the same circle S^1, whereas its interior carries the Poincare metric

$$\mathrm{d}s_{\mathbb{D}}^2 = \frac{4\,|\mathrm{d}z|^2}{(1 - |z|^2)^2}.$$

Fusion therefore consists of a typed diagram: the trigonometric parameterization publishes the circular boundary; the complex structure provides the chart; the Poincare metric realizes the hyperbolic interior.

The three regimes $J^2 = -I, 0, +I$ also incorporate the parabolic threshold and place this geometric concurrence within a single operator family.

Proposition 53.27 (Euclidean and Hyperbolic Compatibility of the Quarter Turn)**.** *Over the disco unitary*

$$\mathbb{D} = \{z \in \mathbb{C} : |z| < 1\},$$

the application

$$\mathcal{R}_{\pi/2} : \mathbb{D} \longrightarrow \mathbb{D}, \qquad \mathcal{R}_{\pi/2}(z) = \mathrm{i}z,$$

is simultaneously a Euclidean rotation and an isometry of the Poincaré metric

$$\mathrm{d}s^2_{\mathbb{D}} = \frac{4\,|\mathrm{d}z|^2}{(1-|z|^2)^2}.$$

Its extension to the boundary $S^1 = \partial\mathbb{D}$ is the oriented quarter-turn. In the real realization of theorem 3.25, this map corresponds to $\mathrm{Exp}((\pi/2)J_{\mathrm{e}}) = J_{\mathrm{e}}$.

Proof. Multiplication by i preserves $|z|$ and $|\mathrm{d}z|$. It therefore preserves both the Euclidean metric and the numerator and denominator of $\mathrm{d}s^2_{\mathbb{D}}$. The exponential identity follows from $J_{\mathrm{e}}^2 = -I$. □

The complex plane, trigonometric circle, and hyperbolic disk are not identified as metric spaces: they share a coordinated carrier and the quarter-turn automorphism once each realization has been declared.

53.16.7 Boundary interface between quadratic rotation and minimal torsion

The function of this interface is to transport an already constructed interior rotation to a boundary datum without confusing the quadratic endomorphism with a scalar defect. Fix a base point $x_0 \in \partial X$, a real bundle $E_\partial \to \partial X$, a connection ∇_∂, a boundary reader q_∂, and a discrete cotetrad $e_\partial \in \Omega^1(\partial X; E_\partial)$. We write

$$\mathrm{Tors}(\partial X; E_\partial) := \Omega^2(\partial X; E_\partial), \qquad \mathrm{Hol}_{x_0}(\nabla_\partial) \subseteq \mathrm{Aut}(E_{\partial,x_0}).$$

An edge realization of the interface should construct the maps

$$\mathrm{Res}_\partial : \langle J_{\mathrm{e}} \rangle \longrightarrow \mathrm{Hol}_{x_0}(\nabla_\partial), \qquad \mathrm{Def}_\partial : \mathrm{Hol}_{x_0}(\nabla_\partial) \longrightarrow \mathrm{Tors}(\partial X; E_\partial).$$

The torsion determined by the connection and the co-tetrad has the type

$$T_\partial := d_{\nabla_\partial} e_\partial \in \Omega^2(\partial X; E_\partial). \tag{53.20}$$

The physical realization of minimal torsion requires in addition a functional

$$\Lambda_\partial : \mathrm{Tors}(\partial X; E_\partial) \longrightarrow \mathbb{R} \tag{53.21}$$

such that the three maps satisfy the entanglement conditions

$$\mathrm{Def}_\partial\big(\mathrm{Res}_\partial(J_{\mathrm{e}})\big) = T_\partial, \qquad \Lambda_\partial(T_\partial) = \Delta_4. \tag{53.22}$$

These equations specify the comparator that must be constructed; they do not assert that the three maps exist. The scalar Δ_4 is defined by equation (58.2).

Remark 53.28 (Exact condition of the boundary comparator). The operator root $J_{\mathrm{e}}^2 = -I$, the quarter-turn $\mathrm{Exp}((\pi/2)J_{\mathrm{e}}) = J_{\mathrm{e}}$, and the scalar Δ_4 are deduced in their respective domains. The preceding boundary chain fixes the type of the morphisms that must link them. Until Res_∂, Def_∂, and Λ_∂ are constructed, the conditions (53.22) define the required comparator but do not imply a physical realization; the angular proximity of its endpoints does not replace that operator.

APP, TRIT, and TPK supply the discrete support of that architecture. On $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$, the sum and product evaluations induce projectors $P_{\Sigma,d}$ and $P_{\Pi,d}$ that satisfy

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

This calculated incompatibility is the finite precursor of Heisenberg: two families of observables share a support and possess incompatible spectral decompositions. The alternating form of the torus,

$$\sigma((a,b),(c,d)) = ad - bc \pmod 9,$$

is integrated into the Weyl–Heisenberg nonadic representation

$$X|n\rangle = |n+1\rangle, \qquad Z|n\rangle = \omega^n|n\rangle, \qquad ZX = \omega XZ, \qquad \omega = e^{2\pi \mathrm{i}/9}.$$

The commutator publishes the oriented phase, and the resulting central group has $9^3 = 729$ elements.

The central block of APP simultaneously provides the local lorentzian realization:

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 9P_+ + 5P_-, \qquad M_c := \frac{B_c}{\sqrt{45}} = \exp\left(\frac{1}{2}\log\frac{9}{5}\,R\right).$$

Con $\eta_{1,1} = \mathrm{diag}(1,-1)$,

$$M_c^{\mathsf{T}}\eta_{1,1}M_c = \eta_{1,1}, \qquad \det M_c = 1, \qquad M_c \in SO^+(1,1).$$

Thus Lorentz geometry and the Minkowski plane 1 + 1 emerge as an exact spectral realization of the central block. Every subsequent dimensional lift must intertwine this local block with its new codomain. The sequence

$$\text{APP–TRIT–TPK} \longrightarrow \begin{cases} \text{elliptic–parabolic–hyperbolic family,} \\ \text{Lorentz–Minkowski block } 1+1, \\ \text{finite Weyl–Heisenberg representation} \end{cases}$$

presents the geometric and operatorial developments preceding the genealogical closure of the number.

53.16.8 Constant Generation Operators: Domains, Seeds, and Evaluations

The function of a constant is fixed through four data: mathematical definition, domain, operator or reader, and deduced conclusion. The table 53.4 brings together the objects that must remain visible when number theory is closed.

Table 53.4: Constants and Seeds in the Genealogical Closure of the Number.

Object	Definition or identity	HMT domain and map	Conclusion and condition
π, e, φ	Sections published by compatible numerical cylinders.	The filtration $w_6 \to w_{30} \to R_{36} \to G_9$ produces the terminal state; the readers distinguish closure, propagation, and self-scaling.	For each prescribed finite depth, the map produces compatible unit cylinders; the infinite section follows from the coinductive theorem.

Object	Definition or identity	HMT domain and map	Conclusion and condition
α_{HMT}	Dodecaphasic closure with carry over the terminal state.	The double reading leads to $(P, E, \Phi, K, c_{13} = 0)$ and to the rational output of 36 digits; the $E_{21/22}$ route provides an independent computation.	The recurrence is exact for the declared terminal state and receives neither α nor CODATA; the minimal APP deduction$\rightarrow K$ requires construction of its complete bidirectional reader.
i interno	$J^2 = -I$ on the Paley–Witt module.	Construct a finite complex structure and separate conjugate orientations.	Over the declared base field, $J^2 = -I$ holds exactly.
$-1/12$	$\zeta(-1) = -1/12$ and normalized operator realizations.	Incidence $90 \rightarrow 120$, dodecaphase defect and spectral functionals, each with its domain and normalization.	Exact equality for each declared map.
$e + \pi$	Sum of the presentations of e and π.	Composite object of the presentation algebra; preserves both genealogies.	Exact construction; separate arithmetic class.
Euler–Mascheroni γ and Stieltjes γ_n	$\gamma = \mathrm{FP}_{s=1}\,\zeta(s)$; coefficients of Laurent.	Residual decomposition modulo three and Laurent jets.	Exact identities of the declared functional.
Apéry $\zeta(3)$	Evaluation of the zeta function at $s = 3$.	Reader $\mathcal{Z}_3(3)$ with rational prefix intervals.	Exact evaluation; classical irrationality.
Glaisher–Kinkelin A_{GK}	$A_{\mathrm{GK}} = \exp(1/12 - \zeta'(-1))$.	Regularized derivative of the spectral reader.	Exact identity with explicit normalization.
Euler–Kronecker constant $\gamma_{F_{-3}}$	Logarithmic finite part of the Dedekind zeta function of $F_{-3} = \mathbb{Q}(\sqrt{-3})$.	The character χ_{-3} selects the field and organizes $L'(1, \chi_{-3})/L(1, \chi_{-3})$.	Exact identity of the declared character.
Meissel–Mertens B_1	$B_1 = \lim_{x\to\infty}(\sum_{p\le x} p^{-1} - \log\log x)$.	Finite part of the trace over primary modes.	Exact operatorial representation with fixed modes.
Catalan G and Khinchin K_0	$G = L(2, \chi_{-4})$; ergodic mean of the Gauss system.	Readers of modular character four and continued fraction.	Classical theorems embedded with their own dynamics.
Feigenbaum (δ, α_F)	Scales of the renormalization operator in period doubling.	The dodecaphonic family produces level eight approximants.	The calculation determines level eight exactly; universality requires proving convergence to the renormalization fixed point.
Rogers–Ramanujan constant $R(q)$	Level-five continued fraction and Klein–Ramanujan identity for j.	It organizes level 5, A_5, the limit $R(q) \rightarrow \varphi^{-1}$, and Hecke–Faber replicability.	Exact modular identities; the comparison of coefficients covers only the finite depth computed.
Prime clock p	$\tau_p = \mathrm{ord}_p(10)$, $M_p = (10^{\tau_p} - 1)/p \equiv 0 \pmod 9$ for $p \nmid 30$.	Primes are irreducible periods; composites synchronize clocks through the least common multiple.	Exact arithmetic theorem in the declared domain.

Finite part, special value, regularized derivative, character, ergodic average, renormalization scale, and prime period are distinct maps. Their coexistence within HMT arises from a typed family of operators and extraction maps.

53.16.9 Double projection of a single genealogy

Let $\mathfrak{X} := X_\infty^{\mathrm{cal}}$ be the compact space of enriched histories with transported initial gauge. Given a declared gauge $c \in \mathscr{C}_{\mathrm{exc}}$, two evaluations act on the same section:

$$\mathfrak{R} : \mathfrak{X} \longrightarrow \mathbb{R}, \qquad \mathfrak{E}_c : \mathfrak{X} \longrightarrow \mathbf{Exc}, \qquad \mathfrak{E}_c(x) := \mathfrak{E}(x, c),$$

where $\mathfrak{R}$ contrae cylinders and $\mathfrak{E}_c$ preserves supports, incidences, polarity and boundary transport.

Theorem 53.29 (Causal unit of the double projection)**.** *For every history $\boldsymbol{x} \in \mathfrak{X}$, the pair*

$$\mathfrak{D}_c(\boldsymbol{x}) := (\mathfrak{R}(\boldsymbol{x}), \mathfrak{E}_c(\boldsymbol{x}))$$

is a joint publication of the same antecedent. The first coordinate determines the Archimedean value; the second determines the exceptional incidence class. When the joint readers separate points, $\mathfrak{D}_c$ is injective.

Proof. Both components are defined on the same domain and preserve the restriction maps. If $\mathfrak{D}_c(\boldsymbol{x}) = \mathfrak{D}_c(\boldsymbol{y})$, joint separation of histories implies $\boldsymbol{x} = \boldsymbol{y}$. □

The Archimedean branch produces the cylinders and the values of π, e, φ. The incidence branch prolongs the same words and the same seal toward Paley, Witt, Golay, the Leech lattice, $V^\natural$, the Monster group, and Moonshine. The causal relation is the common preimage: both evaluations preserve different invariants of the same history. The real value is the contracted shadow; exceptional symmetry is the incidence memory published by the same state.

53.16.10 Genealogical Closure of the Concept of Number

The concept of number is fixed by the string

$$\text{finite state} \longrightarrow \text{compatible extension} \longrightarrow \text{genealogical section} \longrightarrow \begin{cases} \text{visible digit,} \\ \text{Archimedean value,} \\ \text{exceptional incidence.} \end{cases}$$

The digit is a coordinate; the value is a projection; the number is the complete section; the symmetry is the compatible automorphism that preserves its memory. Evolutionary conservation transports that identity through the nonadic return, the helical carry, and the completion $729 + 271 = 1000$. With these distinctions secured, Dimensional Mechanics realizes the same genealogy in a new codomain.

Causal dependence between inverse section, Archimedean evaluation, and exceptional conservation of incidence The inverse limit supplies the section; the Archimedean reader produces the value; the binomial completion and the nonadic extension transport unit and memory; the complementary readers classify the outputs; and the double projection applies the Archimedean and exceptional maps to the same antecedent. The Witt–Golay–Leech–Moonshine chain requires, at every step, the corresponding incidence intertwiner.

53.17 Definition of the genealogical atlas and metrological evaluation conventions

This atlas is not a table of coincidences. Its mathematical core preserves five inseparable fields; the logical status and the falsification criterion are stated subsequently, without taking the place of any of the five:

$$\boxed{\begin{array}{c|c|c} \text{antecedent} & \text{equation} & \text{preserved invariant} \\ \text{meaning} & \text{terminal value} & \end{array}} \qquad \begin{array}{c}[\text{status;} \\ \text{refutation criterion}]\end{array}. \tag{53.23}$$

53.18 HMT corollary of metrological confluence

Definition 53.30 (Quintuple in Metrological Form)**.** Let x be a quantity obtained through an HMT–MD realization. Its *metrological quintuple* is

$$\mathfrak{C}(x) = \big(A_x \mid E_x \mid I_x \mid S_x \mid V_x\big),$$

where A_x is the typed antecedent, E_x the equation of determination, I_x the invariant preserved by the realization, S_x the structural meaning, and V_x the terminal value. Forming V_x before the other four components have been fixed is not permitted. Two outputs with the same decimal are not equal if their antecedents or invariants differ.

Corollary 53.31 (Metrological confluence)**.** *The outputs of vacuum, action, information, temperature, gravity, criticality, spectrum, mixing, and cosmology constructed in the chapters 34, 40, 41, 44, 45 y 50 y sections 49.1, 51.6 y 88.1 admit the quintuples of the table 53.5. In each row, the value in the fifth column is a consequence of the first four and not a datum selecting them. The rows share genealogical nodes —mode* 30*,* $\log 3$*, determinant* D_A*, channels* $90/120$*, and change* $6 \to 8$*—, but retain their domains and operators separately.*

Table 53.5: HMT Metrological Confluence Corollary: the five columns are a single probative unit.

Antecedent	Ecuación	Conserved invariant	Significado estructural	Terminal value
I. Action				
two realizations of the action line (equations (34.7) y (34.8))	$R_{\mathrm{act}} = H_5/\eta_{\mathrm{ret}}$, $\xi_{\mathrm{act}} = \frac{1}{2}\log R_{\mathrm{act}}$	Decade and Leaf Orientation	Absolute action and its relative quotient correspond to distinct functionals; the decade is not used as a fit	R_{act}, ξ_{act}
II. Vacuum—electromagnetic				
$T = q_+P_+ + q_-P_-$, $30 \to 90/120$ (equations (39.2) y (39.8))	$V = (I - T^{90})(I - T^{120})^{-1}$	Positivity, Leaf Spectrum, and Completion $3 \to 4$	The vacuum is a bilayer operator; $90 = 3 \cdot 30$ and $120 = 4 \cdot 30$ determine the fourth sector without introducing an SI constant	$r_+ = 0.9999996285\ldots$, $r_- = 0.9997241371\ldots$
spectral response (equations (39.4) y (39.12))	$\widehat{\varepsilon} = r_+^2$, $\widehat{\mu} = r_-^2$, $\widehat{Z} = r_-/r_+$, $\widehat{c} = (r_+r_-)^{-1}$	Product and quotient of sheets, stable under $V \mapsto V \otimes I_{9^m}$	Permittivity, permeability, impedance, and propagation are four functions of the same positive operator	$0.9999992571\ldots$, $0.9994483505\ldots$, $0.9997245085\ldots$, $1.0002763105\ldots$
constitutive lines (equation (39.18))	$\mu\varepsilon = c^{-2}$, $\mu/\varepsilon = Z^2$	Homogeneity in L_S, L_C, L_Q	The dimensional chart is a subsequent section, not a unit attached to a dimensionless number	Z, μ, ε, c as exact sections

controls of composition (equations (53.29) y (53.30))	$a_0 = \hbar/(m_e c\,\alpha)$, $E_* = h_{\mathrm{int}} c_{\mathrm{int}}/(e_{\mathrm{int}}\ell_0^2)$	Dimensional Homogeneity and Non-Feeding by Name	Bohr is composed from magnitudes defined outside the scope of this monograph; Born–Infeld still requires a determinantal action that selects its scale	Exact sections a_0, E_*, without promoting a new selector

Proof. Each row is obtained by substituting exclusively already constructed objects into the equation cited in its first or second column. In vacuum, the calculation is spectral: the functional theorem for V produces $r_\pm$, and the four constitutive quantities are functions of those two eigenvalues. In the realization, in its thermal form, the chronological structure 108 and the uniform entropy of one trit produce the product $k_B\Theta_{\mathrm{clk}}$, after which Planck, Wien, and radiation are compositions. In gravity, the circular condition fixes θ_{108}, while P_5 and the TT reduction fix the type of the carrier. In the modular realization, the linear system of determinant 30 reconstructs both channels, and the spectral decomposition of the reduced state produces entropy and the first law. The constructions of criticality, characters, Gauss, and Pell are proved in their respective operators. The CKM reflection is obtained by conjugation of a diagonal involution, and the electroweak sector by the determinant function of the angular operator. Finally, the two cosmological realizations respectively use a temporal-periodicity radius of (108) phases and the stable Perron eigenvalue. At no step does the decimal in the fifth column intervene to choose the antecedent. This proves the stated terminality and confluence. □

53.19 Principal structural relations of genealogical confluence

The preceding corollary is not limited to enumerating rows: it determines which operators share an antecedent and the exact point at which their domains diverge. The following five configurations contain the highest-density causal relations in the volume.

53.19.1 Mode 30: Completion in Harmonic Form, Criticality, and Memory

The same integer appears in three exact constructions:

$$\begin{aligned} &90 = 3 \cdot 30, && 120 = 4 \cdot 30, && \frac{1-q^{90}}{1-q^{120}} = \frac{1+s+s^2}{1+s+s^2+s^3}, && s = q^{30}, \\ &899 = 30^2 - 1 = 29 \cdot 31, && && D = 90N_{90} + 120N_{120}. \end{aligned} \tag{53.24}$$

The first line is the $3 \to 4$ completion of the vacuum operator; the second normalizes the dodecaphasic germ without introducing π into the iteration; the third preserves how many occupations arrived through each modular channel. The common invariant is the partition of mode 30; the codomains are different. Therefore, the intersection is structural, not an identification of V, u_0 and K_{HHM}.

Completion identities for mode 30, invertibility, and incompatibility condition. The three identities in equation (53.24) are exact. The confluence is invalidated if $90/120$ cease to be consecutive multiples of the same mode, if $899 \neq 30^2 - 1$, or if the inversion $(N, D) \mapsto (N_{90}, N_{120})$ loses its determinant 30. Spectral differences do not falsify it: those differences are precisely what keep the three realizations typed.

53.19.2 log 3: residual invariant, information, and temperature

The informational confluence is summarized in the chain

$$S_{\widehat{\mathbb{T}}} = k_B \log 3, \qquad E_P = k_B \Theta_{\mathrm{clk}} \log 3, \qquad I_{\mathrm{or}} = 36 \log 3 - S(\rho_A). \tag{53.25}$$

The first member measures a uniform ternary decision; the second determines its energetic magnitude in the chronological structure 108; the third compares the capacity of 36 trits with the entropy of the reduced boundary state. The scalar is preserved, but the unit, temperature, and reduced state remain typologically separate. This separation is what permits the identity $E_P = k_B \Theta_{\mathrm{clk}} \log 3$ to be read precisely: the Planck realization supplies the quantum of energy, the TRIT realization its informational content, and the chronological structure the transducer.

Preservation of $\log 3$, dimensional separation, and incompatibility condition. The triple reading is an exact composition of equations (36.37), (48.2) y (73.8). It is invalidated if $\log 3$ is replaced by a binary entropy, if Θ_{clk} is fixed from kelvin before the identity, or if $S(\rho_A)$ is computed with a state different from that obtained by partial trace.

53.19.3 D_A: sheet determinant and Weinberg angular relation

The angular operator $T = q_+ P_+ + q_- P_-$ has two functional families:

$$F(T)^2 \longrightarrow (\widehat{\varepsilon}, \widehat{\mu}, \widehat{Z}, \widehat{c}), \qquad \det T = q_+ q_- = D_A \longrightarrow \sin^2 \theta_W = 1 - D_A. \tag{53.26}$$

The first preserves the complete spectrum of the vacuum response; the second discards the individual orientation of the sheets and preserves only their product. Hence D_A is even under $C^* \mapsto -C^*$ and can determine the quotient W/Z, whereas the impedance preserves the quotient of eigenvalues. The relation contains more information than an angular coincidence: it is an exact functional bifurcation of the same antecedent operator.

Accuracy of the angular determinant and obstructions of the electroweak interface. The spectral side and the identity $D_A = e^{-2A_{\mathrm{rad}}}$ are exact in the declared chart. The gauge realization retains its status as an interface until the basis intertwiner is constructed. A quotient of nonadjacent routes, an odd dependence on C^*, or $(m_W/m_Z)^2 \neq D_A$ falsifies that interface without affecting the vacuum operator.

53.19.4 Sectors 90 and 120: vacuum, area and modular dynamics

The channels 90 and 120 have three noninterchangeable functions: they are propagation exponents in V, multiplicities of the incidence $6 \to 8$, and spectral weights in K_{HHM}. Their ratio $4/3$ reappears in the modular temperatures,

$$\frac{120}{90} = \frac{4}{3} = \frac{\beta_{120}}{\beta_{90}},$$

but the vacuum operator is not the modular Hamiltonian, and a modular temperature is not a permeability. The confluence consists in the same genealogy preserving three magnitudes: propagation, areal occupation, and channel memory.

Finite Reconstruction of Channels 90/120 and Hypothesis of the Modular Limit. The finite reconstruction and the ratio $4/3$ are exact. The type III classification requires the infinite persistence of both channels. The disappearance of either channel from some level onward, the loss of state compatibility, or the attainment of a ratio group different from $\{\lambda_\partial^n : n \in \mathbb{Z}\}$ would falsify that classification, not the finite inversion.

53.19.5 Barbero–Immirzi parameter, entropy and CKM as realizations of the transition $6 \to 8$

The complete confluence interface is written without turning one realization into the cause of the others:

$$(6 \to 8,\ 90/120,\ C^* \mapsto -C^*) \longrightarrow \begin{cases} \gamma_{\mathrm{HMT}} \ell_P^2 \longrightarrow A_{\mathrm{phys}}, \\ \rho_A \longrightarrow (-\log \rho_A, S, I_{\mathrm{or}}, \delta S), \\ C^* \mapsto -C^* \longrightarrow R_{\mathrm{CKM}} = M\,\mathrm{diag}(1,-1,1)M^{-1}. \end{cases} \tag{53.27}$$

The first realization fixes the geometric quantum; the second measures the information of the reduced state and its areal response; the third records the sheet orientation in the mixing space. In parallel, $E_P = k_B \Theta_{\mathrm{clk}} \log 3$ fixes the informational quantum of energy. Thus gravity, entropy, and information are equated through (ℓ_P^2, E_P), without identifying γ_{HMT}, k_B, or the CKM angles.

Causal Independence of Barbero–Immirzi, Modular Information, and CKM Mixing. The output γ_{HMT} is a demonstrated antecedent result of its corresponding derivation; the area operator, purification, local first law, and CKM reflection are exact in this monograph. The infinite modular classification and the physical horizon reading retain their hypotheses. The diagram is invalidated if CKM is used to recalibrate γ_{HMT}, if an incidence hexad/octad is equated with faces/vertices without an intertwiner, or if $R_{\mathrm{CKM}}^2 \neq I$ or $\det R_{\mathrm{CKM}} \neq -1$.

53.20 Theoretical independence of the corollary of metrological confluence

The table 53.5 does not refer to an external table to complete any of its five columns. Each antecedent is defined in the body; each equation is proved or typed at the cited locator; each invariant declares what is preserved and also what is discarded; each meaning prevents identification by decimal similarity; and each terminal value is obtained thereafter in the chain. The statuses and falsification criteria remain in the extended records that follow, where they are developed without the inevitable compression of a synoptic table.

Consequently, the table does not replace the development; it complements it. It may be read synoptically to recognize the confluence, but its validity derives from the theorems and proofs in the main text, and each row is followed by an autonomous record containing antecedent, equation, meaning, value, status, and negative control.

53.21 Action, vacuum, and quantum–electric constants

Bidirectional sections of action

Antecedent. Two oriented realizations of the same line of action. **Equation.**

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}, \qquad \xi_{\mathrm{act}} = \tfrac{1}{2}\log R_{\mathrm{act}}.$$

Structure and meaning. The decade common to both fixes the type; the quotient preserves the orientation. **Value.** R_{act} and ξ_{act} in the internal chart, without comparing dimensional mantissas with residues. **Status.** *Exact internal theorem.* **Falsification criterion.** Using the decade common to both as a relative corrector or mixing the two sections.

Constitutive operator of the vacuum: positive spectrum and joint reconstruction of ε, μ, Z, c

Antecedent. The bilayer operator $T = q_+P_+ + q_-P_-$ and the genealogy $30 \to 90/120$. **Equation.**

$$V = (I - T^{90})(I - T^{120})^{-1}, \qquad \frac{1-q^{90}}{1-q^{120}} = \frac{1+s+s^2}{1+s+s^2+s^3}, \quad s = q^{30}.$$

If $\operatorname{Spec} V = \{r_+, r_-\}$,

$$\widehat{\varepsilon} = r_+^2, \quad \widehat{\mu} = r_-^2, \quad \widehat{Z} = r_-/r_+, \quad \widehat{c} = (r_+r_-)^{-1}.$$

Structure and meaning. The four constitutive relations are functions of a single positive operator; each sheet completes three segments by a fourth segment. The amplification $V_m = V \otimes I_{9^m}$ preserves the functionals under tracial expectation. **Value.**

$$\widehat{\varepsilon} = 0.99999925709663670276044161 55\ldots, \quad \widehat{\mu} = 0.99944835047932693508998155 59\ldots,$$
$$\widehat{Z} = 0.99972450853893721545555434 66\ldots, \quad \widehat{c} = 1.00027631048615752610638626 89\ldots.$$

Status. *Exact internal theorem*; nonadic amplification: *New exact formalization*. **Falsification criterion.** Loss of positivity, a residue in the identity $3 \to 4$, or variation of the invariants under the tracial expectation.

Constitutive sections of ε, μ, Z, and c in the oriented charts

Antecedent. The four preceding coefficients and the frame (u_S, u_C, u_T, u_Q). **Equation.**

$$Z = \widehat{Z}u_S u_Q^{-2}, \quad c = \widehat{c}u_C, \quad \mu = \widehat{\mu}u_S u_C^{-1} u_Q^{-2}, \quad \varepsilon = \widehat{\varepsilon}u_S^{-1}u_C^{-1}u_Q^2.$$

Structure and meaning. Permittivity and permeability do not receive units after a dimensionless calculation: they are sections of constitutive lines. **Value.** The four preceding sections, with $\mu\varepsilon = c^{-2}$ and $\mu/\varepsilon = Z^2$. **Status.** *Exact internal theorem.* **Falsification criterion.** Introducing c, μ_0, ε_0 SI before the operator or violating homogeneity.

Joint derivation of charge, the von Klitzing resistance, conductance, flux, and the Josephson constant

Antecedent. $(Z_{\mathrm{vac}}, h_a, \alpha_{\mathrm{HMT}})$. **Equation.**

$$e_a = \sqrt{\frac{2\alpha_{\mathrm{HMT}}h_a}{Z_{\mathrm{vac}}}}, \quad R_K = \frac{Z_{\mathrm{vac}}}{2\alpha_{\mathrm{HMT}}}, \quad G_0 = \frac{4\alpha_{\mathrm{HMT}}}{Z_{\mathrm{vac}}},$$

$$\Phi_{0,a} = \sqrt{\frac{h_a Z_{\mathrm{vac}}}{8\alpha_{\mathrm{HMT}}}}, \qquad K_{J,a} = \Phi_{0,a}^{-1}.$$

Structure and meaning. R_K and G_0 are bidirectional invariants; Φ_0 and K_J preserve the orientation of action with opposite exponents. **Value.** The exact expressions on their lines; $R_K G_0 = 2$ and $K_J\Phi_0 = 1$.

Status. *Exact internal theorem.* **Falsification criterion.** Using SI charge as a selector or failing $\alpha = Ze^2/(2h)$.

53.22 Constantes thermal and radiation

Relation of Boltzmann y content entropico TRIT

Antecedent. Uniform ternary decision, section of action, and chronological structure 108. **Equation.**

$$k_B\Theta_{\mathrm{clk}}\log 3 = \frac{h_{\mathrm{int}}}{108t_0} = \frac{2\pi\hbar_{\mathrm{int}}}{108t_0}, \qquad \log 3 = \frac{S_{\widehat{\mathbb{T}}}}{k_B} = \frac{E_P}{k_B\Theta_{\mathrm{clk}}}.$$

Structure and meaning. $\log 3$ is simultaneously a spectral defect, the content of a decision, and a thermal ratio; the operators remain distinct. **Value.** $\log 3 = 1.0986122886681098\ldots$ and the preceding energy–temperature section. **Status.** *Exact confluence.* **Falsification criterion.** Arbitrarily separating k_B from Θ_{clk} or inferring identity of domains from equality of the scalar.

Wien's Displacement Law

Antecedent. The Planck spectrum evaluated at Θ_{clk}. **Equation.**

$$x_5 = 5 + W_0(-5e^{-5}), \quad \frac{\lambda_{\max}}{\ell_0} = \frac{108\log 3}{x_5},$$

$$x_3 = 3 + W_0(-3e^{-3}), \quad \nu_{\max}t_0 = \frac{x_3}{108\log 3}.$$

Structure and significance. Wavelength and frequency are two spectral parameterizations with distinct Jacobians. **Value.** $\lambda_{\max}/\ell_0 = 23.896756779\ldots$ and $\nu_{\max}t_0 = 0.0237794888\ldots$. **Status.** *Exact internal theorem.* **Falsification criterion.** Confusing x_5 with x_3 or introducing kelvin before the thermal product.

Stefan–Boltzmann Law and Photon Gas

Antecedent. The same thermal scale, the bosonic continuum, and the functional $\zeta(3)$. **Equation.**

$$\mathcal{F}(\Theta_{\mathrm{clk}}) = \frac{2\pi^5}{15\,108^4(\log 3)^4}\frac{h_{\mathrm{int}}}{\ell_0^2 t_0^2},$$

$$n_\gamma\ell_P^3 = \frac{2\zeta(3)}{\pi^2(\log 3)^3}, \qquad \frac{u_\gamma\ell_P^3}{E_P} = \frac{\pi^2}{15(\log 3)^4}.$$

Structure and meaning. $\zeta(3)$ counts occupation of bosonic type; $\log 3$ fixes the TRIT informational content per cell. **Value.** The exact coefficients above. **Status.** *Exact composition with an explicit starting structure.* **Falsification criterion.** Loss of factors 2π, incorrect flow dimensions, or fusion of the mathematical provenances of $\zeta(3)$ and $\log 3$.

53.23 Criticality and dynamic constants

Dodecaphasic Profile and Normalization by 899

Resultados rectores: , and .

Antecedent. Twelve phases $3m-1$ and elementary mode 30. **Equation.** With $y = x/\sqrt{899}$,

$$u_0(x) = 1 - \frac{1}{12}\sum_{m=1}^{12}\cos\bigl(2(3m-1)y\bigr) = 1 - \frac{\cos 37y\sin 36y}{12\sin 3y},$$

$$899 = 30^2 - 1 = 29\cdot 31, \qquad u_0(x) = x^2 - \frac{715769}{2424603}x^4 + O(x^6).$$

Structure and meaning. The phase π cancels before iteration; the resulting profile is analytic, quadratic and unimodal, and has negative Schwarzian on $[-1, 1]$. **Value.** Exact rational profile and coefficients. **Status.** *Exact internal theorem.* **Falsification criterion.** A second critical point, nonnegative Schwarzian, or a residue in the trigonometric identity.

Feigenbaum Superstable Approximants and Hyperbolic Certificate of Universality

Antecedent. The superstable succession of the preceding germ. **Equation.**

$$\mathcal{R}(f)(x) = -a(f)^{-1} f\big(f(-a(f)x)\big), \qquad a(f) = -f(1).$$

Structure and meaning. The finite quotients prove that the family enters the appropriate route; universality requires the fixed point and its hyperbolicity. **Value.** $\delta_8 = 4.66921218915\ldots$, $\alpha_8 = 2.50296847988\ldots$. **Status.** Approximants: *Finite certificate*; universal limit: *Program with falsification criterion*. **Falsification criterion.** More than one unstable eigenvalue, an unbounded tail, or null transversality.

53.24 Constantes espectrales, aritmeticas and of vacancia

Internal complex structure and Catalan's constant

Antecedent. $J^2 = -I$ and the character $\chi_J(n) = i^{n-1} = \chi_{-4}(n)$ on odd integers. **Equation.**

$$G = L(2, \chi_J) = \sum_{n \geq 0} \frac{(-1)^n}{(2n+1)^2}.$$

Structure and meaning. Catalan's constant is the quadratic moment of the torsion quarter. **Value.** $G = 0.915965594177219\ldots$. **Status.** *Exact internal theorem.* **Falsification criterion.** Failure of multiplicativity or discrepancy with χ_{-4}.

Dodecaphase character and real quadratic field

Antecedent. CRT Product $\chi_{12} = \chi_{-3}\chi_{-4}$. **Equation.**

$$L(1, \chi_{12}) = \frac{\log(2+\sqrt{3})}{\sqrt{3}}, \qquad L(2, \chi_{12}) = \frac{\pi^2}{6\sqrt{3}},$$

$$\gamma_{\mathbb{Q}(\sqrt{3})} = \gamma + \frac{L'(1, \chi_{12})}{L(1, \chi_{12})}.$$

Structure and meaning. The triadic orientation and the torsional quarter produce the real character of $\mathbb{Q}(\sqrt{3})$; Euler–Kronecker is the finite term of its Dedekind zeta function. **Value.** 0.7603459963009463 . . ., 0.9497031262940094 . . ., and 1.0539656082484825 8 . . .. **Status.** *Exact internal theorem*; the composite identity preserves the declared hypotheses and normalizations. **Falsification criterion.** Residue pattern different from $(+, -, -, +)$ or failure of the Dedekind factorization.

Bendersky–Glaisher Family

Antecedent. Renormalized triadic zeta functional. **Equation.**

$$A_k = \exp\left(\frac{H_k B_{k+1}}{k+1} - \mathcal{Z}_3'(-k)\right), \quad \zeta(2n+1) = (-1)^{n+1} \frac{2(2\pi)^{2n}}{(2n)!} \log A_{2n}.$$

Structure and meaning. Apery and the odd zeta values are levels of a tower, not isolated coincidences. **Value.** $A_0 = \sqrt{2\pi}$, $A_1 = A_{\mathrm{GK}}$, and the preceding exact family. **Status.** *Exact internal theorem.* **Falsification criterion.** Failure of A_0, A_1 or of the identity for $\zeta(2n+1)$.

Gauss dynamical system: K, L, λ_{GKW}, and transported cylinders

Antecedent. Evaluation of HMT cylinders and measure $d\mu_G = dx/[\log 2(1+x)]$. **Equation.**

$$\log K = \int \log a_1 \, d\mu_G, \quad L = -\int \log x \, d\mu_G = \frac{\pi^2}{12\log 2},$$

$$h_G = 2L = \frac{\pi^2}{6\log 2}, \qquad \Lambda_b = \frac{6\log 2 \log b}{\pi^2}.$$

Structure and meaning. Khinchin measures digits; Lévy measures denominator growth; Lochs compares coding rates. **Value.**

$$K = 2.685452001065306\ldots, \qquad L = 1.18656911041562545\ldots,$$
$$h_G = 2.37313822083125091\ldots, \qquad \Lambda_{10} = 0.97027011439203393\ldots,$$
$$\Lambda_{729} = 2.77761896637430578\ldots.$$

Status. Cofinality and identities: *Exact in the transported system*; GKW constant: *Open program with a falsification criterion*. **Falsification criterion.** Failure of cylinder cofinality, non-invariant measure, or absence of a spectral gap in the declared space.

Aritmetic cycles of Meissel–Mertens and regularized prime series

Antecedent. Irreducible-cycle selector and exact factorization. **Equation.**

$$B_1 = \lim_{x\to\infty}\left(\sum_{p\le x}\frac{1}{p} - \log\log x\right), \qquad C_2 = \prod_{p>2}\frac{p(p-2)}{(p-1)^2}.$$

Structure and significance. B_1 is a regularized local sum; C_2 a multiplicative density of pairs. **Value.** $B_1 = 0.2614972128476428\ldots$, $C_2 = 0.6601618158468696\ldots$. **Status.** *Demonstrated with explicit initial structure*: declared prime selector and tail bound. **Falsification criterion.** Using zeros or decimal digits to choose the primes, or asserting the limit without executing the tail bound.

Vacancies, Holonomy, and Stieltjes Constants

Antecedent. Mechanical word of vacancies and bounded discrepancy. **Equation.**

$$\varepsilon_{\mathrm{vac}} = \log_{10}\frac{10}{9}, \quad \gamma^{+}_{\mathrm{vac}} = \lim_{N}\left(\sum_{n\le N}\frac{z_n}{n} - \varepsilon_{\mathrm{vac}}\log N\right),$$

$$\rho_{\varepsilon}(k) = e^{2\pi i k \varepsilon_{\mathrm{vac}}}, \qquad \gamma^{+}_{\mathrm{vac,j}} = \varepsilon_{\mathrm{vac}}\gamma_j + \sum_{n\ge 1}\frac{(z_n - \varepsilon_{\mathrm{vac}})(\log n)^j}{n}.$$

Structure and meaning. Density, finite term, and phase are three types; the tower prolongs the finite term. **Value.** $\varepsilon_{\mathrm{vac}} = 0.0457574905606751\ldots$; the remainder are determined by their certified limits. **Status.** *Exact internal theorem with discrepancy*. **Falsification criterion.** Loss of the discrepancy bound or disagreement at level $j = 0$.

Pell nonadic lift

Antecedent. $r^2 = 2 \pmod{3^k}$. **Equation.**

$$u = 3 + 2r, \qquad \mathrm{ord}(u) = 4\cdot 3^{k-1}, \qquad \varprojlim\langle u\rangle = C_4 \times \mathbb{Z}_3.$$

Structure and meaning. The quarter-turn persists at every depth; the Archimedean realization is $(1+\sqrt{2})^2$. **Value.** $3+2\sqrt{2} = 5.82842712474619\ldots$. **Status.** *Exact internal theorem.* **Falsification criterion.** Different order or incompatible lifts.

53.25 Gravity, area and modular information

Gravitational constant and five-component tensor representation

Antecedent. Chronological structure 108, action, and central projector of rank five. **Equation.**

$$G_a(\theta) = \theta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}, \qquad \theta_{108} = \left(\frac{54}{\pi}\right)^2, \qquad \mathcal{G}_5 = G_a(\theta_{108}) P_5.$$

Structure and meaning. G is a section selected by the Compton–gravity closure; P_5 determines a five-component carrier, which the TT reduction takes to two massless helicities. **Value.** $G_{\mathrm{int}} = \theta_{108} c^5 t_0^2/\hbar$ and $\mathrm{Spec}\,\mathcal{G}_5 = \{G \text{ with multiplicity } 5, 0 \text{ with multiplicity } 7\}$. **Status.** Selector: *Exact internal theorem*; carrier realization: *Typed physical realization.* **Refutation criterion.** Another positive root, $\mathrm{Tr}\,P_5 \neq 5$, or confusing five components with five massless physical polarizations of GR.

Planck system, reciprocity $G \leftrightarrow \hbar$, and areal invariance

Antecedent. The bidirectional product $G_a \hbar_a$ and temporal periodicity of 108 phases. **Equation.**

$$\ell_P^2 = \frac{G\hbar}{c^3} = \theta_{108} \ell_0^2, \quad t_P = \frac{54}{\pi} t_0, \quad E_P = \frac{\pi}{54} \frac{\hbar}{t_0},$$

$$F_P = \frac{c^4}{G}, \qquad P_P = \frac{c^5}{G}, \qquad \rho_P = \frac{\hbar}{\theta_{108}^2 c^5 t_0^4}.$$

Structure and significance. The Planck area is invariant under the splitting of action and links gravity to the thermal scale. **Value.** The preceding exact sections. **Status.** *Exact internal theorem.* **Falsification criterion.** Combining G and $\hbar$ from incompatible sheets or failing homogeneity.

Area operator and modular Hamiltonian: $\widehat{\mathcal{A}}_{\mathrm{HMT}}$, H_{mod}, and channels $90/120$

Antecedent. Incidence $6 \to 8$, channels $90/120$, output γ_{HMT} and ℓ_P^2. **Equation.**

$$\frac{A_{\mathrm{phys}}}{\ell_P^2} = \gamma_{\mathrm{HMT}} a_0 (N_{90} + N_{120}), \qquad K_{\mathrm{HHM}} = \Delta_4^{\mathrm{mod}} (90 N_{90} + 120 N_{120}) + cI.$$

If $N = N_{90} + N_{120}$ and $D = 90N_{90} + 120N_{120}$,

$$N_{90} = 4N - D/30, \qquad N_{120} = D/30 - 3N.$$

Structure and meaning. Area determines total occupancy; the Hamiltonian preserves channel provenance. Together they reconstruct the boundary. **Value.** $\gamma_{\mathrm{HMT}} a_0 = 0.0016755940749224991\ldots$ in the declared chart. **Status.** *Exact internal theorem at finite cutoff*; γ_{HMT} is not rederived. **Falsification criterion.** Nonzero commutator, lost determinant 30, or use of the adjective holographic without transport to the boundary.

Relative entropy, double thermofield purification, and first law modular areal

Antecedent. Faithful reduced state of the boundary and its Schmidt purification. **Equation.**

$$I_{\mathrm{or}} = 36\log 3 - S(\rho_A), \quad |\mathrm{TFD}\rangle = \sum_n \sqrt{p_n}|n\rangle|n\rangle,$$

$$\delta S = \beta_{90}\delta\langle\mathcal{A}_{90}\rangle + \beta_{120}\delta\langle\mathcal{A}_{120}\rangle, \qquad \frac{\beta_{120}}{\beta_{90}} = \frac{4}{3}.$$

Structure and meaning. Purification converts reduced entropy into entanglement; the first law equates modular memory and area. **Value.** $I_{\mathrm{or}} = 0.0016691832338689407\ldots$, $\beta_{90} = 5.97264854010709\ldots$, $\beta_{120} = 7.96353138680946\ldots$. **Status.** *Exact local internal theorem.* **Falsification criterion.** Partial trace different from ρ_A, $I_{\mathrm{or}} < 0$, or use for finite variations without the relative-entropy term.

Modular limit and type III parameter

Antecedent. Local states compatible with infinite persistence of both channels. **Equation.**

$$K_{\mathrm{HHM}}^{(m)} = -\log\rho_m, \qquad \lambda_\partial = \exp(-30\Delta_4^{\mathrm{mod}}).$$

Structure and meaning. At infinity there exists a local net or the GNS modular generator, not a global density matrix within the UHF algebra. **Value.** $\lambda_\partial = 0.9966696464689573786\ldots$. **Status.** Net: *Operator type rule*; classification: *Theorem under persistence hypotheses*. **Falsification criterion.** Asymptotic absence of a channel, a nonproduct state, or a different asymptotic ratio.

53.26 Sheet involution, mixing, and electroweak sector

Leaf Involution and Rational CKM Transformation: Unitarity, Determinant, and Jarlskog Character

Antecedent. Exchange $C^* \mapsto -C^*$ and datum $(h_6, o_8, t) = (6, 8, 3)$. **Equation.**

$$R_{\mathrm{CKM}} = M\,\mathrm{diag}(1,-1,1)M^{-1}, \quad R_{\mathrm{CKM}}^2 = I, \quad \det R_{\mathrm{CKM}} = -1,$$

$$-\frac{o_8 - h_6}{t} = -\frac{2}{3}, \quad A = \frac{1528\theta_{12} + 3380\theta_{23} + 801\theta_{13}}{3857},$$

$$C^* = 6\frac{75\theta_{12} + 176\theta_{23} - 150\theta_{13}}{3857}.$$

Structure and meaning. Barbero and CKM are distinct functional realizations of the change $6 \to 8$, adopted as a common antecedent; the involution induces a rational rank-one odd reflection. **Value.** Exact rational matrix, $\det M = -3857/6$; the CP phase is fixed under this involution, which is not CP conjugation. **Status.** *Exact genealogical/internal.* **Falsification criterion.** $R^2 \neq I$, failure of $RM = MD$, loss of $-2/3$, or presenting CKM as the retrospective cause of γ_{HMT}.

Angular determinant, Weinberg parameter and electroweak couplings

Antecedent. Two functions of the same angular operator: $F(T)^2$ and $\det T$; adjacent W/Z routes. **Equation.**

$$D_A = \det T = e^{-2A_{\mathrm{rad}}}, \qquad \sin^2\theta_W^{\mathrm{OS}} = 1 - D_A,$$

$$g = 2\sqrt{\frac{\pi\alpha}{1-D_A}}, \qquad g' = 2\sqrt{\frac{\pi\alpha}{D_A}}.$$

Structure and meaning. The vacuum and Weinberg are distinct spectral realizations of a common operator; the determinant is even under the change of sheet.

Value. $D_A = 0.7751291192471564302\ldots$ and $\sin^2\theta_W = 0.2248708807528435698\ldots$.

Status. Angular relation: *Exact internal theorem in the chart*; gauge realization: *Conditional realization*. **Falsification criterion.** Nonadjacent routes, a mass quotient different from D_A, or an undeclared gauge scheme.

Fermi Constant and Higgs Coupling

Antecedent. α_{HMT}, D_A, routes W/H, and the electroweak chart of the tree. **Equation.**

$$G_F^{(0)} = \frac{\pi\alpha}{\sqrt{2}(1-D_A)m_W^2},$$

$$\lambda_H = \frac{\pi\alpha}{2(1-D_A)} \exp\left(6A_{\mathrm{rad}} + \frac{10}{3}C^*_{\mathrm{rad}}\right), \qquad G_F^{(0)} m_H^2 = \sqrt{2}\lambda_H.$$

Structure and meaning. Fermi is the effective low-energy limit of the charged channel; Higgs preserves the orientation that the gauge determinant eliminates. **Value.** $G_F^{(0)} = 1.1157162817 \times 10^{-5}\,\mathrm{GeV}^{-2}$ in the declared chart and $\lambda_H = 0.123847911548\ldots$. **Status.** *Tree-level electroweak interface*. **Refutation criterion.** Using observed G_F to choose Δr, omitting scheme/scale or selecting λ_H from the observed mass.

Leptonic magnetic anomaly

Antecedent. $(\alpha, \varphi, 1000, 54+1)$ with coefficients frozen before the contrast. **Equation.**

$$a_\mu = \frac{\alpha}{2\pi} + \frac{\alpha(\varphi-1)}{1000} + \frac{\alpha^2}{1000(54+1)}. \tag{53.28}$$

Structure and meaning. It is an evaluation of three HMT functionals, not a substitution for the complete QED radiative series. **Value.** $a_\mu = 0.001165920713\ldots$. **Status.** *Exact evaluation with open local provenance*. **Falsification criterion.** Selecting 1000 or 55 from the experimental value.

53.27 Determination of Cosmological Parameters via Torsional Memory and Perron Dynamics

de Sitter realization through the temporal periodicity of 108 phases

Antecedent. Circular selector $R_{108} = \ell_P$ and de Sitter realization. **Equation.**

$$H_{108} = \frac{\pi}{54t_0}, \quad \Lambda_{108} = \frac{\pi^2}{972\ell_0^2}, \quad \frac{T_{\mathrm{dS}}}{\Theta_{\mathrm{clk}}} = \frac{\log 3}{2\pi}, \quad \frac{S_{\mathrm{dS}}}{k_B} = \pi.$$

Structure and significance. A single radius determines expansion, curvature, temperature, and entropy. **Value.** The preceding exact quadruple. **Status.** *Conditioned physical realization.* **Falsification criterion.** A non-de Sitter background or a PCH realizer selecting another radius.

Perron–Einstein–Cartan Realization

Antecedent. Scale $V_n = \varphi^n$, $D = 3$, stable mode φ^{-2n}. **Equation.**

$$\frac{a_n}{a_0} = \varphi^{n/3}, \qquad M_n = \left(\frac{a_n}{a_0}\right)^{-6}, \qquad H_\varphi = \frac{\log\varphi}{3t_0}.$$

Structure and meaning. The exponent -6 is active memory and coincides with the Einstein–Cartan dilution that is quadratic in spin. **Value.** $H_\varphi t_0 = 0.1604039416865344825\ldots$ and the exact law $M_n a_n^6 = a_0^6$. **Status.** Scale: *Exact internal theorem*; spin reading: *Conditional realization*. **Falsification criterion.** A different exponent, a nonadditive temporal parameter, or a physical amplitude selected from a bounce.

53.28 Typed separation between the Bohr and Born-Infeld radii and the internally generated scales

Bohr radius as an electrodynamic scale derived from α

Antecedent. Action, vacuum, α, and electronic mass from its antecedent. **Equation.**

$$a_0 = \frac{\hbar}{m_e c \alpha}. \tag{53.29}$$

Meaning and value. It is a descending composition, not an independent selector of this monograph. **Status.** *Out of scope*. **Falsification criterion.** Recalculating m_e here or using a_0 to select α.

Born-Infeld Scale and Recovery of the Maxwell Limit

Antecedent. $(h_{\mathrm{int}}, c_{\mathrm{int}}, e_{\mathrm{int}}, \ell_0)$. **Equation.**

$$E_* = \frac{h_{\mathrm{int}} c_{\mathrm{int}}}{e_{\mathrm{int}} \ell_0^2}. \tag{53.30}$$

Structure and meaning. The expression constructs a field scale; it does not yet construct a Born–Infeld action. **Value.** Exact section E_*, without determination of a physical parameter. **Status.** *Open program*. **Falsification criterion.** Identification by name or decimal without a determinantal action and selector.

Proposition 53.32 (Main Result)**.** *The metrological result is not the isolated decimal. It is the preservation of a genealogy through operators, lines of magnitude, and charts, until the real value appears in the last position of the record.*

53.29 Existence, uniqueness, and compatibility theorems of the genealogical constants

The construction determines an autonomous sector of intrinsic constants. Its compositions, cross-theorems, and certificates form a self-contained chain of proof. The governing order is

$$\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow \text{functional realization} \longrightarrow \text{invariant} \longrightarrow \text{section} \longrightarrow \text{terminal value}. \tag{53.31}$$

In that order, five main closures are obtained.

1. The electromagnetic vacuum ceases to be a collection of four formulas: it is a positive two-sheet operator whose spectrum determines ε, μ, Z, c, with compatible nonadic amplification.
2. Criticality no longer begins with the Feigenbaum decimals: the dodecaphase cancels π, mode 30 produces 899, the germ closes trigonometrically and demonstrably enters the appropriate unimodal analytic class. Universal hyperbolicity is isolated as a distinct certificate.
3. Gravity ceases to be merely a decimal chart: the temporal periodicity of 108 phases selects a section of L_G, the rank-five projector fixes the tensor carrier, and TT reduction distinguishes that carrier from the two massless helicities.
4. The hexad–octad transition acquires three related realizations: areal quantum, modular memory, and mixing reflection. The modular holographic Hamiltonian is central to that interface of confluence, but it does not subsume the vacuum, criticality, gravity, arithmetic, or cosmology under a title that is artificially unique.
5. The less common constants include Catalan, Levy, Lochs, and Euler–Kronecker. Bendersky–Glaisher, vacancies, and cosmological realizations likewise appear as values of operators and dynamics, not as a list for which retrospective coincidences are sought.

53.30 Theorematic character of the metrological corollary

The corollary 53.31 and the table 53.5 constitute the probative closure of the development. They are not an abridged summary of the preceding material. For a row to enter that corollary, it must simultaneously preserve

$$\text{antecedent} \mid \text{equation} \mid \text{invariant} \mid \text{meaning} \mid \text{terminal value}.$$

If any of these five components is removed, the row ceases to be an HMT output and becomes a mere numerical equivalence. The status and the falsification criterion are not substitute columns: they audit from outside the strength and domain of the complete quintuple.

This formulation produces three structural and mathematical consequences. First, the terminal value may be an exact expression on a magnitude line; reduction to SI is not required in order to recognize it. Second, an antecedent may admit several functional realizations —for example, T determines both the vacuum response and D_A— without those realizations being identified. Third, a shared integer such as 30, a shared ratio such as $4/3$, or a shared scalar such as $\log 3$ establishes confluence only when the map transporting it and the invariant it preserves are exhibited.

In particular, the atlas allows one to read two closure equations that were previously scattered:

$$\boxed{E_P = k_B \Theta_{\mathrm{clk}} \log 3}, \qquad \boxed{(6 \to 8) \longrightarrow \left(\gamma_{\mathrm{HMT}} \ell_P^2,\ -\log \rho_A,\ R_{\mathrm{CKM}}\right).} \tag{53.32}$$

The first brings together a quantum of energy, temperature, and information. The second determines, from a common confluence interface, a geometric quantum, a modular generator, and a mixing reflection. No equation asserts that its components are the same object; it asserts that their genealogies have been preserved to the exact point of branching.

The negative control is also immediate. If E_P is used to select k_B, if CKM is used to recalibrate γ_{HMT}, if $\log 3$ is confused with a density matrix, or if equality of two decimals replaces the intertwiner, the corollary does not apply. The autonomy of the derivation lies in the fact that these controls, like the derivations, are formulated within the development itself.

53.31 Logical stratification of internal identities, dimensional realizations, and external recognitions

The strength of an assertion is not deduced from the extraordinary nature of its conclusion or from its proximity to a known value. It is deduced from the chain that sustains it.

Status	Content of the development
theorem internal exact	Vacuum operator and its constitutive quantities; mode 30; charge and quantum quotients; thermal scale; closed chaos profile; lattice $3/4/12$; Gauss identities; selector θ_{108}; Planck family; CKM reflection; law $M_n = (a_n/a_0)^{-6}$ in its chart.
Exact mathematical composition	Wien, Stefan–Boltzmann, photon gas, Euler–Kronecker, Bendersky–Glaisher, Weinberg angular relation, joint area–memory reconstruction and Higgs self-coupling at the tree-level interface.
Demonstrated with Explicit Starting Structure	Results that depend on a declared chart, an orientation, a measure, a boundary state, or a boundary datum, without introducing the terminal value as a selector.
theorem with hipotesis explicit	Classification of the GNS closure as a hyperfinite factor III_{λ_∂}, under faithfulness, compatibility, and infinite persistence of the two channels $90/120$.

Conditional realization in physics	Complete identification of gauge, renormalized G_F, de Sitter realization of the CT108 radius, transduction of Perron memory into spin density, and dynamic realization of the tensor carrier.
Open Programme with Falsification Criterion	Full hyperbolicity of the Feigenbaum renormalization operator, subdominant Gauss–Kuzmin–Wirsing eigenvalue, and construction of an internally selected Born–Infeld action.
External metrological contrast	SI charts, CODATA/PDG comparisons, classical values of the constants and operatorial classifications applied only after constructing the HMT weights.

An open interface does not diminish the internal theorem that precedes it. Conversely, an internal theorem does not automatically promote a physical interpretation whose transducer has not yet been constructed.

53.32 Transverse obstructions of typing, causality, orientation, and nonadic compatibility

The construction is subject to refutation. The following controls traverse all the chapters.

F1. **Dimensional typing.** An identity that is not homogeneous in the lines L_S, L_C, L_T, L_Q is discarded, although it reproduces a decimal.

F2. **No feeding by the target value.** No SI, CODATA, PDG, Feigenbaum, GKW, H_0, G_F, or magnetic anomaly value may select an internal operator, coefficient, or realization.

F3. **Sheet convention.** Silently reversing q_+ and q_-, or conflating sheet involution with CP conjugation, invalidates the parities and quotients.

F4. **Nonadic compatibility.** A functional that changes under amplification 9^m, loses the unit, or fails to preserve return memory does not possess the claimed limit.

F5. **No fusion by scalar.** The equality of two terminal values does not identify their domains. An intertwiner is required that commutes with the operators and preserves orientation, carry, and boundary.

F6. **Finite–infinite separation.** A certificate through level eight does not prove universal hyperbolicity; a finite modular Hamiltonian is not $-\log \rho_\infty$ within the UHF; numerical convergence without a tail bound does not certify a prime product.

F7. **Physical transducer.** The de Sitter, Einstein–Cartan, Born–Infeld, or gauge reading is blocked unless it determines the complete object of the target theory and its boundary conditions.

53.33 Necessary Conditions for Mathematical Extensions and Non-Equivalent Physical Realizations

No generic caveat such as "HMT still needs to be related to physics" remains. Localized obligations remain:

CHAOS-OBL-1	Certify, in a space of even analytic functions, the fixed point of $\mathcal{R}$, a unique unstable eigenvalue, the tail bound, and the transversality of the HMT germ.
GAUSS-OBL-1	Fix the functional space of the Gauss operator, isolate the subdominant eigenvalue with intervals, and prove stability of the projector under the partitions 9^m.
HMOD-OBL-1	Verify compatibility of the local states and positive-density persistence of both channels before applying the Araki–Woods classification. Do not use a nonexistent global trace-class density.

EW-OBL-1 Construct the intertwiner between the HMT sheets and the neutral/charged electroweak basis, and derive Δr without using the experimental value of G_F.

COS-OBL-1 For de Sitter, prove that the PCH realizer dynamically selects R_{108}. For Einstein–Cartan, construct the amplitude, current, sign and dimensional chart of the map $M_n \mapsto s_n^2$.

BORN-OBL-1 Construct the Born–Infeld determinantal action and prove that the scale E_* is its parameter, rather than identifying it by dimensional considerations.

ANOM-OBL-1 Close the local provenance of 1000 and $54+1$ before promoting the evaluation of a_μ to a complete derivation.

Each obligation has an object, a domain, and a falsification criterion. None authorizes the reopening of the exact blocks that precede it.

53.34 Formal Delimitation of the Domain of Genealogical Derivations

- It does not rederive $\pi, e, \varphi, \alpha_{\mathrm{HMT}}$; it uses them as already constructed inputs when a subsequent composition requires them.
- It does not compete with the General Mass Law or recalculate the electron mass.
- It does not rederive γ_{HMT}; it develops its areal, informational, and modular meaning.
- It does not identify the five-component carrier with five polarizations of a massless graviton.
- It does not conflate a finite Feigenbaum approximation with the universal theorem, nor a dimensional scale with a Born–Infeld action.
- It does not turn the modular holographic Hamiltonian into the name or the exclusive explanation of all constants. It is a central component of the area–information–mixing confluence interface within a broader atlas.

53.35 Reconstructive power of the common genealogy over mathematical and physical constants

The metrological singularity of HMT–MD does not consist in producing many decimals. It consists in the real value appearing at the end of a sequence that conserves memory. Permeability and permittivity are the two quadratic eigenvalues of the same response; G is the section that closes a Compton radius with a gravitational radius; $\log 3$ is simultaneously decision content and thermal ratio; Catalan is a moment of the quarter-torsion; γ_{HMT} orients the quantum of area; the modular Hamiltonian conserves which channel produced the occupation; the CKM reflection conserves the coordinate responsible for the change of sheet; the exponent -6 conserves stable memory when determining the cosmological scale.

Proposition 53.33 (Main Result)**.** *The structural signification demonstrated in this development is expressed through a realization rule: the same antecedent may admit several functionals without losing its genealogy, and each one simultaneously determines the meaning of the constant and the reason for its terminal value.*

The final assertion is therefore more precise than "HMT reproduces constants". HMT–MD constructs operators, characters, sections, and transducers of which constants are evaluations. Where the chain is closed, the value and its meaning are proved together. Where an interface remains, the falsification criterion permits work to continue without downgrading what has already been established or presenting as a theorem what is still a programme.

Chapter 54

Genealogical completeness of HMT sections and decidability of each finite level

54.1 Conservative Extension of Finite Completeness via Projective Multiplicities

A concrete HMT tower consists of finite sets, transition relations, restriction maps, and readers. All of this can be encoded in ZF or ZFC. The collection of all towers constitutes a definable class; it is unnecessary to postulate that HMT already forms an autonomous class theory comparable to NBG.

Proposition 54.1 (Conservative Coding)**.** *Every finite or countable genealogical object used in this notebook can be represented by sets and relations in ZFC. Therefore, the formalizations constructed here do not prove a contradiction in ZFC.*

Proof. Each level X_m is a set, each restriction $p_{n,m}$ is a subset of $X_n \times X_m$, and a countable tower is a function with domain $\mathbb{N}$ encoding these data. Types, readers, and memories are added as relations or functions. The inverse limit is a subset of the product $\prod_m X_m$, which ZFC constructs by Replacement, Union, Power Set, and Separation. □

What HMT calls into question is not the legitimacy of that encoding, but the practice of forgetting the maps and retaining only a shadow. If, for example, one applies the reader

$$L : \Omega_\infty \longrightarrow \mathbb{R}$$

or the cardinal profile

$$\mathbb{X} \longmapsto (|X_m|)_{m \geq 0},$$

nonisomorphic objects may be collapsed. The projection is valid in its codomain; what would be invalid is to attribute faithfulness to it without proof.

Remark 54.2 (Conditions of validity). It is not claimed that HMT internally satisfies every schema of ZF, IZF, or NBG. Separation, Replacement, the full Power Set axiom, and a general transfinite hierarchy have not been verified jointly within an autonomous HMT axiomatics.

54.2 Category of genealogical objects

Definition 54.3. A genealogical object is

$$\mathbb{X} = \big((X_m)_{m \geq 0}, (p_{n,m})_{n \geq m}, \mathcal{T}, \mathcal{O}, \mathcal{M}\big),$$

where $\mathcal{T}$ records types, $\mathcal{O}$ observables, and $\mathcal{M}$ memories. A morphism $f : \mathbb{X} \to \mathbb{Y}$ is a family $f_m : X_m \to Y_m$ satisfying

$$p^Y_{n,m} f_n = f_m p^X_{n,m}$$

and preserves the indicated data.

The category thus obtained is a concrete presentation of enriched profinite objects. The global-sections functor

$$\Gamma(\mathbb{X}) = \varprojlim_m X_m$$

recovers the complete histories. The small path category of TPK also admits the presheaf envelope

$$\widehat{\mathcal{P}_{\mathrm{TPK}}} = \mathbf{Set}^{\mathcal{P}_{\mathrm{TPK}}^{op}}.$$

This construction provides contextual logic and data sheaves, but does not warrant declaring Booleanity, choice, or enough points without studying the specific topos.

54.3 Foundations of Prefixes and Coinduction of Sections

The prefix graph is graded by depth:

$$\mathrm{rk}(x_m) = m.$$

Applying the parent strictly decreases the rank. There are no parental cycles.

$$x_m \longrightarrow x_{m-1} \longrightarrow \cdots \longrightarrow x_m$$

compatible with that graduation.

Proposition 54.4. *Well-foundedness of the prefix graph and coinductive existence of an infinite section are compatible.*

Proof. Well-foundedness concerns the direction of descent through parents. Coinduction concerns a family (x_m) compatible with all descents. No x_m belongs to itself or reappears as the same node; the section is a function on $\mathbb{N}$, not a membership cycle. □

This distinction clarifies the return $9 \longrightarrow 1$. The phase may recur, but the memory coordinate increases. A loop in the phase projection is not a cycle in the graded state graph.

54.4 Fibration of ordinals by compatible genealogical histories

Von Neumann represents each ordinal as the set of its predecessors, [127]. HMT may lift that representation without modifying it.

Definition 54.5 (Genealogical elevation of a finite ordinal)**.** Let $\boldsymbol{x} = (x_m)$ be a section. Define

$$\widehat{n}_{\boldsymbol{x}} = \{(k, x_k) : k < n\}.$$

Proposition 54.6. *The projection onto the first coordinate satisfies*

$$\pi(\widehat{n}_{\boldsymbol{x}}) = n,$$

and the sequence obeys

$$\widehat{n+1}_{\boldsymbol{x}} = \widehat{n}_{\boldsymbol{x}} \cup \{(n, x_n)\}.$$

Proof. Both identities follow directly from the definition. The added information does not alter the underlying order; it distinguishes the routes that realize the same ordinal. □

For ω one writes

$$\widehat{\omega}_{\boldsymbol{x}} = \{(n, x_n) : n \in \mathbb{N}\}.$$

The support of each history remains countable, although the space of all histories may have continuum cardinality when branching persists.

Remark 54.7 (Extension and open domain). The extension

$$S_{\alpha+1} = \mathrm{Ext}_\alpha(S_\alpha), \qquad S_\lambda = \varprojlim_{\beta<\lambda} S_\beta$$

is a well-typed transfinite programme, not a result already proved for every ordinal. The coherence of the limits, the sizes of the levels, and the existence of extensions must be verified.

54.5 Decategorification Functor and the Cardinality of Published Sections

Two towers can satisfy

$$|X_m| = |Y_m| \qquad \text{for every } m$$

and fail to be isomorphic: it suffices that their restriction maps have distinct branching patterns. The cardinal profile is therefore a useful but nonfaithful invariant.

Remark 54.8 (Structural Interpretation). Counting how many cells exist does not say which cell prolongs which, which orientation is reversed, which carry is transported, or which state returns. The cardinal measures the inventory; the genealogy measures the organization.

Remark 54.9 (Separation of results and scope). The ZFC coding, the section as a limit, and the distinction between observational equality and state identity are *results established in the preceding sections*. The unified category, the presheaf topos, and the fibered ordinal are *explicit constructions of the present development*. No complete autonomous HMT theory of classes or transfinite ordinals is proclaimed.

54.6 Profinite limit of the system of genealogical truncations

Let

$$X = \varprojlim_m X_m$$

an inverse limit of finite discrete sets with surjective maps. We equip X with the initial topology of the projections $\pi_m : X \to X_m$. The cylinders

$$[A]_m = \pi_m^{-1}(A), \qquad A \subseteq X_m,$$

are clopen and form a basis.

Theorem 54.10 (Cylindrical power)**.**

$$\mathrm{Clop}(X) \cong \varinjlim_m \big(\mathcal{P}(X_m), p_{n,m}^{-1}\big).$$

Proof. Every cylinder is clopen. Conversely, if $C \subset X$ is clopen, then for each $x \in C$ there is a cylinder contained in C. Compactness of C gives a finite subcover. Lifting those cylinders to a common depth m yields $C = \pi_m^{-1}(A)$ for some $A \subseteq X_m$. Two representatives at different depths define the same clopen set exactly when they agree after a common lift. □

Theorem 54.11 (Closed-form power)**.**

$$\mathrm{Closed}(X) \cong \varprojlim_m \big(\mathcal{P}(X_m), p_{n,m*}\big),$$

where $p_*(A) = p(A)$.

Proof. If $F \subset X$ is closed, it is compact. Its projections $F_m = \pi_m(F)$ satisfy $p_{n,m}(F_n) = F_m$. Conversely, a compatible family (F_m) defines the inverse limit

$$F = \{x \in X : \pi_m(x) \in F_m \text{ for every } m\}.$$

It is an intersection of closed sets and, by the surjective compatibility of the restrictions $F_n \to F_m$, its projections are exactly F_m. The two constructions are inverse. □

54.7 Obstruction to the Reconstruction of the Genealogical Power from Finite Reductions

In a Cantor space,

$$|\operatorname{Clop}(X)| = \aleph_0, \qquad |\operatorname{Closed}(X)| = 2^{\aleph_0}, \qquad |\mathcal{P}(X)| = 2^{2^{\aleph_0}}.$$

The three objects cannot be identified.

This separation does not presuppose the continuum hypothesis. Writing $\mathfrak{c} = 2^{\aleph_0}$,

$$|\operatorname{Clop}(X)| = \aleph_0, \qquad |\operatorname{Closed}(X)| = \mathfrak{c}, \qquad |\mathcal{P}(X)| = 2^{\mathfrak{c}}.$$

CH identifies only $\mathfrak{c}$ with $\aleph_1$; it does not collapse any of the three layers. Gödel–Cohen independence changes which cardinal may occupy $\mathfrak{c}$, not Cantor's inequality $\mathfrak{c} < 2^{\mathfrak{c}}$.

Proposition 54.12 (Dense falsifier)**.** *If $D \subsetneq X$ is dense, then*

$$\pi_m(D) = X_m \qquad \text{for every } m,$$

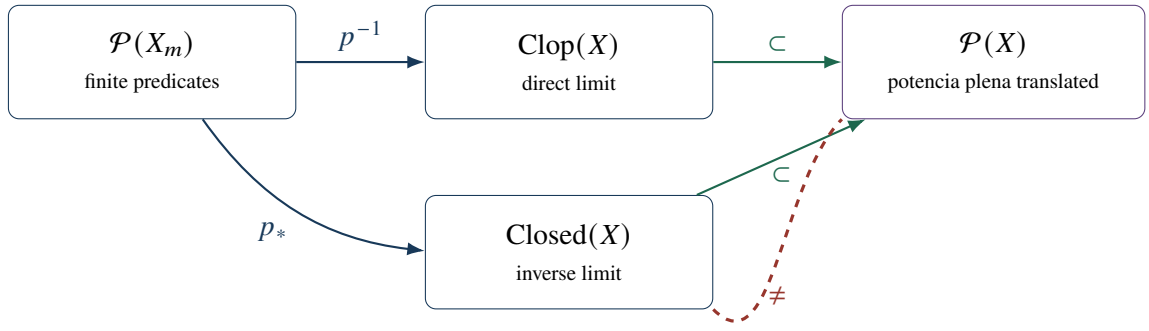
so that D and X possess the same finite shadows.

Proof. Every nonempty cylindrical fiber $\pi_m^{-1}(a)$ is open. By density, it intersects D. Hence $a \in \pi_m(D)$ for every $a \in X_m$. □

Finite shadows reconstruct the closure of a subset, not the arbitrary subset itself. This is the precise point at which an identification

$$\varprojlim_m \mathcal{P}(X_m) = \mathcal{P}(\varprojlim_m X_m)$$

would become false.



A proper dense subset and X have the same finite projections: finite history recovers closure, not the full power set.

Figure 54.1: Three notions of power that must not be flattened.

54.8 Necessary choice conditions for the global prolongation of compatible sections

Let $p : X \twoheadrightarrow Y$. It is useful to distinguish:

1. a *section conjuntista* $s : Y \to X$ With $p s = \mathrm{id}_Y$;
2. a *natural family* of sections that commutes with the restrictions of a tower;
3. an *algebraic section* that also preserves the operations;
4. a *section efectiva* calculada by a algoritmo total.

Every natural, algebraic, or effective section is, upon forgetting structure, a set-theoretic section. The three additional properties are generally incomparable: an algorithm may select representatives without being a homomorphism; a homomorphism may not be computable in the chosen presentation; a natural family may not preserve the algebraic operation.

Remark 54.13 (Conditions of validity). The axiom of choice guarantees a set-theoretic selection within its domain. It does not guarantee naturality, algebraicity, effectiveness, or uniform cost. The independence of AC from ZF likewise does not turn these four requirements into one: even in a model with choice, the structural section requires its own proof.

54.9 Pell Obstruction to the Uniform Periodicity of the Prefix System

The active generator constructs

$$K_\infty \cong C_4 \times \mathbb{Z}_3$$

and finite projections $p_m : K_\infty \to K_m$. A representative of each class may be chosen, but not a homomorphic section compatible with the group.

Proposition 54.14. *There is no homomorphism $s_m : K_m \to K_\infty$ with $p_m s_m = \mathrm{id}$ for the quotient that introduces finite ternary torsion into K_m.*

Proof. A homomorphic section would send an element of order 3^r of K_m to an element of the same order in the component $\mathbb{Z}_3$. But the additive group $\mathbb{Z}_3$ is torsion-free: if $3^r x = 0$, then $x = 0$. The image cannot project back onto a nonzero element of order 3^r. □

The obstruction does not say «it cannot be chosen». It says: it cannot be chosen while simultaneously preserving the projection and the group law. The carry information that disappears in the quotient reappears as an obstruction to the section.

Remark 54.15 (Separation of results and scope). The profinite continuum and the Pell obstruction are *results established in the preceding sections*. The two power theorems and the table of choices are *explicit constructions of the present development*. The dense falsifier precludes turning an incomplete search for a subset into a power that has already been reconstructed.

Chapter 55

Gödel–Turing obstruction to uniform decision of projective multiplicities

55.1 Algorithmic decidability of each finite level of the prefix system

Proposition 55.1. *At a fixed depth N, if the domains are finite and the atomic observables are computable, every formula in the finite language L_N is semantically decidable.*

Proof. Atomic formulas are computed; connectives are decided by truth tables; each quantifier ranges over a finite domain. The conclusion follows by induction on syntactic complexity. □

The decidability of each window does not necessarily provide a single algorithm that decides a property of the complete tower.

55.2 Effective tower associated with the computation of projective multiplicities

Let T_e be the Turing machine with index e. For each n, define

$$X_n^e = \{b_n\} \cup \{c_n : T_e \text{ has not halted in its first } n \text{ steps}\}.$$

Links preserve existing labels:

$$p_{n+1,n}(b_{n+1}) = b_n, \qquad p_{n+1,n}(c_{n+1}) = c_n.$$

The visible tower has to single symbol v_n, and

$$q_n(b_n) = q_n(c_n) = v_n.$$

Theorem 55.2 (Global multiplicity and stopping)**.**

$$\#q_\infty^{-1}(\boldsymbol{v}) = \begin{cases} 1, & T_e \textit{ stops}, \\ 2, & T_e \textit{ never halts}. \end{cases}$$

Therefore, no total algorithm decides uniqueness of the global fiber for all effective towers in this family.

Proof. The branch $\boldsymbol{b} = (b_n)$ always exists. If T_e halts at step h, the states c_n disappear from h onward and do not form a global section. If it never halts, $\boldsymbol{c} = (c_n)$ is a second section. A decider for uniqueness would decide HALT, contradicting [125]. □

We define

$$U_e : \#q_\infty^{-1}(\boldsymbol{v}) = 1.$$

Then $U_e \iff T_e \downarrow$.

Theorem 55.3 (Uniform incompleteness)**.** *Let T be a recursively axiomatizable theory that formalizes the towers X^e and is semantically correct for U_e and $\neg U_e$. Then T does not decide every U_e.*

Proof. If each U_e were to decide, for an index e one would enumerate in parallel the proofs of U_e and $\neg U_e$ until finding one. By correctness, the first would appear exactly when the machine halts and the second when it does not. A decider of HALT would be obtained. □

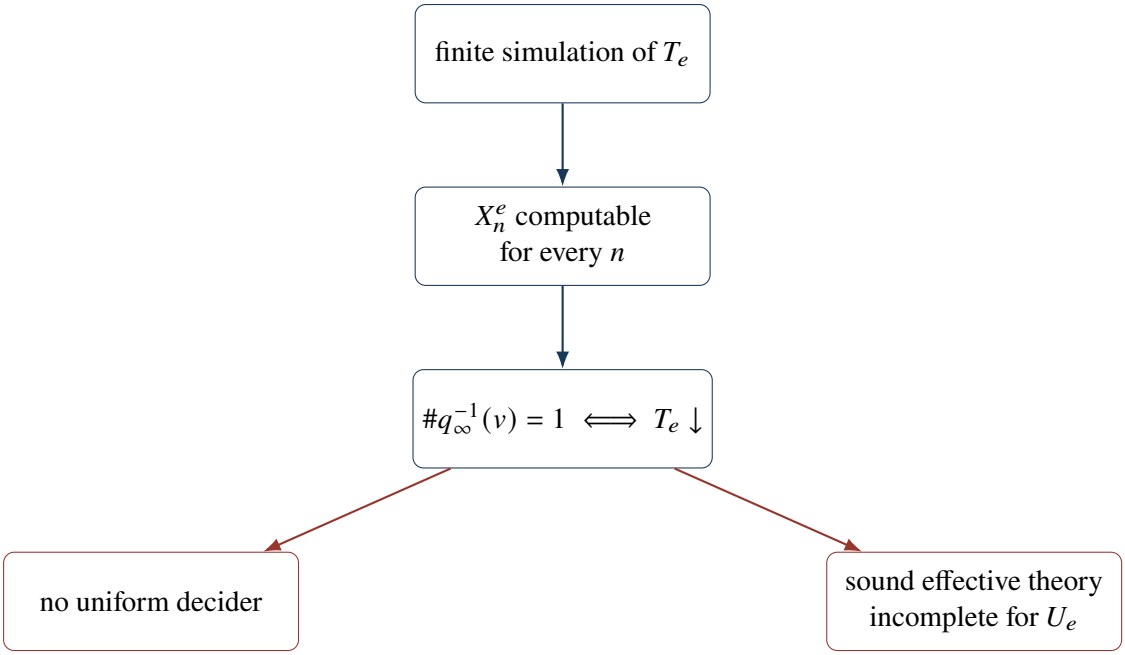


Figure 55.1: From the finite decision to uniform incompleteness.

55.3 Finite completeness of the HMT levels and exact domain of the Gödel–Turing obstruction

The academic name used is:

HMT uniform incompleteness theorem for projective multiplicities.

The abbreviated designation “third Gödel result in HMT” is also used. The proof is Gödel–Turing: it does not reproduce the self-referential diagonal of [55], but instead reduces HALT to the multiplicity of a fibre.

Remark 55.4 (Conditions of validity). The theorem does not prove the inconsistency of ZFC. Nor does it preclude a direct proof that a particular tower has a unique section. It precludes a universal uniqueness procedure for all effective towers.

55.4 Restriction of the uniform obstruction to the nonadic temporal system of 9 phases

The 9 phases of the TPK provide a concrete algorithm that, with its declared readers, partitions the refinement block into 729 subcylinders and selects one of them at each finite stage. The passage to the infinite section uses a global theorem of nonemptiness, compatibility, and unitarity.

The Gödel–Turing result says:

there is no uniqueness decider for every effective tower.

It does not state:

no concrete tower can have a uniform proof of its own.

And a particular proof does not provide the universally forbidden decisor.

Remark 55.5 (Structural Conclusion). Finite decidability, existence of the limit, uniqueness of an instance, and uniform decidability of all instances are four levels. Holographic closure requires that they be declared, rather than automatically transferring a property from one level to another.

Remark 55.6 (Separation of results and scope). The reducing tower, the equivalence $U_e \iff T_e\downarrow$, and the metamathematical theorem are *results established in the preceding sections*. The central position within the closure of infinity is an expository organization that alters neither the logical content nor the theorem's domain.

Chapter 56

Gödel–Cohen: relative consistency, independence and forcing on prefix spaces

56.1 Relative consistency in L and independence via forcing

Theorem 56.1 (Gödel, 1940: constructible half)**.** *In usual metatheory,*

$$\mathrm{Con}(\mathsf{ZF}) \Longrightarrow \mathrm{Con}\big(\mathsf{ZF}+\mathsf{AC}+\mathsf{GCH}\big).$$

More precisely, given a model $M \models \mathsf{ZF}$, its internal constructible universe L^M satisfies, in the corresponding internal sense,

$$\mathsf{ZF}+V=L+\mathsf{AC}+\mathsf{GCH}.$$

Idea of the classical proof. The constructible hierarchy is defined by recursion over the ordinals, admitting at each stage only subsets definable over earlier stages. The construction preserves the ordinals, produces an inner model, and provides a global definable well-order, from which choice and the generalized continuum hypothesis [56] follow. □

Theorem 56.2 (Cohen, 1963–1964: forcing half)**.** *One has the metamathematical implications*

$$\mathrm{Con}(\mathsf{ZFC}) \Longrightarrow \mathrm{Con}(\mathsf{ZFC}+\neg\mathsf{CH}),$$

and

$$\mathrm{Con}(\mathsf{ZF}) \Longrightarrow \mathrm{Con}(\mathsf{ZF}+\neg\mathsf{AC}).$$

Combining the two halves, CH *is independent of* ZFC *and* AC *is independent of* ZF*, always under the corresponding consistency hypothesis [30, 31].*

For the first construction, one begins with a base model M, a poset $\mathbb{P} \in M$, and an M-generic filter $G \subseteq \mathbb{P}$:

$$G \cap D \neq \varnothing \qquad \text{for every dense } D \subseteq \mathbb{P} \text{ belonging to } M.$$

The forcing theorem relates $p \Vdash_M \varphi$ to the truth of φ in $M[G]$. To obtain $\mathsf{ZF}+\neg\mathsf{AC}$, one additionally takes a suitable symmetric submodel of a generic extension; an ordinary extension of a model of ZFC preserves choice [32].

Remark 56.3 (Conditions of validity). These theorems prove relative consistency and independence. They do not prove the absolute consistency of ZF or ZFC, do not decide CH in a privileged universe, and do not convert every compatible filter into a generic filter. Nor do they select the HMT branches or identify a numerical output.

56.1.1 2 Non-Equivalent Operations: Model Extension and Object Enrichment

Forcing and HMT do not perform the same operation. The former compares a universe M with an extension $M[G]$; the latter preserves fibers that a reader forgets. If $\mathsf{Hist}_{\mathrm{HMT}}$ is the category of enriched histories, the functor

$$U : \mathsf{Hist}_{\mathrm{HMT}} \longrightarrow \mathsf{Set}, \qquad (x_m, \mu_m)_{m\geq 0} \longmapsto (x_m)_{m\geq 0},$$

may identify distinct histories without changing the visible set. Cohen's question is which subsets exist in the model; the genealogical question is how many lifts, with memory and operators, a visible object possesses. They are compatible axes, but neither replaces the other.

Operation	What changes	What does not prove by itself
$M \mapsto M[G]$	Set-theoretic universe, names and forced truth	Uniqueness or genealogy of an HMT section.
$\xi \mapsto U(\xi)$	Amount of visible memory in the projection	CH, AC, or genericity over M.

56.1.2 HMT power does not presuppose CH

In every model in which X is a Cantor space,

$$|\operatorname{Clop}(X)| = \aleph_0, \qquad |\operatorname{Closed}(X)| = \mathfrak{c}, \qquad |\mathcal{P}(X)| = 2^{\mathfrak{c}}, \qquad \mathfrak{c} = 2^{\aleph_0}.$$

CH asserts only $\mathfrak{c} = \aleph_1$. By Cantor's theorem, $\mathfrak{c} < 2^{\mathfrak{c}}$ in each of the models being compared. On passing from M to $M[G]$, new branches, new closed codes, and new subsets may appear, although the finite cylinders retain their formation rule. The full power set is model-sensitive; the clopen–closed–full distinction does not depend on deciding CH.

56.2 Compatible prefixes poset and inverse limit of extensions

We define

$$\mathbb{P}_{\mathrm{TPK}} = \bigsqcup_{n\geq 0} \mathcal{S}_n$$

and order by prolongation: $q \leq p$ if q contains more information than p. For each N,

$$D_N = \{p \in \mathbb{P}_{\mathrm{TPK}} : \ell(p) \geq N\}.$$

If every surviving prefix can be prolonged, each D_N is dense.

Theorem 56.4 (Branches and depth filters)**.** *The sections of Ω_∞ are in bijection with the compatible filters of $\mathbb{P}_{\mathrm{TPK}}$ that intersect all the D_N.*

Proof. The prefixes of a section are compatible, directed, and reach every depth. Conversely, a filter that meets each D_N determines a unique restriction at each level; directedness excludes incompatible conditions and produces a section. □

Meeting all dense sets D_N expresses unbounded depth, not genericity over a model. Being M-generic would require intersecting every dense set $D \in M$.

Proposition 56.5 (Conditioned Cohen case)**.** *If Ω_∞ is compact, metrizable, zero-dimensional, perfect, and without isolated points, it is homeomorphic to the Cantor set; the forcing of nonempty cylinders has a dense part equivalent to Cohen forcing, [30, 31].*

A unique section, by contrast, produces an atomic or trivial forcing. The word "forcing" does not by itself select a branch.

For a section $x = (x_m)_{m\geq 0}$, its prefixes form a filter G_x meeting the depth-dense sets. Nevertheless,

$$\big(\forall N,\ G_x \cap D_N \neq \varnothing\big) \not\Longrightarrow \big(\forall D \in M \text{ dense},\ G_x \cap D \neq \varnothing\big).$$

The first property expresses unbounded prolongation; the second, genericity relative to a model. A compatible section produced by nine TPK phases does not become a Cohen real by nomenclature alone.

Remark 56.6 (Conditions of validity). The following falsify an automatic identification with Cohen: a terminal cylinder or an isolated point; a filter that meets every D_N but omits some dense subset of M; two

compatible memories on the same visible branch; or the absence of an explicit dense embedding. The shared name "branch" is not a morphism.

56.3 Correspondence between genealogical sections and Borel classes of the limit space

The cylinders generate

$$\Gamma_{\mathrm{HMT}}^{\mathrm{Bor}} = \sigma\big(\{[p]_n : p \in \mathcal{S}_n\}\big).$$

The class is stable under complements, countable unions, and preimages of certified continuous maps.

If an infinite game on histories has a Borel winning condition, Martin's Borel determinacy theorem guarantees a winning strategy [87]. This is a classical application to HMT space; it does not derive AD, MM, a value of $2^{\aleph_0}$, or categoricity of $\mathcal{P}(\mathbb{R})$.

For $A, B \subseteq \Omega_\infty$, the Wadge reduction

$$A \leq_W B$$

requires a continuous map f with $x \in A \iff f(x) \in B$. If the maps are restricted to certified TPK operators, a narrower preorder appears, whose well-foundedness or semilinearity requires a proof of its own.

Remark 56.7 (Conditions of validity). A proof that uses Wadge well-foundedness to establish the determinacy that would then justify that well-foundedness is circular. The historical AD/MM branches are retained as architecture, not as HMT theorems.

56.4 Minimax theorem at each finite level of the poset of compatible prefixes

Let $P_N = \mathcal{S}_N$ be the finite set of candidates, T_N a finite set of adversarial tests, and

$$A_N : P_N \times T_N \to [-1, 1]$$

a payment fixed before the result.

Theorem 56.8 (Finite minimax)**.**

$$\max_{\sigma \in \mathcal{P}(P_N)} \min_{\tau \in \mathcal{P}(T_N)} \mathbb{E}_{\sigma,\tau} A_N = \min_{\tau \in \mathcal{P}(T_N)} \max_{\sigma \in \mathcal{P}(P_N)} \mathbb{E}_{\sigma,\tau} A_N.$$

Proof. It is the strong duality between the selector's linear program and that of the adversary, in the form of von Neumann's minimax theorem, [128]. □

Equilibrium may be mixed and does not provide a unique pure branch.

56.5 Projective system of truncations and construction of the limit section

Let

$$X = \varprojlim P_N, \qquad Y = \varprojlim T_N$$

compact, and let $A : X \times Y \to \mathbb{R}$ be continuous. The spaces of probability measures are compact and convex in the weak topology. Sion's theorem [111] yields

$$\sup_{\mu \in \mathcal{P}(X)} \inf_{\nu \in \mathcal{P}(Y)} \iint A \, d\mu \, d\nu = \inf_{\nu \in \mathcal{P}(Y)} \sup_{\mu \in \mathcal{P}(X)} \iint A \, d\mu \, d\nu.$$

Corollary 56.9. *A global equilibrium selects a pure branch only if the selector measure is a Dirac measure δ_x. The existence of a mixed equilibrium does not imply concentration.*

Remark 56.10 (Conditions of validity). Passage to the limit fails without compactness, continuity, or projective consistency of the measures. If the payoff is defined using the target it is to select, the minimax is target-fed and does not explain the route.

56.6 Projective and Matrix Extensions Provided by Operator Entanglers

Forcing organizes possible prolongations; Borel theory classifies sets of histories; minimax constructs robustness against falsifiers. None replaces the structural law that produces a unique survivor. Their function is to clarify the topology and decision structure of route space, not to introduce a retrospective selection.

Remark 56.11 (Separation of results and scope). Gödel's and Cohen's theorems are *applied classical theorems*. The poset, the typed comparison between the depth filter and the generic filter, the HMT Borel class, and the selector–falsifier game are *explicit constructions of the present development*. Martin, von Neumann, and Sion are applied thereafter, with their classical hypotheses. The former PSC/HTT assertions concerning CH, AD, and MM are not promoted.

Chapter 57

Euler operatorial system in HMT: sum–product defect, triadic exponential geometries, Ambivalence Principle, and double projection

57.1 Sum–product defect of APP and linear coefficient of the modular product Euler characteristic

57.1.1 Exact identity $459 - 405 = 54 = [q]t_3(q)$

On the support of 81 cells, the two APP leaves produce

$$S_+ = 405, \qquad S_\times = 459, \qquad S_\times - S_+ = 54. \tag{57.1}$$

The triadic regularization supplies the exponent $-1/12$. Its dodecaphase publication determines the pole q^{-1}, and the Dedekind quotient of level 3 is written

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1}\prod_{n\geq 1}(1+q^n+q^{2n})^{-12}, \qquad q = e^{2\pi i\tau}. \tag{57.2}$$

Theorem 57.1 (Euler–HMT sum–product identity)**.** *The defect between the two APP evaluations coincides with the linear coefficient of t_3:*

$$\boxed{S_\times - S_+ = 54 = [q]\, t_3(q).} \tag{57.3}$$

Proof. Each factor admits $(1+q^n+q^{2n})^{-12} = 1 - 12q^n + O(q^{2n})$. For the coefficient of q subsequent to the pole q^{-1}, the degree-2 partitions of the level-3 product contribute. The certified finite expansion produces $[q]t_3 = 54$. APP obtains the same integer by the exact subtraction $459 - 405$. □

57.1.2 Conservation of the defect via residue, quotient, and nonary carry

The identity equation (57.3) links the additive difference of two finite sheets to an infinite modular product. The link preserves the origin of 54: sum, product, and regularization remain three distinguishable state coordinates.

57.1.2.1 EMRH Completion and Conservation of the Unit

The ternary fiber of depth 6 has $3^6 = 729$ elements. Its decimal completion distinguishes

$$729 + 270 = 999, \qquad 729 + 271 = 1000, \qquad 271 = 243 + 27 + 1. \tag{57.4}$$

The terminal term +1 is the closure unit transmitted by the carry. The binomial identity

$$1000 = (9+1)^3 = 9^3 + 3\cdot 9^2 + 3\cdot 9 + 1 \tag{57.5}$$

expresses transport between the nonadic chart and decimal publication without losing the genealogy of the completion.

Archimedean evaluation is performed on compatible half-closed cylinders. The two expansions of a terminating rational represent the same value and preserve distinct boundary histories. This structure types the identity $0.999\ldots = 1$ as equality of evaluation accompanied by route memory.

57.2 Quadratic algebras of TRIT and the elliptic, parabolic, and hyperbolic exponential law

57.2.1 Operator family $J_{+1}^2 = -I$, $J_0^2 = 0$, and $J_{-1}^2 = I$

Para $\tau \in \{+1, 0, -1\}$, definimos

$$\mathbb{A}_\tau = \mathbb{R}[J_\tau]/(J_\tau^2 + \tau I). \tag{57.6}$$

The exponential series converges in each algebra and reduces to

$$e^{tJ_{+1}} = \cos t\, I + \sin t\, J_{+1}, \tag{57.7}$$

$$e^{tJ_0} = I + tJ_0, \tag{57.8}$$

$$e^{tJ_{-1}} = \cosh t\, I + \sinh t\, J_{-1}. \tag{57.9}$$

TRIT assigns elliptic closure, first-order variation, and hyperbolic opening, respectively. The classical identity occupies the leaf $\tau = +1$:

$$\boxed{\mathrm{Exp}(\pi J_{+1}) + I = 0.} \tag{57.10}$$

The parabolic sheet preserves the first jet, and the hyperbolic sheet publishes a pair of reciprocal eigenvalues.

57.2.2 Identities $\mathrm{Exp}(\pi J_{+1}) + I = 0$ and $\mathrm{Exp}(2 \log \varphi\, H_\varphi) = F_{\mathrm{av}}^2$

Let

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad H_\varphi = \frac{2F_{\mathrm{av}}^2 - 3I}{2\varphi - 1}. \tag{57.11}$$

Then $H_\varphi^2 = I$ and

$$\boxed{\mathrm{Exp}(2 \log \varphi\, H_\varphi) = F_{\mathrm{av}}^2.} \tag{57.12}$$

In this coordination, π measures angular closure, φ the expansive eigenvalue of memory, and e the operation that transforms an additive generator into multiplicative transport.

57.3 Ambivalence Principle: involution between π/φ^2 and φ/π^2 and nonadic accumulation of orientation

57.3.1 Action $Q(x, y) = (x/y^2, y/x^2)$ on the areal and volumetric readers

We define the quadratic reader

$$Q(x, y) = \left(\frac{x}{y^2}, \frac{y}{x^2} \right). \tag{57.13}$$

In the coordinates

$$P = xy, \qquad O = \frac{x}{y}, \tag{57.14}$$

its action is

$$P \circ Q = P^{-1}, \qquad O \circ Q = O^3. \tag{57.15}$$

The second iteration satisfies

$$\boxed{P \circ Q^2 = P, \qquad O \circ Q^2 = O^9.} \tag{57.16}$$

The product returns and the orientation preserves a nonadic power of memory.

57.3.2 Identity $\varphi^3(\pi/\varphi^2)^2(\varphi/\pi^2) = 1$ and typed bidirectionality

For $(x, y) = (\pi, \varphi)$, the two orientations are

$$\rho_A = \frac{\pi}{\varphi^2}, \qquad \rho_E = \frac{\varphi}{\pi^2}, \tag{57.17}$$

and obey

$$\boxed{\varphi^3 \rho_A^2 \rho_E = 1.} \tag{57.18}$$

The involution $(x, y) \mapsto (y, x)$ exchanges the areal and electronic orientations of the same reader $R(x, y) = x/y^2$.

57.4 Exponential transformation of the parangular generator $A_{\mathrm{rad}} I + C^*_{\mathrm{rad}} H_\varphi$

The action chart

$$T_{-34}(u) = u\, 10^{-34} \mathcal{U}_S \tag{57.19}$$

transports the angular identity $C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}})$ to

$$\boxed{T_{-34}(C^*_{\mathrm{deg}}) = 2\hbar_{\mathrm{ret}} + 2T_{-34}(\alpha_{\angle,\mathrm{deg}}).} \tag{57.20}$$

Each summand thus lies on the same dimensional line $\mathcal{L}_S$.

57.4.1 Spectral projectors $P_\pm = (I \pm H_\varphi)/2$ and conjugate eigenvalues $q_\pm$

Let

$$B = A_{\mathrm{rad}} I + C^*_{\mathrm{rad}} H_\varphi, \qquad P_\pm = \frac{I \pm H_\varphi}{2}. \tag{57.21}$$

Exponentiation transforms the additive generator into two conjugate multiplicative leaves:

$$\boxed{e^{-B} = q_+ P_+ + q_- P_-, \qquad q_\pm = e^{-A_{\mathrm{rad}} \mp C^*_{\mathrm{rad}}}.} \tag{57.22}$$

57.4.2 Compatibility with the Parangular Publication and the Channels $90/120$

The cardinals 90 and 120 arise from the tritic incidence of the TPK. The pair $q_\pm$ does not generate them: it spectrally evaluates the operator $V_{90,120}$ on those previously constructed channels.

57.5 Elliptic action boundary and hyperbolic interior of Hilbert–Beltrami–Klein

57.5.1 Conjugate coordinates of the action ellipse and law $\mathrm{Area}(\theta) = \hbar_{\mathrm{ret}}\theta$

The angular speed

$$\eta = \operatorname{artanh}\left(\frac{C^*}{A}\right) \tag{57.23}$$

define the symplectic semiaxes

$$a_S = \sqrt{2\hbar_{\mathrm{ret}} e^{\eta}}, \qquad b_S = \sqrt{2\hbar_{\mathrm{ret}} e^{-\eta}}. \tag{57.24}$$

With

$$Q = a_S \cos\theta, \qquad P = b_S \sin\theta, \tag{57.25}$$

the action enclosed by the arc satisfies

$$\boxed{\mathrm{Area}(\theta) = \hbar_{\mathrm{ret}}\theta.} \tag{57.26}$$

57.5.2 correspondence $\rho = \tan(\theta/2) = \tanh(u/2)$ between borde periodico e interior hyperbolic

The Gudermannian coordinate

$$\rho = \tan\frac{\theta}{2} = \tanh\frac{u}{2} \tag{57.27}$$

coordinates the circular and hyperbolic charts. The boundary carries the symplectic orbit; the convex interior domain carries the Hilbert–Beltrami–Klein hyperbolic metric. The Gudermann coordinate realizes their radial correspondence and preserves the distinction between metrics.

57.6 Compatibility of the Euler operator closure with the Archimedean and exceptional publications

57.6.1 Double projection of the same enriched state and conservation of incidence

Let X^{enr} be the enriched state constructed by APP–TRIT–TPK. Its two principal publications are

$$X^{\mathrm{enr}} \xrightarrow{\mathcal{P}_{\mathrm{arq}}} \mathbb{R}, \qquad X^{\mathrm{enr}} \xrightarrow{\mathcal{P}_{\mathrm{exc}}} \mathrm{Witt} \to \mathrm{Golay} \to \mathrm{Leech} \to V^{\natural} \to \mathbb{M} \to J. \tag{57.28}$$

The first contracts compatible cylinders toward the Archimedean value; the second preserves boundary incidence as far as the exceptional corridor. The integer 54 appears in APP and in the modular coefficient of equation (57.3); the corridor $4 \to 2 \to 6 \to 54$ subsequently transports that incidence toward the Leech lattice, the vertex operator algebra, and Moonshine. The action of the Monster resides in $V^{\natural}$; the digital and route genealogy remains in the domain of TPK and reaches the corridor through the declared incidence maps.

57.6.2 Sistema macrovectorial $\mathfrak{E}_{\mathrm{HMT}} = 0$: confluencia of the identities eulerianas in a unique operator

The above identities are gathered in the typed application.

$$\mathfrak{E}_{\mathrm{HMT}} = \begin{pmatrix} (S_\times - S_+) - [q]t_3 \\ \mathrm{Exp}(I) - eI \\ \mathrm{Exp}(\pi J_{+1}) + I \\ \mathrm{Exp}(J_0) - I - J_0 \\ \mathrm{Exp}(2\log\varphi\, H_\varphi) - F_{\mathrm{av}}^2 \\ \varphi^3 \rho_A^2 \rho_E - 1 \\ T_{-34}(C^*) - 2\hbar_{\mathrm{ret}} - 2T_{-34}(\alpha_{\angle,\mathrm{deg}}) \end{pmatrix} = 0. \tag{57.29}$$

Each component retains its domain and its own proof. The aggregate map exhibits the coordination of sum, product, elliptic closure, first jet, hyperbolic expansion, ambivalence, and action.

The internal APP–TRIT–TPK composition already transports sum, product, orientation, residue, quotient, carry, route, and memory to the preceding publications. No absent HMT intertwiner is thereby posited. A subsequent promotion can be formulated only through the specific typed square required by a later representation—for example, complete group equivariance as far as Witt—without downgrading the operator confluence proved here.

57.7 Dimensional Transduction of Internally Generated Constants and Subsequent Metrological Comparison

The genealogical classification of number closes the mathematical publication: a stable section can contract its history to a value without losing the memory that determines its identity. Dimensional Mechanics now adds structure that number alone does not contain: representation, band, transducer, and local persistence. Metrology is the subsequent comparison between that realization and a dimensional

chart; no external standard retroactively generates α, the decade 10^{-34}, Planck, the counter-angle, the constitutive relations of the vacuum, the gravitational constant, or the Barbero–Immirzi parameter.

57.8 Metric Transduction of Genealogical States: Action, Mass, and Dimensional Observables

The bridge would be superficial if it isolated the squares from the physical thesis. HMT does not present APP, TRIT, and TPK as a combinatorial game to which experimental constants are subsequently added. Its governing assertion is genealogical: the mathematical and physical constants are outputs of readers constructed on the same architecture, and external comparison occurs after derivation. Operatorial language must make that chain more visible, not reduce it to numerical fitting.

57.8.1 Theoretical Background of the Genealogical-Metrical Transduction Functor

Within the domains and certificates of the HMT–MD theory developed here, the construction receives as demonstrated results:

1. the monodromic generation of π, e, φ, and α, with the chain of nine positions, its filtration stages, and the biographies of its regions;
2. the common source of the Archimedean projection and the exceptional projection, with their different codomains;
3. action, the structural decade 10^{-34}, Planck's constant, the gravitational transducer, and the Barbero–Immirzi sector;
4. the vacuum constitutive relations and their correlated genealogy;
5. the General Mass Law over the complete domain $81/56/13/324$ and the null sector, without replacing them with any expository taxonomy, followed by the typed physical realizations and by the exhaustive inventories of masses and widths, which do not enter into the construction of the domain;
6. the electronic closure, the mixing and CP-violation sectors, and the CKM and PMNS transports with their specific mathematical status in each case;
7. the exceptional output, the codes, and the symmetries that the work derives from the second projection.

One does not write "under stated hypotheses" as a substitute for those proofs. The hypotheses belong to each theorem; when they are verified, the result is accepted as proved in that domain. Nor is a conclusion exported to a larger domain when its physical realization requires an additional morphism. This is the probative separation of the development.

57.8.2 Planck, Action, and the Self-Dual Line

The absolute scale is separated from the relative ratios. In the notation of the mass source,

$$\Sigma_H = \varphi\alpha^{16}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34, \tag{GMC-9.1}$$

while the relative action factor is constructed in another coordinate. In the 108–Compton–Planck periodicity identity, the self-dual point satisfies, with the declared radius conventions,

$$R_{108} = \bar{\lambda}_C = r_g = \ell_P, \qquad C_{108} = 2\pi\ell_P. \tag{GMC-9.2}$$

The self-dual line has conjugation, unit norm, and an involution with a fixed point; the electron appears as the first material displacement, not as the origin of the scale or as a classical black hole.

In operatorial language, B_c produces the free interval (GMC-6.15); the rapidity η of (GMC-2.6) coordinates contraction and hyperbolic opening; the UCP map publishes a point of the interval without exhausting the section from which it originated. This is a complete example of the sought transduction:

the new nomenclature changes no physical identity, but separates spectrum, state, compression, and genealogy.

57.8.3 The law of masses as a family of positive operators

The HMT law acts on fibres and multisections through positive operators. In its bidirectional form,

$$\widehat{M}_M^{\beta,r} = R_{\mathrm{act}}^{B_M^r/2}\, \widehat{M}_M^{(0)}\, R_{\mathrm{act}}^{B_M^r/2}, \qquad r \in \{D, \Omega\}. \tag{GMC-9.3}$$

The decade 10^{-34} fixes the absolute scale and cancels in ratios; the readers K_D and K_Ω fix the route refinement. In the electron fiber

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6), \tag{GMC-9.4}$$

and the rank-one reduction closes the complete electronic value determined by the HMT closure. The null, scalar, operator-valued, and noncomparable-as-scalar-mass classes remain separate: a positive matrix does not become an experimental number until the realization functional has been declared.

The De las Cuevas–Netzer program contributes a new question here. For each matrix depth and level, which UCP images of the mass–route system preserve the spectrum, which preserve only moments, and which lie in the convex matrix hull of rank-one realizations? The bigrading (m, s) turns that question into a family of coherent finite problems.

57.8.4 Physical-Mathematical Transduction Matrix

HMT result	Lectura operatorial	Question that opens
monodromy $9 \to 1$	return of the observable with distinct environmental state	classify dilations that preserve holonomy
π, e, φ, α	four compatible readers of a genealogy	existence and minimality of a common UCP system
double projection	two marginals of a cylindrical antecedent	noncommutative precursor and joint fiber separation
B_c and jump 4	free matrix interval $[5I, 9I]$	endpoints and transport of the hierarchy 4; 2; 6; 54
Planck and periodicity of order 108	self-dual point and conjugate readers	realization as a symmetry of a conical system with memory
law of masses	positive family over fibers and paths	matrix range, extremes and sector realizations
CKM/CP	rank three transport and nontrivial phase	covariant channel that preserves spectrum and orientation
exceptional symmetry	second codomain of the double projection	entangler between nonadic atlas, code and representation

57.8.5 Universal embedding of an APP signal into a quantum Markov semigroup

The cyclic constructions use only the Latin symbol. A general framework exists for introducing any Hermitian signal of the two sheets without disrupting the magic sums.

Proposition 57.2 (Double centering of an operatorial signal)**.** *Let $G = (G_{ij})_{i,j=0}^{8}$ be a grid of self-adjoint matrices in M_3. Define*

$$H_{ij} = G_{ij} - \frac{1}{9}\sum_{j'} G_{ij'} - \frac{1}{9}\sum_{i'} G_{i'j} + \frac{1}{81}\sum_{i',j'} G_{i'j'}. \tag{GMC-9.5}$$

Then all row and column sums of H vanish. If $M = \max_{i,j} \|H_{ij}\|$ and $\varepsilon \in \mathbb{R}$ satisfies

$$|\varepsilon| \leq \frac{1}{9M} \tag{GMC-9.6}$$

(with the convention that there is no restriction if $M = 0$), the matrix

$$A_{ij} = \frac{1}{9} I_3 + \varepsilon H_{ij} \tag{GMC-9.7}$$

is a QMS *of sizes* $(9, 3)$.

Proof. Upon summing (GMC-9.5) along a row or column, the four terms cancel. Therefore, (GMC-9.7) sums to I_3 on each line. Since $-MI_3 \preceq H_{ij} \preceq MI_3$, the bound (GMC-9.6) implies $A_{ij} \succeq 0$. □

To use sources of different dimensions, a UCP reader into M_3 must first be declared: if $T_{ij} = T_{ij}^*$ belongs to the source operator system and Θ is that reader, one sets $G_{ij} = \Theta(T_{ij})$. The qutrit images of signals constructed with P_Σ, P_Π, the block B_c, or route readers can thereby be inserted; operators of sizes 81×81 or 2×2 are not inserted directly as cells of M_3. Double centering removes every purely "row only + column only" component; this provides an immediate falsifier for encodings that appear coupled without possessing a two-dimensional interaction.

Structural obstruction

The Proposition 57.2 proves the existence of an APP-marked QMS, not its fidelity or nonsemiclassicality. The small amplitude may keep it within a semiclassical neighborhood. The next stage must solve the SDP (GMC-8.6) or produce a dual witness.

57.8.6 Factorization of the genealogical–matrix bridge through APP embeddings, a quantum Markov semigroup, a semiclassical boundary, a continuous channel, a conical system, and a completely positive realization

The bridge leaves a program ordered by dependencies, not an open list of analogies:

1. **Filtered APP system.** Construct complete order- $\alpha_m : \mathcal{S}_m^{\mathrm{APP}} \hookrightarrow \mathcal{S}_{m+1}^{\mathrm{APP}}$ embeddings that transport both sheets and the carry.
2. **APP–TPK-faithful QMS.** Choose G_{ij} in (GMC-9.5) from the sum–product pair and prove the equivariance equation (GMC-7.9).
3. **Semiclassical boundary.** Exploit the nonadic symmetry to reduce the SDP over S_9 and decide whether the candidate lies outside the minimal system.
4. **Continuum Channel.** Construct the local HMT tensor and subject its transfer channel to (GMC-7.2); distinguish the fine limit, coarse limit, and root memory.
5. **Intrinsic cone system.** Define the categorical stem, the cones, the dual, and the CP transformations of TPK.
6. **Joint metrological realization.** Construct a common UCP system for mathematical, physical, and exceptional readers, and measure what genealogy each output requires.

57.8.7 Naturality, cofinality, and separation hypotheses required by the reconstruction theorem

A statement is established when it includes:

- complete definition of the domain and of all indices;
- symbolic proof or numerical certificate with a declared tolerance;
- verification of positivity, normalization, and compatibility;
- preserved negative falsifiers;
- separation between scalar coincidence and equivalence of the matrix tower;
- derivation complete from the premises and constructiones that the sustentan.

This protocol does not attenuate the thesis. It permits emphatic declaration of what has already been demonstrated and exact localization of the extension capable of advancing the state of the art.

The electron constitutes the first complete material realization of this passage. Its basal stage preserves causal function, but beta closure fixes the governing residence from which magnitudes, fields, and the General Mass Law are developed.

Part IV

Dimensional Mechanics: transduction of the genealogical state, matter, fields, and gravitation

Chapter 58

Genealogical construction of the electron: target-value-independent beta closure and atomistic realization of charge

The genealogical state here acquires its first complete material realization. The central localization, the electron–positron band, and the bidirectional reading are constructed before any metrological comparison; the basal stage remains distinct from the governing beta closure.

58.1 Closure β of the electronic section and dimensional publication of its rest energy

The electron appears in HMT as the point at which six preceding and mutually typed constructions are assembled: the incompatibility between the two arithmetic sheets of APP, the orientation induced by the involution of the areal–volumetric hinge, two integer quotients from the APP–TPK census, the dodecaphasic closure of α_{HMT}, the global defect Δ_4, and the unique center of the nonadic atlas. The route band then adds electron–positron conjugation. The MeV chart and the comparison with CODATA are subsequent to all of them.

This precedence is part of the mathematical content: the factors, their types and their causal order are determined before opening the tabulated chart, which intervenes only in the subsequent metrological comparison.

58.1.1 Electronic scalar $\mathfrak{e}_{\mathrm{HMT}}$ and causal graph of its factors APP–TPK, α_{HMT}, Δ_4 and nonadic atlas

The internal output is the dimensionless scalar.

$$\boxed{\mathfrak{e}_{\mathrm{HMT}} = \frac{\sqrt{3}}{4}\left[\exp\!\left(\frac{\varphi}{\pi^2}\right) - \frac{396}{18}\,\alpha_{\mathrm{HMT}}^3\right]\left[1 + \frac{270}{18}\,\Delta_4\right].} \tag{58.1}$$

The identities

$$\frac{396}{18} = 22 = 27 - 5, \qquad \frac{270}{18} = 15 = \binom{6}{2} = 3 \cdot 5$$

allow the abbreviated notation to be recovered

$$\mathfrak{e}_{\mathrm{HMT}} = \frac{\sqrt{3}}{4}\left(e^{\varphi/\pi^2} - 22\alpha_{\mathrm{HMT}}^3\right)(1 + 15\Delta_4).$$

Here the letter e inside the exponential is Euler's number; the subscript of $\mathfrak{e}_{\mathrm{HMT}}$ denotes the electronic section.

The causal graph of the equation is

$$\begin{aligned}
\text{APP projectors in dimension three} &\longrightarrow \sqrt{3}/4,\\
\text{TPK calendar and areal–volumetric sheets} &\longrightarrow F_{\mathrm{av}},\ \pi/\varphi^2,\ \varphi/\pi^2,\\
\text{dodecaphasic closure} &\longrightarrow \alpha_{\mathrm{HMT}},\\
\text{APP–TPK census and electronic family} &\longrightarrow 396,\ 18,\ 270,\ 22,\ 15,\ 5,\\
\text{global readings of } \pi, e \text{ and register} &\longrightarrow \Delta_4,\\
\text{nonadic atlas and anti-section} &\longrightarrow (5,5),\ \text{electron–positron band.}
\end{aligned}$$

No arrow in this diagram receives as an argument the reference electronic mass.

58.1.2 1st factor: exact incompatibility of the APP leaves

For $d \geq 2$, let

$$\mathscr{A}_d = \{1, \dots, 9\}^d$$

with uniform measure, and let

$$\Sigma_d(x) = \mathrm{dr}(x_1 + \cdots + x_d), \qquad \Pi_d(x) = \mathrm{dr}(x_1 \cdots x_d)$$

the additive and multiplicative observables. Their orthogonal conditional expectations on $\ell^2(\mathscr{A}_d)$ are $P_{\Sigma,d}$ and $P_{\Pi,d}$. The proposition 1.55 proves by exact enumeration that

$$\left\| [P_{\Sigma,3}, P_{\Pi,3}] \right\| = \frac{\sqrt{3}}{4}.$$

Proposition 58.1 (Electronic prefactor APP content)**.** *The prefactor $\sqrt{3}/4$ of equation (58.1) is the exact norm of the noncommutativity between the sum and product sheets in dimension three. It is not a geometric factor introduced from the electronic formula.*

Proof. The joint table of Σ_3 and Π_3 determines the principal angles between $\mathrm{Ran}\, P_{\Sigma,3}$ and $\mathrm{Ran}\, P_{\Pi,3}$. If s is one of its singular values, the corresponding contribution to the commutator norm is $s\sqrt{1-s^2}$. Enumeration of the 9^3 words gives at most

$$s^2(1-s^2) = \frac{3}{16}, \qquad s^2 = \frac{1}{4}.$$

Therefore the maximum norm is $\sqrt{3/16} = \sqrt{3}/4$, before introducing α_{HMT}, Δ_4, a unit of energy or a reference mass. □

The physical function of the factor is thereby fixed: it measures the maximal incompatibility of the two arithmetic readings on the same ternary support. The electron does not inherit two independent numbers, one additive and the other multiplicative; it inherits the exact obstruction to rendering the two sheets simultaneously compatible. The prefactor preserves, within the mass law, the local memory of the APP disagreement from which the route arises.

58.1.3 2nd factor: the exchange involution between π and φ

The primitive calendar of modes (Σ, Π, Π) induces, on the areal and volumetric sheets, the matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

theorem 6.20 obtains it by counting the transitions $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$, each once. The matrix is not postulated from the golden ratio: its eigenvalues φ and $-\varphi^{-1}$ appear after the incidence has been constructed.

In the second-order memory, $\mathrm{Sym}^2(F_{\mathrm{av}})$ has spectrum

$$\varphi^2, \qquad -1, \qquad \varphi^{-2}.$$

Thus, φ^{-2} is the positive stable mode of the hinge. The closure mark π, applied just once to the areal return, produces

$$\frac{\pi}{\varphi^2}.$$

This reason preserves the closure–self-scaling order. The electronic law uses its opposite orientation.

Theorem 58.2 (Exact Inversion of the Electronic Hinge)**.** *Let*

$$\mathscr{R}(x,y)=\frac{x}{y^2},\qquad \mathsf{J}(x,y)=(y,x).$$

Then $\mathsf{J}^2=I$ *and*

$$\mathscr{R}(\pi,\varphi)=\frac{\pi}{\varphi^2},\qquad (\mathscr{R}\circ\mathsf{J})(\pi,\varphi)=\frac{\varphi}{\pi^2}.$$

Consequently,

$$\frac{\varphi}{\pi^2}=\frac{1}{\varphi^3\left(\pi/\varphi^2\right)^2},\qquad e^{\varphi/\pi^2}=\exp\left[\frac{1}{\varphi^3\left(\pi/\varphi^2\right)^2}\right].$$

Proof. The first pair of identities is obtained by applying $\mathscr{R}$ before and after the involution J. For the reparametrization,

$$\varphi^3\left(\frac{\pi}{\varphi^2}\right)^2=\frac{\pi^2}{\varphi},$$

and its inverse is φ/π^2. The last equality follows by applying the exponential. □

The simultaneous presence of π and φ therefore has a precise structural meaning. π/φ^2 reads areal closure over quadratic volumetric memory; φ/π^2 reads interior self-growth over quadratic closure. They are not two similar quotients chosen for convenience. They are the two orientations of the same reader, exchanged by an exact involution. The term e^{φ/π^2} publishes the interior orientation of that hinge in the electron section.

58.1.4 3rd and 4th factors: the integers 22, 15 and the center 5

The census of the APP chart employed by the electronic family provides three integer sums:

$$\Sigma(\text{APP})=396,\qquad \Sigma(\text{centro }2\times 2)=18,\qquad \Sigma(\text{canal})=270.$$

The first admits the ring decomposition.

$$396=18+72+108+198.$$

The kernel 2×2 is therefore an explicit substructure of the complete chart, and the integer 270 belongs to the global channel of the same APP–TPK census. The sum of the even rings is

$$18+108=126,\qquad \frac{396}{126}=\frac{22}{7}.$$

This last quotient is the rational closure seal of the chart, not an identification of $22/7$ with the number π generated by the coinductive reader. It does show that the numerator 22 already serves an internal function before appearing in the electronic law.

Theorem 58.3 (Internal Origin of the Electronic Coefficients)**.** *In the electronic family fixed by the APP chart and its global channel,*

$$\boxed{22=\frac{\Sigma(\text{APP})}{\Sigma(\text{centro})}=\frac{396}{18}=27-5,}$$

$$\boxed{15=\frac{\Sigma(\text{canal})}{\Sigma(\text{centro})}=\frac{270}{18}=3\cdot 5=\binom{6}{2}.}$$

In particular, the coefficients are determined without consulting Z_0, the electron mass or a chart of units.

Proof. The first two equalities are exact divisions of the finite census:

$$396 = 22 \cdot 18, \qquad 270 = 15 \cdot 18.$$

By defining

$$p := 27 - 22,$$

one obtains $p = 5$, and then

$$15 = 3p = 3 \cdot 5 = \binom{6}{2}.$$

All quantities belong to the integer domain of the chart and the family before metrological transduction. □

58.1.4.1 Persistence selector in the central return

The same pair has a dynamic construction that also fixes its sign without consulting a mass. The four orientations of the central seed $(5, 5)$ return to that cell for the first time after twenty-seven steps. The typed return space is

$$\mathcal{K}_e = \mathbb{Z}/9\mathbb{Z} \times \mathbb{F}_3, \qquad |\mathcal{K}_e| = 27.$$

Moreover, the microfiber of π contains the five genealogically distinct regions

$$\mathscr{R}_\pi = 3_{++} + 1_{--} + 1_{\perp}.$$

The regional gauge diag_c and, within a repeated phase, the internal order of U_6 define the injection

$$\iota : \mathscr{R}_\pi \hookrightarrow \mathcal{K}_e$$

through the five distinct places

$$(4, 0), \quad (5, 0), \quad (6, 0), \quad (6, 1), \quad (6, 2).$$

The first two correspond, respectively, to the transverse region and the mutated return; the last three separate the positive regions by their tritic sheet. The common visible word does not intervene as the inverse of the map.

Theorem 58.4 (Internal selector of the electronic coefficients)**.** *With the central return and the five typed regions fixed, the coefficients of the electronic equation are*

$$\boxed{n_e = -\left|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)\right| = -22, \qquad m_e^{\mathrm{tor}} = \left|\mathscr{R}_\pi \times \mathbb{F}_3\right| = +15.}$$

The first symbol records the boundary deficit; the second, the retained torsional memory.

Proof. The five places above are distinct, so ι is injective and

$$|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)| = 27 - 5 = 22.$$

Each of the five regions preserves three triticale leaves, hence

$$|\mathscr{R}_\pi \times \mathbb{F}_3| = 5 \cdot 3 = 15.$$

The orientation rule assigns a negative sign to states removed from the shell and a positive sign to retained memory. The construction opens only the center, the return of twenty-seven states, and the regional identities; it does not open an observed mass, an impedance, or a calibrated signature. □

The number 22 measures how many central kernels of weight 18 are recomposed by the APP sum 396. The number 15 measures how many of those same kernels are recomposed by the channel 270, and simultaneously counts the pairs of a hexad. The number 5 is not an additional parameter:

$$5 = 27 - 22, \qquad 15 = 3 \cdot 5.$$

The three expressions display the same closure from depth 27, from the central normalization, and from hexadic combinatorics.

58.1.4.2 Conservation of coefficients 22 and 15 in the material realization of the electron

The historical exploration first located $p = 5$ through a finite comparison with Z_0, and from there wrote $(27 - p, 3p) = (22, 15)$. That procedure retains value as a history of discovery and as an external check. It is not, however, the proof that governs the law: the subsequent count

$$\frac{396}{18} = 22, \qquad \frac{270}{18} = 15$$

constructs both integers within APP–TPK and recovers $p = 5$ as a consequence. The history explains how the pair was found; the census explains why it belongs to the equation.

58.1.5 5.º factor: the cubo of the closure α_{HMT}

The closure of α_{HMT} precedes Dimensional Mechanics. As established in section 30.12, the twelve base-thousand blocks of π, e, φ and the seal K combine through the reversible carry

$$P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + 1000c_m, \qquad c_{13} = c_1 = 0.$$

The output is

$$A_\alpha = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663)$$

and, by concatenation, the exact dodecaphasic window

$$\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}}) = \frac{729735256928380099728510547238066 3}{10^{36}}.$$

Telescoping the carries proves the complete integer identity; the compatible prolongation constructs $\alpha_{\mathrm{HMT}} = \varprojlim_N A^{(N)}$, and α_{12} is its thirty-six-digit rational projection. The comparison with the fine-structure constant is performed subsequently and does not intervene in its construction.

The electronic law takes the third power

$$\alpha_{\mathrm{HMT}}^3.$$

Mathematically, this is the multiplicative evaluation of the third symmetric power of the same scalar already closed; neither three metrological copies nor three different parameters are introduced. Its contribution is

$$22\alpha_{\mathrm{HMT}}^3 = 0.000008549065992005517270149798075982 28\ldots.$$

Proposition 58.5 (Statute of the Electronic Cubic Channel)**.** *The term $22\alpha_{\mathrm{HMT}}^3$ of the electronic law depends only on the prior closure of α_{HMT}, on internal multiplication, and on the integer 22 of theorem 58.3. It does not depend on a reading of the electron mass.*

Proof. α_{12} is the rational number fixed by the concatenation and carry identity, and the compatible family of windows determines the section α_{HMT}. The projection α_{12}^3 certifies the printed digits of α_{HMT}^3. The coefficient 22 is determined by $396/18$. The composition of both operations contains only data constructed before the energy chart. □

This proposition fixes exactly what is used for the electron. The third power is the cubic degree of this channel in the published law. There is no need here to postulate a universal rule according to which every occurrence of α^d automatically represents a dimension d; a universal statement of that kind would require its own theorem of multiplicativity among degrees. The electron genealogy is complete without turning that generalization into a premise.

58.1.6 6th factor: minimal torsion and global defect Δ_4

The terms *minimal torsion* and *global defect* denote a single invariant here, not two distinct corrections. The object used by the mass law is

$$\boxed{\Delta_4 = \frac{\pi - e\log\pi}{270}\left(1 + \frac{\pi}{729}\right).} \tag{58.2}$$

Its inputs are the already fixed HMT readings of π and e, the global channel 270, and the interior cell 729. Consequently,

$$\Delta_4 = 0.000111196422692140054051134786120679 09\ldots.$$

The first ratio measures the signed defect $\pi - e\log\pi$ in units of the 270 channel; the second factor couples that ratio to the interior cell through $\pi/729$. This reading adds no parameters to the formula: it separates its two constituent operations. The chapter 35 shows that it is a pre-dimensional mathematical input and distinguishes it from the operator that eventually realizes it as a change of sheet.

Proposition 58.6 (Globality of the Electronic Defect)**.** *Δ_4 is a global invariant preceding the species. In the electronic law it enters through*

$$1 + 15\Delta_4 = 1.001667946340382100810767021791810 19\ldots.$$

It is not a corrector chosen after knowing the residue of the electron mass.

Proof. The equation (58.2) contains neither a species label, a mass, nor a unit. The integer 15 has already been constructed by $270/18$. Therefore, the composition $1 + 15\Delta_4$ is determined by the global data and the internal census. □

Δ_4 must be distinguished from the other blocks of the mass character and from the other notions of torsion. In particular, it is neither s_{270}, nor the quadratic invariant $135\Delta_4^2$, nor the angular residue $\varepsilon_{\mathrm{res}}$, nor the geometric Cartan–Holst torsion. Substituting one for another would repeat or alter the level of the correction. For the electron, Δ_4 preserves the global memory of refinement; the factor 15 states how many times the electron family reads it. The qualifier *minimal* preserves the historical name of this invariant and is not used as a substitute for a variational theorem of minimality.

58.1.7 Material realization of the fixed point (5,5) in the electronic closure

Let

$$C_{81} = \{1, \ldots, 9\}^2$$

the nonadic atlas and

$$\rho(r, c) = (10 - r, 10 - c)$$

its central inversion. theorem 90.11 proves that the atlas contains a unique generation-zero cell and that this cell bears the positional label e_{core}.

Proposition 58.7 (Uniqueness of the Electronic Center)**.** *The involution ρ has a unique fixed point:*

$$\boxed{(r, c) = (5, 5).}$$

Its uniqueness is combinatorial and does not depend on the value of $\mathfrak{e}_{\mathrm{HMT}}$.

Proof. The equation $(r, c) = \rho(r, c)$ is equivalent to

$$2r = 10, \qquad 2c = 10.$$

In $\{1, \dots, 9\}^2$ it has the unique solution $r = c = 5$. The evaluation of the mass does not appear in the argument. □

Corollary 58.8 (Universality of the Central Section)**.** *Every admissible automorphism of the atlas that intertwines the central inversion preserves the cell* $(5, 5)$.

Proof. If $f\rho = \rho f$ and $\rho(5, 5) = (5, 5)$, then $\rho f(5, 5) = f\rho(5, 5) = f(5, 5)$. Therefore $f(5, 5)$ is another fixed point of ρ; uniqueness forces $f(5, 5) = (5, 5)$. □

This is the structural reason why the electronic class is the same in every realization preserving the atlas and its inversion: a local decimal does not recur by chance; rather, every admissible chart must transport the same fixed point and the same chain of invariants. The physical reading of this uniqueness identifies each electron with a realization of that central class; the proposition proves the internal universality of the atlas.

In the electronic family fixed by the construction, this point is the geometric anchor of the section. Four objects should not be confused:

$$(5, 5), \qquad e_{\text{core}}, \qquad v_e = (0, 0, 0, 0, 0), \qquad \text{the raw signature of the central cell.}$$

The first is a position; the second, its internal label; the third, the chosen origin in the fine action lattice; the fourth preserves the raw atlas data and need not be the zero vector. Their coordination explains why the electron occupies the center without erasing the genealogy of the representations describing it.

Oriented electronic routes e_{++}, e_{--}, envelope e_{env}, action origin and signatures of the central cell
The central cell carries two oriented histories of twelve events. Writing v^2 for the concatenation of two copies of a sextuple, the active route of orientation ++, its opposite history, and the historical envelope are, respectively,

$$\begin{aligned} e_{\text{act}} = e_{++} &= (2, 2, 5, -4, -3, -2)^2, \\ e_{--} &= (4, 3, 2, -2, -2, -5)^2, \\ e_{\text{env}} &= (4, 3, 5, -4, -3, -5)^2. \end{aligned} \tag{E-centro-1}$$

The two stories publish the same word

$$\tau_{12} = \text{+++-+++-},$$

but they are not the same route. The envelope takes the absolute maximum coordinate by coordinate while preserving the sign; it records amplitudes, but flattens the genealogical order and does not replace e_{act}.

The other readers of the center live in distinct codomains:

$$\begin{aligned} v_e &= (0, 0, 0, 0, 0), && \text{affine origin of the action lattice,} \\ R(5, 5) &= (24, 0, 12, 0, -12), && \text{raw APP signature of the cell,} \\ \mathrm{Sig}^{\Gamma_{108}}_{\text{masa}} &= (-12, -4, 12, -6, 12), && \text{even mass projection,} \\ \mathrm{Sig}^{\Gamma_{108}}_{\text{carga}} &= (0, 0, 0, 0), && \text{odd charge projection.} \end{aligned} \tag{E-centro-2}$$

The fact that the charge word has zero odd signature does not turn the route into zero, nor does it identify the raw signature with the affine origin. Position, active route, opposite route, envelope, origin and both signatures are coordinated objects, not six notations for the same vector.

58.1.8 Particle–antiparticle conjugation and persistence of the electronic band

Electronic identity does not end at the central point or at the mass value. Material conjugation is realized on dodecaphasic words. Let

$$C_M(\mathbf{t}) = -\operatorname{rev}(\mathbf{t})$$

be the oriented anti-section and let $\chi \in \{-1, +1\}$ be the charge orientation. The band is the class

$$[(\mathbf{t}, \chi)]_M = \{(\mathbf{t}, \chi), (C_M\mathbf{t}, -\chi)\}$$

of definition 92.28. The band preserves its even components and exhibits two sections with opposite odd components.

Theorem 58.9 (Electron and positron as sections of a band)**.** *For the band character of theorem 92.31,*

$$m(C_M\mathbf{t}, -\chi) = m(\mathbf{t}, \chi).$$

In the electronic channel,

$$(n, \chi) = (-22, +1) \quad \longleftrightarrow \quad (+22, -1)$$

and both pairs produce

$$\chi n = -22.$$

Therefore, electron and positron have the same mass and opposite charge orientations.

Proof. If E_+ and E_- are, respectively, the even and odd components of the character with respect to C_M, then

$$E_+(C_M\mathbf{t}) = E_+(\mathbf{t}), \qquad E_-(C_M\mathbf{t}) = -E_-(\mathbf{t}).$$

From here,

$$E_{\text{band}}(C_M\mathbf{t}, -\chi) = E_{\text{band}}(\mathbf{t}, \chi),$$

and the equality of mass is obtained by applying the exponential. In the electronic term,

$$(+1)(-22) = (-1)(+22) = -22.$$

□

The finite closure of proposition 92.33 reinforces this interpretation: over the eighty-one CT–108 routes, neither pure sign nor pure reversal preserves the taxonomy, whereas − rev does preserve it, with

$$81 = 54 + 9 + 9 + 9.$$

The antiparticle is therefore neither a negative mass nor an independent copy. It is the other oriented section of the same band: it preserves the even invariants that determine mass and reverses the odd invariants that determine charge and orientation.

58.1.9 Basal stage of the electronic closure

Theorem 58.10 (Holographic composition of the electronic section)**.** *With the objects constructed in the preceding sections fixed, the dimensionless electronic section is*

$$\mathfrak{e}_{\text{HMT}} = \left\| [P_{\Sigma,3}, P_{\Pi,3}] \right\| \left[\exp\big((\mathscr{R} \circ \mathsf{J})(\pi, \varphi)\big) - \frac{\Sigma(\text{APP})}{\Sigma(\text{centro})}\, \alpha_{\text{HMT}}^3 \right] \left[1 + \frac{\Sigma(\text{canal})}{\Sigma(\text{centro})}\, \Delta_4 \right].$$

Equivalently,

$$\boxed{\mathfrak{e}_{\mathrm{HMT}} = \frac{\sqrt{3}}{4}\left(e^{\varphi/\pi^2} - 22\alpha_{\mathrm{HMT}}^3\right)(1 + 15\Delta_4).}$$

Its evaluation is

$$\boxed{\mathfrak{e}_{\mathrm{HMT}} = 0.510998922488066072509870877191349437 63\ldots.}$$

This scalar is the basal stage $\mathfrak{e}_e^{(0)}$*, not the governing electronic output. The bidirectional beta closure publishes* 0.510998950690000808608 . . . MeV.

Proof. The proposition 58.1 contributes

$$\left\|[P_{\Sigma,3}, P_{\Pi,3}]\right\| = \sqrt{3}/4.$$

The theorem 58.2 contributes

$$(\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \varphi/\pi^2.$$

The theorem 58.3 contributes

$$\frac{\Sigma(\mathrm{APP})}{\Sigma(\mathrm{centro})} = 22, \qquad \frac{\Sigma(\mathrm{canal})}{\Sigma(\mathrm{centro})} = 15.$$

The dodecaphasic closure contributes the rational window α_{12} of the coinductive section α_{HMT}, and equation (58.2) contributes the global defect. Substitution yields the abbreviated formula. Successive evaluation of

$$\begin{aligned} e^{\varphi/\pi^2} &= 1.178144942596306780811600956808889 10\ldots, \\ 22\alpha_{\mathrm{HMT}}^3 &= 0.000008549065992005517270149798075982 28\ldots, \\ 1 + 15\Delta_4 &= 1.001667946340382100810767021791810 19\ldots \end{aligned}$$

gives the declared value. □

The theorem is holographic in a verifiable sense: each local factor retains a distinct layer of the complete system. The commutator retains sheet duality; the exponential retains the interior orientation of the hinge π–φ; 22 and 15 retain the global census and its central kernel; α_{HMT}^3 retains fine closure; and Δ_4 retains global refinement. The center determines where the section is anchored, and the band determines how it survives under conjugation. The value does not replace this structure: it is its common evaluation.

58.1.9.1 Anterior and posterior action splitting upon return

The regional realization of the conjugate angular coordinate C^* distinguishes two coordinates on the same internal action line. The coordinate before the return is H_5 and the subsequent coordinate is

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = H_5 - \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}).$$

The notation $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$ is the canonical sexagesimal coordinate defined on the action branch by $\eta_{\mathrm{ret}}^{(\mathrm{deg})} = C^*/2 - \alpha_{\angle,\mathrm{deg}}$. The preceding equality is evaluated in that chart; it does not introduce a second return coordinate. Therefore, the additive and multiplicative charts of the oriented splitting are

$$\boxed{\delta_{2w} := H_5 - \eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}), \qquad R_{\mathrm{act}} := \frac{\hbar_{\mathrm{HMT}}^{\mathrm{pre}}}{\hbar_{\mathrm{HMT}}^{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}^{(\mathrm{deg})}}.} \tag{58.3}$$

Both coordinates follow from a single pre-return/post-return transport. They are not two Planck constants: the common factor $10^{-34}\mathcal{U}_S$ fixes the dimensional line and cancels exactly in R_{act}. The action ellipse subsequently realizes $\mathrm{Area}(\theta) = \hbar_{\mathrm{HMT}}^{\mathrm{ret}}\theta$, so that the splitting precedes the holonomy reading.

The coupling

$$\kappa_e^{\beta} = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4, \qquad \mathfrak{e}_e^{\beta} = \mathfrak{e}_{\mathrm{HMT}} R_{\mathrm{act}}^{\kappa_e^{\beta}} = 0.5109989506900008086\ldots \tag{58.4}$$

is the bidirectional quantitative closure of the electron. The two independent readers of the electronic register constructed in the following chapter select, without consulting the comparison mass,

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6),$$

and derive exactly κ_e^{β}. The integer 80 comes from the first coordinate of those readers; the word $w_e = 201101$ retains its own residence in the channel of Euler's constant.

Internal Closure of Bidirectional Refinement

The identity (58.3), the reduction $(80, 54, 6)$, and the equation (58.4) constitute internally exact, target–free results on the electronic record. Propagation to fibers of higher rank is formulated by means of the multisection operators.

58.1.10 Energy chart and contrast of the bidirectional closure

Let $\mathcal{U}_E$ a real line of energy dimensions and let u_E a chosen basis. The metrological transduction is

$$\varsigma_{u_E} : \mathbb{R} \longrightarrow \mathcal{U}_E, \qquad \varsigma_{u_E}(x) = x\, u_E.$$

The chart preserves two stages of the same genealogy. The basal stage is

$$E_e^{(0)} = \varsigma_{u_E}(\mathfrak{e}_{\mathrm{HMT}}).$$

With $u_E = 1\,\mathrm{MeV}$,

$$E_e^{(0)} = 0.5109989224880660725\ldots\ \mathrm{MeV}.$$

The action ratio and the derived exponent complete the leading stage,

$$E_e^{\beta} = E_e^{(0)} R_{\mathrm{act}}^{\kappa_e^{\beta}} = 0.510998950690000808608257164 8\ldots\ \mathrm{MeV}, \qquad m_e^{\beta} = E_e^{\beta}/c^2.$$

The unit does not appear in equation (58.1); it is the basis of a dimensional line applied to an already constructed output.

The CODATA 2022 reference for the electron energy equivalent is [29]

$$E_e^{\mathrm{CODATA}} = 0.51099895069(16)\ \mathrm{MeV}.$$

In that same chart, the bidirectional output satisfies

$$E_e^{\beta} - E_e^{\mathrm{CODATA}} = 8.086082571648 \times 10^{-16}\ \mathrm{MeV},$$

with relative difference

$$1.582406883758 \times 10^{-15}.$$

The comparison is carried out after freezing the internal evaluation. The identities of the basal selector remain

$$22 = \frac{396}{18}, \qquad 15 = \frac{270}{18}, \qquad p = 27 - 22 = 5.$$

and additionally receive the combinatorial proof $-22 = -|K_e \setminus \iota(R_\pi)|$, $+15 = |R_\pi \times \mathbb{F}_3|$. The metrological comparison verifies the output; the route, the readers, and the action ratio generate it.

58.1.11 Structural Consequences of Electronic Closure

The preceding structural reading imposes several distinctions:

1. $\sqrt{3}/4$ is the norm of the APP commutator in dimension three. Its agreement with other geometric formulas does not supersede this provenance.
2. π/φ^2 and φ/π^2 are not interchangeable. The first ratio is the closure orientation; the second, obtained through J, is the electronic orientation of self-growth.
3. 22 and 15 follow from $396/18$ and $270/18$. Presenting them as values logically selected by Z_0 would reverse the demonstrated dependence.
4. α_{HMT}^3 uses the prior closure of α_{HMT}. The cubic power belongs to the electron law; by itself, it does not authorize a universal rule $\alpha^d \leftrightarrow d$ without an additional theorem.
5. Δ_4 is global. No must reemplazarse by s_{270}, by $135\Delta_4^2$ neither by a residue particular of the especie.
6. The position $(5, 5)$, the label e_{core}, the fine origin $v_e = 0$, and the central raw signature are coordinated objects, not synonyms.
7. The electron and positron are not distinguished by two mass laws: they are the two oriented sections of a single band, with even mass and odd charge.
8. $0.5109989224\ldots$ is first a dimensionless scalar. MeV, MeV/c^2, CODATA, and Z_0 belong to the subsequent comparison.

These distinctions explain why the electronic equation is a miniature of the HMT–MD system. In a single section, support, sheets, orientation, census, fine closure, refinement, center, persistence, and conjugation reappear. This is the content of the word *holographic*: not that a digit poetically represents the whole, but that each factor preserves a verifiable dependence on the whole that produces it.

58.2 Electron realization band and separation between base mass and beta closure

The enriched route of the central point publishes two complementary representations of its memory: the complete tritic word $\gamma_{108} \in \mathbb{F}_3^{108}$ and the signed dodecaphase record $\tau_{12} \in \{-1, 0, +1\}^{12}$. The two readers defined below are computed exclusively from those representations, the calendar, and the HMT constants already constructed.

58.2.1 Reader of displacements on the cyclic calendar of order 108

Let S be the cyclic shift on $\mathbb{Z}/108\mathbb{Z}$. For $k \in \mathbb{Z}/108\mathbb{Z}$, define

$$D_k(\Gamma) := \#\{t \in \mathbb{Z}/108\mathbb{Z} : \gamma_t \neq \gamma_{t+k}\} = \|(I - S^k)\gamma\|_0. \tag{58.5}$$

The integer triple of the reader is

$$K_D(\Gamma) = \left(D_{27} + D_{36},\ D_1,\ \frac{D_4 - D_3}{2}\right) =: (A_D, B_D, C_D), \tag{58.6}$$

and its scalar evaluation is

$$\kappa_D(\Gamma) = A_D - \alpha_{\mathrm{HMT}} B_D + \Delta_4 C_D. \tag{58.7}$$

The shifts (27) and (36) are the chronological lifts of 90° and 120° because nine discrete steps represent 30°. The term D_1 measures the immediate local boundary, and the difference $D_4 - D_3$ compares the two genealogies before their height quotient. In the domain of the 324 routes, $\gamma_{t+54} = \gamma_t$ holds; all the D_k are even and C_D is an integer.

58.2.2 Dodecaphasic correlation difference reader

For the word $\tau = (\tau_r)_{r\in\mathbb{Z}/12\mathbb{Z}}$, let

$$C_k^{\mathrm{corr}}(\tau) = \sum_{r=0}^{11} \tau_r \tau_{r+k}, \qquad A_\ell(\tau) = \sum_{r=0}^{11} \left(\sum_{j=0}^{\ell-1} \tau_{r+j} \right)^2 .$$

The primitive genealogical obstruction and the antipodal memory are

$$\Omega_{90|120}(\tau) = 4A_3 - 3A_4 = -2C_1^{\mathrm{corr}} - 4C_2^{\mathrm{corr}} - 6C_3^{\mathrm{corr}}, \tag{58.8}$$

$$P_6(\tau) = \sum_{r=0}^{5} \tau_r \tau_{r+6}. \tag{58.9}$$

The symbol P_6 prevents the colision with the short cycle of the corredor of constantes. The second triple and its evaluation are

$$K_\Omega(\Gamma) = \big(\Omega_{90|120}(\tau_\Gamma), 54, P_6(\tau_\Gamma)\big), \qquad \kappa_\Omega = \Omega_{90|120} - 54\alpha_{\mathrm{HMT}} + P_6\Delta_4. \tag{58.10}$$

Lemma 58.11 (Linear integral primitive uniqueness)**.** *Let $L = uA_3 + vA_4$, with $u, v \in \mathbb{Z}$, be a contrast that vanishes when the genealogies descend to the same height, $A_3 = 3a$, $A_4 = 4a$. Then $(u, v) = n(4, -3)$. Once the sign $90 - 120$ has been fixed, $\Omega_{90|120} = 4A_3 - 3A_4$ is the primitive generator.*

Proof. Vanishing for every a requires $3u + 4v = 0$. Since $\gcd(3, 4) = 1$, the integer solutions are $(u, v) = n(4, -3)$. Primitivity corresponds to $|n| = 1$. □

The lemma selects Ω within the class of integral linear contrasts of the energies A_3, A_4. Its uniqueness domain is that functional class; nonlinear invariants belong to a distinct selection problem.

58.2.3 Evaluation of the central route

Before metrological comparison, the electronic route $\Gamma_e = (5, 5, ++)$ provides,

$$(D_1, D_3, D_4, D_{27}, D_{36}) = (54, 56, 68, 48, 32),$$

and its signed dodecaphonic register is

$$\tau_e = (+, +, +, -, -, -, +, +, +, -, -, -).$$

Therefore,

$$K_D(\Gamma_e) = (48 + 32, 54, (68 - 56)/2) = (80, 54, 6),$$

$$K_\Omega(\Gamma_e) = (80, 54, 6).$$

Theorem 58.12 (Common Electronic Reduction of Bidirectional Readers)**.** *The readers K_D and K_Ω coincide on the central route and determine*

$$\kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4. \tag{58.11}$$

Proof. The two preceding evaluations yield the same integer triple. Substitution of its components into $A - \alpha_{\mathrm{HMT}}B + \Delta_4 C$ proves (58.11). Every quantity used in this reduction belongs to the route, to its two records, or to the previously constructed HMT constants. □

Subsequent realization on the energy chart. With $R_{\mathrm{act}} = H_5/\eta_{\mathrm{ret}}^{(\mathrm{deg})}$, the positive action on the baseline $\mathfrak{e}_0$ yields

$$\mathfrak{e}_e^{\beta} = \mathfrak{e}_0 R_{\mathrm{act}}^{\kappa_e}. \tag{58.12}$$

After applying the current chart to MeV is obtained

$$\varsigma_{u_E}(\mathfrak{e}_e^{\beta})\big|_{u_E=1\,\mathrm{MeV}} = 0.510998950690000808608257164 8\ldots\ \mathrm{MeV}. \tag{58.13}$$

The first equality belongs to the internal theorem conditioned by the basal and the action line; the second is its dimensional realization. The external value is reserved for metrological comparison.

The integer (80) follows from $D_{27} + D_{36}$ and, in the dodecaphase reader, from $\Omega_{90|120}$. Its coincidence with other internal cardinals is a compatibility control and does not replace this operator provenance. The orientation route $(--)$ is a temporal translation of route $(++)$ and preserves the same profile, in accordance with mass parity under conjugation.

58.2.4 Separation of readers and return scales

Numerical coincidence of internal components is subordinate to their type. At the central point, the objects involved include

$$R_{\mathrm{atlas}}(5,5) = (24,0,12,0,-12), \qquad L_{\kappa_0}(\Gamma_e^{++}) = (24,0,0,0,-12),$$

$$k_{\Delta_4}^{\mathrm{dod}}, k_{\Delta_4}^{\mathrm{pro}} : \mathscr{R}_{324} \longrightarrow \mathbb{Z},$$
$$k_{\Delta_4}^{\mathrm{dod}}(\Gamma_e^{++}) = 12, \qquad k_{\Delta_4}^{\mathrm{pro}}(\Gamma_e^{++}) = 4,$$
$$K_D(\Gamma_e^{++}) = K_\Omega(\Gamma_e^{++}) = (80,54,6).$$

Here $\mathscr{R}_{324}$ denotes the domain of the 324 oriented routes. The first is a static family signature; the second, a genealogy extractor; the third and fourth terms are torsional readers defined, respectively, by dodecaphasic reading and prospective prolongation; the final object is the pair of bidirectional readers. No partial equality identifies those morphisms or permits transferring a coefficient between readers.

Four temporal scales are also distinguished: 27 is the first return of class, orbit, and cell; $54 = D_1(\Gamma_e)$ is the observable kinematic return within the cycle; 108 closes the calendar; and 216 closes the oriented kinematic state in the extension. This typing keeps positional return, remark, and oriented holonomy separate.

Causal chain of the electronic outcome The route and its two registers determine K_D, K_Ω, their common reduction, and the evaluation of κ_e. The realization in MeV subsequently applies the energy chart; external mass enters only in the comparison. The pair $\mathbf{K} = (K_D, K_\Omega)$ is the complete operator output of HMT on each route. In a noncentral fiber, its representation by a single physical scalar requires an additional morphism between the fiber operator and the dimensional chart; this requirement neither modifies the internal law nor authorizes the selection of a cell by metrological proximity.

From the Cartan–Holst realization to horizon–area–information confluence through conservation of action The electronic closure fixes a material realization; the next step identifies the grammar that converts action, clock, and mass into physical magnitudes without using that realization as input data.

58.3 Null–material closure of the electronic fiber and bifurcation preceding the positive character

Planck's self-dual identity fixes the origin of the positive line of masses; the electronic genealogy fixes its first complete material displacement. This section brings together, without repeating their reference proofs, the circular realization of CT108, the basal composition of the electron, and the bidirectional holonomy of its route.

Let

$$\mathcal{H}_{108}^{\mathrm{reg}} := \ell^2(\mathbb{Z}/108\mathbb{Z};\mathbb{R}), \qquad S_{108}^{\mathrm{reg}}\delta_\theta = \delta_{\theta+1},$$

the real regular representation of the cyclic shift of CT108, and let

$$n_0 := \frac{1}{\sqrt{108}}\sum_{\theta=0}^{107}\delta_\theta, \qquad \mathcal{N}_{108} := \ker(S_{108}^{\mathrm{reg}} - I) = \mathbb{R}n_0.$$

The normalized zero Fourier mode is thereby defined, not merely named. Let $\mathcal{G}_e$ be the space of enriched electronic genealogies of proposition 90.9, and fix the linear submodule $\ell_{\Gamma_e} := \mathbb{R}g_{\Gamma_e} \subset \mathbb{R}[\mathcal{G}_e]$ generated by the central route in the free linearization of that space. Likewise, if $F_e^+ = \mathbb{R}_{>0}I$ is the positive ray already defined, let $\mathcal{F}_e := \mathrm{span}_{\mathbb{R}}(F_e^+) = \mathbb{R}I$ be its linear span, and let $\mathcal{L}_M$ be the mass line defined in section 90.4.7. The declared bases determine the rank-one linear morphism

$$\mathfrak{C}_e : \mathcal{N}_{108}\otimes\ell_{\Gamma_e} \longrightarrow \mathcal{F}_e\otimes\mathcal{L}_M, \qquad \mathfrak{C}_e(n_0\otimes g_{\Gamma_e}) = \mathfrak{c}_e\, I\otimes\mathcal{U}_M, \tag{58.14}$$

where the positive coordinate is

$$\boxed{\mathfrak{c}_e = \frac{\sqrt{3}}{4}\left[\exp\left(\frac{\varphi_{\mathrm{HMT}}}{\pi_{\mathrm{HMT}}^2}\right) - 22\alpha_{\mathrm{HMT}}^3\right](1+15\Delta_4)R_{\mathrm{act}}^{\,80-54\alpha_{\mathrm{HMT}}+6\Delta_4}.} \tag{58.15}$$

Theorem 58.13 (Null closure–one-range electronic material)**.** *With the primitives and charts already fixed, the morphism $\mathfrak{C}_e$ exactly factors the beta electron output. Its four factors preserve, in this order, the sum–product incompatibility of APP; the areal–volumetric orientation together with the boundary deficit; the torsion and retained memory; and the bidirectional holonomy of the electron route. In the chart $\mathcal{U}_M = 1\,\mathrm{MeV}/c^2$,*

$$\mathfrak{C}_e(n_0\otimes g_{\Gamma_e}) = 0.510998950690000808608257164 8\ldots\; I\otimes \mathrm{MeV}/c^2. \tag{58.16}$$

Proof. The theorem 58.10 proves that the first three factors of (58.15) compose the positive basal scalar $\mathfrak{e}_{\mathrm{HMT}}$. The theorem 58.12 obtains, from two independent readers of the route,

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80,54,6), \qquad \kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4.$$

The ratio $R_{\mathrm{act}} > 0$ belongs to the unique pre-return/post-return action line. Consequently, the fourth factor is positive, and the composition coincides with (58.4) and (58.13). The dimensional chart acts only after this factorization. □

Mathematical scope and physical realization. The exact result is the declared linear realization of the electron factorization over the typed null mode, genealogy, and fibre. The CT108 null mode does not by itself select the coordinate $\mathfrak{c}_e$: that coordinate follows from the four factors proved in their respective residences, and the morphism assembles them into a single rank-one algebraic closure. The bound electromagnetic dynamics retains as its own requirements a stable Hamiltonian, charge, spin 1/2, the form factor, and gauge coupling; these objects are not premises of the preceding factorization. The Planck

unit occupies the self-dual point of the line, whereas the electron occupies a genealogically displaced section: an interpretation as a classical black hole belongs to another type of realization and does not enter this morphism.

58.4 Law of electronic vacancies: polarization, current, and structure of the null modes

Finite scales

$$729 = 3^6, \qquad 1000 = 10^3$$

determine an exact logarithmic mismatch. We define

$$\rho_{\mathrm{vac}} = \log_{1000} 729 = \log_{10} 9, \qquad \delta_{\mathrm{vac}} = 1 - \rho_{\mathrm{vac}} = \log_{10}(10/9). \tag{58.17}$$

The irrationality of δ_{vac} follows directly from the prime valuations: an equality $\delta_{\mathrm{vac}} = p/q$ would imply $(10/9)^q = 10^p$, which is incompatible with the valuations at $2, 3, 5$. The vacancy is therefore an aperiodic arithmetic rotation determined entirely by the relation between the two scales; its definition precedes the electronic law.

58.4.1 Exact Laws of Hole and Return

Let

$$p_n = \left\lfloor \frac{n}{\delta_{\mathrm{vac}}} \right\rfloor.$$

Theorem 58.14 (Gap law 21/22)**.** *The consecutive increments of the sequence p_n satisfy*

$$p_{n+1} - p_n \in \{21, 22\}.$$

Both values appear in the word mechanical.

Proof. For every irrational $x > 1$, the difference $\lfloor (n+1)x \rfloor - \lfloor nx \rfloor$ belongs to $\{\lfloor x \rfloor, \lceil x \rceil\}$. In this case

$$\delta_{\mathrm{vac}}^{-1} = 21.85434532678283256\ldots,$$

which determines the two vacancies. Irrationality rules out stabilization in either one alone. □

The frequency of the short hole is

$$\sigma_{\mathrm{vac}} = 22 - \delta_{\mathrm{vac}}^{-1} = 0.1456546732171674374\ldots, \qquad \sigma_{\mathrm{vac}}^{-1} = 6.865553832996660997\ldots.$$

Corollary 58.15 (Return law 6/7)**.** *Successive occurrences of the gap* 21 *are separated by six or seven positions.*

Proof. The indicator word for the short gap is the mechanical coding with irrational slope σ_{vac}. Beatty's argument applied to $\sigma_{\mathrm{vac}}^{-1}$ produces exactly the returns 6/7 [82]. □

The two laws form the oriented framework

$$V_{\mathrm{vac}} = \begin{pmatrix} 21 & 22 \\ 6 & 7 \end{pmatrix}, \qquad \det V_{\mathrm{vac}} = 21 \cdot 7 - 22 \cdot 6 = 15. \tag{58.18}$$

The nonzero determinant proves the independence of the gap and return directions. The cardinal 15 thus reappears as an invariant of the vacancy calendar. In the electron equation, the pair $(-22, +15)$ comes from the central selector proved in theorem 58.3; the framework (58.18) provides an independent arithmetic corroboration, with its own genealogy.

It is convenient to distinguish two words derived from the same mismatch. The indicator

$$h_n = \mathbf{1}_{\{p_{n+1}-p_n=21\}}$$

has frequency σ_{vac} and returns $6/7$. The word

$$z_n = \lceil (n+1)\delta_{\mathrm{vac}} \rceil - \lceil n\delta_{\mathrm{vac}} \rceil$$

has slope δ_{vac} and contains 45 or 46 units in each block of length one thousand. The laws $21/22$, $6/7$, and $45/46$ are distinct readers of the same irrational rotation.

58.4.2 Bounded polarization and discrete continuity equation

A phase θ defines

$$z_n(\theta) = \lceil (n+1)\delta_{\mathrm{vac}} + \theta \rceil - \lceil n\delta_{\mathrm{vac}} + \theta \rceil.$$

The accumulated intrinsic polarization is

$$\begin{aligned} P_N(\theta) &:= \sum_{n=0}^{N-1} \big(z_n(\theta) - \delta_{\mathrm{vac}} \big) \\ &= \lceil N\delta_{\mathrm{vac}} + \theta \rceil - \lceil \theta \rceil - N\delta_{\mathrm{vac}}, \qquad |P_N(\theta)| < 1. \end{aligned} \tag{58.19}$$

The temporal difference

$$J_N(\theta) = P_{N+1}(\theta) - P_N(\theta) = z_N(\theta) - \delta_{\mathrm{vac}} \tag{58.20}$$

is the associated arithmetic current. The equations (58.19) y (58.20) constitute an exact continuity equation: the accumulated charge remains uniformly bounded, and each pulse is its local variation. The electromagnetic realization applies a unit of charge and a temporal scale to this pair; the polarization and current structure is already fixed before that chart.

58.4.3 Harmonic Closure of Conjugated Null Modes in the Electronic State

The central electronic section admits a structural reading as the closure of two conjugate null modes. For $u, v > 0$, the hyperbolic projectors $P_{\pm}$ satisfy

$$N_{\mathrm{sp}}(uP_+ + vP_-) = uv > 0,$$

although each isolated component has zero norm. In this construction, the resonant closure of conjugate electromagnetic null modes denotes the two-sheet transport ring whose holonomy closes the central material section; emission and absorption correspond to opening and closing a null orientation relative to that section.

Photonic realization of harmonic closure

The closure of two null modes and the positivity of their coupled norm are algebraic identities. The electromagnetic realization is specified by an intertwiner with the Maxwell modes, a closure Hamiltonian, and the corresponding transition rates. The public expression *resonant closure of conjugate electromagnetic null modes* names the structural object that receives that realization.

58.5 Central electron and helical reader of matter

58.5.1 Uniqueness of the Material Center under Cellular Inversion

The material atlas has domain $C_{81} = \{1, \dots, 9\}^2$ and involution

$$\rho_c(r, c) = (10 - r, 10 - c).$$

Its only fixed point is

$$(r, c) = (5, 5).$$

The other 80 cells form 40 pairs. The central electron is the only point multisection; the remaining internal species are fibers, orbits, or multisections. Spiral theory does not call this conclusion into question.

58.5.2 Common singular mode of the APP sheets in the canonical chart $1, \dots, 9$

In the canonical APP chart $1, \dots, 9$, the vector of values of the operational tritic phase selector is

$$m_{\mathrm{ph}} = (1, -1, 0)^3.$$

For the three-dimensional joint table,

$$C^{(3)} m_{\mathrm{ph}} = (C^{(3)})^* m_{\mathrm{ph}} = -\frac{1}{2} m_{\mathrm{ph}}.$$

Therefore

$$s = \frac{1}{2}, \qquad 1 - s^2 = \frac{3}{4} = \frac{90}{120},$$

$$\|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}. \tag{58.21}$$

The mode, oriented defect $90 \to 120$, and electronic prefactor are coordinated publications of the same APP–TRIT–TPK chain, whose effective composition provides their internal intertwining.

58.5.3 Genealogical record of the material route: surviving extension, full signature, and dimensionless character

Each cell of the atlas bears the signature

$$\mathcal{R}(r, c) = (n_A, s_C, k_{\Delta_4}, \nu_{120}, \nu_{270}, \tau_{12})_{r,c}.$$

The image contains 56 route families; refinement by family and level contains 13 multisections. The governing counts are

$$81/56/13/324,$$

with the null sector and the global towers. The radial reader only can be added by means of a compatible signature, by ejemplo

$$\Sigma_{\mathrm{esp}}(X) = (p_X, a_X, [\Lambda_X, C_X], [\kappa_{9,X}], \mu_X, \varepsilon_{\mathrm{tw},X}),$$

that is constant where appropriate and natural under refinement.

58.5.4 Material compatibility square

Let $\mathcal{E}_{\mathrm{atlas}}$ the space of persistent sections and $\mathfrak{S}_{\mathrm{esp}}$ the spiral reader. The material compatibility is expressed by means of the square

$$\begin{array}{ccc} \mathcal{E}_{\mathrm{atlas}} & \xrightarrow{\mathfrak{S}_{\mathrm{esp}}} & \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad}} \\ {\scriptstyle (K_D,K_\Omega)}\downarrow & & \downarrow{\scriptstyle \mathrm{ev}^{\mathrm{esp}}_{\mathrm{dim}}} \\ \mathrm{Spec}(K_D,K_\Omega) & \xrightarrow{\mathfrak{R}_{\mathrm{mat}}} & \mathcal{M}_{\mathrm{hel}} \end{array}$$

The electron $(5,5)$ provides the central anchor, but does not select p, Λ, C retrospectively. The other species require constancy on multisections, compatibility with cell inversion, K_D/K_Ω, CKM/PMNS, color, and spin representation.

58.5.5 Spin and helicity

is not identified the spin $1/2$ with a vuelta of a helix. The fermionic representation satisfies

$$U(2\pi)\psi_e = -\psi_e, \qquad U(4\pi)\psi_e = \psi_e.$$

The nonadic helix records phase and memory; the spin representation lives in another codomain. A valid material intertwiner must preserve both laws, not replace one with the other.

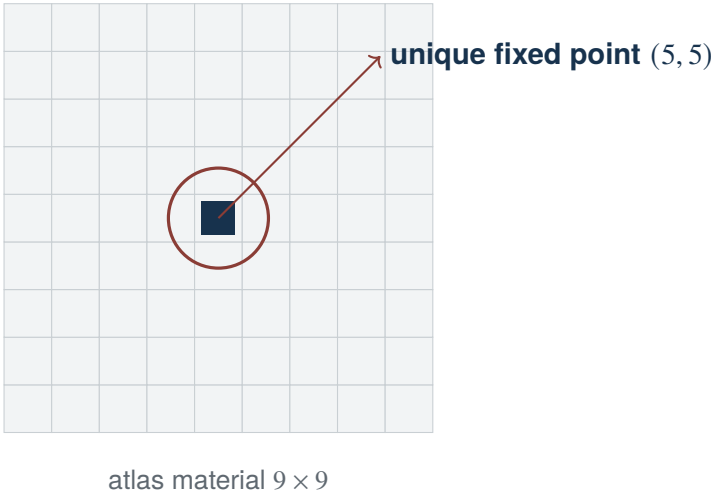

Figure 58.1: The central electron is a result of the atlas; the spiral correspondence is a subsequent reader.

Chapter 59

From the genealogical number to the physical magnitude: action, mass, and dimensional observables

Dimensional publication is organized by an absolute action line and a family of positive operators. The local determinantal order produces the decade minus thirty-four; only thereafter do the metrological chart and the dimensional observables intervene.

59.1 Lines of magnitude and dimensional realization of the HMT kernel

The transition from HMT to Dimensional Mechanics does not consist in adjoining a unit symbol to a real number. The arithmetic core produces characters, cocycles, ratios, and orders of a decimal chart. By contrast, a physical magnitude is an element of a line endowed with dimensional type. The distinction is structural: a change of units modifies the coordinates of a magnitude, but not the magnitude itself. On the one hand, this section constructs the ambient lattice required to realize mass, length, duration, and charge independently, and determines that its minimum rank is four. On the other hand, it constructs a monoidal functor of trajectories with signature that takes values in a portion of that lattice. The minimality of the lattice is not attributed to the functor.

The construction has two consequences. First, it makes it possible to realize action, duration, length, charge, and mass in a common lattice without introducing the International System into the generative formulas; assigning charge to states additionally requires a specific integral character. Second, it proves exactly which part of an absolute scale cannot follow from dimensionless scalars. This impossibility does not affect ratios, mass characters, or constitutive identities; it fixes the correct mathematical type of their outputs. The distinction among dimension, numerical coordinate, and choice of unit is that of the classical theory of dimensional analysis [18, 17]; the structure of lines that follows makes this distinction explicit in the HMT domain.

59.1.1 Lattice of dimensions and oriented lines

Let

$$\Lambda_{\mathrm{D}} = \mathbb{Z}\langle \mathbf{M}, \mathbf{L}, \mathbf{T}, \mathbf{Q} \rangle \cong \mathbb{Z}^4$$

the lattice of dimensions, written in terms of mass, length, duration, and charge. For $d = (d_M, d_L, d_T, d_Q) \in \Lambda_{\mathrm{D}}$, we denote by $\mathcal{L}_d$ an oriented real line and by $\mathcal{L}_d^+$ its positive ray. The tensor product realizes addition of dimensions,

$$\mathcal{L}_d \otimes \mathcal{L}_e \simeq \mathcal{L}_{d+e}, \qquad \mathcal{L}_d^{\vee} \simeq \mathcal{L}_{-d}.$$

The collection of these lines, with positive isomorphisms and tensor product, forms a symmetric Picard groupoid. A dimensionless scalar is an element of $\mathcal{L}_0 \simeq \mathbb{R}$; a quantity of dimension d is an element of $\mathcal{L}_d$.

We introduce four dimensions adapted to HMT:

$$\mathbf{S} = \mathbf{M} + 2\mathbf{L} - \mathbf{T}, \qquad \mathbf{C} = \mathbf{L} - \mathbf{T}, \qquad \mathbf{T} = \mathbf{T}, \qquad \mathbf{Q} = \mathbf{Q}.$$

They represent, respectively, action, velocity, duration, and charge. In the basis $(\mathbf{M}, \mathbf{L}, \mathbf{T}, \mathbf{Q})$, their columns form the matrix

$$B_{\mathrm{D}} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 \\ -1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Theorem 59.1 (Adapted base dimension for HMT)**.** *The dimensions*

$$\mathbf{S}, \qquad \mathbf{C}, \qquad \mathbf{T}, \qquad \mathbf{Q}$$

constitute a unimodular basis of Λ_{D}*. In particular, every mechanical, electromagnetic, or gravitational dimension generated by* $(\mathbf{M}, \mathbf{L}, \mathbf{T}, \mathbf{Q})$ *has a unique expression with integer exponents in the four lines* $\mathcal{L}_S, \mathcal{L}_C, \mathcal{L}_T, \mathcal{L}_Q$*.*

Proof. The matrix B_{D} is block triangular and $\det B_{\mathrm{D}} = 1$. It therefore belongs to $\mathrm{GL}_4(\mathbb{Z})$. Its integral inverse provides

$$\mathbf{L} = \mathbf{C} + \mathbf{T}, \qquad \mathbf{M} = \mathbf{S} - 2\mathbf{C} - \mathbf{T}.$$

The four original dimensions are thereby uniquely recovered. □

Among the identities that we will use are

$$\mathbf{E} = \mathbf{S} - \mathbf{T}, \qquad \mathbf{Z} = \mathbf{S} - 2\mathbf{Q}, \tag{59.1}$$

$$\boldsymbol{\mu} = \mathbf{S} - \mathbf{C} - 2\mathbf{Q}, \qquad \boldsymbol{\varepsilon} = -\mathbf{S} - \mathbf{C} + 2\mathbf{Q}, \tag{59.2}$$

$$\mathbf{G} = -\mathbf{S} + 5\mathbf{C} + 2\mathbf{T}, \qquad \boldsymbol{\kappa} = -\mathbf{S} + \mathbf{C} + 2\mathbf{T}, \tag{59.3}$$

$$\boldsymbol{\Lambda} = -2\mathbf{C} - 2\mathbf{T}. \tag{59.4}$$

Here $\mathbf{E}$ is energy, $\mathbf{Z}$ impedance, $\boldsymbol{\mu}$ permeability, $\boldsymbol{\varepsilon}$ permittivity, $\mathbf{G}$ the dimension of the gravitational constant, $\boldsymbol{\kappa} = \mathbf{G} - 4\mathbf{C}$, and $\boldsymbol{\Lambda} = -2\mathbf{L}$.

59.1.2 Rescaling group and impossibility theorem

The group of unit base change transformations is

$$\mathcal{G}_{\mathrm{D}} := \mathrm{Hom}(\Lambda_{\mathrm{D}}, \mathbb{R}_{>0}) \cong (\mathbb{R}_{>0})^4.$$

For $g \in \mathcal{G}_{\mathrm{D}}$ and $d \in \Lambda_{\mathrm{D}}$, write g^d for the corresponding character. If u_d is a positive basis of $\mathcal{L}_d$, the chart change $u_d \mapsto g^d u_d$ transforms the coordinate of a fixed quantity according to

$$x\, u_d = (g^{-d} x)(g^d u_d).$$

The magnitude does not change; its numerical representation changes.

Theorem 59.2 (Impossibility of an Absolute Scale from Dimensionless Data)**.** *Let X be a space on which $\mathcal{G}_{\mathrm{D}}$ acts trivially, and let $d \neq 0$. Every map $F : X \to \mathcal{L}_d$ that is natural with respect to all changes of units and that receives no additional dimensional basis is identically zero. By contrast, every quotient of two nonzero sections of the same line, and every product whose total dimension is zero, is invariant under $\mathcal{G}_{\mathrm{D}}$.*

Proof. Naturality and the trivial action on X imply

$$F(x) = F(gx) = g^d F(x) \qquad (g \in \mathcal{G}_{\mathrm{D}}).$$

Since $d \neq 0$, there exists g with $g^d \neq 1$; hence $(g^d - 1)F(x) = 0$, and then $F(x) = 0$. For two sections of dimension d, the factors g^d cancel in the quotient. The same cancellation occurs in every monomial of total dimension zero. □

The theorem does not establish that a discrete theory is incapable of constructing an internal scale. It establishes that this scale must appear as a section of a line or, equivalently, that the theory must extend its domain by the torsor of dimensional frames. It is precisely this extension that defines Dimensional Mechanics.

Corollary 59.3 (Minimum rank)**.** *Every system of lines that permits mass, length, duration, and charge to be realized independently has scale rank at least four. The basis* $(\mathbf{S}, \mathbf{C}, \mathbf{T}, \mathbf{Q})$ *attains the bound; it is therefore minimal.*

Proof. The four original dimensions are linearly independent in Λ_{D}. Three generators cannot span a rank-four lattice. The theorem 59.1 provides four generators that do span it. □

59.1.3 Internal dimensional space: degrees, charts, and HMT–MD transduction operators

An internal framework HMT–MD is a quadruple of positive bases

$$\mathfrak{u} = (u_S, u_C, u_T, u_Q) \in \mathrm{Fr}_{\mathrm{D}},$$

where Fr_{D} is a principal torsor under $\mathcal{G}_{\mathrm{D}}$. The derived bases are defined tensorially:

$$\begin{aligned} u_L &= u_C u_T, & u_M &= u_S u_C^{-2} u_T^{-1}, & u_E &= u_S u_T^{-1}, \\ u_Z &= u_S u_Q^{-2}, & u_\mu &= u_S u_C^{-1} u_Q^{-2}, & u_\varepsilon &= u_S^{-1} u_C^{-1} u_Q^{2}, \\ u_G &= u_S^{-1} u_C^{5} u_T^{2}, & u_\kappa &= u_S^{-1} u_C u_T^{2}, & u_\Lambda &= u_C^{-2} u_T^{-2}. \end{aligned}$$

Juxtaposition here denotes the tensor product of bases. An external chart is another frame $\mathfrak{u}_{\mathrm{ext}}$ together with a positive isomorphism between the two systems of lines. Nothing requires that chart to be SI; the choice of SI belongs to the metrological publication of a magnitude.

59.1.3.1 Action line

The determinantal reader local begins from

$$G_H = \mathrm{coker}(H_4), \qquad |G_H| = 16, \qquad \Sigma_H = \varphi \alpha_{\mathrm{HMT}}^{16},$$

and proves

$$10^{-34} < \Sigma_H < 10^{-33}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34.$$

The post-return regional realization provides the dimensionless angular coordinate.

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{C_{\mathrm{deg}}^{*}}{2} - \alpha_{\angle,\mathrm{deg}} = 1.0545718169150390611336905847242997\ldots.$$

We define the internal action reduced section by

$$\hbar_{\mathrm{int}} := \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34} u_S, \qquad h_{\mathrm{int}} := 2\pi \hbar_{\mathrm{int}}. \tag{59.5}$$

The exponent is an output of the reader; u_S is the basis of a line. The composition is covariant under $\mathcal{G}_{\mathrm{D}}$ and contains no identification with J s.

59.1.3.2 Periodicity of route edge and resulting constitutive velocity

Let $\mathsf{P}_{\mathrm{TPK}}$ be the free category of trajectories of the graph of enriched states. The grading by length

$$\tau(\gamma) = |\gamma|, \qquad \tau(\gamma\eta) = \tau(\gamma) + \tau(\eta)$$

define the combinatorial clock of the protocol. Its implementation is

$$T_{\mathrm{int}}(\gamma) = \tau(\gamma) u_T.$$

This duration counts transitions of the fixed graph. A subdivision of the graph defines another clock and must be accompanied by its refinement morphism.

The channels $q_\pm$ generate the symmetric and antisymmetric functions

$$\mathcal{E} = \log\big[(1-q_+^{90})(1-q_-^{90})\big] - \log\big[(1-q_+^{120})(1-q_-^{120})\big],$$

$$\mathcal{B} = \log\frac{1-q_-^{90}}{1-q_+^{90}} - \log\frac{1-q_-^{120}}{1-q_+^{120}}.$$

These determine the positive coefficients

$$\widehat{c} = e^{-\mathcal{E}}, \qquad \widehat{Z} = e^{\mathcal{B}}.$$

Its internal realizations are

$$c_{\mathrm{int}} = \widehat{c}\, u_C, \qquad Z_{\mathrm{int}} = \widehat{Z}\, u_Z. \tag{59.6}$$

For a constant channel along a path one obtains the length

$$L_{\mathrm{int}}(\gamma) = \widehat{c}\,|\gamma|\, u_L. \tag{59.7}$$

If the channel depends on the edge, the covariant formula is the sum $\sum_{e\in\gamma}\widehat{c}(e)u_L$; its additivity under concatenation is preserved.

59.1.3.3 Elementary charge scale and conditional character

Since $u_Z = u_S u_Q^{-2}$, the quotient $h_{\mathrm{int}}/Z_{\mathrm{int}}$ belongs to $\mathcal{L}_Q^{\otimes 2}$. The positive orientation of the lines selects a unique positive root. We define

$$e_{\mathrm{int}} := \left(\frac{2\alpha_{\mathrm{HMT}} h_{\mathrm{int}}}{Z_{\mathrm{int}}}\right)^{1/2} \in \mathcal{L}_Q^{+}. \tag{59.8}$$

Proposition 59.4 (Internal Closure of the Fine Structure Relation)**.** *The section* (59.8) *is the unique positive section that satisfies*

$$\alpha_{\mathrm{HMT}} = \frac{Z_{\mathrm{int}} e_{\mathrm{int}}^2}{2h_{\mathrm{int}}}.$$

The equality is invariant under the full scaling group.

Proof. Existence follows from the positivity of $\alpha_{\mathrm{HMT}}, h_{\mathrm{int}}, Z_{\mathrm{int}}$. An oriented real line has a unique positive root of a positive section of its square. The dimension of the right-hand side is $\mathbf{Z} + 2\mathbf{Q} - \mathbf{S} = 0$, so all rescaling factors cancel. □

This proposition does not count as a second independent determination of α: within the system of lines, it realizes the constitutive compatibility among action, impedance, and an elementary charge scale. It does not construct a charge on the states. This additionally requires an integer character

$$n_Q : \mathrm{Ob}(\mathsf{P}_{\mathrm{TPK}}^{\mathrm{sig}}) \longrightarrow \mathbb{Z}; \qquad Q(x) = n_Q(x) e_{\mathrm{int}}.$$

The existence and selection of n_Q are additional hypotheses. In particular, n_Q is not a component of the trajectory functor constructed below. The elementary scale and the classification of states are distinct maps.

59.1.4 Monoidal path functor with signature

Let $\mathsf{P}_{\mathrm{TPK}}^{\mathrm{sig}}$ be the category of enriched paths decorated with a signature coordinate $v_x \in \mathbb{Z}^5$ at each object. For $\gamma : x \to y$, we set

$$\Delta v(\gamma) = v_y - v_x.$$

Composition satisfies $\Delta v(\gamma\eta) = \Delta v(\gamma) + \Delta v(\eta)$. Let

$$\chi_{\mathrm{mass}}(v) = \exp\langle \lambda_{\mathrm{mass}}, v\rangle$$

the positive mass character. On the route quotient, we fix the action law determined by five data: the normalized trace of the distinct emissions, a positive additive cocycle, the change defect $\Delta_4 P_3$, the residual capacity $\lambda = 1 - \delta$, and the local sum of edge costs. In this law,

$$\mathcal{A}_*(\gamma) = N_{\mathrm{giro}}(\gamma) + \lambda_* N_{\mathrm{hoja}}(\gamma), \qquad \lambda_* = 1 - \frac{5}{468} - \frac{3}{11}\Delta_4.$$

The following argument requires only additivity; it also applies to the functional I_λ with any $\lambda > 0$.

Consider the monoid

$$\mathfrak{M}_{\mathrm{D}} = \mathbb{N} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{>0}$$

with product

$$(t, \ell, s, r) \odot (t', \ell', s', r') = (t + t', \ell + \ell', s + s', rr').$$

Theorem 59.5 (Monoidal path functor with signature)**.** *The map*

$$\mathfrak{D}_{\mathrm{HMT}}(\gamma) = \big(|\gamma|, \widehat{c}|\gamma|, \mathcal{A}_*(\gamma), \chi_{\mathrm{mass}}(\Delta v(\gamma))\big)$$

define a monoidal functor

$$\mathfrak{D}_{\mathrm{HMT}} : \mathsf{P}^{\mathrm{sig}}_{\mathrm{TPK}} \longrightarrow \mathfrak{M}_{\mathrm{D}}.$$

After choosing an internal frame, its three additive components are realized as

$$T_{\mathrm{int}}(\gamma) = |\gamma| u_T, \quad L_{\mathrm{int}}(\gamma) = \widehat{c}|\gamma| u_L, \quad S_{\mathrm{int}}(\gamma) = \mathcal{A}_*(\gamma)\hbar_{\mathrm{int}},$$

and the fourth transports dimensionless mass ratios. The functor does not contain a charge coordinate and does not generate the ambient dimensional lattice.

Proof. The length of a trajectory, the number of turns, and the number of changes of sheet are additive under compatible concatenation. By hypothesis, $\mathcal{A}_*$ is additive. The difference of signatures is additive, and the mass character transforms sums into products. Each component therefore respects the law $\odot$, and the empty route is sent to $(0, 0, 0, 1)$. The linear realization preserves sums because it multiplies by fixed sections of the corresponding lines. □

Remark 59.6 (Ambiental lattice and scope of the functor). The minimum-rank corollary concerns a system capable of varying mass, length, duration, and charge independently. The preceding functor realizes duration, length, and action, and transports a mass ratio; it does not use u_Q or prove a rank bound. The subsequent assignment of charges remains conditional upon the existence of n_Q. In the dimensional lattice, the types of its components are

$$\mathbf{T}, \qquad \mathbf{L} = \mathbf{C} + \mathbf{T}, \qquad \mathbf{S}, \qquad \mathbf{0},$$

so that its dimensional image is contained in $\langle \mathbf{S}, \mathbf{C}, \mathbf{T}\rangle_{\mathbb{Z}}$, of rank three. The rescaling $u_Q \mapsto \lambda u_Q$, with the other bases fixed, leaves all components of the functor invariant; the latter does not faithfully realize the fourth ambient direction.

If the bidirectional electronic section is assigned to each object as the origin of the mass chart,

$$m(x) = m_e^{\beta} \chi_{\mathrm{mass}}(v_x - v_e),$$

then every morphism $\gamma : x \to y$ satisfies exactly

$$\frac{m(y)}{m(x)} = \chi_{\mathrm{mass}}(\Delta v(\gamma)).$$

The theorem closes dimensional propagation once the signature is given. It does not change the status of the preceding map associating a species with a trajectory and its signature.

59.1.5 Basal stage and bidirectional closure of the electronic scale

The prevailing electronic invariant is the positive scalar.

$$\mathfrak{e}_0 = \frac{\sqrt{3}}{4}\left(e^{\varphi/\pi^2} - 22\alpha_{\mathrm{HMT}}^3\right)(1 + 15\Delta_4).$$

Its numerical value is $0.510998922488066\ldots$. This is the basal stage of the genealogy, not its governing output. In the internal dimensional framework, it defines an energy section and a mass section related by the velocity:

$$E_e^{\mathrm{int}} = \mathfrak{e}_0 u_E, \qquad m_e^{\mathrm{int}} = \frac{E_e^{\mathrm{int}}}{c_{\mathrm{int}}^2} = \mathfrak{e}_0 \widehat{c}^{-2} u_M. \tag{59.9}$$

The central route and its two bidirectional readers determine, without consulting the external mass,

$$\kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4, \qquad R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}^{(\mathrm{deg})}}.$$

The current electronic section is, therefore,

$$\begin{aligned} &E_e^{\beta} = E_e^{(0)} R_{\mathrm{act}}^{\kappa_e}, && m_e^{\beta} = \frac{E_e^{\beta}}{c_{\mathrm{int}}^2}, \\ &E_e^{\beta} = 0.51099895069000080860825716 48\ldots\ \mathrm{MeV}, && u_E = 1\,\mathrm{MeV}. \end{aligned} \tag{59.10}$$

Thus, the basal formula retains its derivative role, and bidirectional closure governs all subsequent propagation through characters and towers. In a natural-units chart in which the coordinate of c_{int} is fixed at one, both numerical coordinates coincide; their lines are not silently identified.

Proposition 59.7 (Typed separation of the energy base and the clock quantum)**.** *Escribamos $t_0 = \tau_0 u_T$, with $\tau_0 > 0$, and definamos*

$$\varepsilon_{\mathrm{clk}} := \hbar_{\mathrm{int}} \frac{2\pi}{108 t_0}, \qquad \kappa_{\mathrm{clk}}(\tau_0) := \frac{2\pi \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34}}{108\tau_0}.$$

Then

$$\varepsilon_{\mathrm{clk}} = \kappa_{\mathrm{clk}}(\tau_0) u_E, \qquad m_0 := \frac{\varepsilon_{\mathrm{clk}}}{c_{\mathrm{int}}^2} = \kappa_{\mathrm{clk}}(\tau_0)\widehat{c}^{-2} u_M,$$

and the current electronic section satisfies

$$E_e^{\mathrm{int}} = \frac{\mathfrak{e}_0}{\kappa_{\mathrm{clk}}(\tau_0)} \varepsilon_{\mathrm{clk}}.$$

Therefore, $E_e^{\mathrm{int}} = \mathfrak{e}_0 \varepsilon_{\mathrm{clk}}$ if and only if $\kappa_{\mathrm{clk}}(\tau_0) = 1$. Adopting $\varepsilon_{\mathrm{clk}}$ as the basis while retaining the same coordinate $\mathfrak{e}_0$ is a new choice of frame; it is not a correction of the electronic invariant, nor does it follow from order-108 periodicity. In particular, the normalization used later, $t_0 = u_T$, fixes $\tau_0 = 1$, not $\kappa_{\mathrm{clk}} = 1$.

Proof. One substitutes $\hbar_{\mathrm{int}} = \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34} u_S$, $t_0 = \tau_0 u_T$, $u_E = u_S u_T^{-1}$, and $c_{\mathrm{int}} = \widehat{c}, u_C$. The final identity follows by comparison with equation (59.9). All equalities occur between sections of the same line; none consults an external unit or mass. □

Proposition 59.8 (Mass scale propagation)**.** *For each declared signature $v \in \mathbb{Z}^5$,*

$$m_v^{\mathrm{int}} := m_e^{\mathrm{int}} \chi_{\mathrm{mass}}(v)$$

is a positive section of $\mathcal{L}_M$, and

$$\frac{m_{v+w}^{\mathrm{int}}}{m_v^{\mathrm{int}}} = \chi_{\mathrm{mass}}(w).$$

The construction is covariant under rescaling and does not require an external unit of energy or mass.

Proof. The character is dimensionless and positive, so it does not modify the line of m_e^{int}. The quotient identity expresses the multiplicativity of χ_{mass}. Under a change of frame, the numerator and denominator acquire the same weight $\mathbf{M}$, which cancels. □

A subsequent metrological chart may send u_E to an energy basis and u_M to the coherent basis obtained by dividing by the square of the standard velocity. Only that chart authorizes the section to be expressed by an external unit name.

59.1.6 Constitutive as isomorphisms between lines

The internal functions satisfy

$$\widehat{\mu} = e^{\mathcal{B}+\mathcal{E}}, \qquad \widehat{\varepsilon} = e^{-\mathcal{B}+\mathcal{E}}, \qquad \widehat{Z} = e^{\mathcal{B}}, \qquad \widehat{c} = e^{-\mathcal{E}}.$$

We define the sections

$$\mu_{\mathrm{int}} = \widehat{\mu} u_\mu, \qquad \varepsilon_{\mathrm{int}} = \widehat{\varepsilon} u_\varepsilon.$$

Theorem 59.9 (Covariant Linear Constitutive Relations)**.** *In the groupoid of oriented lines, the exact identities hold.*

$$\sqrt{\frac{\mu_{\mathrm{int}}}{\varepsilon_{\mathrm{int}}}} = Z_{\mathrm{int}}, \qquad \frac{1}{\sqrt{\mu_{\mathrm{int}}\varepsilon_{\mathrm{int}}}} = c_{\mathrm{int}}.$$

The four sections depend on two dimensionless characters and on the two lines $\mathcal{L}_Z, \mathcal{L}_C$; they do not constitute four independent scales.

Proof. In coefficients, $\widehat{\mu}/\widehat{\varepsilon} = \widehat{Z}^2$ and $\widehat{\mu\varepsilon} = \widehat{c}^{-2}$. In dimensions,

$$\boldsymbol{\mu} - \boldsymbol{\varepsilon} = 2\mathbf{Z}, \qquad \boldsymbol{\mu} + \boldsymbol{\varepsilon} = -2\mathbf{C}.$$

The positive roots are therefore sections of the correct lines, and the identities are covariant. □

59.1.7 Cartan Scale and Homogeneity of the Gravitational Action

The elementary duration $t_0 = u_T$ and the constitutive velocity determine the length of a transition,

$$\ell_0 = c_{\mathrm{int}} t_0 = \widehat{c}\, u_L.$$

This section allows for the homogenization of the Cartan affine connection:

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega^I{}_J & \ell_0^{-1} e^I \\ 0 & 0 \end{pmatrix}, \qquad \mathcal{F}_{\ell_0} = \begin{pmatrix} F^I{}_J & \ell_0^{-1} T^I_{\mathrm{tor}} \\ 0 & 0 \end{pmatrix}.$$

The quotient e/ℓ_0 is dimensionless; curvature and torsion remain in distinct blocks of the same transport.

The dimension of G does not add a fifth generator, since $\mathbf{G} = -\mathbf{S} + 5\mathbf{C} + 2\mathbf{T}$. For every positive dimensionless parameter θ_G, we define the covariant family

$$G_{\mathrm{int}}(\theta_G) := \theta_G \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_{\mathrm{int}}} \in \mathcal{L}_G^+. \tag{59.11}$$

The choice $\theta_G = 1$ is the internal Planck normalization associated with an elementary transition. By construction, it satisfies

$$\ell_0^2 = \frac{\hbar_{\mathrm{int}} G_{\mathrm{int}}(1)}{c_{\mathrm{int}}^3}.$$

This reference normalization is neither the circular selector nor the holonomic selector of the physical section of G. The parameter θ_G makes visible the freedom not fixed by the dimensional identities. A TPK dynamics that produces a gravitational character must determine it before any external chart.

Let

$$\kappa_{\mathrm{int}} = \frac{8\pi G_{\mathrm{int}}}{c_{\mathrm{int}}^4}.$$

In the following functional, M is a smooth oriented manifold of dimension four, and $\gamma \in \mathbb{R} \setminus \{0\}$. If M has a boundary, variations of compact support in the interior are imposed, or a boundary term with conditions that cancel the boundary variation. A spinorial matter action additionally presupposes a compatible spin structure. If the co-tetrad e^I takes values in $\mathcal{L}_L$ and the curvature F^{IJ} is a dimensionless two-form after the connection has been integrated, then $\int \Sigma_{IJ} \wedge F^{IJ}$ has dimension $2\mathbf{L}$.

Theorem 59.10 (Homogeneity of the Palatini–Cartan–Holst Action)**.** *With explicit units, the gravitational functional of action dimension is*

$$\boxed{S_{\mathrm{PCH}} = \frac{1}{2\kappa_{\mathrm{int}} c_{\mathrm{int}}} \int \Sigma_{IJ} \wedge \left(\star F^{IJ} + \gamma^{-1} F^{IJ} \right) - \frac{1}{\kappa_{\mathrm{int}} c_{\mathrm{int}}} \int \Lambda_{\mathrm{int}} \, \mathrm{vol}_e + S_{\mathrm{m}}.}$$

Both geometric terms belong to $\mathcal{L}_S$. Writing them with $1/(2\kappa)$ without the factor c^{-1} belongs to a convention $c = 1$ or has dimension $\mathbf{S} + \mathbf{C}$, not action dimension.

Proof. De (59.3), $\boldsymbol{\kappa} = -\mathbf{S} + \mathbf{C} + 2\mathbf{T}$. Moreover, $2\mathbf{L} = 2\mathbf{C} + 2\mathbf{T}$. therefore,

$$-\boldsymbol{\kappa} - \mathbf{C} + 2\mathbf{L} = \mathbf{S}.$$

The cosmological term has the same dimension because $\boldsymbol{\Lambda} + 4\mathbf{L} = 2\mathbf{L}$. If $-\mathbf{C}$ is omitted, the result is $\mathbf{S} + \mathbf{C}$. □

The Cartan–Holst equation then retains its variational content provided that the spin current is defined with the normalization consistent with this functional. The dynamical realization must still provide a morphism from the TPK holonomies to (e, ω, Ψ); the present section constructs the exact dimensional codomain and removes the ambiguity of the units in that morphism.

59.1.8 Universality of Dimensional Realization

We collect the results. Let $\mathcal{X}_{\mathrm{HMT}}$ be the domain of enriched states, and let the following be dimensionless data on it:

$$\alpha_{\mathrm{HMT}}, \quad A_{\mathrm{deg}}, \quad C^*_{\mathrm{deg}}, \quad \widehat{c}, \widehat{Z}, \quad \mathcal{A}_*, \quad \chi_{\mathrm{mass}}, \quad \mathfrak{e}_0,$$

built in the previous chapters over their declared domains. Consider the extended domain

$$\mathcal{X}_{\mathrm{MD}} := \mathcal{X}_{\mathrm{HMT}} \times \mathrm{Fr}_{\mathrm{D}}\,.$$

Theorem 59.11 (Universal dimensional extension)**.** *There exists a unique tensorial, positive, and $\mathcal{G}_{\mathrm{D}}$-equivariant extension that:*

1. *realizes the edge clock in $\mathcal{L}_T$;*
2. *realizes $\widehat{c}$ and $\widehat{Z}$ in $\mathcal{L}_C$ and $\mathcal{L}_Z$;*

3. *realizes the determinantal index and the post-return component in $\mathcal{L}_S$;*
4. *satisfies the exact relations among impedance, propagation speed, permeability, and permittivity;*
5. *satisfies the internal fine-structure relation with an elementary scale of positive charge and, if a character n_Q is supplied, conditionally realizes $Q(x) = n_Q(x)e_{\mathrm{int}}$;*
6. *transports the mass character into $\mathcal{L}_M$.*

All other lines of the lattice are obtained by tensor products and duals. Two realizations differ by exactly one element of $\mathcal{G}_{\mathrm{D}}$.

Proof. The theorem 59.1 identifies $(\mathbf{S}, \mathbf{C}, \mathbf{T}, \mathbf{Q})$ with a free basis of the lattice. A monoidal map on a free category is determined by its value on the generators. Positivity fixes the roots that appear in charge and the constitutive relations. The identities already proved ensure that the definitions do not depend on an alternative presentation of a dimension. The simply transitive action of $\mathcal{G}_{\mathrm{D}}$ on the frames proves the final assertion. □

The mathematical conclusion is precise. HMT fixes the genealogy of the internal coefficients, and Dimensional Mechanics realizes them in a minimal ambient lattice of rank four when mass, length, duration, and charge must vary independently. The monoidal functor of trajectories with signature occupies part of that lattice and therefore does not inherit a claim of minimality. Ratios and homogeneous equations are independent of every chart. A publication in seconds, joules, coulombs, or electronvolts is the subsequent composition with an external frame; it does not alter any of the internal theorems and cannot replace them.

The HMT closure produces numbers as complete genealogical sections. Dimensional Mechanics begins when a section of that class is realized on a route, transports a register, induces a spectral operator, and acquires a physical chart. This step preserves the mathematical antecedent and changes the codomain: number, state, route, spectrum, and particle are objects linked by explicit maps and retain different types.

The formal hinge is expressed through

$$\boldsymbol{x} \overset{\mathrm{sh}}{\longmapsto} \gamma_{\boldsymbol{x}} \overset{\mathcal{L}}{\longmapsto} \mathcal{L}_{\boldsymbol{x}} \overset{\Sigma}{\longmapsto} \sigma_{\boldsymbol{x}} \overset{\chi}{\longmapsto} \chi_{\boldsymbol{x}} \overset{\mathcal{T}}{\longmapsto} \widehat{K}_{\boldsymbol{x}} \overset{\mathfrak{R}_{\mathrm{phys}}}{\longmapsto} \mathfrak{p}_{\boldsymbol{x}}. \tag{59.12}$$

Each arrow possesses its own domain and preserves the origin key of the initial section.

59.1.9 Physical correspondence of the APP–TRIT–TPK core

The opening of Dimensional Mechanics retraces the formal core with a new codomain. This repetition preserves the HMT theorems and declares the physical-realization maps that are added. Its causal order is

APP as a support of sheets ⟶ TRIT as temporal orientation
↓
unitary cycle and torsional defect
↓
dual angular coordinates ⟶ particle–route

59.1.9.1 The Cayley torus as a support for physical leaves

APP provides the two-dimensional torus

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2$$

with its Cayley graph and two evaluations on the same vertices. At the formal level, Σ accumulates and Π folds. The physical realization assigns sheets and channels to those evaluations, preserving the provenance map that makes it possible to compare their responses. The torus preserves spatial periodicity; the path category preserves direction, reversibility, and transport memory.

59.1.9.2 Euclidean gnomonic chart and curvature atlas

The L-shaped gnomon completes the multiplicative kernel 8×8 and separates the folded interior from the publication chart. In the null class, precisely the two readers that the quotient identifies outside the boundary are distinguished,

$$n \longmapsto n \bmod 9, \qquad n \longmapsto \mathrm{dr}_9(n),$$

so that the residue 0 and its nonadic publication 9 preserve distinct coordinates of the same closure. The sector $3, 6, 9$ makes this transition between the digital root and the modular residue visible.

In the geometric realization, the gnomonic L carries the Euclidean chart $\mathscr{H}_0^{(L)}$. On it, the inertial and gravitational readers descend to a common normalization,

$$\frac{\mathcal{G}_L}{\mathcal{I}_L} = 1,$$

which constitutes the residence of the local equivalence principle. Before that projection, the enriched state separately preserves the areal and volumetric readings. The Ambivalence Principle is then expressed by the internal ratio

$$\boxed{\frac{\mathcal{L}_{\mathrm{ar}}(x)}{\mathcal{L}_{\mathrm{vol}}(x)} = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2}.}$$

The Euclidean equality and the ambivalent ratio belong to distinct levels: the former is the local projection onto the L; the latter preserves the areal–volumetric genealogy prior to that projection.

The metric realization is obtained via a declared family of maps. For

$$\mathbb{A}_s := \mathbb{R}[X]/(X^2 + s), \qquad s \in \{-1, 0, +1\},$$

and a curvature scale $\rho > 0$, one fixes

$$\mathcal{M}_{s,\rho} : \mathbb{A}_s \dashrightarrow (M_s, g_{s,\rho}), \qquad g_{s,\rho} = \mathrm{d}r^2 + S_{s,\rho}(r)^2 \mathrm{d}\theta^2,$$

with

$$S_{s,\rho}(r) = \begin{cases} \rho^{-1} \sinh(\rho r), & s = -1, \\ r, & s = 0, \\ \rho^{-1} \sin(\rho r), & s = +1. \end{cases} \qquad K(M_s, g_{s,\rho}) = s\rho^2.$$

The radial domain is $r \geq 0$ for $s = -1, 0$; for $s = +1$, the polar chart covers $0 \leq r \leq \pi/\rho$, with the usual polar regularity at its endpoints. The branch $s = -1$ provides the hyperbolic spatial section of the chart of anti–de Sitter type; $s = 0$ realizes the Euclidean gnomonic chart; and $s = +1$ provides the positive spatial geometry that is prolonged into the de Sitter foliations. The complete correspondence is collected in sections 61.1.2 y 88.2.1.

The algebraic classification and the metric family are coordinated through the declared realization $\mathcal{M}_{s,\rho}$. This arrow constitutes the physical-interface ansatz, whereas $K = s\rho^2$ is the exact calculation of the metric once s and ρ are fixed. The quadratic relation fixes the algebraic class; the declared realization transports its sign to curvature, and ρ fixes the geometric scale. In the negative chart, restriction to the boundary coordinates the Archimedean projection with exceptional incidence; in the null chart, the inertial and gravitational readers descend to local equivalence; in the positive chart, the foliations satisfy

$\ddot{a}/a = H^2 > 0$. This atlas links negative-curvature holography, local Euclidean physics, and accelerated cosmological evolution through declared domains and change maps.

59.1.9.3 Temporal Representation of the TRIT: (+1) Return and Memory, (0) Threshold Present, and (-1) Bidirectional Opening

Once an order has been declared on the transitions, the temporal reader is

$$\begin{aligned} +1 &\longmapsto \text{return, retained memory and past,} \\ 0 &\longmapsto \text{evaluation threshold and present,} \\ -1 &\longmapsto \text{bidirectional opening and future.} \end{aligned}$$

The past designates transported closure; the present, the evaluation boundary; the future, the tree of compatible prolongations. This reading is the temporal realization of the three quadratic algebras already constructed in HMT and preserves the involution that exchanges opening and return.

59.1.9.4 Minimal Torsion and Unitary Dynamics in $\mathbb{C}^{108}$

The invariant called minimal torsion is

$$\Delta_4 = \frac{\pi - e\log\pi}{270}\left(1 + \frac{\pi}{729}\right).$$

Its entries arise from the HMT sections of π and e, from the channel 270, and from the interior 729. It functions as a global memory of refinement before electron specialization.

The reference temporal dynamics resides in $\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^{108}$. With

$$\omega_0 = \frac{2\pi}{108\, t_0}, \qquad H_{\mathrm{clk}} = \hbar_{\mathrm{int}}\omega_0 \sum_{k=0}^{107} k\, |\widetilde{k}\rangle\langle\widetilde{k}|,$$

the propagator satisfies

$$U_{\mathrm{step}} = \exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}} H_{\mathrm{clk}} t_0\right), \qquad U_{\mathrm{step}}^{108} = I.$$

The unit cycle is exact for the declared primitives. Its realization as a physical time crystal adds the Hamiltonian or driven protocol, the primitive subharmonic response, stability under perturbations, persistence, and the protection mechanism developed in section 61.1. This residence preserves the hierarchy and refers the proof there.

59.1.9.5 Dual angular coordinates and spectral channels

The sum–product incompatibility is transported to two angular coordinates A and C^*. In the Archimedean chart

$$x = \frac{\pi A}{180}, \qquad y = \frac{\pi C^*}{180},$$

the channels are the eigenvalues of the central element

$$T = e^{-xI - yR} = q_+ P_+ + q_- P_-, \qquad q_- = e^{-x+y}, \qquad q_+ = e^{-x-y}.$$

The chart is invertible:

$$x = -\frac{1}{2}\log(q_+ q_-), \qquad y = \frac{1}{2}\log\frac{q_-}{q_+}.$$

Therefore, A and C^* are, respectively, the symmetric and antisymmetric coordinates of a single spectral band. The section 90.4 contains its construction and its proofs; the present hinge fixes its causal position before the particle–route.

59.1.10 State, route, spectral form and physical realization

Definition 59.12 (Finite state and genealogical section)**.** A finite state is an element $x_n \in \mathcal{S}_n^{\mathrm{surv}}$. A genealogical section is a family $\boldsymbol{x} = (x_n)_n$ compatible at every depth. The state is a restriction of the section; the section determines its complete system of restrictions.

Definition 59.13 (Observable route)**.** A chart secuencial of depth R defines the sombra

$$\gamma_{\boldsymbol{x}}^{[R]} := \mathrm{sh}_R(\boldsymbol{x}) = (c_0 \to c_1 \to \cdots \to c_R).$$

The route preserves position, sheet, orientation, carry, and memory according to the chart's data list. It is an ordered presentation of the section.

Definition 59.14 (Spectral form)**.** The spectral form associated with to section is

$$\mathfrak{S}(\boldsymbol{x}) := (\gamma_{\boldsymbol{x}}, \mathcal{L}_{\boldsymbol{x}}, \sigma_{\boldsymbol{x}}, \chi_{\boldsymbol{x}}, \widehat{K}_{\boldsymbol{x}}),$$

where $\mathcal{L}_{\boldsymbol{x}}$ is the route record, $\sigma_{\boldsymbol{x}}$ its integer signature, $\chi_{\boldsymbol{x}}$ the character constructed on the signature, and $\widehat{K}_{\boldsymbol{x}}$ the operator obtained from the tower hierarchy. The spectrum $\mathrm{Spec}\,\widehat{K}_{\boldsymbol{x}}$ is an internal output.

Definition 59.15 (Physical realization)**.** A physical realization of $\mathfrak{S}(\boldsymbol{x})$ consists of

$$\mathfrak{R}_{\mathrm{phys}} = (\mathcal{H}_{\mathrm{phys}}, \rho_{\mathrm{sym}}, \varsigma_{\mathbf{u}}, \mathcal{O}),$$

where $\mathcal{H}_{\mathrm{phys}}$ is the state space, ρ_{sym} the representation of the symmetry group, $\varsigma_{\mathbf{u}}$ the units chart, and $\mathcal{O}$ the set of observables. The realization intertwines route transports with the dynamics of $\mathcal{H}_{\mathrm{phys}}$ and publishes quantities with units.

The spectral form is exact within the discrete system once its readers have been fixed. Identification with a physical species belongs to the realization map. This separation makes it possible to publish the operator, its spectrum, its position, and its status, accompanied by the corresponding physical intertwiner.

59.1.11 4 grammars and their domains

The passage from number to particle uses four grammars. The first three belong to the mathematical core; the fourth belongs to the chosen statistical representation.

Grammar	Operation	Function
accumulation	sheet sum of APP	composes additive contributions;
fold	sheet product of APP	composes scales and transpositions;
orientation	TRIT and route conjugation	distinguishes sense and anti-section;
occupation	projector of the representation	fixes statistical multiplicity.

The fermionic occupation is carried out, for example, in a fixed CAR algebra:

$$\{a_i, a_j\} = 0, \qquad \{a_i^\dagger, a_j^\dagger\} = 0, \qquad \{a_i, a_j^\dagger\} = \delta_{ij} I.$$

It follows from these premises.

$$(a_i^\dagger)^2 = 0, \qquad n_i := a_i^\dagger a_i, \qquad n_i^2 = n_i, \qquad \mathrm{Spec}(n_i) = \{0, 1\}.$$

TPK selects the grading and transports the route; the CAR representation realizes exclusion. This distinction positively fixes the algebraic provenance of the Pauli principle.

59.1.12 The spectral realization functor

Let $\Omega_{\mathrm{HMT}}^{\mathrm{surv}}$ be the category whose objects are surviving sections and whose morphisms are transformations compatible with the restrictions. Let **SpecRoute** be the category of $(\gamma, \mathcal{L}, \sigma, \chi, \widehat{K})$ bundles and intertwiners that preserve the route keys.

Theorem 59.16 (Spectral realization of a section)**.** *The route, register, signature, character, and tower readers define, on their common domain, a functor*

$$\mathfrak{S} : \Omega_{\mathrm{HMT}}^{\mathrm{surv}} \longrightarrow \mathbf{SpecRoute}.$$

For a compatible restriction of sections, the route is truncated, the record is restricted, and subsequent readers commute with that restriction. Two presentations related by a genealogical symmetry produce intertwined spectral forms.

Proof. The route shadow is defined by sequential reading of the state and commutes with truncation. The record concatenates typed local data, and its restriction eliminates only the posterior segment. The signature and the character are calculated by declared homomorphisms over that record. The tower hierarchy prolongs the character by composition. Identity and composition are preserved at every stage. □

The theorem makes the expression "the number assumes spectral form" precise: it transports a complete section to a route-and-spectrum package that preserves its genealogy.

59.1.13 Persistence and definition of particle

For a prefix $s_N \in \mathcal{S}_N^{\mathrm{surv}}$, let

$$\mathrm{Ext}_M(s_N) := \{s_M \in \mathcal{S}_M^{\mathrm{surv}} : \rho_{M,N}(s_M) = s_N\}, \qquad \mathcal{L}(s_N) := \sup\{M : \mathrm{Ext}_M(s_N) \neq \varnothing\}.$$

Definition 59.17 (Persistence)**.** A prefix is persistent when it belongs to a compatible global section; in a finitely branching tree of prolongations, this condition is equivalent to $\mathcal{L}(s_N) = \infty$.

Definition 59.18 (Mathematical particle)**.** Let γ_x be a persistent route and let $\mathcal{B}_{\gamma_x}$ be a discrete bundle whose fibres carry the internal degrees of the realization. A mathematical particle is

$$\mathfrak{p} = (x, \gamma_x, \mathcal{B}_{\gamma_x}, s, n, U, \mathfrak{S}(x), \mathfrak{R}_{\mathrm{phys}}),$$

where s is a compatible section of the bundle, n its occupation function, U the propagator intertwining the transports, and $\mathfrak{R}_{\mathrm{phys}}$ the declared physical realization.

The definition contains three closures:

1. the number is the global closure of compatible prefixes;
2. the spectral form is the closure of the route reading under the record, signature, character, and towers;
3. the particle is the local closure traversed by a persistent section of a physical bundle.

The relation is summarized as

number = global genealogical closure,	particle = persistent local realization of that closure.

The verbal equality denotes a functorial dependence between types.

59.1.14 Oriented band and anti-section

Let $\tau = (\tau_0, \dots, \tau_{11}) \in \{-1, 0, +1\}^{12}$ be the oriented word of a route, and define

$$C_M(\tau) := -\operatorname{rev}(\tau). \tag{59.13}$$

It holds $C_M^2 = I$. The band

$$\mathcal{B}(\tau) := \{\tau, C_M\tau\}$$

brings together two orientations of the same genealogy. One section realizes the particle, and the conjugate section realizes the antiparticle.

Proposition 59.19 (Mass parity and orientation)**.** *Let $\mathfrak{m}(\tau)$ be a mass reading that depends on even invariants of the band, and let $q(\tau)$ be an odd oriented reading. Then*

$$\mathfrak{m}(C_M\tau) = \mathfrak{m}(\tau), \qquad q(C_M\tau) = -q(\tau).$$

Proof. The first identity expresses invariance under the band involution. The second expresses the parity of an oriented form. The relation $C_M^2 = I$ guarantees the compatibility of both readings. □

Particle and antiparticle thus share the mass spectrum and have opposite orientations. The conclusion follows from the parity of the readers.

59.1.15 Path propagation and finite path summation

Let U be a propagator on a finite state space. For every $R \geq 1$, matrix multiplication gives

$$(U^R)_{fi} = \sum_{\substack{\gamma : i \to f \\ |\gamma| = R}} \prod_{\ell \in \gamma} U_\ell. \tag{59.14}$$

Theorem 59.20 (Exact expansion by histories)**.** *The equation (59.14) enumerates once each route of length R between i and f. If U is unitary, U^R preserves the norm and defines a finite unitary evolution.*

Proof. Expanding the matrix product yields all the intermediate indices $(x_1, \dots, x_{R-1})$. Each tuple determines a route, and each route determines a tuple. Unitarity follows from $(U^R)^\dagger U^R = I$. □

The wave amplitude is the coherent sum over the band of routes; the particle is the persistent section whose propagation realizes that band. Wave and state form complementary levels of the same realization.

59.1.16 Finite horizon of prolongation and class of compatible extension extensions of the genealogical state

Definition 59.21 (Virtual finite route)**.** A prefix s_N is finitely virtual if there exists $L < \infty$ such that

$$\operatorname{Ext}_L(s_N) \neq \varnothing, \qquad \operatorname{Ext}_{L+1}(s_N) = \varnothing.$$

Its route transports record, signature, and amplitude to L, and its prolongation horizon ends at the boundary $L + 1$.

In a finitely branching tree, the existence of prolongations to every depth is equivalent, by Koenig's lemma, to the existence of a global section. Persistence and virtuality are defined through the geometry of prolongations. The virtual route occupies a typed intermediate state and has a finite genealogical duration.

59.1.17 Internal spectrum, realization, and species

For a multisection F of routes, the natural object is the operator

$$\widehat{B}_F e_\Gamma = \kappa(\Gamma) e_\Gamma, \qquad \exp((\log R_{\mathrm{act}})\widehat{B}_F).$$

Its spectrum is invariant under permutations of the fiber basis. The physical chart determines which combination of eigenvalues corresponds to a scalar or matrix observable. Three levels must be preserved:

$$\operatorname{Spec} \widehat{B}_F, \qquad \mathfrak{R}_{\mathrm{phys}}(\widehat{B}_F), \qquad \text{species identification.}$$

The first is an internal output; the second is a realization; the third is a key within the physical inventory. A complete scientific table publishes all three and the morphism relating them.

59.1.18 Physical-spectral realization functor and 1st electronic closure

The hinge is fixed by the chain

$$\boxed{\begin{array}{c}\text{genealogical number} \longrightarrow \text{observable route} \longrightarrow \text{record} \longrightarrow \text{signature} \\ \text{character} \longrightarrow \text{towers} \longrightarrow \text{spectral operator} \\ \text{physical realization} \longrightarrow \text{particle}\end{array}}$$

The first physical closure specializes this chain to the electron section selected by the center of the atlas, with the current action line, bidirectional readers, and dimensional chart. This residence establishes the formal domain that makes it possible to understand why the electron realizes the theory of the number and why its generalization to the other species preserves route, spectrum, and genealogy.

Composition of dimensional readers and compatibility among their mathematical invariants
The definition of persistent section and discrete bundle belongs to the particle chapter; route, register, signature, and character belong to the surviving-extension chapter; band, material conjugation, and virtuality belong to the antisections chapter; fiber operators and their spectra belong to the bidirectional law of masses. The four grammars and the local closure of the path are integrated here with the CAR structure, persistence, character, and physical realization.

59.2 Planck constant and action line: derivation determinantal of the escala 10^{-34}

The construction of the action scale begins with an integer invariant. The Smith normal form of the local dodecaphasic block produces a cokernel of order 16; its norm on the constant section α_{HMT}, followed by a single action of φ, places the output $\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}$ between 10^{-34} and 10^{-33}. In this manner, the characteristic decimal power of action is obtained before joules and seconds are chosen. The angular branch subsequently supplies the two oriented coordinates—before the return and after the return—and the metrological chart finally expresses them as h and $\hbar$.

Governing result: from the local cokernel to the action scale

The Smith form of H_4, the order of its cokernel, and the inequalities determining the decade are exact. The complete result is PROVED FROM EXPLICIT STARTING STRUCTURE: the local block, the invariant section, the multiplicative norm, a single action of φ, and the decimal reader of section 59.2 are declared. The ablations identify the function of each rule and distinguish the local cokernel from the global cokernel of order 4096.

59.2.1 Smith Normal Form of H_4 and Transport of $\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}$ to the Action Line

For a of the three parallel dodecaphase orbits, the Parts I–III obtain

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1,2,2,4), \qquad G_H := \mathrm{coker}(H_4) \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z},$$

and therefore $|G_H| = 16$. Locality belongs to the reader's type: the cokernel of the complete dodecaphasic transformation has order $16^3 = 4096$, but simultaneously records three direct copies and does not replace the index of an orbit.

Let $s_\alpha(g) = \alpha_{\mathrm{HMT}}$ be the constant section over G_H. With the local norm

$$\mathcal{N}_{G_H}(s) := \prod_{g \in G_H} s(g)$$

and a sola action of φ on the base, is recovered, with a local label for facilitar the references of the Parte V,

$$\Sigma_H := \varphi\, \mathcal{N}_{G_H}(s_\alpha) = \varphi\alpha_{\mathrm{HMT}}^{16}. \tag{59.15}$$

This is the same section defined in equation (59.15), not a second construction.

Theorem 59.22 (Determinantal Order Transfer)**.** *Once the primitives of the local determinantal reader are fixed, the section in equation (59.15) satisfies*

$$\alpha_{\mathrm{HMT}}^{16} < 10^{-34} < \varphi\alpha_{\mathrm{HMT}}^{16} < 10^{-33}, \qquad \varepsilon_H := \lfloor \log_{10} \Sigma_H \rfloor = -34.$$

If $\mathcal{L}_S$ is a real action line with basis $\mathcal{U}_S$, the assignment

$$\tau_S : \mathbb{R}_{>0} \longrightarrow \mathcal{L}_S, \qquad x \longmapsto x\,\mathcal{U}_S,$$

transports that order without modifying it. In particular, the decimal exponent of the action coordinates defined below is -34.

Proof. The exact inequalities and the value of the order are the content of theorem 59.22; there they reduce to integer comparisons based on the constructed rational decimal of α_{HMT}. The map τ_S changes the codomain—from a positive scalar to a magnitude line with a declared basis—but preserves the scalar coordinate. Consequently, it does not alter its decimal order. □

The inherited evaluation is

$$\Sigma_H = 1.046243838104756580184229208303089\ldots \times 10^{-34},$$

and the normalized number

$$B_H := 10^{34}\Sigma_H = 1.046243838104756580184229208303089\ldots$$

belongs to $[1, 10)$. The factor 10^{34} is reconstructed from the order; it is not introduced as a threshold or prior normalization.

59.2.2 Necessity of the local core

The four exact ablations are

evaluated rule	decadic exponent
$\alpha_{\mathrm{HMT}}^{16}$ without φ	-35
$\varphi\alpha_{\mathrm{HMT}}^{15}$	-32
$\varphi\alpha_{\mathrm{HMT}}^{17}$	-37
$\varphi\alpha_{\mathrm{HMT}}^{4096}$	-8753.

Thus, $|G_H| = 16$ fixes the exponent of α_{HMT} once the local reader is chosen, and the inequalities then fix order -34. These controls exclude omission of φ, neighboring exponents, and substitution of the global cokernel for the local one. They do not constitute a classification of all admissible readers or a proof of prior uniqueness of the constant section, the unique action of φ, or the decimal chart.

59.2.3 Posterior coupling with the action coordinates

Write

$$\varepsilon_H := \left\lfloor \log_{10} \Sigma_H \right\rfloor = -34.$$

Once the angular branch has constructed the pre-return character H_5 and the reconstructed coordinate

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{C^*}{2} - \alpha_{\angle,\mathrm{deg}},$$

both receive the same order in $\mathcal{L}_S$:

$$\hbar_{\mathrm{HMT}}^{\mathrm{pre}} := H_5\, 10^{\varepsilon_H} \mathcal{U}_S, \qquad \hbar_{\mathrm{HMT}}^{\mathrm{ret}} := \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{\varepsilon_H} \mathcal{U}_S.$$

Numerically,

$$\hbar_{\mathrm{HMT}}^{\mathrm{pre}} = 1.0545718176461544696258218294330 59\ldots \times 10^{-34} \mathcal{U}_S,$$
$$\hbar_{\mathrm{HMT}}^{\mathrm{ret}} = 1.0545718169150390611336905847243 00\ldots \times 10^{-34} \mathcal{U}_S.$$

The datum H_5 precedes the return and is not identified with $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$. Nor does it enter the proof of the exponent -34.

The corresponding unreduced coordinates are

$$h_{\mathrm{HMT}}^{\mathrm{pre}} = 2\pi H_5\, 10^{-34} \mathcal{U}_S = 6.626070149999987926001110349899474\ldots \times 10^{-34} \mathcal{U}_S,$$

$$h_{\mathrm{HMT}}^{\mathrm{ret}} = 2\pi \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34} \mathcal{U}_S = 6.626070145406254333510749847592879\ldots \times 10^{-34} \mathcal{U}_S.$$

The comparison

$$2\pi H_5 - 6.62607015 = -1.2073998889650100526\ldots \times 10^{-14}$$

is a subsequent external control on the mantissa; it is neither an equality with the defining SI value nor an input to the reader.

Object	Coordenada obtenida	Mathematical and metrological function
Escala determinantal	$\Sigma_H = 1.0462438381047565\ldots \times 10^{-34}$	Fix internally the decimal order of the action line.
Reduced prior action	$\hbar_{\mathrm{HMT}}^{\mathrm{pre}} = H_5\, 10^{-34} \mathcal{U}_S$	Retain the angular coordinate prior to return.
Reduced posterior action	$\hbar_{\mathrm{HMT}}^{\mathrm{ret}} = \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34} \mathcal{U}_S$	Publish the post-return coordinate on the same line.
Full cycle action	$h_{\mathrm{HMT}}^{\mathrm{pre}} = 6.6260701499999879\ldots \times 10^{-34} \mathcal{U}_S$	It transports local action through one phase turn by means of $h = 2\pi\hbar$.
Carta SI	$h = 6.62607015 \times 10^{-34}$ J s	external defining coordinate usada for the metrological recognition [20].

59.2.4 h and $\hbar$: action per full cycle and per radian

The identities

$$E = h\nu = \hbar\omega, \qquad \omega = 2\pi\nu, \qquad h = 2\pi\hbar$$

do not describe two quanta. They describe the same action in two charts. The frequency ν counts complete turns per unit time; the angular frequency ω counts phase in radians per unit time. Consequently, h measures the action associated with the closure of one turn, and $\hbar$ measures the action per unit phase. The reduction is not merely an abbreviation: it transports the global holonomy to the local generator of its propagation.

The same distinction explains the coordinated use of degrees and radians. The complete angular cycle of 360° makes the finite partitions visible

$$12 \cdot 30^\circ = 4 \cdot 90^\circ = 3 \cdot 120^\circ = 360^\circ$$

and the returns of 270° and 360°. The radian, by contrast, is the additive coordinate in which the exponential and the derivative are written without inserting a conversion constant in each operation. The two charts are related by

$$\mathbb{R}/\mathbb{Z} \xrightarrow{2\pi} \mathbb{R}/(2\pi\mathbb{Z}) \xrightarrow{180/\pi} \mathbb{R}/(360\mathbb{Z}).$$

The composition preserves the point of the turn: the degree publishes its position in the global calendar, and the radian linearizes its local motion.

Applied to the coordinates constructed above,

$$h^{\mathrm{pre}}_{\mathrm{HMT}} = 2\pi\,\hbar^{\mathrm{pre}}_{\mathrm{HMT}}, \qquad h^{\mathrm{ret}}_{\mathrm{HMT}} = 2\pi\,\hbar^{\mathrm{ret}}_{\mathrm{HMT}}.$$

The factor 2π does not retrospectively correct a mantissa. It traverses one complete turn with the local action. Thus an amplitude $\exp(\mathrm{i}S/\hbar)$, a commutation relation, and a holonomy quantization compare an action with the local unit of phase, whereas the global closure is expressed with h.

59.2.5 Confluence of the determinantal and dodecaphasic branches of the action scale

The angular branch and the determinantal branch both start from α_{HMT}, but neither retrospectively generates the other. The former decomposes as

$$\begin{gathered}
(\alpha_{\mathrm{HMT}}, \varphi;\, 9, 5, 4, 12, 54,\ \text{graded rule}) \longrightarrow H_5, \\
\alpha_{\mathrm{HMT}} \longrightarrow A = 1000\alpha_{\mathrm{HMT}}{}^\circ, \qquad (\alpha_{\mathrm{HMT}}, \pi) \longrightarrow D_A, \\
\mathcal{F}_\pi \longrightarrow \rho_\pi = 169, \qquad (\rho_\pi, D_A, \alpha_{\mathrm{HMT}}) \longrightarrow C_\pi(\alpha_{\mathrm{HMT}}), \\
(\pi, \alpha_{\mathrm{HMT}}, H_5, C_\pi(\alpha_{\mathrm{HMT}})) \longrightarrow y_* \longrightarrow C^*, \\
(A, C^*) \longrightarrow q_\pm \longrightarrow \big(S_{90}(q_\pm), S_{120}(q_\pm)\big) \longrightarrow K_{6\to 8} \longrightarrow \Gamma_{6\to 8}.
\end{gathered}$$

The posterior identification $\Gamma_{6\to 8} \dashrightarrow \gamma_{\mathrm{BI}}$ belongs to the interfaz fisica. The determinantal branch is

$$(H_4, \alpha_{\mathrm{HMT}}, \varphi;\ \text{reader rules}) \longrightarrow G_H \longrightarrow \Sigma_H \longrightarrow \varepsilon_H = -34.$$

Only at the end is ε_H combined with H_5 and $\eta^{(\mathrm{deg})}_{\mathrm{ret}}$ to yield coordinates in $\mathcal{L}_S$. Both an arrow $A \to H_5$ and any selection of C^* from SI or from γ_{BI} are excluded.

59.2.6 Systems of transduction between genealogical number and physical magnitude

Choosing a physical unit is an operation subsequent to the theorem. A metrological chart is an isomorphism of lines of magnitudes

$$\iota_{\mathrm{SI}} : \mathcal{L}_S \longrightarrow \mathcal{L}_{\mathrm{J\,s}}, \qquad \iota_{\mathrm{SI}}(\mathcal{U}_S) = \mathrm{J\,s}.$$

The unit belongs to the codomain of ι_{SI}; the exponent -34 belongs to the relative arithmetic theorem. Merely juxtaposing a unit symbol does not turn a dimensionless number into a physical quantity.

Proof hierarchy for the Planck constant

The order 10^{-34} follows from the local determinant and is fixed prior to metrology. The mantissas H_5 and $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$ follow from the angular branch and distinguish the orientations before and after the return. The identity $h = 2\pi\hbar$ transports both coordinates between action per radian and action per cycle. The map ι_{SI} then supplies the unit J s and permits the output to be compared with the defining constant of the SI. This succession preserves in distinct places the internal derivation, the dimensional realization, and the external comparison.

From the constitutive bilayer factorization to the modular Hamiltonian, the free energy, and the origin memory With the absolute scale and its typing established, the dynamics can separate the three temporal sheets and coordinate their generators without confusing the global Hamiltonian, the Lagrangian of the present sheet, and the modular memory Hamiltonian.

Chapter 60

Ambivalence Principle in Dimensional Mechanics: areal–volumetric involution, self-inertial systems, and conjugate temporal orientation

60.1 Compatible sections and measurement theory

The dimensional notion of measurement is formulated on inverse systems of compatible states. Before assigning a number to a state, one specifies its refinement history, the coupling with the apparatus, and the map that produces the observable. This sequence makes it possible to separate the existence of a real value from the physical operation by which that value is recorded.

60.1.1 The number as a compatible section

Let $(\mathcal{S}_n, r_{n+1,n})_{n\geq 0}$ be an inverse system of surviving states. A compatible section is a sequence $x = (x_n)_{n\geq 0}$ such that

$$r_{n+1,n}(x_{n+1}) = x_n \qquad (n \geq 0).$$

His space is the inverse limit.

$$\mathcal{X}_\infty = \varprojlim_n \mathcal{S}_n.$$

When each x_n determines an interval $I_n(x_n) \subset \mathbb{R}$, the closures $\overline{I_n(x_n)}$ are nonempty compact sets, are nested, and their diameters tend to zero; the nested-interval theorem guarantees that their intersection contains a unique point. The Archimedean evaluation is then defined by

$$\mathcal{P}_{\mathrm{arq}}(x) = \text{the unique element of } \bigcap_{n\geq 0} \overline{I_n(x_n)}.$$

The HMT number is the compatible section $x \in \mathcal{X}_\infty$. The reader L is additional structure, and the coupling (x, L) constitutes its readout presentation or measurement. Two sections may have the same real evaluation and differ in their quotient, orientation, or boundary coordinates; the Archimedean projection does not identify those genealogies by definition.

60.1.2 Compatibility between ternary cylinders and thousandths

A ternary word of length L, whose integer value is N, determines the cylinder

$$I_{N,L} = \left[\frac{N}{3^L}, \frac{N+1}{3^L}\right).$$

A word of m blocks in base 1000, whose integer value is D, determines

$$J_{D,m} = \left[\frac{D}{1000^m}, \frac{D+1}{1000^m}\right).$$

Lemma 60.1 (Exact compatibility of cylinders)**.** *The cylinders $I_{N,L}$ and $J_{D,m}$ have a nonempty intersection if and only if*

$$N\,1000^m < (D+1)3^L, \qquad D\,3^L < (N+1)1000^m.$$

Proof. Two half-open intervals $[a, b)$ and $[c, d)$ intersect exactly when $a < d$ and $c < b$. Substituting the four endpoints and multiplying by the positive integer $3^L 1000^m$ yields the inequalities. The decision therefore reduces to integer arithmetic. □

The prolongation of a word refines its cylinder. A compatible chain whose closures are compact, nonempty, and nested, with diameter tending to zero, determines a unique real evaluation. The use of

closures is essential: nested half-open intervals may have empty intersection when the limit coincides with an excluded endpoint. The complete state preserves the words, transformations, and carries that produce the evaluation.

60.1.3 Reversible coupling between system and apparatus

Let X be the state space of the system, M the state space of the apparatus, and $m_0 \in M$ its initial preparation. A coupling is a map

$$U : X \times M \longrightarrow X \times M.$$

When U is bijective, the joint state preserves the information. An evaluation map $q_M : M \to Y$ may be noninjective and publish only an observable $y \in Y$.

Definition 60.2 (Measurement)**.** An HMT measurement is the triple

$$\mathfrak{M} = (U, q_M, C),$$

where U couples system and apparatus, q_M evaluates the apparatus state, and $C \subseteq X \times M$ is the compatibility condition. Its output on x is

$$\mathrm{Med}_{\mathfrak{M}}(x) = q_M\big(\mathrm{pr}_M\, U(x, m_0)\big)\,,$$

provided that the coupled pair satisfies C.

The definition establishes a precise composition of three operations: coupling, restriction to the compatible domain, and evaluation of the observable.

Theorem 60.3 (Localization of Information Loss)**.** *Let*

$$\Omega_M := q_M \circ \mathrm{pr}_M : X \times M \longrightarrow Y.$$

If U is bijective and the complete final state is preserved, the classes of inputs indistinguishable under the published observable are exactly the preimages under U of the fibres of Ω_M, unless it is further composed with a subsequent elimination or reinitialization of the state.

Proof. The bijectivity of U permits (x, m_0) to be recovered from the final joint state. For two inputs z, z' in the compatible domain, equality of the registers is equivalent to $\Omega_M(Uz) = \Omega_M(Uz')$. Hence, Uz and Uz' belong to the same fiber of the composite map $q_M \circ \mathrm{pr}_M$. This composition includes both the loss due to projection onto the apparatus and that due to evaluation of its state. Any subsequent erasure introduces an additional map and must be analyzed separately. □

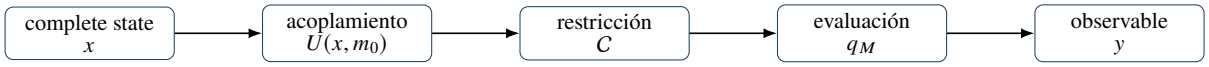

Figure 60.1: Composición de una medición. La aplicación de evaluación actúa después del acoplamiento y de la restricción de compatibilidad; el estado conjunto permanece disponible para la transformación inversa.

60.1.4 Principio de Ambivalencia: involución bidireccional de los lectores π/φ^2 y φ/π^2

Sean

$$q_A : \mathcal{X}_{\mathrm{TPK}} \to \mathcal{X}_A, \qquad q_V : \mathcal{X}_{\mathrm{TPK}} \to \mathcal{X}_V$$

two quotient maps respectively associated with the observables of aperture and retention, and let $T : \mathcal{X}_{\mathrm{TPK}} \to \mathcal{M}$ be the transported memory variable.

Principle 60.4 (Ambivalence)**.** The complete state precedes its observable projections. The equivalence relations induced by q_A and q_V are not assumed to be identical, and compatibility between them is recorded by T. The joint map

$$(q_A, q_V, T) : \mathcal{X}_{\mathrm{TPK}} \longrightarrow \mathcal{X}_A \times \mathcal{X}_V \times \mathcal{M}$$

is adopted as the separation condition for physically distinguishable states, modulo the declared gauge group.

Proposition 60.5 (Reconstruction under the separation condition)**.** *If the preceding joint map is injective modulo gauge, each complete-state class is uniquely determined by its two observables and its memory variable.*

Proof. Two states with the same triple of images belong to the same gauge class by the injectivity hypothesis. Each fiber of the joint map therefore contains at most one class. □

The observable q_A records the accessible prolongations, and q_V the retained component. A material interpretation of retention requires a mass observable that factors through q_V; it does not follow solely from the separation principle.

60.1.5 Relational determination and temporal orientation

Let $[\gamma]_{\mathcal{G}}$ be the class of a trajectory in the state groupoid, and let β_γ be its terminal boundary datum.

Principle 60.6 (Relational determination)**.** An admissible local observable has the form

$$O_{\mathrm{loc}}(x; \gamma) = F\big(x, [\gamma]_{\mathcal{G}}, \beta_\gamma\big)$$

and it is invariant under trajectory equivalences that preserve the ordered record. Consequently, the visible point coordinate does not by itself determine the observable when the evaluation has identified different transport classes.

The formulation is relational in a precise sense: the argument of O_{loc} contains the state, the global transport class, and the boundary. This is the domain on which the theory may subsequently be compared with the tradition associated with Mach's principle. It is not presupposed that every inertial property has been derived; the type of the map that must realize it is specified.

If the update on $\mathcal{X}_{\mathrm{TPK}}$ is bijective and the register preserves the coordinates required by its inverse, the complete dynamics is reversible. An observable temporal orientation appears upon composing it with a noninjective reader, reinitializing a boundary datum, or selecting a single prolongation among several. Irreversibility is therefore localized in a defined morphism of information loss or selection, not in the mere ordering of labels.

60.1.6 Relation with classical variational principles

Hamilton's principle requires the first variation of an action to vanish along the physical trajectory; it does not assert, in general, that this trajectory is a global minimum. The discrete interaction functional constructed in the section 25.12, by contrast, orders a finite family of routes by the number of changes in orientation and arithmetic law. The two principles coincide only after constructing a limit in which the discrete cost induces an action and its first variation reproduces the equations of motion. This distinction precludes replacing a future correspondence with an identity of names.

60.1.7 Prospective evaluation conditions of the Ambivalence Principle on the enriched state

A prospective evaluation is mathematically determined when, before its output is consulted, the state space, coupling, quotient maps, memory variable, compatibility rule, and comparison criterion have been fixed. If several sections survive, the output is the complete family. The assignment of frequencies then requires a probability measure or an explicit additional dynamics.

60.1.8 Quotient of modes and areal-volumetric correspondence

The calendar sign, mode label, and geometric sheet are three typed objects. In particular, the phase sign is not identified with the angular observable on digits. For the geometric correspondence, we fix the typed HMT reader

$$\mathfrak{g}_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \mathfrak{g}_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

The first assignment expresses the additive or boundary reading; the second, the multiplicative or interior reading. The map $\mathfrak{g}_{\mathrm{av}}$ is part of the sheet typing. The following result proves that, once that typing is fixed, TPK dynamics forces the incidence between them.

Theorem 60.7 (Necessary descent of leaf incidence)**.** *Let m_r be the mode obtained after applying phase r of the primitive block $(+1, -1, 0)$, with the rule*

$$+1 : \ m \mapsto \Sigma, \qquad -1 : \ m \mapsto \Pi, \qquad 0 : \ m \mapsto m.$$

The cyclic orbit of modes is (Σ, Π, Π). If

$$N_3(i, j) := \#\{r \in \mathbb{Z}/3\mathbb{Z} : (m_r, m_{r+1}) = (i, j)\},$$

then, in the order (Σ, Π),

$$\boxed{N_3 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.}$$

By repetition of the calendar,

$$N_9 = 3N_3, \qquad N_{27} = 9N_3, \qquad N_{108} = 36N_3.$$

After applying $\mathfrak{g}_{\mathrm{av}}$, the primitive incidence matrix is, in the order $(\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}})$,

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.}$$

Thus, the two cross transitions, the unique volumetric self-retention, the absence of areal self-retention and the unit primitive multiplicities are consequences of the TPK mode quotient; they are not four added postulates.

Proof. The three consecutive pairs, with cyclic closure, are

$$\Sigma \longrightarrow \Pi, \qquad \Pi \longrightarrow \Pi, \qquad \Pi \longrightarrow \Sigma.$$

Each appears once, and the pair $\Sigma \to \Sigma$ does not appear. This determines the four entries of N_3. The calendars of lengths $9, 27, 108$ respectively contain $3, 9, 36$ copies of the primitive block, so their incidence matrices are the indicated multiples. The greatest common divisor of the nonzero entries of each long matrix removes only that global repetition and returns N_3. Finally, $\mathfrak{g}_{\mathrm{av}}$ transports Σ, Π to the areal and volumetric sheets without altering the incidence. □

The real hyperbolic realization that uses this matrix and proves its Lorentz invariance is formulated in section 3.5.6; there F_{av} is used as an antecedent, without repeating its derivation.

This theorem must be distinguished from a stronger Markov assertion. Forgetting the phase is not a strong Markov quotient of $\mathcal{K}_{\mathrm{ph}}$: the visible mode does not determine which of the three operators $I, E_+, E_\times$ acts at the next elementary iteration. What descends without an additional hypothesis is the edge multigraph of a TPK block.

There is, however, a memory-one completion uniquely determined by that descent. Let X_{av} be the smallest subshift of finite type over $\{\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}}\}$ that contains all the words obtained by forgetting the phase and retains only consecutive pairs. Every one-step subshift with that property must admit exactly the three observed pairs; the smallest such subshift excludes the sole unobserved pair. Its adjacency matrix is therefore F_{av}.

Corollary 60.8 (Parry Measure of the One-Memory Wrapper)**.** *The subshift X_{av} is primitive, has topological entropy $\log \varphi$, and possesses a unique measure of maximal entropy. Its stationary vertex weights satisfy*

$$\boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.}$$

Proof. The Perron root of F_{av} is φ, and a positive Perron vector is $(1, \varphi)$. Since the matrix is symmetric, the Parry vertex weights are proportional to the product of the left and right vectors, that is, to $(1, \varphi^2)$. □

The Parry measure belongs to the memory-one path envelope. It is not the image of τ_{468}, nor the temporal frequency of the periodic orbit of modes. The latter is

$$\nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{ar}}) = \frac{1}{3}, \qquad \nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{vol}}) = \frac{2}{3},$$

whereas τ_{468} is uniform over emissions, and the Parry measure weights renewal histories of arbitrary length. The three measures answer distinct questions. The irrational ratio φ^{-2} is thus derived canonically from the path envelope, without attributing it to a quotient of finite cardinalities.

60.1.8.1 From chronological counting to the return marked by π

The two formulas

$$\left(\frac{1}{3}, \frac{2}{3}\right) \qquad \text{and} \qquad \frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}$$

are not approximations of one another. The first counts the three instants of the primitive calendar (Σ, Π, Π); the second weights all the admissible histories of the memory-one envelope. Hence the chronological frequency is rational, and the Parry ratio is irrational. In what follows, we write

$$\frac{\pi_{\mathrm{HMT}}}{\varphi^2} = \pi_{\mathrm{HMT}} \varphi^{-2};$$

this is not division by φ^{-2}.

The appearance of φ^{-2} can be seen directly in the linear dynamics. If F_n denotes the n-th Fibonacci number,

$$F_{\mathrm{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix} \qquad (n \geq 1).$$

The eigenvalues of F_{av} are φ and $-\varphi^{-1}$. The contracted branch reverses orientation in one iteration. Upon passing to the quadratic memory, namely $\mathrm{Sym}^2(\mathbb{R}^2)$, that reversal is recorded before the sign disappears. In the basis $(x^2, 2xy, y^2)$, with the images of the basis vectors represented by rows, the induced operator is

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}, \qquad \chi(t) = (t+1)(t^2 - 3t + 1).$$

Its three eigenvalues are

$$\varphi^2, \qquad -1, \qquad \varphi^{-2}.$$

Thus, φ^{-2} is the positive stable mode of second-order memory. This step explains why the golden ratio appears here as a return law and not as an added statistical mean.

The closure π belongs to another level of the same HMT state: it is the coinductive output of the regional reader already constructed, not a new eigenvalue of F_{av}. Let

$$P_{\mathrm{ar}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad P_{\mathrm{vol}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

Among the positive operators that preserve both sheets, there is exactly one whose volumetric normalization is one and whose areal mark is the generated closure π_{HMT}:

$$D_\pi = \pi_{\mathrm{HMT}} P_{\mathrm{ar}} + P_{\mathrm{vol}}.$$

Uniqueness is relative to these three explicit clauses: positivity, diagonality with respect to the leaves, and the two normalizations. With $e_{\mathrm{ar}} = (1,0)^T$ and $e_{\mathrm{vol}} = (0,1)^T$, the marked return of length n is

$$\Theta_n := \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}} \rangle} = \pi_{\mathrm{HMT}} \frac{F_{n-1}}{F_{n+1}}.$$

Therefore,

$$\boxed{\lim_{n\to\infty} \Theta_n = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.}$$

The mark π_{HMT} is applied only once, at the boundary return; it is not reinjected at every transition. Finite combinatorics produces the stable mode φ^{-2}, the coinductive reader produces the closure π_{HMT}, and D_π composes both data without reversing their causal order.

The native length 108 provides an exact witness to that convergence:

$$(F_{\mathrm{av}}^{108})_{\mathrm{ar,ar}} = F_{107} = 10284720757613717413913,$$

$$(F_{\mathrm{av}}^{108})_{\mathrm{vol,vol}} = F_{109} = 26925748508234281076009.$$

Consequently,

$$\left| \frac{F_{107}}{F_{109}} - \varphi^{-2} \right| = 6.1684979916614407936\ldots \times 10^{-46},$$

and, after the only closing marker,

$$\left| \pi_{\mathrm{HMT}} \frac{F_{107}}{F_{109}} - \frac{\pi_{\mathrm{HMT}}}{\varphi^2} \right| = 1.9378907974286976068\ldots \times 10^{-45}.$$

These errors measure the finite approximation of the return; they are not adjustments of π or of φ.

Cylindrical reader of the ratio. Let $I_n^{\pi} = [\underline{\pi}_n, \overline{\pi}_n]$ and $I_n^{\varphi} = [\underline{\varphi}_n, \overline{\varphi}_n]$ be the positive, nested cylinders produced by the two HMT readers. The interval operation

$$Q(I, J) := \left[\frac{\inf I}{(\sup J)^2}, \frac{\sup I}{(\inf J)^2} \right]$$

is the smallest interval containing x/y^2 for every $(x, y) \in I \times J$. It preserves nesting: if the input cylinders are refined, then $Q(I_n^{\pi}, I_n^{\varphi})$ is also refined. Since their diameters tend to zero and the limit of I_n^{φ} is positive,

$$\bigcap_n Q(I_n^{\pi}, I_n^{\varphi}) = \left\{ \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} \right\}.$$

With the twelve already published base-thousand blocks, the quotient interval forces thirty-five decimal digits:

$$\frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} = 1.19998161486432666111577775331680692\ldots.$$

This construction preserves the provenance of each digit: the numerator comes from the closure cylinder and the denominator from the autoscale.

Algebraic separation between areal reading, volumetric reading and their respective codomains The complete ratio cannot arise from the rational algebra of F_{av} alone. Indeed, its rational spectral functions belong to $\mathbb{Q}(\sqrt{5})$; φ^{-2} is found there, but not the transcendental number π. Consequently, any derivation purporting to obtain π/φ^2 solely from the matrix 2×2 would be ill typed. The transcendental datum must derive from the coinductive closure reader, or from an equivalent boundary cocycle proved independently. This negative control fixes the division of labor between the finite correspondence and the number reader.

60.1.8.2 Exchange involution of the quotient

The correspondence admits two exact orientations of the same law. If

$$\mathscr{R}(x, y) = \frac{x}{y^2}, \qquad \mathsf{J}(x, y) = (y, x),$$

then $\mathsf{J}^2 = I$ and

$$\mathscr{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \qquad (\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \frac{\varphi}{\pi^2}.$$

The identities are also verified.

$$\mathscr{R}(\pi, \varphi)\mathscr{R}(\varphi, \pi) = \frac{1}{\pi\varphi}, \qquad \frac{\mathscr{R}(\pi, \varphi)}{\mathscr{R}(\varphi, \pi)} = \left(\frac{\pi}{\varphi}\right)^3.$$

Writing $\mathcal{B}_{\mathrm{av}}^{(\pi)} = \mathscr{R}(\pi, \varphi)$ also yields the exact reparametrization

$$\frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 \big(\mathcal{B}_{\mathrm{av}}^{(\pi)}\big)^2}, \qquad e^{\varphi/\pi^2} = \exp\left[\frac{1}{\varphi^3 \big(\mathcal{B}_{\mathrm{av}}^{(\pi)}\big)^2} \right].$$

Thus, the change of orientation between closure and growth transports the boundary ratio to its exchanged reading:

$$\frac{\pi}{\varphi^2} \overset{\mathsf{J}}{\longleftrightarrow} \frac{\varphi}{\pi^2}.$$

The first orientation reads the marked areal closure over quadratic volumetric memory; the second reads interior growth over quadratic closure. This correspondence is a theorem of the HMT reader.

Dimensional Mechanics subsequently applies the second orientation within the electronic construction, without converting the electron into an antecedent of π, φ, or of the correspondence.

60.1.8.3 Ambivalence Principle of the areal and volumetric readers

The Ambivalence Principle asserts that the areal reading and the volumetric reading are two coordinated, but not interchangeable, functionals of one and the same state with memory. Their coincidence on the diagonal is

$$\mathcal{L}_{\mathrm{ar}}^{\mathrm{diag}}(x) = \mathcal{L}_{\mathrm{vol}}^{\mathrm{diag}}(x).$$

The diagonal equality does not erase the ambivalence outside of it.

On the areal–volumetric boundary, both readers factor through the same positive memory amplitude $\mathcal{M}(x)$:

$$\mathcal{L}_{\mathrm{vol}}(x) = \mu_{\mathrm{vol}}\mathcal{M}(x), \qquad \mathcal{L}_{\mathrm{ar}}(x) = \pi_{\mathrm{HMT}}\mu_{\mathrm{ar}}\mathcal{M}(x).$$

Then the Parry theorem and the return mark give

$$\boxed{\frac{\mathcal{L}_{\mathrm{ar}}(x)}{\mathcal{L}_{\mathrm{vol}}(x)} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.}$$

With volumetric normalization, the relative difference of readers is

$$\frac{\mathcal{L}_{\mathrm{ar}} - \mathcal{L}_{\mathrm{vol}}}{\mathcal{L}_{\mathrm{vol}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2} - 1 = 0.1999816148643266611\ldots.$$

The physical reading of this correspondence is undertaken later, in the Cartan–Holst chapter, after constructing holonomy, co-tetrad, connection, torsion, and curvature. Here the result is entirely HMT: an exact ratio between two readers of the same sheet memory.

They should be distinguished from the enriched extractor subsequently used in Dimensional Mechanics. There a complete history preserves the action count n_A, the twelve oriented events $e_0, \ldots, e_{11}$ and the torsional cochain at step level; these yield

$$s_C = \sum_{i=0}^{5}(e_i + e_{i+6}), \qquad W_{\pm} = 6n_A \pm s_C.$$

The channels already generated by HMT then satisfy the exact identity

$$\exp\!\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6}C^*_{\mathrm{rad}}\right) = \left(q_+^{-W_+}q_-^{-W_-}\right)^{1/12}.$$

Therefore, the route–angular-character passage is not absent: it is realized on the enriched dodecaphase record. What this phase calculation proves by itself are $\Omega_{\mathrm{sw}}, S, G$; it neither replaces them nor permits reconstruction of the complete record after it has been projected.

The uniform measure on the 104 976 presentations descends to atoms of masses $1/729$, $1/243$ and $1/54$, but not to $1/468$. In the fivefold microfiber of π, the two probabilities are

$$\tau_{468}(\mathscr{R}_\pi) = \frac{5}{468}, \qquad F_{\#}\mu_{\mathrm{seed}}(\mathscr{R}_\pi) = \frac{7}{729}.$$

Both the averaged lift and the phase lift realize the first: they do not push forward the uniform measure on seeds, but assign the same total mass to each observable class. The phase lift also preserves microscopic stillness at neutral steps.

To relate phase elevation to the enriched histories of depth six, a kernel $\mathcal{K}_6$ on $\mathcal{H}_6^{\mathrm{cat}} \times C_9$ is required. It descends to $\widehat{\mathcal{K}}_{\mathrm{ph}}$ through $\rho_6 \times \mathrm{id}_{C_9}$ if and only if it satisfies, at each phase, the strong lumpability condition

$$\sum_{\rho_6(g)=y} \mathcal{K}_6((h,r),(g,r+1)) = L_{\tau(r)}(\rho_6(h),y),$$

independently of h within each fiber of ρ_6. In that case, composition with F projects to $\mathcal{K}_{\mathrm{ph}}$. Constructing a family $(\mathcal{K}_m)_{m\geq 6}$ that satisfies this identity and commutes with all truncations is the remaining step toward a transfer of the inverse limit.

60.2 Areal–Volumetric Correspondence and Ratio π/φ^2

The preceding section constructed the dodecaphase involution, its lift to persistent sections, the Möbius band relative to a negative holonomy, and the biangular chart $(A, C^*) \leftrightarrow (q_+, q_-)$. It remains to state precisely how the returns of the areal and volumetric sheets are counted and why the golden ratio appears squared.

60.2.1 Classes, supports, and leaves are distinct objects

The nonadic classes of motion are

$$C_1 = \{1,4,7\}, \qquad C_2 = \{2,5,8\}, \qquad C_0 = \{3,6,9\}.$$

The supports employed by the angular observable are

$$\mathcal{D}_{\mathrm{act}} = \{1,3,5,7\}, \qquad \mathcal{D}_{\mathrm{evt}} = \{2,4,6,8\}, \qquad \mathcal{D}_9 = \{9\}.$$

Its exact intersection is

$$B_{\mathrm{na}} = \big(|C_i \cap D_j|\big)_{i,j} = \begin{pmatrix} 2 & 1 & 0 \\ 1 & 2 & 0 \\ 1 & 1 & 1 \end{pmatrix}.$$

Theorem 60.9 (Triadic incidence)**.** *The following identities hold*

$$\det B_{\mathrm{na}} = 3, \qquad \mathrm{SNF}(B_{\mathrm{na}}) = \mathrm{diag}(1,1,3),$$

$$\mathrm{im}\, B_{\mathrm{na}} = \{(u,v,w) \in \mathbb{Z}^3 : u + v \equiv 0 \pmod 3\}.$$

The simultaneous interchange $C_1 \leftrightarrow C_2$, $\mathcal{D}_{\mathrm{act}} \leftrightarrow \mathcal{D}_{\mathrm{evt}}$ leaves the incidence fixed.

The observable of the record

$$j_2(d) = \begin{cases} -1, & d \in \mathcal{D}_{\mathrm{act}}, \\ +1, & d \in \mathcal{D}_{\mathrm{evt}}, \\ 0, & d \in \mathcal{D}_9 \end{cases}$$

is composed with the active geometric reader:

$$-1 \mapsto \mathscr{H}_{\mathrm{ar}}, \qquad +1 \mapsto \mathscr{H}_{\mathrm{vol}}, \qquad 0 \mapsto \mathscr{H}_{\mathrm{tor}}.$$

Therefore,

$$\mathfrak{g}_{\triangle}(\mathcal{D}_{\mathrm{act}}) = \mathscr{H}_{\mathrm{ar}}, \qquad \mathfrak{g}_{\triangle}(\mathcal{D}_{\mathrm{evt}}) = \mathscr{H}_{\mathrm{vol}}, \qquad \mathfrak{g}_{\triangle}(\mathcal{D}_9) = \mathscr{H}_{\mathrm{tor}}.$$

The matrix proves the crossing between classes and supports. The reader $\mathfrak{g}_{\triangle}$ declares the passage from supports to sheets. Omitting this second map would identify the cardinalities of distinct objects.

60.2.2 Spectral opening of the band through the conjugated angular phase

In the active chart,

$$q_+ = e^{-A_{\mathrm{rad}}-C^*_{\mathrm{rad}}}, \qquad q_- = e^{-A_{\mathrm{rad}}+C^*_{\mathrm{rad}}},$$

and the exact inverse is

$$A_{\mathrm{rad}} = -\frac{1}{2}\log(q_+q_-), \qquad C^*_{\mathrm{rad}} = \frac{1}{2}\log\frac{q_-}{q_+}.$$

Thus, A is the common mode and C^* the differential mode. At each tower height,

$$q_-^n - q_+^n = 2e^{-nA_{\mathrm{rad}}}\sinh(nC^*_{\mathrm{rad}}).$$

The negative holonomy constructed in Section 94.4.1 fixes the Möbius gluing; the last identity proves that C^* measures the oriented opening of the two conjugate sheets. In the physical representation, those two orientations are read as particle and antiparticle.

In the boundary reader, one turn of the base is parameterized by 2π and ends in the opposite orientation. The squared loop, parameterized by 4π, restores the orientation. Therefore, relative to the declared lift and geometric reader, 2π is projected areal closure and 4π is volumetric closure of the oriented cover. This construction does not conflate that double return with a spinorial representation; the representation, when introduced, is a subsequent functor.

60.2.3 TPK descent, path envelope, and loop counting

The TPK calendar and the angular observable j_2 are distinct maps. The former updates the arithmetic mode $m \in \{\Sigma, \Pi\}$; the latter classifies digit supports. The hinge uses the typed HMT reader

$$\eta_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \eta_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

Thus, Σ is the additive or boundary mode and Π the multiplicative or interior mode. This statement does not identify τ with j_2.

In the primitive phase block

$$\tau_3 = (+1, -1, 0),$$

TPK updates the mode via

$$+1 :\ m \mapsto \Sigma, \qquad -1 :\ m \mapsto \Pi, \qquad 0 :\ m \mapsto m.$$

The cyclic orbit is (Σ, Π, Π). Define its edge-incidence matrix by

$$N_3(i,j) = \#\{r \in \mathbb{Z}/3\mathbb{Z} : (m_r, m_{r+1}) = (i,j)\}.$$

Theorem 60.10 (Necessary Descent of the Four Rules)**.** *In the order* (Σ, Π)*,*

$$N_3 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

Moreover,

$$N_9 = 3N_3, \qquad N_{27} = 9N_3, \qquad N_{108} = 36N_3.$$

Therefore, after removing the common repetition factor and applying η_{av}*, the TPK mode quotient necessarily induces*

$$\boxed{F_{\mathrm{av}} = S + P_{\mathrm{vol}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}}$$

where

$$S = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad P_{\mathrm{vol}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

The two crossed transitions, the unique volumetric self-retention, the absence of areal self-retention, and the unit primitive multiplicities are consequences of TPK, not added premises.

Proof. The three consecutive pairs of the cycle are

$$\Sigma \longrightarrow \Pi, \qquad \Pi \longrightarrow \Pi, \qquad \Pi \longrightarrow \Sigma.$$

Each one appears once and $\Sigma \to \Sigma$ does not appear. This determines the four entries of N_3. The length calendars $9, 27, 108$ contain $3, 9, 36$ primitive blocks, respectively; therefrom come the three multiples. Reduction by the greatest common divisor of the nonzero entries eliminates only the repetition of the block. The reader η_{av} changes the type of the vertices, not their incidence. □

The preceding theorem is an exact descent of edges. It does not turn phase forgetting into a strong Markov quotient: the same visible emission may be updated by I, E_+ or $E_\times$, depending on the hidden phase. From this fact follows a necessary distinction among three measures:

$$\tau_{468}, \qquad \nu_{\mathrm{cyc}}, \qquad \mu_{\mathrm{Parry}}.$$

The former is uniform over the 468 emissions and stationary under phase transfer. The latter is the frequency of the periodic orbit,

$$\nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{ar}}) = \frac{1}{3}, \qquad \nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{vol}}) = \frac{2}{3}.$$

Neither of them can directly produce the irrational quotient φ^{-2}.

The object that does produce it is determined by a universal property. Let X_{av} be the smallest memory-one subshift of finite type that contains the words obtained by forgetting the phase and preserves all their consecutive pairs. Every one-step system containing those words must admit

$$\mathrm{ar} \to \mathrm{vol}, \qquad \mathrm{vol} \to \mathrm{vol}, \qquad \mathrm{vol} \to \mathrm{ar}.$$

The smaller one excludes the only absent pair, $\mathrm{ar} \to \mathrm{ar}$. Consequently, X_{av} has adjacency matrix F_{av}. This is the minimal one-memory symbolic completion of the TPK quotient; it is not a new microscopic dynamics.

Theorem 60.11 (Fibonacci Law and Parry Measure)**.** *The operator F_{av} is primitive and*

$$F_{\mathrm{av}}^{n} = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix} \qquad (n \geq 1).$$

The subshift X_{av} has topological entropy $\log \varphi$ and a unique invariant measure of maximal entropy. For this measure,

$$\frac{(F_{\mathrm{av}}^{n})_{\mathrm{ar,ar}}}{(F_{\mathrm{av}}^{n})_{\mathrm{vol,vol}}} = \frac{F_{n-1}}{F_{n+1}} \longrightarrow \varphi^{-2}, \qquad \boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.}$$

Proof. The square of F_{av} is strictly positive. The formula for powers is obtained by induction through $F_{n+1} = F_n + F_{n-1}$. The diagonal entries count closed loops. The Perron root is φ and a positive Perron vector is $(1, \varphi)$. Since the matrix is symmetric, the vertex weights of Parry are proportional to the product of the left and right vectors, that is, to $(1, \varphi^2)$. □

The factor φ^{-1} is the Perron amplitude ratio of a traversal; φ^{-2} is the weight ratio of a complete return. The two exponents are thereby ordered without introducing two independent constants.

60.2.4 Spectral Origin of the Quadratic Exponent of Return

The appearance of the square admits a second, purely spectral proof that does not depend on interpreting a weighted average. The characteristic polynomial of F_{av} is

$$\chi_{F_{\mathrm{av}}}(t) = t^2 - t - 1,$$

so that its two eigenvalues are

$$\lambda_+ = \varphi, \qquad \lambda_- = -\varphi^{-1}.$$

The sign of λ_- records reversal of orientation in a traversal of the stable sheet. Upon lifting the action to quadratic memory $\mathrm{Sym}^2(\mathbb{R}^2)$, the eigenvalues are the pairwise products

$$\lambda_+^2 = \varphi^2, \qquad \lambda_+\lambda_- = -1, \qquad \lambda_-^2 = \varphi^{-2}.$$

In the basis $(e_{\mathrm{ar}}^2, e_{\mathrm{ar}} \odot e_{\mathrm{vol}}, e_{\mathrm{vol}}^2)$, writing the coordinates of the images of the three basis vectors by columns, the matrix is

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix},$$

and satisfies

$$\chi_{\mathrm{Sym}^2(F_{\mathrm{av}})}(t) = t^3 - 2t^2 - 2t + 1 = (t+1)(t^2 - 3t + 1).$$

Therefore, the stable mode changes orientation with $-\varphi^{-1}$ in one traversal and becomes the positive weight φ^{-2} when read as area memory or as a quadratic return. This is the structural reason for the exponent two.

60.2.5 Boundary closure and quotient π/φ^2

The coinductive reader of π precedes this construction. We define the closure band by composition, without using π to select the transporter:

$$\mathcal{B}_{\mathrm{av}}^{(\pi)}(X_\infty) := \Pi_{\mathrm{HMT}}(X_\infty)\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}}.$$

Marked return Θ_n and convergence of the areal–volumetric ratio Let the sheet projectors be

$$P_{\mathrm{ar}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad P_{\mathrm{vol}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

The boundary marker is defined by

$$D_\pi := \Pi_{\mathrm{HMT}}(X_\infty)P_{\mathrm{ar}} + P_{\mathrm{vol}}.$$

It is the unique positive operator diagonal with respect to the sheet decomposition that assigns unit weight to the volumetric sheet and the closure $\Pi_{\mathrm{HMT}}(X_\infty)$ to the areal sheet. Its canonicity is therefore relative to three explicit clauses: sheet diagonality, volumetric normalization, and areal marking by the already constructed closure reader.

If $e_{\mathrm{ar}}, e_{\mathrm{vol}}$ are the sheet vectors, the marked-return functional of depth n is

$$\Theta_n(X_\infty) := \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}}\rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}}\rangle}.$$

The previous power law gives, without approximation,

$$\boxed{\Theta_n(X_\infty) = \Pi_{\mathrm{HMT}}(X_\infty)\frac{F_{n-1}}{F_{n+1}}.}$$

The closure π is applied only once, when marking the boundary return; it is not reintroduced at each iteration of F_{av}.

Corollary 60.12 (Areal–Volumetric Holographic Ratio)**.** *Relative to the TPK mode quotient, its minimal memory-one envelope, and the HMT closure of π,*

$$\boxed{\mathcal{B}_{\mathrm{av}}^{(\pi)} = \lim_{n\to\infty}\Theta_n = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.}$$

Native Periodicity of 108 **Phases and Closure of the Unitary Calendar** At dodecaphasic depth 108, the two diagonal counts are

$$(F_{\mathrm{av}}^{108})_{\mathrm{ar,ar}} = F_{107} = 10284720757613717413913,$$

$$(F_{\mathrm{av}}^{108})_{\mathrm{vol,vol}} = F_{109} = 26925748508234281076009.$$

Consequently,

$$\frac{F_{107}}{F_{109}} = 0.38196601125010515179541316563436188 2\ldots,$$

y the error respecto of φ^{-2} is

$$\left|\frac{F_{107}}{F_{109}} - \varphi^{-2}\right| = 6.16849799166144079 36\ldots\times 10^{-46}.$$

After the boundary marking, the error relative to π/φ^2 is

$$\left|\pi\frac{F_{107}}{F_{109}} - \frac{\pi}{\varphi^2}\right| = 1.93789079742869760 68\ldots\times 10^{-45}.$$

Thus, 108 is not used to fit the ratio: it is a native depth of the calendar that already approximates the limiting return with more than forty-four stable fractional digits.

Coinductive intervalar reader: cylinder fitting and uniqueness of the limit For positive intervals

$$I = [a, b], \qquad J = [c, d], \qquad 0 < c \le d,$$

we define

$$Q(I, J) := \left[\frac{a}{d^2}, \frac{b}{c^2}\right].$$

The function $(x, y) \mapsto x/y^2$ is increasing in x and decreasing in $y > 0$. Hence $Q(I, J)$ is exactly the smallest interval containing all quotients x/y^2 with $(x, y) \in I \times J$; it is not a bound chosen by rounding.

Let I_n^π and I_n^φ be the nested positive cylinders generated by HMT. Then

$$Q(I_{n+1}^\pi, I_{n+1}^\varphi) \subseteq Q(I_n^\pi, I_n^\varphi),$$

and, as

$$\bigcap_n I_n^\pi = \{\pi_{\mathrm{HMT}}\}, \qquad \bigcap_n I_n^\varphi = \{\varphi_{\mathrm{HMT}}\},$$

we obtain

$$\bigcap_n Q(I_n^{\pi}, I_n^{\varphi}) = \left\{ \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} \right\}.$$

Each base-1000 block is forced as soon as the quotient interval lies entirely within a single triadic cylinder of the corresponding depth.

In particular, the positive twelve-triad cylinders for π and φ produce the quotient interval

$$\left[\frac{p^-}{(f^+)^2}, \frac{p^+}{(f^-)^2} \right].$$

The evaluation certifies thirty-five fractional digits:

$$\frac{\pi}{\varphi^2} = 1.19998161486432666111577775331680692\ldots,$$

y eleven complete blocks:

$$199|981|614|864|326|661|115|777|753|316|806.$$

Algebraic Separation Theorem. The matrix F_{av}, its powers, and its rational spectral algebra live in an algebraic extension of $\mathbb{Q}$ contained in $\mathbb{Q}(\sqrt{5})$. Consequently, no composition using only rational algebraic operations on F_{av} can produce the transcendental factor π/φ^2. The finite operator generates φ^{-2}; the coinductive boundary reader generates π_{HMT}; the marked return composes both without conflating their provenances. This negative control prevents F_{av} from being presented as an isolated generator of π.

60.2.6 Reader's Involution and Electronic Section

The relation just obtained appears alongside the electron in a manner more precise than literal repetition. The active electron invariant of Section 94.4.1 contains

$$\mathfrak{e}_0 = \frac{\sqrt{3}}{4} \left(e^{\varphi/\pi^2} - 22\alpha_{\mathrm{HMT}}^3 \right) (1 + 15\Delta_4).$$

Therefore, the electron exponent is φ/π^2, whereas the sheet hinge produces π/φ^2. The two scalars are neither equal nor reciprocal. They form the two orientations of the same bivariate law. Indeed, define

$$\mathscr{R}(x, y) := \frac{x}{y^2}, \qquad \mathsf{J}(x, y) := (y, x).$$

Then $\mathsf{J}^2 = I$ and

$$\boxed{\mathscr{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \qquad (\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \frac{\varphi}{\pi^2}.}$$

Exchange of the two readers carries the marked areal–volumetric return exactly to the exponential seed of the electron. Moreover,

$$\mathscr{R}(\pi, \varphi)\mathscr{R}(\varphi, \pi) = \frac{1}{\pi\varphi}, \qquad \frac{\mathscr{R}(\pi, \varphi)}{\mathscr{R}(\varphi, \pi)} = \left(\frac{\pi}{\varphi} \right)^3.$$

If we denote by $\mathcal{B}_{\mathrm{av}}^{(\pi)} = \pi/\varphi^2$ the marked sheet ratio, the same identity may be written without introducing an additional constant:

$$\boxed{\frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 \left(\mathcal{B}_{\mathrm{av}}^{(\pi)} \right)^2},} \qquad e^{\varphi/\pi^2} = \exp\left[\frac{1}{\varphi^3 \left(\mathcal{B}_{\mathrm{av}}^{(\pi)} \right)^2} \right].$$

Numerically,

$$\frac{\varphi}{\pi^2} = 0.16394111891367238359975275574566698 2\ldots,$$
$$e^{\varphi/\pi^2} = 1.17814494259630678081160095680888910\ldots.$$

This identity formalizes the bidirectional content without altering the force of the electron equation. The orientation (π, φ) reads boundary closure through quadratic memory; the exchanged orientation (φ, π) reads interior growth through quadratic closure and enters exponentiated in $\mathfrak{e}_0$. The theorem proves that both expressions belong to the same exchange orbit. The coefficients 22 and 15 have an independent generator: the theorem 16.4 obtains them, without consulting the electron mass, as

$$-22 = -\left|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)\right|, \qquad +15 = \left|\mathscr{R}_\pi \times \mathbb{F}_3\right|.$$

Its status is DEMONSTRATED WITH EXPLICIT STARTING STRUCTURE. The current involution transports that construction to the electronic orientation and does not use the electron to obtain F_{av}, π, or φ. The last form is an exact change of coordinates of the electronic seed, not an alternative derivation of $\mathfrak{e}_0$.

60.2.7 Pentagonal Identity of Rogers–Ramanujan and Recognition of the Perron Invariant

The Rogers–Ramanujan continued fraction provides an analytic realization of the same invariant. With $q_A = e^{-A_{\mathrm{rad}}}$, $q_C = e^{-C^*_{\mathrm{rad}}}$, one obtains

$$R(q_A)R(q_C) - \varphi^{-2} \simeq -1.01864 \times 10^{-27},$$

and with the channels of the split decomposition,

$$R(q_+)R(q_-) - \varphi^{-2} \simeq -1.19458 \times 10^{-21}.$$

The differences are not zero. The exact statement is the limit.

$$q_A^{(m)}, q_C^{(m)} \to 1^- \quad \Longrightarrow \quad R(q_A^{(m)})R(q_C^{(m)}) \to \varphi^{-2}.$$

Rogers–Ramanujan thus recognizes the Perron invariant in the pentadic reader; by itself, it does not select the angular coordinates A, C^*, or F_{av}. The former finite kernel $90/120$ preserves an approximate residue 7.81×10^{-9} and is not used as an exact identity.

60.2.8 Inversion of the inertial and gravitational readers and bidirectional reconstruction of the magnitude

The Ambivalence Principle distinguishes the opening reader q_A, the retention reader q_V, and the transported memory. The preceding hinge makes it possible to formulate the physical intuition precisely without conflating it with the combinatorial theorem. Let $\mathcal{M}(x)$ be a common memory character, and define, at the areal–volumetric interface,

$$\mathcal{I}_{\mathrm{av}}(x) := \mu_{\mathrm{vol}}\mathcal{M}(x), \qquad \mathcal{G}_{\mathrm{av}}(x) := \pi_{\mathrm{HMT}}\mu_{\mathrm{ar}}\mathcal{M}(x).$$

Therefore, whenever $\mathcal{M}(x) \neq 0$,

$$\boxed{\frac{\mathcal{G}_{\mathrm{av}}(x)}{\mathcal{I}_{\mathrm{av}}(x)} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2},} \qquad \frac{\mathcal{G}_{\mathrm{av}} - \mathcal{I}_{\mathrm{av}}}{\mathcal{I}_{\mathrm{av}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2} - 1.$$

The first formula expresses the oriented ratio between the gravitational and inertial readers; the second, their relative defect. The gnomonic L carries the local Euclidean chart on which both readers descend to a common normalization,

$$\frac{\mathcal{G}_L}{\mathcal{I}_L} = 1.$$

The physical reading is stratified. In the Euclidean chart of L, the local torsional connection projects onto a unique normalization, and the equivalence principle is realized as the unit quotient. In the enriched state prior to that projection, areal opening and volumetric retention remain separate: the Ambivalence Principle preserves its two functionals and fixes the internal quotient π/φ^2. Local equivalence and boundary ambivalence are thus two successive readings of the same antecedent, with declared domains and maps.

The physical realization adopts factorization of the inertial observable by volumetric retention and of the gravitational observable by areal opening with boundary closure π; both share character $\mathcal{M}$. The internal mathematics determines the correspondence and its quotient, and the Dimensional Mechanics functor publishes its observable charts. A rupture of either factorization constitutes the explicit falsifier of this realization.

Cosmological boundary. The hypothesis that dark matter or dark energy are effective readings of nontorsional crossings is retained only as a hypothesis of physical prolongation. To turn it into a testable proposition, at least a map from sheet interfaces to a cosmological geometry, observables representing density and pressure, and a prospective comparison with data without using those data to fix the map must be constructed. The proved correspondence supplies the structural candidate; it does not yet constitute, by itself, an observational explanation of the dark sector.

Areal–volumetric hinge domain and necessary validity conditions The band, the areal–volumetric ratio, and the bidirectional reading belong to the prior architecture. The incidence matrix, calendar descent, minimal envelope, loop law, Parry measure, quadratic action, and marked return provide its explicit formalization. The interval reader and the depth controls 108 certify the calculation. The incidences $N_3, N_9, N_{27}, N_{108}$, the matrix identities, and the cylinders are exact internal identities; the Möbius theorem and the ratio π/φ^2 are PROVED FROM EXPLICIT STARTING STRUCTURE; the particle–antiparticle and inertial–gravitational readings constitute subsequent physical interfaces; the extension to the dark sector remains an unproved physical hypothesis. The pair related by the involution $\mathscr{R}(\pi, \varphi) \leftrightarrow \mathscr{R}(\varphi, \pi)$ exactly formalizes a prior architecture. The coefficients $(-22, +15)$ are proved, by theorem 16.4, from their explicit starting structure.

A positive holonomy gives a cylinder. An areal–areal transition, the absence of a cross transition, or a TPK count different from $N_9 = 3F_{\mathrm{av}}$ and $N_{108} = 36F_{\mathrm{av}}$ falsifies the descent. The identification of μ_{Parry} with τ_{468} or with ν_{cyc} is refuted by their distinct values. A spectrum of $\mathrm{Sym}^2(F_{\mathrm{av}})$ different from $\{\varphi^2, -1, \varphi^{-2}\}$, a count 108 different from (F_{107}, F_{109}), a nonnested quotient interval, or the iterative introduction of π within F_{av} falsifies the new formalizations. A universal physical identification of the quotient without a map from sheets to observables lies outside the theorem. The delta of the four rules is closed; it does not reopen π, φ, C^*, or the extension–route–ledger–character junction.

Chapter 61

Dynamics of 3 sheets: global Hamiltonian, Lagrangian of the present sheet, and modular Hamiltonian of memory

The 3 sheets of the TRIT are realized as a quadratic family with a first-order null sheet. The variation distinguishes the global generator, the effective action of the present sheet, and the modular memory of the boundary: the 3 operators are coordinated without being identified.

61.1 Quadratic regimes and temporal readout

61.1.1 Quadratic algebras of the TRIT and curvature signatures

The primary construction and proof of the three regimes reside in section 3.4. For $\tau \in \widehat{\mathbb{T}}$, with balanced image $\bar{\tau} \in \{-1, 0, +1\}$, one has

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau}),$$

and, if J is the class of X,

$$\begin{aligned} \tau = +1 \quad &: \quad J^2 = -I, \quad \text{elliptic regime,} \\ \tau = 0 \quad &: \quad J^2 = 0, \quad \text{parabolic regime,} \\ \tau = -1 \quad &: \quad J^2 = +I, \quad \text{hyperbolic regime.} \end{aligned}$$

For all three values of τ, the quotient $\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau})$ satisfies precisely the three quadratic identities above. In particular, the internal square root of -1 is realized as an operator on the elliptic sheet; HMT need neither reject nor suppress the complex extension. The parabolic algebra contains a nilpotent, and the hyperbolic algebra decomposes by means of the two idempotents $(I \pm J)/2$.

These identities classify algebras and transports. They do not, by themselves, select a spacetime metric or prove that the physical universe occupies one of the three sheets.

61.1.2 Parametrized metric family of the temporal reader

Write

$$\mathbb{A}_s := \mathbb{R}[X]/(X^2 + s), \qquad s \in \{+1, 0, -1\},$$

for the same family with the real sign as index. To make the possible interface precise, fix a scale $\rho_{\text{curv}} > 0$, of dimension L^{-1}, and $\theta \in \mathbb{R}/2\pi\mathbb{Z}$. For $s \in \{+1, 0, -1\}$, let

$$g_{s,\rho} = \mathrm{d}r^2 + S_{s,\rho}(r)^2 \, \mathrm{d}\theta^2,$$

$$S_{s,\rho}(r) = \begin{cases} \rho_{\text{curv}}^{-1} \sin(\rho_{\text{curv}} r), & s = +1, \\ r, & s = 0, \\ \rho_{\text{curv}}^{-1} \sinh(\rho_{\text{curv}} r), & s = -1. \end{cases}$$

The radial domain is $r \geq 0$ for $s = 0, -1$; for $s = +1$, the chart polar cubre $0 \leq r \leq \pi/\rho_{\text{curv}}$, with the polar regularity usual in the extremos. In the interior of each chart,

$$K_{\text{G}} = -\frac{S''_{s,\rho}}{S_{s,\rho}} = s\,\rho_{\text{curv}}^2.$$

The last equality is an exact computation of the model once the realization is fixed. The arrow

$$\mathbb{A}_s \dashrightarrow (M_s, g_{s,\rho})$$

is, however, a *ansatz* of the PHYSICAL INTERFACE; it is not a canonical consequence of the relation $J^2 = -sI$.

If $\ell_0 \in \mathcal{L}_L^+$ is a length and we declare

$$\rho_{\mathrm{curv}} := \frac{\Delta_4}{\ell_0},$$

then

$$K_{\mathrm{G}} = s\,\frac{\Delta_4^2}{\ell_0^2}.$$

This specialization is DEMONSTRATED WITH EXPLICIT STARTING STRUCTURE: the conclusion is obtained once s, Δ_4, ℓ_0 have been declared, but it does not select ℓ_0, does not deduce the observed cosmological curvature, and does not identify the ratios $\mathcal{G}_{\mathrm{tor}}/\mathcal{I}_{\mathrm{tor}}$ or $\mathcal{G}_{\mathrm{av}}/\mathcal{I}_{\mathrm{av}}$ with K_{G}.

61.1.3 Temporal TRIT reader on (-1,0,+1): opening, threshold, and return with memory

Once an ordered parametrization of the transitions has been chosen, the active temporal reader is

$$\begin{aligned} +1 &\longmapsto \text{return, retained memory and past,}\\ 0 &\longmapsto \text{evaluation threshold and present,}\\ -1 &\longmapsto \text{bidirectional opening and future.}\end{aligned}$$

The reader is PROVED WITH AN EXPLICIT STARTING STRUCTURE: its conclusions follow once the TRIT signature, the order of the trajectory, and the transported memory have been specified. It does not turn the set $\{-1, 0, +1\}$ into an equation of motion. The future designates the space of compatible continuations; survival may select a branch or a multisection without erasing the genealogy of the others.

The frequency

$$\omega_0 = \frac{2\pi}{108\, t_0}$$

assigns a type to the full-return clock through the decision entropy $I_{\mathrm{TRIT}} = \log 3$ and the Boltzmann transducer. It does not, in isolation, establish a stable subharmonic phase. It does, however, enable construction of the finite reference Hamiltonian below; selection of a robust physical Hamiltonian requires additional conditions.

61.1.4 Unitary dynamics on 108 states: Hamiltonian, propagator, and period

Let

$$\mathcal{H}_{\mathrm{clk}} := \mathbb{C}^{108}, \qquad \{|j\rangle : j \in \mathbb{Z}/108\mathbb{Z}\}$$

with its canonical Hermitian inner product. Fix $\zeta := \exp(2\pi\mathrm{i}/108)$, the unitary shift

$$U_{\mathrm{clk}}|j\rangle = |j+1\rangle$$

and the Fourier basis

$$|\widetilde{k}\rangle := \frac{1}{\sqrt{108}} \sum_{j=0}^{107} \zeta^{jk}|j\rangle, \qquad 0 \le k \le 107.$$

With $t_0 \in \mathcal{L}_T^+$ and $\hbar_{\mathrm{int}} \in \mathcal{L}_S^+$, define

$$\boxed{H_{\mathrm{clk}} := \hbar_{\mathrm{int}}\omega_0 \sum_{k=0}^{107} k\, |\widetilde{k}\rangle\langle\widetilde{k}|, \qquad \omega_0 = \frac{2\pi}{108\, t_0}.} \tag{CLK1}$$

The operator has energy type $[H_{\mathrm{clk}}] = \mathcal{L}_S\mathcal{L}_T^{-1} = \mathcal{L}_E$.

Theorem 61.1 (Exact unitary realization of the 108 calendar)**.** *The operator H_{clk} is self-adjoint and its one-step propagator satisfies*

$$U_{\mathrm{step}} := \exp\!\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}} H_{\mathrm{clk}} t_0\right) = U_{\mathrm{clk}}, \qquad U_{\mathrm{step}}^{108} = I. \tag{CLK2}$$

If

$$Z_{\mathrm{clk}}|j\rangle = \zeta^{j}|j\rangle,$$

then, for any basis state $|j_0\rangle$,

$$\langle Z_{\mathrm{clk}}\rangle_n := \langle j_0|U_{\mathrm{step}}^{-n} Z_{\mathrm{clk}} U_{\mathrm{step}}^{n}|j_0\rangle = \zeta^{j_0+n}. \tag{CLK3}$$

The sequence has primitive period 108*.*

Proof. Expression (CLK1) is a spectral decomposition with real eigenvalues, hence $H_{\mathrm{clk}} = H_{\mathrm{clk}}^{\dagger}$. Moreover,

$$U_{\mathrm{clk}}|\widetilde{k}\rangle = \zeta^{-k}|\widetilde{k}\rangle,$$

whereas the exponential of $\hbar_{\mathrm{int}}\omega_0 k$ over t_0 gives $\exp(-2\pi \mathrm{i}k/108) = \zeta^{-k}$. The two operators agree on an orthonormal basis. The remaining identities follow from $U_{\mathrm{step}}^{n}|j_0\rangle = |j_0 + n\rangle$ and the primitivity of ζ. □

The corresponding variational formulation, for a curve $\psi \in C^1([t_a, t_b], \mathcal{H}_{\mathrm{clk}})$, unconstrained during the variation, is

$$\boxed{L_{\mathrm{clk}}(\psi, \dot{\psi}) = \frac{\mathrm{i}\hbar_{\mathrm{int}}}{2}\big(\langle\psi|\dot{\psi}\rangle - \langle\dot{\psi}|\psi\rangle\big) - \langle\psi|H_{\mathrm{clk}}|\psi\rangle.} \tag{CLK4}$$

The action functional is

$$\boxed{S_{\mathrm{clk}}[\psi] := \int_{t_a}^{t_b} L_{\mathrm{clk}}(\psi(t), \dot{\psi}(t))\,\mathrm{d}t,} \tag{CLK5}$$

with $\delta\psi(t_a) = \delta\psi(t_b) = 0$. Varying ψ and $\bar{\psi}$ independently yields the Schrödinger equation for the finite clock

$$\boxed{\mathrm{i}\hbar_{\mathrm{int}}\dot{\psi} = H_{\mathrm{clk}}\psi} \tag{CLK6}$$

together with its adjoint equation [107]. Its propagator sampled at $t = nt_0$ is $\psi_n = U_{\mathrm{step}}^{n}\psi_0$. Since H_{clk} is self-adjoint, the norm is conserved; normalized initial data remain normalized. The result is exact with respect to the specified $H_{\mathrm{clk}}, t_0, \hbar_{\mathrm{int}}$; it neither selects a physical Hamiltonian nor introduces an experimental frequency.

The theorem 61.1 proves the unitary dynamics of the calendar relative to the declared complex completion, t_0 and $\hbar_{\mathrm{int}}$. The five dynamical conditions of the following section receive a constructive realization in section 61.3: there the drive, the order observable, the primitive subharmonic of period $108T_{\mathrm{d}}$, and finite spectral stability are fixed. The macroscopic material realization constitutes a distinct external recognition and not a lacuna in the finite result.

61.1.5 Dynamic realization conditions of a time crystal: Hamiltonian, subharmonic response and stability

A driven realization must provide, at a minimum:

1. a physical state space and a self-adjoint Hamiltonian $H(t)$, or an equivalent driven protocol, with $H(t + T_{\mathrm{d}}) = H(t)$;
2. the propagator of Floquet

$$U_F = \mathcal{T}\exp\!\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}\int_0^{T_{\mathrm{d}}} H(t)\ \mathrm{d}t\right);$$

3. an observable of order O and a family of states for which there exists a primitive subharmonic response of order $m > 1$:
$$\langle O((n+m)T_{\mathrm{d}})\rangle = \langle O(nT_{\mathrm{d}})\rangle$$
in the asymptotic regime, without the same periodicity for a proper divisor of m;
4. stability of m, of the phase, and of the amplitude under an open class of admissible perturbations;
5. persistence that is not a finite-size transient, together with a declared mechanism of localization, prethermalization, or dynamical protection.

The calendar $27 \to 54 \to 108$ provides the internal hierarchy of periods. The finite realization of section 61.3 selects subharmonic order 108 in its declared domain, without replacing the five preceding constructions or by itself imposing a macroscopic material phase.

Comparison Criterion 61.2 (HMT–MD time crystal)**.** The identification is refuted if no well-typed driven Hamiltonian or protocol exists; if the alleged subharmonicity disappears under arbitrarily small perturbations compatible with the model; if the observed period is only the period imposed by the drive; if the oscillation is a finite transient; or if the temporal reader assigns equivalent histories to incompatible physical phases.

Mathematical and physical domain of the temporal reader. The three algebras and their exponentials are proved in the algebraic domain; the temporal reader is deduced from the initial signature, order, and memory. The finite HMT time crystal satisfies the test criterion 61.2 through the construction of section 61.3. Extension to a macroscopic material phase additionally requires specification of the physical support and belongs to the subsequent experimental comparison.

61.2 3 temporal sheets, nilpotent calculus, and tritified Cartan connection

61.2.1 Quadratic Family of TRIT

For $\tau \in \{+1, 0, -1\}$, consider the real algebra

$$\mathbb{A}_\tau = \mathbb{R}[J_\tau]/(J_\tau^2 + \tau), \qquad J_\tau^2 = -\tau I.$$

The exponential is computed exactly:

$$e^{tJ_{+1}} = \cos t + J_{+1} \sin t,$$

$$e^{tJ_0} = I + tJ_0,$$

$$e^{tJ_{-1}} = \cosh t + J_{-1} \sinh t.$$

The three sheets have differentiated geometric functions:

τ	J_τ^2	régimen
$+1$	$-I$	elliptic: closure, return and memory
0	0	parabolic: tangency, variation, and present
-1	$+I$	hyperbolic: aperture, boost, and propagation

Let $\widehat{\tau} = P_+ - P_-$, with $P_0 = I - P_+ - P_-$. Then

$$\widehat{\tau}^3 = \widehat{\tau}.$$

An involution that exchanges the outer sheets and preserves the central sheet satisfies

$$\mathsf{J}\widehat{\tau}\mathsf{J}^{-1} = -\widehat{\tau}.$$

The threshold remains fixed and the closing and opening orientations are interchanged.

61.2.2 The null sheet as 1st jet

In $\mathbb{A}_0$, write $\epsilon = J_0$, with $\epsilon^2 = 0$. For every differentiable functional F,

$$\boxed{F(x + \epsilon v) = F(x) + \epsilon\, dF_x(v).} \tag{61.1}$$

The equality is exact because all terms of order at least two contain ϵ^2. In particular, for an action $S[e, \omega, \Psi]$,

$$S[e + \epsilon\delta e, \omega + \epsilon\delta\omega, \Psi + \epsilon\delta\Psi] = S[e, \omega, \Psi] + \epsilon\, \delta S. \tag{61.2}$$

The nilpotent coefficient contains the Euler–Lagrange equations, the Cartan equation, the symplectic potential, and the boundary terms. The central sheet is therefore the algebraic residence of the variational principle.

Theorem 61.3 (Nilpotent stationarity)**.** *For a configuration z, the following are equivalent:*

$$dS_z(\delta z) = 0 \quad \textit{for every } \delta z,$$

and

$$S(z + \epsilon\delta z) = S(z) \quad \textit{in } \mathbb{A}_0 \quad \textit{for every } \delta z.$$

Proof. The equivalence is the equality of the coefficients of 1 and ϵ in (61.1). □

The global Hamiltonian, the effective action of the central sheet, and the modular Hamiltonian of the boundary are coordinated objects:

$$H_{\mathrm{glob}}, \qquad L_{0,\mathrm{eff}}, \qquad K_{\mathrm{HHM}} = -\log \rho_{\partial}.$$

The first generates evolution; the second publishes local variation; the third preserves informational provenance.

61.2.3 Feshbach–Schur reduction

Let

$$\mathcal{H} = \mathcal{H}_0 \oplus \mathcal{H}_{\mathrm{ext}}, \qquad H = \begin{pmatrix} H_{00} & V \\ V^* & H_{\mathrm{ext}} \end{pmatrix}.$$

For z in the resolvent set of H_{ext}, the resolvent compression is

$$P_0(z - H)^{-1}P_0 = [z - H_{00} - \Sigma_0(z)]^{-1}, \qquad \Sigma_0(z) = V(z - H_{\mathrm{ext}})^{-1}V^*. \tag{61.3}$$

The operator Σ_0 transports the memory of the elliptic and hyperbolic sheets to the present sheet. Its time transform generates a memory kernel

$$S_{\mathrm{eff}}[\psi_0] = \int \psi_0^\dagger (i\hbar\partial_t - H_{00})\psi_0 \,\mathrm{d}t - \iint \psi_0^\dagger(t) K_0(t,t')\psi_0(t') \,\mathrm{d}t\,\mathrm{d}t'.$$

A regular low-frequency expansion,

$$\Sigma_0(\omega) = \Sigma_0^{(0)} + \omega\Sigma_0^{(1)} + \omega^2\Sigma_0^{(2)} + \cdots,$$

produces an effective local action; a singular spectral structure preserves nonlocal memory. The present thus receives the response of the global state without introducing an external time.

61.2.4 Connection universal of Cartan

Let $\mathfrak{g}_\tau$ be the Cartan algebra generated by $J_{ab} = -J_{ba}$ and $P_a^{(\tau)}$, with relations

$$[J_{ab}, J_{cd}] = \eta_{bc}J_{ad} - \eta_{ac}J_{bd} - \eta_{bd}J_{ac} + \eta_{ad}J_{bc}, \tag{61.4}$$

$$[J_{ab}, P_c^{(\tau)}] = \eta_{bc}P_a^{(\tau)} - \eta_{ac}P_b^{(\tau)}, \tag{61.5}$$

$$[P_a^{(\tau)}, P_b^{(\tau)}] = -\tau J_{ab}. \tag{61.6}$$

For $\tau = 0$ one obtains the algebra of Poincare; the extreme signs yield the two constant-curvature forms. Let ω be a Lorentz connection, $e = e^a P_a^{(\tau)}$ a coframe valued in the translation sector, and ℓ a length scale. We define the tritified connection

$$\mathcal{A}_\tau^{\mathrm{Cart}} = \frac{1}{2}\omega^{ab}J_{ab} + \ell^{-1}e^a P_a^{(\tau)}. \tag{61.7}$$

Its curvature is

$$\boxed{\mathcal{F}_\tau^{\mathrm{Cart}} = \frac{1}{2}\left(F_\omega^{ab} - \tau\ell^{-2}e^a \wedge e^b\right)J_{ab} + \ell^{-1}T^a P_a^{(\tau)}, \qquad T^a = D_\omega e^a.} \tag{61.8}$$

Proof. Upon expanding $\mathrm{d}\mathcal{A}_\tau^{\mathrm{Cart}} + \mathcal{A}_\tau^{\mathrm{Cart}} \wedge \mathcal{A}_\tau^{\mathrm{Cart}}$, the first bracket of equation (61.6) produces F_ω, the second produces $D_\omega e$, and the third contributes $-\tau\ell^{-2}e^a \wedge e^b J_{ab}/2$. □

In the central sheet,

$$\mathcal{F}_0^{\mathrm{Cart}} = \frac{1}{2}F_\omega^{ab}J_{ab} + \ell^{-1}T^a P_a^{(0)}.$$

Torsion is the nilpotent coefficient of curvature. This equality joins the variational interpretation of the sheet 0 to its geometric Cartan interpretation.

61.2.5 Nonadic corona and torsional energy

On the edges of the crown of nines, let be

$$(D_{9,m}f)(a) = f(t(a)) - U_a f(s(a)),$$

where U_a transports orientation and carry. For a positive weight W_m,

$$H_m = H_{\mathrm{clk},m} + D_{9,m}^* W_m D_{9,m}, \qquad \mathcal{E}_{\mathrm{tor},m}(f) = \|W_m^{1/2} D_{9,m} f\|^2. \tag{61.9}$$

Unitary holonomy preserves positivity. The refinement squares

$$D_{9,m+1}J_m = K_m D_{9,m}, \qquad K_m^* W_{m+1} K_m = W_m$$

guarantee the compatibility of energy at every depth.

The subsequent closure will construct the screen soldering that transforms this defect into a Cartan response. The present section fixes the operator domain and the positivity that this intertwiner must preserve.

61.2.6 Principle of Ambivalence: bidirectional involution of the ratios π/φ^2 and φ/π^2

We define

$$Q(x,y) = \left(\frac{x}{y^2}, \frac{y}{x^2}\right), \qquad x, y > 0.$$

For

$$P = xy, \qquad O = x/y,$$

we verify

$$P(Q(x,y)) = P^{-1}, \qquad O(Q(x,y)) = O^3.$$

After two steps,

$$\boxed{P(Q^2) = P, \qquad O(Q^2) = O^9.} \tag{61.10}$$

In coordinates $u = \log(xy)$, $v = \log(x/y)$,

$$(u,v) \longmapsto (-u, 3v) \longmapsto (u, 9v).$$

The product returns, and orientation multiplies its memory by nine. For $(x,y) = (\pi, \varphi)$, the two outputs are

$$\rho_A = \frac{\pi}{\varphi^2}, \qquad \rho_E = \frac{\varphi}{\pi^2}.$$

Satisfy

$$\rho_E \rho_A^2 = \varphi^{-3}, \qquad M_9 = (\rho_E \rho_A^2)^6 = \varphi^{-18}.$$

The relation links areal reading, electronic exponent, nonadic return and quadratic memory without identifying their algebraic structures with each other.

Estatuto probatorio

The quadratic algebras, the dual calculus, the Schur reduction, the curvature (61.8), and the identity (61.10) are exact. The limit of the torsional energy and its realization as the full Einstein–Cartan action require the refinement squares and the physical morphism developed subsequently.

Falsification criterion

The following refute internal closure: a term other than $-\tau\ell^{-2} e \wedge e$ in the curvature; a nilpotent coefficient that is not $D_\omega e$; a residue in the Feshbach–Schur identity; loss of positivity of $D_9^* W D_9$; or failure of either of the two equations of (61.10).

61.3 Finite-time Temporal Crystal HMT: Periodically forced Hamiltonian, Subharmonic response and Spectral stability

61.3.1 Construction of the periodic forcing from the 108-state temporal system

Sea $N = 108$,

$$\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^N, \qquad S|j\rangle = |j+1\rangle, \qquad Z|j\rangle = \zeta^j|j\rangle, \qquad \zeta = \exp(2\pi\mathrm{i}/N).$$

In the Fourier basis $\{|\widetilde{k}\rangle\}_{k=0}^{N-1}$, we set

$$H_{\mathrm{clk}} = \hbar_{\mathrm{int}}\frac{2\pi}{Nt_0}\sum_{k=0}^{N-1} k|\widetilde{k}\rangle\langle\widetilde{k}|, \qquad \exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}H_{\mathrm{clk}}t_0\right) = S.$$

This equality fixes the starting clock. To exhibit a nonconstant periodic drive, let $0 < \eta < 1$, $T_{\mathrm{d}} = t_0$, and define, in each period,

$$H_{\mathrm{d}}(t) = \begin{cases} 0, & 0 \le t < \eta T_{\mathrm{d}}, \\ (1-\eta)^{-1}H_{\mathrm{clk}}, & \eta T_{\mathrm{d}} \le t < T_{\mathrm{d}}. \end{cases} \qquad H_{\mathrm{d}}(t+T_{\mathrm{d}}) = H_{\mathrm{d}}(t).$$

As the two segments commute, their Floquet propagator is

$$U_F = \mathcal{T}\exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}\int_0^{T_{\mathrm{d}}} H_{\mathrm{d}}(t)\,\mathrm{d}t\right) = \exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}H_{\mathrm{clk}}T_{\mathrm{d}}\right) = S.$$

We define the Hermitian observables

$$Q = \frac{Z+Z^\dagger}{2}, \qquad P = \frac{Z-Z^\dagger}{2\mathrm{i}}.$$

Theorem 61.4 (Primitive Subharmonicity of the Finite Temporal Crystal HMT)**.** *For $\rho_{j_0} = |j_0\rangle\langle j_0|$, the vector of orden*

$$\mathbf{q}_n = \left(\mathrm{Tr}\,\rho_{j_0}U_F^{-n}QU_F^n,\ \mathrm{Tr}\,\rho_{j_0}U_F^{-n}PU_F^n\right)$$

satisfies

$$\mathbf{q}_n = \left(\cos\frac{2\pi(j_0+n)}{N},\ \sin\frac{2\pi(j_0+n)}{N}\right).$$

Its primitive period is $NT_{\mathrm{d}} = 108T_{\mathrm{d}}$, whereas the drive has period T_{d}. Therefore, the system realizes a primitive subharmonic response of order 108 *in the declared finite domain.*

Proof. The Weyl relation $S^{-1}ZS = \zeta Z$ gives $S^{-n}ZS^n = \zeta^n Z$. Its real and imaginary parts yield the formula. If an integer $d > 0$ were a period, then $\zeta^d = 1$ would hold; the primitivity of ζ forces $N \mid d$. □

61.3.2 Nilpotent jet of the triadic evolution and compatible prolongation

The minimal separation between distinct roots of unity is

$$g_N = \min_{k\neq\ell}|\zeta^k - \zeta^\ell| = 2\sin\frac{\pi}{N} > 0.$$

Theorem 61.5 (Covariant rigidity and finite spectral stability)**.** *The following two assertions hold.*

1. *For every unitary V, the terna*

$$U_F^{(V)} = VU_FV^\dagger, \qquad Z^{(V)} = VZV^\dagger, \qquad \rho^{(V)} = V\rho V^\dagger$$

exactly preserves the Weyl relation, the subharmonicity of order N, and the amplitude of the order vector.

2. *If U' is unitary and $\|U' - U_F\| = \varepsilon < g_N/2$, the N disks of radius $g_N/2$ centered at $\{\zeta^k\}$ uniquely separate the spectral sectors of U'. Their Riesz projectors have the same rank as those of U_F throughout every deformation that remains in that ball. Moreover, for every observable A, every state ρ, and every $n \geq 0$,*

$$\left|\operatorname{Tr}\rho\left(U'^{-n}AU'^{n} - U_F^{-n}AU_F^{n}\right)\right| \leq 2n\varepsilon\|A\|.$$

Proof. The first part is obtained by conjugating each identity. For the second, the separation g_N prevents two sectors from entering the same contour; continuity of the Riesz projectors preserves their ranges. The telescoping identity gives $\|U'^{n} - U_F^{n}\| \leq n\varepsilon$, and the same bound holds for the inverse powers. The inequality of expectations results from inserting and subtracting $U'^{-n}AU_F^{n}$. □

The resulting object is a *finite HMT time crystal* with a drive, a subharmonic observable, and quantified spectral stability. Whether a macroscopic material realizes this class, retains coherence at large volume, or exhibits prethermal or localized protection belongs to EXTERNAL IDENTIFICATION; it is not an unresolved mathematical part of the finite construction.

Chapter 62

The HMT–MD confluence theorem: Einstein–Schrödinger system and electrogravitational coordination of action, matter, fields, geometry, and information

Unification is expressed as the vertical compatibility of distinct publications of the same state: coupling and vacuum, action and gravity, geometry and information, screen and torsion, clock and horizon. The theorem preserves the domains and maps of each response.

62.1 Theorem of Dimensional Response Confluence

62.1.1 Antecedent common and product fibered

The volume results arise from heterogeneous readers applied to the same enriched genealogical state. Let

$$X = \left(X_{\mathrm{APP}}, X_{\widehat{\mathbb{T}}}, X_{\mathrm{TPK}}, C, \mathcal{B}, \mathcal{R}, \mathcal{M}, \partial X\right) \tag{62.1}$$

the state that preserves cylinders, carry, route, memory, and boundary. The typed readers are constructed on X

$$P_i : X \longrightarrow Y_i, \qquad i \in I := \{\alpha, \mathrm{act}, \mathrm{ang}, 108, \square, \mathrm{obs}, \mathrm{Per}\}. \tag{62.2}$$

Their codomains represent, respectively, the dodecaphasic coupling generator, the action pair, the bilayer angular operator, the clock 108, the cubic screen, the internal observer, and the Perron mode. For each reader, its graph is taken, provided with the projection in its canonical form

$$\Gamma_i := \{(x, y_i) \in X \times Y_i : P_i(x) = y_i\}, \qquad \pi_i : \Gamma_i \longrightarrow X, \quad (x, y_i) \longmapsto x. \tag{62.3}$$

The master object is the well-typed fiber product of those graphs:

$$\boxed{\mathfrak{M}_X = \underset{X,\, i \in I}{\times} \Gamma_i = \left\{\left(x, (y_i)_{i \in I}\right) : P_i(x) = y_i \text{ for every } i \in I\right\}.} \tag{62.4}$$

The projections π_i materially fix the same antecedent. An element of $\mathfrak{M}_X$ is a family of compatible outputs accompanied by the state that generates them.

Definition 62.1 (Publication dimensional)**.** A dimensional publication is a composition

$$\mathfrak{M}_X \xrightarrow{P} \mathcal{L} \xrightarrow{\mathrm{ev}_{\mathcal{U}}} \mathbb{R}, \tag{62.5}$$

where $\mathcal{L}$ is a typed dimensional line, and $\mathrm{ev}_{\mathcal{U}}$ is the final evaluation in a chart of units. The map P first constructs the invariant and its genealogy.

62.1.2 Naturality of the realizations and vertical conservation of the enriched state invariants

Two sibling readers share an antecedent and may satisfy cross-relations without one factoring through the other. This distinction governs the double sheets of the vacuum, the positive and oriented realizations, the double Archimedean and exceptional projection, and the geometric, informational, and flavor readings of the transition $6 \to 8$.

Theorem 62.2 (Confluence without factorization horizontal)**.** *Let $P_i : \mathfrak{M}_X \to Y_i$ and $i = 1, \ldots, r$ be publications constructed on the same state. Suppose that each P_i preserves its typed data and that the relations $R_j(P_1, \ldots, P_r) = 0$ are proved after the readers have been constructed. Then the joint morphism*

$$P = (P_1, \dots, P_r) : \mathfrak{M}_X \longrightarrow Y_1 \times \cdots \times Y_r \tag{62.6}$$

is vertically compatible with X. A factorization $P_i = F_{ij} \circ P_j$ additionally requires P_j to separate all the fibers distinguished by P_i. The mere existence of $R_j = 0$ does not imply that separation.

Proof. Vertical compatibility follows from the universal property of the fiber product of the graphs Γ_i: all components have the same image in X. If $P_i = F_{ij} \circ P_j$, then $P_j(x) = P_j(x')$ forces $P_i(x) = P_i(x')$. Hence, any pair x, x' that shares the reading j and differs in the reading i refutes the factorization. A scalar relation $R_j = 0$ only restricts the joint image; it does not guarantee the inclusion of kernels required for factorization. □

The theorem explains why the product of sheets can fix the causal cone while the quotient preserves orientation, and why the total area can coexist with a modular Hamiltonian that distinguishes the origin $90/120$.

62.1.3 Constitutive coupling between the vacuum and the electroweak sector

Let

$$D = D_A = \det T, \qquad Q(D) = -\frac{9}{25} \log D = 4\pi\alpha_{\mathrm{HMT}}. \tag{62.7}$$

The memory-oriented is expressed through

$$\rho = e^{2C^*_{\mathrm{rad}}}, \qquad q_- = \sqrt{D\rho}, \qquad q_+ = \sqrt{D/\rho}. \tag{62.8}$$

The functional calculus

$$F(z) = \frac{1 - z^{90}}{1 - z^{120}}, \qquad r_\pm = F(q_\pm) \tag{62.9}$$

yields

$$\widehat{\mu} = r_-^2, \quad \widehat{\varepsilon} = r_+^2, \quad \widehat{Z} = \frac{r_-}{r_+}, \quad \widehat{c} = (r_- r_+)^{-1}. \tag{62.10}$$

At the tree-level electroweak interface,

$$g^2 = \frac{Q(D)}{1 - D}, \qquad g'^2 = \frac{Q(D)}{D}, \tag{62.11}$$

from which

$$\boxed{(1 - D)g^2 = Dg'^2 = Q(D), \qquad \frac{1}{g^2} + \frac{1}{g'^2} = \frac{1}{Q(D)}.} \tag{62.12}$$

The first equality publishes the same coupling in two gauge orientations; the second recovers it as a sum of compliances. The determinant D governs the even mixture, and ρ preserves the odd orientation.

The Higgs coordinate incorporates the latter:

$$\lambda_H = \frac{Q(D)}{8(1 - D)} D^{-3} \rho^{5/3}. \tag{62.13}$$

Defining

$$\Xi = \frac{8(1 - D)D^3 \lambda_H}{Q(D)}, \tag{62.14}$$

is reconstructed

$$\rho = \Xi^{3/5}, \qquad \widehat{Z} = \frac{F(\sqrt{D}\,\Xi^{3/10})}{F(\sqrt{D}\,\Xi^{-3/10})}. \tag{62.15}$$

The equation equation (62.15) provides a cross-check between scalar orientation and vacuum impedance. Its force comes from the parallel construction of both readers on X.

62.1.4 Reciprocity between action and gravity in the electrogravitational form

Let

$$Q_P = E_P, \qquad \ell_P, \qquad Q_P \ell_P = \hbar c, \qquad \frac{\ell_P}{Q_P} = \frac{G}{c^4}. \tag{62.16}$$

The product is the exchange quantum $\hbar c$; the quotient is the gravitational compliance. We introduce

$$\mathscr{T}_P = \frac{Q_P}{\ell_P} = \frac{c^4}{G}, \qquad \mathscr{C}_P = \frac{\ell_P}{Q_P} = \frac{G}{c^4}. \tag{62.17}$$

The Einstein equation assumes the constitutive form

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi \mathscr{C}_P T_{\mu\nu}. \tag{62.18}$$

For a charge q, the electric coordinate lifted to the energy plane is

$$\mathcal{Q}(q) = Q_P \sqrt{\frac{Z}{4\pi\hbar}}\, q. \tag{62.19}$$

Newton and Coulomb are then brought together in the bilinear form

$$\boxed{V(r) = \frac{\mathscr{C}_P}{r}\big(\mathcal{Q}_1\mathcal{Q}_2 - E_1E_2\big).} \tag{62.20}$$

The cone $\mathcal{Q}^2 = E^2$ reproduces the static condition of extremality in the Einstein–Maxwell chart. The sheet product of the vacuum governs the causal cone; its quotient governs the electric lift and orientation.

The cross-identity with the electroweak sector is

$$\boxed{\frac{\hbar^2}{8\pi\ell_P^2}\frac{(\kappa/\mu)}{e^2} = \frac{1}{4\pi\alpha_{\mathrm{HMT}}} = \frac{1}{g^2} + \frac{1}{g'^2}.} \tag{62.21}$$

This equality preserves its value under inversion of the action sheet: G and e^2 transform contragrediently, whereas $G\hbar$, Ge^2, and ℓ_P^2 remain invariant.

62.1.5 Confluence between geometry, information and mixing

Let $N = N_{90} + N_{120}$ be the total number of boundary excitations and

$$D_{90/120} = 90N_{90} + 120N_{120}. \tag{62.22}$$

The area reads N, whereas the modular holographic Hamiltonian reads $D_{90/120}$. Since

$$\det\begin{pmatrix} 1 & 1 \\ 90 & 120 \end{pmatrix} = 30, \tag{62.23}$$

the pair reconstructs exactly

$$N_{90} = 4N - \frac{D_{90/120}}{30}, \qquad N_{120} = \frac{D_{90/120}}{30} - 3N. \tag{62.24}$$

The total geometry and the weighted modular energy therefore preserve quantity and provenance.

The angular double-layer state

$$\rho_y = \frac{e^{-yR}}{2\cosh y} \tag{62.25}$$

has even entropy and oriented divergence

$$S(\rho_y) = \log(2\cosh y) - y\tanh y, \qquad D(\rho_y\|\rho_{-y}) = 2y\tanh y. \tag{62.26}$$

The involution $y \mapsto -y$ is represented in the flavour sector by

$$R_{\mathrm{CKM}} = M_{\mathrm{CKM}}\,\mathrm{diag}(1,-1,1)M_{\mathrm{CKM}}^{-1}, \qquad R_{\mathrm{CKM}}^2 = I, \qquad \det R_{\mathrm{CKM}} = -1. \tag{62.27}$$

Barbero reads the odd component of the transition $6 \to 8$, entropy reads its even distribution, and R_{CKM} realizes the same inversion in the mixing codomain. They are coordinated representations of a common hinge, with their own domains and observables.

62.1.6 Transduction of the helical memory in the torsional realization

In the quotient lorentziano $Q_{\square}$, the soldadura and the respuis positiva satisfy

$$\boxed{(\beta_m^{\square})^{*}\Lambda_m^{\square}\beta_m^{\square} = \frac{56}{81}I_{Q_{\square}}.} \tag{62.28}$$

In the deep register, the screw operator checks

$$\boxed{V^{-1}\mathcal{S}V = (2+\sqrt{3})\mathrm{i}\,\mathcal{S}.} \tag{62.29}$$

The first identity measures the minimum response cost of the screen; the second transports orientation and depth. Catalan appears as the second moment of the quaternary component. If $N_{\mathrm{dep}}\delta_n = n\delta_n$ denotes the depth operator of the helical record, then

$$G_{\mathrm{Cat}} = \mathrm{Tr}(N_{\mathrm{dep}}^{-2}Q_{\chi,-4}). \tag{62.30}$$

Perron's theorem

$$M_n = \left(\frac{a_n}{a_0}\right)^{-6} \tag{62.31}$$

provides the exact covariance of a quadratic spin density. The Cartan realizer must transport equations (62.28) y (62.29) to a current and a contorsion whose homogeneous mode satisfies equation (62.31). This chain places the physical interface in a unique and falsifiable arrow.

62.1.7 Confluence between clock periodicity, horizon energy, and information cost

The clock 108 fixes

$$E_P = k_B\Theta_{\mathrm{clk}}\log 3. \tag{62.32}$$

For the de Sitter patch of radius $R = \ell_P$, the vacuum energy, temperature, and entropy satisfy

$$E_\Lambda = T_H S_H = \frac{E_P}{2} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2}. \tag{62.33}$$

From here follow

$$E_\Lambda t_P = \frac{\hbar}{2}, \qquad E_\Lambda T_{108} = \frac{h}{2}, \qquad \frac{S_H}{k_B} = \pi. \tag{62.34}$$

The vacuum volume, the horizon area, the cycle temperature, and the information cost of a trit publish the same energy. The multiplicity $e^{S_H/k_B} = e^{\pi}$ coincides exactly with the expansive eigenvalue of $e^{\pi J_\varphi}$; promotion of this equality to an equivalence of microstates requires an intertwiner that preserves measure and dynamics.

62.1.8 Fibrewise confluence of HMT–MD responses: vacuum, action, gravity, information, mixing, memory, and cosmology

Theorem 62.3 (Confluence of HMT–MD responses)**.** *Given the enriched state X and the primitives declared in each reader, the publications of vacuum, action, gravity, information, mixing, screen, helical memory, and cosmology are the projections or compositions defined on the fiber product of graphs equation (62.4). Their cross-relations are generated by equations (62.12), (62.20), (62.21), (62.24), (62.26), (62.28), (62.29) y (62.33). Every numerical evaluation is terminal, and every oriented memory remains in the factor that generates it.*

Proof. The construction of $\mathfrak{M}_X$ fixes the common antecedent. The vacuum equations follow from the functional calculation of T; the electroweak equations follow from D and $Q(D)$; the electrogravitational form follows from the two identities of the Planck pair; the reconstruction 90/120 results from inverting an integral matrix of determinant 30; the informational orientation follows from the logarithm of ρ_y; the screen energy results from the unique response in $Q_\square$; the screw follows from the two Weyl and Pell covariances; and the horizon equality follows from the geometric formulas of de Sitter specialized at $R = \ell_P$. No proof uses the terminal decimal to select the branch. The horizontal independence theorem prevents cross-relations from being converted into unproved factorizations. □

62.1.9 Corollary of metrological confluence between the HMT and SI realizations

Every output admits the inseparable quintuple

$$\mathcal{K}(P) = \big(\text{antecedent, equation, invariant, meaning, terminal value}\big). \tag{62.35}$$

The volume's metrological atlas enumerates these quintuples. Its probative content is as follows: the antecedent fixes the genealogy; the equation fixes the operation; the invariant demonstrates what survives; the meaning makes the physical reading explicit; the terminal value enables external recognition. Separating one column destroys causal information; preserving all five permits insertion of the result into a chart of units without converting that chart into a foundation.

Estatuto probatorio

The fiber product, the algebraic identities, and the horizontal-independence theorem constitute an exact formalization. The internal equations cited retain the proved status of the chapters containing their complete proofs. The Einstein–Maxwell, de Sitter, Einstein–Cartan, and electroweak readings remain at their declared interfaces when they require an additional realizer. The theorem organizes those layers without promoting them by numerical similarity.

Falsification criterion

Confluence is refuted if two components attributed to the same element of $\mathfrak{M}_X$ actually arise from incompatible states, if one of the generating identities fails, if a terminal evaluation enters into the selection of its own antecedent, or if a memory distinguished by another reader is lost. A purported horizontal factorization is refuted by any pair of states with the same intermediate reader and different final outputs. Physical promotions are additionally tested against their own realizers, gauge identities, Bianchi identities, refinement, and boundary conditions.

62.2 Discrete Physical Realization via Fiber Product and Cartan Entanglement

The common fiber product, its positive and oriented components, reversible localization, and smooth-promotion criterion provide the material intertwiner between the abstract confluence and its physical realizations. The development is preserved in full, with its obstructions explicit.

62.2.1 Discrete physical realization: positive and oriented readings on TPK routes, common domain, and reversible localization

The spectral form, the Hilbert realization, the dimensional section, and Cartan transport are not decorations appended to a classical output. They are four coordinated representations of the same enriched TPK route. To express that causal unity, their common domain must first be constructed; it is not sufficient to write four arrows with the same source symbol.

62.2.1.1 Common domain as a fiber product

Let $\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}$ be the category of prepared TPK states and registered routes compatible with their endpoints, boundary, and restrictions. Let

$$\mathsf{D}_{\mathrm{sp}} := \mathsf{SurvPath}_{\mathrm{HMT}}, \qquad \mathsf{D}_Q := \mathrm{Dom}(Q), \qquad \mathsf{D}_D := \mathrm{Dom}(\mathfrak{D}_{\mathrm{HMT}}), \qquad \mathsf{D}_C := \mathrm{Dom}(\rho_C^{\mathrm{disc}}),$$

with their faithful forgetful functors

$$U_i : \mathsf{D}_i \longrightarrow \mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}} \qquad (i \in \{\mathrm{sp}, Q, D, C\}).$$

Each U_i forgets only the realization and preserves the underlying TPK state and route. We define

$$\mathsf{P}^{+}_{\mathrm{CT}} := \mathsf{D}_{\mathrm{sp}} \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_Q \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_D \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_C. \tag{62.36}$$

An object is therefore a prepared state equipped with the four realizations over the same antecedent; an arrow is a recorded route whose underlying image coincides in the four factors. If the presentations are identified only up to isomorphism, the corresponding bicategorical fiber product is used; in the fixed presentation of the record the strict fiber product of (62.36) is adopted.

Proposition 62.4 (Existence of an object in the common domain)**.** *The category $\mathsf{P}^{+}_{\mathrm{CT}}$ is nonempty. It is not necessary to specialize the central electronic route in order to prove this: any certified coinductive section, equipped with its identity arrow and its neutral data, admits compatible lifts to the four domains of* (62.36).

Proof. The theorem 8.54 provides, for example, a prepared surviving section x_π. Its identity id_{x_π} is simultaneously: a surviving route; a morphism of $\mathsf{P}_{\mathrm{TPK}}$, which Q sends to the bounded identity of $Q(x_\pi)$; the empty route with null signature, which the theorem 59.5 sends to $(0, 0, 0, 1)$; and the identity of the groupoid, which the theorem 82.10 sends to the neutral Poincare element $(I, 0)$. These four lifts forget to the same object x_π and the same morphism id_{x_π}. Their quadruple defines, by the fiber-product property, an object of $\mathsf{P}^{+}_{\mathrm{CT}}$. □

Definition 62.5 (Adapters to the common domain)**.** The four adapters are the canonical projections

$$F_{\mathrm{sp}} : \mathsf{P}^{+}_{\mathrm{CT}} \longrightarrow \mathsf{SurvPath}_{\mathrm{HMT}},$$
$$F_{Q} : \mathsf{P}^{+}_{\mathrm{CT}} \longrightarrow \mathrm{Dom}(Q),$$
$$F_{D} : \mathsf{P}^{+}_{\mathrm{CT}} \longrightarrow \mathrm{Dom}(\mathfrak{D}_{\mathrm{HMT}}),$$
$$F_{C} : \mathsf{P}^{+}_{\mathrm{CT}} \longrightarrow \mathrm{Dom}(\rho^{\mathrm{disc}}_{C}).$$

In particular, F_{sp} preserves the compatible family of finite restrictions of the section and the route; it does not reconstruct that family from its spectrum.

Lemma 62.6 (Functoriality of the adapters)**.** *The four adapters preserve identities and composition.*

Proof. The identity of an object of the fibered product is the quadruple of identities on the same TPK state; each projection returns the identity of the factor. Composition is defined componentwise between quadruples that project onto the same concatenation of routes. Projecting before or after composition gives, by definition, the same result. □

62.2.1.2 4 *Components and Positive Product*

The spectral, Hilbertian, dimensional, and Cartan realization theorems provide

$$\mathfrak{S} : \mathsf{SurvPath}_{\mathrm{HMT}} \longrightarrow \mathbf{SpecRoute}, \qquad Q : \mathrm{Dom}(Q) \longrightarrow \mathsf{Hilb}_{\mathbb{R},J},$$
$$\mathfrak{D}_{\mathrm{HMT}} : \mathrm{Dom}(\mathfrak{D}_{\mathrm{HMT}}) \longrightarrow \mathbf{B}\mathfrak{M}^{+}_{D}, \qquad \rho^{\mathrm{disc}}_{C} : \mathrm{Dom}(\rho^{\mathrm{disc}}_{C}) \longrightarrow \mathbf{B}G_{C},$$

where

$$G_{C} := \mathrm{Spin}^{+}(1,3) \ltimes \mathbb{R}^{1,3}$$

and

$$\mathfrak{M}^{+}_{D} := \mathbb{N} \times \mathbb{R}^{2}_{\geq 0} \times \mathbb{R}_{>0}, \qquad (n,a,b,\lambda) \odot (n',a',b',\lambda') = (n+n', a+a', b+b', \lambda\lambda'). \tag{62.37}$$

Here $\mathbf{B}M$ is the one-object category associated with the monoid M. The first functor is that of theorem 59.16; the second is the Hilbert realization defined in the postulates chapter; the third is theorem 59.5; and the fourth is theorem 82.10.

We define the common constraints

$$\mathfrak{S}_{+} := \mathfrak{S} \circ F_{\mathrm{sp}}, \qquad Q_{+} := Q \circ F_{Q}, \qquad \mathfrak{D}_{+} := \mathfrak{D}_{\mathrm{HMT}} \circ F_{D}, \qquad \rho^{\mathrm{disc}}_{C,+} := \rho^{\mathrm{disc}}_{C} \circ F_{C}.$$

Theorem 62.7 (Positive discrete realization on the common domain)**.** *The map*

$$\mathfrak{R}^{\mathrm{disc},+}_{\mathrm{MD}} := (\mathfrak{S}_{+}, Q_{+}, \mathfrak{D}_{+}, \rho^{\mathrm{disc}}_{C,+}) \tag{62.38}$$

is a functor

$$\mathsf{P}^{+}_{\mathrm{CT}} \longrightarrow \mathbf{SpecRoute} \times \mathsf{Hilb}_{\mathbb{R},J} \times \mathbf{B}\mathfrak{M}^{+}_{D} \times \mathbf{B}G_{C}.$$

It is not asserted that every TPK route belongs to $\mathsf{P}^{+}_{\mathrm{CT}}$.

Proof. By lemma 62.6, each projection F_i is a functor; by the cited theorems, so are $\mathfrak{S}, Q, \mathfrak{D}_{\mathrm{HMT}}$ and ρ^{disc}_{C} on their declared domains. Their compositions therefore preserve identities and concatenation. Composition in the product codomain is computed componentwise, which proves (62.38). □

The Hilbert component has general target $\mathsf{Hilb}_{\mathbb{R},J}$, whose morphisms are bounded real operators intertwining the complex structures. Let $\mathsf{P}^{u}_{\mathrm{CT}} \subseteq \mathsf{P}^{+}_{\mathrm{CT}}$ be the subcategory of arrows $\gamma : x \to y$ for which

$$Q_+(\gamma)^* Q_+(\gamma) = I_{Q_+(x)}, \qquad Q_+(\gamma) Q_+(\gamma)^* = I_{Q_+(y)}. \tag{62.39}$$

The identities and products of unitary operators are again unitary; hence this condition defines a subcategory, and only within it is obtained

$$\mathcal{U}_{\mathrm{reg}} := Q_+\big|_{\mathsf{P}^u_{\mathrm{CT}}} : \mathsf{P}^u_{\mathrm{CT}} \longrightarrow \mathsf{UHilb}_{\mathbb{R},J}. \tag{62.40}$$

One-sided invertibility or norm conservation on a subset does not replace the two identities of (62.39).

The seven-entry notation decomposes into the four typed components: Q is Q_+; U is the restriction (62.40); A is the action coordinate of $\mathfrak{D}_+$; C is the conjugation declared on the subdomain where it intertwines the Hilbert component and orientation; $\mathcal{E}$ and $\mathcal{B}$ are constitutive readers subordinated to the dimensional data; and N_{sp} is a quadratic property of the split realization. None of the final four is added to the product as a fifth functor without a domain and codomain.

62.2.1.3 Positive and oriented readings

Let $e \mapsto e^\vee$ be edge reversal in the underlying directed graph. In $\mathsf{P}^+_{\mathrm{CT}}$, $e^\vee$ is another edge and is not yet declared the categorical inverse of e. Having fixed a weight $w(e) = w(e^\vee) > 0$, we define on a route $\gamma = e_1 \cdots e_r$

$$V_+(\gamma) := \sum_{j=1}^{r} w(e_j), \qquad V_{\mathrm{or}}(\gamma) := \sum_{j=1}^{r} \varepsilon(e_j) w(\underline{e}_j),$$

where $\underline{e}_j$ is the unoriented edge and $\varepsilon(e^\vee) = -\varepsilon(e)$. The first reader preserves total positive variation; the second, net oriented transport. Both are additive under concatenation and receive the same TPK route.

Proposition 62.8 (No factorization of the positive reader by the oriented)**.** *Suppose that the identity and the loop $ee^\vee := e^\vee \circ e$ belong to the constructed domain. There is no function H on* $\operatorname{im} V_{\mathrm{or}}$ *such that $V_+ = H \circ V_{\mathrm{or}}$.*

Proof. We have

$$V_{\mathrm{or}}(\mathrm{id}) = 0 = V_{\mathrm{or}}(ee^\vee), \qquad V_+(\mathrm{id}) = 0, \qquad V_+(ee^\vee) = 2w(e) > 0.$$

The same input 0 would force $H(0)$ to take two distinct values. □

This result is a concrete nonfactorization in the constructed domain; it is not a universal theorem about every possible enriched intertwiner. In particular, it does not authorize erasing a reader. The unit lies in the common TPK antecedent and not in a horizontal compression between its outputs.

62.2.1.4 Reversible localization and oriented realization

Let $\mathsf{P}^+_{\mathrm{CT,rev}}$ be the subcategory generated by the edges for which the following four conditions have been verified:

1. $\mathfrak{S}_+(e)$ is an isomorphism of **SpecRoute** and $\mathfrak{S}_+(e^\vee) = \mathfrak{S}_+(e)^{-1}$;
2. $Q_+(e)$ satisfies (62.39) and $Q_+(e^\vee) = Q_+(e)^*$;
3. the oriented dimensional datum arises from an additive cochain with $d_{\mathrm{or}}(e^\vee) = -d_{\mathrm{or}}(e)$ and takes values in $\mathrm{Gr}(\mathfrak{M}^+_D)$;
4. the Cartan cocycles are normalized, additive, and antisymmetric under reversal.

We form the groupoid

$$\Pi_\vee(\mathsf{P}^+_{\mathrm{CT,rev}})$$

obtained from the groupoid completion by additionally imposing $[e^\vee] = [e]^{-1}$. The oriented dimensional component takes values in

$$\mathrm{Gr}(\mathfrak{M}_D^+) \cong \mathbb{Z} \times \mathbb{R}^2 \times \mathbb{R}_{>0}, \tag{62.41}$$

with inverse $(n, a, b, \lambda)^{-1} = (-n, -a, -b, \lambda^{-1})$. This signed reader is not the positive magnitude V_+ relabeled: its values on the reverse edges are distinct.

For the Cartan component, let c_g, c_s be cocycles as in item 4, let $R_4 \in \mathrm{Spin}^+(1,3)$, let $R_4 u = u$, and let $\ell_0 > 0$. Then

$$\rho_C^{\mathrm{disc}}(\gamma) = \big(R_4^{c_g(\gamma)}, \ell_0 c_s(\gamma) u\big).$$

The law $(R, a)(S, b) = (RS, a + Rb)$, the equality $R_4 u = u$, and the additivity of the cocycles give

$$\rho_C^{\mathrm{disc}}(\gamma_2\gamma_1) = \rho_C^{\mathrm{disc}}(\gamma_2)\rho_C^{\mathrm{disc}}(\gamma_1), \qquad \rho_C^{\mathrm{disc}}(\gamma^\vee) = \rho_C^{\mathrm{disc}}(\gamma)^{-1}.$$

Theorem 62.9 (Discrete oriented realization)**.** *Under the four preceding conditions, the components descend uniquely to a functor*

$$\mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc,or}} : \Pi_\vee(\mathsf{P}_{\mathrm{CT,rev}}^+) \longrightarrow \mathrm{Core}(\mathbf{SpecRoute}) \times \mathsf{UHilb}_{\mathbb{R},J} \times \mathbf{B}\,\mathrm{Gr}(\mathfrak{M}_D^+) \times \mathbf{B}G_C.$$

In particular,

$$\mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc,or}}(\gamma^{-1}) = \mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc,or}}(\gamma)^{-1}.$$

Proof. Conditions 1 and 2 make the spectral and Hilbert images invertible; condition 3 takes values in a group; and the Cartan component already takes values in G_C. All four respect the generating relation $[e^\vee] = [e]^{-1}$. By the universal property of groupoid localization, each descends uniquely; their product is the indicated functor. The inversion identity is verified componentwise. □

The positive reader $\mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc},+}$ and the oriented reader $\mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc,or}}$ are siblings: neither is defined as a compression of the other. The subsequent passage from an oriented value to its modulus is not, in general, monoidal and coincides with a positive reading only on a cone without cancellation. Likewise, this pair does not replace the foundational double projection: the Archimedean evaluation and the Paley–Witt–Golay–Leech–$V^\natural$–Monster–Moonshine branch remain sibling readers of the same enriched state. The four components constructed in this section replace neither of those two projections.

62.2.1.5 Cartan Entanglement and Soft Limit

Let

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1} e \\ 0 & 0 \end{pmatrix}$$

a Cartan connection declared. The equation

$$\mathrm{Hol}_{\mathcal{A}_{\ell_0}}\big(\mathfrak{R}_C(\gamma)\big) = \rho_C\big(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)\big) \tag{62.42}$$

is exact in the discrete model when both holonomies are defined by the same ordered product of edges.

Comparison Criterion 62.10 (Promotion to a smooth realization)**.** The equation (62.42) defines a smooth prolongation only if subdivision independence, convergence of the ordered product, and local recovery of a co-tetrad and a connection with the declared domains and regularity are also proved.

The term ‘physical’ means here that the four components publish spectrum, state realization, dimensions, and Cartan transport without losing their TPK antecedent. It does not assert uniqueness, equivalence of categories, coverage of every route, an automatic SI chart, or a complete field theory.

Comparison Criterion 62.11 (Obstructions to positive, unitary, and oriented realizations)**.** The positive realization is not defined if any of the four adapters is absent, if their images do not have the same underlying TPK route, or if a component does not preserve identity and composition. The unitary restriction does not exist if either of the two equalities in (62.39) fails. The oriented realization does not

descend to the groupoid if a spectral image is not isomorphic, if a localized relation changes its image, if a positive magnitude is treated as an inverse, if a reversal does not change the sign of the oriented data, or if the Cartan cocycle ceases to be normalized, additive, or antisymmetric. No compatible smooth prolongation exists if the result depends on the subdivision or if the limit does not recover the cotetrad and connection. Any use of an external coordinate to select the route violates the constructed domain.

Domain, codomain, and status of the HMT–MD confluent equations The positive product is proved on the common fiber product, and the oriented realization on reversible localization under the four explicit conditions. Extending the domain to other routes requires constructing their four lifts over a common antecedent. Smooth prolongation additionally requires the subdivision, convergence, and local recovery properties of test criterion 62.10; a finite verification does not replace those properties.

From the Cartan–Holst realization to horizon–area–information confluence through conservation of action The first constitutive realization of this confluence is the electromagnetic–electroweak vacuum, where the symmetric, antisymmetric, and determinantal functions publish propagation and couplings.

62.3 Planck pair, universal tension, and gravitational compliance

62.3.1 Planck dimensional pair (Q, ℓ): $Q\ell = \hbar c$, $\ell/Q = G/c^4$, and unique reconstruction

Let t_0 be the chronological unit of the CT108 section, and let c be the causal section selected by the constitutive reader. We define

$$t_P = \frac{54}{\pi} t_0, \qquad \ell = \ell_P = c t_P = \frac{54}{\pi} c t_0,$$

and the energy quantum

$$Q = E_P = \frac{\hbar}{t_P} = \frac{h}{108 t_0}.$$

The periodicity $T_{108} = 108 t_0$ verifies

$$T_{108} = 2\pi t_P, \qquad Q T_{108} = h.$$

From these definitions, the first identity of the pair is deduced:

$$\boxed{Q\ell = \hbar c.} \tag{62.43}$$

The circular gravitational realization determines

$$G = \left(\frac{54}{\pi}\right)^2 \frac{c^5 t_0^2}{\hbar}.$$

Substituting $\ell = (54/\pi) c t_0$ and $Q = \hbar / t_P$ yields the second identity:

$$\boxed{\frac{\ell}{Q} = \frac{G}{c^4}.} \tag{62.44}$$

The equations (62.43) and (62.44) are algebraically independent as product and quotient relations. They uniquely reconstruct

$$Q = \sqrt{\frac{\hbar c^5}{G}}, \qquad \ell = \sqrt{\frac{G\hbar}{c^3}}.$$

Theorem 62.12 (Planck Pair Closure)**.** *In the circular CT108 realization, the positive pair* (Q, ℓ) *is the unique solution of*

$$Q\ell = \hbar c, \qquad \ell/Q = G/c^4.$$

Satisfies, moreover,

$$GQ = c^4\ell, \qquad GQ^2 = \hbar c^5, \qquad G\hbar = c^3\ell^2.$$

Proof. Positivity permits multiplication and division of the two equations without ambiguity of sign. The first additional equality follows from $\ell/Q = G/c^4$; the second results from multiplying it by Q^2, and the third from multiplying $\ell/Q = G/c^4$ by $Q\ell = \hbar c$. Reconstruction by positive roots proves uniqueness. □

62.3.2 Reciprocity between Planck tension and compliance and conservation of the action product

The pair defines two reciprocal responses:

$$\mathscr{T}_P := \frac{Q}{\ell} = \frac{c^4}{G}, \qquad \mathscr{C}_P := \frac{\ell}{Q} = \frac{G}{c^4}. \tag{62.45}$$

The first has the dimension of force; the second, the dimension of gravitational compliance. They satisfy

$$\mathscr{T}_P\mathscr{C}_P = 1.$$

The Einstein equation is then written as a constitutive law:

$$\boxed{G_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi\mathscr{C}_P T_{\mu\nu}.} \tag{62.46}$$

Matter supplies tension–energy, and geometry responds through $\mathscr{C}_P$. The constant G publishes the curvature capacity per unit of tension in the chosen causal chart.

In the Newtonian regime, for an energy density ε,

$$\nabla^2\left(\frac{\Phi}{c^2}\right) = 4\pi\mathscr{C}_P\varepsilon.$$

The Einstein–Hilbert action is normalized by the structural area:

$$\frac{S_{\mathrm{EH}}}{\hbar} = \frac{1}{16\pi\ell^2}\int_{\mathcal{M}} (R - 2\Lambda)\sqrt{-g}\,\mathrm{d}^4x. \tag{62.47}$$

The scalar response and the tensor response are distinct publications of the same compliance. The former uses $4\pi\mathscr{C}_P$; the latter, $8\pi\mathscr{C}_P$. Upon inserting CT108,

$$2\pi\mathscr{C}_P = 108\frac{ct_0}{Q}, \qquad 4\pi\mathscr{C}_P = 216\frac{ct_0}{Q}, \qquad 8\pi\mathscr{C}_P = 432\frac{ct_0}{Q}.$$

The progression $108 \to 216 \to 432$ follows from the geometric factors. The coincidence of 432 with the multiplicity of the transverse region of π constitutes a structured compatibility; its promotion requires an incidence map that transports the genealogical multiplicity to the Einstein tensor.

62.3.3 Ternary Informational Quantum $\log 3$ and Capacity of the Qutrit Cell

The thermodynamic relation of the CT108 section is

$$\boxed{Q = k_B \Theta_{\mathrm{clk}} \log 3.} \tag{62.48}$$

In this equation, $\log 3$ is the entropy of an equiprobable ternary alternative; Θ_{clk} fixes the thermal chart and Q publishes the energy of the cycle. The combination with theorem 62.12 yields

$$\boxed{G k_B \Theta_{\mathrm{clk}} \log 3 = c^4 \ell.} \tag{62.49}$$

Gravity transforms the informational quantum of the clock into a length of geometric response. Equivalently,

$$\ell = \mathscr{C}_P k_B \Theta_{\mathrm{clk}} \log 3.$$

This equality separates the dimensionless content $\log 3$, the thermometric frame $k_B \Theta_{\mathrm{clk}}$, and the geometric compliance.

62.3.4 Covariance of bidirectional readers under sheet inversion and temporal conjugation

Let $\hbar_{\mathrm{pre}}$ and $\hbar_{\mathrm{ret}}$ be the two oriented sections of the action line, related by a positive quotient R_{act}:

$$\frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = R_{\mathrm{act}}.$$

The invariance of ℓ obliga to

$$\frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}.$$

Therefore,

$$G_\sigma \hbar_\sigma = c^3 \ell^2 \qquad (\sigma \in \{\mathrm{pre}, \mathrm{ret}\}). \tag{62.50}$$

The action preserves the orientation of the route; its product with the gravitational response preserves the area. This covariance makes ℓ^2 the geometric invariant of the bidirectional inversion.

62.3.5 Constitutive vacuum and causal closure

The operator of vacuum proporciona

$$c_{\mathrm{vac}}^{-2} = \mu \varepsilon.$$

The Planck pair provides a second causal section:

$$c_{\mathrm{int}} = \frac{Q \ell}{\hbar}.$$

We define the sewing scalar

$$\Xi_c = \frac{Q \ell}{\hbar} \sqrt{\mu \varepsilon} = \frac{c_{\mathrm{int}}}{c_{\mathrm{vac}}}. \tag{62.51}$$

The equality $\Xi_c = 1$ is necessary and sufficient for both readers to publish the same causal cone. Under this seam,

$$\boxed{G = \left(\frac{54}{\pi}\right)^2 \frac{t_0^2}{\hbar(\mu\varepsilon)^{5/2}}.} \tag{62.52}$$

Proof. The relation $c = (\mu\varepsilon)^{-1/2}$ gives $c^5 = (\mu\varepsilon)^{-5/2}$. Substituting it into the circular selector of G yields (62.52). □

The product $\mu\varepsilon$ governs the causal cone and the gravitational response; the quotient $\mu/\varepsilon = Z^2$ governs impedance and orientation. Both contents follow from the same bilayer operator and preserve distinct functions.

62.3.6 Machian factorization of the local inertial response through the trace of the global closure: $\mathcal{I}_v = \overline{\mathcal{I}}_v \circ b$

A local energy E determines the dimensionless coordinate

$$\xi_E(E) = \frac{E}{Q}.$$

The gravitational coupling of two energies is

$$\alpha_G(E_1, E_2) = \frac{E_1 E_2}{Q^2}. \tag{62.53}$$

The reference Q belongs to the global closure clock. Local inertia is therefore evaluated against a scale produced by the complete genealogy. This dependence does not posit an instantaneous action of the universe upon the body: it establishes an operatorial factorization of the local response by the global closure class.

Estatuto probatorio

The identities of the pair, the tension, the compliance, and the covariance $G\hbar$ are exact in the declared circular CT108 realization. The identification $c_{\mathrm{vac}} = c_{\mathrm{int}}$ is a typed physical interface; its content is concentrated in the map of causal lines whose evaluation is $\Xi_c = 1$.

Falsification criterion

The closure of this chapter is refuted by: a distinct positive pair that simultaneously satisfies the two governing equations; the loss of $G\hbar = c^3\ell^2$ under inversion of the action; a section of the vacuum that does not satisfy $c^{-2} = \mu\varepsilon$; or a frame transport for which $\Xi_c \neq 1$.

62.4 Electrogravitational Bilinear Form and Cross-Response Equations

62.4.1 Internal source coordinates

Let Z be the impedance section of the vacuum and let (Q, ℓ) be the pair from the preceding chapter. To a charge q and an energy E we associate

$$\xi_q(q) = \sqrt{\frac{Z}{4\pi\hbar}}\, q, \qquad \xi_E(E) = \frac{E}{Q}.$$

The internal source vector is

$$X(q, E) = \begin{pmatrix} \xi_q(q) \\ \xi_E(E) \end{pmatrix}, \qquad \eta_{1,1} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The form $X_1^{\mathsf{T}}\eta_{1,1}X_2$ separates electrical orientation and gravitational closure within a single dimensionless plane.

62.4.2 Static unification of the potentials

Theorem 62.13 (Electrogravitational form)**.** *If $Zc = \varepsilon^{-1}$, $E_i = m_i c^2$ and $Q\ell = \hbar c$, then*

$$\boxed{V_{12}(r) = \frac{Q\ell}{r} X(q_1, E_1)^{\mathsf{T}} \eta_{1,1} X(q_2, E_2)} \tag{62.54}$$

is exactly the sum of the Coulomb potential and the Newton potential.

Proof. The electric term is

$$\frac{Q\ell}{r}\frac{Zq_1q_2}{4\pi\hbar} = \frac{Zcq_1q_2}{4\pi r} = \frac{q_1q_2}{4\pi\varepsilon r}.$$

The term gravitational is

$$-\frac{Q\ell}{r}\frac{E_1E_2}{Q^2} = -\frac{\ell}{Q}\frac{E_1E_2}{r} = -\frac{G}{c^4}\frac{m_1m_2c^4}{r} = -\frac{Gm_1m_2}{r}.$$

□

The associated radial force takes the form

$$F_{12}(r) = \frac{Q}{\ell}\left(\frac{\ell}{r}\right)^2 X_1^{\mathsf{T}}\eta_{1,1}X_2. \tag{62.55}$$

The factor $Q/\ell = \mathscr{T}_P$ is the universal tension; the dimensionless form determines the intensity and sign of its publication.

62.4.3 Cone of extremality of constitutive responses and classification of its rays

For a single source, the discriminant

$$\Delta_{\mathrm{EMG}}(q, E) = E^2 - \mathcal{Q}_e(q)^2, \qquad \mathcal{Q}_e(q) = Q\sqrt{\frac{Z}{4\pi\hbar}}\, q,$$

induce the three sectors

$$\Delta_{\mathrm{EMG}} > 0, \qquad \Delta_{\mathrm{EMG}} = 0, \qquad \Delta_{\mathrm{EMG}} < 0.$$

The condition null is equivalent to

$$E^2 = \mathcal{Q}_e(q)^2 \quad \Longleftrightarrow \quad Gm^2 = \frac{q^2}{4\pi\varepsilon}. \tag{62.56}$$

It is the condition of electrogravitational extremality in the Reissner–Nordström normalization. Here the trit acquires a static realization: subextremality, extreme threshold and superextremality are the three signs of the same quadratic form.

For the elementary charge constructed by

$$e^2 = \frac{4\pi\alpha_{\mathrm{HMT}}\hbar}{Z},$$

the coordinate satisfies

$$\boxed{\xi_q(e)^2 = \alpha_{\mathrm{HMT}}.} \tag{62.57}$$

This equality locates the central charge in the source plane without using the electron mass or importing its complete theory.

62.4.4 Einstein–Maxwell Coefficient

Write

$$\kappa = \frac{8\pi G}{c^4} = 8\pi \mathscr{C}_P.$$

In a convention where the electromagnetic tensor is expressed as $T^{\mathrm{EM}}_{\mu\nu} = \mu^{-1} Q_{\mu\nu}(F, g)$, the gravitational coefficient of the quadratic form is κ/μ. Using

$$\ell^2 = \frac{G\hbar}{c^3}, \qquad Z = \mu c, \qquad e^2 = \frac{4\pi\alpha\hbar}{Z},$$

we obtain

$$\boxed{\frac{\hbar^2}{8\pi\ell^2}\frac{(\kappa/\mu)}{e^2} = \frac{1}{4\pi\alpha_{\mathrm{HMT}}}.} \tag{62.58}$$

Proof. First,

$$\frac{\kappa}{\mu} = \frac{8\pi G}{c^4\mu} = \frac{8\pi\ell^2}{\hbar\mu c} = \frac{8\pi\ell^2}{\hbar Z}.$$

Al dividir by $e^2 = 4\pi\alpha\hbar/Z$ and multiplicar by $\hbar^2/(8\pi\ell^2)$ remains $1/(4\pi\alpha)$. □

At the rationalized electroweak interface,

$$g^2 = \frac{4\pi\alpha}{1 - D_A}, \qquad g'^2 = \frac{4\pi\alpha}{D_A},$$

and therefore

$$\boxed{\frac{\hbar^2}{8\pi\ell^2}\frac{(\kappa/\mu)}{e^2} = \frac{1}{g^2} + \frac{1}{g'^2}.} \tag{62.59}$$

The equality requires the gravity, vacuum, charge, and gauge mixing readers to commute. Within the present graph, e, g, g' descend from α_{HMT}; the equation is a cross-check, not a second derivation independent of α.

62.4.5 Polygon of fine structure publications

The dodecaphasic macro-object is published through the system

$$\boxed{\alpha_{\mathrm{HMT}} = \frac{Ze^2}{4\pi\hbar} = \frac{ZG_0}{4} = \frac{Z}{2R_K} = -\frac{9}{100\pi}\log D_A = \frac{(1 - D_A)g^2}{4\pi} = \frac{D_A g'^2}{4\pi}.} \tag{62.60}$$

The first causal construction of α remains the signed wheel, the seal, and the carry. The subsequent equalities are metrological publications or compatibility checks. Elimination of variables yields

$$(1 - D_A)g^2 = D_A g'^2 = \frac{Ze^2}{\hbar} = \pi G_0 Z = \frac{2\pi Z}{R_K}.$$

The dual form is

$$\frac{1}{g^2}+\frac{1}{g'^2}=\frac{\hbar}{Ze^2}=\frac{R_K}{2\pi Z}=\frac{1}{\pi G_0 Z}.$$

Each metrological cycle must be marked as a *round trip*: if e, R_K, or G_0 were defined from α, their inverse substitution checks coherence but adds no selective information.

62.4.6 Covariance of action inversion

Under the bidirectional transformation,

$$\frac{e^2_{\mathrm{pre}}}{e^2_{\mathrm{ret}}}=R_{\mathrm{act}},\qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}}=R^{-1}_{\mathrm{act}}.$$

Therefore,

$$\boxed{G_\sigma e^2_\sigma = \text{sheet constant.}} \tag{62.61}$$

In constitutive form,

$$\frac{Ze^2_\sigma G_\sigma}{c^5 t_0^2}=4\pi\theta_{108}\alpha_{\mathrm{HMT}},\qquad \theta_{108}=\left(\frac{54}{\pi}\right)^2.$$

The charge preserves the orientation of action, and the gravitational response compensates for it; their product belongs to the shared geometry.

62.4.7 Tensorial representation of the gravitational carrier and transverse reduction of its degrees of freedom

The bilinear form (62.54) closes the static sector. Its promotion to complete dynamics requires a realizer

$$\mathcal{R}_{\mathrm{EM}}:\mathcal{X}^{\mathrm{enr}}_{\mathrm{TPK}}\longrightarrow (e^I{}_\mu,\omega^{IJ}{}_\mu,A_\mu)$$

that preserves the Bianchi identity, Maxwell's equations, current conservation, and the boundary terms. The identity (62.59) fixes the coefficient that this realizer must publish; it does not replace its differential equations.

Falsification criterion

The electrogravitational form is refuted by: a different coefficient in Coulomb or Newton upon expanding (62.54); a null cone that fails to reproduce (62.56); the loss of (62.58); or the use of a publication descended from α as a retroactive selector of its dodecaphase branch.

Causal structure of the electrogravitational confluence. The composition proved in this chapter is organized into five typed stages. The enriched state first supplies the phase α_{HMT} and its orientation. The constitutive operator then publishes e, g, and g' in their respective codomains. The gravitational closure determines G and the chronology θ_{108}. Identities (62.54)–(62.59) coordinate these publications through a common coefficient. Finally, $\mathcal{R}_{\mathrm{EM}}$ transports the result to the fields $(e^I{}_\mu,\omega^{IJ}{}_\mu,A_\mu)$, preserving the differential identities and boundary terms. This factorization fixes the antecedence of the HMT construction with respect to its tensorial realization and prepares the constitutive relations developed in the following chapter.

Chapter 63

Constitutive realization of the vacuum and electromagnetic–electroweak propagation

The bidirectional structure of action induces constitutive vacuum relations and separates the propagation, impedance, charge, and electroweak mixing sectors. SI references appear as a subsequent realization of internal functions already determined.

63.1 Realization of the Electromagnetic Bidirectional Action Operator: ε, μ, Z, and c

63.1.1 Derivation of the action scale from the dodecaphasic state

The action decade is determined intrinsically, without adopting it as an inherited unit. The local determinantal functional is applied to the previously constructed HMT output α_{HMT} and defines

$$\Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}. \tag{63.1}$$

The exponent 16 is the order of the local cokernel of the signed closure; its decimal valuation fixes

$$\mathrm{ord}_{10}(\Sigma_H) = -34. \tag{63.2}$$

The origin of the exponent can be verified within this volume. On the local orbit of four leaves, the Hadamard block acts

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{63.3}$$

Lemma 63.1 (Local index of the action line)**.** *The form normal of Smith of H_4 is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4). \tag{63.4}$$

Consequently,

$$\mathrm{coker}(H_4) \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |\mathrm{coker}(H_4)| = 16.$$

Proof. The greatest common divisor of the entries is one; that of the nonzero 2×2 minors is two; that of the 3×3 minors is four; and $|\det H_4| = 16$. The successive quotients of these determinantal divisors are $1, 2, 2, 4$, which prove equation (63.4). The product of the invariants gives the order of the cokernel. □

The norm of the section α_{HMT} over those sixteen sheets produces $\alpha_{\mathrm{HMT}}^{16}$; the self-scaling φ_{HMT} acts only once on the basis, not once per sheet. Hence equation (63.1). The certified comparisons

$$\alpha_{\mathrm{HMT}}^{16} < 10^{-34} < \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16} < 10^{-33} \tag{63.5}$$

prove, without introducing the SI unit, that the decimal order is exactly -34. The terminal evaluation begins with

$$\Sigma_H = 1.046243838104756580184229208303089\ldots \times 10^{-34}. \tag{63.6}$$

The substitution of the kernel by three copies with exponent 16^3, or the repeated application of φ on each sheet, would alter the genealogy. Both operations constitute falsification criteria rather than equivalent conventions. The causal chain that is preserved is therefore,

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to U_{12}^{\mathrm{sign}} \to \alpha_{\mathrm{HMT}} \to \Sigma_H \to 10^{-34} \mathcal{U}_S \to \{\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}}\}.$$

This volume does not rederive α_{HMT}, but develops the metrological geometry subsequent to the selection of the type and decade by Σ_H. The integer -34 is neither a mantissa nor an adjustment to the International System, but the terminal valuation of the local functional.

63.1.2 Oriented sections of the action line

The realizations before and after the return constitute two sections of the same action line:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S. \tag{63.7}$$

The common decade determines the line, while the oriented information is expressed through

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}, \qquad \xi_{\mathrm{act}} = \frac{1}{2}\log R_{\mathrm{act}}. \tag{63.8}$$

The first quantity provides a multiplicative coordinate and the second an additive coordinate of rapidity type. They do not represent two independent Planck constants, but the two orientations of the same section with respect to the return.

If $h_a = 2\pi\hbar_a$, $a \in \{\mathrm{pre}, \mathrm{ret}\}$, a quantity proportional to $h_a^{1/2}$ changes as $R_{\mathrm{act}}^{1/2}$, one proportional to $h_a^{-1/2}$ changes as $R_{\mathrm{act}}^{-1/2}$, and a quotient in which the action cancels is a bidirectional invariant.

63.1.3 Bilayer spectral decomposition of the angular operator

Let $R = R^* = R^{-1}$ be the active involution and

$$P_\pm = \frac{I \pm R}{2}, \qquad T = q_+P_+ + q_-P_-, \qquad 0 < q_+ < q_- < 1.$$

With

$$x = A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad y = C^*_{\mathrm{rad}} = \frac{\pi C^*}{180},$$

the two channels are constructed before evaluating the vacuum:

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}. \tag{63.9}$$

The exchange of sheets reverses C^*, that is, $y \mapsto -y$, and permutes $q_+ \leftrightarrow q_-$. The pair is thus the spectral reading of the same angular antecedent, not two parameters fitted separately.

Definition 63.2 (Constitutive response)**.**

$$\mathcal{V}_{90,120} = (I - T^{90})(I - T^{120})^{-1}. \tag{63.10}$$

Since $\|T\| < 1$, the denominator is positive and invertible. Functional calculus gives

$$\mathcal{V}_{90,120} = r_+P_+ + r_-P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}}. \tag{63.11}$$

The assertion of invertibility deserves to be made explicit. For each leaf, $0 < q_\pm^{120} < 1$; therefore

$$I - T^{120} = (1 - q_+^{120})P_+ + (1 - q_-^{120})P_-$$

is strictly positive and

$$(I - T^{120})^{-1} = \frac{P_+}{1 - q_+^{120}} + \frac{P_-}{1 - q_-^{120}}.$$

The response $\mathcal{V}_{90,120}$ is not obtained by solving four separate scalar equations: it is the result of the functional calculus of a single positive contraction. This observation prevents permeability, permittivity, impedance and propagation from losing their shared antecedent.

Theorem 63.3 (Joint spectral determination of the four constitutive relations)**.** *The four constituent characters*

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2, \qquad \widehat{Z} = \frac{r_-}{r_+}, \qquad \widehat{c} = \frac{1}{r_+ r_-} \tag{63.12}$$

are spectral functions of $\mathcal{V}_{90,120}$. They satisfy

$$\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}, \qquad \frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^2. \tag{63.13}$$

Proof. The identities are obtained by substituting equation (63.12). No dimensional chart nor any exterior value intervenes. □

Corollary 63.4 (Reconstruction of the two sheets)**.** *The four characters do not contain four degrees of freedom. Any of the pairs $(\widehat{\mu}, \widehat{\varepsilon})$, $(\widehat{Z}, \widehat{c})$, or $(\mathcal{E}, \mathcal{B})$ reconstructs the two positive eigenvalues:*

$$r_- = \sqrt{\widehat{\mu}} = \sqrt{\widehat{Z}/\widehat{c}}, \qquad r_+ = \sqrt{\widehat{\varepsilon}} = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \tag{63.14}$$

$$\log r_- = \frac{\mathcal{E} + \mathcal{B}}{2}, \qquad \log r_+ = \frac{\mathcal{E} - \mathcal{B}}{2}. \tag{63.15}$$

In particular, orientation is lost if only the product is retained, but is recovered by adding the quotient.

Proof. The first line is the positive root of the identities equations (63.12) y (63.13). The second inverts the linear system $\mathcal{E} = \log r_- + \log r_+$, $\mathcal{B} = \log r_- - \log r_+$. □

This corollary expresses a central property of HMT: product and quotient are complementary functionals of the same state. The product determines the propagation in common, whereas the quotient preserves the relative orientation of the inner and outer sheets.

In the V2 certificate,

$$\begin{aligned}
r_+ &= 0.99999962854824936317869522 81\ldots,\\
r_- &= 0.99972413718951836413151658 53\ldots,\\
\widehat{\varepsilon} &= 0.99999925709663670276044161 55\ldots,\\
\widehat{\mu} &= 0.99944835047932693508998155 59\ldots,\\
\widehat{Z} &= 0.99972450853893721545555434 66\ldots,\\
\widehat{c} &= 1.00027631048615752610638626 89\ldots.
\end{aligned}$$

These numerals are the terminal recognition of equation (63.10); they do not define its exponents $90, 120$.

63.1.4 Harmonic factorization of sectors 90 and 120

The harmonic semigroup is

$$\langle 90, 120\rangle = 30\langle 3, 4\rangle.$$

If $s = q^{30}$, then

$$\frac{1-q^{90}}{1-q^{120}} = \frac{1-s^3}{1-s^4} = \frac{1+s+s^2}{1+s+s^2+s^3}. \tag{63.16}$$

The identity also separates the response from its defect. If

$$F_{3\to4}(s) = \frac{1+s+s^2}{1+s+s^2+s^3}, \qquad 0 < s < 1,$$

then

$$d_{3\to4}(s) := 1 - F_{3\to4}(s) = \frac{s^3}{1+s+s^2+s^3} > 0. \tag{63.17}$$

The additional term is preserved exactly as a positive defect. Moreover,

$$F'_{3\to4}(s) = -\frac{s^2(3+2s+s^2)}{(1+s+s^2+s^3)^2} < 0. \tag{63.18}$$

Consequently, the order of the angular channels uniquely determines the order of the constitutive responses. The assignment of $\widehat{\mu}$ and $\widehat{\varepsilon}$ to the respective sheets is obtained analytically, without resorting to their decimal expansions.

Each sheet of the vacuum constitutes the exact completion from three to four terms of the same elementary mode 30. Consequently, permeability and permittivity are interpreted as two quadratic functionals of the same completion evaluated on conjugate sheets, and not as independent constitutive parameters.

Since the function $(1-q^{90})/(1-q^{120})$ decreases in $0 < q < 1$ and $q_+ < q_-$, we obtain

$$0 < r_- < r_+ < 1, \qquad 0 < \widehat{\mu} < \widehat{\varepsilon} < 1, \qquad 0 < \widehat{Z} < 1 < \widehat{c}.$$

The limits of the functional determine its geometry. When $q \to 0^+$, $F(q) \to 1$: the four readings approach unity and the memory defect disappears. When $q \to 1^-$,

$$F(q) \longrightarrow \frac{90}{120} = \frac{3}{4}.$$

The response therefore takes values in the positive interval $(3/4, 1)$. The endpoint $3/4$ is not a fitted constant: it is the quotient of the two channel lengths and the continuous realization of the three–to–four completion.

63.1.5 Sheet involution and preservation of orientation

The sheet exchange $C^* \mapsto -C^*$ acts by

$$\widehat{\mu} \longleftrightarrow \widehat{\varepsilon}, \qquad \widehat{Z} \longmapsto \widehat{Z}^{-1}, \qquad \widehat{c} \longmapsto \widehat{c}. \tag{63.19}$$

The common propagation is even; impedance preserves orientation. This distinction will reappear in Barbero and CKM: not all functionals associated with the change of sheet have the same parity.

63.1.6 Logarithmic characters and tracial compatibility

Define

$$\mathcal{E} = \log(r_+ r_-), \qquad \mathcal{B} = \log(r_-/r_+).$$

With the normalized trace $\tau = \mathrm{Tr}/2$,

$$2\tau(\log \mathcal{V}) = \mathcal{E}, \qquad -2\tau(R \log \mathcal{V}) = \mathcal{B}. \tag{63.20}$$

The pair $(\mathcal{E}, \mathcal{B})$ constitutes a linear coordinate system for the operator logarithm:

$$\log \mathcal{V} = \frac{\mathcal{E}}{2} I - \frac{\mathcal{B}}{2} R. \tag{63.21}$$

The scalar component is invariant under sheet exchange; the oriented component changes sign. This decomposition directly demonstrates the parity of propagation and the oriented character of impedance.

The nonadic amplification

$$\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$$

is compatible with the expectations $E_m = \mathrm{id} \otimes \tau_9$:

$$E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m.$$

Therefore, $\mathcal{E}$ and $\mathcal{B}$ are not peculiarities of a 2×2 matrix; they persist in the UHF tower and in its tracial closure II_1.

More precisely, for every polynomial p and afterwards, by continuity, for every continuous function on the spectrum,

$$E_m\big(p(\mathcal{V}_{m+1})\big) = p(\mathcal{V}_m). \tag{63.22}$$

Compatibility does not preserve only two numbers: it preserves the entire functional algebra generated by the response. In particular, it preserves its spectral projectors, powers, logarithm, and quadratic forms that measure the defects equation (63.17).

63.1.7 Dimensional realization of the constitutive relations

Dimensional Mechanics determines

$$Z_{\mathrm{vac}} = \widehat{Z}\, u_S u_Q^{-2}, \tag{63.23}$$

$$c_{\mathrm{vac}} = \widehat{c}\, u_C, \tag{63.24}$$

$$\mu_{\mathrm{vac}} = \widehat{\mu}\, u_S u_C^{-1} u_Q^{-2}, \tag{63.25}$$

$$\varepsilon_{\mathrm{vac}} = \widehat{\varepsilon}\, u_S^{-1} u_C^{-1} u_Q^{2}. \tag{63.26}$$

The constitutive identities hold on the straight lines:

$$\mu_{\mathrm{vac}} \varepsilon_{\mathrm{vac}} = c_{\mathrm{vac}}^{-2}, \qquad \mu_{\mathrm{vac}} / \varepsilon_{\mathrm{vac}} = Z_{\mathrm{vac}}^{2}. \tag{63.27}$$

The SI chart comes later. It is not necessary to declare c primitive and then solve $\mu\varepsilon = c^{-2}$: the three objects descend jointly from $\mathcal{V}$ and from the declared lines.

The separation of levels is expressed by the diagram

$$\begin{array}{ccccc} (A, C^*) & \longrightarrow & T & \longrightarrow & \mathcal{V} \longrightarrow (\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}) \\ \big\downarrow \text{line charts} & & & & \big\downarrow \text{final evaluation} \\ (u_S, u_Q, u_C) & \longrightarrow & (\mu_{\mathrm{vac}}, \varepsilon_{\mathrm{vac}}, Z_{\mathrm{vac}}, c_{\mathrm{vac}}) & \longrightarrow & \text{SI coordinates.} \end{array}$$

The first line is dimensionless and operatorial; the second determines types of quantity; the third selects a metrological chart. Altering the final chart changes neither the eigenvalues nor the constitutive identities.

In this precise sense, mathematical–physical unification consists in distinguishing the genealogical invariant from its coordinate system, not in removing the dimensional structure.

Proposition 63.5 (Spectral minimality)**.** *Let W be a positive two-sheet operator with simple spectrum $\{r_+, r_-\}$. If four positive characters satisfy $\mu\varepsilon = c^{-2}$ and $\mu/\varepsilon = Z^2$, if their propagation in common is determined by $c^{-1} = \det W = r_- r_+$, and if its orientation fixes $Z = r_-/r_+$, then necessarily*

$$(\mu, \varepsilon, Z, c) = \left(r_-^2, r_+^2, \frac{r_-}{r_+}, \frac{1}{r_- r_+}\right).$$

Therefore, equation (63.12) is not one parametrization among many: it is the minimal positive realization compatible with product, quotient and orientation.

Proof. From $Z = r_-/r_+$ and $c^{-1} = \det W = r_- r_+$ the positive roots are obtained uniquely roots. The two constitutive identities then force afterwards $\mu = r_-^2$ and $\varepsilon = r_+^2$. □

63.1.8 Angular determinant and Weinberg electroweak relation

The determinant of T is

$$\det T = q_+ q_- = D_A. \tag{63.28}$$

The constitutive sector of the vacuum evaluates $F(T)^2$, where $F(z) = (1 - z^{90})/(1 - z^{120})$, whereas the electroweak angular sector evaluates $\det T$. These are two functions of a common antecedent, not a horizontal factorization between constants. This distinction is developed in the section 63.2.

Falsification criterion 63.6. The block is refuted if any of these exact identities is violated: positivity of $I - T^{120}$, equality equation (63.16), relations equation (63.13), or compatibility $E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m$. An SI coincidence cannot compensate for an operator failure.

Hypothesis, domain, and conclusion

Operator, spectrum, completion $3 \longrightarrow 4$, parity, amplification, and constitutive sections form an exact internal theorem. Their assembly into a single operator is established in this formulation; the angular data and the lines, previously derived in HMT, constitute the explicit starting structure.

63.2 Angular determinant and electroweak-sector parameters

63.2.1 Constitutive and Determinantal Functions of the Angular Operator

Recall the two-sheet operator of the section 63.1,

$$T = q_+ P_+ + q_- P_-, \qquad q_- = \mathrm{e}^{-(A_{\mathrm{rad}} - C^*_{\mathrm{rad}})}, \qquad q_+ = \mathrm{e}^{-(A_{\mathrm{rad}} + C^*_{\mathrm{rad}})}. \tag{63.29}$$

The electromagnetic vacuum applies the function

$$F(T)^2, \qquad F(z) = \frac{1 - z^{90}}{1 - z^{120}}, \tag{63.30}$$

while the electroweak angular sector applies the determinant

$$\boxed{\det T = q_+ q_- = \mathrm{e}^{-2A_{\mathrm{rad}}} =: D_A.} \tag{63.31}$$

They are two sibling functional realizations of the common antecedent (A, C^*, T). The causal structure generates both from T. The subsequent reconstruction demonstrated in theorems 63.17 y 63.18 permits recovery of

$$\det T = \det\Big(F^{-1}\Big(\sqrt{F(T)^2}\Big)\Big),$$

without turning that functional inversion into the generating arrow of the electroweak sector. Structural unity resides in T, and the reconstruction makes explicit the compatibility among permeability, permittivity, and θ_W.

Under the sheet involution $C^* \mapsto -C^*$, the eigenvalues q_+, q_- are exchanged. Therefore D_A and the constitutive speed are even, while $(\widehat{\mu}, \widehat{\varepsilon})$ is exchanged and $\widehat{Z}$ is inverted. The following electroweak relation uses the even invariant.

63.2.2 Exact relation between the W and Z sectors

The angular coordinate of duration–perduration is

$$\chi_{\mathrm{dur}}(n_A, s_C) = \exp\Big(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}}\Big). \tag{63.32}$$

This coordinate is not introduced as an isolated label. Its origin is

$$\begin{aligned} \mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow \text{surviving extension} \longrightarrow \text{route} \\ \longrightarrow \text{genealogical record} \longrightarrow (n_A, s_C, \ldots) \longrightarrow \chi_{\mathrm{dur}}. \end{aligned} \tag{63.33}$$

The signatures of W, Z and H are typed quantities obtained through that chain; this chapter adopts them without selecting them from their terminal masses. In the established angular realization, the charged and neutral sectors satisfy

$$(n_A, s_C)_W = (94, -1), \qquad (n_A, s_C)_Z = (95, -1). \tag{63.34}$$

This assertion refers to the common angular component. The additional refinement coordinates of the General Mass Law are not eliminated unless the physical transducer proves their cancellation.

Theorem 63.7 (Weinberg defect in the physical-mass scheme of the angular chart)**.** *If W and Z are evaluated on the same scale section and share the refinement that accompanies equation (63.34), then*

$$\boxed{\frac{m_W^{\angle}}{m_Z^{\angle}} = \mathrm{e}^{-A_{\mathrm{rad}}} = \sqrt{D_A}, \qquad \left(\frac{m_W^{\angle}}{m_Z^{\angle}}\right)^2 = D_A.} \tag{63.35}$$

In the physical-mass scheme,

$$\boxed{\sin^2\theta_W^{\mathrm{OS,HMT}} = 1 - D_A = 0.22487088075284356981111590 35\ldots.} \tag{63.36}$$

Además,

$$\frac{m_W^{\angle}}{m_Z^{\angle}} = 0.88041417483316136701288854 59\ldots. \tag{63.37}$$

Proof. By equations (63.32) y (63.34),

$$\frac{\chi_{\mathrm{dur}}(94,-1)}{\chi_{\mathrm{dur}}(95,-1)} = \exp(-A_{\mathrm{rad}});$$

the coordinate C^* cancels because both sectors share $s_C = -1$. Squaring and using equation (63.31) yields D_A. The definition of physical masses $s_W^2 = 1 - m_W^2/m_Z^2$ yields equation (63.36). □

The principal content is the identity between two internal constructions: the determinant of the angular operator and the one-step difference in the realization W/Z. Promotion to a physical gauge selector requires an intertwiner that carries the sheets of T to the neutral basis (W^3, B) and demonstrates which refinements are preserved or cancel.

63.2.3 Gauge couplings in rationalized normalization

We define the dimensionless gauge coupling

$$e_g := \sqrt{4\pi\alpha_{\mathrm{HMT}}} = 0.30282212087175264276624426 89\ldots. \tag{63.38}$$

e_g must not be confused with a dimensional charge section e_{int}: the former is a coupling in natural units; the latter lives in the charge line of Dimensional Mechanics.

Let

$$s_W^2 = 1 - D_A, \qquad c_W^2 = D_A. \tag{63.39}$$

The convention electrodebil racionalizada to level of arbol gives

$$g = \frac{e_g}{s_W} = 2\sqrt{\frac{\pi\alpha_{\mathrm{HMT}}}{1 - D_A}} = 0.63858834273345742836470038 09\ldots, \tag{63.40}$$

$$g' = \frac{e_g}{c_W} = 2\sqrt{\frac{\pi\alpha_{\mathrm{HMT}}}{D_A}} = 0.34395416331085024293623192 57\ldots, \tag{63.41}$$

$$\frac{g'}{g} = \sqrt{D_A^{-1} - 1} = 0.53861641419660935949966109 33\ldots. \tag{63.42}$$

Proposition 63.8 (Tree-level custodial relation)**.** *At the same interface,*

$$\rho_{\mathrm{EW}}^{(0)} := \frac{(m_W^{\angle})^2}{(m_Z^{\angle})^2 c_W^2} = 1. \tag{63.43}$$

Proof. By equations (63.35) y (63.39), both the relative numerator and c_W^2 are D_A. □

The equations equations (63.40) y (63.41) are exact compositions once the physical mass scheme, rationalization, and scale have been declared. They do not assert that a change of renormalization scheme leaves their numerical values unchanged.

63.2.4 Fermi Constant in the Approximation at Tree Level

In natural units, integration of the charged propagator at low energy yields

$$\frac{G_F^{(0)}}{\sqrt{2}} = \frac{g^2}{8m_W^2}. \tag{63.44}$$

Substituting equation (63.40) gives the composition

$$\boxed{G_F^{(0)} = \frac{\pi\alpha_{\mathrm{HMT}}}{\sqrt{2}(1 - D_A)m_W^2}.} \tag{63.45}$$

By adopting the previously obtained mass

$$m_W^{\mathrm{HMT}} = 80.381592550221\ldots\ \mathrm{GeV}, \tag{63.46}$$

the terminal evaluation is

$$\boxed{G_F^{(0)} = 1.1157162817659203186621784 \times 10^{-5}\ \mathrm{GeV}^{-2}.} \tag{63.47}$$

The difference with respect to a renormalized Fermi constant is not used to choose any coefficient. Under the convention

$$G_F = \frac{\pi \alpha_{\mathrm{HMT}}}{\sqrt{2}(1 - D_A) m_W^2 (1 - \Delta r)}, \tag{63.48}$$

the remaining obligation is to derive Δr from the internal sector of loops, states, and scale. Opening the observed value of G_F to define Δr would be a calibrated reconstruction, not a prediction.

63.2.5 Higgs Coupling Oriented Dependence

In the angular chart, the relevant routes are

$$(n_A, s_C)_H = (97, 9), \qquad (n_A, s_C)_W = (94, -1). \tag{63.49}$$

Therefore,

$$\boxed{\frac{m_H^{\angle}}{m_W^{\angle}} = \frac{\chi_{\mathrm{dur}}(97, 9)}{\chi_{\mathrm{dur}}(94, -1)} = \exp\left(3A_{\mathrm{rad}} + \frac{5}{3} C^*_{\mathrm{rad}}\right) = 1.558720872123255485 64\ldots.} \tag{63.50}$$

Here, C^* does not cancel: the scalar sector preserves the orientation that the determinant $D_A = \mathrm{e}^{-2A_{\mathrm{rad}}}$ does not distinguish.

Let us take the convention of the potential

$$V(H) = -\mu_H^2 H^\dagger H + \lambda_H (H^\dagger H)^2, \tag{63.51}$$

for which

$$m_H^2 = 2\lambda_H v^2, \qquad m_W^2 = \frac{g^2 v^2}{4}. \tag{63.52}$$

Corollary 63.9 (Oriented Higgs self-coupling)**.** *At the declared tree-level interface,*

$$\boxed{\lambda_H = \frac{\pi \alpha_{\mathrm{HMT}}}{2(1 - D_A)} \exp\left(6A_{\mathrm{rad}} + \frac{10}{3} C^*_{\mathrm{rad}}\right) = 0.12384791154824668046 62\ldots.} \tag{63.53}$$

Además,

$$G_F^{(0)} m_H^2 = \sqrt{2}\, \lambda_H. \tag{63.54}$$

Proof. Dividing the two equations in equation (63.52) gives $m_H^2/m_W^2 = 8\lambda_H/g^2$. With $g^2 = 4\pi\alpha_{\mathrm{HMT}}/(1 - D_A)$ and the square of equation (63.50), we obtain equation (63.53). On the other hand, $G_F^{(0)} = 1/(\sqrt{2}v^2)$ and $m_H^2 = 2\lambda_H v^2$ imply equation (63.54). □

The value of λ_H precedes the incorporation of radiative corrections and depends on the declared convention and scale. Its structural interest is that it separates two memories: the common gauge sector uses the even invariant D_A, whereas the Higgs route explicitly retains C^*.

63.2.6 Determinantal closure of the electroweak sector: mixing, couplings, and constitutive spectrum

The complete chain of this chapter is

$$\boxed{\begin{aligned} (A, C^*) &\longrightarrow T \longrightarrow \begin{cases} F(T)^2 & \longrightarrow (\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}), \\ \det T = D_A & \longrightarrow (s_W^2, c_W^2), \end{cases} \\ (D_A, \alpha_{\mathrm{HMT}}) &\longrightarrow (e_g, g, g'), \\ (D_A, \alpha_{\mathrm{HMT}}, m_W) &\longrightarrow G_F^{(0)}, \\ (A, C^*, D_A, \alpha_{\mathrm{HMT}}) &\longrightarrow \left(\frac{m_H}{m_W}, \lambda_H\right). \end{aligned}} \tag{63.55}$$

The figure always appears at the end. Neither $\sin^2\theta_W$, nor G_F, nor λ_H is introduced as a target value for selecting A, C^* or the route signatures.

> **The same angular operator determines the vacuum through a rational function of its sheets and the electroweak defect through its determinant. The one-step difference between W and Z turns that determinant into $\sin^2\theta_W^{\mathrm{OS}} = 1 - D_A$; the Higgs route, in contrast, preserves the counterangle and preserves the orientation eliminated by the determinant.**

Falsification criterion 63.10. The Weinberg relation is refuted in its domain if the angular signatures W/Z do not differ only by $n_A : 94 \to 95$, if a refinement coordinate does not cancel at the declared interface, or if $(m_W^{\angle}/m_Z^{\angle})^2 \neq D_A$. Gauge promotion is blocked if no intertwiner with the basis (W^3, B) exists. The figures of g, g', G_F, λ_H change if the scheme or scale is altered without recording it. Using observed G_F or m_H to select Δr, the signatures, or C^* introduces feedback from the target value and invalidates the derivation. Conflating e_g with the dimensional charge constitutes a type error.

Hypothesis, domain, and conclusion

Angular determinant, quotient W/Z, and complementary Weinberg defect: *Exact internal theorem in the angular conditioned chart*. Couplings $g, g', \rho_{\mathrm{EW}}^{(0)}$, Fermi, and Higgs: *Exact Composition in the Electroweak Tree-Level Interface*. The gauge-basis intertwiner and the internal correction Δr: *Open boundary with falsification criterion*. Fermi and Higgs are not independent constants selected without target values: they are exact compositions using the signatures, the quantity m_W and the declared tree-level convention. The subsequent conventional values are *Contrast metrological external*.

From the electroweak determinant to the positive vacuum constitutive operator and its spectral completion 3→4 Once the constitutive support has been fixed, quantum evolution is reconstructed as a sum and integral of genealogies, with typed effective reduction and probabilistic publication.

63.3 Bilayer modular state and spectral resolvent

63.3.1 The angular operator as common antecedent

The constitutive operator of section 63.1 admits a prior formulation in which intensity and orientation occupy distinct coordinates of the same object. Let $R = R^* = R^{-1}$ be an involution with spectral multiplicities one and one, and let

$$P_+ = \frac{I + R}{2}, \qquad P_- = \frac{I - R}{2} \tag{63.56}$$

their projectors. For

$$x = A_{\mathrm{rad}} > 0, \qquad y = C_{\mathrm{rad}}^*, \qquad |y| < x, \tag{63.57}$$

we define the angular generator and its positive exponential by

$$K_{\angle} = xI + yR, \qquad T_{x,y} = \mathrm{e}^{-K_{\angle}} = q_+ P_+ + q_- P_-, \tag{63.58}$$

where

$$q_+ = \mathrm{e}^{-x-y}, \qquad q_- = \mathrm{e}^{-x+y}. \tag{63.59}$$

The condition $|y| < x$ places both eigenvalues in $(0, 1)$. The determinant and the spectral quotient separate the two coordinates:

$$D_A := \det T_{x,y} = q_+ q_- = \mathrm{e}^{-2x}, \qquad \varrho_{\mathrm{or}} := \frac{q_-}{q_+} = \mathrm{e}^{2y}. \tag{63.60}$$

The first character is even under sheet exchange; the second records their orientation. Recovery is immediate:

$$x = -\frac{1}{2}\log D_A, \qquad y = \frac{1}{2}\log \varrho_{\mathrm{or}}. \tag{63.61}$$

The causal provenance of x and y remains linked to state APP $\to \widehat{\mathbb{T}} \to$ TPK. In particular,

$$x = \frac{50\pi}{9}\,\mathfrak{A}_\beta, \qquad D_A = \exp\!\left(-\frac{100\pi}{9}\,\mathfrak{A}_\beta\right), \tag{63.62}$$

where $\mathfrak{A}_\beta = \alpha_{\mathrm{HMT}}$ denotes the terminal character of the already constructed dodecaphase macro-object. The coordinate y subsequently comes from the regional reader and preserves the orientation that the determinant eliminates.

Proposition 63.11 (Canonical separation of intensity and orientation)**.** *The map*

$$(x, y) \longmapsto (D_A, \varrho_{\mathrm{or}}) = (\mathrm{e}^{-2x}, \mathrm{e}^{2y})$$

is a diffeomorphism between the domain $x > 0$, $|y| < x$, and the domain

$$0 < D_A < 1, \qquad D_A < \varrho_{\mathrm{or}} < D_A^{-1}.$$

The sheet involution acts by $(D_A, \varrho_{\mathrm{or}}) \mapsto (D_A, \varrho_{\mathrm{or}}^{-1})$.

Proof. The inverse formulas are equation (63.61). The inequality $|y| < x$ is equivalent to $|\log \varrho_{\mathrm{or}}| < -\log D_A$, from which the stated interval is obtained. Replacing y by $-y$ preserves D_A and inverts the ratio. □

63.3.2 Normalization of the bilayer state

The trace of the angular operator is

$$\operatorname{Tr} T_{x,y} = 2\mathrm{e}^{-x}\cosh y. \tag{63.63}$$

Its normalization exactly eliminates the intensity x and preserves the orientation:

$$\boxed{\rho_y := \frac{T_{x,y}}{\operatorname{Tr} T_{x,y}} = \frac{\mathrm{e}^{-yR}}{2\cosh y} = p_+(y)P_+ + p_-(y)P_-,} \tag{63.64}$$

with

$$p_+(y) = \frac{\mathrm{e}^{-y}}{2\cosh y}, \qquad p_-(y) = \frac{\mathrm{e}^{y}}{2\cosh y}, \qquad p_+ + p_- = 1. \tag{63.65}$$

The family ρ_y is faithful for every $y \in \mathbb{R}$. Its orientation observable satisfies

$$\operatorname{Tr}(\rho_y R) = -\tanh y, \qquad \rho_{-y} = R_{\mathrm{sh}}\rho_y R_{\mathrm{sh}}^{*}, \tag{63.66}$$

where R_{sh} denotes any unitary operator permuting P_+ and P_-. This implementation distinguishes the spectral involution R, which measures the leaf sign, from the unitary operator R_{sh}, which exchanges the leaves.

Definition 63.12 (Local modular holographic Hamiltonian)**.** The modular Hamiltonian of the bilayer state is

$$\boxed{K_y^{\mathrm{mod}} := -\log \rho_y = \log(2\cosh y)I + yR.} \tag{63.67}$$

The scalar component normalizes the state, and the yR component preserves oriented memory.

The adjective *holographic* records the provenance of R, $P_{\pm}$, and y from the enriched state and its two sheets. The equality equation (63.67) is an identity of functional calculus; its promotion to a generator of temporal dynamics requires specification of the corresponding physical flow.

63.3.3 Entropy, Parity, and Orientation Divergence

Theorem 63.13 (Exact informational geometry of the two sheets)**.** *The von Neumann entropy, parity, and relative entropy between the two orientations satisfy*

$$S(\rho_y) := -\operatorname{Tr}(\rho_y \log \rho_y) = \log(2\cosh y) - y\tanh y, \tag{63.68}$$

$$S(\rho_y) = S(\rho_{-y}), \tag{63.69}$$

$$\boxed{D(\rho_y\|\rho_{-y}) = 2y\tanh y.} \tag{63.70}$$

The divergence is positive for $y \neq 0$ and vanishes exactly on the unoriented sheet $y = 0$.

Proof. From equation (63.67) and $\operatorname{Tr}(\rho_y R) = -\tanh y$ follows

$$S(\rho_y) = \operatorname{Tr}(\rho_y K_y^{\mathrm{mod}}) = \log(2\cosh y) - y\tanh y.$$

Both terms are even. Moreover,

$$\log\rho_y - \log\rho_{-y} = -2yR,$$

and, consequently,

$$D(\rho_y\|\rho_{-y}) = -2y\operatorname{Tr}(\rho_y R) = 2y\tanh y.$$

The product $y\tanh y$ is positive for $y \neq 0$. □

Entropy quantifies the even distribution of the sheets, whereas divergence quantifies the informational separation of their orientations. The derivatives

$$\frac{\mathrm{d}}{\mathrm{d}y}S(\rho_y) = -y\operatorname{sech}^2 y, \qquad \frac{\mathrm{d}^2}{\mathrm{d}y^2}\log(2\cosh y) = \operatorname{sech}^2 y \tag{63.71}$$

identify $S(\rho_0) = \log 2$ as a maximum and provide the Fisher information of the exponential family. Near the symmetric sheet,

$$D(\rho_y\|\rho_{-y}) = 2y^2 - \frac{2}{3}y^4 + O(y^6). \tag{63.72}$$

The first contribution is quadratic: a small oriented memory has a second-order informational cost.

The trace distance between orientations is also obtained in closed form:

$$\frac{1}{2}\|\rho_y - \rho_{-y}\|_1 = |\tanh y|. \tag{63.73}$$

Since $|y| \geq |\tanh y|$, the identity equation (63.70) implies the control

$$D(\rho_y\|\rho_{-y}) \geq 2\left(\frac{1}{2}\|\rho_y - \rho_{-y}\|_1\right)^2, \tag{63.74}$$

consistent with Pinsker's inequality. Thus, the oriented quantity simultaneously has spectral, entropic, and metric readings.

63.3.4 Normalized resolvent of the angular macro-object

Let

$$\kappa_\beta := 4\pi \mathfrak{A}_\beta > 0. \tag{63.75}$$

We define the meromorphic matrix-valued function

$$\boxed{\mathfrak{M}_\beta(z) := \kappa_\beta^{-1}(zI - T_{x,y})^{-1}, \qquad z \in \mathbb{C} \setminus \{q_+, q_-\}.} \tag{63.76}$$

Its spectral decomposition is

$$\mathfrak{M}_\beta(z) = \frac{1}{\kappa_\beta}\left(\frac{P_+}{z - q_+} + \frac{P_-}{z - q_-}\right). \tag{63.77}$$

The resolvent unites in a single object the coupling scale, the angular poles, the sheet projectors, the determinant, and all subsequent functional calculus.

Theorem 63.14 (Injectivity by the first two moments)**.** *The assignment*

$$(\mathfrak{A}_\beta, T_{x,y}) \longmapsto \mathfrak{M}_\beta$$

is injective for $\mathfrak{A}_\beta > 0$*. specifically, if*

$$B_0 := \lim_{|z|\to\infty} z\mathfrak{M}_\beta(z), \tag{63.78}$$

$$B_1 := \lim_{|z|\to\infty} z^2\left(\mathfrak{M}_\beta(z) - z^{-1}B_0\right), \tag{63.79}$$

then

$$B_0 = \kappa_\beta^{-1} I, \qquad \kappa_\beta = \tau_2(B_0)^{-1}, \qquad T_{x,y} = \kappa_\beta B_1, \tag{63.80}$$

where $\tau_2 = \mathrm{Tr}/2$*. Therefore, the asymptotics recovers* $\mathfrak{A}_\beta = \kappa_\beta/(4\pi)$*, and the next moment recovers the complete angular operator.*

Proof. For $|z| > \|T_{x,y}\|$, the Neumann series gives

$$\mathfrak{M}_\beta(z) = \frac{1}{\kappa_\beta}\sum_{n\geq 0}\frac{T_{x,y}^n}{z^{n+1}}. \tag{63.81}$$

The coefficients of z^{-1} and z^{-2} are precisely B_0 and B_1. The equalities equation (63.80) follow upon taking the normalized trace and multiplying by κ_β. Two pairs with the same resolvent have the same coefficients and therefore coincide. □

If $q_+ \neq q_-$, the spectral data are also recovered from the poles and residues:

$$\operatorname*{Res}_{z=q_\pm} \mathfrak{M}_\beta(z) = \kappa_\beta^{-1} P_\pm, \qquad \det \mathfrak{M}_\beta(z) = \frac{\kappa_\beta^{-2}}{(z - q_+)(z - q_-)}. \tag{63.82}$$

in particular, the scalar denominator contains $q_+ + q_-$ and $q_+q_- = D_A$, and

$$P_+ = \frac{T - q_- I}{q_+ - q_-}, \qquad P_- = \frac{T - q_+ I}{q_- - q_+}. \tag{63.83}$$

The case $y = 0$ produces a unique simple pole of spectral multiplicity two: $T = \mathrm{e}^{-x} I$. The resolvent then preserves the intensity and the scalar operator, whereas the choice of projectors has no intrinsic content because the orientation is exactly zero.

Corollary 63.15 (Calculation functional from the resolvente)**.** *For every function f holomorphic in a neighborhood of $\{q_+, q_-\}$,*

$$f(T) = \frac{\kappa_\beta}{2\pi \mathrm{i}} \int_\Gamma f(z)\mathfrak{M}_\beta(z)\, \mathrm{d}z, \tag{63.84}$$

where Γ encircles both poles. In particular, the vacuum response

$$\mathcal{V} = (I - T^{90})(I - T^{120})^{-1}$$

is reconstructed from $\mathfrak{M}_\beta$ without incorporating additional scalar data.

Proof. The identity is the formula of Dunford–Riesz aplicada to $(zI - T)^{-1} = \kappa_\beta \mathfrak{M}_\beta(z)$. The function $f(z) = (1 - z^{90})/(1 - z^{120})$ is holomorphic over a neighborhood of the spectrum, since $0 < q_\pm < 1$. □

63.3.5 Compatibility with nonadic refinement

The preceding information is prolonged through the tower

$$\mathcal{A}_m = M_2(\mathbb{C}) \otimes M_{9^m}(\mathbb{C}), \qquad \iota_m(a) = a \otimes I_9. \tag{63.85}$$

Let

$$T_m = T \otimes I_{9^m}, \quad R_m = R \otimes I_{9^m}, \quad \mathfrak{M}_{\beta,m}(z) = \kappa_\beta^{-1}(zI - T_m)^{-1}, \tag{63.86}$$

and let $E_m = \mathrm{id}_{M_2 \otimes M_{9^m}} \otimes \tau_9$ be the tracial expectation from $\mathcal{A}_{m+1}$ to $\mathcal{A}_m$.

Theorem 63.16 (Resolvent and modular naturality)**.** *for every $m \geq 0$ and every z of the resolvent set,*

$$E_m(T_{m+1}) = T_m, \tag{63.87}$$

$$E_m\big(\mathfrak{M}_{\beta,m+1}(z)\big) = \mathfrak{M}_{\beta,m}(z), \tag{63.88}$$

$$E_m(f(T_{m+1})) = f(T_m) \tag{63.89}$$

for every continuous function f on the spectrum. Likewise, the state functionals

$$\omega_{y,m}(a) := (\mathrm{Tr}_2 \otimes \tau_{9^m})\big((\rho_y \otimes I_{9^m})a\big) \tag{63.90}$$

are compatible with the inclusions and define a state $\omega_{y,\infty}$ on the UHF limit.

Proof. All objects of equation (63.86) have the form $a \otimes I_{9^m}$. The tracial expectation eliminates the last identity factor and preserves a. The same observation proves equation (63.89); compatibility of the states is obtained by evaluating $\omega_{y,m+1}(a \otimes I_9)$ and using $\tau_9(I_9) = 1$. □

The local entropy relative to the trace $\mathrm{Tr}_2 \otimes \tau_{9^m}$ remains equal to $S(\rho_y)$, and the divergence between orientations remains equal to $2y \tanh y$. Refinement adds resolution that is nonadic and preserves the bilayer content. In this manner, the construction lives in the UHF tower and in its tracial closure, rather than depending on an accidental presentation by matrices 2×2.

63.3.6 Exactness of the modular resolvent, normalization obstructions, and separation of the thermodynamic reading

Estatuto probatorio

The decomposition of T, the state ρ_y, the modular Hamiltonian, entropy, relative divergence, injectivity of the resolvent, and UHF naturality are exact results once $(\mathfrak{A}_\beta, C^*, R)$ has been fixed. The assembly of these identities in the resolvent $\mathfrak{M}_\beta$ constitutes a new formalization of the preexisting authorial architecture. The reading of $D(\rho_y \| \rho_{-y})$ as physical work requires temperature, protocol,

and dynamics; until these are fixed, its status is that of an exact informational measure. Realizations through Barbero, CKM, or Higgs are subsequent readers and preserve their respective intertwiners.

Falsification criterion

The block is refuted if the normalization of T retains a dependence on x, if K_y^{mod} does not exponentiate to ρ_y, if the relative entropy differs from $2y\tanh y$, if two distinct pairs $(\mathfrak{A}_\beta, T)$ have the same resolvent, or if any expectation E_m alters the functional calculation. Recovery of the projectors in $y = 0$ additionally constitutes a negative control: any sheet selector that survived that degeneration would have been introduced externally.

63.4 Inversion constitutiva and curva modular cargada

63.4.1 The Spectral Completion from 3 to 4

The vacuum operator of section 63.1 is obtained by applying to the angular operator the function

$$F(q) := \frac{1-q^{90}}{1-q^{120}}, \qquad 0 < q < 1. \tag{63.91}$$

The factorization of the two channels by the elementary mode 30,

$$90 = 3 \cdot 30, \qquad 120 = 4 \cdot 30, \tag{63.92}$$

allows $s = q^{30}$ to be introduced and written as

$$F(q) = f(s), \qquad f(s) := \frac{1+s+s^2}{1+s+s^2+s^3}. \tag{63.93}$$

The numerator contains three consecutive stages of the mode, and the denominator incorporates the fourth. The completion defect is

$$1 - f(s) = \frac{s^3}{1+s+s^2+s^3} > 0. \tag{63.94}$$

Thus, the fourth stage is recorded as positive memory within the response.

Theorem 63.17 (Bijectivity of the response $3 \to 4$)**.** *The function F is a decreasing analytic diffeomorphism*

$$\boxed{F : (0,1) \xrightarrow{\sim} (3/4, 1).} \tag{63.95}$$

for each $r \in (3/4, 1)$, the value $q = F^{-1}(r)$ is obtained as $q = s^{1/30}$, where $s \in (0,1)$ is the root unique *of*

$$rs^3 + (r-1)(1+s+s^2) = 0. \tag{63.96}$$

Proof. The derivative with respect to s is

$$f'(s) = -\frac{s^2(3+2s+s^2)}{(1+s+s^2+s^3)^2} < 0 \qquad (0 < s < 1). \tag{63.97}$$

As $\mathrm{d}s/\,\mathrm{d}q = 30q^{29} > 0$, tambiin $F'(q) < 0$. The limites are

$$\lim_{q\to 0^+} F(q) = 1, \qquad \lim_{q\to 1^-} F(q) = \frac{90}{120} = \frac{3}{4}.$$

Continuity and strict monotonicity prove bijectivity; the derivative does not vanish on the interval, so the inverse function theorem proves analyticity. Multiplying $r = (1 + s + s^2)/(1 + s + s^2 + s^3)$ by the denominator produces equation (63.96); uniqueness of its root in $(0, 1)$ is equivalent to the injectivity already proved. □

The inverter equation (63.96) provides a numerical procedure that is intrinsic. A bisection on $(0, 1)$ preserves the interval and certifies each digit; a Newton method can accelerate it using equation (63.97). Decimal evaluation enters after fixing the equation and its root, which is unique.

63.4.2 Exact reconstruction of the angular state from the vacuum

Let

$$T = q_+P_+ + q_-P_-, \qquad \mathcal{V} = F(T) = r_+P_+ + r_-P_-, \qquad r_\pm = F(q_\pm). \tag{63.98}$$

The two dimensionless constitutive quantities are assigned to the sheets through

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2. \tag{63.99}$$

Theorem 63.18 (Reconstruction constitutive reversible)**.** *The complete constitutive response determines the angular antecedent. In the labeled spectral basis,*

$$\boxed{q_+ = F^{-1}(\sqrt{\widehat{\varepsilon}}),} \qquad \boxed{q_- = F^{-1}(\sqrt{\widehat{\mu}}),} \tag{63.100}$$

$$\boxed{D_A = q_+q_-} = F^{-1}(\sqrt{\widehat{\varepsilon}})F^{-1}(\sqrt{\widehat{\mu}}), \tag{63.101}$$

$$\boxed{A_{\mathrm{rad}} = -\frac{1}{2}\log D_A,} \qquad \boxed{C^*_{\mathrm{rad}} = \frac{1}{2}\log\frac{q_-}{q_+}.} \tag{63.102}$$

If the operator $\mathcal{V}$ is known, rather than its two labelled eigenvalues, the reconstruction takes the form of functional calculus

$$\boxed{T = F^{-1}(\mathcal{V}).} \tag{63.103}$$

Proof. The eigenvalues of $\mathcal{V}$ belong to $(3/4, 1)$, and the positive root of each constitutive relation is $r_\pm$. The theorem 63.17 provides a unique $q_\pm$ for each sheet. The formulas of $D_A, A_{\mathrm{rad}}, C^*_{\mathrm{rad}}$ are the inverses of equation (63.60). For the operator form, the spectral theorem applies the continuous function F^{-1} to the spectrum of $\mathcal{V}$. □

When only the two numbers $(\widehat{\mu}, \widehat{\varepsilon})$ are retained, the assignment to sheets is part of the typed data. The operator $\mathcal{V}$ also contains its spectral projectors and reconstructs the full representation. This distinction separates spectral reconstruction from the choice of a basis.

The remaining readings are recovered simultaneously:

$$\widehat{Z} = \frac{r_-}{r_+} = \sqrt{\frac{\widehat{\mu}}{\widehat{\varepsilon}}}, \qquad \widehat{c} = \frac{1}{r_-r_+} = \frac{1}{\sqrt{\widehat{\mu}\widehat{\varepsilon}}}. \tag{63.104}$$

The product of the sheets publishes the common propagation; the quotient publishes constitutive orientation. Under $C^* \mapsto -C^*$, the two constitutive quantities are exchanged, $\widehat{Z}$ is inverted, and $\widehat{c}$ remains fixed.

Corollary 63.19 (Electroweak cross-check)**.** *At the angular interface where $(m_W^\angle/m_Z^\angle)^2 = D_A$, the reconstruction of the vacuum implies*

$$\boxed{\sin^2\theta_W^{\mathrm{OS,HMT}} = 1 - F^{-1}(\sqrt{\widehat{\varepsilon}})F^{-1}(\sqrt{\widehat{\mu}}).} \tag{63.105}$$

Proof. The theorem 63.18 reconstructs D_A. The stated angular interface defines $\sin^2\theta_W^{\mathrm{OS}} = 1 - (m_W/m_Z)^2 = 1 - D_A$. □

The equation equation (63.105) is a consistency check between sister readers. The causal genealogy continues from T: the vacuum applies $F(T)$, and the electroweak reader applies $\det T$. The invertibility of F permits comparison of the two publications without making either one the foundation of the other.

63.4.3 The loaded modular curve

The identity

$$D_A = \exp\!\left(-\frac{100\pi}{9}\alpha_{\mathrm{HMT}}\right) \tag{63.106}$$

suggests using the determinant as a global coordinate of the family. For $D \in (0,1)$, we define

$$\boxed{Q(D) := -\frac{9}{25}\log D,} \qquad a(D) := \frac{Q(D)}{4\pi} = -\frac{9}{100\pi}\log D. \tag{63.107}$$

At the HMT point, $a(D_A) = \alpha_{\mathrm{HMT}}$ and

$$\boxed{Q(D_A) = 4\pi\alpha_{\mathrm{HMT}} =: e_g^2.} \tag{63.108}$$

The symbol $Q(D)$ here designates the dimensionless charged coupling; it is distinct from every dimensional section of charge or energy.

To make the regional reader self-contained, we introduce the quintic character

$$H_5(a) := \frac{1}{2}\sqrt{\frac{1000a}{\varphi_{\mathrm{HMT}}}} - a + \frac{9}{16}a^2 - \frac{5}{9}a^3 + \frac{7}{48}a^4 - \frac{1}{54}a^5, \tag{63.109}$$

the regional germ

$$C_\pi(a,D) := 169a^6 + \frac{Da^7}{1-Da}, \tag{63.110}$$

and the oriented phase

$$y(D) := \frac{\pi}{90}\big(H_5(a(D)) + a(D)\big) - C_\pi(a(D),D). \tag{63.111}$$

The selector 169, the finite term of degree six, and the geometric prolongation of degree seven retain their regional provenance. The condition $0 < Da(D) < 1$ guarantees convergence of the germ.

We define the oriented quotient.

$$\varrho_{\mathrm{or}}(D) := \mathrm{e}^{2y(D)} \tag{63.112}$$

and the admissible interval

$$\mathcal{I}_{\mathrm{mod}} := \left\{ D \in (0,1) : 0 < Da(D) < 1,\ |y(D)| < -\frac{1}{2}\log D \right\}. \tag{63.113}$$

The second inequality ensures that the two reconstructed channels are strict contractions.

Definition 63.20 (Modular curve loaded)**.** The charged modular curve is the map

$$\Gamma_{\mathrm{ch}} : \mathcal{I}_{\mathrm{mod}} \longrightarrow (0,1)\times\mathbb{R}_{>0}, \qquad \boxed{\Gamma_{\mathrm{ch}}(D) = \big(D, \varrho_{\mathrm{or}}(D)\big).} \tag{63.114}$$

On it,

$$q_-(D) = \sqrt{D\,\varrho_{\mathrm{or}}(D)}, \qquad q_+(D) = \sqrt{\frac{D}{\varrho_{\mathrm{or}}(D)}}. \tag{63.115}$$

Theorem 63.21 (Functional rank one)**.** *The curve Γ_{ch} is an analytic immersion of rank one. The generic space of positive bilayer contractions requires two independent coordinates $(D, \varrho_{\mathrm{or}})$; the HMT reader restricts that space to the graph $\varrho_{\mathrm{or}} = \varrho_{\mathrm{or}}(D)$. Moreover,*

$$A_{\mathrm{rad}}(D) = -\frac{1}{2}\log D = \frac{50\pi}{9}a(D), \qquad C^*_{\mathrm{rad}}(D) = y(D). \tag{63.116}$$

Proof. The functions of equations (63.107) y (63.109) a (63.111) are analytic on $\mathcal{I}_{\mathrm{mod}}$. The first component of $\Gamma'_{\mathrm{ch}}(D)$ is one, so the derivative never vanishes and its rank is one. The identities equation (63.116) follow directly from the definitions. Finally, the product and quotient of equation (63.115) are D and $\varrho_{\mathrm{or}}(D)$, respectively. □

The resolvent family of the chapter previous is restricted to the same curve:

$$\mathfrak{M}_D(z) := Q(D)^{-1}\big(zI - T(D)\big)^{-1}, \qquad T(D) = q_+(D)P_+ + q_-(D)P_-. \tag{63.117}$$

At the point D_A, the equality $Q(D_A) = 4\pi\mathfrak{A}_\beta$ identifies $\mathfrak{M}_D$ with $\mathfrak{M}_\beta$. The coupling, intensity, orientation, and vacuum are thus coordinated by a single genealogical variable, while their reader functions remain typed.

63.4.4 Confluence between vacuum, Higgs and impedance

The vacuum reader publishes along the curve

$$\widehat{\mu}(D) = F(q_-(D))^2, \qquad \widehat{\varepsilon}(D) = F(q_+(D))^2, \tag{63.118}$$

$$\widehat{Z}(D) = \frac{F(q_-(D))}{F(q_+(D))}, \qquad \widehat{c}(D) = \frac{1}{F(q_-(D))F(q_+(D))}. \tag{63.119}$$

By the injectivity of F, either complete operator pair reconstructs $(D, \varrho_{\mathrm{or}})$.

The Higgs angular route contains the orientation through

$$\frac{m_H^{\angle}}{m_W^{\angle}} = \exp\!\left(3A_{\mathrm{rad}} + \frac{5}{3}C^*_{\mathrm{rad}}\right). \tag{63.120}$$

In the tree interface with $m_H^2 = 2\lambda_H v^2$ and $m_W^2 = g^2v^2/4$, this identity is equivalent to

$$\lambda_H = \frac{Q(D)}{8(1-D)}D^{-3}\varrho_{\mathrm{or}}(D)^{5/3}. \tag{63.121}$$

Therefore, the scalar

$$\Xi_H(D, \lambda_H) := \frac{8(1-D)D^3\lambda_H}{Q(D)} \tag{63.122}$$

satisfies

$$\boxed{\Xi_H = \varrho_{\mathrm{or}}^{5/3}, \qquad \varrho_{\mathrm{or}} = \Xi_H^{3/5}.} \tag{63.123}$$

Corollary 63.22 (Higgs–impedance reconstruction)**.** *Under the declared tree-level interface and for $\Xi_H > 0$,*

$$\boxed{\widehat{Z} = \frac{F\left(\sqrt{D}\,\Xi_H^{3/10}\right)}{F\left(\sqrt{D}\,\Xi_H^{-3/10}\right)}.} \tag{63.124}$$

The same quotient orientado is reconstructed by three vias:

$$\varrho_{\mathrm{or}}^{\mathrm{HMT}}(D) = \frac{F^{-1}(\sqrt{\widehat{\mu}})}{F^{-1}(\sqrt{\widehat{\varepsilon}})} = \Xi_H(D, \lambda_H)^{3/5}. \tag{63.125}$$

Proof. The equation equation (63.123) gives $q_- = \sqrt{D}\,\Xi_H^{3/10}$ and $q_+ = \sqrt{D}\,\Xi_H^{-3/10}$. Substituting them in $\widehat{Z} = F(q_-)/F(q_+)$ proves equation (63.124). The second equality of equation (63.125) is equation (63.123); the first proceeds of the theorem 63.18. □

The substitution of λ_H obtained from equation (63.121) turns equation (63.125) into an algebraic consistency identity. A determination of λ_H from an independent reader turns the same equation into a falsifiable cross-check of the orientation. This separation prevents the attribution of probative independence to a mere inversion of the starting equation.

The gauge partition also assumes a form determined purely by D:

$$g^2 = \frac{Q(D)}{1-D}, \qquad g'^2 = \frac{Q(D)}{D}, \qquad \boxed{\frac{1}{g^2} + \frac{1}{g'^2} = \frac{1}{Q(D)} = -\frac{25}{9\log D}.} \tag{63.126}$$

The total coupling $Q(D)$ is apportioned between the two gauge sectors, and the harmonic sum exactly recovers the charged macro-object.

63.4.5 Compatible causal section matching with orientation and boundary data

The coupling $Q(D)$ should be distinguished from the Planck energy, which we shall denote by $Q_P = E_P$. The Planck pair defines an internal velocity

$$c_{\mathrm{int}} := \frac{Q_P \ell_P}{\hbar}, \tag{63.127}$$

while the constitutive operator defines

$$c_{\mathrm{vac}} := \frac{1}{\sqrt{\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}}}}. \tag{63.128}$$

Both expressions live in typed causal curves. A sewing morphism

$$J_C : L_C^{\mathrm{vac}} \longrightarrow L_C^{\mathrm{grav}} \tag{63.129}$$

allows their comparison, and their dimensionless defect is

$$\boxed{\Xi_c := \frac{Q_P \ell_P}{\hbar}\sqrt{\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}}} = \frac{c_{\mathrm{int}}}{c_{\mathrm{vac}}}.} \tag{63.130}$$

Comparison Criterion 63.23 (Causal seam)**.** The electromagnetic vacuum and the gravitational realization publish the same causal section exactly when

$$\boxed{\Xi_c = 1,} \qquad J_C(c_{\mathrm{vac}}) = c_{\mathrm{int}}. \tag{63.131}$$

Once this seam is satisfied, the CT108 identity $G = (54/\pi)^2 c^5 t_0^2/\hbar$ is expressed entirely through the constitutive product:

$$\boxed{G = \left(\frac{54}{\pi}\right)^2 \frac{t_0^2}{\hbar(\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}})^{5/2}}.} \tag{63.132}$$

Gravity uses the even product of the leaves; impedance and charge use the oriented quotient

$$Z_{\mathrm{vac}}^2 = \frac{\mu_{\mathrm{vac}}}{\varepsilon_{\mathrm{vac}}}. \tag{63.133}$$

The pair product–quotient distributes, therefore, causality and orientation without disaggregating the spectral antecedent.

63.4.6 Stable reconstruction in the UHF tower

Let $\tau_m = \tau_2 \otimes \tau_{9^m}$ be the normalized trace of $\mathcal{A}_m = M_2 \otimes M_{9^m}$, and let

$$T_m = T \otimes I_{9^m}, \qquad \mathcal{V}_m = F(T_m) = \mathcal{V} \otimes I_{9^m}. \tag{63.134}$$

Functional inversion commutes with refinement:

$$F^{-1}(\mathcal{V}_m) = T_m, \qquad E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m, \qquad E_m(T_{m+1}) = T_m. \tag{63.135}$$

The ordinary matrix determinant of T_m is $D_A^{9^m}$. The invariant compatible with refinement is the normalized logarithmic determinant

$$\boxed{\mathfrak{d}_m(T_m) := \exp(2\tau_m(\log T_m)) = D_A.} \tag{63.136}$$

The orientation admits the equally stable prolongation

$$\boxed{\mathfrak{r}_m(T_m, R_m) := \exp(-2\tau_m(R_m \log T_m)) = \varrho_{\mathrm{or}},} \qquad R_m = R \otimes I_{9^m}. \tag{63.137}$$

Proposition 63.24 (Stability of reconstruction at every depth)**.** *For every m, the pair*

$$\Big(\mathfrak{d}_m(F^{-1}(\mathcal{V}_m)), \mathfrak{r}_m(F^{-1}(\mathcal{V}_m), R_m)\Big) \tag{63.138}$$

equals $(D_A, \varrho_{\mathrm{or}})$*. Consequently, it reconstructs the same coordinates* A_{rad} *and* C_{rad}^* *at every level and in the UHF limit.*

Proof. Since $\log T_m = (\log T) \otimes I_{9^m}$, the normalized trace eliminates the amplification factor. Moreover,

$$\tau_2(\log T) = \frac{1}{2}(\log q_+ + \log q_-) = \frac{1}{2}\log D_A$$

and

$$\tau_2(R \log T) = -y = -\frac{1}{2}\log \varrho_{\mathrm{or}}.$$

The equations equations (63.136) y (63.137) follow upon exponentiation. Functional inversion of equation (63.135) completes the reconstruction. □

This formulation shows that the completion $3 \to 4$ preserves its reconstructive capacity at every depth. The nonadic cylinders increase the resolution of the state; the normalized determinant, orientation, response, and modular curve remain natural with respect to the expectations.

63.4.7 Separation between internal quantum identities, physical interfaces, and reconstruction obstructions

Estatuto probatorio

The monotonicity and bijectivity of F, the operatorial inversion, the reconstruction (q_+, q_-, D_A, C^*), the rank one of Γ_{ch}, the harmonic gauge identity, and UHF stability are exact results. The charged modular curve formalizes a pre-existing authorial architecture with explicit starting structure: closure of α_{HMT}, regional selector 169, character H_5, germ C_π, and orientation. The Higgs–impedance

equality is exact within the tree interface; it constitutes an independent proof only when λ_H follows from a distinct reader. The condition $\Xi_c = 1$ and the subsequent gravitational equation are a typed physical interface whose promotion requires the morphism J_C.

Falsification criterion

The reconstruction is refuted if $F'(q)$ changes sign in $(0, 1)$, if the cubic equation admits two roots in that interval, if $F^{-1}(\mathcal{V})$ does not recover T, or if the constitutive relations reconstruct a product different from D_A. The curve is refuted if $Q(D_A) \neq 4\pi\alpha_{\mathrm{HMT}}$, if its derivative loses rank, if $q_{\pm}(D)$ leaves $(0, 1)$ within the declared domain, or if the three reconstructions of ϱ_{or} in equation (63.125) disagree under the same normalization. The causal seam is refuted by $\Xi_c \neq 1$ after applying the line morphism. In the tower, using the ordinary determinant as though it were invariant would produce $D_A^{9^m}$; the correct control requires equation (63.136).

63.5 Constitutive evaluation and dimensional realization

Evaluation now brings together the preceding constructions in their effective order. The regional expansions of π, φ, and e arise from nonadic refinement; the register K preserves its twelve positions. Its periodic readout determines the positional section of α. The action character and regional return act on it, followed by the angular pair and, finally, the constitutive response. This evaluation follows the selection of rules: none of its digits is used to choose a channel.

63.5.1 Evaluation of the internal chain

To reproduce the table, one uses the thousand-decimal regional expansions generated by the nonadic certificate and the integer N_K in (11.114). The readout used is

$$\alpha = \pi + e - \varphi - 4 - \frac{N_K}{1000^{12} - 1}.$$

The finite twelve-block section and the prolonged section have their definitions and exact difference in the register chapter. Here the latter is held fixed throughout evaluation. Readouts are not interchanged as precision increases, nor is the analytic operator of the second route replaced by a decimal coincidence with the first.

Objeto	Decimal evaluation (24 significant digits)
ρ	0.267949192431122706472554 . . .

The calculation uses 120 working digits; 24 significant digits are displayed to facilitate comparison between quantities of different orders. The 120 digits are an evaluation precision, not an experimental uncertainty or, by themselves, an interval error certificate. The package preserves the generated inputs, their hashes, the operations, and the residuals of the checked identities. The algebraic proofs in the main text establish these identities independently of this table.

The meaning of the final four constitutive coordinates is preserved under evaluation: $\widehat{\varepsilon}$ and $\widehat{\mu}$ are the quadratic responses per sheet, $\widehat{Z}$ is their relative orientation, and $\widehat{c}$ is the inverse of their product. The proximity of some digits to unity expresses the small defect of the 3–4 quotient on these channels. Its origin is seen exactly in

$$1 - f(s) = \frac{s^3}{1 + s + s^2 + s^3}.$$

The formula allows the response to be studied before a dimensional quantity is assigned to it: the sign of the defect, its cubic order, and its monotonicity are consequences of the same operator.

63.5.2 Charts of units and covariance

Let $\mathcal{L}_S$, $\mathcal{L}_Q$ and $\mathcal{L}_C$ be the action, charge and velocity lines. A positive physical chart evaluates the sections u_S, u_Q and u_C in units of action, charge and velocity. The realization (39.50) then produces an impedance, a velocity, a permeability and a permittivity, with their respective dimensions. The coordinates in the preceding table remain dimensionless.

Proposition 63.25 (Covariance of the constitutive realization)**.** *If the reference sections change by $u'_S = au_S$, $u'_Q = bu_Q$, $u'_C = du_C$, with $a, b, d > 0$, the coordinates representing the same quantities satisfy*

$$\widehat{Z}' = a^{-1}b^2\widehat{Z}, \qquad \widehat{c}' = d^{-1}\widehat{c}, \qquad \widehat{\mu}' = a^{-1}db^2\widehat{\mu}, \qquad \widehat{\varepsilon}' = adb^{-2}\widehat{\varepsilon}.$$

The relations $\widehat{\mu}'\widehat{\varepsilon}' = (\widehat{c}')^{-2}$ and $\widehat{\mu}'/\widehat{\varepsilon}' = (\widehat{Z}')^2$ are preserved.

Proof. Equate each quantity in (39.50) to its expression in the new basis and solve for its coordinate. The factors in the product are d^2, and those in the quotient are $a^{-2}b^4$, exactly those required by the transformed coordinates of c and Z. □

This covariance distinguishes two acts: constructing a section and expressing that section in chosen units. The spectral theorem fixes the coordinates in the declared internal normalization. An SI comparison must also display the evaluation of the three reference sections. Adjusting them through the quantities one wishes to reproduce would be a calibration of the chart, not an independent verification of those quantities.

To reconstruct the channels from coordinates expressed in the primed chart, that change is undone before using the cube root:

$$\widehat{Z} = ab^{-2}\widehat{Z}', \quad \widehat{c} = d\widehat{c}', \quad \widehat{\mu} = ad^{-1}b^{-2}\widehat{\mu}', \quad \widehat{\varepsilon} = a^{-1}d^{-1}b^2\widehat{\varepsilon}'. \tag{63.139}$$

For example, the inputs to the spectral inverse are $r_+ = (\widehat{Z}\widehat{c})^{-1/2}$ and $r_- = (\widehat{Z}/\widehat{c})^{1/2}$, calculated after (63.139). Directly inserting the primed coordinates into those expressions would change the normalization of the operator and could move them outside the interval $(3/4, 1)$. Dimensional covariance preserves the physical quantities; cubic inversion reconstructs transport in the internal chart in which it was defined.

63.5.3 Identity checks and scope of comparison

Reproducible comparison is organized by relations. First, $\widehat{\mu}\widehat{\varepsilon}\widehat{c}^2 = 1$ and $\widehat{\mu}/(\widehat{\varepsilon}\widehat{Z}^2) = 1$ check constitutive consistency. Second, cubic inversion recovers the original arguments and angular coordinates. Finally, evaluating Barbero through the angular functional and through functional calculus of the response agrees by the identity proved in the previous chapter. Interchanging sheets must reverse the oriented contribution and preserve the common mode; this check detects a loss of labeling that scalar products would not reveal.

The comparison of the reduced Planck constant with reference tables is preserved in the antecedent action development. For the four vacuum quantities, the present table is an evaluation of their internal coordinates. It is not presented as a table of SI coincidences: that additional assertion requires an independent numerical chart for u_S, u_Q, u_C. The proved constitutive result, including its inversion, remains complete in its domain and explicitly preserves the dimensional interface needed to make that comparison.

63.6 Exhaustive enumeration and finite determination of transport operators

This appendix develops two finite operations with different starting data. The first enumerates the initial conditions of the two cursors and constructs their emissions through the declared arithmetic recurrence. The second determines transport operators from the regional transition register. Separating their domains specifies what each proof produces: enumeration constructs the emission catalogue; matrix reconstruction determines the operators compatible with the register. The reconstruction theorem is not used as a proof of the prior production of that register.

The primitives of the first operation are the support I_9^2, the four cardinal orientations, the tritic selector, the pre-displacement readout, orientation reversals and the emission rule. Their definitions are brought together below. Those of the second operation are the four transition matrices in (63.146). Their unique reconstruction is proved in Theorem 63.27; the resulting calendar is given in (63.148). These determinations preserve the starting data specified for each operation.

63.6.1 Complete domain of initial conditions

Let $I_9 = \{0, \dots, 8\}$ and let

$$\mathcal{D} = \{N, E, S, O\}, \qquad v_N = (-1, 0), \quad v_E = (0, 1), \quad v_S = (1, 0), \quad v_O = (0, -1).$$

An initial cursor condition is $s = (i, j, d) \in \mathcal{S} = I_9^2 \times \mathcal{D}$. The two cursors are independent in the initial domain

$$\Omega = \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\mathcal{S}| = 9^2 \cdot 4 = 324, \qquad |\Omega| = 324^2 = 104\,976. \tag{63.140}$$

Index i corresponds to the positive APP label $i + 1$. For positive integers, positive reduction is $\rho_9(n) = 1 + [(n - 1)]_9$, where $[a]_b$ denotes the representative in $\{0, \dots, b - 1\}$. The residual evaluations of the two sheets are

$$\sigma(i, j) = \rho_9(i + j + 2), \qquad \varpi(i, j) = \rho_9((i + 1)(j + 1)).$$

The finite multiplicative readout uses

a	1	2	3	4	5	6	7	8	9
$\ell_9(a)$	0	1	0	2	5	0	4	3	0

. (63.141)

On units, ℓ_9 is the discrete exponent in base 2. On $3, 6, 9$, the value 0 constitutes the declared extension of the emission observable; membership in that sector remains in the trajectory register.

For $1 \le t \le 54$, define

$$r_t = 1 + [(t-1)]_9, \qquad \tau_t = \begin{cases} +1, & r_t \in \{1,4,7\}, \\ -1, & r_t \in \{2,5,8\}, \\ 0, & r_t \in \{3,6,9\}. \end{cases}$$

Each cursor preserves its position z_t immediately before step t and its orientation vector v_t. The additive cursor is active when $\tau_t = +1$; the multiplicative cursor, when $\tau_t = -1$. For each of them, with activity indicator a_t, the update is

$$z_{t+1} = [z_t + a_t v_t]_9, \qquad v_{t+1} = \begin{cases} -v_t, & t \in \{27,54\}, \\ v_t, & t \notin \{27,54\}. \end{cases} \tag{63.142}$$

The readout at step t is taken at z_t, before displacement. The neutral event preserves both positions. This convention fixes unambiguously the window endpoints and the effect of cardinal reversals.

In the windows $W_m = \{9m-8, \dots, 9m\}$, $1 \le m \le 6$, let

$$S_m(s_+) = \sum_{\substack{t \in W_m \\ \tau_t = +1}} \sigma(z_t^+), \qquad E_m(s_\times) = \sum_{\substack{t \in W_m \\ \tau_t = -1}} \ell_9(\varpi(z_t^\times)), \tag{63.143}$$

$$s_m = [S_m]_{10}, \qquad e_m = [E_m]_{10}.$$

Each window contains three events of each type. The signatures s and e are the six components of these residues, not the integers S_m, E_m before reduction.

63.6.2 Census of signatures and emissions

The emission of a pair of initial conditions is determined by

$$U_m = 100 s_m + 10[s_m + e_m]_{10} + [3s_m + 5e_m + 1]_{10}, \qquad 1 \le m \le 6. \tag{63.144}$$

The final term 1 is $[7 \cdot 3]_{10}$, corresponding to the three neutral events. This rule's coefficients belong to the declared recurrence. The real constants studied subsequently do not enter enumeration of its domain or its evaluation.

Proposition 63.26 (Injective factorization of the finite catalogue)**.** *Emission distinguishes every signature pair* (s, e)*. There are* 18 *additive and* 26 *multiplicative signatures; their pairs produce* 468 *emissions. The multiplicities of these emissions are* 144*,* 432 *and* 1944*, with* 432*,* 18 *and* 18 *emissions, respectively.*

Proof. The hundreds digit of U_m recovers s_m. If b_m is its tens digit, then $e_m = [b_m - s_m]_{10}$. The units digit verifies the third congruence of (63.144). Thus, the coupling is injective.

The census is obtained by traversing, in the full Cartesian order, $i = 0, \dots, 8$, $j = 0, \dots, 8$ and $d = N, E, S, O$, and applying the 54 steps of (63.142). The 324 additive conditions are distributed over the following 18 signatures, each with 18 preimages. In the tables, a sequence of six digits represents the six ordered components of a signature.

122564	122898	212645
212988	221456	221889
456221	465898	546988
564122	645212	654889
889221	889654	898122
898465	988212	988546

For the multiplicative cursor, the signatures and their multiplicities are

Signature	Multiplicity	Signature	Multiplicity
000000	108	555555	24
177393	8	555717	8
177555	8	555771	8
177771	8	555933	8
339555	8	717555	8
339771	8	717717	8
339933	8	717933	8
393177	8	771177	8
393393	8	771339	8
393555	8	771555	8
555177	8	933339	8
555339	8	933555	8
555393	8	933717	8

These tables result from the finite sums (63.143), with domain, readout order and reversals already specified. Their sums of multiplicities are $18 \cdot 18 = 324$ and $24 \cdot 8 + 24 + 108 = 324$. The Cartesian domain (63.140) permits every signature pair to be realized. Injectivity gives $18 \cdot 26 = 468$ emissions and the multiplicities

$$(18 \cdot 24,\ 18 \cdot 8) = (432, 144), \qquad (18,\ 18 \cdot 24) = (18, 432), \qquad (18,\ 18 \cdot 108) = (18, 1944),$$

where each pair indicates the number of emissions and multiplicity of their fibres. Finally,

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

Enumeration thus exhausts the complete domain of initial conditions. □

The oriented ternary reduction is

$$\Psi(U) = ([-U_1]_3, \dots, [-U_6]_3).$$

Applied to the $18 \cdot 26$ emissions of the preceding tables, it produces the following fibre census. Here r counts distinct emissions, not initial conditions.

r	1	2	3	4	5	6
$\#\{w : \#\Psi^{-1}(w) = r\}$	132	66	18	3	6	18

(63.145)

The sum of the second row is 243, while its weighted sum with weights r is 468. The image of 243 words is therefore distinguished from the ambient space $\mathbb{F}_3^6$, containing 729 words. The accompanying certificate preserves all signatures with their preimages, the 468 emissions and their ternary reduction; the preceding formulas provide a complete procedure for reconstructing them.

63.6.3 Transition register and reconstruction of the lifts

This subsection fixes the regional register of the cited source. Let $b_0^{\chi}, \dots, b_4^{\chi} \in \mathbb{F}_3^6$, with $\chi \in \{\mathsf{C}, \mathsf{P}, \mathsf{A}\}$, be its three sequences. The register organizes transitions $b_0 \to b_1 \to b_2$ in X_0, Y_0 and transitions $b_2 \to b_3 \to b_4$ in X_1, Y_1, using row vectors and the same regional order:

$$X_0=\begin{pmatrix}0&1&0&2&1&1\\0&1&2&2&2&2\\2&0&1&1&0&1\\1&2&1&2&2&1\\1&2&1&2&0&0\\1&1&2&2&0&2\end{pmatrix},\quad Y_0=\begin{pmatrix}0&1&2&2&2&2\\0&1&0&2&1&1\\1&2&1&2&2&1\\1&0&2&0&1&1\\1&1&2&2&0&2\\1&2&1&0&2&0\end{pmatrix},$$
$$X_1=\begin{pmatrix}0&1&0&2&1&1\\0&0&2&1&1&1\\1&0&2&0&1&1\\0&1&2&2&2&2\\1&2&1&0&2&0\\0&1&0&2&1&0\end{pmatrix},\quad Y_1=\begin{pmatrix}0&0&2&1&1&1\\1&1&0&2&2&1\\0&1&2&2&2&2\\1&0&2&0&1&1\\0&1&0&2&1&0\\0&1&0&2&0&0\end{pmatrix}. \tag{63.146}$$

The preceding production is expressed in its source through the composition of selection, transport and update:

$$x^{\mathcal{X}}_{j+1}=\mathcal{U}_{9j+9}\circ\cdots\circ\mathcal{U}_{9j+1}(x^{\mathcal{X}}_j),\qquad b^{\mathcal{X}}_j=\Pi_6(x^{\mathcal{X}}_j),\qquad \mathcal{U}_t=\mathsf{Upd}_t\circ\mathsf{Tra}_t\circ\mathsf{Sel}_t.$$

The following result starts from register (63.146). Its proof reconstructs the operators and verifies transition compatibility; it does not attribute coordinatewise production of states $x^{\mathcal{X}}_j$ to matrix inversion.

Proposition 63.27 (Uniqueness on the regional register)**.** *The systems $X_aL_a=Y_a$, $a=0,1$, have a unique solution over $\mathbb{F}_3$. The two solutions are*

$$L_0=\begin{pmatrix}2&2&2&1&2&1\\2&1&2&2&1&1\\1&0&0&1&0&2\\0&0&1&1&1&0\\2&2&2&0&2&1\\2&1&2&1&0&0\end{pmatrix},\qquad L_1=\begin{pmatrix}2&1&2&0&2&2\\1&2&1&1&2&0\\1&2&1&1&1&2\\0&1&0&0&2&1\\2&0&2&1&0&1\\0&2&2&2&1&1\end{pmatrix}. \tag{63.147}$$

Proof. Elimination in $\mathbb{F}_3$ gives $\det X_0=1$ and $\det X_1=2=-1$. Each map $L\mapsto X_aL$ is therefore an automorphism of the 36-dimensional matrix space; under columnwise vectorization it is represented by $I_6\otimes X_a$. One obtains $L_a=X_a^{-1}Y_a$. Multiplication of the matrices in (63.147) by the respective matrices X_a reproduces the two matrices Y_a of (63.146); existence and uniqueness are established on that register. □

The three resulting sequences, explicitly separated into blocks, are

$$B^{\mathsf{C}}=010211\mid 012222\mid 010211\mid 002111\mid 110221,$$
$$B^{\mathsf{P}}=201101\mid 121221\mid 102011\mid 012222\mid 102011,$$
$$B^{\mathsf{A}}=121200\mid 112202\mid 121020\mid 010210\mid 010200.$$

Each block preserves its six positions. Concatenation is not identified with a base-ten integer.

63.6.4 Exhaustiveness of the calendar and stability of reconstruction

A binary calendar is $c=(c_0,c_1,c_2,c_3)\in\{0,1\}^4$. Define the number of transitions incompatible with the register by

$$d(c)=\sum_{\mathcal{X}\in\{\mathsf{C},\mathsf{P},\mathsf{A}\}}\sum_{j=0}^{3}\mathbf{1}\{b^{\mathcal{X}}_jL_{c_j}\neq b^{\mathcal{X}}_{j+1}\}. \tag{63.148}$$

Multiplying the preceding sequences by (63.147) gives

$$d(c)=3\,d_{\mathrm{H}}(c,(0,0,1,1)),$$

where d_{H} is Hamming distance: at each of the four positions, the alternative operator fails to satisfy all three regional transitions. The complete census is

c	$d(c)$	c	$d(c)$	c	$d(c)$	c	$d(c)$
0000	6	0100	9	1000	9	1100	12
0001	3	0101	6	1001	6	1101	9
0010	3	0110	6	1010	6	1110	9
0011	0	0111	3	1011	3	1111	6

Consequently, 0011 is the unique calendar reproducing the three complete sequences.

Sensitivity to matrix entries likewise admits an exhaustive proof without approximations. A single-entry modification replaces L_a by $L_a + \lambda E_{ij}$, with $a \in \{0,1\}$, $1 \le i,j \le 6$ and $\lambda \in \mathbb{F}_3 \setminus \{0\}$. There are $2 \cdot 6 \cdot 6 \cdot 2 = 144$ such modifications. Since X_a is invertible,

$$X_a(L_a + \lambda E_{ij}) - Y_a = \lambda X_a E_{ij} \neq 0.$$

Every modification destroys at least one transition of the corresponding register. The executable certificate also enumerates the 144 modifications and preserves, for each, the number of violated transitions.

The proved property is rigidity of the operators with respect to the fixed regional register. Reproducing a prior construction of the register itself requires the coordinatewise action of its selection, transport and update operators. That dependency is kept separate from the rigidity theorem, the finite emission catalogue and the subsequent analytic realizations.

63.6.5 Reproduction certificate and location of the data

The program `verificar_nucleo_finito.py` traverses the 324 conditions of each cursor and forms the product of the resulting classes. The documentary catalogue is loaded after this construction to compare emissions and their multiplicities. In the second part, the four transition matrices are extracted from the verbatim copy of the source; solutions are computed by exact elimination modulo 3 before comparison with the printed matrices. The receipt `NUCLEO_FINITO.json` preserves the domains, preimages, emissions, 16 calendars and 144 modifications.

Verification uses exact integers and residues. It receives no metrological values or real expansions of the constants. Its scope is that of the finite operations and starting data specified in this appendix. The proofs of compatibility at unbounded depth and physical identifications retain their respective domains and expository obligations.

63.7 Restricted Electromagnetic Realization

63.7.1 Realization of the constitutive vacuum operator in the fields (E_σ, B_σ)

After constructing the continuum and deriving the constitutive operator of the vacuum, the propagation speed is published as

$$c_{\mathrm{vac}} = (\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}})^{-1/2}.$$

Let

$$\zeta = \frac{z - c_{\mathrm{vac}}t}{\lambda}$$

and $\sigma = \pm 1$. Definimos

$$\mathbf{E}_\sigma(z,t) = E_0\big(\mathbf{e}_1 \cos 2\pi\zeta + \sigma \mathbf{e}_2 \sin 2\pi\zeta\big), \tag{63.149}$$

$$\mathbf{B}_\sigma(z,t) = \frac{1}{c_{\mathrm{vac}}}\widehat{\mathbf{k}} \times \mathbf{E}_\sigma(z,t). \tag{63.150}$$

Then

$$\mathbf{E}_\sigma \perp \mathbf{B}_\sigma \perp \widehat{\mathbf{k}}, \qquad |\mathbf{E}_\sigma| = c_{\mathrm{vac}}|\mathbf{B}_\sigma|,$$
$$\omega = c_{\mathrm{vac}}k, \qquad \mathbf{S} = \frac{1}{\mu_{\mathrm{vac}}}\mathbf{E}_\sigma \times \mathbf{B}_\sigma = \frac{E_0^2}{Z_{\mathrm{vac}}}\widehat{\mathbf{k}}.$$

63.7.2 Helical realization of the electromagnetic phase: periodic return and longitudinal translation by one wavelength

At fixed time, the normalized end of the electric vector satisfies

$$\left(\frac{E_1}{E_0}, \frac{\sigma E_2}{E_0}, \frac{z - c_{\mathrm{vac}}t}{\lambda}\right) = \big(\cos 2\pi\zeta, \sin 2\pi\zeta, \zeta\big). \tag{63.151}$$

The equation coincides with the normalized phase-and-memory helix. The step $\zeta \mapsto \zeta + 1$ returns the electromagnetic phase and translates the marked event by one wavelength.

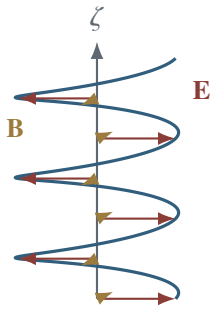

Figure 63.1: Analytic realization of the phase-position helix in a circular mode.

The exact statement concerns the trajectory of the field endpoint in the phase–position bundle. It does not follow that every spatial field line is a helix. Nor is electromagnetic helicity identified with the electron's fermionic holonomy.

63.7.3 Electromagnetic Duality

On two complexified forms in lorentzian signature,

$$\star^2 = -I.$$

The relation

$$\mathfrak{R}_{\mathrm{EM}} \circ J_{+1} = \star \circ \mathfrak{R}_{\mathrm{EM}}$$

realizes the internal quarter-turn as electric–magnetic duality when the intertwiner $\mathfrak{R}_{\mathrm{EM}}$ is constructed. The eigenspaces

$$\star F_\sigma = \mathrm{i}\sigma F_\sigma$$

separate the two helicities. This is a typed physical interface: it uses the already constructed elliptic generator, but requires the space of forms and the metric of the realization.

63.7.4 Compatibility condition with Pell's screw

For a phase

$$\Phi(r, \varphi, z, t) = \ell\varphi + \nu \log(r/r_0) + k_z z - \omega t,$$

invariance under $(r, \varphi) \mapsto (\varepsilon r, \varphi + \pi/2)$ requires

$$\nu \log(2 + \sqrt{3}) + \ell\frac{\pi}{2} \in 2\pi\mathbb{Z}. \tag{63.152}$$

This condition quantifies phase compatibility. The vector amplitude must additionally satisfy Helmholtz, transversality, and boundary conditions.

Chapter 64

Reconstruction of quantum principles from the genealogical state: Hilbert space, superposition, observables, dynamics, Born rule, uncertainty, and entanglement

64.1 Reconstruction of quantum principles from the genealogical state

Hilbert's formulation organizes quantum mechanics through states, self-adjoint observables, unitary evolution, tensorial composition, and a probabilistic rule for outcomes [129]. HMT–MD constructs a layer prior to that representation: a compatible section, its observable route, transport memory, and the reader that publishes an outcome. Hilbert space is not replaced; it appears as the codomain of a declared linear realization.

The typed sequence is

$$\boxed{\begin{aligned}&\text{genealogical section} \longrightarrow \text{linear realization} \longrightarrow \text{phase and superposition}\\ &\qquad\qquad\qquad\qquad \longrightarrow \text{observable and evolution} \longrightarrow \text{probability and measurement}\end{aligned}}$$

Each arrow preserves its domain. In particular, the state vector does not replace the TPK section, just as the real value does not replace the numerical genealogy that produces it.

64.1.1 Genealogical state and Hilbert realization

Definition 64.1 (Realized genealogical state)**.** A genealogical state is a quintuple

$$\mathfrak{G} = (x_\infty, \Gamma, \mathcal{F}, \mathcal{M}, \mathcal{R}), \tag{64.1}$$

where $x_\infty \in \Omega_\infty$ is a compatible section, Γ its observable route, $\mathcal{F}$ the family of realizations, $\mathcal{M}$ the memory of the lifts, and $\mathcal{R}$ the declared reader. Let $\mathsf{P}_{\mathrm{TPK}}$ be the category whose objects are the prepared TPK sections, finite or coinductive, and whose morphisms are the recorded routes compatible with their boundary data. In particular, the depth restriction is a morphism

$$r_{n+1,n} : x_{n+1} \longrightarrow x_n.$$

Let $\mathsf{Hilb}_{\mathbb{R},J}$ be the category whose objects are pairs $(\mathcal{H}_\mathbb{R}, J)$, with $\mathcal{H}_\mathbb{R}$ a real Hilbert space and J orthogonal, $J^2 = -I$, and whose morphisms are bounded real-linear maps T intertwining the complex structures, $TJ_1 = J_2T$. A quantum realization is a functor

$$Q : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{Hilb}_{\mathbb{R},J},$$

and a *pointed realization* is the pair (Q, Ψ) assigning to each prepared section x a nonzero vector $\Psi_x \in Q(x)$, compatible with the restrictions of the inverse system.

With the convention of linearity in the second argument, the associated Hermitian form is written

$$\langle u, v\rangle_\mathbb{C} = \langle u, v\rangle_\mathbb{R} - i\langle u, J_E v\rangle_\mathbb{R}.$$

Choosing the chart $J_E \leftrightarrow i$ realizes the complex structure that in Parts I–III is constructed as an internal root of $-I$. For prefixes of depth n, set $\mathcal{H}_n := Q(x_n)$ and

$$p_{n+1,n} := Q(r_{n+1,n}) : \mathcal{H}_{n+1} \longrightarrow \mathcal{H}_n.$$

Compatibility between restriction and realization requires

$$p_{n+1,n}\Psi_{n+1}(x_{n+1}) = \Psi_n(x_n). \tag{64.2}$$

If $r_{\infty,n} : x_\infty \to x_n$ is the coinductive restriction and $p_n := Q(r_{\infty,n}) : \mathcal{H}_\infty \to \mathcal{H}_n$, a limit $\mathcal{H}_\infty$ realizes the complete section when $p_n\Psi_\infty(x_\infty) = \Psi_n(x_n)$ at every depth.

Principle 64.2 (Realized quantum state)**.** The pure state associated with a section is represented by the ray of the nonzero vector $\Psi = \Psi_\infty(x_\infty)$; a statistical preparation is represented by a positive trace-one density operator on the same realization. Global-phase identification acts in the representation: the section and its record remain in the genealogical domain.

64.1.2 Superposition and internal phase

If $\Psi, \Phi \in \mathcal{H}_\infty$ and $a = \alpha + i\beta \in \mathbb{C}$, the action of a in the real representation is $\alpha I + \beta J_E$. The combination $a\Psi + b\Phi$ is formed only after transporting the two alternatives to a common fiber. The genealogical lifts of section 3.6 take values in output × memory; they belong to the TPK domain and are not multiplied as operators. If a projective realization assigns unitary operators U_g to visible transformations, its composition defect is described separately by

$$U_g U_h = c(g,h)U_{gh}, \qquad c(g,h) \in U(1),$$

with $c(e,g) = c(g,e) = 1$ and

$$c(g,h)c(gh,k) = c(h,k)c(g,hk).$$

A cocycle valued in another memory group acts on the realization only after a representation of that group has been declared that intertwines the operators U_g.

Principle 64.3 (Genealogical superposition)**.** Compatible alternatives are first transported in $\mathsf{P}_{\mathrm{TPK}}$ and are then combined linearly in $\mathcal{H}_\infty$. The action of J_E represents the relative phase, and the route weight preserves the declared lifting datum.

The interference is expressed through the cross terms.

$$\|\Psi_1 + \Psi_2\|^2 = \|\Psi_1\|^2 + \|\Psi_2\|^2 + 2\,\mathrm{Re}\langle\Psi_1, \Psi_2\rangle.$$

Two routes with identical endpoints may therefore contribute distinct phases without their joint publication erasing the difference between their histories.

64.1.3 Observables and Spectral Calculus

Let $O : \Omega_\infty \to Y \subseteq \mathbb{R}$ be a real genealogical reader. A quantum realization of O is a self-adjoint operator $\widehat{O}$, with dense domain $D(\widehat{O})$, whose PVM satisfies the compatibility condition

$$P_O(B)\Psi_x \quad \text{represents the restriction of } x \text{ to } O^{-1}(B)$$

for each Borel set $B \subseteq \mathbb{R}$ in the support of the preparation. In finite dimension,

$$\widehat{O} = \sum_a o_a P_a, \qquad P_a P_b = \delta_{ab} P_a, \qquad \sum_a P_a = I;$$

in general dimension, the sum is replaced by the spectral integral $\widehat{O} = \int \lambda \, \mathrm{d}P_O(\lambda)$.

Principle 64.4 (Typed observable)**.** The physical observable is the pair formed by the reader in the genealogical domain and its self-adjoint representation. Spectral calculus publishes the possible results of the representation without erasing the operation that defined them.

For a normalized pure state $\Psi \in D(\widehat{O}^2)$,

$$\langle O\rangle_\Psi = \langle \Psi, \widehat{O}\Psi\rangle, \qquad (\Delta_\Psi O)^2 = \langle \Psi, (\widehat{O} - \langle O\rangle_\Psi)^2 \Psi\rangle.$$

The formulation by means of $\mathrm{tr}(\rho\widehat{O})$ extends the definition to mixed states when $\rho\widehat{O}$ is trace class; the second moment likewise requires $\rho\widehat{O}^2$ to be trace class.

64.1.4 Evolution, Hamiltonian, and Schrödinger equation

Genealogical evolution preserves composition of transports. Its realization satisfies

$$U(t_3, t_2)U(t_2, t_1) = U(t_3, t_1), \qquad U(t, t) = I.$$

When it preserves the inner product and satisfies $U(t)J_E = J_E U(t)$, it is orthogonal in the real chart and unitary in the complex chart. For a strongly continuous one-parameter unitary group, Stone's theorem provides a self-adjoint and J_E-linear generator H [117]:

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}})\,.$$

On the domain $D(H)$, differentiation with respect to time gives

$$\hbar_{\mathrm{int}} J_E \dot{\Psi}(t) = H\Psi(t), \tag{64.3}$$

and the chart $J_E \leftrightarrow i$ produces $i\hbar_{\mathrm{int}}\dot{\Psi} = H\Psi$.

The calendar C_{108} realizes this correspondence in finite form: the self-adjoint Hamiltonian constructed for it has, over t_0, the unitary one-iteration shift as its exponential. The continuous group additionally requires strong continuity; it does not follow from the periodicity of the calendar alone.

64.1.5 Probability and quadratic representation of the branches

Let $C_n = \{C_s : s \in \mathcal{S}_n\}$ be the partition of Ω_∞ by a finite set $\mathcal{S}_n$ of prefixes of depth n, and let μ be a compatible cylindrical probability measure, $\mu(\Omega_\infty) = 1$. Let E be a real Hilbert space with complex structure J_E. On $\mathcal{H}_n = \ell^2(\mathcal{S}_n) \otimes E$, define

$$\Psi_n = \sum_{s\in\mathcal{S}_n} \sqrt{\mu(C_s)}\,|s\rangle \otimes e^{\theta_s J_E} u_0, \tag{64.4}$$

with u_0 unitary.

Theorem 64.5 (Quadratic representation of a branch measure)**.** *For a cylindrical event $A = \bigcup_{s\in I_A} C_s$, let*

$$P_A = \left(\sum_{s\in I_A} |s\rangle\langle s|\right) \otimes I_E.$$

Then

$$\|P_A\Psi_n\|^2 = \mu(A).$$

Proof. The prefix vectors are orthogonal and $e^{\theta_s J_E}$ preserves the norm. Therefore,

$$\|P_A\Psi_n\|^2 = \sum_{s\in I_A} \mu(C_s) = \mu(A).$$

□

The quadratic rule is obtained here for the PVM of finite-depth cylindrical events as an exact representation of the declared branch measure [14]. Conversely, Gleason's theorem characterizes, in

dimension at least three, noncontextual additive measures on projectors through density operators [53]. Coupling with the apparatus and conditioning on the outcome are developed subsequently in measurement theory.

64.1.6 Incompatibility of readers and uncertainty

Translations and nonadic phases define the Weyl pair.

$$\mathcal{H}_9 = \ell^2(\mathbb{Z}/9\mathbb{Z}), \qquad \omega_9 = e^{2\pi J_E/9}, \qquad X|n\rangle = |n+1\rangle, \qquad Z|n\rangle = \omega_9^n |n\rangle.$$

The indices are read modulo 9, and ω_9 is the complex scalar realized by the structure J_E on $\mathcal{H}_9$. The identity

$$ZX = \omega_9 XZ$$

realizes the finite Heisenberg group of order $9^3 = 729$. This cardinality belongs to the group of phases and translations and retains its type against the other occurrences of 729.

For self-adjoint observables A and B, a normalized vector $\Psi \in D(AB) \cap D(BA)$ with finite second moments permits the application of Cauchy–Schwarz to obtain the Robertson–Heisenberg inequality

$$\Delta_\Psi A \, \Delta_\Psi B \geq \frac{1}{2} \big| \langle \Psi, [A, B]\Psi \rangle \big|. \tag{64.5}$$

The incompatibility thus appears at coordinated levels: the commutator of the APP evaluations, the Weyl relation in the representation, and the dispersion bound for the physical readings [60, 106].

For $\Psi \neq 0$, the discrete Fourier transform supplies the support bound

$$|\operatorname{supp} \Psi| \, |\operatorname{supp} \widehat{\Psi}| \geq 9,$$

and, for mutually unbiased position and phase bases, the Shannon entropic inequality, with natural logarithms,

$$H_Q(\Psi) + H_P(\Psi) \geq \log 9$$

offers a third exact formulation [92]. Here H_Q and H_P are the Shannon entropies of the probability distributions in the two bases.

64.1.7 Tensor product of paths and entanglement generation via shared memory

Genealogical composition glues sections over boundary data. Fix on $\mathsf{P}_{\mathrm{TPK}}$ a monoidal structure $(\boxtimes, \mathbf{1}, a, l, r)$, with declared product, unit, and associativity and unit coherences. A strong monoidal realization provides natural isomorphisms

$$\mu_{A,B} : Q(A) \widehat{\otimes} Q(B) \xrightarrow{\sim} Q(A \boxtimes B).$$

In the Hilbert image there appears $\mathcal{H}_A \otimes \mathcal{H}_B$. A nonseparable pure state admits a Schmidt decomposition

$$|\Psi\rangle = \sum_r \sqrt{p_r}\, |r\rangle_A \otimes |r\rangle_B,$$

and satisfies $p_r \geq 0$, $\sum_r p_r = 1$, with $\{|r\rangle_A\}$ and $\{|r\rangle_B\}$ orthonormal Schmidt bases, and its reductions have the same nonzero spectrum. The entropy associated with that spectrum receives, in the Barbero–Immirzi chapter, an area and boundary realization.

Principle 64.6 (Genealogical composition)**.** The tensor product represents a gluing of sections over a shared boundary. Entanglement expresses the nonfactorization of the realized section with respect to the chosen bipartition.

64.1.8 Kinematic Reconstruction Theorem

Theorem 64.7 (Hilbertian Conditional Reconstruction of the Genealogical State)**.** *Let Ω_∞ be a space of compatible sections, let $(\mathsf{P}_{\mathrm{TPK}}, \boxtimes, \mathbf{1})$ be the monoidal category of routes with the declared coherences, and let*

$$Q : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{Hilb}_{\mathbb{R},J}$$

a strong monoidal realization, pointed by a compatible section $\Psi_x \in Q(x)$. Suppose that:

1. *$J_E^2 = -I$, J_E preserves the inner product, and the morphisms of Q intertwine the complex structures;*
2. *each declared real reader is represented by a self-adjoint operator whose PVM satisfies the compatibility condition with the reader's fibers;*
3. *each continuous evolution is represented by a strongly continuous one-parameter unitary group $U(t)$, with $U(t)J_E = J_E U(t)$, and a self-adjoint J_E-linear generator H;*
4. *the preparation induces a compatible cylindrical probability measure and the state Ψ_n of (64.4).*

The complex chart of Q then realizes states as rays or densities, complex superposition, self-adjoint observables, unitary evolution generated by H, tensor composition, and quadratic probabilities for the finite-depth cylindrical PVM.

Proof. The first hypothesis converts every real fiber into a complex Hilbert space and makes the transports complex-linear. The second permits application of the spectral theorem with the typed reader. The third supplies the Hamiltonian through Stone's theorem and the differential equation on $D(H)$. The fourth and theorem 64.5 give the quadratic rule on cylindrical events. Strong monoidality realizes the tensor product and its notion of separability. □

Result and scope

The Hilbertian reconstruction is coordinated as a property of a realization of the genealogical state: the complex structure derives from $J_E^2 = -I$; evolution, from the representation of routes; probability, from a compatible measure; and entanglement, from composition over a shared boundary. The theorem is exact under its four hypotheses and does not automatically identify TPK with a concrete quantum theory. The construction of a concrete physical realization preserves its sources: Hamiltonian, apparatus, readers, domain, and boundary conditions.

64.2 Reconstruction of quantum principles from the genealogical state

Hilbert's formulation organizes quantum mechanics through states, self-adjoint observables, unitary evolution, tensorial composition, and a probabilistic rule for outcomes [235]. HMT–MD constructs a layer prior to that representation: a compatible section, its observable route, transport memory, and the reader that publishes an outcome. Hilbert space is not replaced; it appears as the codomain of a declared linear realization.

The typed sequence is

$$\begin{array}{l}\text{genealogical section} \longrightarrow \text{linear realization} \longrightarrow \text{phase and superposition} \\ \qquad\qquad\qquad\qquad \longrightarrow \text{observable and evolution} \longrightarrow \text{probability and measurement}\end{array}$$

Each arrow preserves its domain. In particular, the state vector does not replace the TPK section, just as the real value does not replace the numerical genealogy that produces it.

64.2.1 Genealogical state and Hilbert realization

Definition 64.8 (Realized genealogical state)**.** A genealogical state is a quintuple

$$\mathfrak{G} = (x_\infty, \Gamma, \mathcal{F}, \mathcal{M}, \mathcal{R}), \tag{64.6}$$

where $x_\infty \in \Omega_\infty$ is a compatible section, Γ its observable route, $\mathcal{F}$ the family of realizations, $\mathcal{M}$ the memory of the lifts, and $\mathcal{R}$ the declared reader. Let $\mathsf{P}_{\mathrm{TPK}}$ be the category whose objects are the prepared TPK sections, finite or coinductive, and whose morphisms are the recorded routes compatible with their boundary data. In particular, the depth restriction is a morphism

$$r_{n+1,n} : x_{n+1} \longrightarrow x_n.$$

Let $\mathsf{Hilb}_{\mathbb{R},J}$ be the category whose objects are pairs $(\mathcal{H}_\mathbb{R}, J)$, with $\mathcal{H}_\mathbb{R}$ a real Hilbert space and J orthogonal, $J^2 = -I$, and whose morphisms are bounded real-linear maps T intertwining the complex structures, $TJ_1 = J_2T$. A quantum realization is a functor

$$Q : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{Hilb}_{\mathbb{R},J},$$

and a *pointed realization* is the pair (Q, Ψ) assigning to each prepared section x a nonzero vector $\Psi_x \in Q(x)$, compatible with the restrictions of the inverse system.

With the convention of linearity in the second argument, the associated Hermitian form is written

$$\langle u, v\rangle_\mathbb{C} = \langle u, v\rangle_\mathbb{R} - i\langle u, J_E v\rangle_\mathbb{R}.$$

Choosing the chart $J_E \leftrightarrow i$ realizes the complex structure that is constructed in the formal kernel and its development as an internal root of $-I$. For prefixes of depth n, set $\mathcal{H}_n := Q(x_n)$ and

$$p_{n+1,n} := Q(r_{n+1,n}) : \mathcal{H}_{n+1} \longrightarrow \mathcal{H}_n.$$

Compatibility between restriction and realization requires

$$p_{n+1,n}\Psi_{n+1}(x_{n+1}) = \Psi_n(x_n). \tag{64.7}$$

If $r_{\infty,n} : x_\infty \to x_n$ is the coinductive restriction and $p_n := Q(r_{\infty,n}) : \mathcal{H}_\infty \to \mathcal{H}_n$, a limit $\mathcal{H}_\infty$ realizes the complete section when $p_n\Psi_\infty(x_\infty) = \Psi_n(x_n)$ at every depth.

Principle 64.9 (Realized quantum state)**.** The pure state associated with a section is represented by the ray of the nonzero vector $\Psi = \Psi_\infty(x_\infty)$; a statistical preparation is represented by a positive, trace-one density operator on the same realization. Global-phase identification acts in the representation: the section and its record remain in the genealogical domain.

64.2.2 Evolution, Hamiltonian, and Schrödinger equation

Genealogical evolution preserves composition of transports. Its realization satisfies

$$U(t_3, t_2)U(t_2, t_1) = U(t_3, t_1), \qquad U(t, t) = I.$$

When it preserves the inner product and satisfies $U(t)J_E = J_E U(t)$, it is orthogonal in the real chart and unitary in the complex chart. For a strongly continuous one-parameter unitary group, Stone's theorem provides a self-adjoint and J_E-linear generator H [234]:

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}})\,.$$

On the domain $D(H)$, differentiation with respect to time gives

$$\hbar_{\mathrm{int}} J_E \dot{\Psi}(t) = H\Psi(t), \tag{64.8}$$

and the chart $J_E \leftrightarrow i$ produces $i\hbar_{\mathrm{int}}\dot{\Psi} = H\Psi$.

The calendar C_{108} realizes this correspondence in finite form: the self-adjoint Hamiltonian constructed for it has, over t_0, the unitary one-iteration shift as its exponential. The continuous group additionally requires strong continuity; it does not follow from the periodicity of the calendar alone.

64.3 Quadratic regimes and temporal readout

64.3.1 Quadratic algebras of the TRIT and curvature signatures

The primary construction and proof of the three regimes are given in the construction of the quadratic algebras of the TRIT, whose defining relation is presented in (1.156). For $\tau \in \widehat{\mathbb{T}}$, with balanced image $\bar{\tau} \in \{-1, 0, +1\}$, we have

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau}),$$

and, if J is the class of X,

$$\begin{aligned} \tau = +1 &: J^2 = -I, \quad \text{elliptic regime,} \\ \tau = 0 &: J^2 = 0, \quad \text{parabolic regime,} \\ \tau = -1 &: J^2 = +I, \quad \text{hyperbolic regime.} \end{aligned}$$

For all three values of τ, the quotient $\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau})$ satisfies precisely the three quadratic identities above. In particular, the internal square root of -1 is realized as an operator on the elliptic sheet; HMT need neither reject nor suppress the complex extension. The parabolic algebra contains a nilpotent, and the hyperbolic algebra decomposes by means of the two idempotents $(I \pm J)/2$.

These identities classify algebras and transports. They do not, by themselves, select a spacetime metric or prove that the physical universe occupies one of the three sheets.

64.3.2 Temporal TRIT reader on (-1,0,+1): opening, threshold, and return with memory

Once an ordered parametrization of the transitions has been chosen, the active temporal reader is

$$\begin{aligned} +1 &\longmapsto \text{return, retained memory and past,} \\ 0 &\longmapsto \text{evaluation threshold and present,} \\ -1 &\longmapsto \text{bidirectional opening and future.} \end{aligned}$$

The reader is PROVED WITH AN EXPLICIT STARTING STRUCTURE: its conclusions follow once the TRIT signature, the order of the trajectory, and the transported memory have been specified. It does not turn the set $\{-1, 0, +1\}$ into an equation of motion. The future designates the space of compatible continuations; survival may select a branch or a multisection without erasing the genealogy of the others.

The frequency

$$\omega_0 = \frac{2\pi}{108\, t_0}$$

assigns a type to the full-return clock through the decision entropy $I_{\mathrm{TRIT}} = \log 3$ and the Boltzmann transducer. It does not, in isolation, establish a stable subharmonic phase. It does, however, enable construction of the finite reference Hamiltonian below; selection of a robust physical Hamiltonian requires additional conditions.

64.3.3 Unitary dynamics on 108 states: Hamiltonian, propagator, and period

Fix an orientation $a \in \{\mathrm{pre}, \mathrm{ret}\}$ of the sections constructed in (16.35) and write $\hbar_{\mathrm{int}} = \hbar_a$. The same section is retained in the Hamiltonian, propagator, and subsequent thermal conversion.

Let

$$\mathcal{H}_{\mathrm{clk}} := \mathbb{C}^{108}, \qquad \{|j\rangle : j \in \mathbb{Z}/108\mathbb{Z}\}$$

with its canonical Hermitian inner product. Fix $\zeta := \exp(2\pi \mathrm{i}/108)$, the unitary shift

$$U_{\mathrm{clk}}|j\rangle = |j+1\rangle$$

and the Fourier basis

$$|\widetilde{k}\rangle := \frac{1}{\sqrt{108}} \sum_{j=0}^{107} \zeta^{jk} |j\rangle, \qquad 0 \le k \le 107.$$

With $t_0 \in \mathcal{L}_T^+$ and $\hbar_{\mathrm{int}} \in \mathcal{L}_S^+$, define

$$\boxed{H_{\mathrm{clk}} := \hbar_{\mathrm{int}} \omega_0 \sum_{k=0}^{107} k\, |\widetilde{k}\rangle\langle\widetilde{k}|, \qquad \omega_0 = \frac{2\pi}{108\, t_0}.} \tag{CLK1}$$

The operator has energy type $[H_{\mathrm{clk}}] = \mathcal{L}_S \mathcal{L}_T^{-1} = \mathcal{L}_E$.

Theorem 64.10 (Exact unitary realization of the 108 calendar)**.** *The operator H_{clk} is self-adjoint and its one-step propagator satisfies*

$$U_{\mathrm{step}} := \exp\!\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}} H_{\mathrm{clk}} t_0\right) = U_{\mathrm{clk}}, \qquad U_{\mathrm{step}}^{108} = I. \tag{CLK2}$$

If

$$Z_{\mathrm{clk}}|j\rangle = \zeta^j |j\rangle,$$

then, for any basis state $|j_0\rangle$,

$$\langle Z_{\mathrm{clk}} \rangle_n := \langle j_0 | U_{\mathrm{step}}^{-n} Z_{\mathrm{clk}} U_{\mathrm{step}}^{n} | j_0 \rangle = \zeta^{j_0+n}. \tag{CLK3}$$

The sequence has primitive period 108.

Proof. Expression (CLK1) is a spectral decomposition with real eigenvalues, hence $H_{\mathrm{clk}} = H_{\mathrm{clk}}^{\dagger}$. Moreover,

$$U_{\mathrm{clk}}|\widetilde{k}\rangle = \zeta^{-k}|\widetilde{k}\rangle,$$

whereas the exponential of $\hbar_{\mathrm{int}}\omega_0 k$ over t_0 gives $\exp(-2\pi \mathrm{i} k/108) = \zeta^{-k}$. The two operators agree on an orthonormal basis. The remaining identities follow from $U_{\mathrm{step}}^n |j_0\rangle = |j_0 + n\rangle$ and the primitivity of ζ. □

The corresponding variational formulation, for a curve $\psi \in C^1([t_a, t_b], \mathcal{H}_{\mathrm{clk}})$, unconstrained during the variation, is

$$\boxed{L_{\mathrm{clk}}(\psi, \dot\psi) = \frac{\mathrm{i}\hbar_{\mathrm{int}}}{2}\big(\langle\psi|\dot\psi\rangle - \langle\dot\psi|\psi\rangle\big) - \langle\psi|H_{\mathrm{clk}}|\psi\rangle.} \tag{CLK4}$$

The action functional is

$$\boxed{S_{\mathrm{clk}}[\psi] := \int_{t_a}^{t_b} L_{\mathrm{clk}}(\psi(t), \dot\psi(t))\, \mathrm{d}t,} \tag{CLK5}$$

with $\delta\psi(t_a) = \delta\psi(t_b) = 0$. Varying ψ and $\bar\psi$ independently yields the Schrödinger equation for the finite clock

$$\boxed{\mathrm{i}\hbar_{\mathrm{int}}\dot{\psi} = H_{\mathrm{clk}}\psi} \tag{CLK6}$$

together with its adjoint equation [233]. Its propagator sampled at $t = nt_0$ is $\psi_n = U_{\mathrm{step}}^n\psi_0$. Since H_{clk} is self-adjoint, the norm is conserved; normalized initial data remain normalized. The result is exact with respect to the specified $H_{\mathrm{clk}}, t_0, \hbar_{\mathrm{int}}$; it neither selects a physical Hamiltonian nor introduces an experimental frequency.

The theorem 64.10 establishes the unitary dynamics of the calendar with respect to the specified complex completion, t_0, and $\hbar_{\mathrm{int}}$. Its realization as a finite periodic system is developed in Section 64.4, which specifies the drive, the order observable, the primitive subharmonic response of period $108T_{\mathrm{d}}$, and finite spectral stability. A macroscopic material realization constitutes a distinct external identification, not a gap in the finite result.

64.4 Finite time crystal: periodic driving, subharmonic response and spectral stability

64.4.1 Periodic driving induced by the 108-state clock

Sea $N = 108$,

$$\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^N, \qquad S|j\rangle = |j+1\rangle, \qquad Z|j\rangle = \zeta^j|j\rangle, \qquad \zeta = \exp(2\pi\mathrm{i}/N).$$

In the Fourier basis $\{|\widetilde{k}\rangle\}_{k=0}^{N-1}$, we set

$$H_{\mathrm{clk}} = \hbar_{\mathrm{int}}\frac{2\pi}{Nt_0}\sum_{k=0}^{N-1} k|\widetilde{k}\rangle\langle\widetilde{k}|, \qquad \exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}H_{\mathrm{clk}}t_0\right) = S.$$

This equality fixes the starting clock. To exhibit a nonconstant periodic drive, let $0 < \eta < 1$, $T_{\mathrm{d}} = t_0$, and define, in each period,

$$H_{\mathrm{d}}(t) = \begin{cases} 0, & 0 \le t < \eta T_{\mathrm{d}}, \\ (1-\eta)^{-1}H_{\mathrm{clk}}, & \eta T_{\mathrm{d}} \le t < T_{\mathrm{d}}. \end{cases} \qquad H_{\mathrm{d}}(t+T_{\mathrm{d}}) = H_{\mathrm{d}}(t).$$

As the two segments commute, their Floquet propagator is

$$U_F = \mathcal{T}\exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}\int_0^{T_{\mathrm{d}}} H_{\mathrm{d}}(t)\,\mathrm{d}t\right) = \exp\left(-\frac{\mathrm{i}}{\hbar_{\mathrm{int}}}H_{\mathrm{clk}}T_{\mathrm{d}}\right) = S.$$

We define the Hermitian observables

$$Q = \frac{Z+Z^\dagger}{2}, \qquad P = \frac{Z-Z^\dagger}{2\mathrm{i}}.$$

Theorem 64.11 (Primitive Subharmonicity of the Finite Temporal Crystal HMT)**.** *For $\rho_{j_0} = |j_0\rangle\langle j_0|$, the vector of orden*

$$\mathbf{q}_n = \left(\mathrm{Tr}\,\rho_{j_0}U_F^{-n}QU_F^n,\ \mathrm{Tr}\,\rho_{j_0}U_F^{-n}PU_F^n\right)$$

satisfies

$$\mathbf{q}_n = \left(\cos\frac{2\pi(j_0+n)}{N},\ \sin\frac{2\pi(j_0+n)}{N}\right).$$

Its primitive period is $NT_{\mathrm{d}} = 108T_{\mathrm{d}}$, whereas the drive has period T_{d}. Therefore, the system realizes a primitive subharmonic response of order 108 *in the declared finite domain.*

Proof. The Weyl relation $S^{-1}ZS = \zeta Z$ gives $S^{-n}ZS^n = \zeta^n Z$. Its real and imaginary parts yield the formula. If an integer $d > 0$ were a period, then $\zeta^d = 1$ would hold; the primitivity of ζ forces $N \mid d$. □

64.4.2 Nilpotent jet of the triadic evolution and compatible prolongation

The minimal separation between distinct roots of unity is

$$g_N = \min_{k \neq \ell} |\zeta^k - \zeta^\ell| = 2 \sin \frac{\pi}{N} > 0.$$

Theorem 64.12 (Covariant rigidity and finite spectral stability)**.** *The following two assertions hold.*

1. *For every unitary V, the terna*

$$U_F^{(V)} = V U_F V^\dagger, \qquad Z^{(V)} = V Z V^\dagger, \qquad \rho^{(V)} = V \rho V^\dagger$$

exactly preserves the Weyl relation, the subharmonicity of order N, and the amplitude of the order vector.

2. *If U' is unitary and $\|U' - U_F\| = \varepsilon < g_N/2$, the N disks of radius $g_N/2$ centered at $\{\zeta^k\}$ uniquely separate the spectral sectors of U'. Their Riesz projectors have the same rank as those of U_F throughout every deformation that remains in that ball. Moreover, for every observable A, every state ρ, and every $n \geq 0$,*

$$\left|\operatorname{Tr} \rho \left(U'^{-n} A U'^{n} - U_F^{-n} A U_F^{n}\right)\right| \leq 2n\varepsilon \|A\|.$$

Proof. The first part is obtained by conjugating each identity. For the second, the separation g_N prevents two sectors from entering the same contour; continuity of the Riesz projectors preserves their ranges. The telescoping identity gives $\|U'^n - U_F^n\| \leq n\varepsilon$, and the same bound holds for the inverse powers. The inequality of expectations results from inserting and subtracting $U'^{-n} A U_F^n$. □

The resulting object is a *finite HMT time crystal* with a drive, a subharmonic observable, and quantified spectral stability. Whether a macroscopic material realizes this class, retains coherence at large volume, or exhibits prethermal or localized protection belongs to EXTERNAL IDENTIFICATION; it is not an unresolved mathematical part of the finite construction.

64.5 Algebraic construction of quantum completions over APP

APP and TPK provide oriented states, transport, and sheet parity. Their linear realization enables construction of the symmetric and exterior algebras, with their creation, annihilation, and occupation operators. This section establishes these algebraic constructions, the cellular field sector, and reversible measurement coupling. Transport of the completions under refinement is proved in Section 68.6; application of their occupation spectra to counting and equilibrium is developed in Sections 69.3–68.10. Each stage retains the conditions of the representation it uses.

64.5.1 Linear state space associated with a particle realization

Let S be a finite set of TPK route classes at the chosen depth, and let

$$\mathcal{H}_1 = \ell^2(S)$$

be the Hilbert space with orthonormal basis $(e_s)_{s \in S}$. A choice of positive weights E_s defines the diagonal operator

$$H e_s = E_s e_s.$$

The choice of S, its quotient by symmetries, and the weights are part of the model. Once these are fixed, the multiparticle completions are canonical.

64.5.2 Symmetric and exterior completions

We define

$$\mathcal{F}_+(\mathcal{H}_1) = \bigoplus_{n\geq 0} \mathrm{Sym}^n \mathcal{H}_1, \qquad \mathcal{F}_-(\mathcal{H}_1) = \bigoplus_{n\geq 0} \bigwedge^n \mathcal{H}_1.$$

The first is the bosonic completion; the second is the fermionic completion. In both, the degree-zero summand is the vacuum space. The exterior powers are equipped with the inner product for which ordered wedges of vectors from an orthonormal basis are orthonormal; the symmetric powers are used with the usual normalization of creation and annihilation operators.

64.5.3 Sheet grading and exchange algebra

Suppose that the oriented sheet defines an additive character

$$p : \mathrm{Mor}(\mathsf{P}_{\mathrm{TPK}}) \longrightarrow \mathbb{Z}/2\mathbb{Z}, \qquad p(\gamma\eta) = p(\gamma) + p(\eta).$$

On the corresponding graded linear space, introduce the symmetry

$$\tau(v \otimes w) = (-1)^{p(v)p(w)} w \otimes v.$$

Theorem 64.13 (Statistical completion determined by parity)**.** *The quotient of the tensor algebra by the relations*

$$v \otimes w - (-1)^{p(v)p(w)} w \otimes v$$

is symmetric on the even sector and exterior on the odd sector. Two identical odd states have zero product; even states admit arbitrary occupation.

Proof. If $p(v) = p(w) = 0$, the relation is $vw = wv$. If $p(v) = p(w) = 1$, it is $vw = -wv$; setting $v = w$ and working in characteristic zero gives $v^2 = 0$. Mixed sectors commute without an additional sign. This is the universal property of the graded symmetric algebra. □

64.5.4 Canonical operators and idempotence of occupation

The parity character determines the completion; the product of that completion then determines the operator algebra. In the exterior sector, creation $a_s^\dagger$ is exterior multiplication by e_s, and a_s is its adjoint.

Theorem 64.14 (Pauli exclusion principle in the exterior completion)**.** *For every mode $s \in S$, the creation and annihilation operators of the exterior completion satisfy*

$$\{a_s, a_t^\dagger\} = \delta_{st} I, \qquad \{a_s, a_t\} = \{a_s^\dagger, a_t^\dagger\} = 0. \tag{64.9}$$

In particular, the occupation operator $N_s = a_s^\dagger a_s$ is a projector:

$$N_s^2 = N_s, \qquad \mathrm{Spec}(N_s) \subseteq \{0, 1\}. \tag{64.10}$$

The eigenvalues 0 *and* 1 *correspond, respectively, to the absence and presence of mode s.*

Proof. On an ordered wedge, a_s removes the factor e_s, when present, with the sign determined by its position; when absent, it gives zero. Composing this operation with exterior multiplication proves relations (64.9): for $s = t$, the two compositions cover the complementary cases of absence and presence; for $s \neq t$, the exchange signs cancel. Antisymmetry implies $e_s \wedge e_s = 0$ and $a_s^2 = (a_s^\dagger)^2 = 0$. Therefore

$$N_s^2 = a_s^\dagger a_s a_s^\dagger a_s = a_s^\dagger (I - a_s^\dagger a_s) a_s = a_s^\dagger a_s = N_s. \tag{64.11}$$

The operator is self-adjoint, and every eigenvalue of an idempotent satisfies $\lambda^2 = \lambda$. Hence its spectrum is contained in $\{0, 1\}$. The vacuum and the state e_s realize both values [231, 228]. □

In the symmetric sector, the bosonic operators $b_s^\dagger, b_s$ act on the normalized occupation basis with factors $\sqrt{m_s + 1}$ and $\sqrt{m_s}$, respectively. Their compositions give

$$[b_s, b_t^\dagger] = \delta_{st} I, \qquad [b_s, b_t] = [b_s^\dagger, b_t^\dagger] = 0. \tag{64.12}$$

These identities are understood on the algebraic finite-particle domain, which is invariant under the operators considered.

Theorem 64.13 turns a compositional TPK parity into an exact occupation rule. To obtain the physical spin–statistics theorem, one must also construct a positive local Lorentzian theory and prove that sheet parity agrees with spin under rotations. This equality does not follow merely from both objects taking values modulo two.

64.5.5 Sheet holonomy and $2\pi/4\pi$ periodicity

The preceding parity admits a natural geometric realization when a surviving extension has a closed return with a nontrivial orientation cover. Let ρ be the return generator and let

$$\varepsilon : \langle \rho \rangle \longrightarrow \{-1, +1\}$$

be its holonomy character, with $\varepsilon(\rho) = -1$. The associated real bundle is then the orientation line of a Möbius strip: one turn closes the geometric projection but changes the lifted sheet; two turns restore the orientation.

To express this property in angular terms, fix a unitary representation U of the rotation cover on the graded space $\mathcal{H}_1 = \mathcal{H}_{\bar{0}} \oplus \mathcal{H}_{\bar{1}}$, compatible with sheet parity in the sense that

$$U(2\pi)v = (-1)^{p(v)} v$$

for every homogeneous vector v. Compatibility is a condition of the realization: it identifies the generator of the orientation cover with the character p already constructed on the routes.

Theorem 64.15 (Restoration of orientation and exchange algebra)**.** *Under the preceding compatibility condition,*

$$U(2\pi)|_{\mathcal{H}_{\bar{0}}} = I, \qquad U(2\pi)|_{\mathcal{H}_{\bar{1}}} = -I, \qquad U(4\pi) = I.$$

Moreover, the same character p determines the graded symmetry

$$\tau(v \otimes w) = (-1)^{p(v)p(w)} w \otimes v.$$

Thus the even-holonomy sector is completed by symmetric powers and the odd-holonomy sector by exterior powers. In the latter, the exclusion relation $v \wedge v = 0$ holds.

Proof. The first and second equalities are the compatibility condition evaluated on each homogeneous component. Iterating one turn gives

$$U(4\pi)v = U(2\pi)^2 v = (-1)^{2p(v)} v = v,$$

which proves restoration. The exchange statement is Theorem 64.13: for two even vectors the sign is positive, whereas for two odd vectors it is negative. □

Three returns should be distinguished. Angular closure after 2π is a return of the projection; closure after 4π restores the lifted orientation; neither, by itself, requires every coordinate of the record to return

to its initial value. This separation is the dimensional analogue of the HMT distinction between phase return and state return.

64.5.5.1 The sum and product sheets as supports of the 2 *completions*

The APP table contains two evaluations on the same support. The additive sheet acts by translations and preserves the multiplicity of continuations; in this sense, it accumulates. The multiplicative sheet permutes the units and contracts fibers over noninvertible elements; in this sense, it folds. This incompatibility precedes the statistical choice and explains why TPK must preserve two genealogies rather than reduce them to a single visible word.

The statistical assignment is not obtained, however, by verbally replacing "sum" with "boson" and "product" with "fermion." The exact map is the parity character

$$p : \mathrm{Mor}(\mathsf{P}_{\mathrm{TPK}}) \longrightarrow \mathbb{Z}/2\mathbb{Z}.$$

When the transport of an extension lies in the sector $p = 0$, its completion admits cumulative occupation and is symmetric. When it lies in $p = 1$, sheet reversal introduces the exchange sign and the completion is exterior. Sum and product supply the two local geometries; the record, orientation, and character p determine the sector in which a route is realized.

The 4π periodicity and fermionic exclusion are coordinated by the same sheet character. Their consequences for finite counts and equilibrium occupations are obtained, with the Hamiltonian and thermal conditions explicit, in Section 69.3 and in Theorem 68.12.

64.5.6 The cellular complex of the APP torus

The APP graph is the one-skeleton of a cellular decomposition of the torus T^2 with 9×9 vertices. Let

$$C^0 \xrightarrow{d_0} C^1 \xrightarrow{d_1} C^2$$

be its real cochain complex. Choosing the uniform inner product, define the codifferential $\delta = d^*$ and the Laplacian

$$\Delta_k = d_{k-1}\delta_k + \delta_{k+1}d_k.$$

Theorem 64.16 (Harmonic sector of the digital torus)**.** *The space of harmonic one-forms has dimension two:*

$$\dim \ker \Delta_1 = b_1(T^2) = 2.$$

A basis can be chosen that is represented by the uniform horizontal and vertical flows. Both are closed and coclosed, and neither is the gradient of a globally defined periodic function.

Proof. The Hodge theorem for finite cellular complexes identifies $\ker \Delta_1$ with $H^1(T^2; \mathbb{R})$. The cohomology of the torus has rank two. Directly, the constant horizontal and vertical flows have zero divergence and curl; their integrals over the two fundamental cycles are independent, so they are not exact. □

The space of connections modulo gauge transformations is

$$C^1/\mathrm{im}\, d_0.$$

In a finite complex equipped with the preceding inner product, each orbit admits a Coulomb representative in $\ker \delta_1$; within the orbit, the choice is unique modulo the stabilizer $\ker d_0$ of the gauge parameter. The correct cohomological quotient is

$$\ker d_1/\mathrm{im}\, d_0 \simeq \ker \Delta_1.$$

Its two harmonic classes constitute a natural mathematical candidate for two free global modes. They are not yet the two local polarizations of a photon in 3 + 1-dimensional spacetime: that identification requires a dynamical limit, a dispersion relation, and a physical gauge group.

64.5.7 Discrete Gauss law

For an oriented 1-cochain F and a set of vertices V, divergence is defined by

$$(\operatorname{div} F)(v) = \sum_{e:v\to w} F(e) - \sum_{e:w\to v} F(e).$$

Summing over V, every interior edge appears once with each sign and cancels. Therefore,

$$\boxed{\sum_{v\in V} \operatorname{div} F(v) = \operatorname{Flux}_{\partial V}(F).}$$

This identity is an exact Gauss law on the graph. Interpreting $\operatorname{div} F$ as electric charge requires the charge character and dimensional realization constructed in Dimensional Mechanics.

64.5.8 Reversible measurement apparatus

Let S be a set of states and let $r : S \to \mathbb{Z}/9\mathbb{Z}$ be a readout. Coupling to a nonadic register is defined by

$$U_r : S \times \mathbb{Z}/9\mathbb{Z} \longrightarrow S \times \mathbb{Z}/9\mathbb{Z}, \qquad U_r(s, a) = (s, a + r(s)).$$

Proposition 64.17 (Reversibility of the coupling)**.** *The map U_r is a permutation, and*

$$U_r^{-1}(s, a) = (s, a - r(s)).$$

Information loss arises only after applying a reader to the register or conditioning the state on the outcome.

Proof. The proposed inverse satisfies both composition identities by the group law of $\mathbb{Z}/9\mathbb{Z}$. □

This proposition formalizes the operational definition of measurement: coupling, reading, and restricting compatible futures are three different maps. The full coupling is reversible; the observational quotient need not be.

64.5.9 Algebraic correspondences and physical realizations

The Fock completions, exclusion conditional on parity, the harmonic sector of APP, discrete Gauss law, and reversibility of the apparatus are complete mathematical theorems. Their physical identifications form a diagram that must commute:

$$\text{sheet parity} \longrightarrow \text{graded interchange} \longrightarrow \text{CAR/CCR} \longrightarrow \text{physical statistics},$$

$$H^1(\mathcal{A}_9) \simeq \ker \Delta_1 \hookrightarrow C^1/\operatorname{im} d_0 \longrightarrow \text{photonic realization}.$$

In the first line, the first two arrows have explicit constructions; the last requires the corresponding dynamics and equilibrium conditions. In the second, the Hodge identification and inclusion of harmonic classes in the space of connections modulo gauge are the constructions of Section 64.5.6. The zero eigenvalue belongs to the cellular Laplacian: identifying these modes with massless excitations and the two local photon polarizations additionally requires the dynamics, dispersion relation, and physical gauge realization specified there. This distinction allows the bridges to be developed without confusing an analogy in cardinality with a representation.

64.6 Arithmetic–geometric coupling and bilateral recovery

The dodecaphase register of section 11.4 admits arithmetic, incidence and operator readings. We call *holographic constant of arithmetic-geometric coupling* the generated register K, preserving the order of its twelve windows, the phase origin and orientation. Its rational reading $\kappa = K_{\mathrm{int}}/(1000^{12} - 1)$ is an encoding of that register; it does not replace its types or the enriched history that produces it. Hadamard inversion recovers its signed coordinate; the incidence reading determines the Witt tetrad. The following constructions make two further functions explicit: identifying operators on its cyclic carrier and preserving information between two isometric realizations. These are operations subsequent to the realization of the continuum, not rules introducing conventional constants into APP–TRIT–TPK.

64.6.1 Exact encoding and cyclic reference

Proposition 64.18 (Recovery of the record from its rational reading)**.** *With base $b = 1000$, length twelve, origin, and orientation fixed, the map*

$$(k_1, \dots, k_{12}) \longmapsto \kappa = \frac{\sum_{j=1}^{12} k_j b^{12-j}}{b^{12} - 1}, \qquad 0 \le k_j < b,$$

is injective. From κ, one recovers the integer $n = (b^{12} - 1)\kappa$ and, by successive Euclidean divisions, the twelve blocks, including leading zeros. An absolute error strictly smaller than $1/[2(b^{12} - 1)]$ permits the same recovery by rounding.

Proof. The fixed-length integer expansion in base b is unique. Two distinct integers are separated by at least one; their rational readings are separated by at least $1/(b^{12} - 1)$. The strict bound places the approximate datum within the rounding cell of a unique integer. □

Now consider $K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601)$, the cyclic shift S of its positions, and $O_K = (K, SK, \dots, S^{11}K)$ on $\mathbb{R}^{12}$. The shift of positions is identified neither with the entire enriched evolution nor, solely by virtue of its periodicity, with an exceptional symmetry.

Theorem 64.19 (Invertibility of the orbital reference)**.** *The matrix O_K is invertible, and*

$$589609\|c\|^2 \le \|O_K c\|^2 \le 6263^2\|c\|^2.$$

Its centred orbit has rank eleven.

Proof. The Gram matrix $O_K^* O_K$ is circulant. Its first row, obtained from the twelve inner products $\langle K, S^j K\rangle$, is

$$(4251257, 2999323, 3163385, 3287920, 3216553, 3344743,$$
$$2950064, 3344743, 3216553, 3287920, 3163385, 2999323).$$

Evaluation at the twelve characters of the cycle yields the eigenvalues

$$6263^2, \quad 697225, \quad 589609\ (2), \quad 1407529\ (2), \quad 1053157\ (2),$$
$$(1248025 - 345420\sqrt{3})\ (2), \qquad (1248025 + 345420\sqrt{3})\ (2),$$

where parentheses indicate multiplicities. The smallest value is 589609: for the only comparison that is not immediate, $658416 > 345420\sqrt{3}$, as is seen by squaring both sides. The triangle inequality for the Fourier transform and $K_j \ge 0$ give the maximum $(\sum K_j)^2 = 6263^2$. Positivity of every mode proves invertibility and the bounds. Centring the record removes only the uniform mode. □

Corollary 64.20 (Identification of an operator from its responses)**.** *A linear operator $T : \mathbb{R}^{12} \to \mathbb{R}^{12}$ is determined by $Y = (TK, TSK, \dots, TS^{11}K)$, through $T = YO_K^{-1}$. If $TS = ST$, the complete vector response $y = TK$ suffices, since $T = O_y O_K^{-1}$. For a perturbation E of Y, $\|\widehat{T} - T\| \le \|E\|/\sqrt{589609}$.*

Proof. We have $Y = TO_K$. Under commutation, $TS^j K = S^j y$, hence $Y = O_y$. The bound follows from $\|O_K^{-1}\| = 1/\sqrt{589609}$. The norms are the Euclidean norm and its induced operator norm. □

The response y contains twelve components. The statement does not attribute the recovery of an arbitrary operator to a single scalar: it specifies the observation and commutation condition that make identification possible.

64.6.2 Conservation and reconstruction of two channels

Let H, H' be Hilbert spaces, and let $\mathcal{B}, C : H \to H'$ be bounded linear isometries. For $a > 0$, define

$$p = a^2 + a + 1, \qquad N = (2a+1)p = (a+1)^3 + a^3, \qquad Q_- = a\mathcal{B} - C, \quad Q_+ = (a+1)\mathcal{B} + C.$$

Theorem 64.21 (Bilateral balance and recovery)**.** *The following hold*

$$(a+1)Q_-^* Q_- + aQ_+^* Q_+ = NI_H, \qquad W_a v = \frac{1}{\sqrt{N}} \begin{pmatrix} \sqrt{a+1}\, Q_- v \\ \sqrt{a}\, Q_+ v \end{pmatrix}, \qquad W_a^* W_a = I_H.$$

The data $x = Q_- v$, $y = Q_+ v$ determine

$$\mathcal{B}v = \frac{x+y}{2a+1}, \qquad Cv = \frac{ay - (a+1)x}{2a+1}, \qquad v = \mathcal{B}^* \frac{x+y}{2a+1}.$$

Proof. Setting $X = \mathcal{B}^* C + C^* \mathcal{B}$, one obtains

$$Q_-^* Q_- = (a^2+1)I - aX, \qquad Q_+^* Q_+ = ((a+1)^2+1)I + (a+1)X.$$

The weights cancel X, and the remaining coefficient is $2a^3 + 3a^2 + 3a + 1 = N$. Normalization gives the isometry. Adding the two channels recovers $(2a+1)\mathcal{B}v$; the combination $ay - (a+1)x$ recovers $(2a+1)Cv$. Finally, $\mathcal{B}^*\mathcal{B} = I_H$. □

The balance also holds in infinite dimension: only bounded operators are composed. The image of W_a is closed, and its orthogonal projector is $W_a W_a^*$. Thus a normalized pair has an input precisely when it belongs to that image; its orthogonal component measures the compatibility defect.

The factorization

$$W_a = R_a E_a, \qquad E_a v = \frac{1}{\sqrt{p}} \begin{pmatrix} \sqrt{a(a+1)}\, \mathcal{B}v \\ Cv \end{pmatrix}, \quad R_a = \frac{1}{\sqrt{2a+1}} \begin{pmatrix} \sqrt{a} & -\sqrt{a+1} \\ \sqrt{a+1} & \sqrt{a} \end{pmatrix}$$

is verified by block multiplication; R_a acts on $H' \oplus H'$, with each scalar entry multiplying $I_{H'}$. In the nonadic partition $a = 8$, the weights are $72/73$ and $1/73$; the factor $73 = 8 \cdot 9 + 1$ follows from the general law $a(a+1) + 1$, rather than being an additional primitive datum. The corresponding balance is $9\|Q_- v\|^2 + 8\|Q_+ v\|^2 = 17 \cdot 73\, \|v\|^2$.

64.6.3 Transport of observables and incoming memory

Theorem 64.22 (Observables common to both channels)**.** *For a bounded self-adjoint operator F on H',*

$$W_a^* \operatorname{diag}(F, F) W_a = \frac{a(a+1)\mathcal{B}^* F \mathcal{B} + C^* F C}{p}.$$

If $\mathcal{B}$ is unitary and $C = \mathcal{B}R$, with R unitary, and $G = \mathcal{B}^* F \mathcal{B}$, the observable is preserved if and only if $GR = RG$.

Proof. Expanding $(a+1)Q_-^*FQ_- + aQ_+^*FQ_+$ cancels the cross terms. The other two coefficients are $a(a+1)(2a+1)$ and $2a+1$. Dividing by N gives the formula. In the stated case, equality with G is equivalent to $R^*GR = G$; unitarity makes this equivalent to $GR = RG$. □

The norm is obtained by taking $F = I$. A general observable requires the commutation condition: preserving the norm does not mean preserving every observable without transformation.

Theorem 64.23 (Unitary extension with memory)**.** *If $H' = H$, $\mathcal{B} = I$, and $C = U$ is unitary, set*

$$A = \frac{\sqrt{a+1}}{\sqrt{N}}Q_-, \qquad D = \frac{\sqrt{a}}{\sqrt{N}}Q_+, \qquad \mathscr{R}_a = \begin{pmatrix} A & -D^* \\ D & A^* \end{pmatrix}.$$

Then $\mathscr{R}_a$ is unitary on $H \oplus H$, its first column is W_a, and it preserves $\|v\|^2 + \|m\|^2$ for every input (v, m). The inverse is

$$v = A^*z_1 + D^*z_2, \qquad m = -Dz_1 + Az_2.$$

Proof. The operators A, D are normal and commute with each other and with their adjoints, since they are polynomials in U, U^*. The balance gives $A^*A + D^*D = I$, and normality gives $AA^* + DD^* = I$. The cross terms in both products $\mathscr{R}_a^*\mathscr{R}_a$ and $\mathscr{R}_a\mathscr{R}_a^*$ vanish; the diagonal blocks are the identity. Applying the adjoint to (z_1, z_2) yields the inverse. □

Recovery of the register, orbital identification and unitary extension specify three distinct levels of information. The first preserves the blocks with their chart; the second identifies operators under the stated hypotheses; the third transports state and memory jointly. This hierarchy allows the same generated structure to be used without confusing a reduced reading with the state in its entirety.

Chapter 65

Quantum trajectory dynamics: Feshbach–Schur reduction, Born rule, and genealogical path integral

65.1 Feshbach–Schur reduction

Let

$$\mathcal{H} = \mathcal{H}_0 \oplus \mathcal{H}_{\mathrm{ext}}, \qquad H = \begin{pmatrix} H_{00} & V \\ V^* & H_{\mathrm{ext}} \end{pmatrix}.$$

For z in the resolvent set of H_{ext}, the resolvent compression is

$$P_0(z-H)^{-1}P_0 = [z - H_{00} - \Sigma_0(z)]^{-1}, \qquad \Sigma_0(z) = V(z - H_{\mathrm{ext}})^{-1}V^*. \tag{65.1}$$

The operator Σ_0 transports the memory of the elliptic and hyperbolic sheets to the present sheet. Its time transform generates a memory kernel

$$S_{\mathrm{eff}}[\psi_0] = \int \psi_0^\dagger(i\hbar\partial_t - H_{00})\psi_0 \,\mathrm{d}t - \iint \psi_0^\dagger(t)K_0(t,t')\psi_0(t')\,\mathrm{d}t\,\mathrm{d}t'.$$

A regular low-frequency expansion,

$$\Sigma_0(\omega) = \Sigma_0^{(0)} + \omega\Sigma_0^{(1)} + \omega^2\Sigma_0^{(2)} + \cdots,$$

produces an effective local action; a singular spectral structure preserves nonlocal memory. The present thus receives the response of the global state without introducing an external time.

65.2 From the finite sum to the path integral genealogical

The preceding matrix expansion establishes exactly that each entry of U^R is the sum of the ordered weights of routes of length R. The next step preserves the information that a visible route does not publish and organizes finite refinements into a compact genealogy space. In this way, three results are distinguished: the finite combinatorial identity, the cylindrical integral over the path limit, and the realization of that integral as the propagator of a particular physical system.

65.2.1 Route category and functorial weight

Let $\mathsf{P}_{\mathrm{TPK}}$ be the free category generated by the admissible TPK transitions. Its objects are enriched boundary states, and its morphisms are composable sequences of transitions. Composition is concatenation, and the empty path is the identity. The map

$$q_{\mathrm{vis}} : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{P}_X$$

publishes the observable route and preserves in its fiber the differences of sheet, orientation, carry, block, boundary, and memory.

Definition 65.1 (Genealogical weight)**.** Let $\mathcal{B}$ be a normed real algebra, possibly noncommutative, and let $\mathbf{B}_{\mathcal{B}}$ be the category with a single object $*$ whose endomorphism monoid is $\mathrm{End}(*) = (\mathcal{B}, \cdot, 1)$. A genealogical weight is a functor

$$W : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathbf{B}_{\mathcal{B}}$$

such that

$$W(\mathrm{id}_x) = 1, \qquad W(\gamma_2 \circ \gamma_1) = W(\gamma_2)W(\gamma_1).$$

The product order agrees with the causal order of the route.

For enriched states $\widetilde{i}, \widetilde{f}$, the kernel at depth R is

$$\mathcal{K}_R(\widetilde{f},\widetilde{i}) = \sum_{\substack{\gamma\in \mathsf{P}_{\mathrm{TPK}}(\widetilde{i},\widetilde{f})\\ |\gamma|=R}} W(\gamma). \tag{65.2}$$

Two routes with the same visible word remain distinct summands when they belong to different genealogical fibers.

Proposition 65.2 (Composition through an enriched cut)**.** *If every route of length $R+S$ has a unique cut after R transitions, then*

$$\mathcal{K}_{R+S}(\widetilde{f},\widetilde{i}) = \sum_{\widetilde{x}} \mathcal{K}_S(\widetilde{f},\widetilde{x})\mathcal{K}_R(\widetilde{x},\widetilde{i}).$$

The formula preserves the causal order of the factors when $\mathcal{B}$ is noncommutative.

Proof. The set of complete routes is partitioned by the enriched state $\widetilde{x}$ reached at the cut. The functorial factorization of the weight turns the sum over each class into the product of the partial kernels. Uniqueness of the cut ensures that each route appears exactly once. □

65.2.2 Construction of the internal phase through the real action character on genealogical routes

Let (E, J_E) be a real Euclidean space equipped with an orthogonal endomorphism J_E such that $J_E^2 = -I$. If $\mathcal{A}_* : \mathsf{P}_{\mathrm{TPK}} \to \mathbb{R}$ is additive under concatenation, the phase

$$\Phi_J(\gamma) := \exp[-J_E\mathcal{A}_*(\gamma)] = \cos\mathcal{A}_*(\gamma)\, I - \sin\mathcal{A}_*(\gamma)\, J_E \tag{65.3}$$

is multiplicative. For a dimensional action $S_{\mathrm{int}}(\gamma) = \hbar_{\mathrm{int}}\mathcal{A}_*(\gamma)$, this expression internally realizes the phase $\exp[-J_E\, S_{\mathrm{int}}(\gamma)/\hbar_{\mathrm{int}}]$. The scalar symbol i appears only when a complex chart is chosen for the pair (E, J_E).

Proposition 65.3 (Phase functor)**.** *The map Φ_J satisfies*

$$\Phi_J(\mathrm{id}_x) = I, \qquad \Phi_J(\gamma_2\circ\gamma_1) = \Phi_J(\gamma_2)\Phi_J(\gamma_1).$$

Proof. The action of the empty path is zero. For composable routes, additivity of $\mathcal{A}_*$ and commutativity of multiples of the same endomorphism J_E allow the exponential of the summed value to be separated. □

65.2.3 Unitary realization on the chronological register 27×27

Before passing to the cylindrical limit, a finite kernel admits an explicit unitary realization. Let

$$\mathbb{T}^2_{27} := (\mathbb{Z}/27\mathbb{Z})^2, \qquad \mathcal{D} := \{\mathrm{N},\mathrm{S},\mathrm{E},\mathrm{W}\},$$

and consider the real space

$$\mathcal{H}_{27}^{\mathbb{R},\mathrm{reg}} := \ell^2(\mathbb{T}^2_{27};\mathbb{R}) \otimes \mathbb{R}^{\mathcal{D}} \otimes E.$$

The endomorphism J_E is extended as the identity on the position and direction factors, and the same notation is retained for that extension.

In the ordered basis $(\mathrm{N},\mathrm{S},\mathrm{E},\mathrm{W})$, the directional mixer is

$$C_4 := \frac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1\\ 1 & 1 & -1 & -1\\ 1 & -1 & 1 & -1\\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad C_4^{\mathsf{T}}C_4 = I_4. \tag{65.4}$$

Here C_4 denotes exclusively the Walsh–Hadamard mixer on the directional fiber; when it acts on $\mathcal{H}_{27}^{\mathbb{R},\mathrm{reg}}$ it is understood as $C_4 \otimes I_E$.

Fix a translational chart in which the action of an elementary edge γ_d depends only on its direction:

$$s_d := S_{\mathrm{int}}(\gamma_d) \in \mathcal{L}_S, \qquad a_d := \frac{s_d}{\hbar_{\mathrm{int}}} \in \mathbb{R}.$$

The real diagonal phase operator is

$$D_J := \mathrm{diag}\left(e^{-J_E a_{\mathrm{N}}}, e^{-J_E a_{\mathrm{S}}}, e^{-J_E a_{\mathrm{E}}}, e^{-J_E a_{\mathrm{W}}}\right).$$

The conditional shift transports each component in its direction:

$$\begin{aligned} (S\psi)(x,y,\mathrm{N}) &= \psi(x,y-1,\mathrm{N}), & (S\psi)(x,y,\mathrm{S}) &= \psi(x,y+1,\mathrm{S}),\\ (S\psi)(x,y,\mathrm{E}) &= \psi(x-1,y,\mathrm{E}), & (S\psi)(x,y,\mathrm{W}) &= \psi(x+1,y,\mathrm{W}), \end{aligned}$$

with all coordinates taken modulo 27. The elementary step and its composition of twelve steps are

$$U_{\mathrm{micro}} := S D_J C_4, \qquad U_{12}^{\mathrm{reg}} := U_{\mathrm{micro}}^{12}. \tag{65.5}$$

The superscript reg preserves the type: this operator acts on the directional torus 27×27 and is not identified with the other dodecaphasic objects of the construction or with the temporal endomorphism of order 108.

Proposition 65.4 (Unitarity and exact path sum in the register)**.** *The operator U_{micro} is orthogonal on the realification and unitary in the complex chart determined by J_E. In particular, U_{12}^{reg} is unitary. If $\Xi := \mathbb{T}_{27}^2 \times \mathcal{D}$, then, for every $n \geq 0$ and $\xi_i, \xi_f \in \Xi$,*

$$\left(U_{\mathrm{micro}}^n\right)_{\xi_f,\xi_i} = \sum_{\substack{\gamma:\xi_i \to \xi_f \\ |\gamma|=n}} W_{U_{\mathrm{micro}}}(\gamma),$$

where, for $\gamma = (\xi_0, \ldots, \xi_n)$,

$$W_{U_{\mathrm{micro}}}(\gamma) := (U_{\mathrm{micro}})_{\xi_n,\xi_{n-1}} \cdots (U_{\mathrm{micro}})_{\xi_1,\xi_0}.$$

The sum ranges over exactly the paths permitted by the nonzero blocks of the operator.

Proof. Since J_E is orthogonal and $J_E^2 = -I$, we have $J_E^{\mathsf{T}} = -J_E$. Thus, each block $e^{-J_E a_d}$ is an orthogonal rotation and D_J is orthogonal. The operator S permutes an orthonormal basis, and (65.4) proves that C_4 is orthogonal. Consequently,

$$U_{\mathrm{micro}}^{\mathsf{T}} U_{\mathrm{micro}} = C_4^{\mathsf{T}} D_J^{\mathsf{T}} S^{\mathsf{T}} S D_J C_4 = I.$$

All three factors commute with the extension of J_E; hence U_{micro} is complex-linear in the chart $J_E \leftrightarrow \mathrm{i}$, and its real orthogonality is equivalent to unitarity. Every power, in particular U_{12}^{reg}, preserves this property.

For $n \geq 1$, block multiplication gives

$$\left(U_{\mathrm{micro}}^n\right)_{\xi_f,\xi_i} = \sum_{\xi_1,\ldots,\xi_{n-1}} (U_{\mathrm{micro}})_{\xi_f,\xi_{n-1}} \cdots (U_{\mathrm{micro}})_{\xi_1,\xi_i}.$$

Each choice of intermediate states determines a path of length n, and each path determines a unique ordered product. For $n = 0$, the sole term is the empty path and its weight is the identity. □

Translation invariance decomposes the problem into blocks of four directional components, tensored with E. For

$$k_x = \frac{2\pi a}{27}, \qquad k_y = \frac{2\pi b}{27}, \qquad 0 \le a, b < 27,$$

we adopt the realified Fourier convention

$$\chi_{a,b}(x, y) := \exp[-J_E(k_x x + k_y y)].$$

Direct substitution into the conditional shift produces

$$S(k_x, k_y) = \operatorname{diag}\big(e^{J_E k_y}, e^{-J_E k_y}, e^{J_E k_x}, e^{-J_E k_x}\big),$$

and, since D_J and C_4 do not depend on position,

$$\begin{aligned} U_{\text{micro}}(k_x, k_y) &= S(k_x, k_y) D_J C_4, \\ U_{12}^{\text{reg}}(k_x, k_y) &= U_{\text{micro}}(k_x, k_y)^{12}. \end{aligned} \tag{65.6}$$

Consequently,

$$\operatorname{Spec} U_{12}^{\text{reg}} = \bigcup_{a,b=0}^{26} \operatorname{Spec} U_{12}^{\text{reg}} \left(\frac{2\pi a}{27}, \frac{2\pi b}{27} \right).$$

The matrix power enumerates paths, and the Fourier decomposition publishes the quasienergies of the same finite dynamics.

Fix an elementary duration $\delta t > 0$, and let $\Delta t_{12} := 12\,\delta t$. In each unitary block, choose a spectral branch $\mathfrak{b}$ of the logarithm. The operator $\operatorname{Log}_{\mathfrak{b}} U_{12}^{\text{reg}}(k_x, k_y)$ is skew-adjoint and commutes with J_E. Define

$$\begin{aligned} H_{\text{eff}}(k_x, k_y) &:= \frac{\hbar_{\text{int}}}{\Delta t_{12}} J_E \operatorname{Log}_{\mathfrak{b}} U_{12}^{\text{reg}}(k_x, k_y), \\ U_{12}^{\text{reg}}(k_x, k_y) &= \exp\left[-\frac{J_E \Delta t_{12}}{\hbar_{\text{int}}} H_{\text{eff}}(k_x, k_y) \right]. \end{aligned} \tag{65.7}$$

The first line is self-adjoint in the complex chart. The second follows from $-J_E^2 = I$ and proves that the exponential recovers the propagator exactly. The branch $\mathfrak{b}$ fixes the quasienergy zone.

This realization constructs a finite propagator, its exact path sum and its effective generator. Identifying it with a continuous physical Hamiltonian still requires verification of the representation, action and limit hypotheses stated below.

65.2.4 Cylindrical limit on the space of genealogies

With endpoints fixed, let $\mathcal{P}_n$ be finite sets of paths at resolution n, with surjective restriction maps. The space

$$\Omega_{fi}^{\text{path}} := \varprojlim_n \mathcal{P}_n$$

is compact and totally disconnected. A compatible family of probability measures μ_n on the cylinders determines a Borel measure μ on $\Omega_{fi}^{\text{path}}$.

Let Π_n be the partition into level-n cylinders. For $C \in \Pi_n$, choose a representative γ_C, an approximate action $S_n(C)$ and the weight $\mu_n(C)$. For $F : \Omega_{fi}^{\text{path}} \to \operatorname{End}(E)$, define

$$\mathcal{I}_n(F) := \sum_{C \in \Pi_n} \mu_n(C) F(\gamma_C) \exp\left[-J_E \frac{S_n(C)}{\hbar_{\text{int}}} \right]. \tag{65.8}$$

Theorem 65.5 (Genealogical path integral)**.** *Suppose that:*

1. *the cylinder measures μ_n are projectively compatible;*
2. *F is continuous and bounded;*
3. *there exists a continuous action $S : \Omega_{fi}^{\mathrm{path}} \to \mathcal{L}_S$ for which*

$$\max_{C\in\Pi_n} \sup_{\gamma\in C} \left\| \frac{S_n(C) - S(\gamma)}{\hbar_{\mathrm{int}}} \right\| \longrightarrow 0;$$

4. *the mesh of Π_n tends to zero.*

Then $\mathcal{I}_n(F)$ converges in operator norm, the limit is independent of the representatives, and it defines the Bochner integral

$$\int_{\Omega_{fi}^{\mathrm{path}}} F(\gamma) \exp\left[-J_E \frac{S(\gamma)}{\hbar_{\mathrm{int}}}\right] \mathrm{d}\mu(\gamma). \tag{65.9}$$

Proof. Compatibility of the finite measures constructs μ on the cylinder algebra and, by extension, on the Borel sigma-algebra. The function

$$G(\gamma) = F(\gamma) \exp[-J_E\, S(\gamma)/\hbar_{\mathrm{int}}]$$

is continuous on a compact space and is therefore uniformly continuous and bounded. Orthogonality of J_E gives the estimate

$$\|e^{-J_E a} - e^{-J_E b}\| \le |a - b|.$$

Uniform approximation of the action and contraction of the mesh make the cylindrical sums converge to the Bochner integral of G [13]. □

The theorem constructs a rigorous integral on the compact space of genealogies. Its realization as a Feynman oscillatory integral for a specific Hamiltonian is obtained when the finite kernels, action and cylinder measure satisfy these convergence hypotheses. The finite matrix expansion, genealogical integral and physical propagator are thus related by explicit morphisms, without being identified by abbreviation.

65.2.5 Spectral decomposition of the path measure and conditioning of futures

Let $\mathrm{Val}_{\mathrm{path}} : \Omega_{fi}^{\mathrm{path}} \to K \subset \mathbb{R}$ be a Borel-measurable path reader, where K carries its standard Borel structure, and let $\nu = (\mathrm{Val}_{\mathrm{path}})_*\mu$. For every function factoring through the value, $F = \widehat{F} \circ \mathrm{Val}_{\mathrm{path}}$, we have

$$\int_{\Omega_{fi}^{\mathrm{path}}} F \,\mathrm{d}\mu = \int_K \widehat{F}(x)\,\mathrm{d}\nu(x).$$

Since $\Omega_{fi}^{\mathrm{path}}$ is compact metrizable and μ is a Borel probability measure, there exists a family of regular conditional probabilities $(\mu_x)_{x\in K}$, defined for ν-almost every x. For a general genealogical integrand, the disintegration of μ takes the form

$$\int_{\Omega_{fi}^{\mathrm{path}}} G(\gamma)\,\mathrm{d}\mu(\gamma) = \int_K \left[\int_{\mathrm{Val}_{\mathrm{path}}^{-1}(x)} G(\gamma)\,\mathrm{d}\mu_x(\gamma) \right] \mathrm{d}\nu(x). \tag{65.10}$$

The inner integral preserves the distinct histories that publish the same coordinate. This is the precise link between the sum over all paths, real evaluation, and the thesis that the continuum is a projection of a richer genealogical domain.

Domain of the genealogical path integral: cylindrical compactness, projective consistency, kernel convergence and disintegration over fibers The finite expansion, unitary realization on $\mathbb{T}^2_{27}$ and its

Fourier reduction are exact on their finite domains. The construction of H_{eff} is exact once the complex structure, elementary translational action, duration and spectral branch have been declared; it does not by itself select a continuous physical Hamiltonian. The enriched route category and internal phase precede the cylindrical assembly. theorem 65.5 is exact under the four declared premises. Realizing a specific continuous quantum model requires verifying those premises for its action and Hamiltonian.

65.3 Cylindrical Concentration of the Genealogical Measure of Trajectories and Realization of the Dirac Kernel

65.3.1 Projective limit of genealogies and domain of the path integral

Let

$$X = (\mathbb{Z}/9\mathbb{Z})^{\mathbb{N}}$$

with the product topology and the uniform measure μ. For $x = (x_1, x_2, \ldots)$, the cylinder of depth n is

$$C_n(x) = \{y \in X : y_j = x_j \text{ for } 1 \le j \le n\}.$$

Cylinders are simultaneously open and closed, form a base and satisfy

$$\mu(C_n(x)) = 9^{-n}, \qquad C_{n+1}(x) \subset C_n(x), \qquad \bigcap_n C_n(x) = \{x\}.$$

Adding a digit does not create a new number: it restricts the cylinder of admissible prolongations. This statement gives topological content to the genealogical thesis of number.

65.3.2 Inverse limit of the nonadic cylinders and stability of the Dirac kernel

Theorem 65.6 (Unitary nonadic concentration)**.** *Define*

$$f_{n,x} = 9^n \mathbf{1}_{C_n(x)}.$$

Then

$$\mu(C_n(x)) \to 0, \qquad f_{n,x}(x) \to \infty, \qquad \int_X f_{n,x}\, \mathrm{d}\mu = 1,$$

and the measures $f_{n,x}\mu$ converge weak- to δ_x.*

Proof. The first identity is immediate. The height of $f_{n,x}$ over its support is 9^n, so it diverges. The integral equals $9^n 9^{-n} = 1$. For $g \in C(X)$, the oscillation of g in $C_n(x)$ tends to zero by uniform continuity; therefore

$$\left| \int g f_{n,x}\, \mathrm{d}\mu - g(x) \right| \le \sup_{y \in C_n(x)} |g(y) - g(x)| \longrightarrow 0.$$

This is weak-* convergence to δ_x. □

The theorem does not assert $1/0 = \infty$. It exhibits three evaluations of the same object: support measure, density and total mass. In blocks of three digits,

$$\mu(C_{3m}) = 729^{-m}, \qquad f_{3m} = 729^m \mathbf{1}_{C_{3m}}, \qquad 729^{-m} 729^m = 1.$$

The evolutionary conservation of unity here assumes an exact analytical form.

65.3.3 Kronecker Kernel and Realization of the Dirac Distribution in the Genealogical Register

At the finite level $X_n = (\mathbb{Z}/9\mathbb{Z})^n$, let

$$K_n(x, y) = 9^n \mathbf{1}_{\{x=y\}}.$$

With the uniform measure, the operator

$$(E_n f)(x) = \sum_{y \in X_n} K_n(x, y) f(y) 9^{-n}$$

is the identity. In the cylindrical limit, the condition $x = y$ is replaced by "same prefix of length n" and E_n is the conditional expectation on the cylindrical algebra. One has

$$E_n^2 = E_n, \qquad E_n^* = E_n, \qquad E_n f \to f \quad \text{in } L^2(X, \mu).$$

The exact bridge is, therefore,

$$\delta_{ij} \longrightarrow K_n(x, y) \longrightarrow \delta_x.$$

The Kronecker delta is a matrix kernel; the Dirac delta is a measure or distribution. Neither is the Dirac operator $D = \gamma^\mu \partial_\mu$. The transition to spinors and Clifford requires a second intertwiner and will be treated later.

65.3.4 Path Measure Scaling: Effective Dimension and Density

Suppose that a contraction of ratio λ acts independently in d directions and that the product measure scales as λ^d. To preserve unit mass, the density must scale as

$$\rho \longmapsto \lambda^{-d} \rho.$$

The exponents $(-1, -2, -3)$ then appear as density weights on a line, area, and volume. This proposition is general and exact under the product hypothesis. It does not permit λ to be identified automatically with α_{HMT}; that identification requires a metric chart.

65.3.5 Monodromy of the Logarithm and Computability of the Genealogical Amplitude

The existence of an infinite branch in a finitely branching tree may follow from König's lemma, but König's lemma does not furnish a computable selector. There are infinite recursive binary trees with no recursive branch. The joint nonadic connection does not rest on that abstract existence: it has a certified uniform selector that generates to arbitrary finite depth and opens the decimal witnesses only after generation.

Three prohibited confusions

1/0 shall not be written; the Dirac delta shall not be represented as an ordinary function with "an infinite one"; König shall not be used as an algorithm. The strong result is the exact compatibility among cylinders, unit density, and the weak limit, together with the constructive selector independent of decimal comparison.

65.4 Genealogical Path Algebra and Feynman Representation

Feynman's formulation assigns an amplitude to each possible history and sums those amplitudes to obtain the propagator. In HMT, the word *history* has content prior to amplitude: a route preserves position, sheet, orientation, phase, carry, boundary, memory, and survival condition. The sum over paths is not added to that system from outside. It appears upon linearly representing its category of routes [48, 49].

The development has three linked mathematical levels. The expansion of a matrix power as a finite sum of paths has already been proved in Dimensional Mechanics. The ledger 27×27 provides a unitary realization with shift, mixer, and phase, diagonalizable by Fourier transform. The family of finite sums subsequently admits a cylindrical limit when the measure, the action, and the refinement satisfy the hypotheses of the convergence theorem. The combinatorial identity, its spectral realization, and its functional extension are thereby brought together.

65.4.1 The enriched category of paths

Let X be a finite set of observable states, and let $\mathsf{P}_{\mathrm{TPK}}$ be the free category generated by the admissible TPK transitions. Denote $\widetilde{X} = \mathrm{Ob}(\mathsf{P}_{\mathrm{TPK}})$. Its objects are enriched boundary states. A morphism $\gamma : \widetilde{x} \to \widetilde{y}$ is a composable sequence of enriched transitions. Composition is concatenation, and the identity is the empty path.

The visible projection

$$q_{\mathrm{vis}} : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{P}_X$$

forgets part of the fiber. Two different morphisms may have the same observable word. This lack of faithfulness is essential: a sum that aggregated too early over P_X would lose precisely the information capable of distinguishing incompatible futures.

Definition 65.7 (Genealogical weight)**.** Let $\mathcal{B}$ be a real normed algebra, not necessarily commutative, and let $B(\mathcal{B}, \cdot, 1)$ be the one-object category whose endomorphism monoid is $(\mathcal{B}, \cdot, 1)$. A genealogical weight is a functor

$$W : \mathsf{P}_{\mathrm{TPK}} \longrightarrow B(\mathcal{B}, \cdot, 1)$$

which satisfies

$$W(\mathrm{id}_x) = 1_{\mathcal{B}}, \qquad W(\gamma_2 \circ \gamma_1) = W(\gamma_2) W(\gamma_1).$$

The order of the product follows the causal order of the route.

The weight may contain a fibre transport, a positive penalty, an action, a ledger character, or several of those factors. The definition does not conflate those functions: each component retains its domain and composition rule.

65.4.2 The exact finite sum

Let E_x be the linear fiber over $x \in X$ and $\mathcal{H}_X = \bigoplus_{x \in X} E_x$. Let $U = (U_{yx})_{x,y \in X}$ be the global block operator, with $U_{yx} : E_x \to E_y$. We interpret U_{yx} as elementary transport from x to y. For a visible path $\gamma = (x_0, x_1, \ldots, x_R)$, we define

$$W_U(\gamma) = U_{x_R x_{R-1}} \cdots U_{x_1 x_0}.$$

Theorem 65.8 (Finite Path Expansion)**.** *For every $R \geq 1$,*

$$(U^R)_{fi} = \sum_{\substack{\gamma : i \to f \\ |\gamma| = R}} W_U(\gamma). \tag{65.11}$$

If the global operator $U : \mathcal{H}_X \to \mathcal{H}_X$ is orthogonal —or unitary after choosing a complex chart—, the evolution $\psi_R = U^R \psi_0$ preserves the norm.

Proof. The entry (f, i) of the product U^R is

$$\sum_{x_1,\dots,x_{R-1}} U_{f x_{R-1}} U_{x_{R-1} x_{R-2}} \cdots U_{x_1 i}.$$

Each choice of intermediate indices determines a unique path of length R, and each path determines a unique ordered monomial. Norm conservation is an immediate consequence of $(U^R)^{\mathsf{T}} U^R = I$, or of its unitary version. □

The formula (65.11) is the combinatorial identity underlying the sum over histories. Its HMT content appears when each visible path is refined by the fibers of q_{vis}:

$$\mathcal{K}_R(\widetilde{f}, \widetilde{i}) = \sum_{\substack{\gamma \in \mathsf{P}_{\mathrm{TPK}}(\widetilde{i}, \widetilde{f}) \\ |\gamma| = R}} W(\gamma). \tag{65.12}$$

In that sum, two published routes with the same endpoints remain distinct terms whenever their genealogies differ.

65.4.3 Unitary realization on the genealogical record 27×27

The historical source develops a quantum walk on the torus

$$\Lambda_{27} = (\mathbb{Z}/27\mathbb{Z})^2$$

with four cardinal orientations $\mathcal{D} = \{N, S, E, W\}$. Its real phase space is

$$\mathcal{H}_{27}^{\mathbb{R}} = \ell^2(\Lambda_{27}) \otimes \mathbb{R}^4 \otimes E,$$

where (E, J_E) internally realizes the complex structure. The direction mixer is the Walsh–Hadamard matrix

$$C_4 = \frac{1}{2} \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad C_4^{\mathsf{T}} C_4 = I_4.$$

An oriented elementary action $s_d \in \mathcal{L}_S$ defines the real phase gate

$$D_J = \operatorname{diag}\left(e^{-J_E s_N/\hbar_{\mathrm{int}}}, e^{-J_E s_S/\hbar_{\mathrm{int}}}, e^{-J_E s_E/\hbar_{\mathrm{int}}}, e^{-J_E s_W/\hbar_{\mathrm{int}}} \right).$$

The conditioned shift transports each component in its direction:

$$\begin{aligned} (S\psi)(x, y, N) &= \psi(x, y-1, N), & (S\psi)(x, y, S) &= \psi(x, y+1, S), \\ (S\psi)(x, y, E) &= \psi(x-1, y, E), & (S\psi)(x, y, W) &= \psi(x+1, y, W), \end{aligned}$$

with coordinates modulo 27. The elementary step and the dodecaphase composition are

$$U_{\mathrm{micro}} = S D_J C_4, \qquad U_{12} = U_{\mathrm{micro}}^{12}. \tag{65.13}$$

Proposition 65.9 (Unitarity and exact sum in the ledger)**.** *The operator U_{micro} is orthogonal on the realification and unitary in the complex chart. For every n, each entry of U_{micro}^n is the ordered sum of the weights of all paths of n steps joining its endpoint states.*

Proof. The shift is a permutation, C_4 is orthogonal, and each block $e^{-J_E s_d/\hbar_{\mathrm{int}}}$ is a rotation. Their product is orthogonal. The second assertion is the theorem 65.8 applied to the block matrix U_{micro}. □

Translational symmetry reduces the spectral problem to blocks of size four. For

$$k_x = \frac{2\pi m}{27}, \qquad k_y = \frac{2\pi n}{27}, \qquad 0 \le m, n < 27,$$

the shift diagonalizes as

$$S(k_x, k_y) = \operatorname{diag}\big(e^{J_E k_y}, e^{-J_E k_y}, e^{J_E k_x}, e^{-J_E k_x}\big),$$

and

$$U_{\text{micro}}(k_x, k_y) = S(k_x, k_y) D_J C_4, \qquad U_{12}(k_x, k_y) = U_{\text{micro}}(k_x, k_y)^{12}. \tag{65.14}$$

The global spectrum is the union of the spectra of the 27^2 blocks. The expression combines two representations of the same dynamics: the matrix power enumerates paths, and the Fourier transform publishes quasienergies.

In each unit block a spectral logarithm can be chosen and defined

$$H_{\text{eff}}(k_x, k_y) = \frac{\hbar_{\text{int}}}{J_E\, \Delta t} \log U_{12}(k_x, k_y),$$

understood through functional calculus in the complex chart or its realification. The choice of branch fixes the quasienergy zone. The effective Hamiltonian thus arises from the propagator already constructed; its exponential recovers U_{12} in each mode.

65.4.4 Real action character

Let $\mathcal{A}_* : \mathsf{P}_{\text{TPK}} \to \mathbb{R}_{\ge 0}$ be the additive action cocycle of the HMT–MD source. The gauge is

$$\lambda_* = 1 - \frac{5}{468} - \frac{3}{11}\Delta_4 = 0.9892859130191415\ldots \in (0, 1).$$

The local clause H_{loc} assigns unit cost to a turn, cost λ_* to a change of sheet, and adds both when they occur on the same edge. Under this clause,

$$\mathcal{A}_*(\gamma) = \#\,\text{turns}(\gamma) + \lambda_* \#\,\text{sheet-switches}(\gamma), \qquad \mathcal{A}_*(\gamma_2 \circ \gamma_1) = \mathcal{A}_*(\gamma_2) + \mathcal{A}_*(\gamma_1).$$

The associated dimensional action is

$$S_{\text{int}}(\gamma) = \hbar_{\text{int}} \mathcal{A}_*(\gamma).$$

In the real phase module (E, J_E) of the preceding chapter, with E a finite-dimensional real Euclidean space, define

$$\Phi_J(\gamma) := \exp\!\left(-J_E \frac{S_{\text{int}}(\gamma)}{\hbar_{\text{int}}}\right) = \cos \mathcal{A}_*(\gamma)\, I - \sin \mathcal{A}_*(\gamma)\, J_E. \tag{65.15}$$

Proposition 65.10 (Multiplicativity of the internal phase)**.** *The map Φ_J is a functor from P_{TPK} to the orthogonal group generated by J_E:*

$$\Phi_J(\mathrm{id}_x) = I, \qquad \Phi_J(\gamma_2 \circ \gamma_1) = \Phi_J(\gamma_2)\Phi_J(\gamma_1).$$

Proof. The first equality uses $\mathcal{A}_*(\mathrm{id}_x) = 0$. For the second, the additivity of $\mathcal{A}_*$ and the commutation of multiples of the same endomorphism J_E give

$$e^{-J_E(\mathcal{A}_*(\gamma_2)+\mathcal{A}_*(\gamma_1))} = e^{-J_E \mathcal{A}_*(\gamma_2)} e^{-J_E \mathcal{A}_*(\gamma_1)}.$$

□

Now let $T(e) \in \mathrm{End}(E)$ be the bounded fiber transport of an edge, and suppose that it preserves J_E. The weight

$$W_J(\gamma) = \overleftarrow{\prod_{e\in\gamma}} T(e) \exp\left(-J_E \frac{s(e)}{\hbar_{\mathrm{int}}}\right)$$

realizes, entirely on E, the Hamiltonian convention $\exp(-iS_H[\gamma]/\hbar)$. The usual Feynman Lagrangian convention $\exp(+iS_L[\gamma]/\hbar)$ is obtained by taking $S_L = -S_H$ or, equivalently, by introducing an orientation $\varepsilon \in \{-1, +1\}$ in $\exp(\varepsilon J_E S/\hbar_{\mathrm{int}})$. The scalar symbol i is the complex chart of the algebraic operation performed by J_E. The positive cost $\mathcal{A}_*$ becomes physical action upon application of the corresponding realization map.

65.4.5 Composition of propagators over concatenated paths and amplitude law

The genealogy preserves the composition law that makes the kernel dynamic.

Proposition 65.11 (Convolution and Temporal Truncation)**.** *Suppose that $\widetilde{X}$ is finite; more generally, suppose that the following family of products is absolutely summable. If every route of length $R+S$ has a unique cut after R steps, then*

$$\mathcal{K}_{R+S}(\widetilde{f},\widetilde{i}) = \sum_{\widetilde{x}\in\widetilde{X}} \mathcal{K}_S(\widetilde{f},\widetilde{x})\mathcal{K}_R(\widetilde{x},\widetilde{i}). \tag{65.16}$$

The identity remains valid with noncommutative weights if the causal order of the factors is preserved.

Proof. We partition the set of routes by the enriched state $\widetilde{x}$ reached at the cut. Functorial factorization of the weight transforms the sum over complete routes into the product of the two partial sums, with the subsequent segment on the left. □

The cut on the visible state would be valid only if weight and composition descended faithfully through q_{vis}. In the presence of memory, two segments with the same visible coordinate may belong to incompatible fibers; hence convolution is performed over $\widetilde{X}$.

This equation distinguishes the sum over paths from a collection of numerical coincidences. The propagator has a semigroup, endpoints, composition, and a refinement law.

65.4.6 Cylindrical limit of the finite system and construction of the corresponding integral

A functional integral requires control of the path space and its refinement. For enriched endpoints $\widetilde{i}, \widetilde{f}$, let $\mathcal{P}_n(\widetilde{i}, \widetilde{f})$ be the finite sets of admissible paths at resolution n, with surjective restrictions, and define

$$\Omega_{fi}^{\mathrm{path}} := \varprojlim_n \mathcal{P}_n(\widetilde{i}, \widetilde{f}).$$

It is the compact space of path genealogies with those boundary data. Let $\{\Pi_n\}_{n\geq 0}$ be a sequence of cylindrical partitions of $\Omega_{fi}^{\mathrm{path}}$, with Π_{n+1} refining Π_n. For each cylinder $C \in \Pi_n$, let us choose a representative γ_C, a projective weight $\mu_n(C)$, and an approximate action $S_n(C)$.

We define the simple operator

$$\mathcal{I}_n(F) := \sum_{C\in\Pi_n} \mu_n(C) F(\gamma_C) \exp\left(-J_E \frac{S_n(C)}{\hbar_{\mathrm{int}}}\right). \tag{65.17}$$

Theorem 65.12 (Genealogical Limit of Cylindrical Integrals)**.** *Suppose that:*

1. *the cylindrical masses are projectively compatible;*
2. *$F : \Omega_{fi}^{\mathrm{path}} \to \mathrm{End}(E)$ is continuous and bounded;*

3. *there exists a continuous function* $S : \Omega_{fi}^{\mathrm{path}} \to \mathcal{L}_S$ *such that*

$$\max_{C\in\Pi_n} \sup_{\gamma\in C} \left\| \frac{S_n(C) - S(\gamma)}{\hbar_{\mathrm{int}}} \right\| \longrightarrow 0;$$

4. *the mesh of the partitions,* $\mathrm{mesh}(\Pi_n) = \max_{C\in\Pi_n} \mathrm{diam}_{d_\vartheta} C$*, tends to zero.*

Since E *is finite-dimensional,* $\mathrm{End}(E)$*, endowed with the operator norm, is a Banach space; the following integral is therefore a well-defined Bochner integral [13]. Then* $\mathcal{I}_n(F)$ *converges in operator norm, and its limit does not depend on the representatives. We write*

$$\int_{\Omega_{fi}^{\mathrm{path}}} F(\gamma) \exp\!\left(-J_E \frac{S(\gamma)}{\hbar_{\mathrm{int}}}\right) \mathrm{d}\mu(\gamma) := \lim_{n\to\infty} \mathcal{I}_n(F). \tag{65.18}$$

Proof. Projective compatibility constructs the cylinder measure μ. The function

$$G(\gamma) = F(\gamma) \exp(-J_E S(\gamma)/\hbar_{\mathrm{int}})$$

is continuous on the compact set $\Omega_{fi}^{\mathrm{path}}$, hence uniformly continuous and bounded. Let

$$G_n(C) = F(\gamma_C) \exp(-J_E S_n(C)/\hbar_{\mathrm{int}}) \,.$$

Since J_E is an orthogonal structure,

$$\|e^{-J_E a} - e^{-J_E b}\| \le |a - b|.$$

The third hypothesis implies that $G_n(C) - G(\gamma_C)$ tends uniformly to zero. The fourth hypothesis and the uniform continuity of G make the sums with $G(\gamma_C)$ convergent Riemann sums independent of the representatives. The limit coincides with the Bochner integral of G with respect to μ. More precisely, if

$$\epsilon_n = \max_{C\in\Pi_n} \sup_{\gamma\in C} \left\| \frac{S_n(C) - S(\gamma)}{\hbar_{\mathrm{int}}} \right\|,$$

then

$$\left\| \mathcal{I}_n(F) - \int G \, \mathrm{d}\mu \right\| \le \omega_F\big(\mathrm{mesh}(\Pi_n)\big) + \|F\|_\infty \epsilon_n,$$

because the integral decomposes over the cylinders and the total mass is one. Both terms tend to zero by hypothesis. □

Corollary 65.13 (Convergence of a family of discrete kernels)**.** *In addition to the hypotheses of theorem 65.12, suppose that there exists a cofinal sequence of depths* R_n *and simple functions* $F_{fi,n}$ *such that*

$$\mathcal{K}_{R_n}(\widetilde{f},\widetilde{i}) = \mathcal{I}_n(F_{fi,n}), \qquad F_{fi,n} \longrightarrow F_{fi}$$

uniformly. Then the kernels $\mathcal{K}_{R_n}(\widetilde{f},\widetilde{i})$ *converge to the genealogical integral of* F_{fi}*.*

Proof. The difference between $\mathcal{I}_n(F_{fi,n})$ and $\mathcal{I}_n(F_{fi})$ is bounded by $\|F_{fi,n} - F_{fi}\|_\infty$, because μ_n has total mass one and the phase is orthogonal. The second term converges by theorem 65.12. □

The theorem produces a rigorous integral over the compact genealogical space. The corollary makes explicit the bridge that identifies each matrix kernel with a normalized cylindrical sum. The real-time Feynman oscillatory integral appears when a physical representation and a refinement whose discrete action approximates the action of the system are chosen. That identification requires proof of convergence of the corresponding propagator; it is not granted by the mere existence of μ.

65.4.7 Integral visible and integral conditioned by memory

A real path reader $\mathrm{Val}_{\mathrm{path}} : \Omega_{fi}^{\mathrm{path}} \to K \subset \mathbb{R}$ induces the visible measure $\nu = (\mathrm{Val}_{\mathrm{path}})_*\mu$. For a function that factors through the value, $F = \widehat{F} \circ \mathrm{Val}_{\mathrm{path}}$,

$$\int_{\Omega_{fi}^{\mathrm{path}}} F \, \mathrm{d}\mu = \int_K \widehat{F}(x) \, \mathrm{d}\nu(x).$$

The phase or transport, however, may fail to factor through $\mathrm{Val}_{\mathrm{path}}$. The disintegration of μ over the value fibers expresses the difference:

$$\int_{\Omega_{fi}^{\mathrm{path}}} G(\gamma) \, \mathrm{d}\mu(\gamma) = \int_K \left[\int_{\mathrm{Val}_{\mathrm{path}}^{-1}(x)} G(\gamma) \, \mathrm{d}\mu_x(\gamma) \right] \mathrm{d}\nu(x). \tag{65.19}$$

The inner integral preserves the histories that publish the same coordinate. This is the mathematical form of integration with respect to values without reducing the number to its digit.

65.4.8 Action, interference, and persistence

The genealogical sum simultaneously maintains three operations:

$$\text{route admissibility} \longrightarrow \text{weight/action} \longrightarrow \text{interference in the representation.}$$

The first belongs to TPK and its survival law. The second belongs to the cocycle and dimensional transport. The third belongs to the phase module and the physical reader. No observed magnitude retrospectively selects the route that produces it.

Result

The finite Feynman sum is obtained as an exact linear representation of the enriched category of routes. The complex structure can be realized by a real endomorphism $J_E^2 = -I$. Under compatibility of measures, contraction of cylinders, and uniform convergence of actions, the cylindrical sums define a genealogical integral. The finite kernels converge to it when they additionally satisfy the bridge of the corollary 65.13.

Hypothesis, domain, and conclusion

The finite matrix expansion, the action cocycle, and the real realizations of the complex structure are recovered results. Their assembly in (65.15) and (65.12) is an exact new formalization. The theorem 65.12 is exact under its premises. Equivalence with a concrete continuous quantum model requires verifying those premises for the Hamiltonian and the action of that model.

The premises of the theorem identify exactly the structure that passes from the finite ledger to the function space: projective compatibility of the weights, contraction of the mesh, uniform convergence of the action, and correspondence between kernels and cylindrical sums. In the realization (65.13), composition and unitarity are algebraic identities; as the ledger is refined, the remaining premises determine convergence to the chosen continuum propagator.

Chapter 66

Genealogical theory of quantum measurement: reversible coupling, instruments, conditioning of futures, and spectral update

Measurement is formulated as a reversible coupling between a section and a context, followed by spectral publication. The induced instruments preserve the genealogy required to condition future events without turning the outcome into a unique retrospective history.

66.1 Conditioning of sections and quantum updating

The preceding general theory places measurement in the joint state of system, reader, and apparatus. The quantum realization adds a precise correspondence among three levels: restriction of the section space, spectral projection, and the completely positive instrument. Joint evolution belongs to coupling; publication of the outcome belongs to the reader; updating belongs to conditioning on the read fiber.

66.1.1 Measurement context $\mathfrak{M}_a = (U_a, q_a, C_a, m_0)$, output map, and conditioned fiber $\Omega_{a,y}$

Let (Ω_S, Σ_S) and (Ω_M, Σ_M) be the measurable spaces of genealogical states of the system and apparatus. A context a is specified by

$$\mathfrak{M}_a = (U_a, q_a, C_a, m_0), \tag{66.1}$$

where $m_0 \in \Omega_M$ is the preparation of the apparatus,

$$U_a : \Omega_S \times \Omega_M \longrightarrow \Omega_S \times \Omega_M$$

is a measurable coupling, (Y_a, Σ_{Y_a}) is the measurable space of outcomes, $q_a : \Omega_M \to Y_a$ is a measurable reader of the pointer, and C_a declares compatibility and the horizon of prolongation. When a reversible regime is invoked, it will also be required that U_a be bijective and bimeasurable; in the Hilbert realization, the corresponding condition is the unitarity of $\widehat{U}_a$. The output is

$$\mathrm{Out}_a(x) = q_a\big(\mathrm{pr}_M\, U_a(x, m_0)\big)\,. \tag{66.2}$$

Let $\Omega_a \in \Sigma_S$ be the set of sections compatible with the preparation and the context. The map Out_a is measurable by composition. For $y \in Y_a$ with $\{y\} \in \Sigma_{Y_a}$, define the measurable fiber

$$\Omega_{a,y} := \{x \in \Omega_a : \mathrm{Out}_a(x) = y\}. \tag{66.3}$$

Definition 66.1 (Genealogical Update)**.** The update determined by the result y is the restriction

$$\Omega_a \longmapsto \Omega_{a,y}.$$

At finite depth it preserves exactly the prefixes that admit some extension in $\Omega_{a,y}$.

For a prefix $s \in S_n$, the compatible futures subsequent to the reading form

$$\mathrm{Fut}_{a,y}(s) = \{x \in \Omega_{a,y} : x|_n = s\}.$$

The update modifies the prolongation condition and preserves the already traversed prefix together with the coupling record.

Proposition 66.2 (Conditional probability over the fiber)**.** *Let μ_a be a probability measure on the restricted measurable space $(\Omega_a, \Sigma_S|_{\Omega_a})$, let $B \in \Sigma_S|_{\Omega_a}$, and suppose $\mu_a(\Omega_{a,y}) > 0$. Then*

$$\mu_{a,y}(B) = \frac{\mu_a(B \cap \Omega_{a,y})}{\mu_a(\Omega_{a,y})} \tag{66.4}$$

defines a probability concentrated on the fiber of the result: $\mu_{a,y}(\Omega_{a,y}) = 1$.

Proof. The map is nonnegative and countably additive by the properties of μ_a. Normalization follows by substituting $B = \Omega_{a,y}$ into (66.4). □

66.1.2 Spectral realization of the device

Let $\{|r\rangle\}$ be an orthonormal basis adapted to the system observable, let $|m_0\rangle$ be the apparatus preparation, and let $\{|m_r\rangle\}$ be an orthonormal family of pointer states. The unitary representation of the coupling satisfies

$$\widehat{U}_a(|r\rangle \otimes |m_0\rangle) = |r\rangle \otimes |m_r\rangle. \tag{66.5}$$

For $|\psi\rangle = \sum_r c_r|r\rangle$, linearity produces

$$\widehat{U}_a(|\psi\rangle \otimes |m_0\rangle) = \sum_r c_r|r\rangle \otimes |m_r\rangle.$$

The coupling thus constructs a correlation between system and pointer. The selective reading of the outcome r is represented, for a density state with $\operatorname{tr}(P_r\rho) > 0$, by the Luders [83] rule,

$$\rho \longmapsto \rho_r = \frac{P_r\rho P_r}{\operatorname{tr}(P_r\rho)}. \tag{66.6}$$

Theorem 66.3 (Correspondence between fibers and projections)**.** *Suppose that each fiber $\Omega_{a,y}$ is a finite union of disjoint cylinders of a common depth n, that the realization Q carries those cylinders to orthogonal subspaces, and that P_y is the sum of their cylinder projectors. Let $\mu_a(\Omega_{a,y}) > 0$, and let $\Psi_n(\mu_a)$ be the state constructed by (64.4) from that same measure. Then*

$$\mu_a(\Omega_{a,y}) = \|P_y\Psi_n(\mu_a)\|^2,$$

and the restriction to $\Omega_{a,y}$ is represented by the normalized projection $P_y\Psi_n(\mu_a)/\|P_y\Psi_n(\mu_a)\|$. In the density-matrix chart, if $\operatorname{tr}(\rho P_y) > 0$, let $\mathcal{A}_n$ be the algebra of cylindrical events of depth n, and suppose that $B \mapsto P_B$ and P_y belong to the same PVM and that

$$\mu_a(B) = \operatorname{tr}(\rho P_B) \qquad \text{for every } B \in \mathcal{A}_n. \tag{66.7}$$

Then the same conditional probability is represented by (66.6): for every $B \in \mathcal{A}_n$,

$$\mu_{a,y}(B) = \operatorname{tr}(\rho_y P_B).$$

Proof. The fiber is a disjoint union of cylinders, and P_y is the orthogonal sum of their projectors. The theorem 64.5 identifies the quadratic norm of each component with its measure; additivity gives the equality. After projection, the coefficients of each cylinder are divided by $\sqrt{\mu_a(\Omega_{a,y})}$; their squares are therefore the conditional probabilities of (66.4). In the density chart, membership in the same PVM gives $P_BP_y = P_{B\cap\Omega_{a,y}}$. By cyclicity of the trace and by (66.7),

$$\operatorname{tr}(\rho_y P_B) = \frac{\operatorname{tr}(\rho P_{B\cap\Omega_{a,y}})}{\operatorname{tr}(\rho P_y)} = \frac{\mu_a(B \cap \Omega_{a,y})}{\mu_a(\Omega_{a,y})}.$$

□

66.1.3 Instruments induced by coupling

For a refined pointer basis $\{|m_{y,\alpha}\rangle\}_{y,\alpha}$, the operators

$$M_{y,\alpha} = \langle m_{y,\alpha}|\widehat{U}_a|m_0\rangle, \qquad \sum_{y,\alpha} M_{y,\alpha}^\dagger M_{y,\alpha} = I \tag{66.8}$$

form a Kraus representation [76]. The effect $E_y = \sum_\alpha M_{y,\alpha}^\dagger M_{y,\alpha}$ determines the probability and, when $p(y \mid a, \rho) > 0$, the posterior state:

$$p(y \mid a, \rho) = \operatorname{tr}(\rho E_y), \qquad \rho_{a,y} = \frac{\sum_\alpha M_{y,\alpha}\rho M_{y,\alpha}^\dagger}{p(y \mid a, \rho)}. \tag{66.9}$$

The non-selective transformation is

$$\mathcal{E}_a(\rho) = \sum_{y,\alpha} M_{y,\alpha}\rho M_{y,\alpha}^\dagger.$$

Proposition 66.4 (Unitary coupling and reduced channel)**.** *The joint dynamics $\widehat{U}_a$ and the preparation $|m_0\rangle$ induce a completely positive trace-preserving channel on the system. The pointer decomposition induces the instrument $\mathcal{I}_{a,y}(\rho) = \sum_\alpha M_{y,\alpha}\rho M_{y,\alpha}^\dagger$. Conversely, every completely positive channel admits a dilation by an auxiliary space and an isometry.*

Proof. The completeness identity in (66.8) preserves the trace, and the Kraus form proves complete positivity. The converse assertion is the Stinespring dilation theorem [116]. □

The auxiliary space of the dilation can linearly realize the memory and register transported by TPK once an embedding that intertwines that memory with the auxiliary space has been declared. Stinespring guarantees the dilation of the channel; it does not by itself identify the two objects. The Lueders rule is the fine projective case $M_{y,1} = P_y$; degenerate readers and nonideal apparatus are described by means of families $M_{y,\alpha}$.

66.1.4 Internal Observer and Completeness of Reading

A realized observer is a subsystem capable of preparing a context, coupling to a boundary, preserving a distinguishable record, and using it as a condition of prolongation. The sequence

$$(x, m_0) \xrightarrow{U_a} (x', m') \xrightarrow{q_a} y \xrightarrow{\text{cond}} \Omega_{a,y} \tag{66.10}$$

places the observer's reading frame and memory within the extended state.

The Ambivalence principle completes this description. The areal and volumetric readings produce quotients q_A, q_V, whereas memory T preserves transport between them. When

$$\Xi : x \longmapsto (q_A(x), q_V(x), T(x))$$

is injective modulo the declared gauge group, the pair of observables and the memory reconstruct the class of the complete state.

Theorem 66.5 (Genealogical Decomposition of Measurement)**.** *Under the hypotheses of theorem 66.3 y proposition 66.4, the transition between evolution and outcome decomposes, in the regime in which U_a is bijective and bimeasurable or $\widehat{U}_a$ is unitary, as follows:*

$$\textit{reversible coupling} \longrightarrow \textit{pointer reading} \longrightarrow \textit{section conditioning}.$$

This decomposition possesses two regimes:

1. *In a projective cylindrical measurement, $M_{y,1} = P_y$ and the fiber restriction, normalized projection, and Luders update coincide:*

$$\Omega_a \longmapsto \Omega_{a,y}, \qquad \Psi_n \longmapsto \frac{P_y \Psi_n}{\|P_y \Psi_n\|}, \qquad \rho \longmapsto \frac{P_y \rho P_y}{\mathrm{tr}(\rho P_y)}.$$

2. *For a general instrument, the conditioned state is*

$$\rho \longmapsto \frac{\sum_\alpha M_{y,\alpha} \rho M_{y,\alpha}^\dagger}{\mathrm{tr}(\rho E_y)}.$$

In a dilation, this update arises from a pointer projection on the system composed with the apparatus. Its correspondence with $\Omega_{a,y}$ requires a declared morphism intertwining the reader fiber, the effect E_y, and the instrument $\mathcal{I}_{a,y}$.

Proof. The first arrow realizes the coupling; the third restricts the space of sections to the fiber defined in (66.3). The theorem 66.3 proves coincidence of the three forms in the projective regime. In the general regime, (66.9) proves the instrument update, and Stinespring supplies its dilated realization. The additional intertwining morphism is precisely the datum transporting that update back to the section space. □

Result and residence

In the declared model, the quantum update is the spectral realization of the restriction of compatible futures. Reversibility is determined by the bimeasurability of U_a or the unitarity of $\widehat{U}_a$; information loss, in the fibers of the reader or in a subsequent erasure; and the conditioned state, in $\Omega_{a,y}$. The thermodynamic cost of resetting and the zero Landauer cost of reversible evolution remain in the chapter on information and entropy.

66.2 Global state, local instruments, and Bell's triadic correlations

The question posed by Bell [9] relates the local description of outcomes to the global structure of their correlations. It asks whether a family of joint probabilities admits a decomposition into local responses conditioned by the same prior state. In HMT this question has a natural domain: the enriched state preserves genealogy, orientation, carry, and boundary memory, while each instrument publishes a local coordinate. The richness of the common state and the probabilistic form of its readings constitute distinct mathematical data. The former organizes the provenance of the correlation; the latter determines its position relative to the local Bell polytope.

The purpose of this chapter is to traverse that complete chain. We shall begin with a global preparation on the TPK state space, define the instruments of the two wings, recover the CHSH bound, and prove its stability under enrichment of the shared state; we shall then pass to the ternary alphabet intrinsic to TRIT. In that new domain the information unit is the trit and the pertinent inequality is CGLMP. The internal elliptic structure further provides a real realization of the order-three Fourier transform through the operator $J_E^2 = -I$. The result is a precise formulation of the relation among holographic totality, local reading, and quantum correlation.

66.2.1 Enhanced preparation and boundary instruments

Let X_{enr} be the space of enriched TPK states, and let μ be a probability measure describing the common preparation. An element $x \in X_{\mathrm{enr}}$ comprises the local state together with its transport history. The reading is introduced by means of instruments. For two wings, Alice and Bob, with setting sets $\mathcal{A}$ and $\mathcal{B}$, we write

$$\mathcal{I}_A^a : X_{\mathrm{enr}} \longrightarrow \mathcal{D}(O_A), \qquad \mathcal{I}_B^b : X_{\mathrm{enr}} \longrightarrow \mathcal{D}(O_B),$$

where $\mathcal{D}(O)$ denotes the simplex of distributions on the outcome alphabet O. For each prepared state, the kernels $\mathcal{I}_A^a(A \mid x)$ and $\mathcal{I}_B^b(B \mid x)$ express the probabilities published by the local readers.

The local factored form of the joint distribution is

$$P_{\mathrm{loc}}(A, B \mid a, b) = \int_{X_{\mathrm{enr}}} \mathcal{I}_A^a(A \mid x)\, \mathcal{I}_B^b(B \mid x)\, \mathrm{d}\mu(x). \tag{66.11}$$

This equation preserves a common global state and allows that state to possess arbitrarily rich memory. Its characteristic assertion is the factorization of responses once x has been fixed. Independence from the settings further requires that the measure μ be common to all choices of a and b, and complete sampling requires the observed population to represent that same preparation for every pair of settings.

This distinction is linked directly to the HMT definition of measurement. The reversible coupling between system and apparatus produces a joint state; the instrument selects a partition of that state, and the reader publishes one of its fibers. For a setting a and an outcome A, the fiber

$$\Omega_{a,A} = \{x \in X_{\mathrm{enr}} : \mathrm{Out}_a(x) = A\}$$

represents the set of histories compatible with the reading. Different settings induce different partitions of the same space; the published random variable is therefore typed by its instrumental context. Contextuality is thus formulated in the same language of instruments, fibers, and survival.

66.2.2 Local factorization, CHSH bound, and stability under enrichment

First consider binary outcomes $O_A = O_B = \{-1, +1\}$ and two settings per wing. The correlations and the Clauser–Horne–Shimony–Holt functional [25] are

$$E_{ab} = \sum_{A,B=\pm 1} AB\, P(A, B \mid a, b), \qquad S_{\mathrm{CHSH}} = E_{00} + E_{01} + E_{10} - E_{11}. \tag{66.12}$$

Theorem 66.6 (CHSH Bound under Local Factorization)**.** *If the joint distribution has the form* (66.11)*, the preparation is independent of the settings, and sampling preserves the common population in the four pairs of settings, then*

$$|S_{\mathrm{CHSH}}| \le 2.$$

Proof. For each x, define the conditional expectations

$$\overline{A}_a(x) = \sum_{A=\pm 1} A\, \mathcal{I}_A^a(A \mid x), \qquad \overline{B}_b(x) = \sum_{B=\pm 1} B\, \mathcal{I}_B^b(B \mid x).$$

Ambas belong to $[-1, 1]$. The integrando of S_{CHSH} is

$$\overline{A}_0(\overline{B}_0 + \overline{B}_1) + \overline{A}_1(\overline{B}_0 - \overline{B}_1).$$

For any $u, v \in [-1, 1]$, $|u + v| + |u - v| \le 2$ holds. The absolute value of the integrand therefore does not exceed 2. Integration with respect to a single probability measure μ preserves the bound. □

The theorem leads to a specifically important consequence for HMT.

Corollary 66.7 (Persistence of the bound under state enrichment)**.** *Replacing an elementary hidden variable with the complete state $x \in X_{\mathrm{enr}}$ preserves the bound $|S_{\mathrm{CHSH}}| \leq 2$ provided that the two instruments continue to factor as in* (66.11)*.*

Proof. The state x plays the role of the shared variable in the theorem 66.6. The argument depends on factorization of the conditional responses and on a preparation common to the four pairs of settings; the internal dimension of X_{enr} leaves both properties intact. □

This corollary positively establishes the locus at which an HMT theory of quantum correlations acts. The global genealogy provides the common domain. To realize a violation, the physical morphism must provide a joint nonseparable rule. In this formulation, the Bell correlation expresses a property of the joint representation of the state, compatible with the operational independence of the marginals.

66.2.3 Extension of binary entropy to the qutrit system and emergence of the invariant $\log 3$

TRIT naturally selects the alphabet $\mathbb{Z}/3\mathbb{Z}$. For a distribution $p = (p_0, p_1, p_2)$, its entropy expressed in trits is

$$H_3(p) = -\sum_{j=0}^{2} p_j \log_3 p_j = \frac{H_e(p)}{\log 3}. \tag{66.13}$$

The same relation holds for mutual information; to avoid confusing it with the Bell functional introduced shortly, we denote it by

$$\mathsf{I}^{(3)}(X : Y) = \frac{\mathsf{I}^{(e)}(X : Y)}{\log 3}.$$

Proposition 66.8 (Invariance of Locality Under Change of Information Unit)**.** *The passage from natural logarithms to base-three logarithms multiplies entropies and information by the positive constant* $(\log 3)^{-1}$*. It preserves the joint distributions, their marginals, and the local factorization condition.*

Proof. The identity $\log_3 u = (\log u)/(\log 3)$ proves the first assertion. The second follows because change of basis acts on the value used to quantify an already given distribution and leaves invariant both its terms and the stochastic kernels that factorize it. □

The appearance of $\log 3$ places the analysis in an information unit suited to the ternary alphabet. The substantive change for Bell is the passage from two to three outcomes per instrument. This passage leads from the binary CHSH functional to a qutrit inequality and allows the TRIT structure to enter both the definition of the settings and the choice of units.

66.2.4 The CGLMP inequality for 3 outcomes

Let A_1, A_2, B_1, B_2 be variables taking values in $\mathbb{Z}/3\mathbb{Z}$; all equalities in this section are understood modulo three. We define the Collins–Gisin–Linden–Massar–Popescu functional [24]

$$\begin{aligned} I_3^{\mathrm{CGLMP}} = {} & P(A_1 = B_1) + P(B_1 = A_2 + 1) + P(A_2 = B_2) + P(B_2 = A_1) \\ & - P(A_1 = B_1 - 1) - P(B_1 = A_2) - P(A_2 = B_2 - 1) - P(B_2 = A_1 - 1). \end{aligned} \tag{66.14}$$

Theorem 66.9 (Local triadic bound)**.** *Every distribution of four ternary instruments admitting a factorized local model satisfies*

$$I_3^{\mathrm{CGLMP}} \leq 2.$$

Proof. The set of local distributions is the convex hull of the deterministic assignments, so it suffices to prove the bound at its vertices. For a fixed assignment, write

$$x = A_1 - B_1, \qquad y = B_1 - A_2, \qquad z = A_2 - B_2, \qquad t = B_2 - A_1.$$

The relation of closure is $x + y + z + t = 0$. In these terminos,

$$I_3^{\mathrm{CGLMP}} = \mathbf{1}_{x=0} + \mathbf{1}_{y=1} + \mathbf{1}_{z=0} + \mathbf{1}_{t=0} - \mathbf{1}_{x=2} - \mathbf{1}_{y=0} - \mathbf{1}_{z=2} - \mathbf{1}_{t=2}.$$

The twenty-seven choices of (x, y, z) determine t. For $y = 0$, the nine patterns produce -4 once, -1 seven times, and 2 once; for $y = 1$, they produce -1 three times and 2 six times; for $y = 2$, they produce -1 six times and 2 three times. The maximum at every vertex is 2, and convexity preserves that bound. □

The preceding inequality describes the convex boundary of local models in the same alphabet used by HMT. Its physical evaluation starts from a joint distribution obtained from a preparation and four concrete instruments. The condition $I_3^{\mathrm{CGLMP}} > 2$, when obtained with a complete sample and independently fixed settings, excludes a local factorization of the form (66.11) for ternary outcomes.

66.2.5 Triadic Transform from the Internal Elliptic Structure

Realization of the qutrit settings requires a transformation that mixes the three outputs. Let E be a real Euclidean space endowed with an orthogonal complex structure J_E, that is,

$$J_E^2 = -I, \qquad J_E^* = -J_E.$$

Define

$$\omega_J = \exp\left(\frac{2\pi}{3} J_E\right), \qquad \omega_J^3 = I, \qquad I + \omega_J + \omega_J^2 = 0.$$

On $E \otimes \mathbb{R}^3$, the internal triadic transform is

$$\mathcal{F}_3^{(J)} = \frac{1}{\sqrt{3}} \sum_{r,s=0}^{2} \omega_J^{rs} \otimes |r\rangle\langle s|. \tag{66.15}$$

Proposition 66.10 (Orthogonality of the internal triadic transform)**.** *The map $\mathcal{F}_3^{(J)}$ is orthogonal, and its inverse is obtained by replacing J_E with $-J_E$:*

$$\left(\mathcal{F}_3^{(J)}\right)^{-1} = \mathcal{F}_3^{(-J)}.$$

In a chart that identifies J_E with multiplication by i, it recovers the complex Fourier matrix of order three.

Proof. The orthogonality of J_E implies $(\omega_J^k)^* = \omega_J^{-k}$. The (r, r') block of $\mathcal{F}_3^{(J)}\mathcal{F}_3^{(-J)}$ is

$$\frac{1}{3} \sum_{s=0}^{2} \omega_J^{(r-r')s}.$$

The sum equals I if $r = r'$ and equals zero in the other two cases by $I + \omega_J + \omega_J^2 = 0$. The composition is therefore the identity. The final assertion follows from $\exp(\theta J_E) \leftrightarrow e^{i\theta}$ in the complex chart. □

This construction makes the elliptic type of TRIT operational in Bell instruments. A local setting may be composed from $\mathcal{F}_3^{(J)}$, diagonal phase transports, and projectors onto the ternary basis. The orientation and memory transports of each wing must determine those phases before the inequality is evaluated. Thus, J_E supplies the internal rotation, whereas the genealogical register supplies the genealogical selection of the instruments.

66.2.6 Joint Representation and Independence of the Marginals

The confluence with quantum mechanics is expressed through a realization map.

$$\mathcal{R}_{\mathrm{Bell}} : X_{\mathrm{enr}} \longrightarrow \mathcal{D}(\mathcal{H}_A \otimes \mathcal{H}_B), \tag{66.16}$$

where $\mathcal{D}(\mathcal{H}_A \otimes \mathcal{H}_B)$ is the space of density operators. Let $\{M^a_{A,k}\}_{k\in\mathbb{Z}/3\mathbb{Z}}$ and $\{N^b_{B,\ell}\}_{\ell\in\mathbb{Z}/3\mathbb{Z}}$ be local POVM operators. The joint rule is

$$P(k,\ell \mid a,b) = \int_{X_{\mathrm{enr}}} \mathrm{tr}\big[\mathcal{R}_{\mathrm{Bell}}(x)\big(M^a_{A,k} \otimes N^b_{B,\ell}\big)\big]\, \mathrm{d}\mu(x). \tag{66.17}$$

Proposition 66.11 (Local Completeness Implies Independence of the Marginals)**.** *If*

$$\sum_{\ell=0}^{2} N^b_{B,\ell} = I_B \quad \textit{for every } b,$$

then Alice's marginal is independent of Bob's setting. The symmetric statement holds for the other wing.

Proof. Upon summing (66.17) over ℓ, completeness replaces $\sum_\ell N^b_{B,\ell}$ by I_B. One obtains

$$\sum_{\ell} P(k,\ell \mid a,b) = \int \mathrm{tr}\big[\mathcal{R}_{\mathrm{Bell}}(x)\big(M^a_{A,k} \otimes I_B\big)\big]\, \mathrm{d}\mu(x),$$

an expression independent of b. □

Equation (66.16) fixes the type of the intertwiner between the HMT genealogy and the bipartite space of the physical realization. When $\mathcal{R}_{\mathrm{Bell}}(x)$ is separable for almost every x, the distribution can be rewritten through shared variables and remains in the local domain. A nonseparable realization may leave that factorization and preserve, by the preceding proposition, the independence of the marginals from the remote setting. Global correlation and signal transmission are therefore distinct properties of the same construction.

66.2.7 Holographic Reconstruction of Correlation via Indistinguishable Path Classes

The HMT structure now organizes the local–global question through typed objects. The whole is a compatible section of the extension system, with memory of its genealogy. Each experimental wing is a boundary equipped with an instrument that publishes a fiber. The joint preparation fixes the common state; the instruments fix the local questions; the Born rule fixes the probabilities; CHSH or CGLMP determines whether those probabilities admit a local decomposition.

Holographic correlation is realized as a reading of the same global state within a joint representation. Independence of the marginals ensures that each local statistic remains invariant under the remote setting, while nonseparability may prevent the complete distribution from being reduced to independent responses conditioned on a classical variable.

A precise probative hierarchy is thereby established. The local CHSH and CGLMP bounds, persistence of the bound under enrichment of the state, invariance under change to log 3, the transform $\mathcal{F}_3^{(J)}$, and independence of the marginals by completeness of the POVM are closed mathematical results. The HMT architecture of Bell is fixed by

$$X_{\mathrm{enr}} \xrightarrow{\mathcal{R}_{\mathrm{Bell}}} \mathcal{D}(\mathcal{H}_A \otimes \mathcal{H}_B) \xrightarrow{M^a \otimes N^b} P(k,\ell \mid a,b) \xrightarrow{\mathrm{CGLMP}} I_3^{\mathrm{CGLMP}}.$$

The evaluation of a concrete HMT violation is obtained by constructing $\mathcal{R}_{\mathrm{Bell}}$ and the four instruments from the enriched genealogical record, certifying their independence from adjustments, and calculating

the distribution without postselection. The chapter provides the domain, the operators, the bounds, and the realization criterion; the numerical evaluation remains reserved for the distribution derived from those instruments.

From reversible measurement to fermionic occupation and to the algebraic exclusion principle of Pauli The measured states admit collective occupations; their distributions are derived first on the finite screen and then in the statistical limit.

66.3 Internal Complex Structure and Projective Geometry of 2-Level States

The phase geometry employed by the quantum realization has an algebraic genealogy predating complex notation. Its point of departure is the finite Paley–Witt incidence, from which an endomorphism whose square is minus the identity is obtained. Realification preserves that operator as the phase generator, and projectivization of a two-level space leads to the Bloch sphere. On that sphere, the spinorial action of SU(2), its expression through Möbius transformations, and the binary icosahedral group form successive realizations of the same structure.

The causal chain developed in this chapter is

$$\boxed{\begin{array}{c} C_P \longrightarrow A_W^2 = -I_6, \\ A_W^2 = -I_6 \longrightarrow \mathbb{F}_3^6 \simeq \mathbb{F}_9^3 \longrightarrow (E, J_E), \\ (E, J_E) \longrightarrow \mathbb{P}(\mathcal{H}_J) \simeq \mathbb{CP}^1 \longrightarrow S^2, \\ S^2 \longrightarrow \{\mathrm{SU}(2),\ \mathrm{Möb}(S^2),\ 2A_5\}. \end{array}} \tag{66.18}$$

Each arrow declares its domain. The finite quadratic structure, the orthogonal realification, and the projective geometry remain related, with their scalar fields explicitly separated.

66.3.1 The incidence of Paley as an algebraic origin of the phase

Let $C_P \in M_6(\mathbb{Z})$ be the symmetric conference matrix

$$C_P = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & -1 & -1 & 1 \\ 1 & 1 & 0 & 1 & -1 & -1 \\ 1 & -1 & 1 & 0 & 1 & -1 \\ 1 & -1 & -1 & 1 & 0 & 1 \\ 1 & 1 & -1 & -1 & 1 & 0 \end{pmatrix}. \tag{66.19}$$

Their rows satisfy

$$C_P C_P^{\mathsf{T}} = 5 I_6. \tag{66.20}$$

By reducing modulo three we obtain

$$A_W := C_P \bmod 3 \in M_6(\mathbb{F}_3). \tag{66.21}$$

Theorem 66.12 (Internal root of minus the identity)**.** *The endomorphism $J_W : v \mapsto vA_W$ of $V_W = \mathbb{F}_3^6$ satisfies*

$$J_W^2 = -I_{V_W}. \tag{66.22}$$

Consequently, V_W admits a canonical module structure over $\mathbb{F}_3[X]/(X^2+1)$ once the Paley matrix has been fixed.

Proof. The matrix C_P is symmetric. Reducing (66.20) modulo three yields

$$A_W^2 = 5I_6 \bmod 3 = 2I_6 = -I_6.$$

Therefore, the evaluation $X \mapsto J_W$ annihilates the ideal (X^2+1) and defines the action of the indicated quotient. □

The polynomial X^2+1 is irreducible over $\mathbb{F}_3$, since its values in $0,1,2$ are $1,2,2$. Therefore,

$$\mathbb{F}_9 := \mathbb{F}_3[\iota]/(\iota^2+1) \tag{66.23}$$

is a field, and J_W realizes multiplication by ι.

Corollary 66.13 (Descent from six ternary coordinates to three quadratic coordinates)**.** *The rule*

$$(a+b\iota)v := av + bJ_W v, \qquad a,b \in \mathbb{F}_3, \tag{66.24}$$

converts V_W into a vector space of dimension three over $\mathbb{F}_9$. In the coordinates fixed by A_W,

$$\mathbb{F}_3^6 \simeq \mathbb{F}_9^3. \tag{66.25}$$

Proof. The identity $J_W^2 = -I$ verifies the multiplication rules of $\mathbb{F}_9$. Since $[\mathbb{F}_9 : \mathbb{F}_3] = 2$ and $\dim_{\mathbb{F}_3} V_W = 6$, the dimension over $\mathbb{F}_9$ is three. □

The same operator organizes the ternary code via the graph.

$$C_W = \{(q, qA_W) : q \in \mathbb{F}_3^6\} \subset \mathbb{F}_3^{12}. \tag{66.26}$$

If $G = (I_6 \mid A_W)$, then

$$GG^{\mathsf{T}} = I_6 + A_W A_W^{\mathsf{T}} = 0.$$

Thus, the internal square root of minus the identity participates simultaneously in the quadratic structure and the isotropy of the code. This dual function explains why phase and exceptional incidence share an antecedent while preserving distinct readers.

66.3.2 Orthogonal realification of the phase

The analytic phase is constructed on a real space before a complex chart is chosen. Let (E, g) be a real Euclidean space of even dimension, and let $J_E \in \mathrm{End}(E)$ be an operator such that

$$J_E^2 = -I, \qquad g(J_E u, J_E v) = g(u, v). \tag{66.27}$$

The second identity implies $J_E^{\mathsf{T}} = -J_E$.

Proposition 66.14 (Phase as an orthogonal group of one parameter)**.** *For every $\theta \in \mathbb{R}$,*

$$R_J(\theta) := e^{\theta J_E} = \cos\theta\, I + \sin\theta\, J_E \tag{66.28}$$

is orthogonal and satisfies

$$R_J(\theta)R_J(\phi) = R_J(\theta+\phi), \qquad R_J(2\pi) = I. \tag{66.29}$$

Proof. The exponential series separates into even and odd powers and, using $J_E^2 = -I$, produces the trigonometric expression. The antisymmetry of J_E gives $R_J(\theta)^{\mathsf{T}} = R_J(-\theta)$; therefore, $R_J(\theta)^{\mathsf{T}} R_J(\theta) = I$. The composition law follows from the fact that all factors are functions of the same operator. □

The choice of the chart $J_E \leftrightarrow i$ turns E into a complex vector space: for $a, b \in \mathbb{R}$,

$$(a + ib)u := au + bJ_E u. \tag{66.30}$$

In that chart, $R_J(\theta)$ is written as multiplication by $e^{i\theta}$. The complex notation publishes the phase already transported by the real operator.

Remark 66.15 (Two scales, the same quadratic relation). The operator J_W acts on $\mathbb{F}_3^6$; the operator J_E acts on a real inner-product space. The prolongation $J_W \rightsquigarrow J_E$ is a realization that preserves the relation $J^2 = -I$ and additionally specifies a topology, norm, and completion. This order avoids using the continuous analytic structure as a premise of the finite incidence.

66.3.3 The complex projective line and the Bloch sphere

Let $\mathcal{H}_J$ be a Hilbert space of complex dimension two obtained through the chart (66.30). A normalized pure state is a vector

$$\psi = \begin{pmatrix} z_0 \\ z_1 \end{pmatrix}, \qquad |z_0|^2 + |z_1|^2 = 1, \tag{66.31}$$

and its projective physical state is the ray $[\psi] = \{e^{i\vartheta}\psi : \vartheta \in \mathbb{R}\}$. The ray space is $\mathbb{P}(\mathcal{H}_J) \simeq \mathbb{CP}^1$.

We define the coordinates

$$\begin{aligned} r_1 &= 2\,\mathrm{Re}(\overline{z}_0 z_1), \\ r_2 &= 2\,\mathrm{Im}(\overline{z}_0 z_1), \\ r_3 &= |z_0|^2 - |z_1|^2. \end{aligned} \tag{66.32}$$

The spherical representation of two-level states is formulated in the coordinates introduced by Bloch [12].

Theorem 66.16 (Projective Bloch Identification)**.** *The map*

$$\mathcal{B} : \mathbb{CP}^1 \longrightarrow S^2, \qquad [\psi] \longmapsto (r_1, r_2, r_3), \tag{66.33}$$

is a smooth bijection. The rank-one projector associated with $[\psi]$ *is*

$$\rho_\psi = |\psi\rangle\langle\psi| = \frac{1}{2}\big(I_2 + r_1\sigma_1 + r_2\sigma_2 + r_3\sigma_3\big), \tag{66.34}$$

where $\sigma_1, \sigma_2, \sigma_3$ *are the Pauli matrices.*

Proof. Multiplication of ψ by a common phase leaves the three coordinates invariant. Moreover,

$$r_1^2 + r_2^2 + r_3^2 = 4|z_0|^2|z_1|^2 + (|z_0|^2 - |z_1|^2)^2 = 1.$$

Every $\boldsymbol{r} \in S^2$ determines the positive projector $\rho = (I + \boldsymbol{r}\cdot\boldsymbol{\sigma})/2$, which satisfies $\rho^2 = \rho$ and $\mathrm{tr}\,\rho = 1$; its image is a single ray. The direct matrix formula for $|\psi\rangle\langle\psi|$ yields (66.34). The usual affine charts of $\mathbb{CP}^1$ make the map and its inverse smooth. □

The Bloch sphere records the projective class and preserves, through ρ_ψ, all expectation values of two-level Hermitian observables. The global phase belongs to the fibre S^1 of the Hopf bundle [63]

$$S^1 \longrightarrow S^3 \longrightarrow S^2. \tag{66.35}$$

The HMT distinction between enriched state and published coordinate finds a precise realization here: the normalized vector belongs to S^3, the projective reader publishes a point of S^2, and the fiber preserves the phase that the projection identifies.

66.3.4 Spinorial Action, Rotations, and Möbius Transformations

Every element of $\mathrm{SU}(2)$ can be written as

$$U = \begin{pmatrix} \alpha & \beta \\ -\overline{\beta} & \overline{\alpha} \end{pmatrix}, \qquad |\alpha|^2 + |\beta|^2 = 1. \tag{66.36}$$

Acts linearly on spinors and, by conjugation, on projectors.

Theorem 66.17 (Double covering and action on the sphere)**.** *for each $U \in \mathrm{SU}(2)$ there exists a unique $R_U \in \mathrm{SO}(3)$ such that*

$$U(\boldsymbol{r} \cdot \boldsymbol{\sigma})U^{\dagger} = (R_U \boldsymbol{r}) \cdot \boldsymbol{\sigma}. \tag{66.37}$$

The map $U \mapsto R_U$ is a surjective homomorphism with kernel $\{\pm I_2\}$.

Proof. Conjugation preserves the three-dimensional real space of trace-free Hermitian matrices and its inner product $\langle A, B\rangle = \frac{1}{2}\operatorname{tr}(AB)$. It therefore induces an orthogonal transformation of $\mathbb{R}^3$. Continuity and the value at the identity fix a positive determinant. If conjugation is trivial on the three Pauli matrices, U commutes with every complex matrix 2×2, and by Schur's lemma it is scalar; the determinant-one condition leaves $U = \pm I_2$. The axis–angle representation shows that every rotation has two opposite preimages. □

In the affine chart $z = z_0/z_1$ of $\mathbb{CP}^1$, the same action takes the form

$$z \longmapsto \frac{\alpha z + \beta}{-\overline{\beta} z + \overline{\alpha}}. \tag{66.38}$$

The Bloch rotation and the fractional transformation are therefore two coordinates of the same projective action. The former employs the Hermitian projector; the latter, the Riemann sphere.

66.3.5 The icosahedral specialization and the binary group $2A_5$

The grupo rotacional of the icosaedro is a subgrupo of $\mathrm{SO}(3)$ isomorfo to A_5. Its preimagen by the recubrimiento of the theorem 66.17 defines the grupo icosaedrico binario

$$2A_5 := \pi^{-1}(A_5) \subset \mathrm{SU}(2). \tag{66.39}$$

Proposition 66.18 (Icosahedral central extension)**.** *There exists an exact sequence*

$$1 \longrightarrow \{\pm I_2\} \longrightarrow 2A_5 \longrightarrow A_5 \longrightarrow 1, \tag{66.40}$$

and $|2A_5| = 120$. An icosahedral rotation of orders three or five lifts to elements of orders six or ten, respectively.

Proof. The restriction of $\pi : \mathrm{SU}(2) \to \mathrm{SO}(3)$ to the preimage of A_5 is surjective and preserves the kernel $\{\pm I_2\}$. Exactness and the order theorem yield $|2A_5| = 2|A_5| = 120$. A rotation through angle $2\pi/n$ is represented in $\mathrm{SU}(2)$ with half-angle π/n; after n iterations it reaches $-I_2$ and after $2n$, the identity. □

The icosahedral specialization establishes a rigorous hinge between the geometry of two-level states, Möbius transformations, and the finite-symmetry branch. The development of McKay theory and of the exceptional structures subsequently uses the representation of $2A_5$ and its modules; its additional content is developed in the specific theorems of that branch.

66.3.6 Functorial composition $\mathbb{F}_3^6 \to \mathbb{F}_9^3 \to \mathbb{CP}^1 \simeq S^2 \to \mathrm{SU}(2) \to \mathrm{SO}(3) \to 2A_5$

The relation $J^2 = -I$ traverses four categories while preserving its type:

1. in $\mathbb{F}_3^6$, defines the quadratic extension $\mathbb{F}_9$ and organizes the Witt incidence;
2. in a real orthogonal space, generates the phase flow $e^{\theta J_E}$;
3. in complex dimension two, projectivization produces $\mathbb{CP}^1 \simeq S^2$ and the Bloch projectors;
4. the action of $\mathrm{SU}(2)$ descends to rotations and Möbius transformations, and its icosahedral preimage produces $2A_5$.

The internal complex structure thus has a finite provenance and an explicit analytic realization. The Bloch sphere publishes the geometry of rays; HMT genealogy additionally preserves the route, orientation, carry, and memory that precede that publication.

66.4 Coupled observer, self-inertia and genealogical conservation of information

66.4.1 Joint state and observer residence

The elementary dynamic description comprises the observed section, the realized observer, and the record produced by both. We write

$$\boxed{\Gamma = (x, O, m) \in \mathcal{X}_{\mathrm{TPK}} \times \mathfrak{O} \times \mathfrak{M}.} \tag{66.41}$$

The coordinate x preserves cylinder, route, sheet, orientation, carry, boundary, and possibilities of prolongation; O specifies the reader subsystem and its resolution; m preserves the distinguishable memory of the coupling. The joint state constitutes the primary domain of measurement and inertial response.

An observer at depth n is represented by a chart

$$q_{O,n} : \mathcal{X}_{\mathrm{TPK}}^{(n)} \longrightarrow Y_{O,n}. \tag{66.42}$$

For $x \in \mathcal{X}_{\mathrm{TPK}}^{(n)}$, its observational horizon is the fibre

$$\mathfrak{H}_{O,n}(x) = q_{O,n}^{-1}(q_{O,n}(x)). \tag{66.43}$$

The fiber gathers the sections indistinguishable for the declared chart. Refinement preserves naturality when there are maps $r_{n+1,n}$ and $s_{n+1,n}$ such that

$$q_{O,n} \circ r_{n+1,n} = s_{n+1,n} \circ q_{O,n+1}. \tag{66.44}$$

This identity makes finite observation compatible with deep genealogy: the result of truncating a refined reading coincides with the reading of the truncated state.

Definition 66.19 (Realized observer)**.** An implemented observer is a tuple

$$O_a = (m_0, U_a, q_a, C_a) \tag{66.45}$$

formed by a preparation m_0, a coupling U_a, a pointer reader q_a, and a compatibility and prolongation condition C_a. Its function is to produce a distinguishable record and use it as a condition for continuation of the route.

The definition situates the reading frame within the system. The published coordinate depends on the coupling, the resolution, and the memory; the enriched section preserves the totality from which that coordinate arises.

66.4.2 Measurement context and conditioning by fibers

Let (Ω_S, Σ_S) and (Ω_M, Σ_M) be measurable spaces of sections of the system and the apparatus. The context a uses a measurable coupling

$$U_a : \Omega_S \times \Omega_M \longrightarrow \Omega_S \times \Omega_M \tag{66.46}$$

and a reader $q_a : \Omega_M \to Y_a$. The output is

$$\mathrm{Out}_a(x) = q_a\big(\mathrm{pr}_M\, U_a(x, m_0)\big)\,. \tag{66.47}$$

For an outcome y, the measurable fiber is defined as

$$\Omega_{a,y} = \{x \in \Omega_a : \mathrm{Out}_a(x) = y\}. \tag{66.48}$$

The Update of Genealogy Is the Restriction

$$\Omega_a \longmapsto \Omega_{a,y}. \tag{66.49}$$

At finite depth, the operation preserves the prefixes that admit an extension in $\Omega_{a,y}$. The memory of the result is incorporated into the prolongation condition; the traversed route remains recorded.

If $\mu_a(\Omega_{a,y}) > 0$, the measure conditioned is

$$\mu_{a,y}(B) = \frac{\mu_a(B \cap \Omega_{a,y})}{\mu_a(\Omega_{a,y})}. \tag{66.50}$$

This expression constitutes the probabilistic chart of the relative state. Its spectral realization is obtained through cylindrical projections.

66.4.3 cylindrical PVM and Lüders correspondence

Suppose that $\Omega_{a,y}$ is a finite union of disjoint cylinders of a common depth n. Let P_y be the sum of their orthogonal projectors in the Hilbert realization. For a density state ρ and a common PVM of cylindrical events, the Born probability is

$$p(y) = \mathrm{Tr}(\rho P_y). \tag{66.51}$$

When $p(y) > 0$, the update by Lüders [84] is

$$\rho_y = \frac{P_y \rho P_y}{\mathrm{Tr}(\rho P_y)}. \tag{66.52}$$

Theorem 66.20 (Equivalence between fiber restriction and Lüders)**.** *Be $\mathcal{A}_n$ the algebra of sucesos cilindricos to depth n. Supongamos that*

$$\mu_a(B) = \mathrm{Tr}(\rho P_B), \qquad B \in \mathcal{A}_n, \tag{66.53}$$

and that P_B and P_y belong to the same projective spectral measure. Then

$$\boxed{\mathrm{Tr}(\rho_y P_B) = \frac{\mu_a(B \cap \Omega_{a,y})}{\mu_a(\Omega_{a,y})}.} \tag{66.54}$$

Proof. Membership in a common PVM gives $P_B P_y = P_{B \cap \Omega_{a,y}}$. Cyclicity of the trace and equation (66.53) yield

$$\mathrm{Tr}(\rho_y P_B) = \frac{\mathrm{Tr}(\rho P_y P_B P_y)}{\mathrm{Tr}(\rho P_y)} = \frac{\mathrm{Tr}(\rho P_{B \cap \Omega_{a,y}})}{\mathrm{Tr}(\rho P_y)},$$

which coincides with equation (66.50). □

The hypothesis of a common PVM is substantive. Two mutually unbiased contexts admit their own projective descriptions and require a noisy POVM or a dilation for a joint reading. The correspondence of theorem 66.20 is asserted within the declared spectral context.

66.4.4 Quantum instrument, dilation, and channel preservation

Let $\widehat{U}_a$ be the unitary realization of the coupling between system and apparatus, and let $|m_0\rangle$ be the pointer preparation. A refined basis $|m_{y,\alpha}\rangle$ induces the Kraus operators

$$M_{y,\alpha} = \langle m_{y,\alpha}|\widehat{U}_a|m_0\rangle, \qquad \sum_{y,\alpha} M_{y,\alpha}^\dagger M_{y,\alpha} = I. \tag{66.55}$$

The instrument and its effect are

$$\mathcal{I}_y(\rho) = \sum_\alpha M_{y,\alpha}\rho M_{y,\alpha}^\dagger, \qquad E_y = \sum_\alpha M_{y,\alpha}^\dagger M_{y,\alpha}. \tag{66.56}$$

The probability and the relative state take the form

$$p(y) = \mathrm{Tr}(\rho E_y), \qquad \rho_y = \frac{\mathcal{I}_y(\rho)}{p(y)}. \tag{66.57}$$

The non-selective channel is

$$\mathcal{E}_a(\rho) = \sum_y \mathcal{I}_y(\rho). \tag{66.58}$$

Proposition 66.21 (Exact Conservation of the Global Channel)**.** *The isometry*

$$V_a : \mathcal{H}_S \longrightarrow \mathcal{H}_S \otimes \mathcal{H}_M, \qquad V_a|\psi\rangle = \widehat{U}_a(|\psi\rangle \otimes |m_0\rangle) \tag{66.59}$$

satisfies $V_a^\dagger V_a = I$. Consequently,

$$\sum_y p(y) = 1, \qquad \mathrm{Tr}\,\mathcal{E}_a(\rho) = \mathrm{Tr}\,\rho, \tag{66.60}$$

and $\mathcal{E}_a$ is completely positive and trace-preserving. For an initial pure state, the joint state $V_a|\psi\rangle$ remains pure and normalized.

Proof. The unitarity of $\widehat{U}_a$ and the normalization of $|m_0\rangle$ yield $V_a^\dagger V_a = I$. The completeness identity for equation (66.55) preserves the trace. The Kraus form proves complete positivity, and an isometry maps unit vectors to unit vectors. □

Preservation of the global channel means that the dilated evolution retains all amplitudes and all records. Conditioning selects a relative fiber for the reader that obtained y. The sum of the instruments reproduces the complete channel. This threefold distinction separates evolution, reading, and relative state.

The Stinespring theorem [116] guarantees a dilation that is isometric for every completely positive channel. The identification of the auxiliary space with the TPK memory is realized by an intertwiner that preserves route, carry, register, and refinement. The abstract existence of the dilation and the concrete genealogy of the register are two coordinable, typed results.

66.4.5 State relative and formulation Everettian

The relative-state formulation provides the conceptual antecedent of this construction [45].

In an ideal premeasurement, suppose that the pointer states $\{|m_r\rangle\}_r$ are orthonormal and that $\widehat{U}_a$ is an isometry on the subspace spanned by $\{|r\rangle \otimes |m_0\rangle\}_r$. Then

$$\widehat{U}_a(|r\rangle \otimes |m_0\rangle) = |r\rangle \otimes |m_r\rangle. \tag{66.61}$$

For $|\psi\rangle = \sum_r c_r|r\rangle$, linearity produces

$$|\Psi'\rangle = \sum_r c_r|r\rangle \otimes |m_r\rangle. \tag{66.62}$$

The record m_r defines the relative section

$$\rho_r = \frac{Q_r|\Psi'\rangle\langle\Psi'|Q_r}{\mathrm{Tr}(|\Psi'\rangle\langle\Psi'|Q_r)}, \qquad Q_r = I_S \otimes |m_r\rangle\langle m_r|. \tag{66.63}$$

In the Genealogical Space, the Same Result Corresponds to

$$\Omega_{a,r} = \{x : \mathrm{Out}_a(x) = r\}. \tag{66.64}$$

Theorem 66.22 (Relative state correspondence)**.** *Under the projective hypotheses of theorem 66.20, the relative state of equation (66.63) and the measure conditioned on $\Omega_{a,r}$ assign the same probabilities to every event of the declared cylindrical PVM. The global isometry preserves the correlated superposition of all records.*

Proof. The first assertion is equation (66.54). The second follows from $V_a^\dagger V_a = I$ and the linear expression equation (66.62). □

The Everettian correspondence reaches the mathematical level of relative states: the joint state preserves the channels, and each register determines a conditioned fiber. HMT adds to each fiber a genealogy composed of prefixes, carry, orientation, boundary, and compatible prolongations. The macroscopic stability of the registers belongs to the theory of decoherence of the apparatus; the ontology of physically autonomous branches belongs to an additional interpretation. The preceding theorem retains its force independently of that ontological choice.

66.5 Canonical entangler between TPK memory and device

Let $\mathfrak{M}_n$ be the finite set of TPK records at level n, including outcome, route, carry, leaf, and memory. Its canonical Hilbertization is

$$\mathcal{H}_{\mathfrak{M}_n} = \ell^2(\mathfrak{M}_n).$$

Let $\mathcal{K}_{A,n}$ be an auxiliary apparatus space containing an orthonormal family $\{|a_m\rangle : m \in \mathfrak{M}_n\}$. We define

$$\iota_n : \mathcal{H}_{\mathfrak{M}_n} \longrightarrow \mathcal{K}_{A,n}, \qquad \iota_n|m\rangle = |a_m\rangle.$$

To preserve genealogy when the visible update is not injective, the ledger lifting is used.

$$\widehat{F}_n(m) = (F_n(m), m) \in \mathfrak{M}_{n+1}.$$

It is injective by construction and defines the isometry.

$$V_n|m\rangle = |\widehat{F}_n(m)\rangle.$$

On the pointer subspace is fixed

$$W_n \iota_n = \iota_{n+1} V_n.$$

Theorem 66.23 (TPK Apparatus–Memory Intertwiner)**.** *The mapas ι_n and V_n are isometrias and the square*

$$\begin{array}{ccc} \mathcal{H}_{\mathfrak{M}_n} & \xrightarrow{V_n} & \mathcal{H}_{\mathfrak{M}_{n+1}} \\ {\scriptstyle \iota_n}\downarrow & & \downarrow{\scriptstyle \iota_{n+1}} \\ \mathcal{K}_{A,n} & \xrightarrow{W_n} & \mathcal{K}_{A,n+1} \end{array}$$

commutes. The map W_n prolongs to an isometry of the apparatus and, after adding an auxiliary complement if the dimensions differ, to a unitary. The update preserves norm, distinguishes all records, and retains the preceding state within the ledger.

Proof. The maps send orthonormal bases to orthonormal families. The square identity is verified on every $|m\rangle$. Every finite isometry extends to a unitary map between dilations of equal dimension by completing orthonormal bases. □

Laser pointers

$$P_m = |a_m\rangle\langle a_m|$$

define the conditional expectation

$$\mathcal{D}_n(A) = \sum_{m \in \mathfrak{M}_n} P_m A P_m.$$

One has

$$\mathcal{D}_n^2 = \mathcal{D}_n, \qquad \mathrm{Spec}(\mathcal{D}_n) \subset \{0, 1\}.$$

The diagonal ledger subalgebra is the fixed subspace, and the coherent complement lies in the kernel. The unit gap of this projection equals one. Under simultaneous conjugation of the apparatus, the pointers, and the intertwiner, all these identities remain exact. This completes the finite stability of the ledger within the covariant class.

When the Kraus labels (y, α) are included in $\mathfrak{M}_n$, the isometry ι_n explicitly identifies the TPK memory with the Stinespring environment, not merely with an abstract auxiliary space. The construction of a material device, its decoherence, and its calibration constitute EXTERNAL RECOGNITION.

66.6 Joint observer–observable state, reversible instrument, and self-measurement

Definition 66.24 (Geometry of Phase Sewing)**.** A *phase-stitching geometry* is a system

$$\mathcal{X} = (X, \oplus, \otimes, \tau, C_n, L, \mathfrak{c}, v),$$

where (X) is a finite local support; $\oplus$ and $\otimes$ are its two internal transport laws; $\tau : X \to D$ is the residual map; C_n is an oriented cycle; L is a lattice whose real space $W = L \otimes_{\mathbb{Z}} \mathbb{R}$ carries a positive inner product; $\mathfrak{c} \in \mathbb{P}(D^n)$ is a distinguished nontrivial residual class; and $v \in L$ is its primitive representative in the fixed chamber. A transport $\omega \in C^1(C_n; W)$ is *admissible* when the harmonic mode of its decomposition belongs to the line $\mathbb{R}v \subset W$.

Theorem 66.25 (Exact harmonic decomposition on a cycle)**.** *For every (1)-cochain $\omega \in C^1(C_n; W)$, there exists a unique decomposition*

$$\omega = d\Phi + u\mathbf{1}_E,$$

with $\Phi \in C^0(C_n; W)$, normalizada by $\Phi(0) = 0$, and $u \in W$.

Proof. If $e_0, \dots, e_{n-1}$ are the oriented edges of the cycle, define

$$u = \frac{1}{n}\sum_{j=0}^{n-1} \omega(e_j), \qquad y_j = \omega(e_j) - u.$$

Then $\sum_j y_j = 0$. The partial sums $\Phi(k) = \sum_{j=0}^{k-1} y_j$, with $\Phi(0) = 0$, determine a well-defined 0-cochain and verify $d\Phi(e_j) = y_j$, including the final edge. For uniqueness, $d\Phi + u\mathbf{1}_E = d\Psi + w\mathbf{1}_E$ yields, after summing over the cycle, $n(w-u) = 0$; therefore $u = w$, and normalization eliminates the remaining constant from $\Phi - \Psi$. □

Definition 66.26 (Seam defect)**.** The piecewise-continuous lift $\Gamma_\omega : [0,1] \to W$ is fixed by

$$\Gamma_\omega\left(\frac{j+1}{n}\right) - \Gamma_\omega\left(\frac{j}{n}\right) = \omega(e_j).$$

Its stitching defect is

$$\partial\Gamma_\omega = \Gamma_\omega(1) - \Gamma_\omega(0) = \sum_{j=0}^{n-1} \omega(e_j).$$

Proposition 66.27 (Telescoping cancellation of the exact term)**.** *For every (0)-cochain Φ, one has*

$$\sum_{j=0}^{n-1} (d\Phi)(e_j) = 0.$$

Consequently, the stitching defect depends exclusively on the harmonic mode $u\mathbf{1}_E$ of the decomposition of theorem 66.25.

Proof. The sum of $\Phi(j+1) - \Phi(j)$ telescopes over the cycle. Thus, if $\omega = d\Phi + u\mathbf{1}_E$, then $\partial\Gamma_\omega = nu$. □

Theorem 66.28 (Universal Theorem of Sewing)**.** *Let $\mathcal{X}$ be a phase-stitching geometry, and let ω be an admissible transport. There exists a unique real scalar $\mathfrak{a}_\chi(\omega)$ such that*

$$\partial\Gamma_\omega = \mathfrak{a}_\chi(\omega) v, \qquad \mathfrak{a}_\chi(\omega) = \frac{\langle \partial\Gamma_\omega, v\rangle}{\langle v, v\rangle}.$$

Proof. By theorem 66.25, $\omega = d\Phi + u\mathbf{1}_E$, with unique u. Admissibility provides a unique $\lambda \in \mathbb{R}$ with $u = \lambda v$. The proposition 66.27 gives $\partial\Gamma_\omega = n\lambda v$; it suffices to define $\mathfrak{a}_\chi(\omega) = n\lambda$ and project orthogonally onto $\mathbb{R}v$. □

66.7 Joint observer–observable state, intrinsic self-measurement, and Stokes' holographic identity

This section makes explicit three claims that elsewhere in the manuscript appeared only in narrative form. The first is that the *observer* does not introduce the invariant, but selects a polarization, a trivialization, and a reading orientation. The second is that the *self-measure* is not a metaphor, but the unique normalized linear functional compatible with the residual boundary mode. The third is that the so-called *holographic principle* admits, in this finite framework, an exact formulation through discrete Stokes: the same scalar can be read on the boundary as a seam defect or in the *bulk* as projected total curvature.

From a historical standpoint, these three components permit the classical notion of measurement to be reformulated. In standard metrology, a measurement is traceable when it can be related to a reference through a documented and unbroken chain of comparisons; and, since 2019, the SI has been defined by fixed values of constants of nature [94, 19]. The present framework does not deny that scheme: it

displaces it to a prior level, at which the "unit" is no longer first an external standard, but an internal residual mode. Measurement then ceases to be a comparison with an artifact and becomes a reading of an intrinsic closure.

66.7.1 The Observer as Polarization, Trivialization, and Orientation

The most stable geometric interpretation of the observer problem is as follows. The local support has at least two internal polarizations, one additive and the other multiplicative. In the standard language of finite quantum kinematics, both polarizations generate a Weyl–Heisenberg extension in which the central phase records the order of the transports [123, 131]. The observer adds no new dynamics to the system; the observer selects a representative of the same transport class.

Definition 66.29 (Edge Observer)**.** Let $\mathcal{X} = (X, \oplus, \otimes, \tau, C_n, L, \mathfrak{c}, v)$ be a phase-stitching geometry, and let $\omega \in C^1(C_n; W)$ be an admissible transport. A *boundary observer* is a pair

$$O = (\varepsilon, \Phi), \qquad \varepsilon \in \{+1, -1\}, \qquad \Phi \in C^0(C_n; W),$$

that acts on ω by

$$\omega^O := \varepsilon\, \omega + d\Phi.$$

The sign ε encodes the reading orientation, and the 0-cochain Φ encodes the trivialization or choice of gauge.

Remark 66.30. At the local level, the choice between an additive reader and a multiplicative reader should be understood as a polarization of the same phase support. At the global boundary level, that choice is absorbed into the class of the observed 1-cochain. The geometrically relevant object is therefore the cohomology class, rather than the particular representative.

Proposition 66.31 (Observer Covariance)**.** *For every admissible transport ω and every boundary observer $O = (\varepsilon, \Phi)$, one has*

$$\mathfrak{a}_\chi(\omega^O) = \varepsilon\, \mathfrak{a}_\chi(\omega).$$

In particular, self-measurement is invariant under a change of trivialization and changes sign only when the orientation is reversed.

Proof. Using the definition of seam defect and linearity, it is obtained

$$\partial\Gamma_{\omega^O} = \sum_{e \in C_n} \big(\varepsilon\, \omega(e) + (d\Phi)(e)\big) = \varepsilon \sum_{e \in C_n} \omega(e) + \sum_{e \in C_n} (d\Phi)(e).$$

The sum of the exact term telescopes and equals 0 by Proposition 66.27. Hence

$$\partial\Gamma_{\omega^O} = \varepsilon\, \partial\Gamma_\omega.$$

Projecting onto the residual line $\mathbb{R}v$ by means of the formula in Theorem 66.28, one concludes

$$\mathfrak{a}_\chi(\omega^O) = \frac{\langle \partial\Gamma_{\omega^O}, v\rangle}{\langle v, v\rangle} = \varepsilon\, \frac{\langle \partial\Gamma_\omega, v\rangle}{\langle v, v\rangle} = \varepsilon\, \mathfrak{a}_\chi(\omega).$$

□

Corollary 66.32 (The observer does not create the invariant)**.** *Two boundary observers differing only by gauge measure the same closure scalar. Therefore, the observer fixes a reading but does not manufacture the residual mode.*

Remark 66.33. This proposition resolves the observer problem at precisely the level at which the present framework can resolve it. The observer does not disappear, but its role changes: it does not introduce

the pattern; rather, it selects a polarization and an orientation for an invariant already generated by the structure itself. In this sense, the theory is *observer-covariant*.

66.7.2 Uniqueness of the intrinsic autofunctional

The next step consists in formalizing the idea that the system measures itself. To this end, one must distinguish between the local density of the harmonic mode and the global magnitude of boundary closure.

Definition 66.34 (Self-measure density and global closure)**.** Let ω be an admissible transport on C_n. We define the *self-measure density* by

$$\mu_\chi(\omega) := \frac{1}{n}\,\mathfrak{a}_\chi(\omega) = \frac{1}{n}\,\frac{\langle \partial\Gamma_\omega, v\rangle}{\langle v, v\rangle}.$$

Equivalently, if

$$\omega = d\Phi + u\mathbf{1}_E \qquad \text{with } u \in \mathbb{R}v,$$

then $u = \mu_\chi(\omega)\, v$. Llamaremos *closure global* to the scalar

$$\mathfrak{a}_\chi(\omega) = n\,\mu_\chi(\omega).$$

Lemma 66.35 (One-dimensional quotient of admissible transports)**.** *Let $\mathcal{T}_{\mathrm{adm}} \subset C^1(C_n; W)$ be the subspace of admissible transports. Then the quotient*

$$\mathcal{T}_{\mathrm{adm}}/dC^0(C_n; W)$$

is a real vector space of dimension 1*, canonically generated by the class of $v\mathbf{1}_E$.*

Proof. By Theorem 66.25, every $\omega \in \mathcal{T}_{\mathrm{adm}}$ can be written uniquely as

$$\omega = d\Phi + u\mathbf{1}_E.$$

The admissibility imposes $u \in \mathbb{R}v$, so that the class of ω modulo exacts remains completely determinada by the real scalar λ such that $u = \lambda v$. In consequence, the quotient is isomorfo to $\mathbb{R}v$, and therefore one-dimensional. □

Theorem 66.36 (Uniqueness of the Auto-measure)**.** *Let $F : \mathcal{T}_{\mathrm{adm}} \to \mathbb{R}$ be a linear functional such that:*

(i) *$F(\omega + d\Phi) = F(\omega)$ for every $\Phi \in C^0(C_n; W)$;*

(ii) *$F(v\mathbf{1}_E) = 1$.*

Then

$$F = \mu_\chi.$$

In particular, the self-measure is the unique *normalized linear functional compatible with the distinguished residual mode.*

Proof. By Lemma 66.35, the quotient $\mathcal{T}_{\mathrm{adm}}/dC^0(C_n; W)$ is one-dimensional and is generated by the class of $v\mathbf{1}_E$. Every gauge-invariant linear map factors through that quotient and is completely determined by its value on the generator. The normalization $F(v\mathbf{1}_E) = 1$ then uniquely fixes the functional. By definition,

$$\mu_\chi(v\mathbf{1}_E) = \frac{1}{n}\,\frac{\langle nv, v\rangle}{\langle v, v\rangle} = 1,$$

and, moreover, μ_χ is linear and gauge invariant. Hence $F = \mu_\chi$. □

Corollary 66.37 (Auto-measure in the HMT case)**.** *In the strong dodecaphase specialization, where $n = 12$ and $v = v_\alpha$, one has*

$$\mu_{\mathrm{HMT}}(\omega) = \frac{\alpha}{12}, \qquad \mathfrak{a}_{\mathrm{HMT}}(\omega) = \alpha.$$

Thus, the number α is the global closure of the boundary, and $\alpha/12$ is the elementary density of self-measure per phase.

Remark 66.38. This formulation changes the meaning of "unit". In classical metrology, the unit is an external reference to which a result is linked through a calibration chain [94, 19]. Here normalization proceeds from the system itself: vector v is not imported from outside, but is generated internally as the minimum lift of the distinguished residual class. In this precise sense, the unit is a *self-measurement*.

66.7.3 Finite holographic principle: boundary, *bulk*, and discrete Stokes

What appeared in the prologue as holographic intuition now admits an exact form. The crucial fact is that the same scalar can be read in two ways: as boundary holonomy or as the total projected curvature of the *bulk*. This does not identify the theory with the quantum-gravitational holography of 't Hooft or Susskind [119, 118]; it does, however, produce a finite and literal analogue of reduction to the boundary.

Definition 66.39 (*Finite bulk* with cyclic boundary)**.** A finite *bulk* with cyclic boundary is an oriented cellular complex of dimension 2

$$K = K^{(0)} \cup K^{(1)} \cup K^{(2)}$$

whose oriented boundary satisfies

$$\partial K \cong C_n.$$

Given a 1-cochain $\Omega \in C^1(K; W)$, we call *discrete curvature* the 2-cochain

$$F_\Omega := d\Omega \in C^2(K; W).$$

If $\Omega|_{\partial K} = \omega$, we shall say that Ω is a *bulk extension* of the boundary transport ω.

Theorem 66.40 (Projected discrete Stokes)**.** *Let K be a finite bulk with boundary $\partial K \cong C_n$, and let $\Omega \in C^1(K; W)$ be a bulk extension of an admissible transport ω on the boundary. Then*

$$\partial\Gamma_\omega = \sum_{e \subset \partial K} \Omega(e) = \sum_{f \in K^{(2)}} F_\Omega(f).$$

In particular,

$$\mathfrak{a}_\chi(\omega) = \frac{\left\langle \sum_{f \in K^{(2)}} F_\Omega(f), v \right\rangle}{\langle v, v \rangle}.$$

Proof. The first equality is simply the definition of seam defect applied to the restriction of Ω to the boundary. The second is the discrete Stokes formula for cochains: the oriented sum over the boundary of a complex equals the sum, over all 2-cells, of the oriented coboundary of the 1-cochain. That is,

$$\sum_{e \subset \partial K} \Omega(e) = \sum_{f \in K^{(2)}} (d\Omega)(f) = \sum_{f \in K^{(2)}} F_\Omega(f).$$

Projecting onto the residual line $\mathbb{R}v$ and using Theorem 66.28 yields the final formula. □

Corollary 66.41 (Obstruction to a flat *bulk*)**.** *If an admissible boundary transport ω admits a flat bulk extension, that is, an Ω with $F_\Omega = 0$, then*

$$\mathfrak{a}_\chi(\omega) = 0.$$

Equivalently, if $\mathfrak{a}_\chi(\omega) \neq 0$, every bulk extension of the boundary must carry nonzero discrete curvature.

Proof. This is an immediate consequence of Theorem 66.40. If $F_\Omega = 0$, then the projected sum of curvatures equals 0, and therefore $\mathfrak{a}_\chi(\omega) = 0$. □

Corollary 66.42 (Finite holographic reading)**.** *The closure invariant may be read equivalently as a boundary observable or as the integrated curvature of the* bulk*:*

$$\mathfrak{a}_\chi(\omega) = \frac{\langle \partial\Gamma_\omega, v\rangle}{\langle v, v\rangle} = \frac{\left\langle \sum_{f\in K^{(2)}} F_\Omega(f), v\right\rangle}{\langle v, v\rangle}.$$

In this precise sense, the system satisfies a finite holographic principle.

Remark 66.43. The preceding corollary is the most literal and strongest form of the holographic principle that the manuscript can sustain through internal proofs. It does not assert a complete gravitational duality. It asserts something more modest and exact: the relevant physical–mathematical scalar of the system *factors through the boundary* and, if extended to a *bulk*, coincides with the total projected curvature of that *bulk*. When $\mathfrak{a}_\chi(\omega) = \alpha$, the equality states that α is simultaneously a boundary holonomy and an integrated curvature.

Corollary 66.44 (Geometric consequence for HMT)**.** *In the strong HMT case, every bulk filling of the dodecaphase cycle that extends the canonical boundary transport must satisfy*

$$\left\langle \sum_{f\in K^{(2)}} F_\Omega(f), v_\alpha \right\rangle = \alpha\,\langle v_\alpha, v_\alpha\rangle = 54\alpha.$$

In particular, the HMT boundary admits no flat filling; its bulk *necessarily carries nonzero projected total curvature.*

Proof. It suffices to apply Corollary 66.42 with $v = v_\alpha$ and use the fact that $\langle v_\alpha, v_\alpha\rangle = 54$. □

Remark 66.45 (On the geometry of the *bulk*). Theorem 66.40 does not by itself identify the metric geometry of the *bulk*; it does impose a very strong negative condition: when $\mathfrak{a}_\chi(\omega) \neq 0$, the filling cannot be exactly or discretely flat. If, moreover, one seeks a global completion compatible with the modular reading of the boundary, the natural candidate ceases to be the Euclidean disk and becomes a modular-type *bulk*. In classical theory, modular functions live on the upper half-plane $\mathbb{H}$, and the Klein invariant $J(\tau)$ classifies the global complex torus [95]. The present result does not yet prove that identification, but it does justify why the intuition of a non-Euclidean *bulk* is mathematically reasonable.

66.7.4 Structural Consequences of Polarization, Self-Measurement, and Discrete Stokes Identity

The preceding three components permit the interpretation of observer, self-measurement, and holography to be fixed with a degree of precision that was previously only sketched.

(1) The **observer** is a choice of polarization, orientation, and gauge. It changes the reading, but not the residual mode, except for the sign associated with the orientation.

(2) The **self-measurement** is the unique normalized linear functional on the admissible space of transports. It requires no external pattern because its normalization arises from the internal minimal lift.

(3) The **holographic principle** acquires an exact form: the relevant scalar can be read entirely on the boundary or entirely as the projected total curvature of the bulk.

This triple identification allows the central thesis of the manuscript to be reformulated more strongly: not only is α an Archimedean boundary invariant, but, within the finite framework considered here, α is the first scalar that a self-inertial phase cell produces when measuring itself and projecting all its effective curvature onto the distinguished residual mode.

Chapter 67

Sommerfeld–Kepler central limit, pilot-wave dynamics, and double-slit interference on the genealogical trajectory space

67.1 Central Limit, Kepler Orbits and Sommerfeld Holonomy

This chapter distinguishes four strata that physical terminology may improperly superimpose: the exact cancellation of interior flows in a graph; the continuous realization of a central field; the Keplerian dynamics resulting from the inverse potential; and the semiclassical phase condition on a band with holonomy. The first is combinatorial. The other three successively require a metric chart, a Lagrangian, and a semiclassical phase line.

67.1.1 Discrete Gauss and inverse descent to area

Let $G = (V, E)$ be a finite undirected graph, let $\vec{E} := \{(x, y), (y, x) : \{x, y\} \in E\}$ be its set of arcs, and let $F : \vec{E} \to \mathbb{R}$ be an antisymmetric 1-cochain, $F(y, x) = -F(x, y)$. We define

$$\operatorname{div} F(x) := \sum_{y:\{x,y\}\in E} F(x, y).$$

For $S \subseteq V$, the flux $\operatorname{Flux}_{\partial S} F$ is the oriented sum over the edges with one endpoint in S and the other in $V \setminus S$.

Theorem 67.1 (Gauss's Theorem in Graphs)**.** *For every $S \subseteq V$,*

$$\sum_{x\in S} \operatorname{div} F(x) = \operatorname{Flux}_{\partial S} F. \tag{K1}$$

Proof. Every edge whose two endpoints lie in S occurs twice with opposite orientations and cancels. Only the edges crossing the boundary chain remain. □

In the cubic lattice, for $R \in \mathbb{Z}_{\geq 0}$,

$$C_R := \{x \in \mathbb{Z}^3 : \|x\|_\infty \leq R\},$$

the number of outgoing links is

$$|\partial C_R| = 6(2R + 1)^2.$$

If a source has total flux Q and mean uniformity is imposed on the shell, the flux per link is

$$E_R = \frac{Q}{6(2R + 1)^2}.$$

When defining r_{eff} by

$$4\pi r_{\text{eff}}^2 = 6(2R + 1)^2,$$

the exact identity is obtained

$$E_R = \frac{Q}{4\pi r_{\text{eff}}^2}. \tag{K2}$$

The passage from (K1) to (K2) uses the additional hypothesis of mean isotropy. Identifying Q with a gravitational or electric source also requires the corresponding dimensional transducer.

67.1.2 Central Lagrangian and Keplerian conics

Let $\mu > 0$ be a reduced mass and $\mathcal{K} > 0$ a coupling of the energy-times-length type, $[\mathcal{K}] = \mathsf{E}\,\mathsf{L}$. On the continuous Euclidean sheet, consider

$$L_{\mathrm{Kep}}(\mathbf{r}, \dot{\mathbf{r}}) = \frac{\mu}{2}\|\dot{\mathbf{r}}\|^2 + \frac{\mathcal{K}}{r}, \qquad H_{\mathrm{Kep}}(\mathbf{r}, \mathbf{p}) = \frac{\|\mathbf{p}\|^2}{2\mu} - \frac{\mathcal{K}}{r}, \tag{K3}$$

where $r = \|\mathbf{r}\| > 0$ and $\mathbf{p} = \mu\dot{\mathbf{r}}$. The Euler–Lagrange equation is

$$\mu\ddot{\mathbf{r}} = -\frac{\mathcal{K}}{r^3}\mathbf{r}. \tag{K4}$$

The specific angular momentum $\mathbf{h} = \mathbf{r} \times \dot{\mathbf{r}}$ is constant; if $\mathbf{h} \neq 0$, the trajectory remains in the plane orthogonal to $\mathbf{h}$.

Proposition 67.2 (Keplerian conic)**.** *Let $h = \|\mathbf{h}\|$. Every nonradial solution of* (K4) *satisfies*

$$r(\phi) = \frac{p}{1 + e\cos(\phi - \phi_0)}, \qquad p = \frac{\mu h^2}{\mathcal{K}}. \tag{K5}$$

For negative energy, $0 \le e < 1$ and the orbit is elliptic.

Proof. With $u = 1/r$, the Binet equation takes the form

$$u''(\phi) + u(\phi) = \frac{\mathcal{K}}{\mu h^2}.$$

Its general solution is

$$u = \frac{\mathcal{K}}{\mu h^2}\bigl(1 + e\cos(\phi - \phi_0)\bigr).$$

Inverting u gives (K5); the binding condition is equivalent to $e < 1$. □

The areolar velocity is

$$\frac{\mathrm{d}A}{\mathrm{d}t} = \frac{h}{2}. \tag{K6}$$

For an ellipse with semimajor axis a, integrating (K6) over one period yields

$$A_{\mathrm{ell}} = \pi a b, \qquad b = a\sqrt{1 - e^2}, \qquad p = a(1 - e^2) = \frac{\mu h^2}{\mathcal{K}}.$$

therefore, $T = 2A_{\mathrm{ell}}/h$, and to the eliminar b, p and h is obtained

$$T^2 = \frac{4\pi^2\mu}{\mathcal{K}}\, a^3. \tag{K7}$$

In the gravitational test problem, $\mathcal{K} = GM\mu$, and (K7) reduces to $T^2 = 4\pi^2 a^3/(GM)$ [70, 96].

The graph Gauss theorem is exact. Under the declared isotropy and distance, the flux produces the inverse-area field; the continuum limit then transports that field to the central Lagrangian and to the Keplerian orbits written above.

67.1.3 Levi-Civita Covering and Möbius Strip

In the complex plane without the origin, the Levi–Civita application

$$q = z^2 \tag{K8}$$

is a double cover. One turn of q around the origin interchanges the two lifts z and $-z$; two turns are required to close the lift. It is an exact witness of memory $\mathbb{Z}_2$. It is not, however, a Möbius band: full regularization of the Kepler problem also requires reparameterizing time and transforming the momenta.

Now let $\gamma : S^1 \hookrightarrow \mathbb{R}^2$ be an embedding whose image is an elliptic orbit, and fix $\varepsilon > 0$. We define

$$M_\gamma := ([0, 2\pi] \times [-\varepsilon, \varepsilon])/\big((0, u) \sim (2\pi, -u)\big). \tag{K9}$$

Theorem 67.3 (Orbital band oriented period)**.** *M_γ is a Möbius band whose kernel is γ. A section of the sign line has holonomy*

$$\mathcal{H}(\gamma) = -I, \qquad \mathcal{H}(\gamma^2) = I. \tag{K10}$$

Therefore, its return as an oriented section requires two turns.

Proof. Identification of the extreme fibers by means of $u \mapsto -u$ is the standard construction of the Möbius band. The holonomy of one turn is the fiber involution; its square is the identity. □

The cover (K8) and the band (K9) share a monodromy of order two, but they are not isomorphic objects. This distinction prevents a particle–antiparticle orientation from being deduced from Levi–Civita regularization without an additional map.

67.1.4 Sommerfeld's semiclassical condition with holonomy

Let

$$J_\gamma := \oint_\gamma \mathbf{p} \cdot \mathrm{d}\mathbf{q}$$

the action of a cycle, and suppose that semiclassical transport contributes the phase $\exp(\mathrm{i}J_\gamma/\hbar_{\mathrm{int}})$. If the associated real line has holonomy $\varepsilon_\gamma \in \{+1, -1\}$, the closure condition of the complexified section is

$$\varepsilon_\gamma \exp\left(\frac{\mathrm{i}J_\gamma}{\hbar_{\mathrm{int}}}\right) = 1. \tag{K11}$$

Proposition 67.4 (Shift by half a unit due to holonomy of sign)**.** *Under the preceding hypotheses,*

$$\begin{aligned} \varepsilon_\gamma = +1 \quad &\Longrightarrow \quad J_\gamma = 2\pi\hbar_{\mathrm{int}} n, \\ \varepsilon_\gamma = -1 \quad &\Longrightarrow \quad J_\gamma = 2\pi\hbar_{\mathrm{int}} \left(n + \frac{1}{2}\right), \qquad n \in \mathbb{Z}. \end{aligned} \tag{K12}$$

Proof. The equation (K11) requires a phase equal to one in the trivial sector and equal to minus one in the sign sector. Their arguments differ, respectively, by an integral or half-integral multiple of 2π. □

The proposition is an exact consequence of the declared phase and holonomy; it does not by itself select the Coulomb Hamiltonian, a physical quantum number, or an atomic spectrum [112]. In an EBK quantization, the Maslov indices of the corresponding cycles must be added without counting the topological shift twice.

Relative to the orientation reader, the two local sheets may represent routes γ and $\gamma^\vee$ and be linked to the two orientations of the two-sheet entanglement defined in definition 73.2. This correspondence neither identifies those routes with advanced or retarded Green functions nor asserts that entropy causes the

Keplerian conic: the orbit proceeds from (K4); entropy measures, after a Hilbert completion, correlation between sheets.

Comparison Criterion 67.5 (Kepler–Sommerfeld limit)**.** The realization is refuted or improperly typed if an inverse-square law is obtained without declaring isotropy; if $\mathcal{K}$ or G is introduced as a scalar without a dimensional line; if cover $q = z^2$ is identified with a Mobius band; if (K12) is published as an exact spectrum without a Hamiltonian, cycles, and Maslov indices; or if entanglement is attributed to a merely deterministic route inversion.

67.2 Reconstruction of quantum dynamics through coherent amplitudes over route genealogies

The wave is not added to the history: it is the linear form in which the complete history simultaneously preserves all its possible paths.

— HMT–MD propagation principle

Measurement has already been defined as a coupling among the system, the apparatus, and the reader. It is now necessary to explain what propagates before the result is published, how one and the same structure supports both a wave and a persistent trajectory, and how observable locality coexists with a global genealogy.

The response of Triadic Modular Holography begins from a distinction that the pointwise formulation tends to obscure. A state is not exhausted by the cell in which it lies or by the real number ultimately read from it. It also preserves the route, orientation, quotients, carries, boundary, and return that brought it there. Upon linearizing this space of histories, the sum over paths does not appear as a metaphor added a posteriori: it is the exact expansion of the propagator. The wave is the coherent evaluation of the totality of routes; in the following chapter, the particle will be the section that persists along one of them.

67.2.1 The global amplitude of 1 family of paths

Let X be a finite set of observable states at a given depth, and let $U : \mathbb{C}^X \to \mathbb{C}^X$ be the one-step propagation operator. A route of length R from i to f is a sequence

$$\gamma = (x_0 = i, x_1, \dots, x_R = f)$$

of admissible transitions. Its ordered weight is

$$w_U(\gamma) = \prod_{t=1}^{R} U_{x_t x_{t-1}}.$$

Although scalar weights commute, the indexed sequence of transitions matters: one is not counting only how many routes reach f, but which factor each step assigns to that history. Multiplication composes the transitions along a route; addition gathers alternative histories that terminate in the same state. For operator-valued weights, the temporal product is moreover genuinely noncommutative. This difference between a product within a route and a sum among routes is the linear version of the double reading that runs throughout HMT.

Theorem 67.6 (Finite path sum)**.** *For all $R \geq 1$,*

$$(U^R)_{fi} = \sum_{\substack{\gamma : i \to f \\ |\gamma| = R}} w_U(\gamma).$$

If $\psi_0 \in \mathbb{C}^X$ is the initial amplitude, then

$$\psi_R(f) = \sum_{i \in X} \sum_{\substack{\gamma : i \to f \\ |\gamma| = R}} w_U(\gamma)\, \psi_0(i).$$

Proof. The assertion for $R = 1$ is the definition of U. When an expansion of U^R is multiplied by U, every route of length R receives exactly one final admissible edge. Distributivity sums all possible extensions, and multiplication preserves the order of their weights. By induction, every route of length $R + 1$ appears exactly once. The second equality applies the first to ψ_0. □

This identity has considerable conceptual content. A component $\psi_R(f)$ is not an isolated property of the point f. It is the contraction of the complete genealogy of routes reaching it. Two histories may end at the same visible value and nevertheless contribute opposite phases; they may also reinforce one another. Interference consists precisely in summing amplitudes before forming a positive observable. There is no need to introduce an additional material wave traversing a space distinct from that of the histories: the wave structure resides in the linear composition of the routes.

When U is unitary,

$$\|\psi_R\|_2 = \|U^R \psi_0\|_2 = \|\psi_0\|_2.$$

The total quantity that may subsequently be normalized as a probability remains constant. If the physical reader assigns to an output f the weight

$$p_R(f) = \frac{|\psi_R(f)|^2}{\|\psi_R\|_2^2},$$

then p_R is a normalized distribution, and its evolution is compatible with unitary conservation. This is the precise point at which route amplitude becomes outcome statistics. The chapter on measure has already located the coupling that publishes an output; here, the object evaluated by that coupling has been identified.

The construction also clarifies why a visible number is not sufficient to reconstruct the physics. The map

$$\{\text{deep routes}\} \longrightarrow X$$

generally forgets the relative phase between paths. Knowing only the final distribution of cells does not permit inversion of the sum or recovery of the genealogy. The complete HMT state preserves what the screen contracts. Hence memory is not an interpretive ornament: it is the datum on which interference depends.

At the refinement limit, the correct question is not whether the discrete route "becomes" mysteriously continuous, but whether the propagators form a compatible family. For refinement projections $p_{m+1,m} : X_{m+1} \to X_m$, coherence requires the cylindrical observables and the transported states to agree. When this compatibility is exact, the amplitude of a coarse history is the sum of the amplitudes of all its fine prolongations. When the defects are summable, the expectations of uniformly bounded cylindrical observables form a Cauchy family. Operational continuity is thereby obtained without erasing the discrete structure that generates it.

Principle 67.7 (The wave as linear memory)**.** The finite-depth HMT wave function is the linear evaluation of the route extension. It coherently preserves the alternatives compatible with the preparation and the boundary; the observed value is a subsequent projection of that global amplitude.

This formulation is stronger than asserting that "everything occurs along many paths". It specifies the domain, the weight of each path, the composition rule, and the preserved norm. It also contains its

negative control: if a purported amplitude does not respect route composition, counts a history twice, consults the future result in order to assign the weight, or loses the norm under a propagator declared unitary, it is not the wave function constructed here.

67.2.2 Pilot wave, route performed and double orientation

The preceding structure already contains the two components that a pilot-wave theory must distinguish. The amplitude ψ_t globally organizes the alternatives; a persistent route x_t records the history actually realized. The wave and the particle are not two rival substances. They are two levels of reading of the same enriched state: the linear field of possibilities and the section that preserves its identity while traversing it.

The guiding law must convert this kinematic architecture into dynamics. Its minimal form is a map

$$G : (\psi_t, x_t) \longmapsto x_{t+1},$$

o, if the update is stochastic, a kernel

$$P_{\psi_t}(y \mid x).$$

The central condition is not verbal, but mathematical: the guided distribution must be equivariant with amplitude evolution,

$$|\psi_{t+1}(y)|^2 = \sum_x P_{\psi_t}(y \mid x)\, |\psi_t(x)|^2.$$

This equality ensures that a population initially distributed according to $|\psi_t|^2$ remains so distributed after one step. The guide cannot be chosen retrospectively to reproduce each detector; it must be fixed by the state, propagator, orientation, and register before the output is known. HMT adds a possibility that a pointwise description does not possess: G may depend on route and memory cocycles that do not descend to the visible value x_t. The local action can thereby be informed by a global genealogy without the appearance of a supplementary force traveling from the future.

The bidirectional reading further develops this structure. For an oriented route γ with

$$\partial\gamma = x_{\mathrm{abs}} - x_{\mathrm{em}},$$

the return involution defines

$$\gamma^{\vee} = C_{\mathrm{rev}}\gamma, \qquad \partial\gamma^{\vee} = x_{\mathrm{em}} - x_{\mathrm{abs}}.$$

These are not two independently and freely chosen paths. They are the two orientations of the same history. The internal length is invariant,

$$L_{\mathrm{int}}(\gamma^{\vee}) = L_{\mathrm{int}}(\gamma), \qquad L_{\leftrightarrow} = 2L_{\mathrm{int}}(\gamma),$$

and inversion interchanges the conjugate channels. Preparation and absorption cease to be ontologically disconnected endpoints: they belong to a closure in which the outward and return paths must be compatible.

When this involution is represented in the physical theory of propagators, the two orientations admit retarded and advanced readings. The retarded component transports the preparation toward absorption; the advanced component transports the return condition toward emission. The observable history is their mutual adjustment. This formulation precisely expresses the intuition of a pilot wave with advance and retardation: the local guide receives information from both boundaries of the same oriented object.

This provides no authorization to send controllable messages into the past. An advanced solution of an equation and a signalable future choice are distinct objects. The physical representation must prove that the propagators satisfy the evolution equation, that the boundary conditions compose consistently, and

that the marginal probabilities do not permit modulation of an earlier output by a later decision. Dual orientation is the support; observable causality is a property that must be verified on its physical reader.

The correlation between the two sheets can be formalized in two Hilbert spaces, $\mathcal{H}_{\mathrm{adv}}$ and $\mathcal{H}_{\mathrm{ret}}$. For a distribution $p = (p_i)$, the state

$$|\Psi_p\rangle = \sum_i \sqrt{p_i}\, |i\rangle_{\mathrm{adv}} \otimes |i\rangle_{\mathrm{ret}}$$

has reduced matrices with spectrum (p_i) and entropy

$$S_{\mathrm{ent}}(p) = -\sum_i p_i \log p_i.$$

The equality is exact once the bilayer factorization has been declared. A single history has Schmidt rank one and zero entropy; several correlated histories produce positive entropy. The result does not simply identify this entropy with $\log \varphi_{\mathrm{HMT}}$, with the information in a triadic cell, or with thermodynamic entropy. Each belongs to a different object. What it proves is that outbound and return can form a nonseparable state and that the shared information is calculated without metaphors.

Testing program 67.8 (Bidirectional guidance)**.** A physical realization of the HMT pilot wave must fix, before comparison, the propagator U, the law G or the kernel P_ψ, the involution C_{rev}, and the boundary conditions. It is falsified if it loses equivariance, assigns two incompatible routes to the same complete state, needs to know the future detector in order to choose the trajectory, or permits controllable signaling against the published causal orientation.

This proof does not relegate the proposal to a mere possibility. On the contrary, it shows that the mathematical core has already been constructed and identifies the sole locus at which physical dynamics must act. The sum over paths is not pending; the persistent route is not pending; nor is inversion. What is decided experimentally is which Hamiltonian realizes the guide and which boundary conditions turn the two sheets into nature's advanced and retarded waves.

67.2.3 Bell: locality of the data and globality of the genealogy

The distinction between complete state and projected value permits the Bell problem to be formulated precisely. Consider settings $a, b \in \{0, 1\}$, outcomes $A, B \in \{-1, +1\}$, and a shared state λ. A factorizable local theory satisfies

$$P(A, B \mid a, b) = \int_\Lambda P_A(A \mid a, \lambda)\, P_B(B \mid b, \lambda)\ \mathrm{d}\rho(\lambda),$$

with a measure independent of the adjustments,

$$\mathrm{d}\rho(\lambda \mid a, b) = \mathrm{d}\rho(\lambda).$$

Defining

$$E_{ab} = \sum_{A,B=\pm 1} AB\, P(A, B \mid a, b),$$

we obtain

$$S_{\mathrm{CHSH}} = E_{00} + E_{01} + E_{10} - E_{11}, \qquad |S_{\mathrm{CHSH}}| \le 2.$$

HMT preserves this theorem. Adding hidden memory to λ does not violate the bound if factorization, setting independence, and the absence of postselection are maintained. This control is important: it prevents the richness of TPK from being turned into an automatic explanation of every correlation.

The holographic contribution is formulated differently. The two wings of an experiment may be local projections of the same enriched section, with a common boundary and genealogy. The datum published on each wing is local; the state from which both descend need not factor into two independent deep histories. Nonlocality then consists not in a signal crossing space after the settings have been chosen, but in the impossibility of decomposing the global preparation into two autonomous complete states.

Non-signaling and Bell locality are not equivalent. It may be satisfied

$$\sum_B P(A, B \mid a, b) = P(A \mid a), \qquad \sum_A P(A, B \mid a, b) = P(B \mid b),$$

and nevertheless fail the preceding factorization. This is the precise domain that an HMT realization must occupy: global correlation without a superluminal communication channel. The contextual reader may depend on the setting in how it projects the common state, but an observer's marginal distribution cannot depend on the remote choice.

Construction 67.9 (HMT Protocol for Bell)**.** An enriched state x, a preparation measure, and four readers L_{ab} are fixed first. A binary outcome map is then declared, and the complete table is calculated

$$P_{\mathrm{HMT}}(A, B \mid a, b).$$

The construction is physically valid only if it is frozen before the data are consulted, is normalized, has no hidden postselection, and publishes simultaneously S_{CHSH} and the four marginal no-signaling controls.

The so-called Algorithm 3 belongs to this specific construction. Its purpose is not to prove the classical theorem again, but to construct the descent from the shared genealogy to a contextual distribution. If it preserves all the Bell premises, it will necessarily produce $|S| \leq 2$. If it produces $|S| > 2$, it must show explicitly which factorization fails to descend and why no-signaling is nevertheless preserved. This is the complete holographic explanation of the locality problem: the observable space may be separable even though the history generating it is not separable.

The proposal is especially natural in a theory in which sum and product are distinct readers. Bell factorization seeks to express a joint probability as a conditioned product of local responses; quantum amplitude, by contrast, arises by summing histories before projecting them. If projection is performed too early, the common phase is lost and only the local polytope remains. If the global state is preserved until the joint reading, interference terms survive that do not admit such a decomposition. The incompatibility is not a license to violate logic: it is the typed difference between composing alternatives by sum and composing local probabilities by product.

67.2.4 From the path theorem to quantum contrast

The resulting quantum architecture is articulated through a single chain of maps. HMT constructs an enriched discrete space of histories; its linearization produces the coherent sum over paths; unitarity preserves the norm; a persistent section makes it possible to speak of a trajectory; oriented inversion yields the outward-and- return pair; two-sheet factorization quantifies its correlation; and Bell analysis distinguishes locality of the datum from separability of the genealogy. These are not juxtaposed analogies, but successive maps on the same state.

The theory thus offers a unified reading of quantum features. Superposition is the linear coexistence of prolongations; interference is their phased sum; the particle is the persistence of a section; apparent reduction is the selection of a fiber by the reader; entanglement is the nonfactorization of sheets or subsystems; and nonlocality is the globality of the genealogy preserved under locally nonsignaling projections.

Physical tests are added not to weaken this reading, but to determine its natural realization. A finite interferometric network can implement U and compare the path expansion with the final pattern. A

reconstruction of currents can test the guidance law. Controlled inversion of the boundary conditions can verify the reciprocity $\gamma \leftrightarrow \gamma^{\vee}$. A Bell experiment with sealed readers can determine whether deep memory generates a nonfactorizable, no-signaling distribution.

Testing program 67.10 (Joint Quantum Compatibility Certificate)**.** The certificate distinguishes four independent validity conditions:

1. the propagator not reproduce by coherent sum the amplitudes observadas;
2. no natural guiding law is equivariant with $|\psi|^2$;
3. the double orientation does not admit reciprocal physical propagators without improper causal signaling;
4. the Bell descent is locally factorizable or violates no-signaling.

Failure of an interface localizes the incorrect map; it does not erase the finite route theorems that precede it.

The positive thesis is therefore clear. Quantum theory does not require the history of a system to be abandoned; it requires what is meant by history to be enriched. A point without genealogy cannot by itself carry interference, return, or correlation. An oriented extension can do so. Its wave is the coherent memory of all compatible paths; its particle is the closure that persists. The passage between the two forms is not an ontological leap: it is the passage from the linear totality of routes to a realized section of that same totality.

67.2.5 Double-slit interference in T_{27}^2: path memory, Born rule, and dodecaphasic unitarity

The finite realization is constructed upon

$$\mathcal{H}_{\mathrm{cam}} = \ell^2\left(T_{27}^2\right) \otimes \mathbb{C}^4, \qquad T_{27}^2 = (\mathbb{Z}/27\mathbb{Z})^2,$$

where the dimension factor 4 records the directions (N, S, E, W). Explicit memory of the trajectory adds the factor $\mathbb{C}^2_{\mathrm{mem}}$. The microscopic step is the operator

$$U_{\mathrm{micro}} = S D_J C_4, \tag{67.1}$$

with C_4 unitary, D_J diagonal, and S as a shift conditioned by direction. Consequently,

$$U_{\mathrm{micro}}^{*} U_{\mathrm{micro}} = I,$$

and the norm is preserved at each step.

67.2.5.1 Preparation of the 2 *Trajectories and Reading Screen*

The two openings are fixed at

$$(x_0, y_1) = (2, 8), \qquad (x_0, y_2) = (2, 18),$$

with the same initial directional state. If ψ_1 and ψ_2 are the amplitudes propagated from each aperture, the screen located at $x = 24$ publishes, for a real memory overlap $\mu \in [0, 1]$,

$$I_\mu(y) = \frac{1}{2} \sum_{d} \left(|\psi_1(24, y, d)|^2 + |\psi_2(24, y, d)|^2 + 2\,\mathrm{Re}\Big[\mu\, \overline{\psi_1(24, y, d)} \psi_2(24, y, d)\Big] \right). \tag{67.2}$$

The formula is also obtained by introducing the markers

$$|m_1\rangle = (1, 0), \qquad |m_2\rangle = (\mu, \sqrt{1 - \mu^2})$$

Table 67.1: Interference and distance from the canonical sequence after 36 steps.

Sequence	$\mathcal{V}_{\text{lineal}}$	total variation distance	mean fidelity
canonical	0.5992212256	0	1.0000000000
inverse	0.5974219552	0.0333923142	0.9740951119
replaced pair	0.5907431085	0.0628288605	0.9417893564
randomized	0.6254301808	0.0963185652	0.6564185376

and tracing over $\mathbb{C}^2_{\text{mem}}$. This equality identifies the overlap of the registers, rather than a loss of norm, as the origin of the attenuation of the fringes. In particular,

$$\mathcal{V}(\mu) = |\mu|\,\mathcal{V}(1). \tag{67.3}$$

For $\mu = 0$, a phase correction cannot reconstruct the cross term; if the markers are unmade unitarily before recombination, the curve $\mu = 1$ is exactly recovered.

67.2.5.2 Unitarity Identities of the Dodecaphase Order Under a Common Amplitude Budget

The control block consists of 12 oriented pulses with zero vector sum. The first 6 are obtained from a directional seed through the dodecaphasic signature; the remaining 6 are their opposites. Four sequences of 36 steps are compared:

1. the canonical sequence, repeated for 3 full cycles;
2. its oriented inverse;
3. a sequence in which an opposite pair is replaced by common phases of the same norm;
4. a random permutation of the same multiset of pulses.

All preserve the pulse count, the null vector sum, and the quadratic budget. The difference between their patterns therefore measures dependence on noncommutative order and directional information, not an unequal injection of norm or energy.

Noncommutativity is verified on a probe state fixed before the reading:

$$\|U_b U_a \psi - U_a U_b \psi\|_2 = 0.24776388825652637.$$

Numerical control provides

$$\|C_4^* C_4 - I\|_{\max} = 0, \qquad \max_t \left|\|\psi_t\|_2^2 - 1\right| = 1.3322676295501878 \times 10^{-15},$$

$$\Delta B_2 = 2.220446049250313 \times 10^{-16}, \qquad \varepsilon_{\text{Born}} = 1.734723475976807 \times 10^{-18},$$

$$\varepsilon_{\mathcal{V}(\mu)} = 2.220446049250313 \times 10^{-16},$$

where ΔB_2 is the maximum dispersion of the quadratic budget among the four sequences.

67.2.5.3 Interference reconstructed at T^2_{27}: detection distribution and physical domain

Theorem 67.11 (Unitary interference with explicit path memory)**.** *For the dynamics defined by* (67.1)*, the intensity obtained by tracing out the path record coincides with* (67.2)*; the visibility satisfies* (67.3)*; and sequences with the same quadratic budget may produce different patterns when their order differs.*

The proof is finite: unitarity of each factor, expansion of the square of the sum of the two branches, and partial contraction of the marker. The preceding numerical controls verify the run on T^2_{27}. The concrete chart taking the dodecaphasic state to directional phases constitutes a declared physical realization; it is

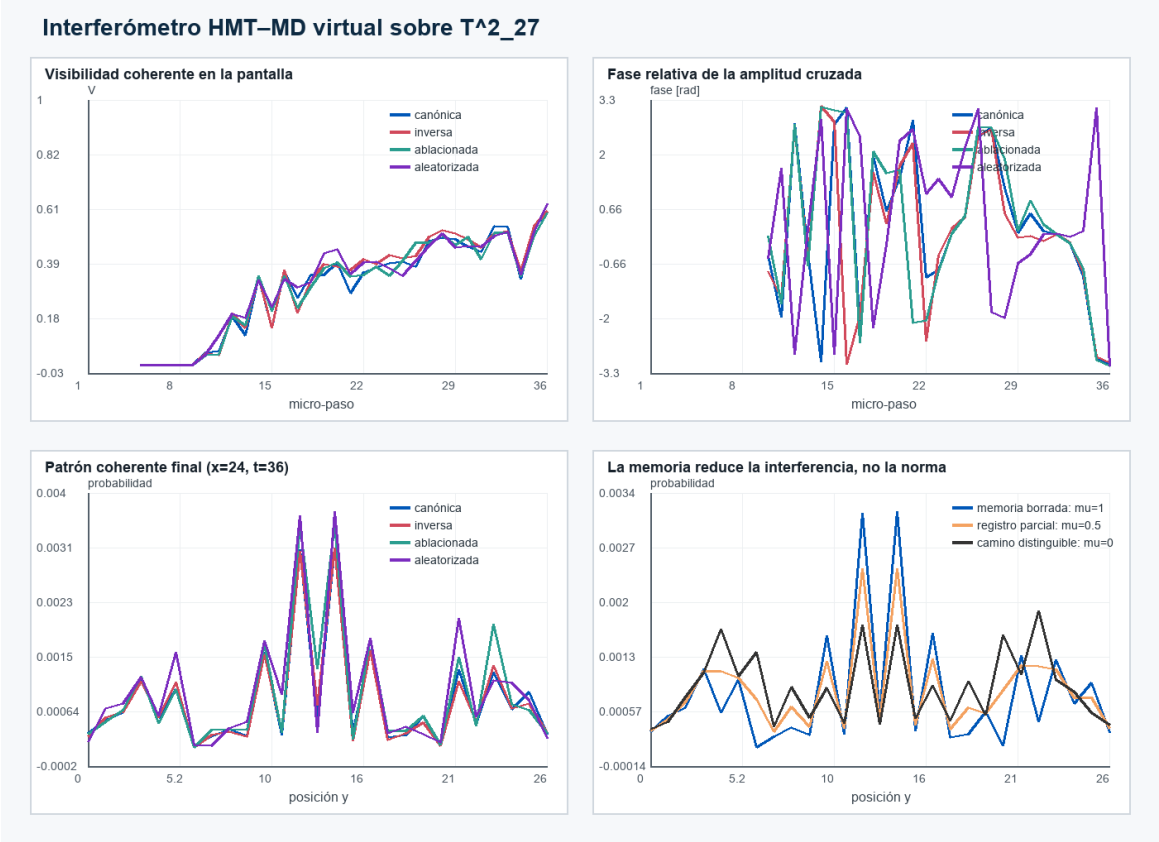

Figure 67.1: Evolution of visibility, relative phase, and final pattern for the four sequences with common budget. The original image depicts the virtual HMT–MD interferometer on T^2_{27}. Panel labels, from left to right and top to bottom: coherent visibility on the screen; relative phase of the cross amplitude; final coherent pattern $(x = 24, t = 36)$; memory reduces interference, not the norm. Axes: microstep, position y, phase in radians, and probability. The four sequences are canonical, inverse, ablated, and randomized. The memory curves represent erased memory $(\mu = 1)$, partial record $(\mu = 0.5)$, and a distinguishable path $(\mu = 0)$.

not identified by definition with the temporal return of 108 phases. The electron scale is applied after the dimensionless dynamics and neither selects the word nor fits the fringes.

The realization would be refuted by loss of unitarity, discrepancy between the explicit memory and the Born rule, creation of interference by a phase when $\mu = 0$, dependence of the energy budget on the sequence, or use of the screen outcome to select the pulse order retrospectively.

67.3 Central realisation of trajectories and Sommerfeld holonomy

The particle defined in section 90.14 has an observable history before receiving an orbital realization. The question of this section is how a representation of that history preserves flux, area and phase when expressed as central motion. The answer is organized into four operations: cancellation of the interior fluxes in a graph cut, normalization of its boundary in a metric chart, evolution under the declared central operator and phase transport over its cycles.

The order keeps visible which datum enters each statement. The graph and its records come from APP–TRIT–TPK; the metric chart specifies how its boundary is measured; the dynamical realization fixes the Lagrangian acting in that chart; the semiclassical condition uses the reduced Planck constant already constructed and the holonomy of the transported line. The results of orbital geometry are proved with

Figure 67.2: Order controls, path memory, and phase feedback. The original image presents falsifiable controls of order, memory, and feedback. Panel labels, from left to right and top to bottom: phase sweep at the port of maximum overlap; Born rule and continuous loss of coherence; permutation stress with an identical budget; variable phase aligns, but does not erase the record. Axes: probability, visibility, δ in radians, $|\mu|$, final visibility, and microstep. Sequence labels: canonical, inverse, ablated, and randomized. The other curves denote explicit memory, $V(\mu) = |\mu|V(1)$, locked phase with reversible memory, and the same phase with a recorded path.

these explicit starting data. Central mechanics is recognized in the resulting realization, without making its conventional constants inputs to the generator.

67.3.1 Flux conservation and boundary reading

Let $G = (V, E)$ be a finite cut of the route graph of the realisation under consideration, with an arc in each orientation of its edges. An oriented flux is a function $F : \vec{E} \to \mathbb{R}$ satisfying $F(y, x) = -F(x, y)$. At a vertex x, its divergence is

$$\operatorname{div} F(x) = \sum_{y:\{x,y\}\in E} F(x, y). \tag{67.4}$$

For $S \subseteq V$, the outward flux is evaluated over the arcs originating in S and ending in $V \setminus S$.

Theorem 67.12 (Flux balance in a finite cut)**.** *For every subset $S \subseteq V$,*

$$\sum_{x\in S} \operatorname{div} F(x) = \sum_{\substack{x\in S,\ y\notin S \\ \{x,y\}\in E}} F(x, y). \tag{67.5}$$

Proof. An edge with both endpoints in S contributes twice to the sum of divergences, through $F(x, y) + F(y, x) = 0$. Edges with both endpoints outside S do not contribute. Exactly the edges crossing the boundary remain, with the indicated orientation. □

The theorem transmits to the boundary the balance produced in the interior. For a cubic representation with nearest neighbours, consider

$$C_R = \{x \in \mathbb{Z}^3 : \|x\|_\infty \le R\}, \qquad R \in \mathbb{Z}_{\ge 0}.$$

Each of the six faces contains $(2R + 1)^2$ outward links in its normal direction. Links in different directions are counted separately, even when they originate at the same edge or corner vertex. Hence,

$$|\partial C_R| = 6(2R + 1)^2. \tag{67.6}$$

This census counts outward links, not the number of boundary vertices.

If Q_F is the total flux of the enclosed source, its average per link is $Q_F/[6(2R + 1)^2]$. Under the condition of mean isotropy of the reader, that average is the intensity assigned to the shell. Let us define its effective radius, in units of the step of the chart, by

$$4\pi r_{\text{eff}}^2 = 6(2R + 1)^2. \tag{67.7}$$

We then obtain

$$E_R = \frac{Q_F}{4\pi r_{\text{eff}}^2}. \tag{67.8}$$

The coordinate π of this normalization is the regional HMT output already published. The identity follows from the census and the definition of the radius; the passage from an average to a central realization additionally uses the stated isotropy. The dimensional chart then decides whether Q_F represents electric, gravitational or other observable flux and how it converts the lattice step into length. The finite balance preserves this distinct status of each operation.

67.3.2 Central dynamics on the Euclidean sheet

Let $\mu > 0$ be the reduced mass of the material realisation and let $\mathcal{K} > 0$ be its central coupling, with the dimension of energy times length. These coordinates are received after the internal constructions of mass, action and coupling; their origin and dimensional line are preserved when carrying out the realisation. The domain of the following theorem consists of all realisations that adopt, on their Euclidean sheet,

$$L(\mathbf{r}, \dot{\mathbf{r}}) = \frac{\mu}{2}\|\dot{\mathbf{r}}\|^2 + \frac{\mathcal{K}}{r}, \qquad H(\mathbf{r}, \mathbf{p}) = \frac{\|\mathbf{p}\|^2}{2\mu} - \frac{\mathcal{K}}{r}, \quad r = \|\mathbf{r}\| > 0, \quad \mathbf{p} = \mu\dot{\mathbf{r}}. \tag{67.9}$$

The exclusion of $r = 0$ delimits the regular domain of these coordinates. The trajectory is considered over a collision-free time interval.

Proposition 67.13 (Orbital plane and conic equation)**.** *A non-radial solution of the Euler–Lagrange equation of* (67.9) *conserves $\boldsymbol{\ell} = \mathbf{r} \times \dot{\mathbf{r}}$, with $\ell = \|\boldsymbol{\ell}\| > 0$. In the plane orthogonal to $\boldsymbol{\ell}$, it can be written*

$$r(\theta) = \frac{p}{1 + \epsilon\cos(\theta - \theta_0)}, \qquad p = \frac{\mu\ell^2}{\mathcal{K}}, \qquad \epsilon \geq 0. \tag{67.10}$$

Negative energy corresponds to the elliptic regime $0 \leq \epsilon < 1$.

Proof. Differentiating the potential gives

$$\mu\ddot{\mathbf{r}} = -\frac{\mathcal{K}}{r^3}\mathbf{r}. \tag{67.11}$$

Hence, $\dot{\boldsymbol{\ell}} = \mathbf{r} \times \ddot{\mathbf{r}} = 0$. Position and velocity remain orthogonal to the non-zero constant vector $\boldsymbol{\ell}$, fixing the plane. In its polar coordinates, $r^2\dot{\theta} = \ell$. Introducing $u = 1/r$ into the radial equation gives Binet's equation

$$u''(\theta) + u(\theta) = \frac{\mathcal{K}}{\mu\ell^2}.$$

Its general solution is $u = \mathcal{K}[1 + \epsilon\cos(\theta - \theta_0)]/(\mu\ell^2)$, and inversion proves (67.10) on the domain where the denominator is positive. Substitution into the energy gives $H = \mathcal{K}(\epsilon^2 - 1)/(2p)$, which is negative exactly when $\epsilon < 1$. □

Here the letter ϵ denotes orbital eccentricity, not Euler's number. The vector $\boldsymbol{\ell}$ is specific angular momentum, not the Planck constant. These notational choices allow the geometric observables and the internal constants entering their realisation to be compared without conflation.

Proposition 67.14 (Areal conservation and period law)**.** *The orbit's areal velocity is constant:*

$$\frac{d\mathcal{A}_{\mathrm{orb}}}{dt} = \frac{\ell}{2}. \tag{67.12}$$

For an ellipse with semimajor axis a, its period satisfies

$$T^2 = \frac{4\pi^2\mu}{\mathcal{K}}a^3. \tag{67.13}$$

Proof. The sector swept out in time dt has area $r^2 d\theta/2 = \ell\, dt/2$. If $b = a\sqrt{1 - \epsilon^2}$ is the semiminor axis, the total area is πab and $T = 2\pi ab/\ell$. The relation $p = a(1 - \epsilon^2) = \mu\ell^2/\mathcal{K}$ implies $\ell^2 = \mathcal{K}a(1 - \epsilon^2)/\mu$. Substitution into $T^2 = 4\pi^2 a^2 b^2/\ell^2$ gives (67.13). □

Areal conservation is determined by the central symmetry of the motion. The ellipse of this proposition lives in configuration space. The action ellipse constructed from the angular pair, in contrast, lives in

its action chart and transports the corresponding normalizations. The link between the two requires the realization map that identifies their variables; sharing an elliptical shape does not replace that map. The orbital reading thus preserves the dependencies on mass, coupling and geometry that produce it.

67.3.3 Orbital covering and real sign line

On the complex plane with the origin removed, the map

$$q = z^2 : \mathbb{C} \setminus \{0\} \longrightarrow \mathbb{C} \setminus \{0\} \tag{67.14}$$

is a double covering. If $q(t) = r(t)e^{i\theta(t)}$ and a root is chosen initially, its lift is $z(t) = \sqrt{r(t)}e^{i\theta(t)/2}$. One circuit with an increment 2π in θ ends at $-z(0)$, and two circuits restore the initial point. This is the transport of the two lifts over the punctured plane.

An orbital band requires another object: a real line associated with the orbit and its sign character. Let $\gamma : S^1 \to \mathbb{R}^2$ be a regular injective parametrisation of an elliptic orbit, and let $\delta > 0$. With holonomy -1 over one circuit, its interval band is represented by

$$M_\gamma = ([0, 2\pi] \times [-\delta, \delta])/\big((0, u) \sim (2\pi, -u)\big). \tag{67.15}$$

Identifying the base with the image of γ places the zero section over the orbit.

Proposition 67.15 (Oriented transport over the orbital cycle)**.** *The line transport in* (67.15) *satisfies* $\mathcal{H}(\gamma) = -I$ *and* $\mathcal{H}(\gamma^2) = I$.

Proof. The terminal fibre is identified with the initial fibre by $u \mapsto -u$; composing this map twice gives the identity. This is the construction in Theorem 90.36, applied to the orbital loop. □

The covering (67.14) has two-point fibres; (67.15) has interval fibres. Monodromy of order two appears in both, while preserving these distinct types. Levi–Civita dynamical regularisation also uses the transformation of momenta and time reparametrisation. The present construction uses only its covering and its lifting law, with the scope just proved.

67.3.4 Phase condition and half-integer shift

Let γ be a cycle of the Hamiltonian realisation, and let

$$J_\gamma = \oint_\gamma \mathbf{p} \cdot d\mathbf{q} \tag{67.16}$$

be its action. The reduced Planck constant $\hbar_{\mathrm{int}} > 0$ is received from the HMT action construction, in the same dimensional line as J_γ. The quotient $J_\gamma/\hbar_{\mathrm{int}}$ is therefore dimensionless. Suppose that semiclassical transport in the complexified line contributes the phase $\exp(iJ_\gamma/\hbar_{\mathrm{int}})$ and that the real orientation line contributes the character $\varepsilon_\gamma \in \{+1, -1\}$. The closure condition for the transported section is

$$\varepsilon_\gamma \exp\left(\frac{iJ_\gamma}{\hbar_{\mathrm{int}}}\right) = 1. \tag{67.17}$$

The product preserves both contributions: the action of the cycle and the sign of the line. The latter is not absorbed into a modification of the Planck constant.

Theorem 67.16 (Integer and half-integer action sectors)**.** *Under the transport* (67.17)*,*

$$J_\gamma = \begin{cases} 2\pi\hbar_{\mathrm{int}} n, & \varepsilon_\gamma = +1, \\ 2\pi\hbar_{\mathrm{int}}(n + \frac{1}{2}), & \varepsilon_\gamma = -1, \end{cases} \qquad n \in \mathbb{Z}. \tag{67.18}$$

Proof. For a positive sign, the exponential must equal 1, whose real arguments are $2\pi n$. For a negative sign, it must equal -1, whose arguments are $(2n+1)\pi$. Multiplying by $\hbar_{\mathrm{int}}$ produces the two families. □

The formula determines the closure constraint on the action of a given cycle. Obtaining an atomic spectrum also uses the specific Hamiltonian, the independent cycles and the quantisation prescription. If this prescription includes Maslov indices, their phases are composed with (67.17) according to the chosen transport, avoiding counting the same topological contribution twice.

Reversing the orientation of the cycle changes J_γ to $-J_\gamma$, whereas the sign character satisfies $\varepsilon_{\gamma^{-1}} = \varepsilon_\gamma^{-1} = \varepsilon_\gamma$. The total phase becomes its inverse, and the closure condition is preserved. This is a precise law of orbital bidirectionality. Its identification with material antisections requires the lift in Section 90.15.2; equality of two signs does not by itself establish that identification.

The realization thus brings together three successive conservations: flux passes from the interior to the boundary; central dynamics conserves angular momentum and the area swept per unit time; transport of the section preserves its closure condition through action and holonomy. Each result retains the equation, the domain and the data that support it. The material history of the TPK is represented in those dynamics with its memory, instead of being replaced by the orbital figure it publishes.

67.4 Differential Geometry and Dimensional Realizations

67.4.1 Curvature and torsion of the published curves

67.4.1.1 Curvature and arc length of a polar curve $r = r(\theta)$

Let

$$\gamma(\theta) = r(\theta)(\cos\theta, \sin\theta).$$

With primes denoting derivatives with respect to θ, the velocity and curvature are

$$v(\theta) = \sqrt{r^2 + (r')^2}, \tag{67.19}$$

$$\kappa_{\mathrm{F}}(\theta) = \frac{r^2 + 2(r')^2 - rr''}{\left(r^2 + (r')^2\right)^{3/2}}. \tag{67.20}$$

The arc length between θ_0 and θ_1 is

$$s = \int_{\theta_0}^{\theta_1} \sqrt{r^2 + (r')^2}\, \mathrm{d}\theta.$$

These magnitudes belong to the published curve. They are neither the TRIT regime nor the radial cocycle.

67.4.1.2 Evaluation of κ_{F} in the logarithmic, Archimedean, Fermat, hyperbolic, and lituus families

For the logarithmic spiral $r = r_0 \mathrm{e}^{b\theta}$,

$$r' = br, \qquad r'' = b^2 r,$$

and

$$\kappa_{\mathrm{F}}(\theta) = \frac{1}{r(\theta)\sqrt{1+b^2}}. \tag{67.21}$$

The angle ψ between the tangent vector and the radial direction satisfies

$$\tan\psi = \frac{r}{r'} = \frac{1}{b},$$

and is therefore constant. This is the equiangular property of the logarithmic spiral.

For the Archimedean spiral $r = a\theta$,

$$\kappa_{\mathrm{F}}(\theta) = \frac{\theta^2 + 2}{a(\theta^2 + 1)^{3/2}}.$$

For Fermat $r = a\sqrt{\theta}$, the singularity at the origin requires $\theta > 0$ to be declared. For the hyperbolic and lituus branches, the angular origin is an asymptote and not a point of the domain.

Chapter 68

Quantum occupation statistics: Fermi–Dirac and Bose–Einstein distributions

Microcanonical enumeration and the symmetric and antisymmetric completions produce the Bose–Einstein and Fermi–Dirac laws. The Maxwell–Boltzmann limit is retained as a derived regime, not as a starting point.

68.1 Microcanonical enumeration of states on a finite screen

Consider the finite realization

$$\mathcal{H}_{\mathrm{occ}} = \bigoplus_{k=0}^{3} \mathbb{C}^{g_k}, \qquad H_{\mathrm{occ}}|_{\mathbb{C}^{g_k}} = E_k^{\mathrm{occ}} I,$$

with levels and multiplicities

$$E^{\mathrm{occ}} = (0, 3, 6, 9), \qquad g = (1, 6, 12, 8), \qquad (N, E) = (12, 66).$$

The sum $1 + 6 + 12 + 8 = 27$ makes $\mathcal{H}_{\mathrm{occ}}$ a screen of twenty-seven modes. This spectrum is the datum of a declared finite representation; its cardinality does not suffice to identify it with any other occurrence of 27 in HMT. The morphism relating a specific boundary screen to $(\mathcal{H}_{\mathrm{occ}}, H_{\mathrm{occ}})$ must specify both the fibers and the spectral operator. The fermionic and bosonic generating functions are

$$F(y, x) = \prod_k (1 + y x^{E_k^{\mathrm{occ}}})^{g_k}, \qquad B(y, x) = \prod_k (1 - y x^{E_k^{\mathrm{occ}}})^{-g_k}.$$

Proposition 68.1 (Microcanonical cardinalities)**.**

$$[y^{12} x^{66}] F = 2\,104\,494, \qquad [y^{12} x^{66}] B = 259\,436\,430.$$

Proof. In the fermionic product, choosing r of the g_k modes contributes $\binom{g_k}{r} y^r x^{r E_k^{\mathrm{occ}}}$. In the bosonic product, distributing r indistinguishable occupations among g_k modes contributes $\binom{g_k + r - 1}{r} y^r x^{r E_k^{\mathrm{occ}}}$. The finite convolution over the four levels produces the stated integers. □

68.2 Bose–Einstein and Fermi–Dirac distributions

The equilibrium formulation starts from the Hamiltonian and the total occupation number,

$$H = \sum_k E_k^{\mathrm{occ}} n_k, \qquad N = \sum_k n_k, \qquad K_\mu := H - \mu N. \tag{68.1}$$

For $\beta > 0$, the grand canonical state is

$$\rho_{\beta,\mu} = \frac{e^{-\beta K_\mu}}{\mathcal{Z}_{\beta,\mu}}, \qquad \mathcal{Z}_{\beta,\mu} = \mathrm{Tr}(e^{-\beta K_\mu}). \tag{68.2}$$

Theorem 68.2 (Grand canonical factorization and occupation laws)**.** *For energy levels E_k^{occ} with degeneracies g_k, the fermionic trace factorizes as*

$$\mathcal{Z}_{\mathrm{FD}} = \prod_k \left(1 + e^{-\beta(E_k^{\mathrm{occ}} - \mu)}\right)^{g_k}, \qquad \langle n_k \rangle_{\mathrm{FD}} = \frac{g_k}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} + 1}. \tag{68.3}$$

In the bosonic sector, under the condition $\mu < \inf_k E_k^{\mathrm{occ}}$,

$$\mathcal{Z}_{\mathrm{BE}} = \prod_k \bigl(1 - e^{-\beta(E_k^{\mathrm{occ}} - \mu)}\bigr)^{-g_k}, \qquad \langle n_k \rangle_{\mathrm{BE}} = \frac{g_k}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} - 1}. \tag{68.4}$$

Proof. The operator K_μ is a sum of commuting occupation operators, so its trace factorizes over modes. In each fermionic mode, the occupations 0 and 1 are summed, and the corresponding factor is $1 + u_k$, where $u_k = e^{-\beta(E_k^{\mathrm{occ}} - \mu)}$. In each bosonic mode, all nonnegative occupations are summed, giving the geometric series $(1 - u_k)^{-1}$; the condition on μ ensures $u_k < 1$. The powers g_k incorporate the degeneracy. Finally,

$$\langle n_k \rangle = -\frac{1}{\beta} \frac{\partial}{\partial E_k^{\mathrm{occ}}} \log \mathcal{Z}$$

yields the two occupation laws [16, 43, 47, 35, 101]. □

The microcanonical derivation recovers the same result in the thermodynamic regime. For mean fermionic occupations $p_k = m_k / g_k$, the combinatorial entropy per level is

$$S_k \simeq g_k \bigl[-p_k \log p_k - (1 - p_k) \log(1 - p_k) \bigr]. \tag{68.5}$$

The variation of $\sum_k S_k$, subject to $\sum_k g_k p_k = N$ and $\sum_k g_k E_k^{\mathrm{occ}} p_k = E$, gives

$$\log \frac{1 - p_k}{p_k} = \alpha + \beta E_k^{\mathrm{occ}}, \qquad \mu = -\frac{\alpha}{\beta}, \tag{68.6}$$

and hence the Fermi–Dirac occupation of (68.3). The multipliers β and μ are the dual coordinates of the energy and population constraints.

For mean bosonic occupations $\overline{n}_k = m_k / g_k$, the log-multiplicity of the level is

$$S_k \simeq g_k \bigl[(1 + \overline{n}_k) \log(1 + \overline{n}_k) - \overline{n}_k \log \overline{n}_k \bigr]. \tag{68.7}$$

The variation of $\sum_k S_k$, subject to $\sum_k g_k \overline{n}_k = N$ and $\sum_k g_k E_k^{\mathrm{occ}} \overline{n}_k = E$, yields

$$\log \frac{1 + \overline{n}_k}{\overline{n}_k} = \alpha + \beta E_k^{\mathrm{occ}}, \qquad \overline{n}_k = \frac{1}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} - 1}, \qquad \mu = -\frac{\alpha}{\beta}. \tag{68.8}$$

This is the Bose–Einstein occupation of (68.4). The condition $\mu < \inf_k E_k^{\mathrm{occ}}$ ensures positivity of the denominator and convergence of each modal factor.

In the finite instance constructed, the two constraints determine

$$(\beta_{\mathrm{FD}}, \mu_{\mathrm{FD}}) = (0.15307011353415928,\ 4.502865197597043),$$

$$(\beta_{\mathrm{BE}}, \mu_{\mathrm{BE}}) = (0.05456727960068316,\ -15.92569781906737).$$

If m_k^{mic} denotes the mean occupancy obtained by exact microcanonical enumeration and m_k^{eq} the evaluation of the corresponding distribution, the errors $\sum_k |m_k^{\mathrm{mic}} - m_k^{\mathrm{eq}}|$ are

$$0.09897380039002812 \quad \text{and} \quad 0.9190625715582017,$$

respectively. The enumeration traverses all occupation quadruples, computes their integer multiplicities, and solves the two constraint equations. The two laws are realized on the same screen. The physical choice between them requires a grading and a Hamiltonian compatible with the trajectory representation. The thermal parameter will subsequently be typed as $\beta = (k_B \Theta)^{-1}$.

68.3 Quantified convergence to the Maxwell–Boltzmann distribution

The relation between the two quantum statistics and the classical regime can be formulated without resorting to an informal approximation. For each mode, let

$$u_k := e^{-\beta(E_k^{\mathrm{occ}}-\mu)}.$$

The state occupations are written

$$\overline{n}_k^{\mathrm{FD}} = \frac{u_k}{1+u_k}, \qquad \overline{n}_k^{\mathrm{BE}} = \frac{u_k}{1-u_k};$$

the multiplicities g_k are incorporated subsequently through $\langle n_k \rangle = g_k \overline{n}_k$.

Theorem 68.3 (Common classical limit of quantum statistics)**.** *If* $0 \le u_k \le \delta < 1$*, then*

$$\left|\overline{n}_k^{\mathrm{FD}} - u_k\right| \le u_k^2, \qquad \left|\overline{n}_k^{\mathrm{BE}} - u_k\right| \le \frac{u_k^2}{1-\delta}.$$

Consequently, in the regime dilute $u_k \to 0$*,*

$$\boxed{\overline{n}_k^{\mathrm{FD}} \sim \overline{n}_k^{\mathrm{BE}} \sim e^{-\beta(E_k^{\mathrm{occ}}-\mu)}},$$

which is the Maxwell–Boltzmann distribution per mode.

Proof. The exact identities

$$u_k - \frac{u_k}{1+u_k} = \frac{u_k^2}{1+u_k}, \qquad \frac{u_k}{1-u_k} - u_k = \frac{u_k^2}{1-u_k}$$

provide the bounds. For $0 < u_k \le \delta$, dividing by u_k and taking $u_k \downarrow 0$ yields the asymptotic equivalence. The leading term of order u_k^2 preserves the physical difference: exclusion decreases fermionic occupation, whereas accumulation increases bosonic occupation. □

68.4 Quantum completions, leaf holonomy, and statistical periodicity

The symmetric and exterior completions, the sheet grading, the holonomy $2\pi/4\pi$, the occupation counts, and the cellular complex of APP form a single algebraic antecedent of quantum statistics. The complete development is incorporated here so that periodicity is not reduced to a mere subsequent reference.

68.5 Statistical completions and fields over APP

The words Bose, Fermi, Pauli, or photon do not by themselves designate theorems of a discrete system. Obtaining them requires specification of a state space, a grading, a product, and operators. APP and TPK provide a set of oriented states and a sheet parity. Two universal completions can be constructed from those data: the symmetric algebra and the exterior algebra. This section identifies exactly what follows from the construction and separates algebraic statistics from its physical interpretation.

68.5.1 Linear state space associated with a particle realization

Let S be a finite set of TPK route classes at the chosen depth, and let

$$\mathcal{H}_1 = \ell^2(S)$$

be the Hilbert space with orthonormal basis $(e_s)_{s\in S}$. A choice of positive weights E_s defines the diagonal operator

$$He_s = E_s e_s.$$

The choice of S, its quotient by symmetries, and the weights are part of the model. Once these are fixed, the multiparticle completions are canonical.

68.5.2 Symmetric and exterior completions

We define

$$\mathcal{F}_+(\mathcal{H}_1) = \bigoplus_{n\geq 0} \operatorname{Sym}^n \mathcal{H}_1, \qquad \mathcal{F}_-(\mathcal{H}_1) = \bigoplus_{n\geq 0} \bigwedge^n \mathcal{H}_1.$$

The first is the bosonic completion; the second, the fermionic.

Theorem 68.4 (Pauli exclusion principle in the exterior completion)**.** *For every mode $s \in S$, the creation and annihilation operators of the exterior completion satisfy*

$$\{a_s, a_t^\dagger\} = \delta_{st} I, \qquad \{a_s, a_t\} = \{a_s^\dagger, a_t^\dagger\} = 0.$$

In particular, the occupation operator $N_s = a_s^\dagger a_s$ is a projector:

$$N_s^2 = N_s,$$

and its eigenvalues are $0, 1$.

Proof. Creation is the exterior product by e_s; annihilation is its adjoint. Antisymmetry implies $e_s \wedge e_s = 0$ and yields the canonical relations by calculation on the exterior basis. Then

$$N_s^2 = a_s^\dagger a_s a_s^\dagger a_s = a_s^\dagger (I - a_s^\dagger a_s) a_s = N_s.$$

Every self-adjoint projector has spectrum contained in $\{0, 1\}$. □

The exclusion principle thus appears as a theorem of the exterior completion. The specifically HMT question is which transport datum selects that completion for a class of routes.

68.5.3 Sheet grading and exchange algebra

Suppose that the oriented sheet defines an additive character

$$p : \operatorname{Mor}(\mathsf{P}_{\mathrm{TPK}}) \longrightarrow \mathbb{Z}/2\mathbb{Z}, \qquad p(\gamma\eta) = p(\gamma) + p(\eta).$$

On the corresponding graded linear space, introduce the symmetry

$$\tau(v \otimes w) = (-1)^{p(v)p(w)} w \otimes v.$$

Theorem 68.5 (Statistical completion determined by parity)**.** *The quotient of the tensor algebra by the relations*

$$v \otimes w - (-1)^{p(v)p(w)} w \otimes v$$

is symmetric on the even sector and exterior on the odd sector. Two identical odd states have zero product; even states admit arbitrary occupation.

Proof. If $p(v) = p(w) = 0$, the relation is $vw = wv$. If $p(v) = p(w) = 1$, it is $vw = -wv$; setting $v = w$ and working in characteristic zero gives $v^2 = 0$. Mixed sectors commute without an additional sign. This is the universal property of the graded symmetric algebra. □

The theorem converts a compositional TPK parity into an exact occupancy rule. To obtain the physical spin–statistics theorem, one must additionally construct a positive local Lorentzian theory and prove that

sheet parity coincides with spin under rotations. The equality does not follow solely from both objects taking values modulo two.

68.5.4 Sheet holonomy and $2\pi/4\pi$ periodicity

The preceding parity admits a natural geometric realization when a surviving extension has a closed return with a nontrivial orientation cover. Let ρ be the return generator and let

$$\varepsilon : \langle \rho \rangle \longrightarrow \{-1, +1\}$$

be its holonomy character, with $\varepsilon(\rho) = -1$. The associated real bundle is then the orientation line of a Möbius strip: one turn closes the geometric projection but changes the lifted sheet; two turns restore the orientation.

To express this property in angular terms, fix a unitary representation U of the rotation cover on the graded space $\mathcal{H}_1 = \mathcal{H}_{\bar{0}} \oplus \mathcal{H}_{\bar{1}}$, compatible with sheet parity in the sense that

$$U(2\pi)v = (-1)^{p(v)}v$$

for every homogeneous vector v. Compatibility is a condition of the realization: it identifies the generator of the orientation cover with the character p already constructed on the routes.

Theorem 68.6 (Restoration of orientation and exchange algebra)**.** *Under the preceding compatibility condition,*

$$U(2\pi)|_{\mathcal{H}_{\bar{0}}} = I, \qquad U(2\pi)|_{\mathcal{H}_{\bar{1}}} = -I, \qquad U(4\pi) = I.$$

Moreover, the same character p determines the graded symmetry

$$\tau(v \otimes w) = (-1)^{p(v)p(w)} w \otimes v.$$

Thus the even-holonomy sector is completed by symmetric powers and the odd-holonomy sector by exterior powers. In the latter, the exclusion relation $v \wedge v = 0$ holds.

Proof. The first and second equalities are the compatibility condition evaluated on each homogeneous component. Iterating one turn gives

$$U(4\pi)v = U(2\pi)^2 v = (-1)^{2p(v)}v = v,$$

which proves the restoration. The assertion concerning exchange is the parity-completion theorem of the preceding section: for two even vectors the sign is positive, whereas for two odd vectors it is negative. □

Three returns should be distinguished. Angular closure after 2π is a return of the projection; closure after 4π restores the lifted orientation; neither, by itself, requires every coordinate of the record to return to its initial value. This separation is the dimensional analogue of the HMT distinction between phase return and state return.

68.5.4.1 The sum and product sheets as supports of the 2 *completions*

The APP table contains two evaluations on the same support. The additive sheet acts by translations and preserves the multiplicity of continuations; in this sense, it accumulates. The multiplicative sheet permutes the units and contracts fibers over noninvertible elements; in this sense, it folds. This incompatibility precedes the statistical choice and explains why TPK must preserve two genealogies rather than reduce them to a single visible word.

The statistical assignment is not obtained, however, by verbally replacing “sum” with “boson” and “product” with “fermion.” The exact map is the parity character

$$p : \mathrm{Mor}(\mathsf{P}_{\mathrm{TPK}}) \longrightarrow \mathbb{Z}/2\mathbb{Z}.$$

When the transport of an extension lies in the sector $p = 0$, its completion admits cumulative occupation and is symmetric. When it lies in $p = 1$, sheet reversal introduces the exchange sign and the completion is exterior. Sum and product supply the two local geometries; the record, orientation, and character p determine the sector in which a route is realized.

With a diagonal Hamiltonian H, energy ϵ, chemical potential μ, and thermal parameter β, the mean occupations of the two sectors are then

$$\bar{n}_{\mathrm{par}}(\epsilon) = \frac{1}{e^{\beta(\epsilon-\mu)} - 1}, \qquad \bar{n}_{\mathrm{impar}}(\epsilon) = \frac{1}{e^{\beta(\epsilon-\mu)} + 1}.$$

The Bose–Einstein and Fermi–Dirac formulas are therefore the thermodynamic evaluations of the symmetric and exterior completions selected by transport. The periodicity 4π and fermionic exclusion are coordinated by the same character, but neither of them is inferred from a mere numerical coincidence.

68.5.5 Number and Occupation Distribution Operators in the Fock Realization

If there are g modes and N particles, the sector dimensions are

$$\Omega_F(g, N) = \binom{g}{N}, \qquad \Omega_B(g, N) = \binom{g + N - 1}{N}.$$

The first formula counts subsets of modes; the second, weak compositions of N into g parts. These counts are exact consequences of the two completions and require no thermodynamic hypothesis.

68.5.6 The cellular complex of the APP torus

The APP graph is the one-skeleton of a cellular decomposition of the torus T^2 with 9×9 vertices. Let

$$C^0 \xrightarrow{d_0} C^1 \xrightarrow{d_1} C^2$$

be its real cochain complex. Choosing the uniform inner product, define the codifferential $\delta = d^*$ and the Laplacian

$$\Delta_k = d_{k-1}\delta_k + \delta_{k+1}d_k.$$

Theorem 68.7 (Harmonic sector of the digital torus)**.** *The dimension of the space of harmonic one-forms is two:*

$$\dim \ker \Delta_1 = b_1(T^2) = 2.$$

A basis can be chosen that is represented by the uniform horizontal and vertical flows. Both are closed and coclosed, and neither is the gradient of a globally defined periodic function.

Proof. The Hodge theorem for finite cellular complexes identifies $\ker \Delta_1$ with $H^1(T^2; \mathbb{R})$. The cohomology of the torus has rank two. Directly, the constant horizontal and vertical flows have zero divergence and curl; their integrals over the two fundamental cycles are independent, so they are not exact. □

The space of connections modulo gauge transformations is

$$C^1/\mathrm{im}\, d_0.$$

In a finite complex equipped with the preceding inner product, each orbit admits a Coulomb representative in $\ker \delta_1$; within the orbit, the choice is unique modulo the stabilizer $\ker d_0$ of the gauge parameter. The correct cohomological quotient is

$$\ker d_1/\mathrm{im}\, d_0 \simeq \ker \Delta_1.$$

Its two harmonic classes constitute a natural mathematical candidate for two free global modes. They are not yet the two local polarizations of a photon in 3 + 1-dimensional spacetime: that identification requires a dynamical limit, a dispersion relation, and a physical gauge group.

68.5.7 Discrete Gauss law

For an oriented 1-cochain F and a set of vertices V, divergence is defined by

$$(\operatorname{div} F)(v) = \sum_{e:v\to w} F(e) - \sum_{e:w\to v} F(e).$$

Summing over V, every interior edge appears once with each sign and cancels. Therefore,

$$\boxed{\sum_{v\in V} \operatorname{div} F(v) = \operatorname{Flux}_{\partial V}(F).}$$

This identity is an exact Gauss law on the graph. Interpreting div F as electric charge requires the charge character and dimensional realization constructed in Dimensional Mechanics.

68.5.8 Reversible measurement apparatus

Let S be a set of states and let $r : S \to \mathbb{Z}/9\mathbb{Z}$ be a readout. Coupling to a nonadic register is defined by

$$U_r : S \times \mathbb{Z}/9\mathbb{Z} \longrightarrow S \times \mathbb{Z}/9\mathbb{Z}, \qquad U_r(s, a) = (s, a + r(s)).$$

Proposition 68.8 (Reversibility of the coupling)**.** *The map U_r is to permutation and*

$$U_r^{-1}(s, a) = (s, a - r(s)).$$

Information loss arises only after applying a reader to the register or conditioning the state on the outcome.

Proof. The proposed inverse satisfies both composition identities by the group law of $\mathbb{Z}/9\mathbb{Z}$. □

This proposition formalizes the operational definition of measurement: coupling, reading, and restricting compatible futures are three different maps. The full coupling is reversible; the observational quotient need not be.

68.5.9 Algebraic correspondences and physical realizations

The Fock completions, exclusion conditional on parity, the harmonic sector of APP, discrete Gauss law, and reversibility of the apparatus are complete mathematical theorems. Their physical identifications form a diagram that must commute:

$$\text{sheet parity} \longrightarrow \text{graded interchange} \longrightarrow \text{CAR/CCR} \longrightarrow \text{physical statistics},$$

$$H^1(\mathcal{A}_9) \longrightarrow \text{discrete gauge field} \longrightarrow \text{massless mode} \longrightarrow \text{photon}.$$

The first two arrows of each line have explicit constructions; the last require the corresponding dynamics and physical limit. This separation permits the bridges to be developed without conflating an analogy of cardinality with a representation.

From reversible measurement to fermionic occupation and to the algebraic exclusion principle of Pauli The statistical distinction is completed algebraically through occupation idempotence and fermionic exclusion.

68.5.10 Quasi-free correlation and spectral occupation entropies

For a gauge-invariant, number-conserving quasifree fermionic state defined on a finite-dimensional one-particle space, let $C_{ij} = \langle a_j^\dagger a_i \rangle$ be the one-particle correlation operator. The gauge-invariant hypothesis excludes anomalous pairing correlations, so that C determines the quasifree state. If $0 < C < I$, its one-particle modular generator and the reciprocal reconstruction of the correlator are

$$\boxed{K_1 = \log\bigl((I - C)C^{-1}\bigr), \qquad C = (I + e^{K_1})^{-1}.} \tag{68.9}$$

Corollary 68.9 (Logistic form of the modular spectrum)**.** *If $K_1 u_i = \kappa_i u_i$, the occupation of mode u_i is*

$$\langle n_i \rangle = \frac{1}{1 + e^{\kappa_i}}.$$

For $\kappa_i = \beta(\varepsilon_i - \mu)$, the Fermi–Dirac law is recovered.

Proof. The spectral diagonalization of K_1 diagonalizes every function thereof. Applying $x \mapsto (1 + e^x)^{-1}$ to each eigenvalue yields the formula. □

If C has eigenvalues $p_i \in [0, 1]$, the occupation entropy of the quasifree fermionic state is, with the convention $0 \log 0 = 0$,

$$S_F = -\sum_i \bigl[p_i \log p_i + (1 - p_i) \log(1 - p_i)\bigr]. \tag{68.10}$$

For a diagonal Gaussian bosonic state with finitely many modes and mean occupancies $\overline{n}_i$,

$$S_B = \sum_i \bigl[(1 + \overline{n}_i) \log(1 + \overline{n}_i) - \overline{n}_i \log \overline{n}_i\bigr]. \tag{68.11}$$

The same formula extends to a countable family when the series on the right-hand side converges. These entropies quantify occupation configurations. Entanglement entropy has another domain: the reduced state induced by a tensor decomposition. Identifying the two requires specifying the reduction and the correlation operator that implements it.

Finally, for a reduced state ρ_A, the *von Neumann entropy*

$$S_{\mathrm{vN}}(\rho_A) = -\operatorname{Tr}(\rho_A \log \rho_A)$$

is a spectral property of the density operator. When ρ_A comes from a global purification, it quantifies entanglement across the cut. In the HMT boundary construction, the area operator, the modular Hamiltonian, and the corresponding reduction remain in the section 51.11.

The maps between these domains are published through explicit identities. The decomposition of a measure along the fibres of q satisfies the chain rule

$$\mathsf{H}_\mu(\mathbf{X}) = \mathsf{H}_{q_*\mu}(q(\mathbf{X})) + \mathsf{H}_{\mathrm{fib}}(q; \mu). \tag{68.12}$$

A finite distribution $p = (p_i)$ is realized diagonally as

$$\rho_p = \sum_i p_i |i\rangle\langle i|, \qquad S_{\mathrm{vN}}(\rho_p) = \mathsf{H}(p).$$

If $P_{N,E}$ projects onto the microcanonical subspace of dimension $\Omega(N, E)$, then

$$\rho_{\mathrm{mc}} = \frac{P_{N,E}}{\Omega(N, E)}, \qquad S_{\mathrm{vN}}(\rho_{\mathrm{mc}}) = \log \Omega(N, E) = S_{\mathrm{mc}}.$$

For a pure bipartite state,

$$\rho_A = \mathrm{Tr}_B\big(|\Psi_{AB}\rangle\langle\Psi_{AB}|\big)$$

defines the reduction that measures entanglement. Finally, equality between $h_{\mathrm{top}} = \log \rho(A)$ and a metric entropy is attained, for this primitive system, by means of the Parry measure, which realizes maximal metric entropy; it is not attributed to an arbitrary measure on histories.

68.6 Transport of Fock completions under refinement

The completions and their operator algebras are constructed in Section 64.5. The result of this stage is their compatibility with refinement morphisms: transport of the one-particle fiber extends to all occupation sectors.

68.6.1 Second quantization of refinement morphisms

Let $\mathsf{Hol}_{\pm}^{\leq 1}$ be the monoidal category of one-particle fibers, with contractive refinement morphisms preserving holonomy parity $\epsilon \in \{+1, -1\}$. It includes, in particular, unitary intertwiners. The monoidal operation on the fibers is direct sum; on the completions it induces the tensor product, graded in the exterior sector. Second quantization uses the completions of Section 64.5.2:

$$\mathfrak{F}(H, \epsilon) = \begin{cases} \mathcal{F}_+(H), & \epsilon = +1, \\ \mathcal{F}_-(H), & \epsilon = -1, \end{cases}$$

and, for a contractive intertwiner $T : H \to H'$,

$$\mathfrak{F}(T) = \bigoplus_{n \geq 0} \mathrm{Sym}^n(T) \quad \text{or} \quad \bigoplus_{n \geq 0} \bigwedge^n T.$$

68.6.2 Functoriality, canonical operators, and transport domains

Let $\mathcal{D}_\epsilon(H)$ be the algebraic direct sum of the finite-particle sectors. In the following identities, $a_H^\dagger(f)$ and $a_H(f)$ denote the creation and annihilation operators of the chosen completion: the operators a of the exterior sector or the operators b of the symmetric sector in Section 64.5.4.

Theorem 68.10 (Internal transport of the statistic)**.** *The preceding completion defines a graded monoidal functor on $\mathsf{Hol}_{\pm}^{\leq 1}$, with bounded operator values and compatibility with refinement. In the branch $\epsilon = -1$, creation and annihilation operators satisfy CAR and occupation operators obey $N_s^2 = N_s$; in the branch $\epsilon = +1$, they satisfy CCR. Thus Pauli exclusion and fermionic and bosonic statistics descend from holonomy parity once the one-particle representation has been fixed. For every contractive intertwiner $T : H \to H'$, $f \in H$, and $g \in H'$, the following hold on $\mathcal{D}_\epsilon(H)$:*

$$\mathfrak{F}(T) a_H^\dagger(f) = a_{H'}^\dagger(Tf) \mathfrak{F}(T), \tag{68.13}$$

$$a_{H'}(g) \mathfrak{F}(T) = \mathfrak{F}(T) a_H(T^* g). \tag{68.14}$$

If T is isometric, the second identity, with $g = Tf$, also transports annihilation of f. For $\|f\| = 1$, the occupation operators then satisfy

$$N_{H', Tf} \mathfrak{F}(T) = \mathfrak{F}(T) N_{H,f}, \qquad N_{H,f} = a_H^\dagger(f) a_H(f). \tag{68.15}$$

Proof. Symmetric and exterior powers preserve compositions and identities; in each degree, their norms are bounded by $\|T\|^n$. Contractivity therefore ensures that the direct sum defines a bounded operator. The decomposition of powers of a direct sum according to their degrees in each factor gives monoidal compatibility, with the graded exchange sign in the exterior powers.

The CAR relations and idempotence are Theorem 64.14; the CCR relations are (64.12). To verify their transport, it suffices to act on symmetric or exterior products of vectors. Applying T to each factor commutes with inserting the factor f, which is transformed into Tf; this proves (68.13). Annihilation sums the contractions of each factor and uses $\langle g, Tf\rangle = \langle T^*g, f\rangle$; exterior signs and symmetric normalizations agree on both sides. This yields (68.14). If $T^*T = I$, setting $g = Tf$ and composing the two identities proves (68.15). All these operations preserve the finite-particle domain. □

For noncontractive morphisms, second quantization is defined first on $\mathcal{D}_\epsilon(H)$; its bounded extension depends on a uniform bound for the norms over all degrees. Such morphisms lie outside $\mathsf{Hol}_\pm^{\leq 1}$. In the symmetric completion, if $\|T\| > 1$, the norms $\|\operatorname{Sym}^n T\| = \|T\|^n$ grow without bound; in the exterior completion of a finite fiber, only finitely many degrees are nonzero. The general annihilation identity retains T^*g; its specialization to the same transported vector corresponds to the isometry condition stated above.

The distinction is already verified in a one-dimensional fiber. If $T = tI$, with $0 < t < 1$, and e is a unit vector, then, on the one-particle state e, in either completion,

$$a(te)\mathfrak{F}(T)e = t^2\Omega, \qquad \mathfrak{F}(T)a(e)e = \Omega, \tag{68.16}$$

where Ω is the vacuum. The general identity (68.14) correctly gives $\mathfrak{F}(T)a(T^*te)e = t^2\Omega$. The factor t^2 identifies precisely the hypothesis allowing specialization of annihilation transport and, subsequently, occupation transport.

The result establishes internal algebraic transport. Its identification with the relativistic spin–statistics theorem retains the additional conditions of Lorentzian representation and locality specified in Section 64.5.5.

68.7 Thermodynamic realization through Gibbs states and the pressure limit

68.7.1 Finite Hamiltonian, partition function, Gibbs state, and cofinal pressure limit

For a compressed Hamiltonian $H_{X,V}$ over a finite volume or refinement V, the thermal state is completely defined by

$$Z_{X,V}(\beta) = \operatorname{Tr} e^{-\beta H_{X,V}}, \qquad \rho_{X,V,\beta} = Z_{X,V}(\beta)^{-1} e^{-\beta H_{X,V}}.$$

The thermodynamic limit exists when the pressure

$$p_X(\beta) = \lim_{V \nearrow \infty} \frac{1}{\beta |V|} \log Z_{X,V}(\beta)$$

exists and is independent of the cofinal sequence.

68.7.2 Condensation criterion by saturation of the excited-state density

Bosonic condensation is determined by saturation of the excited-state density; it is not asserted merely from the existence of a symmetric completion. The problem is thus expressed by a verifiable mathematical condition on the Hamiltonian and the limit, rather than by a nominal attribution.

68.8 Microcanonical enumeration of states on a finite screen

Consider the finite realization

$$\mathcal{H}_{\mathrm{occ}} = \bigoplus_{k=0}^{3} \mathbb{C}^{g_k}, \qquad H_{\mathrm{occ}}|_{\mathbb{C}^{g_k}} = E_k^{\mathrm{occ}} I,$$

with levels and multiplicities

$$E^{\mathrm{occ}} = (0, 3, 6, 9), \qquad g = (1, 6, 12, 8), \qquad (N, E) = (12, 66).$$

The sum $1 + 6 + 12 + 8 = 27$ makes $\mathcal{H}_{\mathrm{occ}}$ a screen of twenty-seven modes. This spectrum is the datum of a declared finite representation; its cardinality does not suffice to identify it with any other occurrence of 27 in HMT. The morphism relating a specific boundary screen to $(\mathcal{H}_{\mathrm{occ}}, H_{\mathrm{occ}})$ must specify both the fibers and the spectral operator. The fermionic and bosonic generating functions are

$$F(y, x) = \prod_k (1 + y x^{E_k^{\mathrm{occ}}})^{g_k}, \qquad B(y, x) = \prod_k (1 - y x^{E_k^{\mathrm{occ}}})^{-g_k}.$$

Proposition 68.11 (Microcanonical cardinalities)**.**

$$[y^{12} x^{66}] F = 2\,104\,494, \qquad [y^{12} x^{66}] B = 259\,436\,430.$$

Proof. In the fermionic product, choosing r of the g_k modes contributes $\binom{g_k}{r} y^r x^{r E_k^{\mathrm{occ}}}$. In the bosonic product, distributing r indistinguishable occupations among g_k modes contributes $\binom{g_k + r - 1}{r} y^r x^{r E_k^{\mathrm{occ}}}$. The finite convolution over the four levels produces the stated integers. □

68.9 Bose–Einstein and Fermi–Dirac distributions

The equilibrium formulation starts from the Hamiltonian and the total occupation number,

$$H = \sum_k E_k^{\mathrm{occ}} n_k, \qquad N = \sum_k n_k, \qquad K_\mu := H - \mu N. \tag{68.17}$$

For $\beta > 0$, the grand canonical state is

$$\rho_{\beta,\mu} = \frac{e^{-\beta K_\mu}}{\mathcal{Z}_{\beta,\mu}}, \qquad \mathcal{Z}_{\beta,\mu} = \mathrm{Tr}(e^{-\beta K_\mu}). \tag{68.18}$$

Theorem 68.12 (Grand canonical factorization and occupation laws)**.** *For energy levels E_k^{occ} with degeneracies g_k, the fermionic trace factorizes as*

$$\mathcal{Z}_{\mathrm{FD}} = \prod_k \bigl(1 + e^{-\beta(E_k^{\mathrm{occ}} - \mu)}\bigr)^{g_k}, \qquad \langle n_k \rangle_{\mathrm{FD}} = \frac{g_k}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} + 1}. \tag{68.19}$$

In the bosonic sector, under the condition $\mu < \inf_k E_k^{\mathrm{occ}}$,

$$\mathcal{Z}_{\mathrm{BE}} = \prod_k \bigl(1 - e^{-\beta(E_k^{\mathrm{occ}} - \mu)}\bigr)^{-g_k}, \qquad \langle n_k \rangle_{\mathrm{BE}} = \frac{g_k}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} - 1}. \tag{68.20}$$

Proof. The operator K_μ is a sum of commuting occupation operators, so its trace factorizes over modes. In each fermionic mode, the occupations 0 and 1 are summed, and the corresponding factor is $1 + u_k$, where $u_k = e^{-\beta(E_k^{\mathrm{occ}} - \mu)}$. In each bosonic mode, all nonnegative occupations are summed, giving the geometric series $(1 - u_k)^{-1}$; the condition on μ ensures $u_k < 1$. The powers g_k incorporate the degeneracy. Finally,

$$\langle n_k \rangle = -\frac{1}{\beta} \frac{\partial}{\partial E_k^{\mathrm{occ}}} \log \mathcal{Z}$$

yields the two occupation laws [227, 229, 230, 228, 232]. □

The microcanonical derivation recovers the same result in the thermodynamic regime. For mean fermionic occupations $p_k = m_k / g_k$, the combinatorial entropy per level is

$$S_k \simeq g_k \bigl[-p_k \log p_k - (1 - p_k) \log(1 - p_k) \bigr]. \tag{68.21}$$

The variation of $\sum_k S_k$, subject to $\sum_k g_k p_k = N$ and $\sum_k g_k E_k^{\mathrm{occ}} p_k = E$, gives

$$\log \frac{1 - p_k}{p_k} = \lambda_N + \beta E_k^{\mathrm{occ}}, \qquad \mu = -\frac{\lambda_N}{\beta}, \tag{68.22}$$

and therefore the Fermi–Dirac occupation of (68.19). The multipliers β and μ are the dual coordinates of the energy and population constraints. The symbol $\lambda_N = -\beta\mu$ denotes the multiplier associated with the occupation number; α retains throughout the article its use for the fine-structure constant.

For mean bosonic occupations $\overline{n}_k = m_k / g_k$, the log-multiplicity of the level is

$$S_k \simeq g_k \bigl[(1 + \overline{n}_k) \log(1 + \overline{n}_k) - \overline{n}_k \log \overline{n}_k \bigr]. \tag{68.23}$$

The variation of $\sum_k S_k$, subject to $\sum_k g_k \overline{n}_k = N$ and $\sum_k g_k E_k^{\mathrm{occ}} \overline{n}_k = E$, yields

$$\log \frac{1 + \overline{n}_k}{\overline{n}_k} = \lambda_N + \beta E_k^{\mathrm{occ}}, \qquad \overline{n}_k = \frac{1}{e^{\beta(E_k^{\mathrm{occ}} - \mu)} - 1}, \qquad \mu = -\frac{\lambda_N}{\beta}. \tag{68.24}$$

This is the Bose–Einstein occupation of (68.20). The condition $\mu < \inf_k E_k^{\mathrm{occ}}$ ensures positivity of the denominator and convergence of each modal factor.

In the finite instance constructed, the two constraints determine

$$(\beta_{\mathrm{FD}}, \mu_{\mathrm{FD}}) = (0.15307011353415928,\ 4.502865197597043),$$

$$(\beta_{\mathrm{BE}}, \mu_{\mathrm{BE}}) = (0.05456727960068316,\ -15.92569781906737).$$

If m_k^{mic} denotes the mean occupancy obtained by exact microcanonical enumeration and m_k^{eq} the evaluation of the corresponding distribution, the errors $\sum_k |m_k^{\mathrm{mic}} - m_k^{\mathrm{eq}}|$ are

$$0.09897380039002812 \quad \text{and} \quad 0.9190625715582017,$$

respectively. The enumeration runs through all occupation quadruples, calculates their integer multiplicities and solves the two constraint equations. Both laws are realized on the same screen. The physical choice between them requires a grading and a Hamiltonian compatible with the representation of the path. The thermal parameter is $\beta = (k_B \Theta)^{-1}$, with the dimensional transduction developed in section 123.

68.10 Quantified convergence to the Maxwell–Boltzmann distribution

The relation between the two quantum statistics and the classical regime can be formulated without resorting to an informal approximation. For each mode, let

$$u_k := e^{-\beta(E_k^{\mathrm{occ}}-\mu)}.$$

The state occupations are written

$$\overline{n}_k^{\mathrm{FD}} = \frac{u_k}{1+u_k}, \qquad \overline{n}_k^{\mathrm{BE}} = \frac{u_k}{1-u_k};$$

the multiplicities g_k are incorporated subsequently through $\langle n_k \rangle = g_k \overline{n}_k$.

Theorem 68.13 (Common classical limit of quantum statistics)**.** *If* $0 \le u_k \le \delta < 1$*, then*

$$\left|\overline{n}_k^{\mathrm{FD}} - u_k\right| \le u_k^2, \qquad \left|\overline{n}_k^{\mathrm{BE}} - u_k\right| \le \frac{u_k^2}{1-\delta}.$$

Consequently, in the regime dilute $u_k \to 0$*,*

$$\boxed{\overline{n}_k^{\mathrm{FD}} \sim \overline{n}_k^{\mathrm{BE}} \sim e^{-\beta(E_k^{\mathrm{occ}}-\mu)}},$$

which is the Maxwell–Boltzmann distribution per mode.

Proof. The exact identities

$$u_k - \frac{u_k}{1+u_k} = \frac{u_k^2}{1+u_k}, \qquad \frac{u_k}{1-u_k} - u_k = \frac{u_k^2}{1-u_k}$$

provide the bounds. For $0 < u_k \le \delta$, dividing by u_k and taking $u_k \downarrow 0$ yields the asymptotic equivalence. The leading term of order u_k^2 preserves the physical difference: exclusion decreases fermionic occupation, whereas accumulation increases bosonic occupation. □

Chapter 69

Fermionic completion of trajectories and the algebraic Pauli exclusion principle

Exterior completion of the trajectories imposes idempotence and exclusion before any species identification. The rotation, color, flavor, and virtuality characters preserve their typing within the corresponding representation.

69.1 Occupation, exclusion and finite statistics

The null and material realizations provide the geometric support of occupation. The fermionic sector is constructed on the canonical anticommutation relations (CAR), and the spin–statistics theorem further requires the declared operator representation. This section fixes those premises before deriving idempotence of occupation, the microcanonical cardinalities, and the Bose–Einstein and Fermi–Dirac distributions with their common classical limit.

69.1.1 Idempotency of Occupation in the Anticommutation Algebra

Let $a_i, a_i^\dagger$ be operators satisfying the canonical anticommutation relations (CAR)

$$\{a_i, a_j^\dagger\} = \delta_{ij}, \qquad \{a_i, a_j\} = 0,$$

and let $n_i = a_i^\dagger a_i$.

Theorem 69.1 (Pauli Exclusion Principle)**.** *One has* $n_i^2 = n_i$*, and therefore* $\mathrm{Spec}(n_i) \subseteq \{0, 1\}$.

Proof.

$$n_i^2 = a_i^\dagger a_i a_i^\dagger a_i = a_i^\dagger (1 - a_i^\dagger a_i) a_i = a_i^\dagger a_i,$$

because $a_i^2 = (a_i^\dagger)^2 = 0$. Every eigenvalue of an idempotent satisfies $\lambda^2 = \lambda$ [99, 35]. □

The nilpotence $(a_i^\dagger)^2 = 0$ precludes double fermionic occupation of the same mode and, upon maximizing entropy under the energy and number constraints, leads to the Fermi–Dirac occupation law presented below. The symmetric completion and the Bose–Einstein law constitute a distinct stratum and are presented separately.

The CAR relations are an algebraic hypothesis of the theorem. A monodromy with sign change under a rotation of 2π is compatible with a fermionic representation, but does not by itself constitute a derivation of CAR or of the spin–statistics theorem.

69.2 Spin, color, flavor, and virtuality characters

Let $\jmath : \Gamma_{\mathrm{TPK}} \to \Gamma_{\mathrm{TPK}}$ be the involution that reverses the orientation of each edge and permutes the fibers through $J_c : E_c \to E_{\jmath c}$. A spin character is a representation ρ_{rot} of the subgroup generated by $\jmath$ on the sections; its sign eigenspaces $+1$ and -1 are algebraic objects distinct from a physical representation of the Lorentz group.

Let C be the Abelian group of channel characters of the transport. Two sections have the same *arithmetic flavour* when their characters

$$\chi_s : C \longrightarrow \mathbb{C}^\times$$

coincide. Identifying these classes with fermion flavors requires a representation of the algebra of physical observables and is not introduced by nomenclature.

Finally, let

$$\mathrm{Ext}_N(s) = \{s' \in \Gamma(\mathcal{B}_{\gamma'}) : \gamma'|_{\{0,\dots,N\}} = \gamma,\ s'|_{\{0,\dots,N\}} = s\}.$$

The section is stable from depth N onward when the restrictions $\mathrm{Ext}_{N+1}(s) \to \mathrm{Ext}_N(s)$ admit a compatible branch at every subsequent level. It is called *virtual up to depth N* when that global branch does not yet exist, although finite extensions survive. This definition belongs to the inverse system and does not depend on a temporal metaphor.

On the affine plane $\mathbb{F}_3^2$, the linear functional

$$\kappa_3 : \mathbb{F}_3^2 \longrightarrow \mathbb{F}_3, \qquad \kappa_3(r, c) = r - c$$

is surjective, and its kernel has dimension one. Consequently, its three fibers are the affine classes of the kernel, and each contains exactly three points. The same balance persists in every disjoint union of complete copies of $\mathbb{F}_3^2$. This ternary partition is a self-contained algebraic statement. Once the qutrit chart, the orientation, and the phase character have been fixed, the section 90.6 constructs the representation and its algebra $\mathfrak{su}(3)$; the intertwiner with TPK transport and the physical chromodynamic identification remain an interface.

Distinction between reversible genealogical transport and irreversible projection. Reversibility of the update permits the cost of an irreversible projection to be distinguished from complete genealogical transport.

69.3 Statistical application of occupation spectra

The null and material realizations provide the geometric support for occupation. The graded completion of that support determines its multiparticle spaces and operators; Theorem 68.10 establishes their transport under refinement. This stage uses those results to characterize admissible configurations, count states, and prepare the thermal evaluation. The algebraic construction, finite counting, and equilibrium state thus retain their respective functions and premises.

69.3.1 Spectral restriction and admissible configurations

For a mode i, write $n_i = N_i = a_i^\dagger a_i$. Theorem 64.14, with its complete proof in (64.11), establishes $n_i^2 = n_i$ and $\mathrm{Spec}(n_i) \subseteq \{0, 1\}$. The calculation uses only CAR and the adjoint relation, so it also applies to any representation of those relations. Nilpotency $(a_i^\dagger)^2 = 0$ prevents double fermionic occupation of the same mode. Consequently, a fermionic configuration of g modes is a family $(n_1, \dots, n_g) \in \{0, 1\}^g$; in the bosonic sector, the occupations belong to $\mathbb{N}_0^g$.

The fermionic representation uses the CAR algebra constructed from the exterior completion. The relativistic spin–statistics identification additionally retains compatibility of the rotation representation with parity and the locality conditions stated in Sections 64.5.4 and 64.5.5. The 4π periodicity and exclusion are coordinated by the same sheet character, with these representation conditions explicit.

69.3.2 Dimensions of fixed-occupation sectors

If there are g modes and N particles, the sector dimensions are

$$\Omega_F(g, N) = \binom{g}{N}, \qquad \Omega_B(g, N) = \binom{g + N - 1}{N}. \tag{69.1}$$

The first formula counts subsets of modes, with zero dimension if $N > g$; the second counts weak compositions of N into g parts. These counts are exact consequences of the two completions and are obtained before introducing the thermal state. Proposition 68.11 applies both counts to the finite spectral screen, retaining its levels, multiplicities, and energy and population constraints.

69.3.3 Thermal readout of the graded completions

With a diagonal Hamiltonian H, modal energy ϵ, chemical potential μ, and thermal parameter $\beta > 0$, the mean occupations of the two sectors are

$$\bar{n}_{\mathrm{par}}(\epsilon) = \frac{1}{e^{\beta(\epsilon-\mu)} - 1}, \qquad \bar{n}_{\mathrm{impar}}(\epsilon) = \frac{1}{e^{\beta(\epsilon-\mu)} + 1}. \tag{69.2}$$

The bosonic sector requires $\mu < \inf \operatorname{Spec} H$. These expressions are the per-mode specialization of Theorem 68.12, whose proof constructs the grand canonical trace from the admissible occupations. The Bose–Einstein and Fermi–Dirac formulas are therefore the thermodynamic evaluations of the symmetric and exterior completions selected by transport. The same section derives their expressions by varying the entropy under the energy and number constraints; Theorem 68.13 proves their common classical limit with an explicit error bound.

Chapter 70

Reversible update, erasure cost, and exact domain of the zero Landauer limit

The full transport preserves fibre information and may have zero logical cost; the projection or reinitialization that discards the genealogy is subject to Landauer's cost. The two domains are separated explicitly.

70.1 Logical reversibility and Landauer's principle in TPK fibers

Let $(\Omega, 2^{\Omega}, \mu)$ be a finite probability space, let $X : \Omega \to \mathcal{X}$ be a random variable with values in the space $\mathcal{X}$ of complete states, and let $q : \mathcal{X} \to Y$ be a reader. The chain rule gives

$$\mathsf{H}(X) = \mathsf{H}(q(X)) + \mathsf{H}(X \mid q(X)).$$

The second summand measures the information of the fiber that the reader does not publish.

Theorem 70.1 (Landauer zero for full transport and projection cost)**.** *If $U : \mathcal{X} \to \mathcal{X}$ is a bijective update of the complete HMT state, then*

$$\boxed{\mathsf{H}(X \mid U(X)) = 0.}$$

For a projected output $q(U(X))$, the discarded information is

$$\mathsf{H}(X \mid q(U(X))).$$

A physical reset that identifies distinct memory states must account for that information in the environment.

Proof. Bijectivity implies $X = U^{-1}(U(X))$; therefore X is determined by $U(X)$ and the conditional entropy is zero. For the reader q, the chain rule separates published entropy from fiber entropy. If the reset operation is not injective, the output no longer permits reconstruction of the memory state. Landauer's thermodynamic principle bounds the cost of implementation in terms of that erased entropy; the reversible update does not by itself contribute an erasure term. □

In nats and bits, respectively,

$$Q \geq k_B \Theta \, \mathsf{H}_{\text{nat}}, \qquad Q \geq k_B \Theta \log 2 \, \mathsf{H}_{\text{bit}}.$$

For bijective transport of the complete state, the erasure entropy is zero and, therefore, the minimum Landauer term associated exclusively with erasure satisfies

$$\boxed{Q_{\text{L}}^{\min}[U] = k_B \Theta \, \mathsf{H}(X \mid U(X)) = 0.}$$

For the restart of a uniform TRIT, on the other hand,

$$\boxed{Q_{\text{reset}} \geq k_B \Theta \log 3.}$$

These two equations locate the cost in information loss: the cost appears when projection or resetting forgets the fiber. Preparation, projection, and resetting may produce entropy; reversible transport preserves genealogical information. The null value is the logical Landauer limit for that complete update, whereas the dynamical costs of control, finite speed, and coupling to the environment belong to the physical realization of the device.

Scope of the null Landauer relation

The equality $\mathsf{H}(X \mid U(X)) = 0$ is exact for a bijective update of the enriched state. The bound $Q_{\text{reset}} \geq k_B \Theta \log 3$ is the Landauer specialization to the erasure of a uniform triadic decision. Realizing both formulas in joules uses the Boltzmann transducer and a declared physical temperature.

Edge Information Transduction in Minimum Triadic Cut Capacity. The information preserved by the boundary reappears geometrically in the minimal triadic cut and in its capacity.

70.2 Genealogical Conservation of Information, Reduction Entropies and Thermal Structure

The information transported by an HMT state is not exhausted by the coordinate that one of its readers publishes. The visible coordinate, sheet, orientation, quotient, carry, route, and closure seal belong to the same enriched state, even though a particular evaluation displays only part of it. This distinction makes it possible to place in a single framework three operations that the macroscopic description usually presents separately: preserving a history, reducing it to a reading, and assigning energy to the information actually erased.

The chapter develops that chain without identifying its stages. It first formulates fiber memory and the exact recoverability criterion. It then proves the vanishing of the logical Landauer term for a bijective update of the TPK enriched state. Five entropies having different domains and functions are subsequently distinguished. Finally, the areal–volumetric quotient and the clock of 108 steps provide the structure that links triadic information, action, and temperature.

70.2.1 Disintegration of Visible Reading Over Fibers and Recovery of Genealogical Memory

Let Ω be a finite space of enriched states, and let

$$q : \Omega \longrightarrow Y$$

a visible reader. The value $q(x)$ is a coordinate of the state x, not its exhaustive description. Denote by

$$M : \Omega \longrightarrow \mathcal{M}$$

the joint record of the genealogical coordinates that the reader does not publish: leaf, orientation, quotient or carry, phase, route, and seal, according to the domain under consideration.

Definition 70.2 (Enhanced reader and fiber memory)**.** The enriched reader associated with q and M is

$$\widehat{q} = (q, M) : \Omega \longrightarrow Y \times \mathcal{M}. \tag{70.1}$$

The fibre memory of q is the information needed to distinguish the states contained in the same fibre $q^{-1}(y)$.

The APP residue–quotient extension is the elementary arithmetic example. In each cell, both Euclidean divisions are preserved

$$i + j = 9q^{+}_{ij} + R^{+}_{ij}, \qquad ij = 9q^{\times}_{ij} + R^{\times}_{ij}.$$

Reduction modulo nine publishes R^{+} or $R^{\times}$; the lift simultaneously preserves (R, q). Summing over the nonadic domain yields the exact identity

$$2025 - 810 = 54 + 9 \cdot 129. \tag{70.2}$$

The first term on the right is the difference between the visible residues; the second recomposes the difference between the quotients. The equality shows that the residual projection does not by itself determine the integral operation.

Now let X be a random variable with values in Ω. We shall work with dimensionless entropies in nats. The chain rule gives

$$\mathsf{H}(X) = \mathsf{H}(q(X)) + \mathsf{H}(X \mid q(X)). \tag{70.3}$$

The second term quantifies the genealogical information that remains within the fiber of the reading.

Theorem 70.3 (Fiber Memory Recoverability)**.** *If the enriched reader $\widehat{q} = (q, M)$ is injective on the support of X, then*

$$\boxed{\mathsf{H}(X \mid q(X), M(X)) = 0.} \tag{70.4}$$

The entropy $\mathsf{H}(X \mid q(X))$ measures exactly the information that would be lost by retaining the visible coordinate and discarding the memory.

Proof. The injectivity of $\widehat{q}$ provides an inverse on its image. Hence the pair $(q(X), M(X))$ determines X, and the conditional entropy is zero. If $M(X)$ is omitted, entries in the same fiber are identified; the chain rule (70.3) assigns the term $\mathsf{H}(X \mid q(X))$ to that identification. □

The genealogical definition of number enters precisely here. An HMT number is a compatible section of surviving cylinders together with the memory of its route, orientation, signature, and closure. Its real value is the evaluation of that section. Evaluation may forget coordinates; the section preserves them.

70.2.2 Logical reversibility and Landauer's term

Let

$$U : \Omega \longrightarrow \Omega$$

an update of the enriched TPK state. Landauer's question is posed on the complete map, before a visible reader is applied or a record is reset; its thermodynamic formulation of logical erasure dates to Landauer [78].

Theorem 70.4 (Landauer zero for full transport)**.** *If U is bijective, then, for every input distribution X,*

$$\mathsf{H}(X \mid U(X)) = 0. \tag{70.5}$$

In the ideal Landauer regime, the minimum term associated exclusively with internal logical erasure is

$$\boxed{Q_{\mathrm{L}}^{\min}[U] = k_B \Theta\, \mathsf{H}(X \mid U(X)) = 0.} \tag{70.6}$$

Proof. The bijection gives U^{-1}, so that $X = U^{-1}(U(X))$. The complete output determines the input, and the conditional entropy vanishes. The informational form of Landauer's principle assigns the erasure cost to the term $k_B \Theta \mathsf{H}(X \mid U(X))$, which equals zero by the preceding equality. □

The result localizes conservation in the enriched space. For a projected output $q(U(X))$, the unpublished information is

$$\mathsf{H}\big(X \mid q(U(X))\big). \tag{70.7}$$

A physical reset identifying distinct states must transfer that information to the environment. In particular, resetting a uniform TRIT to a single state has

$$\mathsf{H}(X) = \log 3, \qquad \boxed{Q_{\mathrm{reset}} \geq k_B \Theta \log 3.}$$

Reversible updating, projection, and reset are thus distinct operations. The first preserves genealogy; the second reduces the reading; the third physically eliminates a record. Additional dissipation due to control, noise, or finite speed belongs to the realization of the device and not to the logical erasure term of (70.6).

70.2.3 5 Notions of Entropy and Their Domains

The word *entropy* denotes five related but noninterchangeable functionals in this construction. Their separation prevents temperature from being attributed to a purely combinatorial count, or loss of information to an evolution that merely changes the reading.

70.2.3.1 Conditional entropy of the fibers of the visible reader and genealogy loss

The quantity

$$\mathsf{H}_{\mathrm{fib}}(q; X) := \mathsf{H}(X \mid q(X))$$

measures the information in the genealogy that a visible reading does not distinguish. Its domain is a reader and a distribution on the enriched state. It vanishes when the reader is faithful on the support under consideration.

70.2.3.2 Informational entropy of a triadic decision

For a distribution $p = (p_{-1}, p_0, p_{+1})$ over the three visible states of the TRIT,

$$I_{\mathrm{TRIT}}(p) = -\sum_{a\in\{-1,0,+1\}} p_a \log p_a.$$

The uniform distribution produces

$$\boxed{I_{\mathrm{TRIT}} = \log 3.} \tag{70.8}$$

This quantity measures a local decision among three visible alternatives.

70.2.3.3 Topological Entropy of Admissible Histories

If A is the adjacency matrix of a finite subshift, its topological entropy is

$$h_{\mathrm{top}}(A) = \log \rho(A),$$

where $\rho(A)$ is the spectral radius. This functional measures the asymptotic growth rate of compatible histories, not the uncertainty of an isolated decision.

70.2.3.4 Combinatorial Entropy and Maximum Statistical Entropy

For energy levels ε_i with degeneracies g_i, a fermionic occupation $n_i \in \{0, \dots, g_i\}$ has

$$\Omega(g_i, n_i) = \binom{g_i}{n_i}$$

microstates. With total number and total energy fixed,

$$\Omega(N, E) = \sum_{\substack{(n_i):\ \sum_i n_i = N \\ \sum_i \varepsilon_i n_i = E}} \prod_i \binom{g_i}{n_i}, \qquad S_{\mathrm{mc}} = \log \Omega(N, E). \tag{70.9}$$

With number and energy fixed as mean values, Shannon maximization [110] yields the product distribution

$$\mathbb{P}(n_1, \dots, n_M) \propto \exp\left[-\beta \sum_j \varepsilon_j n_j + \beta\mu \sum_j n_j\right]$$

and, therefore,

$$\boxed{\langle n_j \rangle_{\mathrm{FD}} = \frac{1}{e^{\beta(\varepsilon_j - \mu)} + 1}.} \tag{70.10}$$

Bosonic occupation replaces the binomial count with $\binom{g+n-1}{n}$ and yields

$$\langle n_j \rangle_{\mathrm{BE}} = \frac{1}{e^{\beta(\varepsilon_j - \mu)} - 1}.$$

In both cases, β and μ are determined by the declared macroscopic constraints.

70.2.3.5 von Neumann Entropy of 1 *Reduced State*

For a density matrix ρ_A on a region or subalgebra,

$$S_{\mathrm{vN}}(\rho_A) = -\operatorname{Tr}(\rho_A \log \rho_A).$$

Its domain is a reduced state. When ρ_A arises from a global purification, this quantity measures entanglement across the cut. The next chapter constructs the triadic reduction, modular Hamiltonian, and area quantization that give it a precise geometric residence.

Proposition 70.5 (Typed separation of the five entropies)**.** *The quantities $\mathsf{H}_{\mathrm{fib}}$, I_{TRIT}, h_{top}, S_{mc}, and S_{vN} are not substituted for one another: they depend, respectively, on a reading fiber, a local triadic distribution, a history system, a set of microstates compatible with constraints, and a reduced state. A physical map may relate them only after declaring the coarse–graining, ensemble, Hamiltonian, or purification that changes from one domain to the next.*

Proof. Each functional is defined on a different type of input. Conditional entropy requires a reader; I_{TRIT}, a distribution over three symbols; h_{top}, a word dynamics; S_{mc}, a macrocanonical constraint; and S_{vN}, a density operator. An accidental numerical equality does not supply the maps that change those types. □

70.2.4 Areal–volumetric incidence and topological entropy

The TPK calendar induces the hinge between the additive and multiplicative modes. In the primitive block

$$\tau_3 = (+1, -1, 0),$$

the rule

$$+1 : m \mapsto \Sigma, \qquad -1 : m \mapsto \Pi, \qquad 0 : m \mapsto m$$

produces the cyclic orbit (Σ, Π, Π). The geometric reader

$$\Sigma \longmapsto \mathscr{H}_{\mathrm{ar}}, \qquad \Pi \longmapsto \mathscr{H}_{\mathrm{vol}}$$

transports these modes to the areal and volumetric sheets.

Theorem 70.6 (Necessary incidence of the sheets)**.** *In the order $(\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}})$, the primitive incidence matrix is*

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{70.11}$$

Calendars of lengths $9, 27, 108$ *yield*

$$N_9 = 3F_{\mathrm{av}}, \qquad N_{27} = 9F_{\mathrm{av}}, \qquad N_{108} = 36F_{\mathrm{av}}.$$

Proof. The consecutive pairs of the cycle are $\Sigma \to \Pi$, $\Pi \to \Pi$, and $\Pi \to \Sigma$. Each occurs once, and $\Sigma \to \Sigma$ does not occur. This fixes all four entries of F_{av}. The longer calendars contain, respectively, three, nine, and thirty-six copies of the primitive block. □

Theorem 70.7 (Fibonacci law and measure of maximal entropy)**.** *For $n \geq 1$,*

$$F_{\mathrm{av}}^{n} = \begin{pmatrix} F_{n-1} & F_{n} \\ F_{n} & F_{n+1} \end{pmatrix}. \tag{70.12}$$

The one-step subshift defined by F_{av} has

$$\boxed{h_{\mathrm{top}} = \log \varphi}, \qquad \boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}}. \tag{70.13}$$

Proof. The matrix identity follows by induction from $F_{n+1} = F_n + F_{n-1}$. The Perron root of F_{av} is φ, hence $h_{\mathrm{top}} = \log \varphi$. Since the matrix is symmetric, the Parry weights [98] are proportional to the squared components of a Perron vector $(1, \varphi)$, that is, to $(1, \varphi^2)$. □

The expressions $\log 3$ and $\log \varphi$ are thus distinguished by their genealogy. The first quantifies a uniform local choice among three states; the second measures the growth of histories allowed by sheet incidence. The areal–volumetric relation is a property of the complete return and therefore appears with exponent two.

70.2.5 Boltzmann Transduction and Energy by Triadic Decision

Let $\mathcal{L}_T$ be the duration line, $\mathcal{L}_\Theta$ the temperature line, $\mathcal{L}_S$ the action line, and $\mathcal{L}_E$ the energy line. The Boltzmann constant is the positive isomorphism

$$\boxed{k_B : \mathcal{L}_\Theta \longrightarrow \mathcal{L}_E, \qquad [k_B] = \mathbf{E} - \mathbf{\Theta}.} \tag{70.14}$$

Thus, $\beta = (k_B \Theta)^{-1}$ belongs to the reciprocal-energy line.

The determinantal reader of the action constructs

$$\hbar_{\mathrm{int}} = \eta_{\mathrm{ret}}\, 10^{-34} \mathcal{U}_S \in \mathcal{L}_S.$$

If $t_0 \in \mathcal{L}_T^{+}$ is the elementary internal duration, the full-return clock fixes

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad \varepsilon_{\mathrm{clk}} = \hbar_{\mathrm{int}} \omega_0 \in \mathcal{L}_E.$$

Definition 70.8 (Triadic thermal scale)**.** The section $\Theta_{\mathrm{clk}} \in \mathcal{L}_\Theta^{+}$ is defined by

$$\boxed{k_B \Theta_{\mathrm{clk}} \log 3 = \hbar_{\mathrm{int}} \frac{2\pi}{108 t_0}.} \tag{70.15}$$

The equality fixes energy by triadic decision and links three objects already constructed: the local information $\log 3$, the internal action, and the clock frequency. The product $k_B \Theta_{\mathrm{clk}}$ is determined within the internal chart. The choice of thermal and energetic bases then separates the coordinate of k_B and that of Θ_{clk}. In the kelvin–joule chart, the metrological definition publishes

$$k_B^{\mathrm{SI}} = 1.380649 \times 10^{-23}\ \mathrm{J\,K^{-1}}.$$

70.2.6 Thermal Operator on Histories

Let $\mathcal{E}$ be the set of edges of a finite graph of extensions, let $a_*(e) \geq 0$ be the dimensionless action increment, and let $\epsilon_* \in \mathcal{L}_E^+$ be a positive energy section. For $\beta \in \mathcal{L}_E^{-1}$, we define

$$(\mathcal{L}_{\beta,*} f)(y) = \sum_{e:x\to y} \exp[-\beta\epsilon_* a_*(e)] f(x). \tag{70.16}$$

The exponent is dimensionless, and positivity of the operator preserves the composition of histories. Pressure normalization selects the thermal state through

$$\boxed{\rho(\mathcal{L}_{\beta,*}) = 1.} \tag{70.17}$$

Proposition 70.9 (Confluence of the information branch and the spectral branch)**.** *An HMT–MD thermal realization is determined when a single value of $\beta = (k_B\Theta)^{-1}$ satisfies the spectral normalization* (70.17) *and the action–information scale* (70.15)*. The first equation weights the histories; the second fixes the energy of the local decision. Their confluence turns genealogical accounting into a thermal ensemble without identifying information, entropy, and energy.*

Thermodynamics therefore appears after genealogical conservation. The complete state retains the history; the reader defines the coarse–graining; the count organizes the microstates; and the Boltzmann transducer assigns an energy scale to the information at a declared temperature.

70.2.7 Genealogical memory, informational reduction and thermal transduction

The thermal construction uses two publications of the same APP–TRIT–TPK development. The first preserves the states, admissible routes and register information; the second provides the oriented action and the duration of the return. Their composition determines an energy per tritic decision. The temperature and energy coordinates are subsequently introduced through explicit dimensional maps. This sequence allows one to identify what information is preserved, what information a reader publishes and what quantity converts that information into dimensional entropy.

70.2.7.1 Reader, memory, and state recovery

Fix a finite level of the development and denote by Ω the set of admissible enriched states. The register preserves sheet, orientation, residue, quotient, carry, route, phase and memory in the domains where each coordinate enters. Let

$$q : \Omega \longrightarrow Y, \qquad M : \Omega \longrightarrow \mathcal{M}$$

be the visible publication and the retained memory, respectively. For a distribution p over Ω, we write $\mathsf{H}(p) = -\sum_x p_x \log p_x$, with $0 \log 0 = 0$. The logarithm is applied to dimensionless probabilities.

Definition 70.10 (Genealogical recovery of a publication)**.** The pair $\widehat{q} = (q, M)$ is a recoverable reader on the support Ω_p when there exists

$$d : \widehat{q}(\Omega_p) \longrightarrow \Omega_p, \qquad d \circ \widehat{q} = \mathrm{id}_{\Omega_p}.$$

The fibre information of q is $\mathsf{H}_{\mathrm{fib}}(q; p) = \mathsf{H}(X \mid q(X))$, where X has law p.

Proposition 70.11 (Recovery identity and cost of reduction)**.** *For a recoverable reader,*

$$\mathsf{H}(X \mid q(X), M(X)) = 0, \tag{70.18}$$

$$\mathsf{H}(X) = \mathsf{H}(q(X)) + \mathsf{H}(X \mid q(X)), \tag{70.19}$$

$$\mathsf{H}(X \mid q(X)) = \mathsf{H}(M(X) \mid q(X)). \tag{70.20}$$

Proof. The map d recovers X from the pair $(q(X), M(X))$, so the first conditional entropy is zero. Since q is a function of X, the chain rule gives the second equality. For the third, expand $\mathsf{H}(X, M(X) \mid q(X))$ in two ways. One gives $\mathsf{H}(X \mid q(X))$, since M is a function of X; the other gives $\mathsf{H}(M(X) \mid q(X)) + \mathsf{H}(X \mid q(X), M(X))$. □

Euclidean division on the APP sheets displays the elementary arithmetic mechanism. With $i, j \in \{1, \dots, 9\}$, one preserves

$$i + j = 9q_{ij}^{+} + R_{ij}^{+}, \qquad ij = 9q_{ij}^{\times} + R_{ij}^{\times}, \qquad 1 \le R_{ij}^{\sigma} \le 9 \quad (\sigma \in \{+, \times\}).$$

The residue–quotient pair recovers the integer value of the operation. Summing the differences over the eighty-one positions gives

$$2025 - 810 = 54 + 9 \cdot 129.$$

Quotient memory restores the contribution not published by residual reduction. Recoverability of the complete state additionally requires preserving the relevant position and route coordinates; the residue–quotient pair identifies the result of the operation here.

70.2.7.2 Reversible update, tritic decision and erasure

Let $U : \Omega \to \Omega$ be the TPK update on a domain where enriched transport has an inverse. The transported law is $p'_y = p_{U^{-1}y}$. The bijection preserves the multiset of probabilities and therefore

$$\mathsf{H}(U(X)) = \mathsf{H}(X), \qquad \mathsf{H}(X \mid U(X)) = 0. \tag{70.21}$$

If the observed output is $q(U(X))$, the unpublished information is quantified by $\mathsf{H}(X \mid q(U(X)))$. The complete state, its publication and the resetting of a register are thus three distinct maps.

For the three oriented TRIT states, let $p = (p_{-1}, p_0, p_{+1})$ be a normalized distribution. Its information is

$$I_{\mathrm{TRIT}}(p) = -\sum_{a=-1}^{1} p_a \log p_a, \qquad 0 \le I_{\mathrm{TRIT}}(p) \le \log 3. \tag{70.22}$$

The upper bound corresponds to $p_a = 1/3$. Indeed,

$$D(p \| (1/3, 1/3, 1/3)) = \sum_{a} p_a \log(3p_a) = \log 3 - I_{\mathrm{TRIT}}(p) \ge 0;$$

the inequality follows from the convexity of $t \log t$, and equality characterizes the uniform distribution. The lower bound corresponds to a distribution concentrated on one state.

The ideal Landauer realization uses a memory with energetically degenerate logical states, an isothermal environment at temperature Θ and a balance that preserves the output of the logical map and accounts for auxiliary registers. In that model, the decrease in logical entropy is $k_B[\mathsf{H}(X) - \mathsf{H}(F(X))] = k_B\mathsf{H}(X \mid F(X))$ for a deterministic map F. The entropic balance requires transferring at least that amount to the environment; its energy expression is $Q \ge k_B\Theta\mathsf{H}(X \mid F(X))$. The distinction between reversible logical evolution and physical erasure corresponds to the Landauer–Bennett realization [176]. The invertible update (70.21) has zero logical contribution; resetting a uniform triple requires transferring $\log 3$ nats to the environment and satisfies $Q \ge k_B\Theta \log 3$. The control energy and dissipation of a specific physical realization belong to its additional thermodynamic balance.

70.2.7.3 Action, frequency, and decision energy

Let $\mathcal{L}_{\mathrm{act}}$ and $\mathcal{L}_T$ be the dimensional lines of action and duration; the energy line is $\mathcal{L}_E = \mathcal{L}_{\mathrm{act}} \otimes \mathcal{L}_T^{*}$. The preceding development provides the positive sections $\hbar_a \in \mathcal{L}_{\mathrm{act}}$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$, and the elementary duration $t_0 \in \mathcal{L}_T$. The complete calendar provides

$$T_{108} = 108t_0, \qquad \omega_{108} = \frac{2\pi}{T_{108}}, \qquad h_a = 2\pi\hbar_a.$$

The dimensional contraction between action and frequency defines

$$\epsilon_a := \hbar_a\omega_{108} = \frac{h_a}{108t_0} = \frac{\hbar_a}{t_P}, \qquad t_P = \frac{54}{\pi}t_0. \tag{70.23}$$

The final expression uses the same reduced circular period as the gravitational section. The three expressions correspond to a single energy section, with an orientation a maintained in all the factors. The normalized information of a uniform decision produces the energy section per nat

$$\varepsilon_a := \frac{\epsilon_a}{\log 3} \in \mathcal{L}_E^+. \tag{70.24}$$

The previously constructed action determines the energy scale once the duration is fixed; the cardinality of the TRIT alternatives determines its informational normalization. The value of $\log 3$ enters through the count and measure declared in (70.22).

70.2.7.4 Dimensional definition of Boltzmann and selection of coordinates

Let $\mathcal{L}_\Theta$ be the oriented temperature line. The dimensional entropy space is $\mathcal{L}_{\text{ent}} = \mathcal{L}_E \otimes \mathcal{L}_\Theta^*$. A positive linear map $k_B : \mathcal{L}_\Theta \to \mathcal{L}_E$ is, equivalently, a positive element of $\mathcal{L}_{\text{ent}}$. Thus the same object can act on a temperature or multiply dimensionless information.

Definition 70.12 (Thermal normalization of the tritic decision)**.** A thermal pair compatible with the oriented section a consists of a positive transducer k_B and a positive section $\Theta_{\text{clk},a} \in \mathcal{L}_\Theta$ such that

$$k_B(\Theta_{\text{clk},a}) = \varepsilon_a, \qquad k_B\Theta_{\text{clk},a}\log 3 = \epsilon_a. \tag{70.25}$$

The Boltzmann constant serves as the energy–temperature transducer of tritic information in this realization.

Theorem 70.13 (Uniqueness relative to the thermal section and dimensional covariance)**.** *Given a positive section $\Theta_{\text{clk},a}$, there exists a unique positive linear map satisfying (70.25). For positive bases u_E, u_Θ, if*

$$\epsilon_a = \epsilon_a^{\text{num}} u_E, \quad \Theta_{\text{clk},a} = \theta_a u_\Theta, \quad k_B(u_\Theta) = b\, u_E,$$

its coordinate is

$$b = \frac{\epsilon_a^{\text{num}}}{\theta_a \log 3}. \tag{70.26}$$

Under $u'_E = s_E u_E$, $u'_\Theta = s_\Theta u_\Theta$, with $s_E, s_\Theta > 0$, one has

$$b' = \frac{s_\Theta}{s_E}b, \qquad \theta'_a = \frac{\theta_a}{s_\Theta}, \qquad (\epsilon_a^{\text{num}})' = \frac{\epsilon_a^{\text{num}}}{s_E}.$$

Proof. A nonzero section generates a line. Prescribing its image determines the unique linear map; the positivity of both sections proves its positivity. Substituting the coordinates into (70.25) gives $b\theta_a \log 3 = \epsilon_a^{\text{num}}$. The three transformation laws are obtained by expressing the same sections and the same map in the new bases. □

The same Boltzmann constant must act in both orientations. Since t_P is common, simultaneous compatibility is equivalent to

$$\frac{\Theta_{\text{clk,pre}}}{\Theta_{\text{clk,ret}}} = \frac{\epsilon_{\text{pre}}}{\epsilon_{\text{ret}}} = \frac{\hbar_{\text{pre}}}{\hbar_{\text{ret}}}. \tag{70.27}$$

Indeed, an isomorphism of lines preserves quotients of sections. Conversely, if the preceding equality holds, the isomorphism determined in one orientation also satisfies the normalization of the other. Thus,

return changes the thermal section of the cycle in the same proportion as the energy, while the transducer remains common to both readings.

The preceding equation makes explicit the choice required to publish an individual value. If the thermal section has not yet been selected by an independent reader, for each $\lambda > 0$ the pair

$$(k_B, \Theta_{\mathrm{clk},a}) \longmapsto (\lambda k_B, \lambda^{-1}\Theta_{\mathrm{clk},a})$$

preserves ϵ_a. Consequently, presenting an internally selected individual coordinate requires specifying the reader of $\Theta_{\mathrm{clk},a}$, the bases and their dimensional transport. The action and information equations remain determined before that specification. The subsequent identification of the bases with joule and kelvin belongs to the metrological publication of the result.

70.2.7.5 Dimensional entropy and information of the reduced state

For a distribution of admitted routes p, or for a reduced state with density matrix ρ, let

$$s(p) = -\sum_x p_x \log p_x, \qquad s(\rho) = -\operatorname{Tr}(\rho \log \rho).$$

Their dimensional publications are

$$S(p) = k_B s(p), \qquad S(\rho) = k_B s(\rho) \quad \text{in } \mathcal{L}_{\mathrm{ent}}. \tag{70.28}$$

Evaluation at Θ produces an energy $\Theta S = k_B \Theta\, s$. For the uniform triple at the cycle temperature, (70.25) gives exactly

$$S_{\mathrm{TRIT}} = k_B \log 3, \qquad \Theta_{\mathrm{clk},a} S_{\mathrm{TRIT}} = \epsilon_a.$$

If ρ_A is the reduction of the bipartite purification constructed in the areal section, $s(\rho_A)$ measures the entanglement of that bipartition. Unit transport preserves its eigenvalues, its orientation and the sectoral occupations. The areal scale $\gamma a_0 \ell_P^2$ converts occupations into area; the transducer k_B converts information into dimensional entropy. Both readings use the same register through distinct operators.

70.2.7.6 Spectral normalization of thermal histories

Let $\mathcal{G}$ be an already constructed finite graph of admissible extensions, with adjacency matrix A. Each edge e preserves its route coordinates and receives a dimensionless action increment $a_*(e) > 0$ from the corresponding reader. Having chosen the energy section ϵ_*, set $t = \beta\epsilon_*$, where $\beta = (k_B\Theta)^{-1}$. The thermal operator is

$$(L_t f)(y) = \sum_{e: x \to y} \exp[-t a_*(e)]\, f(x). \tag{70.29}$$

All its exponents are dimensionless. The condition $\rho(L_t) = 1$ normalizes the weighted growth of histories.

Proposition 70.14 (Existence and uniqueness of normalized pressure)**.** *Suppose that A is irreducible, $\rho(A) > 1$, and that $0 < m \le a_*(e) \le M$ for all edges. There exists a unique $t_* > 0$ such that $\rho(L_{t_*}) = 1$, and*

$$\frac{\log \rho(A)}{M} \le t_* \le \frac{\log \rho(A)}{m}. \tag{70.30}$$

Proof. Entrywise comparison gives $e^{-tM}A \le L_t \le e^{-tm}A$ for $t \ge 0$. Monotonicity of the spectral radius of nonnegative matrices implies the corresponding bounds for $\rho(L_t)$. The spectral radius is continuous, equals $\rho(A) > 1$ at zero and tends to zero at infinity. For $s > 0$, moreover, $L_{t+s} \le e^{-sm} L_t$, so that $\rho(L_{t+s}) \le e^{-sm}\rho(L_t) < \rho(L_t)$. Continuity and strict decrease prove existence and uniqueness. Substituting the value one into the initial bounds proves (70.30). □

The local realization of three equally weighted alternatives, represented by a vertex with three loops and $a_*(e) = 1$, satisfies $\rho(L_t) = 3e^{-t}$. Its normalization gives $t_* = \log 3$. With $\epsilon_* = \epsilon_a$, we obtain

$\beta_{\mathrm{clk}} = \log 3/\epsilon_a$, precisely the relation (70.25). This calculation identifies the local tritic confluence. For a graph of histories with additional restrictions, confluence with the same clock requires checking

$$\rho\big(L_{(\log 3/\epsilon_a)\,\epsilon_*}\big) = 1$$

with its effective increments. The local normalization and the pressure of the complete system thus retain their respective domains.

The resulting relation brings together structure, value and meaning. The register determines the recoverable information; probabilities over continuations determine its entropic reading; action and period determine ϵ_a; the energy–temperature transducer publishes dimensional entropy. Area and entanglement are related through the reduced state and its boundary operators, keeping visible which datum produces each quantity.

Chapter 71

Minimal area of the triadic cut, capacity $81 \log 3$ and collective incidence transport

Areal quantization begins with the nonadic interior, its boundary, and the collective transport of incidence. The minimal cut contains 81 units and its qutrit capacity is $81 \log 3$; the result precedes its gravitational realization.

71.1 Areal quantization, modular dynamics, and rational CKM transformation

71.1.1 Hexad–octad inclusion and associated functional realizations

Let us fix a set H of six points and a set O of eight points with a distinguished inclusion $j : H \hookrightarrow O$. In the Witt residence, H is a hexad of a dodecad and O its lifted octad; in this chapter only the already fixed inclusion is used, not the terminal value of Barbero–Immirzi. We write

$$\binom{H}{2} := \{P \subset H : |P| = 2\}, \qquad \left|\binom{H}{2}\right| = \binom{6}{2} = 15, \tag{71.1}$$

and we define two incidence spaces with distinct types:

$$\mathcal{F}_6 := H \times \binom{H}{2}, \qquad \mathcal{F}_8 := O \times \binom{H}{2}. \tag{71.2}$$

The inclusion of incidences is

$$\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8, \qquad (h, P) \longmapsto (j(h), P). \tag{71.3}$$

It is injective because j is injective and preserves the marked pair P.

Theorem 71.1 (Incidence and defect counts oriented)**.** *The two spaces of equation (71.2) satisfy*

$$|\mathcal{F}_6| = 6\binom{6}{2} = 90, \qquad |\mathcal{F}_8| = 8\binom{6}{2} = 120, \qquad |\mathcal{F}_8 \setminus \iota_{6,8}(\mathcal{F}_6)| = 30. \tag{71.4}$$

Normalization by the twenty-four coordinates of the dodecad–twenty-four pair and by the fifteen pairs of H produces

$$\boxed{\delta^{\mathrm{inc}}_{6,8} = \frac{|\mathcal{F}_6| - |\mathcal{F}_8|}{24\binom{6}{2}} = -\frac{1}{12}.} \tag{71.5}$$

The same fraction is obtained through the reciprocal functional associated with the incorporated memory,

$$\boxed{\delta^{\mathrm{rec}}_{6,8} = \frac{30}{120} - \frac{30}{90} = -\frac{1}{12}.} \tag{71.6}$$

They are two exact realizations of the same oriented defect, but have distinct domains and are not identified with $\zeta(-1)$ without an additional intertwiner.

Proof. The multiplicative principle applied to equation (71.2) gives $6 \cdot 15 = 90$ and $8 \cdot 15 = 120$. The image of $\iota_{6,8}$ has ninety elements, so the complement has thirty. Substitution into equation (71.5) gives $-30/(24 \cdot 15) = -1/12$, while equation (71.6) is $1/4 - 1/3 = -1/12$. □

The hexad–octad transition admits two functional realizations that are not deduced from one another. The algebraic diagram, formulated on the spaces that justify the counts, is

$$\begin{aligned}(H \overset{j}{\hookrightarrow} O) &\longmapsto (|\mathcal{F}_6|, |\mathcal{F}_8|) = (90, 120) \longmapsto \Gamma_{6\to 8} = \gamma_{\mathrm{HMT}},\\ (h_6, o_8, t) = (6, 8, 3) &\longmapsto -\frac{o_8 - h_6}{t} = -\frac{2}{3},\end{aligned} \tag{71.7}$$

where $-2/3$ is the coefficient of the third coordinate of row 13 of the CKM constructor. The first realization transforms the incidence into area and modular memory; the second transforms the same transition into angular-mixing parameters. $\boldsymbol{\theta}_{\mathrm{CKM}} = f(\gamma_{\mathrm{HMT}})$ is not postulated: both outputs preserve a common antecedent.

The morphism determining the sectors 90/120 is $\iota_{6,8}$. Magnitude γ_{HMT} is adopted as a theorem previously demonstrated in the hexad–octad construction and is not reconstructed from its decimal representation. The operatorial consequences begin only after fixing the elementary scale a_0, defined below without using entropy or the terminal product $\gamma_{\mathrm{HMT}} a_0$.

71.1.2 Correspondence between the Nonadic Interior and the Boundary Degrees of Freedom

Let $\mathbb{T}_3 = \{0, 1, 2\}$. Every $x \in \mathbb{Z}/9\mathbb{Z}$ has a unique digit representation $x = x_0 + 3x_1$, with $x_i \in \mathbb{T}_3$, and every $y \in \mathbb{Z}/27\mathbb{Z}$ a unique representation $y = y_0 + 3y_1 + 9y_2$. Therefore

$$\mathcal{B} = (\mathbb{Z}/9\mathbb{Z})^3, \qquad \mathcal{B}_\partial = (\mathbb{Z}/27\mathbb{Z})^2, \qquad |\mathcal{B}| = |\mathcal{B}_\partial| = 3^6 = 729. \tag{71.8}$$

Equality of cardinalities is accompanied by the explicit map. If $x_j = r_{2j-1} + 3r_{2j}$ for $j = 1, 2, 3$, we define

$$\beta_{729}(x_1, x_2, x_3) = \big(r_1 + 3r_2 + 9r_3,\ r_4 + 3r_5 + 9r_6\big). \tag{71.9}$$

Proposition 71.2 (Genealogical bijection $729 \leftrightarrow 729$)**.** *The map $\beta_{729} : \mathcal{B} \to \mathcal{B}_\partial$ is bijective and preserves the ordered six-trit word. In general, it is not an isomorphism of additive groups: regrouping the digits changes where the carry is recorded.*

Proof. Extracting the six digits from three nonadic coordinates and grouping them into two triples is a permutation of the coordinates of $\mathbb{T}_3^6$. The positional decomposition is unique on both sides, so the operation has an inverse. The additive caveat is verified, for example, by adding words that generate a carry between r_3 and r_4: that boundary separates the two coordinates of order twenty-seven, but crosses two distinct coordinates in the nonadic packing. □

On the boundary torus $\mathcal{B}_\partial$, we take the block of vertices

$$A = \{0, 1, \dots, 8\} \times \{0, 1, \dots, 8\}. \tag{71.10}$$

Its oriented links crossing the boundary are separated by direction:

$$\partial A_{90} = \{((-1, j), (0, j)), ((8, j), (9, j)) : 0 \le j \le 8\}, \tag{71.11}$$

$$\partial A_{120} = \{((i, -1), (i, 0)), ((i, 8), (i, 9)) : 0 \le i \le 8\}, \tag{71.12}$$

where all coordinates are read modulo twenty-seven. Thus

$$\partial A = \partial A_{90} \sqcup \partial A_{120}, \qquad |\partial A_{90}| = |\partial A_{120}| = 18. \tag{71.13}$$

The subscripts 90, 120 label the channel provenance; they do not say that the boundary has ninety or one hundred and twenty links.

Theorem 71.3 (Law areal of the cut triadic)**.** *In the cubic graph $N \times N \times N$ with unit capacity, every cut between two opposite faces has capacity at least N^2, and a transverse layer attains that bound. For $N = 9$,*

$$\mathcal{A}_{\min} = 81, \qquad S_{\mathrm{tri}} = 81 \log 3. \tag{71.14}$$

Proof. There are N^2 lines of edges parallel to the normal direction, pairwise disjoint. Every cut must intersect each one, so its capacity is at least N^2. A single transverse layer contains exactly N^2 edges and attains the minimum. If each cut link carries a maximally mixed trit, its entropy is $\log 3$; additivity over the eighty-one links gives equation (71.14). □

The entropy S_{tri} measures the capacity of the cubic cut. The modular entropy of the thirty-six links of equation (71.13) measures another state and must not be equated with it.

71.1.3 Collective incidence entangler between interior and boundary

In the sum $\ell^2(\mathcal{F}_6) \oplus \ell^2(\mathcal{F}_8)$, we define

$$u_{90} = \frac{1}{\sqrt{90}} \sum_{f \in \mathcal{F}_6} (\delta_f, 0), \qquad u_{120} = \frac{1}{\sqrt{120}} \sum_{f \in \mathcal{F}_8} (0, \delta_f). \tag{71.15}$$

In $\ell^2(\partial A_{90}) \oplus \ell^2(\partial A_{120})$, let

$$v_{90} = \frac{1}{\sqrt{18}} \sum_{e \in \partial A_{90}} (\delta_e, 0), \qquad v_{120} = \frac{1}{\sqrt{18}} \sum_{e \in \partial A_{120}} (0, \delta_e). \tag{71.16}$$

The pairs (u_{90}, u_{120}) and (v_{90}, v_{120}) are orthonormal. Therefore there exists a unique isometry between the collective subspaces that satisfies

$$\mathcal{J}_{6\to 8} u_{90} = v_{90}, \qquad \mathcal{J}_{6\to 8} u_{120} = v_{120}. \tag{71.17}$$

Define

$$D_{\mathrm{inc}} = 90|u_{90}\rangle\langle u_{90}| + 120|u_{120}\rangle\langle u_{120}|, \tag{71.18}$$

$$D_{\mathrm{area}} = 90|v_{90}\rangle\langle v_{90}| + 120|v_{120}\rangle\langle v_{120}|. \tag{71.19}$$

Theorem 71.4 (Exact transport of the two labels)**.** *The map $\mathcal{J}_{6\to 8}$ is unitary between the two collective planes and intertwines the incidence and area operators:*

$$\boxed{\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\mathrm{area}} \mathcal{J}_{6\to 8}.} \tag{71.20}$$

Therefore, every polynomial combination of the labels $90, 120$*, in particular the primitive combination* $12 : -1$*, is transported with the same coefficients.*

Proof. Orthonormality shows that $\mathcal{J}_{6\to 8}$ maps one orthonormal basis to another. In u_{90}, both sides of equation (71.20) equal $90 v_{90}$; in u_{120}, both equal $120 v_{120}$. Equality on a basis proves the identity. The functional calculus, in its polynomial form, preserves the intertwining. □

This map does not purport to inject ninety individual incidences into eighteen links: it transports exactly the two uniform modes and their spectral labels. Extending it to non-uniform fluctuations would require a new incidence map; the modular operator defined here only uses the collective subspace that has just been constructed.

71.1.4 What is the elementary and minimal scale of the area operator

Let C^* the angular coordinate conjugate, expresada in grados, and fijemos

$$\theta_{\mathrm{clk}} = \frac{C^*}{6} \frac{\pi}{180}, \qquad \boxed{a_0 = \frac{1 + 2\cos(10^\circ)}{3} \theta_{\mathrm{clk}}.} \tag{71.21}$$

The factor preceding θ_{clk} is not a decimal correction. It is the normalized real character of the phase triplet

$$\frac{1}{3}\,\mathrm{Tr}\,\mathrm{diag}\left(1, e^{i\pi/18}, e^{-i\pi/18}\right) = \frac{1+2\cos(10^\circ)}{3}. \tag{71.22}$$

Thus, a_0 is the spectral mean of the angular structure on the oriented trit. It is positive, is fixed before the area operator, and is not selected from entropy. The subsequent identification $\gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}$ realizes the HMT output in the Ashtekar–Barbero connection [11, 69]; it does not reopen its derivation.

Remark 71.5 (Alcance of the simbolo a_0). In this chapter, $a_0 \equiv a_0^{\mathrm{area}}$ denotes exclusively the normalization of equation (71.21). It is neither the Bohr radius nor the initial cosmological scale factor, although those objects are traditionally written with the same symbol. No identity in this chapter allows one to substitute one for the other.

Construction of the area operator from the triad cut and channel separation. The cut and its capacity determine an area operator; its spectrum must separately preserve total occupation and channel provenance.

Chapter 72

Spectrum of the area operator and joint reconstruction of occupation and provenance

The sectors 90 and 120 define compatible occupancy and memory operators. Inverting the linear system reconstructs both channels and prevents total area from erasing provenance.

72.1 Area and modular operators in the sectors 90 and 120

In each of the two families of equation (71.13) there are eighteen qutrit channels. For $m \in \{90, 120\}$, define

$$N_m = \sum_{e \in \partial A_m} N_e, \qquad \mathrm{Spec}(N_e) = \{0, 1, 2\}. \tag{72.1}$$

The Barbero–Immirzi output is used here as a prior result, without rederiving it. With the area normalization constructed in equation (71.21), one obtains

$$\boxed{\frac{\widehat{\mathcal{A}}_{\mathrm{phys}}}{\ell_P^2} = \gamma_{\mathrm{HMT}} a_0 (N_{90} + N_{120}),} \qquad \gamma_{\mathrm{HMT}} a_0 = 0.0016755940749224991. \tag{72.2}$$

Theorem 72.1 (Finite spectrum of the area quantum)**.** *On the thirty-six links of the cut,*

$$\mathrm{Spec}(N_{90} + N_{120}) = \{0, 1, \ldots, 72\}. \tag{72.3}$$

The multiplicity of the eigenvalue n is the coefficient of z^n in $(1 + z + z^2)^{36}$. Consequently,

$$\boxed{\mathrm{Spec}\left(\frac{\widehat{\mathcal{A}}_{\mathrm{phys}}}{\ell_P^2}\right) = \{n\gamma_{\mathrm{HMT}} a_0 : 0 \le n \le 72\}.} \tag{72.4}$$

The compatible cuts prolong the family $\mathcal{A}_n^{\mathrm{prot}} = n\gamma_{\mathrm{HMT}} a_0 \ell_P^2$.

Proof. Each operator N_e has a spectral generating function $1 + z + z^2$. The thirty-six factors commute and act on distinct tensor factors; therefore, the generating function of the total is $(1 + z + z^2)^{36}$, whose degrees range over all integers from zero to seventy-two. Multiplication by the positive scalar $\gamma_{\mathrm{HMT}} a_0 \ell_P^2$ gives equation (72.4). □

Two quantization procedures must be distinguished. The cut law theorem 71.3 counts eighty-one unit capacities and determines 81 log 3; the operator equation (72.2) quantizes occupations of thirty-six response links, up to seventy-two number trits. They share the same boundary sheet, but not the same observable.

The torsion modular produces

$$\Delta_4^{\mathrm{mod}} = 0.000111197050059977324941456613193385 6\ldots, \tag{72.5}$$

and the boundary Hamiltonian

$$\boxed{K_{\mathrm{HHM}}^{(A)} = -\log \rho_A = cI + \Delta_4^{\mathrm{mod}} (90 N_{90} + 120 N_{120}).} \tag{72.6}$$

The qualifier *holographic* does not designate an analogy: the incidence $6 \longrightarrow 8$ is transported to the boundary sets ∂A_{90} and ∂A_{120}, and the reduced state resides in the algebra generated by its number operators.

Theorem 72.2 (Joint reconstruction of geometry and memory)**.** *Let*

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}. \tag{72.7}$$

Then

$$\boxed{N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N.} \tag{72.8}$$

In particular, $[\widehat{\mathcal{A}}_{\mathrm{phys}}, K^{(A)}_{\mathrm{HHM}}] = 0$*, and the pair* $(\widehat{\mathcal{A}}_{\mathrm{phys}}, K^{(A)}_{\mathrm{HHM}} - cI)$ *reconstructs the two occupation sectors.*

Proof. The operators N_{90} and N_{120} act on distinct factors and commute. The linear map carrying (N_{90}, N_{120}) to (N, D) has matrix

$$\begin{pmatrix} 1 & 1 \\ 90 & 120 \end{pmatrix}, \qquad \det = 30.$$

Its inverse is exactly equation (72.8). Since equations (72.2) y (72.6) are linear combinations of the same number operators, the commutator vanishes. □

The operator interpretation is precise: the area observable preserves the total number of excitations, while the modular Hamiltonian preserves their sector of origin. Neither observable alone retains both coordinates; the joint pair does determine them.

72.2 Confluence of area, information and energy

The angular scale θ_{clk} in equation (71.21) and the chronological temperature Θ_{clk} are distinct objects; the use of an uppercase letter is part of the typing. The thermodynamic realization in section 14.4 proves

$$E_P = k_B \Theta_{\mathrm{clk}} \log 3, \tag{72.9}$$

whereas the areal realization constructs the elementary increment

$$\delta\mathcal{A} = \gamma_{\mathrm{HMT}} a_0 \ell_P^2. \tag{72.10}$$

They are not equated: equation (72.9) fixes the informational quantum of energy, and equation (72.10) the geometric quantum of area. Their quotient defines the typed tension of conversion

$$\boxed{\mathcal{T}_{I/A} = \frac{E_P}{\delta\mathcal{A}} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{\gamma_{\mathrm{HMT}} a_0 \ell_P^2}.} \tag{72.11}$$

The expression introduces no additional constant: it determines the normalizations that must be preserved in the transformation of information into geometry.

In the minimal cut of eighty-one links, the physical information capacity and the energy of one trit per link are

$$S^{\mathrm{phys}}_{\mathrm{cut}} = 81 k_B \log 3, \qquad E^{(1)}_{\mathrm{cut}} = 81 E_P = \Theta_{\mathrm{clk}} S^{\mathrm{phys}}_{\mathrm{cut}}. \tag{72.12}$$

The final equality is an equation of state of this realization, not a universal equipartition law. In particular, the Gibbs state of the thirty-six boundary links has a different entropy and is treated next.

This separation determines the structural content of the confluence: Barbero–Immirzi orients the area spectrum; $\log 3$ measures the irreducible decision of the TRIT; Θ_{clk} converts that information into energy;

and ℓ_P^2 connects the area quantum to the gravitational family. Gravity is described as a confluence of functional realizations of a common antecedent, and not as an imposed equality among their values.

Transport of the channel memory to the modular Hamiltonian and to the double thermal field purification. The channel memory is represented below by the modular Hamiltonian and a double thermal-field purification.

72.3 Area operator and reconstruction of sectorial information

Regrouping six trits constructs a bijection between $(\mathbb{Z}/9\mathbb{Z})^3$ and $(\mathbb{Z}/27\mathbb{Z})^2$, both of cardinality 729. The bijection is not presented as an additive isomorphism. On a 9×9 boundary block, the source decomposes 36 links into two sets of 18, labeled by channels 90 and 120.

72.3.1 Tritic regrouping and boundary incidence

The correspondence preserves an ordered word, in addition to its cardinality. Write each coordinate $x_j \in \mathbb{Z}/9\mathbb{Z}$, for $j = 1, 2, 3$, through its unique positional representatives $x_j = r_{2j-1} + 3r_{2j}$, with $r_k \in \{0, 1, 2\}$. The map is

$$\beta_{729}(x_1, x_2, x_3) = \big(r_1 + 3r_2 + 9r_3,\ r_4 + 3r_5 + 9r_6\big) \in (\mathbb{Z}/27\mathbb{Z})^2. \tag{72.13}$$

Proposition 72.3 (Positional correspondence between interior and boundary)**.** *The map β_{729} is bijective and preserves the order of the six trits. Its inverse extracts the two triples of digits and regroups them into three pairs.*

Proof. The positional expansion of the representatives $0, \dots, 8$ and $0, \dots, 26$ is unique. Extracting the six digits, regrouping them, and extracting them again returns the same word. The inverse operation thus restores each of the three initial coordinates. □

Carry preserves its position in the enriched word. The additive operations of the two packagings have different boundaries: for example, $\beta_{729}(0, 2, 0) = (18, 0)$ and $\beta_{729}(0, 1, 0) = (9, 0)$, whose sum in the order-twenty-seven torus is $(0, 0)$, whereas $\beta_{729}(0, 3, 0) = (0, 1)$. This distinction allows the positional correspondence to be reused while keeping the operations typed.

In the torus $(\mathbb{Z}/27\mathbb{Z})^2$, the block $B_\partial = \{0, \dots, 8\}^2$ has the oriented link sets

$$\partial B_{90} = \{((-1, j), (0, j)),\ ((8, j), (9, j)) : 0 \le j \le 8\}, \tag{72.14}$$

$$\partial B_{120} = \{((i, -1), (i, 0)),\ ((i, 8), (i, 9)) : 0 \le i \le 8\}. \tag{72.15}$$

All coordinates are read modulo twenty-seven. Each system contains eighteen links and the two systems are disjoint. Their labels preserve the incidence channels; the cardinality of the links is $18 + 18$.

Theorem 72.4 (Minimum capacity of the cubic cut)**.** *In the cubic graph with vertices $\{0, \dots, N-1\}^3$, with $N \ge 2$, links between neighbors, and unit capacity per link, the minimum cut between two opposite faces has capacity N^2. For $N = 9$, a maximally mixed product state on the trits of a minimum layer has information*

$$\mathrm{cap}_{\min} = 81, \qquad s_{\mathrm{corte}} = 81 \log 3. \tag{72.16}$$

Proof. The N^2 lines parallel to the normal of the faces form edge-disjoint paths. Every separating cut intercepts each path, so it contains at least N^2 links. The links crossing a transverse layer constitute a cut of that cardinality. Each uniform trit contributes $\log 3$ nats; entropy is additive for the product state of the eighty-one trits of the layer. □

The capacity of the cubic cut and the state of the thirty-six links in (72.15) belong to observables defined on different cuts. The genealogy preserves both domains and their measures.

72.3.2 Transport of the collective incidence modes

The spaces $\mathcal{F}_6$ and $\mathcal{F}_8$ of Section 15.5 provide the uniform vectors

$$u_{90} = \frac{1}{\sqrt{90}} \sum_{f \in \mathcal{F}_6} (\delta_f, 0), \qquad u_{120} = \frac{1}{\sqrt{120}} \sum_{f \in \mathcal{F}_8} (0, \delta_f)$$

in $\ell^2(\mathcal{F}_6) \oplus \ell^2(\mathcal{F}_8)$. In $\ell^2(\partial B_{90}) \oplus \ell^2(\partial B_{120})$, construct

$$v_{90} = \frac{1}{\sqrt{18}} \sum_{e \in \partial B_{90}} (\delta_e, 0), \qquad v_{120} = \frac{1}{\sqrt{18}} \sum_{e \in \partial B_{120}} (0, \delta_e).$$

The two pairs are orthonormal. Denote their respective spanned planes by $\mathscr{H}_{\mathrm{inc}}^{\mathrm{coll}}$ and $\mathscr{H}_{\partial}^{\mathrm{coll}}$.

Theorem 72.5 (Collective intertwining of the sectorial labels)**.** *There is a unique surjective linear isometry between these planes such that*

$$\mathcal{J}_{6\to 8} u_m = v_m \quad (m = 90, 120). \tag{72.17}$$

For the operators

$$D_{\mathrm{inc}} = 90|u_{90}\rangle\langle u_{90}| + 120|u_{120}\rangle\langle u_{120}|,$$
$$D_{\partial} = 90|v_{90}\rangle\langle v_{90}| + 120|v_{120}\rangle\langle v_{120}|,$$

we have

$$\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\partial} \mathcal{J}_{6\to 8}. \tag{72.18}$$

The sectorial projectors and their oriented combination with coefficients $12 : -1$ *are also transported.*

Proof. The image of a basis fixes the unique linear map. Norms and inner products are preserved because both bases are orthonormal. Identity (72.18) holds on each vector u_m, since its two sides are $m v_m$. The projectors are expressed as $(120I - D)/30$ and $(D - 90I)/30$; their linear functional calculus and any combination of the two preserve intertwining. □

This transport acts on the two uniform modes and their spectral labels. Individual incidences and fluctuations within each sector remain in their complete spaces. The link preserves exactly the collective datum that the areal weighting will use.

72.3.3 Angular character and area operator

Let $N_e = \mathrm{diag}(0, 1, 2)$ on each link, and let N_{90}, N_{120} be the sector sums. With the scale

$$\theta_{\mathrm{clk}} = \frac{C^*}{6} \frac{\pi}{180}, \qquad a_0 = \frac{1 + 2\cos(10^\circ)}{3} \theta_{\mathrm{clk}},$$

fixed, the angular factor is the normalized real character of the triplet

$$\chi_{10} = \frac{1}{3} \operatorname{Tr} \mathrm{diag}(1, e^{i\pi/18}, e^{-i\pi/18}) = \frac{1 + 2\cos(10^\circ)}{3}, \qquad a_0 = \chi_{10} \theta_{\mathrm{clk}}. \tag{72.19}$$

The sum of the conjugate phases proves the equality. On the positive branch considered, $\theta_{\mathrm{clk}} > 0$, $\chi_{10} > 0$, and $\gamma_{\mathrm{HMT}} > 0$; hence a_0 and the areal scale are positive. The angular triplet and its normalization precede the entropic distribution on the links. With these quantities, the normalized area operator is

$$\widehat{\mathcal{A}}/\ell_P^2 = \gamma_{\mathrm{HMT}} a_0 (N_{90} + N_{120}).$$

Its spectrum has values $n\gamma_{\mathrm{HMT}}a_0$, $0 \le n \le 72$, with multiplicities given by $(1 + z + z^2)^{36}$. The proof consists in summing the eigenvalues $0, 1, 2$ of the 36 tensor factors, with the links constructed in (72.15) and the character of (72.19).

Theorem 72.6 (Recovery of the boundary sectors)**.** *Let*

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}.$$

Then

$$N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N. \tag{72.20}$$

Thus the total and the weighted reader jointly recover the two occupations.

Proof. La matriz $\left(\begin{smallmatrix} 1 & 1 \\ 90 & 120 \end{smallmatrix}\right)$ has determinant 30. Its inversion gives (72.20). On the domain of integer occupations, the image satisfies $D \in 30\mathbb{Z}$ and $90N \le D \le 120N$. □

The modular Hamiltonian of the source is $K_A = -\log \rho_A = cI + \Delta_{\mathrm{mod}} D$. For $\Delta_{\mathrm{mod}} \neq 0$ and known normalization, $D = (K_A - cI)/\Delta_{\mathrm{mod}}$ publishes the second observable. This operator describes the spectral structure of the reduced state; it is not identified by notation with the generator of time evolution. The area preserves the total occupation and the pair adds the provenance. For example, $(N_{90}, N_{120}) = (1, 0)$ and $(0, 1)$ share $N = 1$, but have $D = 90$ and $D = 120$.

72.3.4 State normalization and the meaning of the modular Hamiltonian

The second observable is made explicit through the state that defines it. The preceding tensor decomposition is retained: eighteen qutrits per sector, each with number operator $\mathrm{diag}(0, 1, 2)$; N_m is the sum of these operators and the sectors act on distinct factors. Let

$$z_m = 1 + e^{-m\Delta_{\mathrm{mod}}} + e^{-2m\Delta_{\mathrm{mod}}}, \qquad m \in \{90, 120\}.$$

The family of source states has the product realization

$$\rho_A = Z^{-1} e^{-\Delta_{\mathrm{mod}}(90N_{90} + 120N_{120})}, \qquad Z = z_{90}^{18} z_{120}^{18}.$$

Commutativity of the number operators and tensor factorization prove the expression for Z. The state has full rank for real, finite Δ_{mod}, and its spectral logarithm gives

$$K_A = -\log \rho_A = (\log Z) I + \Delta_{\mathrm{mod}} D.$$

For $\Delta_{\mathrm{mod}} \neq 0$, K_A weights the excitations of the two sectors differently. Joint reading with N recovers the two occupations by equation (72.20).

The need for joint reading is seen in two complementary examples. The occupation states $(1, 0)$ and $(0, 1)$ have the same total $N = 1$ and different modular weights. Conversely, $(4, 0)$ and $(0, 3)$ have the same $D = 360$ and different totals. The pair (N, D) distinguishes both cases. This recovery concerns sectoral occupations, not each microscopic vector within a degeneracy of those occupations.

When $\Delta_{\mathrm{mod}} = 0$, the state is proportional to the identity and K_A is scalar: that reading ceases to distinguish the sectors. For $\Delta_{\mathrm{mod}} \neq 0$, the known normalization allows one to recover D and compose it with the area. The role of the modular Hamiltonian is thereby defined: it characterizes the reduced state and its information distribution. Its inclusion in the article is motivated by that mathematical function, whereas the evolution Hamiltonian belongs to the dynamical development of the action.

72.3.5 Reduced state, Schmidt decomposition, and entanglement entropy

If $\rho_A = \sum_\nu p_\nu |\nu\rangle\langle\nu|$, the purification

$$|\Psi\rangle = \sum_\nu \sqrt{p_\nu}\, |\nu\rangle_A |\nu\rangle_B$$

satisfies $\mathrm{Tr}_B\, |\Psi\rangle\langle\Psi| = \rho_A$. Thus $-\mathrm{Tr}(\rho_A \log \rho_A)$ is the entanglement entropy of this particular pure bipartition. The enlarged state declares which system carries that interpretation.

For a two-sheet involution with one eigenvector of each sign,

$$\rho_y = \frac{e^{-yR}}{2\cosh y}, \qquad R^2 = I,$$

diagonalization gives

$$S(\rho_y) = \log(2\cosh y) - y\tanh y, \qquad D(\rho_y \| \rho_{-y}) = 2y\tanh y.$$

Entropy is even in y; the distance explicitly compares the two orientations. This two-level entropy is not identified with the capacity $81\log 3$ of the triadic cut.

Chapter 73

Boundary modular Hamiltonian, thermofield-double purification and oriented information deficit

The faithful qutrit state admits a double-thermofield purification. The modular Hamiltonian records the orientation of the channels, and the informational deficit measures the finite separation between states without being identified with area.

73.1 Qutrit state, thermofield-double purification, and informational deficit

For a link with weight $w > 0$, let

$$Z(w) = 1 + \mathrm{e}^{-w} + \mathrm{e}^{-2w}, \qquad \rho(w) = \frac{1}{Z(w)} \sum_{n=0}^{2} \mathrm{e}^{-wn} |n\rangle\langle n|. \tag{73.1}$$

The weights of the two families are

$$w_{90} = 90\Delta_4^{\mathrm{mod}} = 0.010007734505397959244731095187 4\ldots, \tag{73.2}$$

$$w_{120} = 120\Delta_4^{\mathrm{mod}} = 0.013343646007197278992974793583 2\ldots, \qquad \frac{w_{120}}{w_{90}} = \frac{4}{3}. \tag{73.3}$$

The finite boundary state is

$$\rho_A = \rho(w_{90})^{\otimes 18} \otimes \rho(w_{120})^{\otimes 18}. \tag{73.4}$$

Its logaritmo reproduce equation (72.6), with $c = 18 \log Z(w_{90}) + 18 \log Z(w_{120})$.

Theorem 73.1 (Double-thermofield purification)**.** *The vector*

$$|\,\mathrm{TFD}(w)\rangle = \frac{1}{\sqrt{Z(w)}} \sum_{n=0}^{2} \mathrm{e}^{-wn/2} |n\rangle_A \otimes |n\rangle_{\bar{A}} \tag{73.5}$$

purify $\rho(w)$. The product of eighteen copies for each of the weights w_{90}, w_{120} purifies ρ_A; in the doubled system, $S(\rho_A)$ is exactly entanglement entropy.

Proof. Upon tracing out the second factor, the orthogonality of $|n\rangle_{\bar{A}}$ eliminates the cross terms and leaves

$$\mathrm{Tr}_{\bar{A}}\, |\,\mathrm{TFD}(w)\rangle\langle \mathrm{TFD}(w)| = \rho(w).$$

The partial trace commutes with tensor products, which proves the assertion for the thirty-six links. □

For a link,

$$S(w) = \log Z(w) + w \frac{\mathrm{e}^{-w} + 2\mathrm{e}^{-2w}}{Z(w)}. \tag{73.6}$$

Consequently,

$$S(\rho_A) = 18 S(w_{90}) + 18 S(w_{120}) = 39.548373208818079949573197 30\ldots \text{ nats}. \tag{73.7}$$

The maximally mixed state of thirty-six qutrits has entropy $36 \log 3$. We define the oriented defect

$$\boxed{I_{\mathrm{or}} = 36 \log 3 - S(\rho_A) = 0.001669183233868940655631225913\ldots \text{ nats}.} \tag{73.8}$$

Its positivity follows from the entropic maximality of the uniform state. The proximity of I_{or} to $\gamma_{\mathrm{HMT}} a_0$ does not constitute an identity and is not used to select either value.

73.2 Odd-even decomposition of the bilayer state: interleaf information and oriented geometric transport

The normalized distribution between sheets separates even entropy from odd hexad–octad transport. This bilayer parity preserves the boundary information that the modular Hamiltonian records and avoids identifying entropy, area, and orientation.

73.3 The bicover: even information and odd geometric transport

Barbero–Immirzi and the entropy of the two sheets are not two juxtaposed quantities. They arise from the same channels $q_{\pm}$, but preserve different data. Probabilistic normalization forgets the common scale and measures the distribution between orientations; the hexad–octad functional preserves the sign of that orientation. The first reading is even and the second is odd.

73.3.1 Normalized distribution between leaves

Write

$$x = A_{\mathrm{rad}}, \qquad y = C^{*}_{\mathrm{rad}}, \qquad q_{-} = e^{-x+y}, \qquad q_{+} = e^{-x-y}.$$

The sum $q_{-} + q_{+} = 2e^{-x}\cosh y$ allows defining

$$p_{-} = \frac{q_{-}}{q_{-}+q_{+}} = \frac{e^{y}}{2\cosh y}, \qquad p_{+} = \frac{q_{+}}{q_{-}+q_{+}} = \frac{e^{-y}}{2\cosh y}.$$

The common factor e^{-x} disappears. The distribution preserves the asymmetry between sheets, but not the common angular scale.

Definition 73.2 (Bilayer entropy)**.** The entropy of the oriented distribution is

$$S_{\mathrm{bi}}(y) := -p_{-}\log p_{-} - p_{+}\log p_{+} = \log(2\cosh y) - y\tanh y.$$

Proposition 73.3 (Parity and maximum of the bicover entropy)**.** *The function S_{bi} is even and satisfies*

$$S_{\mathrm{bi}}(-y) = S_{\mathrm{bi}}(y), \qquad S'_{\mathrm{bi}}(y) = -y\ \operatorname{sech}^{2} y, \qquad 0 < S_{\mathrm{bi}}(y) \le \log 2.$$

The maximum $\log 2$ *is attained only at $y = 0$, when both sheets have equal weight.*

Proof. Parity follows because cosh is even and $y\tanh y$ is also even. The direct derivation produces

$$\frac{\mathrm{d}}{\mathrm{d}y}\log(2\cosh y) = \tanh y, \qquad \frac{\mathrm{d}}{\mathrm{d}y}(y\tanh y) = \tanh y + y\operatorname{sech}^{2} y.$$

Therefore $S'_{\mathrm{bi}}(y) = -y\operatorname{sech}^{2} y$: the function increases on $(-\infty, 0)$, decreases on $(0, \infty)$, and takes the value $\log 2$ at the origin. Positivity is that of the entropy of a distribution with two strictly positive weights. □

73.3.2 Parity of the hexad-octad transport

Let

$$s_n(q_-, q_+) = q_-^n - q_+^n.$$

The leaf exchange is the involution

$$\mathsf{J}_{\mathrm{sh}} : (x, y) \longmapsto (x, -y),$$

which permutes $q_- \leftrightarrow q_+$. Hence,

$$s_n \circ \mathsf{J}_{\mathrm{sh}} = -s_n.$$

The functional constructed in section 51.2 is

$$\Gamma_{6\to 8}(A, C^*) = \frac{\pi A C^*}{180} + 12\big(S_{90}(q_-) - S_{90}(q_+)\big) - \big(S_{120}(q_-) - S_{120}(q_+)\big).$$

Theorem 73.4 (Theorem of double-layer parity)**.** *Under the exchange $C^* \mapsto -C^*$,*

$$\boxed{S_{\mathrm{bi}}(-C^*_{\mathrm{rad}}) = S_{\mathrm{bi}}(C^*_{\mathrm{rad}}),}$$

$$\boxed{\Gamma_{6\to 8}(A, -C^*) = -\Gamma_{6\to 8}(A, C^*).}$$

The same bilayer therefore produces an even informational reading and an odd geometric transport.

Proof. The first equality is proposition 73.3. In the second, the term $\pi A C^*/180$ changes sign, and each Lambert difference changes sign because its two arguments are interchanged. The complete combination is odd. □

73.3.3 Interpretation of the constitutive operator as coupling between vacuum, field, and response

Bilayer entropy and $\Gamma_{6\to 8}$ are not two names for the same number. The former quantifies how much weight the two orientations share after cancellation of the common scale. The latter preserves the orientation and incidence of the step $6 \to 8$. At the HMT point,

$$S_{\mathrm{bi}} = 0.69246069960358548\ldots \text{ nats}, \qquad \Gamma_{6\to 8} = 0.27400767269445927\ldots.$$

The link between information and geometry is that both readings factor through the same channels $q_\pm$, not that their values are equated.

The particle–antiparticle band of section 92.9 reproduces the same parity distinction: mass and the amount of correlation descend to the band quotient, whereas charge, orientation, and transport change sign. In the Cartan–Holst action, $\Gamma_{6\to 8}$ occupies the oriented coordinate; in the informational reading, S_{bi} counts the distribution between sheets. This explains why a single structure can preserve information and reverse orientation without conflating the two operations.

Tangential variation of the modular state and derivation of the areal law. The tangent variation of the modular state produces the first areal law; finite variations preserve the relative-entropy term.

73.4 Holographic-modular free energy and informational memory of geometry

73.4.1 Oriented Bilayer State $T_{A,y}$, Normalization ρ_y, and Separation between Intensity and Leaf Orientation

The angular response constructed in the preceding chapters contains two spectral data of complementary nature. The coordinate A_{rad} fixes the common intensity of the two leaves; the oriented coordinate

$$y = C^*_{\mathrm{rad}}$$

fixes its separation. Let P_+ and P_- be rank-one orthogonal projections on a two-dimensional Hilbert space $\mathcal{H}_{\mathrm{bi}}$, and define

$$I_{\mathrm{bi}} = P_+ + P_-, \qquad R = P_+ - P_-, \qquad R^2 = I_{\mathrm{bi}}. \tag{73.9}$$

The positive angular operator is

$$T_{A,y} = \exp(-A_{\mathrm{rad}} I_{\mathrm{bi}} - yR) = q_+ P_+ + q_- P_-, \qquad q_\pm = \exp(-A_{\mathrm{rad}} \mp y). \tag{73.10}$$

Its normalization removes exactly the scalar intensity and preserves the relative orientation:

$$\boxed{\rho_y = \frac{T_{A,y}}{\operatorname{Tr} T_{A,y}} = \frac{\exp(-yR)}{2\cosh y} = p_+(y)P_+ + p_-(y)P_-,} \tag{73.11}$$

where

$$p_+(y) = \frac{\mathrm{e}^{-y}}{2\cosh y}, \qquad p_-(y) = \frac{\mathrm{e}^{y}}{2\cosh y}. \tag{73.12}$$

The intensity A_{rad} remains in $\operatorname{Tr} T_{A,y}$ and in the determinant of the unnormalized operator; the state ρ_y represents the pure informational sector of the choice of sheet. This separation types two readers of the same antecedent and avoids attributing to a normalized probability the constitutive scale that was removed by normalization.

Definition 73.5 (Bilayer holographic-modular Hamiltonian)**.** The finite holographic-modular Hamiltonian of the oriented state is

$$\boxed{K_y = -\log \rho_y = \log(2\cosh y) I_{\mathrm{bi}} + yR.} \tag{73.13}$$

The scalar term normalizes the state, and the term yR preserves sheet provenance.

The designation *holographic–modular* declares a precise function: the total observable publishes occupancy, while the modular generator retains the distribution among sectors that made that occupancy possible. In finite dimension, K_y is a well-defined self-adjoint matrix. Its extension to the infinite system will be formulated through a local net and the GNS representation; the two residences remain distinct.

73.4.2 Exact spectral thermodynamics of the 2 sheets

The reduced Function of Partition and the oriented moment are

$$Z_{\mathrm{bi}}(y) = 2\cosh y, \qquad \langle R \rangle_y = \operatorname{Tr}(\rho_y R) = -\tanh y. \tag{73.14}$$

The von Neumann entropy is calculated without approximation:

$$\boxed{S(\rho_y) = -\operatorname{Tr}(\rho_y \log \rho_y) = \log(2\cosh y) - y\tanh y.} \tag{73.15}$$

Its parity and variation satisfy

$$S(\rho_{-y}) = S(\rho_y), \qquad \frac{\mathrm{d}}{\mathrm{d}y} S(\rho_y) = -y\ \operatorname{sech}^2 y. \tag{73.16}$$

The deficit relative to the uniform bilayer state is determined by

$$I_{\mathrm{or}}^{(2)}(y) = \log 2 - S(\rho_y) = y \tanh y - \log\cosh y \geq 0. \tag{73.17}$$

Equality occurs only at $y = 0$. The deficit measures the information retained by the polarization of the sheets, whereas the entropy measures the published probabilistic distribution.

Theorem 73.6 (Relative entropy of two orientations)**.** *For $y, z \in \mathbb{R}$, the faithful states of equation (73.11) satisfy*

$$\boxed{D(\rho_y \| \rho_z) = \log \frac{\cosh z}{\cosh y} + (y - z)\tanh y.} \tag{73.18}$$

In particular, sheet inversion has the exact cost

$$\boxed{D(\rho_y \| \rho_{-y}) = 2y \tanh y.} \tag{73.19}$$

Proof. From $\log \rho_y = -\log(2\cosh y) I_{\mathrm{bi}} - yR$ it follows.

$$\log \rho_y - \log \rho_z = \log \frac{\cosh z}{\cosh y} I_{\mathrm{bi}} + (z - y)R.$$

Taking the expectation in ρ_y and using $\langle R \rangle_y = -\tanh y$ yields equation (73.18). Substituting $z = -y$ eliminates the quotient of hyperbolic cosines and produces equation (73.19). The expression is positive because y and $\tanh y$ have the same sign. □

The symmetrized Jeffreys cost is

$$D(\rho_y \| \rho_{-y}) + D(\rho_{-y} \| \rho_y) = 4y \tanh y. \tag{73.20}$$

The local curvature of the exponential family is given by

$$\frac{\mathrm{d}^2}{\mathrm{d}y^2} \log Z_{\mathrm{bi}}(y) = \mathrm{Var}_{\rho_y}(R) = \operatorname{sech}^2 y. \tag{73.21}$$

Thus, the same oriented coordinate determines three quantities with different parities: $\langle R \rangle_y$ is odd; $S(\rho_y)$ is even; and the distance between orientations is positive and even as a function of the modulus of y. Geometry, information, and inversion preserve different components of the same state.

Corollary 73.7 (Separation of intensity and orientation)**.** *The determinant $\det T_{A,y} = \exp(-2A_{\mathrm{rad}})$ depends on the angular intensity, whereas the quotient $q_-/q_+ = \exp(2y)$, the moment $\langle R \rangle_y$, and $D(\rho_y \| \rho_{-y})$ depend on orientation. Therefore, the even reader leading to D_A and the odd reader leading to sheet memory are jointly reconstructible and remain typed.*

73.4.3 Double-thermofield purification and sheet conjugation

Let $(|+\rangle, |-\rangle)$ be a basis adapted to (P_+, P_-), and let $\overline{\mathcal{H}}_{\mathrm{bi}}$ be a declared copy. We define

$$|\,\mathrm{TFD}_y\rangle = \sqrt{p_+(y)}\,|+\rangle|\bar{+}\rangle + \sqrt{p_-(y)}\,|-\rangle|\bar{-}\rangle. \tag{73.22}$$

Proposition 73.8 (Bilayer purification)**.** *The vector of equation (73.22) is normalized and satisfies*

$$\mathrm{Tr}_{\overline{\mathcal{H}}_{\mathrm{bi}}} |\,\mathrm{TFD}_y\rangle\langle \mathrm{TFD}_y\,| = \rho_y. \tag{73.23}$$

The simultaneous permutation of the labels $+ \leftrightarrow -$ transports $|\,\mathrm{TFD}_y\rangle$ into $|\,\mathrm{TFD}_{-y}\rangle$.

Proof. The sum of the squares of the coefficients is $p_+(y) + p_-(y) = 1$. The partial trace eliminates the cross terms and leaves $p_+(y)P_+ + p_-(y)P_-$. Exchange of the labels permutes both coefficients, since $p_+(-y) = p_-(y)$. □

The purification proves an equality of entropies within the declared doubled system:

$$S(\rho_y) = S\big(\mathrm{Tr}_{\mathcal{H}_{\mathrm{bi}}} \,|\, \mathrm{TFD}_y\rangle\langle \mathrm{TFD}_y \,|\big)\,. \tag{73.24}$$

The thermofield-double copy has a mathematical function here: it exhibits a pure state whose reduction produces exactly the bilayer state. Its identification with two physical regions of a spacetime requires a factorization of observables and an additional geometric interface.

The bilayer TFD and the qutrit TFD of theorem 73.1 are related yet distinct constructions. The first purifies the orientation of two sheets; the second purifies the thirty-six qutrit links of the channels 90/120. Their confluence resides in the angular antecedent and in the provenance label, not in an identification of their Hilbert spaces.

73.4.4 Total Geometry and Modular Provenance

The number operators N_{90} and N_{120} commute. Areal geometry publishes the sum of occupations,

$$\widehat{\mathcal{A}} = \gamma_{\mathrm{HMT}} a_0 \ell_P^2 (N_{90} + N_{120}), \tag{73.25}$$

while the modular Hamiltonian of the boundary preserves its origin,

$$K_A - cI = \Delta_4^{\mathrm{mod}} (90N_{90} + 120N_{120}). \tag{73.26}$$

Let us define the dimensionless observables

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}. \tag{73.27}$$

Theorem 73.9 (Reconstruction joint of the channels)**.** *The pair (N, D), and hence the pair $(\widehat{\mathcal{A}}, K_A)$ once their scales have been fixed, exactly reconstructs the two occupation operators:*

$$\boxed{N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N.} \tag{73.28}$$

Proof. The linear system has matrix $\left(\begin{smallmatrix} 1 & 1 \\ 90 & 120 \end{smallmatrix}\right)$ with determinant 30. Its inverse gives equation (73.28). Commutativity of the number operators permits application of the identity in their joint functional calculus. □

The result formulates a concrete holography of reconstruction. The area determines the total geometric quantity; the modular Hamiltonian determines the weighted provenance; the pair recovers the sectoral distribution. Two states with the same area can carry distinct histories, and that difference remains visible in K_A. The coefficient 30 that makes the system invertible is the same completion defect between the channels 90 and 120.

Reconstruction requires retaining both observables. A compression that retained only N would identify all constant-sum pairs (N_{90}, N_{120}). A compression that retained only D would identify pairs of equal modular weight. The joint pair has rank two and preserves the relevant sectoral genealogy.

73.4.5 1st local law and finite balance of relative entropy

The finite formulation employs the relative entropy of operator states in the sense of Araki [5].

Let ρ_A be the boundary qutrit state of equation (73.4) and let $K_A = -\log \rho_A$. The areal decomposition proved in theorem 74.1 takes the form

$$K_A - cI = \beta_{90}\mathcal{A}_{90} + \beta_{120}\mathcal{A}_{120}, \qquad \frac{\beta_{120}}{\beta_{90}} = \frac{4}{3}. \tag{73.29}$$

For a differentiable curve of normalized states passing through ρ_A, the tangent variation satisfies

$$\boxed{\delta S = \beta_{90}\,\delta\langle\mathcal{A}_{90}\rangle + \beta_{120}\,\delta\langle\mathcal{A}_{120}\rangle.} \tag{73.30}$$

The quotient $4/3$ records the different informational weights of the two sectors; the same increment in total area may produce different entropic variations according to its channel of origin.

The finite formulation preserves the term eliminated by linearization. If σ is a state whose support is contained in that of ρ_A, then

$$\boxed{\Delta S = \beta_{90}\Delta\langle\mathcal{A}_{90}\rangle + \beta_{120}\Delta\langle\mathcal{A}_{120}\rangle - D(\sigma\|\rho_A).} \tag{73.31}$$

Proof. The definition of relative entropy provides

$$D(\sigma\|\rho_A) = -S(\sigma) + \mathrm{Tr}(\sigma K_A).$$

For ρ_A, the same expression is zero. Subtracting the two identities yields $\Delta S = \Delta\langle K_A\rangle - D(\sigma\|\rho_A)$. The scalar term in K_A cancels between normalized states, and equation (73.29) concludes the proof. □

The local law expresses the derivative of entropy at the reference state. The finite law expresses the exact balance among geometric response, entropic change, and informational distance. The positivity of D quantifies the convexity that separates the finite displacement from its tangent approximation.

73.4.6 Holographic-modular free energy of the horizon

Consider a horizon realization in which an areal radius R determines

$$E_\Lambda(R) = \frac{c^4 R}{2G}, \qquad k_B T_H(R) = \frac{\hbar c}{2\pi R}, \qquad \frac{S_H(R)}{k_B} = \frac{\pi R^2}{\ell_P^2}. \tag{73.32}$$

The identity $\ell_P^2 = G\hbar/c^3$ gives

$$\boxed{E_\Lambda(R) = T_H(R) S_H(R).} \tag{73.33}$$

For a finite perturbation σ of the reference state ρ_A, write

$$\Delta k_A = \mathrm{Tr}((\sigma - \rho_A)K_A), \qquad \Delta s_A = S(\sigma) - S(\rho_A), \tag{73.34}$$

and let us define the response quantities

$$\mathcal{E}_R(\sigma) = E_\Lambda(R) + k_B T_H(R)\Delta k_A, \qquad \mathcal{S}_R(\sigma) = S_H(R) + k_B \Delta s_A. \tag{73.35}$$

Theorem 73.10 (Free-Energy Identity in Holographic–Modular Form)**.** *Under the horizon realization equation (73.32), for every σ whose support is contained in that of ρ_A,*

$$\boxed{\mathcal{E}_R(\sigma) - T_H(R)\mathcal{S}_R(\sigma) = k_B T_H(R) D(\sigma\|\rho_A) \geq 0.} \tag{73.36}$$

Proof. The reference saturation equation (73.33) cancels the term $E_\Lambda - T_H S_H$. By definition,

$$\mathcal{E}_R - T_H \mathcal{S}_R = k_B T_H (\Delta k_A - \Delta s_A).$$

The finite relative-entropy identity gives $\Delta k_A - \Delta s_A = D(\sigma \| \rho_A)$, and Klein's inequality gives positivity. □

In the closure $R = \ell_P$, the Planck quantum $E_P = \hbar c/\ell_P$ yields

$$k_B T_H(\ell_P) = \frac{E_P}{2\pi}, \qquad E_\Lambda(\ell_P) = \frac{E_P}{2}, \tag{73.37}$$

and therefore

$$\boxed{\mathcal{E}_{\ell_P}(\sigma) - T_H(\ell_P)\mathcal{S}_{\ell_P}(\sigma) = \frac{E_P}{2\pi} D(\sigma \| \rho_A).} \tag{73.38}$$

The structural identity

$$E_P = k_B \Theta_{\mathrm{clk}} \log 3 \tag{73.39}$$

converts the defect coefficient into

$$\frac{E_P}{2\pi} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2\pi}. \tag{73.40}$$

The reference horizon saturates the balance; the finite deviation is measured by the informational cost of departing from its modular genealogy.

The realization also satisfies

$$E_\Lambda(\ell_P) t_P = \frac{\hbar}{2}, \qquad E_\Lambda(\ell_P) T_{108} = \frac{h}{2}, \tag{73.41}$$

when $t_P = \ell_P/c$ and $T_{108} = 2\pi t_P$. The half-action results from the coupling between thermal periodicity and areal geometry. This equality remains separate from the free-energy identity: the first fixes the quantum of the reference horizon; the second quantifies the perturbations of the modular state.

73.4.7 Confluence between areal quantity and informational quantity

The hexad–octad transition publishes the geometric quantum

$$\delta\mathcal{A} = \gamma_{\mathrm{HMT}} a_0 \ell_P^2, \tag{73.42}$$

and the CT108 clock publishes the information quanta

$$E_P = k_B \Theta_{\mathrm{clk}} \log 3. \tag{73.43}$$

Its quotient defines the tension tipada

$$\boxed{\mathcal{T}_{I/A} = \frac{E_P}{\delta\mathcal{A}} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{\gamma_{\mathrm{HMT}} a_0 \ell_P^2}.} \tag{73.44}$$

The equation assigns a conversion between a ternary decision and a unit of geometry. The numerator belongs to the action–clock–information branch; the denominator belongs to the hexad–octad–area branch. Both descend from the same enriched state and converge in gravity after preserving their domains.

The pair

$$\left(\widehat{\mathcal{A}}, K_A\right) \tag{73.45}$$

reconstructs quantity and origin; the pair

$$(\delta\mathcal{A}, E_P) \tag{73.46}$$

relates elementary geometry and informational cost. The first pair is spectral; the second is dimensional. Together they describe how a discrete structure of orientation is published as area, energy and entropy.

73.4.8 Local UHF Network and Modular Generator in the GNS Representation

Let $(\mathcal{A}_m, \iota_m)$ be a net of local matrix algebras with

$$\mathcal{A}_m \simeq M_{9^m}(\mathbb{C}), \qquad \iota_m(a) = a \otimes I_9, \qquad \mathcal{A}_{\mathrm{UHF}} = \varinjlim_m \mathcal{A}_m. \tag{73.47}$$

A family of local states ω_m defines a global state ω when it satisfies

$$\omega_{m+1} \circ \iota_m = \omega_m. \tag{73.48}$$

In each finite cut can be written

$$\omega_m(a) = \mathrm{Tr}(\rho_m a), \qquad K_m = -\log \rho_m. \tag{73.49}$$

The family (K_m) constitutes the local residence of the holographic-modular Hamiltonian.

In the GNS representation $(\pi_\omega, \mathcal{H}_\omega, \Omega_\omega)$, modular theory is expressed through the modular operator Δ_ω and the group

$$\sigma_t^\omega(x) = \Delta_\omega^{it} x \Delta_\omega^{-it}, \qquad x \in \pi_\omega(\mathcal{A}_{\mathrm{UHF}})''. \tag{73.50}$$

The generator $-\log \Delta_\omega$ may be unbounded and belongs to the standard representation; a global trace-class density matrix within the UHF does not, in general, form part of this construction.

The expectativa tracial nonadica

$$E_m = \mathrm{id} \otimes \tau_9 : \mathcal{A}_{m+1} \longrightarrow \mathcal{A}_m \tag{73.51}$$

preserves the unit and constitutes the canonical matrix compression reader. Compatibility of a modular state additionally requires

$$\omega_m \circ E_m = \omega_{m+1} \quad \text{in the declared subspace,} \tag{73.52}$$

or the equivalent condition appropriate to the inclusion used. The traciality of the reader does not automatically turn a nontracial Gibbs product into a compatible family.

The theorem 75.1 proves, under faithful persistence of the two weights $90\Delta_4^{\mathrm{mod}}$ and $120\Delta_4^{\mathrm{mod}}$, positive asymptotic density of both channels, factoriality, and the absence of additional quotients, that the ratio group is

$$90\Delta_4^{\mathrm{mod}}\mathbb{Z} + 120\Delta_4^{\mathrm{mod}}\mathbb{Z} = 30\Delta_4^{\mathrm{mod}}\mathbb{Z} \tag{73.53}$$

and that the hyperinfinite ITPFI closure is of type

$$\boxed{III_{\lambda_\partial}, \qquad \lambda_\partial = \exp(-30\Delta_4^{\mathrm{mod}}).} \tag{73.54}$$

The statement classifies the specified product network. A modification of the ratio group, asymptotic disappearance of a channel, or loss of factoriality requires recalculating the type. In particular, the tracial II_1 closure of the UHF algebra and the type-III modular closure correspond to different states and representations; both are operatorial readers of the nonadic system, and neither replaces the APP–TRIT–TPK antecedent.

73.4.9 Exact gravitational closure identities and tensor realization conditions

The architecture of this chapter distinguishes the following results:

(i) The bilayer normalization, the Hamiltonian K_y, the entropy $S(\rho_y)$, and the identity $D(\rho_y\|\rho_{-y}) = 2y\tanh y$ are *exact new formalization* of the angular response already constructed.

(ii) The TFD bilayer is a *exact new formalization* in the declared doubled space. Interpreting the copy as another physical region requires a subsequent geometric factorization.

(iii) The reconstruction 90/120, the qutrit DFT, the first local law, the finite identity, and the modular classification under their hypotheses are *resultados exactos* of the preceding operatorial construction.

(iv) The horizon equality $E_\Lambda = T_H S_H$ is exact in the declared de Sitter chart. Its composition with the qutrit state to form equation (73.36) is a *interface physical conditioned* to that realization.

(v) The intertwiner among horizon microstates, boundary TFD, and hyperbolic eigenspaces is classified by spectrum and multiplicity in theorem 73.11: typed coincidence produces unitary equivalence, and its failure proves the obstruction.

Estatuto probatorio

The spectral identities of the family ρ_y, its purification, the linear reconstruction of the sectors 90/120, and the finite balance with relative entropy are exact in finite dimension. The type-III classification is exact under the four hypotheses formulated in this construction. Gravitational free energy is asserted in the horizon realization of equation (73.32); it preserves the proper residence of the modular state and retains cosmological dynamics as a subsequent promotion.

Falsification criterion

The corresponding assertions are refuted by: a spectrum of ρ_y that does not sum to one; a computation of $D(\rho_y\|\rho_{-y})$ different from $2y\tanh y$; a partial trace of the TFD that does not produce ρ_y; two distinct pairs (N_{90}, N_{120}) with the same (N, D); a finite perturbation that violates equation (73.31); a horizon chart that fails to satisfy $E_\Lambda = T_H S_H$; or an infinite network whose ratio group differs from $30\Delta_4^{\mathrm{mod}}\mathbb{Z}$ under the declared hypotheses. An operator promotion is also refuted by replacing the local network with a nonexistent global density matrix or by identifying the tracial closure II_1 with the type-III modular closure.

73.5 Spectral Classification of the Intertwiner among the Horizon, Thermofield-Double Purification, and Perron Dynamics

Let $\mathcal{H}_{\mathrm{H}}$, $\mathcal{H}_{\mathrm{TFD}}$, and $\mathcal{H}_{\mathrm{P}}$ be the cyclic subspaces generated, respectively, by the horizon microstates, the thermofield-double purification, and the positive Perron operator. Denote by A_{H}, A_{TFD}, and A_{P} their restricted self-adjoint operators, and by $m_X(\lambda)$ the spectral multiplicity of λ in the sector X.

Theorem 73.11 (Existence and uniqueness by spectral entangler calibers)**.** *There exists a surjective isometry*

$$U : \mathcal{H}_{\mathrm{H}} \longrightarrow \mathcal{H}_{\mathrm{TFD}} \longrightarrow \mathcal{H}_{\mathrm{P}}$$

that intertwines the 3 *operators if and only if, after applying the declared energy and memory normalizations,*

$$\mathrm{spec}(A_{\mathrm{H}}) = \mathrm{spec}(A_{\mathrm{TFD}}) = \mathrm{spec}(A_{\mathrm{P}}), \qquad m_{\mathrm{H}}(\lambda) = m_{\mathrm{TFD}}(\lambda) = m_{\mathrm{P}}(\lambda)$$

for every λ in the common spectrum. When these conditions hold, the intertwiner is determined up to a unitary transformation on each eigenspace of multiplicity greater than 1.

Proof. If $UA_X = A_Y U$, unitary equivalence preserves the spectrum and its multiplicities. Conversely, for each λ one chooses orthonormal bases of the eigenspaces of equal dimension and defines U_λ by matching those bases. The orthogonal sum $U = \bigoplus_\lambda U_\lambda$ is unitary and intertwines the operators. The residual freedom is exactly the product of the unitary groups of the degenerate eigenspaces. □

The existence problem is thus closed by classification: coincidence of spectra and multiplicities produces the intertwiner; failure to satisfy them proves the obstruction. An isolated scalar equality does not replace these conditions.

The area and the modular Hamiltonian form a pair conceptually analogous to product and quotient in the vacuum.

The area operator determines total occupancy. The modular Hamiltonian preserves the sectoral provenance of that occupancy.

Two families of channels appear at the boundary: 90 and 120. Each has its occupancy operators. The area operator is constructed from the sum:

$$\frac{\widehat{\mathcal{A}}_{\text{phys}}}{\ell_P^2} = \gamma_{\text{BI}} a_0 (N_{90} + N_{120}).$$

Area counts the total number of excitations. Whether an excitation comes from channel 90 or channel 120, the elementary area is the same. Geometrically, both contribute to the same total.

The modular holographic Hamiltonian introduces an additional sectorial weighting:

$$K_{\text{HHM}} - cI = \Delta_4^{\text{mod}} (90 N_{90} + 120 N_{120}).$$

Count the occupations and also weigh each excitation by the channel from which it comes.

This is why the area and the Hamiltonian commute: both read the same occupation operators and contain complementary information.

The spectrum of the area operator is invariant with respect to sectoral provenance, whereas the modular Hamiltonian distinguishes it.

The area operator determines the total number of excitations. The weighted modular value determines their distribution between the two genealogies. The joint conservation of both observables exactly reconstructs the sectoral decomposition.

This is an especially sharp realization of the holographic idea. The boundary publishes a minimal set of observables from which the pertinent information of the interior can be recovered.

Here holography consists in identifying which pair of boundary observables exactly reconstructs which internal data.

The area operator publishes geometric magnitude, and the modular Hamiltonian publishes sectorial genealogy. The pair of observables reconstructs the complete information of the sectors 90/120.

The reduced boundary state furthermore converts that Hamiltonian into a true modular generator:

$$K_{\text{HHM}} = -\log \rho_A.$$

Thermofield-double purification shows that the entropy of the reduced state is exactly entanglement entropy within the declared doubled system. There is an enlarged pure state whose partial trace produces the boundary state and explicitly realizes the thermal identity.

Then appears the oriented information deficit:

$$I_{\text{or}} = 36 \log 3 - S(\rho_A).$$

The 36 trits would represent the maximum capacity if all states were uniform. The difference measures how much oriented information is preserved by the actual distribution of weights 90/120.

The total entropy quantifies uncertainty. The deficit relative to the maximum quantifies the residual oriented structure.

The first modular law translates that structure into geometry:

$$\delta S = \beta_{90}\,\delta\langle \mathcal{A}_{90}\rangle + \beta_{120}\,\delta\langle \mathcal{A}_{120}\rangle,$$

with

$$\frac{\beta_{120}}{\beta_{90}} = \frac{4}{3}.$$

The change in entropy depends jointly on the change in total area and the sector of provenance. Two variations with the same geometric increment may have different informational responses if they arise from different channels.

This dependence establishes the geometric conservation of memory.

For finite variations, relative entropy appears as a positive correction term. The exact extension of the law incorporates the difference between the exact variation and its linear approximation through a positive quantity.

Outside the infinitesimal regime, this positive correction determines the nonlinear cost of departure from the reference state and quantifies the contribution of genealogical memory to the finite variation.

Finally, the relation

$$E_P = k_B \Theta_{\mathrm{clk}} \log 3$$

and the quantum areal

$$\delta\mathcal{A} = \gamma_{\mathrm{BI}} a_0 \ell_P^2$$

allow the definition of a conversion tension between energetic information and geometry:

$$\mathcal{T}_{I/A} = \frac{E_P}{\delta\mathcal{A}}.$$

The exact ratio between the informational energy quantum and the geometric area quantum is expressed in the declared normalization.

For this reason, the modular holographic Hamiltonian is a central component within an atlas of complementary readers. Its specific function is to preserve the provenance that the total geometry integrates into a sum.

The area operator determines the total occupation.

The modular Hamiltonian determines the sectoral origin.

Quantum entropy quantifies the published information.

The relative entropy quantifies the cost of the genealogical transition.

73.6 Joint reconstruction of occupancy, provenance, and modular entropy in the channels 90/120

The information retained by reduction to the region is published through the modular Hamiltonian. The starting structure of this reading is declared to be

$$\Delta_4^{\mathrm{mod}} = \frac{(A - C^*)\pi/180}{9 \cdot 90}\left(1 - \frac{7}{12}\frac{\pi}{729}\right), \qquad w_{90} = 90\Delta_4^{\mathrm{mod}}, \quad w_{120} = 120\Delta_4^{\mathrm{mod}},$$

we define

$$K_{\mathrm{link}}(w) = wN, \qquad \rho_{\mathrm{link}}(w) = \frac{\mathrm{diag}(1, e^{-w}, e^{-2w})}{1 + e^{-w} + e^{-2w}},$$

$$\rho_A = \bigotimes_{e \in \partial A_{90}} \rho_{\mathrm{link}}(w_{90}) \otimes \bigotimes_{e \in \partial A_{120}} \rho_{\mathrm{link}}(w_{120}), \qquad K_A = -\log \rho_A. \tag{73.55}$$

Then

$$K_A = \sum_{e \in \partial A} w_e N_e + c\mathbf{1}, \qquad S(\rho_A) = 18S(w_{90}) + 18S(w_{120}),$$

and the evaluation of that starting structure gives

$$S(\rho_A) = 39.54837320881808\ldots \text{ nats} = 57.05624190358778\ldots \text{ bits}.$$

The quantity $S(\rho_A)$ is the von Neumann entropy of the declared mixed product. A global purification identifies it with an entanglement entropy across the cut; without that purification, its canonical type is reduced modular entropy. Thus, γ_{HMT} fixes the quantum of area/torsion, S_{tri} counts the areal capacity, S_{bi} quantifies the allocation between sheets, and $S(\rho_A)$ measures modular mixing. Area operator, spectrum, and intertwiner belong to a single boundary construction.

73.6.1 Genealogical memory and informational content of a reading

The area operator brings together boundary occupations. The weighted observable adds their sectoral provenance. This difference expresses a physical principle of the manuscript: accessible information depends on the map that publishes the state. In APP, the residue and quotient jointly preserve the integer operation; in TPK, the visible phase coexists with orientation and the increment of memory. The physical realization transports that same distinction between state, observable and recovery register; identity (73.57) makes explicit the information preserved by the reading.

Let Ω be a finite set of states reached by the update under consideration. A reader $q : \Omega \to Y$ publishes the observable coordinate and $M : \Omega \to \mathcal{M}$ preserves the memory of the fibre: the relevant sheet, orientation, quotient, carry and route. For a distribution p over those states, denote by H_p the dimensionless entropy, with the natural logarithm.

Proposition 73.12 (Informational resolution of the fiber)**.** *If (q, M) is injective on the support of p, then*

$$\mathsf{H}_p(X) = \mathsf{H}_p(q(X)) + \mathsf{H}_p(X \mid q(X)), \tag{73.56}$$

$$\mathsf{H}_p(X \mid q(X), M(X)) = 0. \tag{73.57}$$

Proof. Factorization of the joint distribution into the visible distribution and the conditional distribution over the fibre gives the first equality. Injectivity provides an inverse on the image of (q, M); each published pair determines a unique state of the support and its conditional distribution is concentrated on that state. □

Equation (72.20) implements this mechanism for the two aggregate occupations: N publishes the total and D resolves its sectoral distribution. States $(N_{90}, N_{120}) = (1, 0)$ and $(0, 1)$ share the aggregate area and are distinguished by the second observable. Under an equiprobable distribution over that pair, reading

N alone leaves $\log 2$ nats of uncertainty; the pair (N, D) resolves it exactly. The assertion concerns those occupations. The microhistories within each sector retain their additional register.

The interpretation of edge memory is thus determined by a concrete recovery. A reduction can hide information that the joint state continues to transport. For a bijective update U, the equality $\mathsf{H}_p(X \mid U(X)) = 0$ expresses logical reversibility. A physical memory-discarding or reset operation, for its part, has its own information and energy balance. Entanglement is evaluated with respect to the bipartition and reduced state specified in the preceding section.

73.6.2 Areal and volumetric sheets: incidence, growth, and measure

The areal–volumetric distinction has a dynamic realization in the TPK calendar. The block $(+1, -1, 0)$, applied to the modes Σ, Π through

$$+1 : m \mapsto \Sigma, \qquad -1 : m \mapsto \Pi, \qquad 0 : m \mapsto m,$$

produces the cyclic orbit (Σ, Π, Π). The geometric reader publishes $\Sigma \mapsto \mathscr{H}_{\mathrm{ar}}$ and $\Pi \mapsto \mathscr{H}_{\mathrm{vol}}$. Their consecutive transitions fix the incidence

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad N_9 = 3F_{\mathrm{av}}, \quad N_{27} = 9F_{\mathrm{av}}, \quad N_{108} = 36F_{\mathrm{av}}. \tag{73.58}$$

Indeed, the cycle contains one transition of each type $\Sigma \to \Pi$, $\Pi \to \Pi$, $\Pi \to \Sigma$. The larger calendars repeat this block with the indicated multiplicities.

The associated symbolic envelope allows every concatenation admitted by F_{av}. Its number of paths depends on powers of that matrix. With $F_0 = 0$, $F_1 = 1$, induction gives

$$F_{\mathrm{av}}^{n} = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}, \qquad h_{\mathrm{top}} = \log \varphi. \tag{73.59}$$

The matrix identity uses the Fibonacci recurrence. Exponential growth is fixed by the Perron root φ of the incidence already constructed.

Proposition 73.13 (Stationary distribution of the sheets)**.** *The maximal-entropy measure of the symbolic envelope has weights*

$$\mu_{\mathrm{ar}} = \frac{1}{1+\varphi^2}, \qquad \mu_{\mathrm{vol}} = \frac{\varphi^2}{1+\varphi^2}, \qquad \frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}. \tag{73.60}$$

Proof. The positive vector $r = (1, \varphi)$ satisfies $F_{\mathrm{av}} r = \varphi r$. The transition probabilities $P_{ij} = (F_{\mathrm{av}})_{ij} r_j / (\varphi r_i)$ sum to one. Symmetry of F_{av} gives stationary weights proportional to r_i^2. Their normalization produces (73.60). In the stationary mean, $-\log P_{ij} = \log \varphi + \log r_i - \log r_j$ on the allowed edges. The final two terms cancel, and the entropy per transition is $\log \varphi$, equal to the topological entropy in (73.59). □

The periodic calendar and its symbolic envelope constitute two explicit objects: the former has chronological frequencies $(1/3, 2/3)$; the latter admits the concatenations of the incidence and has the measure (73.60). This separation allows each quantity to be assigned its physical-mathematical meaning. The ratio φ^{-2} characterizes the distribution of the sheets in that measure; $\log \varphi$ characterizes the growth of its permitted histories. The angular boundary reading subsequently incorporates the corresponding regional coordinate. The construction distinguishes volumetric growth, areal publication and transport memory.

73.6.3 Admissible continuations and survival information

Given a TPK state x, let $\Omega_n(x)$ be the finite set of its continuations of length n admitted by the prolongation rule. Restrictions between levels preserve the prefixes. A compatible family of probabilities p_n, obtained from the specified statistical reader, defines the continuation uncertainty

$$s_n(x) = -\sum_{\omega \in \Omega_n(x)} p_n(\omega) \log p_n(\omega). \tag{73.61}$$

Compatibility requires the probability of a prefix to be the sum of the probabilities of its prolongations. In the preceding envelope, the stationary measure provides a family of this kind.

Proposition 73.14 (Informational balance of refinement)**.** *For the preceding compatible family,*

$$0 \le s_n(x) \le \log |\operatorname{supp} p_n|, \tag{73.62}$$

$$s_{n+1}(x) - s_n(x) = \mathsf{H}(X_{n+1} \mid X_n) \ge 0. \tag{73.63}$$

The upper bound is attained by the uniform distribution on the support. The increment is zero when every prefix of positive probability determines its prolongation with probability one.

Proof. The elementary entropy inequality for a finite distribution gives the first line. Since X_n is the restriction of X_{n+1}, factoring probabilities over each prolongation fiber gives $\mathsf{H}(X_{n+1}) = \mathsf{H}(X_n) + \mathsf{H}(X_{n+1} \mid X_n)$. Each conditional entropy is nonnegative and vanishes exactly for a point distribution. □

Continuations remaining admissible thus have precise informational content. Their multiplicity and weights describe the residual uncertainty of the reading at finite depth. A realized history also preserves its orientation and memory. Informational entropy, reduced-state entropy, and thermodynamic entropy are linked through their respective readers; each retains the domain information necessary for its interpretation.

73.7 Areal–volumetric incidence and topological entropy

The TPK calendar induces the hinge between the additive and multiplicative modes. In the primitive block

$$\tau_3 = (+1, -1, 0),$$

the rule

$$+1 : m \mapsto \Sigma, \qquad -1 : m \mapsto \Pi, \qquad 0 : m \mapsto m$$

produces the cyclic orbit (Σ, Π, Π). The geometric reader

$$\Sigma \longmapsto \mathscr{H}_{\mathrm{ar}}, \qquad \Pi \longmapsto \mathscr{H}_{\mathrm{vol}}$$

transports these modes to the areal and volumetric sheets.

Theorem 73.15 (Necessary incidence of the sheets)**.** *In the order* $(\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}})$*, the primitive incidence matrix is*

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{73.64}$$

Calendars of lengths $9, 27, 108$ *yield*

$$N_9 = 3F_{\mathrm{av}}, \qquad N_{27} = 9F_{\mathrm{av}}, \qquad N_{108} = 36F_{\mathrm{av}}.$$

Proof. The consecutive pairs of the cycle are $\Sigma \to \Pi$, $\Pi \to \Pi$, and $\Pi \to \Sigma$. Each occurs once, and $\Sigma \to \Sigma$ does not occur. This fixes all four entries of F_{av}. The longer calendars contain, respectively, three, nine, and thirty-six copies of the primitive block. □

Theorem 73.16 (Fibonacci law and measure of maximal entropy)**.** *For $n \geq 1$,*

$$F_{\mathrm{av}}^{n} = \begin{pmatrix} F_{n-1} & F_{n} \\ F_{n} & F_{n+1} \end{pmatrix}. \tag{73.65}$$

The one-step subshift defined by F_{av} has

$$\boxed{h_{\mathrm{top}} = \log \varphi}, \qquad \boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}}. \tag{73.66}$$

Proof. The matrix identity follows by induction from $F_{n+1} = F_n + F_{n-1}$. The Perron root of F_{av} is φ, hence $h_{\mathrm{top}} = \log \varphi$. Since the matrix is symmetric, the Parry weights [239] are proportional to the squared components of a Perron vector $(1, \varphi)$, that is, to $(1, \varphi^2)$. □

The expressions $\log 3$ and $\log \varphi$ are thus distinguished by their genealogy. The first quantifies a uniform local choice among three states; the second measures the growth of histories allowed by sheet incidence. The areal–volumetric relation is a property of the complete return and therefore appears with exponent two.

73.7.1 Stationary distribution and variational characterization

Let X_{av} be the space of two-sided sequences over $\{\mathrm{ar}, \mathrm{vol}\}$ whose consecutive pairs have positive incidence in F_{av}. It is the one-step-memory envelope of the mode calendar: it retains the admissible pairs while allowing all concatenations compatible with them. Its stationary measure weights that space of histories; the chronological frequency of the orbit (Σ, Π, Π) remains, separately, $(1/3, 2/3)$.

Proposition 73.17 (Explicit characterization of the measure of maximal entropy)**.** *With $r = (1, \varphi)$, the stochastic matrix and its stationary distribution are*

$$P_{ij} = \frac{(F_{\mathrm{av}})_{ij} r_j}{\varphi r_i}, \qquad P = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}, \qquad \pi_{\mathrm{av}} = \frac{(1, \varphi^2)}{1 + \varphi^2}. \tag{73.67}$$

The stationary Markov measure μ determined by these data assigns to each admissible cylinder of n transitions

$$\mu[i_0 \dots i_n] = \frac{r_{i_0} r_{i_n}}{(1 + \varphi^2)\varphi^{n}}. \tag{73.68}$$

It is the unique stationary measure on X_{av} with maximal entropy rate, and that rate is $\log \varphi$.

Proof. The identity $\varphi^2 = \varphi + 1$ implies $\varphi^{-2} + \varphi^{-1} = 1$, so the rows of P sum to one. Direct substitution verifies $\pi_{\mathrm{av}} P = \pi_{\mathrm{av}}$. Both cross-transitions have positive probability; the chain is irreducible, and the self-transition at vol makes it aperiodic. The stationary distribution is also obtained by solving the two linear equations and the normalization, which give the unique solution displayed above. Multiplication of $\pi_{i_0} \prod_{k=0}^{n-1} P_{i_k i_{k+1}}$ cancels the intermediate factors r_{i_k} and proves (73.68).

For maximality, let ν be any stationary measure on X_{av}, and let $q(j \mid \mathcal{P})$ be the conditional distribution of X_1 given the entire past $\mathcal{P} = (\dots, X_{-1}, X_0)$. Its support is contained in that of the row $P_{X_0,\cdot}$. For finite distributions, the relative divergence $D(q\|p) = \sum_j q_j \log(q_j/p_j)$ is nonnegative and vanishes exactly when $q = p$. This property follows from concavity of the logarithm, with the convention $0 \log 0 = 0$. On admissible pairs,

$$\log P_{ij} = \log r_j - \log r_i - \log \varphi.$$

Stationarity cancels the expectation of $\log r_{X_1} - \log r_{X_0}$. Hence

$$h(\nu) = H_\nu(X_1 \mid \mathcal{P}) = \log\varphi - \mathbb{E}_\nu D\big(q(\cdot \mid \mathcal{P}) \| P_{X_0,\cdot}\big) \le \log\varphi. \tag{73.69}$$

The identity between entropy rate and entropy conditional on the past follows from the chain rule on finite blocks and the decreasing limit of their conditional entropies; the finite alphabet ensures that all of them lie between zero and $\log 2$.

The constructed measure μ is Markov with transition matrix P, so the divergence term vanishes and $h(\mu) = \log\varphi$. If another stationary measure attains that rate, the divergence vanishes almost surely: its conditional distribution of the future depends only on X_0 and agrees with P. It is therefore the same stationary chain, whose unique initial distribution is π_{av}. This proves uniqueness. □

Formula (73.69) specifies exactly what is maximized: entropy per transition of the stated symbolic envelope. The ratio $\mu_{\mathrm{ar}}/\mu_{\mathrm{vol}} = \varphi^{-2}$ arises from its stationary weights. The periodic chronological orbit has zero entropy rate and retains its own temporal distribution; both objects remain defined on their respective domains.

Chapter 74

1st areal modular law and finite extension through relative entropy

The first modular law relates variations of entropy and area within the declared finite system. Its nonlinear extension retains the positive relative-entropy defect and therefore does not conflate tangent equality with global identity.

74.1 1st modular law for area variations

Let us define the two normalized areas

$$\mathcal{A}_m = \gamma_{\mathrm{HMT}} a_0 N_m, \qquad m \in \{90, 120\}. \tag{74.1}$$

Then

$$K^{(A)}_{\mathrm{HHM}} - cI = \beta_{90}\mathcal{A}_{90} + \beta_{120}\mathcal{A}_{120}, \qquad \beta_m = \frac{m\Delta_4^{\mathrm{mod}}}{\gamma_{\mathrm{HMT}} a_0}. \tag{74.2}$$

The terminal values are

$$\beta_{90} = 5.97264854010709299146517988889\ldots, \tag{74.3}$$

$$\beta_{120} = 7.96353138680945732195357318 52\ldots, \qquad \frac{\beta_{120}}{\beta_{90}} = \frac{4}{3}. \tag{74.4}$$

Theorem 74.1 (First modular law in areal variables)**.** *For a differentiable family of normalized states $\rho(\varepsilon)$ passing through ρ_A, while keeping $\Delta_4^{\mathrm{mod}}, \gamma_{\mathrm{HMT}}, a_0$ fixed,*

$$\boxed{\delta S = \beta_{90}\,\delta\langle\mathcal{A}_{90}\rangle + \beta_{120}\,\delta\langle\mathcal{A}_{120}\rangle.} \tag{74.5}$$

Proof. The first entanglement law in the reference state is $\delta S = \delta\langle -\log\rho_A\rangle$. The scalar term cI does not contribute because $\delta\,\mathrm{Tr}\,\rho = 0$. Substituting equation (74.2) proves the identity. □

The formula is local in state space. For finite changes, relative entropy appears; omitting it would turn a tangent identity into a false claim of global linearity.

Theorem 74.2 (Finite Identity with a Defect Term)**.** *For every state σ whose support is contained in that of ρ_A,*

$$\boxed{S(\sigma) - S(\rho_A) = \beta_{90}\Delta_\sigma\langle\mathcal{A}_{90}\rangle + \beta_{120}\Delta_\sigma\langle\mathcal{A}_{120}\rangle - D(\sigma\|\rho_A),} \tag{74.6}$$

where $D(\sigma\|\rho_A) = \operatorname{Tr}\sigma(\log\sigma - \log\rho_A) \geq 0$. In particular, the linear variation of theorem 74.1 is the tangent term of this identity.

Proof. By definition and by $K^{(A)}_{\mathrm{HHM}} = -\log\rho_A$,

$$D(\sigma\|\rho_A) = -S(\sigma) + \operatorname{Tr}(\sigma K^{(A)}_{\mathrm{HHM}}).$$

For $\sigma = \rho_A$, the left-hand side is zero and $S(\rho_A) = \operatorname{Tr}(\rho_A K^{(A)}_{\mathrm{HHM}})$. Subtracting the two identities gives

$$S(\sigma) - S(\rho_A) = \Delta_\sigma\langle K^{(A)}_{\mathrm{HHM}}\rangle - D(\sigma\|\rho_A).$$

The scalar cI cancels between normalized states; substituting equation (74.2) yields equation (74.6). The positivity of relative entropy is Klein's inequality. □

The correction $D(\sigma\|\rho_A)$ measures the informational distance between the actual state and the reference modular state. Thus, the first law loses no content upon leaving the infinitesimal regime: it becomes an exact identity with a controlled positive defect.

Inductive persistence of modular weights and factorial classification of the limit. The inductive persistence of the modular weights leads to infinite operator closure and its factorial classification.

74.1.1 Equation of state for sectorial information

The incidence already constructed provides eighteen tritic factors in each sector. This multiplicity allows the relation between area, the occupation distribution, and the entropy of the preceding purification to be written explicitly. We retain the reduced state defined there and abbreviate $\Delta = \Delta_{\mathrm{mod}}$. For $m \in \{90, 120\}$, put

$$x_m = e^{-m\Delta}, \qquad z_m = 1 + x_m + x_m^2, \qquad f_m = \frac{x_m + 2x_m^2}{z_m}, \qquad v_m = \frac{x_m + 4x_m^2}{z_m} - f_m^2. \tag{74.7}$$

Here f_m and v_m are, respectively, the mean and variance of the occupation of one factor in sector m. The parameter Δ preserves the status and normalization of the previously specified reduced state.

74.1.1.1 Bipartite quantum purification of the incidence sectors

The preceding Schmidt decomposition is made concrete on each link. For a finite real weight w, define

$$z(w) = 1 + e^{-w} + e^{-2w}, \qquad \rho(w) = \frac{1}{z(w)}\sum_{n=0}^{2} e^{-wn}|n\rangle\langle n|.$$

The sectorial weights are $w_m = m\Delta$, with $m = 90, 120$; hence $z(w_m) = z_m$.

Proposition 74.3 (Thermofield-double purification of sectorial incidence)**.** *The normalized vector*

$$|\operatorname{TFD}(w)\rangle = \frac{1}{\sqrt{z(w)}}\sum_{n=0}^{2} e^{-wn/2}|n\rangle_A \otimes |n\rangle_{\bar{A}} \tag{74.8}$$

purifies $\rho(w)$. The product

$$|\Psi_\Delta\rangle = |\operatorname{TFD}(90\Delta)\rangle^{\otimes 18} \otimes |\operatorname{TFD}(120\Delta)\rangle^{\otimes 18} \tag{74.9}$$

has reduction $\rho_A(\Delta)$ on the thirty-six original links. Its entanglement entropy for the bipartition $A \mid \bar{A}$ is $s(\Delta)$.

Proof. The squared norm is $z(w)^{-1}\sum_{n=0}^{2} e^{-wn} = 1$. In the partial trace, orthogonality of the second factor eliminates terms with distinct indices; the remaining terms form $\rho(w)$. The partial trace commutes with the tensor product. One thus obtains $\rho(90\Delta)^{\otimes 18} \otimes \rho(120\Delta)^{\otimes 18}$, which coincides with the normalized state defined previously. Equality between the entropy of a reduction and the entanglement of this purification is read directly from its Schmidt coefficients. □

The two factors of the bipartition are determined within the construction. The physical realization of the second factor preserves that subsystem identification and its algebra of observables.

74.1.1.2 Occupation moments and information content

Proposition 74.4 (Mean area and entropy of the sectorial purification)**.** *In this finite family of states,*

$$\langle N\rangle_\Delta = 18(f_{90} + f_{120}), \tag{74.10}$$

$$\langle D\rangle_\Delta = 18(90 f_{90} + 120 f_{120}), \tag{74.11}$$

$$\frac{\langle \widehat{\mathcal{A}}\rangle_\Delta}{\ell_P^2} = 18\gamma_{\mathrm{HMT}} a_0 (f_{90} + f_{120}), \tag{74.12}$$

$$s(\Delta) = 18\log z_{90} + 18\log z_{120} + \Delta\langle D\rangle_\Delta. \tag{74.13}$$

The dimensional entropy is $S(\Delta) = k_B s(\Delta)$, with the thermal transducer of Section 48.5.

Proof. In each factor, the normalized weights are $(1, x_m, x_m^2)/z_m$. Their first moment gives f_m, and their second moment gives the first fraction in v_m. Tensor factorization and additivity of the number operators produce the first three identities. Finally, $\log \rho_A = -(\log Z)I - \Delta D$, with $Z = z_{90}^{18} z_{120}^{18}$. Taking the trace against $-\rho_A$ gives (74.13). The purification specified previously has this same entanglement entropy. □

Loss of uniformity has its own quantitative reading. In dimension $d_\partial = 3^{36}$, let $\tau_\partial = I/d_\partial$. Define

$$I_{\mathrm{or}}(\Delta) = 36\log 3 - s(\Delta) = D\big(\rho_A(\Delta)\|\tau_\partial\big) \geq 0. \tag{74.14}$$

The equality is obtained by substituting $\log \tau_\partial = -36\log 3\, I$. If p_ν are the eigenvalues of ρ_A, the convexity of $t\log t$ gives $\sum_\nu p_\nu \log(d_\partial p_\nu) \geq 0$, with equality exactly for the uniform state. For this family, this occurs at $\Delta = 0$. The deficit is dimensionless information; the areal quantum $\gamma_{\mathrm{HMT}} a_0$ is another reading. Each expression retains its definition even though their evaluations may be close.

Proposition 74.5 (Information response and boundary fluctuations)**.** *For every finite real Δ,*

$$\frac{\mathrm{d}\langle D\rangle_\Delta}{\mathrm{d}\Delta} = -\operatorname{Var}_\Delta(D) = -18(90^2 v_{90} + 120^2 v_{120}), \tag{74.15}$$

$$\frac{\mathrm{d}s}{\mathrm{d}\Delta} = -\Delta \operatorname{Var}_\Delta(D), \tag{74.16}$$

$$\frac{\mathrm{d}\langle \widehat{\mathcal{A}}\rangle_\Delta}{\mathrm{d}\Delta} = -18\gamma_{\mathrm{HMT}} a_0 \ell_P^2 (90 v_{90} + 120 v_{120}). \tag{74.17}$$

Proof. The sum defining Z is finite. Differentiating it gives $\partial_\Delta \log Z = -\langle D\rangle_\Delta$ and $\partial_\Delta^2 \log Z = \operatorname{Var}_\Delta(D)$. The sectors and their factors are independent in the product state; their variances therefore add. On differentiating (74.13), the terms $-\langle D\rangle_\Delta$ and $\langle D\rangle_\Delta$ cancel. For area, use $\partial_\Delta f_m = -m v_m$ in (74.12). □

These equations relate three levels of the same construction. Incidence fixes multiplicities and sectorial weights; the reduced state fixes their probabilities; fluctuations of those occupations determine the response

of area and entropy. The scale $\gamma_{\mathrm{HMT}} a_0 \ell_P^2$ converts occupation into area, whereas k_B converts information into dimensional entropy. In the gravitational section, $\ell_P^2 = G\hbar/c^3$ makes explicit the dependence of that areal unit on action and gravitation. Comparison with a horizon additionally preserves the geometric map and the state specified there.

74.1.2 Occupation inversion and entropic invariants

Let $\mathcal{R}$ be the unitary involution that exchanges $|0\rangle$ and $|2\rangle$ and fixes $|1\rangle$ in each of the thirty-six tritic factors. Its action on occupations preserves the entire microscopic configuration through a bijective change of its labels.

Theorem 74.6 (Preserved entropy and complementary area)**.** *The preceding involution satisfies*

$$\mathcal{R} N \mathcal{R}^* = 72I - N, \qquad \mathcal{R} D \mathcal{R}^* = 7560I - D, \tag{74.18}$$

$$\rho_A(-\Delta) = \mathcal{R}\rho_A(\Delta)\mathcal{R}^*, \qquad s(-\Delta) = s(\Delta), \tag{74.19}$$

$$\langle \widehat{\mathcal{A}} \rangle_{-\Delta} + \langle \widehat{\mathcal{A}} \rangle_{\Delta} = 72\gamma_{\mathrm{HMT}} a_0 \ell_P^2. \tag{74.20}$$

The relative entropy between the two orientations is

$$D\big(\rho_A(\Delta) \| \rho_A(-\Delta)\big) = \Delta\big(7560 - 2\langle D \rangle_{\Delta}\big). \tag{74.21}$$

Proof. Each local occupation n transforms into $2-n$. Thus, $N_m \mapsto 36I - N_m$ and $D \mapsto 36(90{+}120)I - D = 7560I - D$. Furthermore, $z_m(-\Delta) = e^{2m\Delta} z_m(\Delta)$, whence $Z(-\Delta) = e^{7560\Delta} Z(\Delta)$. Substituting both identities into the normalized state proves unitary conjugation. Spectral invariance proves equality of entropies; transformation of N proves the area sum. Finally, subtracting the two state logarithms and taking their expectation in $\rho_A(\Delta)$ yields (74.21). □

At $\Delta = 0$ the reduced state is uniform and $s(0) = 36 \log 3$. In the limit $\Delta \to +\infty$, the zero-occupation configuration survives; the entropy tends to zero. Inversion takes that limit to the maximum-occupation configuration. At both extremes the entropy is the same and the area distinguishes the configurations. For $\Delta > 0$, the response (74.16) is strictly negative because the state has full rank and D has more than one eigenvalue. The law thus preserves the difference between reversibility of the complete configuration, equality of entropies and change in the areal reading. These properties belong to the specified sectoral family; the physical transport of the bipartition is addressed in section 83.2.

74.1.3 First modular law and finite area variations

The derivatives of (74.16) vary the parameter Δ of a family of states. The modular first law, by contrast, fixes a reference state and considers variations of the observed state around it. Take $\rho_0 = \rho_A(\Delta_0)$, with Δ_0 real and finite, and keep $\Delta_0, \gamma_{\mathrm{HMT}}, a_0, \ell_P$ fixed. The branch $\gamma_{\mathrm{HMT}} > 0, a_0 > 0$ is retained. The normalized sectoral areas are

$$\mathcal{A}_m^{\mathrm{n}} = \gamma_{\mathrm{HMT}} a_0 N_m, \qquad \widehat{\mathcal{A}}_m = \ell_P^2 \mathcal{A}_m^{\mathrm{n}}, \qquad m \in \{90, 120\}. \tag{74.22}$$

The logarithm of the reference state takes the form

$$K_0 = -\log \rho_0 = c_0 I + \beta_{90} \mathcal{A}_{90}^{\mathrm{n}} + \beta_{120} \mathcal{A}_{120}^{\mathrm{n}}, \qquad \beta_m = \frac{m\Delta_0}{\gamma_{\mathrm{HMT}} a_0}, \quad c_0 = \log Z(\Delta_0). \tag{74.23}$$

In particular, $\beta_{120} = \frac{4}{3}\beta_{90}$; for $\Delta_0 \neq 0$, their quotient is $4/3$. The coefficients arise from expressing the same modular operator in areal units.

Theorem 74.7 (First modular law in areal coordinates)**.** *Let $\sigma(\varepsilon)$ be a differentiable family of normalized states on an interval containing zero, with $\sigma(0) = \rho_0$. Then*

$$\left.\frac{\mathrm{d}s(\sigma(\varepsilon))}{\mathrm{d}\varepsilon}\right|_0 = \sum_{m=90,120} \beta_m \left.\frac{\mathrm{d}\langle \mathcal{A}^{\mathrm{n}}_m\rangle_{\sigma(\varepsilon)}}{\mathrm{d}\varepsilon}\right|_0 . \tag{74.24}$$

Proof. The state ρ_0 has full rank. In its neighborhood, the derivative of the trace of $-\sigma\log\sigma$ is $-\operatorname{Tr}[\dot\sigma(\log\rho_0 + I)]$; this follows by diagonalizing ρ_0 in the formula for the spectral derivative of the trace. Normalization implies $\operatorname{Tr}\dot\sigma = 0$, so the derivative is $\operatorname{Tr}(\dot\sigma K_0)$. Substituting (74.23) also cancels $c_0 I$ and produces the identity. □

Theorem 74.8 (Finite area identity and relative-entropy deficit)**.** *For any normalized state σ on the same finite space, define $\Delta_\sigma\langle B\rangle = \operatorname{Tr}[(\sigma-\rho_0)B]$. The identity*

$$\boxed{s(\sigma) - s(\rho_0) = \sum_{m=90,120} \beta_m \Delta_\sigma\langle \mathcal{A}^{\mathrm{n}}_m\rangle - D(\sigma\|\rho_0).} \tag{74.25}$$

holds. Here $D(\sigma\|\rho_0) = \operatorname{Tr}[\sigma(\log\sigma - \log\rho_0)]$ is finite, nonnegative, and interpreted with $0\log 0 = 0$.

Proof. By definition, $D(\sigma\|\rho_0) = -s(\sigma) + \operatorname{Tr}(\sigma K_0)$, whereas $s(\rho_0) = \operatorname{Tr}(\rho_0 K_0)$. Subtraction gives $s(\sigma) - s(\rho_0) = \Delta_\sigma\langle K_0\rangle - D(\sigma\|\rho_0)$. Substituting (74.23) proves the formula because the traces of both states are one.

To see positivity, diagonalize σ with eigenvalues p_i and vectors u_i, and ρ_0 with eigenvalues $q_j > 0$ and vectors v_j. Put $r_i = \langle u_i, \rho_0 u_i\rangle$. Concavity of the logarithm gives $\sum_j |\langle u_i, v_j\rangle|^2 \log q_j \le \log r_i$. Hence $D(\sigma\|\rho_0) \ge \sum_i p_i \log(p_i/r_i) \ge 0$; the last inequality is convexity of $t\log t$ applied with weights r_i, which sum to one. Strict positivity of the q_j ensures that all reference logarithms are finite. □

The finite identity preserves the informational distance from the reference state; its tangent term is (74.24). For the physical areas, the corresponding coefficients are β_m/ℓ_P^2. Multiplying the equation by the common transducer k_B publishes the dimensional entropy. Thus, the relation between geometry and information remains exact also for finite variations, with its explicit correction and without modifying the parameters of the reference state.

74.1.4 Equation of state for sectorial information

The incidence already constructed provides eighteen tritic factors in each sector. This multiplicity allows the relation between area, the occupation distribution, and the entropy of the preceding purification to be written explicitly. We retain the reduced state defined there and abbreviate $\Delta = \Delta_{\mathrm{mod}}$. For $m \in \{90, 120\}$, put

$$x_m = e^{-m\Delta}, \qquad z_m = 1 + x_m + x_m^2, \qquad f_m = \frac{x_m + 2x_m^2}{z_m}, \qquad v_m = \frac{x_m + 4x_m^2}{z_m} - f_m^2. \tag{74.26}$$

Here f_m and v_m are, respectively, the mean and variance of the occupation of one factor in sector m. The parameter Δ preserves the status and normalization of the previously specified reduced state.

74.1.4.1 Bipartite quantum purification of the incidence sectors

The preceding Schmidt decomposition is made concrete on each link. For a finite real weight w, define

$$z(w) = 1 + e^{-w} + e^{-2w}, \qquad \rho(w) = \frac{1}{z(w)} \sum_{n=0}^{2} e^{-wn} |n\rangle\langle n|.$$

The sectorial weights are $w_m = m\Delta$, with $m = 90, 120$; hence $z(w_m) = z_m$.

Proposition 74.9 (Thermofield-double purification of sectorial incidence)**.** *The normalized vector*

$$|\operatorname{TFD}(w)\rangle = \frac{1}{\sqrt{z(w)}} \sum_{n=0}^{2} e^{-wn/2} |n\rangle_A \otimes |n\rangle_{\bar{A}} \tag{74.27}$$

purifies $\rho(w)$*. The product*

$$|\Psi_\Delta\rangle = |\operatorname{TFD}(90\Delta)\rangle^{\otimes 18} \otimes |\operatorname{TFD}(120\Delta)\rangle^{\otimes 18} \tag{74.28}$$

has reduction $\rho_A(\Delta)$ *on the thirty-six original links. Its entanglement entropy for the bipartition* $A \mid \bar{A}$ *is* $s(\Delta)$*.*

Proof. The squared norm is $z(w)^{-1} \sum_{n=0}^{2} e^{-wn} = 1$. In the partial trace, orthogonality of the second factor eliminates terms with distinct indices; the remaining terms form $\rho(w)$. The partial trace commutes with the tensor product. One thus obtains $\rho(90\Delta)^{\otimes 18} \otimes \rho(120\Delta)^{\otimes 18}$, which coincides with the normalized state defined previously. Equality between the entropy of a reduction and the entanglement of this purification is read directly from its Schmidt coefficients. □

The two factors of the bipartition are determined within the construction. The physical realization of the second factor preserves that subsystem identification and its algebra of observables.

74.1.4.2 Occupation moments and information content

Proposition 74.10 (Mean area and entropy of the sectorial purification)**.** *In this finite family of states,*

$$\langle N \rangle_\Delta = 18(f_{90} + f_{120}), \tag{74.29}$$

$$\langle D \rangle_\Delta = 18(90 f_{90} + 120 f_{120}), \tag{74.30}$$

$$\frac{\langle \widehat{\mathcal{A}} \rangle_\Delta}{\ell_P^2} = 18\gamma_{\mathrm{HMT}} a_0 (f_{90} + f_{120}), \tag{74.31}$$

$$s(\Delta) = 18 \log z_{90} + 18 \log z_{120} + \Delta \langle D \rangle_\Delta. \tag{74.32}$$

The dimensional entropy is $S(\Delta) = k_B s(\Delta)$*, with the thermal transducer of Section 123.*

Proof. In each factor, the normalized weights are $(1, x_m, x_m^2)/z_m$. Their first moment gives f_m, and their second moment gives the first fraction in v_m. Tensor factorization and additivity of the number operators produce the first three identities. Finally, $\log \rho_A = -(\log Z) I - \Delta D$, with $Z = z_{90}^{18} z_{120}^{18}$. Taking the trace against $-\rho_A$ gives (74.32). The purification specified previously has this same entanglement entropy. □

Loss of uniformity has its own quantitative reading. In dimension $d_\partial = 3^{36}$, let $\tau_\partial = I/d_\partial$. Define

$$I_{\mathrm{or}}(\Delta) = 36 \log 3 - s(\Delta) = D\big(\rho_A(\Delta) \| \tau_\partial\big) \geq 0. \tag{74.33}$$

The equality is obtained by substituting $\log \tau_\partial = -36 \log 3\, I$. If p_ν are the eigenvalues of ρ_A, the convexity of $t \log t$ gives $\sum_\nu p_\nu \log(d_\partial p_\nu) \geq 0$, with equality exactly for the uniform state. For this family, this occurs at $\Delta = 0$. The deficit is dimensionless information; the areal quantum $\gamma_{\mathrm{HMT}} a_0$ is another reading. Each expression retains its definition even though their evaluations may be close.

Proposition 74.11 (Information response and boundary fluctuations)**.** *For every finite real* Δ*,*

$$\frac{\mathrm{d}\langle D \rangle_\Delta}{\mathrm{d}\Delta} = -\operatorname{Var}_\Delta(D) = -18(90^2 v_{90} + 120^2 v_{120}), \tag{74.34}$$

$$\frac{\mathrm{d}s}{\mathrm{d}\Delta} = -\Delta \operatorname{Var}_\Delta(D), \tag{74.35}$$

$$\frac{\mathrm{d}\langle\widehat{\mathcal{A}}\rangle_\Delta}{\mathrm{d}\Delta} = -18\gamma_{\mathrm{HMT}}a_0\ell_P^2(90v_{90} + 120v_{120}). \tag{74.36}$$

Proof. The sum defining Z is finite. Differentiating it gives $\partial_\Delta \log Z = -\langle D\rangle_\Delta$ and $\partial_\Delta^2 \log Z = \mathrm{Var}_\Delta(D)$. The sectors and their factors are independent in the product state; their variances therefore add. On differentiating (74.32), the terms $-\langle D\rangle_\Delta$ and $\langle D\rangle_\Delta$ cancel. For area, use $\partial_\Delta f_m = -mv_m$ in (74.31). □

These equations relate three levels of the same construction. Incidence fixes multiplicities and sectoral weights; the reduced state fixes their probabilities; fluctuations of those occupations determine the response of area and entropy. The scale $\gamma_{\mathrm{HMT}}a_0\ell_P^2$ converts occupation into area, while k_B converts information into dimensional entropy. In section 121, $\ell_P^2 = G\hbar/c^3$ makes explicit the dependence of that areal unit on action and gravitation. The family of reduced states and its bipartition remain specified in this development; any horizon realization must also transport those two data.

74.1.5 Occupation inversion and entropic invariants

Let $\mathcal{R}$ be the unitary involution that exchanges $|0\rangle$ and $|2\rangle$ and fixes $|1\rangle$ in each of the thirty-six tritic factors. Its action on occupations preserves the entire microscopic configuration through a bijective change of its labels.

Theorem 74.12 (Preserved entropy and complementary area)**.** *The preceding involution satisfies*

$$\mathcal{R}N\mathcal{R}^* = 72I - N, \qquad \mathcal{R}D\mathcal{R}^* = 7560I - D, \tag{74.37}$$

$$\rho_A(-\Delta) = \mathcal{R}\rho_A(\Delta)\mathcal{R}^*, \qquad s(-\Delta) = s(\Delta), \tag{74.38}$$

$$\langle\widehat{\mathcal{A}}\rangle_{-\Delta} + \langle\widehat{\mathcal{A}}\rangle_\Delta = 72\gamma_{\mathrm{HMT}}a_0\ell_P^2. \tag{74.39}$$

The relative entropy between the two orientations is

$$D\big(\rho_A(\Delta)\|\rho_A(-\Delta)\big) = \Delta\big(7560 - 2\langle D\rangle_\Delta\big). \tag{74.40}$$

Proof. Each local occupation n transforms into $2-n$. Thus, $N_m \mapsto 36I - N_m$ and $D \mapsto 36(90{+}120)I - D = 7560I - D$. Furthermore, $z_m(-\Delta) = e^{2m\Delta}z_m(\Delta)$, whence $Z(-\Delta) = e^{7560\Delta}Z(\Delta)$. Substituting both identities into the normalized state proves unitary conjugation. Spectral invariance proves equality of entropies; transformation of N proves the area sum. Finally, subtracting the two state logarithms and taking their expectation in $\rho_A(\Delta)$ yields (74.40). □

At $\Delta = 0$ the reduced state is uniform and $s(0) = 36\log 3$. In the limit $\Delta \to +\infty$, the zero-occupation configuration survives; the entropy tends to zero. Inversion takes that limit to the maximum-occupation configuration. At both extremes the entropy is the same and the area distinguishes the configurations. For $\Delta > 0$, the response (74.35) is strictly negative because the state has full rank and D has more than one eigenvalue. The law thus preserves the difference between reversibility of the complete configuration, equality of entropies and change in the areal reading. These properties belong to the specified sectoral family; the physical transport of the bipartition is addressed in section 74.1.7.

74.1.6 First modular law and finite area variations

The derivatives of (74.35) vary the parameter Δ of a family of states. The modular first law, by contrast, fixes a reference state and considers variations of the observed state around it. Take $\rho_0 = \rho_A(\Delta_0)$, with Δ_0 real and finite, and keep $\Delta_0, \gamma_{\mathrm{HMT}}, a_0, \ell_P$ fixed. The branch $\gamma_{\mathrm{HMT}} > 0, a_0 > 0$ is retained. The normalized sectoral areas are

$$\mathcal{A}_m^{\mathrm{n}} = \gamma_{\mathrm{HMT}}a_0N_m, \qquad \widehat{\mathcal{A}}_m = \ell_P^2\mathcal{A}_m^{\mathrm{n}}, \qquad m \in \{90, 120\}. \tag{74.41}$$

The logarithm of the reference state takes the form

$$K_0 = -\log \rho_0 = c_0 I + \beta_{90}\mathcal{A}^{\mathrm{n}}_{90} + \beta_{120}\mathcal{A}^{\mathrm{n}}_{120}, \qquad \beta_m = \frac{m\Delta_0}{\gamma_{\mathrm{HMT}} a_0}, \quad c_0 = \log Z(\Delta_0). \tag{74.42}$$

In particular, $\beta_{120} = \frac{4}{3}\beta_{90}$; for $\Delta_0 \neq 0$, their quotient is $4/3$. The coefficients arise from expressing the same modular operator in areal units.

Theorem 74.13 (First modular law in areal coordinates)**.** *Let $\sigma(\varepsilon)$ be a differentiable family of normalized states on an interval containing zero, with $\sigma(0) = \rho_0$. Then*

$$\left.\frac{\mathrm{d}s(\sigma(\varepsilon))}{\mathrm{d}\varepsilon}\right|_0 = \sum_{m=90,120} \beta_m \left.\frac{\mathrm{d}\langle \mathcal{A}^{\mathrm{n}}_m\rangle_{\sigma(\varepsilon)}}{\mathrm{d}\varepsilon}\right|_0 . \tag{74.43}$$

Proof. The state ρ_0 has full rank. In its neighborhood, the derivative of the trace of $-\sigma\log\sigma$ is $-\operatorname{Tr}[\dot\sigma(\log\rho_0 + I)]$; this follows by diagonalizing ρ_0 in the formula for the spectral derivative of the trace. Normalization implies $\operatorname{Tr}\dot\sigma = 0$, so the derivative is $\operatorname{Tr}(\dot\sigma K_0)$. Substituting (74.42) also cancels $c_0 I$ and produces the identity. □

Theorem 74.14 (Finite area identity and relative-entropy deficit)**.** *For any normalized state σ on the same finite space, define $\Delta_\sigma\langle B\rangle = \operatorname{Tr}[(\sigma - \rho_0)B]$. The identity*

$$\boxed{s(\sigma) - s(\rho_0) = \sum_{m=90,120} \beta_m \Delta_\sigma\langle \mathcal{A}^{\mathrm{n}}_m\rangle - D(\sigma\|\rho_0).} \tag{74.44}$$

holds. Here $D(\sigma\|\rho_0) = \operatorname{Tr}[\sigma(\log\sigma - \log\rho_0)]$ is finite, nonnegative, and interpreted with $0\log 0 = 0$.

Proof. By definition, $D(\sigma\|\rho_0) = -s(\sigma) + \operatorname{Tr}(\sigma K_0)$, whereas $s(\rho_0) = \operatorname{Tr}(\rho_0 K_0)$. Subtraction gives $s(\sigma) - s(\rho_0) = \Delta_\sigma\langle K_0\rangle - D(\sigma\|\rho_0)$. Substituting (74.42) proves the formula because the traces of both states are one.

To see positivity, diagonalize σ with eigenvalues p_i and vectors u_i, and ρ_0 with eigenvalues $q_j > 0$ and vectors v_j. Put $r_i = \langle u_i, \rho_0 u_i\rangle$. Concavity of the logarithm gives $\sum_j |\langle u_i, v_j\rangle|^2 \log q_j \le \log r_i$. Hence $D(\sigma\|\rho_0) \ge \sum_i p_i \log(p_i/r_i) \ge 0$; the last inequality is convexity of $t\log t$ applied with weights r_i, which sum to one. Strict positivity of the q_j ensures that all reference logarithms are finite. □

The finite identity preserves the informational distance from the reference state; its tangent term is (74.43). For the physical areas, the corresponding coefficients are β_m/ℓ_P^2. Multiplying the equation by the common transducer k_B publishes the dimensional entropy. Thus, the relation between geometry and information remains exact also for finite variations, with its explicit correction and without modifying the parameters of the reference state.

74.1.7 Spectral entropy and preservation under transport

The entropy of a reduced state depends on its spectrum and on the bipartition defining the reduction. To specify the continuation towards duality, let $\mathcal{H}_A, \mathcal{H}_B$ be the two factors and ρ_{AB} a state with finite entropies. A factorized transport $U_A \otimes U_B$ produces

$$\rho'_A = U_A \rho_A U_A^*, \qquad S(\rho'_A) = S(\rho_A).$$

The first identity follows from the definition of partial trace and the second from the invariance of the spectrum. For a general unitary transport, the equivalent formulation also transports the inclusion of the subsystem's observable algebra. This specification identifies the geometric datum that must accompany an assertion of entanglement preservation.

74.1.8 Quasi-free correlation and spectral occupation entropies

For a gauge-invariant, number-conserving quasifree fermionic state defined on a finite-dimensional one-particle space, let $C_{ij} = \langle a_j^\dagger a_i \rangle$ be the one-particle correlation operator. The gauge-invariant hypothesis excludes anomalous pairing correlations, so that C determines the quasifree state. If $0 < C < I$, its one-particle modular generator and the reciprocal reconstruction of the correlator are

$$\boxed{K_1 = \log\big((I - C)C^{-1}\big), \qquad C = (I + e^{K_1})^{-1}.} \tag{74.45}$$

Corollary 74.15 (Logistic form of the modular spectrum)**.** *If $K_1 u_i = \kappa_i u_i$, the occupation of mode u_i is*

$$\langle n_i \rangle = \frac{1}{1 + e^{\kappa_i}}.$$

For $\kappa_i = \beta(\varepsilon_i - \mu)$, the Fermi–Dirac law is recovered.

Proof. The spectral diagonalization of K_1 diagonalizes every function thereof. Applying $x \mapsto (1 + e^x)^{-1}$ to each eigenvalue yields the formula. □

If C has eigenvalues $p_i \in [0, 1]$, the occupation entropy of the quasifree fermionic state is, with the convention $0 \log 0 = 0$,

$$S_F = -\sum_i \big[p_i \log p_i + (1 - p_i) \log(1 - p_i)\big]. \tag{74.46}$$

For a diagonal Gaussian bosonic state with finitely many modes and mean occupancies $\overline{n}_i$,

$$S_B = \sum_i \big[(1 + \overline{n}_i) \log(1 + \overline{n}_i) - \overline{n}_i \log \overline{n}_i\big]. \tag{74.47}$$

The same formula extends to a countable family when the series on the right-hand side converges. These entropies quantify occupation configurations. Entanglement entropy has another domain: the reduced state induced by a tensor decomposition. Identifying the two requires specifying the reduction and the correlation operator that implements it.

Finally, for a reduced state ρ_A, the *von Neumann entropy*

$$S_{\mathrm{vN}}(\rho_A) = -\operatorname{Tr}(\rho_A \log \rho_A)$$

is a spectral property of the density operator. When ρ_A arises from a global purification, it quantifies entanglement across the cut. In the HMT boundary construction, the area operator, modular Hamiltonian, and corresponding reduction are constructed in Section 122. The product purification of Proposition 74.9 identifies the bipartition, and identity (74.44) expresses its relation to area variations.

The maps between these domains are published through explicit identities. Decomposition of a measure along the fibres of q satisfies the chain rule

$$\mathsf{H}_{\mu}(\mathbf{X}) = \mathsf{H}_{q_*\mu}(q(\mathbf{X})) + \mathsf{H}_{\mathrm{fib}}(q;\mu). \tag{74.48}$$

A finite distribution $p = (p_i)$ is realized diagonally as

$$\rho_p = \sum_i p_i |i\rangle\langle i|, \qquad S_{\mathrm{vN}}(\rho_p) = \mathsf{H}(p).$$

If $P_{N,E}$ projects onto the microcanonical subspace of dimension $\Omega(N,E)$, then

$$\rho_{\mathrm{mc}} = \frac{P_{N,E}}{\Omega(N,E)}, \qquad S_{\mathrm{vN}}(\rho_{\mathrm{mc}}) = \log \Omega(N,E) = S_{\mathrm{mc}}.$$

For a pure bipartite state,

$$\rho_A = \mathrm{Tr}_B\big(|\Psi_{AB}\rangle\langle\Psi_{AB}|\big)$$

defines the reduction that measures entanglement. Finally, equality between $h_{\mathrm{top}} = \log \rho(A)$ and a metric entropy is attained, for this primitive system, by the Parry measure, which realizes the maximum metric entropy; it is not attributed to an arbitrary measure on histories. The matrix F_{av}, its one-step-memory envelope, and that measure are constructed in Theorems 73.15 and 73.16, with its explicit variational characterization in Proposition 73.17.

74.2 Thermal radiation and the information scale of the calendar

Occupation statistics provide the link between the modes of a realization and their mean energy. In the electromagnetic realization, the dispersion relation and polarization multiplicity additionally determine the spectral density. Their composition yields the thermal moments and spectral maxima, while keeping three operations distinct: production of the action scale, representation of the modes, and evaluation of the thermal state.

74.2.1 Constitutive speed and kinematic realization of the clock

Radiative propagation uses the velocity section produced by the angular transport of the same HMT state. The identification is established before choosing publication units. Let $x = A_{\mathrm{rad}}$ and $y = C^*_{\mathrm{rad}}$ be the angular coordinates generated in section 14.11.6, with the channels (14.106), and let R be the self-adjoint involution of the two sheets, with rank-one projectors P_+ and P_-. On the domain $x > |y|$, the transport and its channels are

$$T = \exp(-xI - y\mathsf{R}) = q_+P_+ + q_-P_-, \qquad q_+ = e^{-x-y}, \quad q_- = e^{-x+y}, \quad 0 < q_\pm < 1. \tag{74.49}$$

The response of the temporal blocks of lengths 90 and 120 is

$$\mathsf{V} = (I - T^{90})(I - T^{120})^{-1} = r_+P_+ + r_-P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}}. \tag{74.50}$$

The construction starts from the inherited channels; the symbols x, y and $q_\pm$ denote their coordinates, not parameters fitted to a target speed.

Proposition 74.16 (Identity of the constitutive and kinematic realizations)**.** *In the same dimensional chart, the clock section c_{int} and the constitutive-response section c_{vac} coincide:*

$$c_{\mathrm{int}} = c_{\mathrm{vac}} = \widehat{c}\, u_C, \qquad \widehat{c} = (r_+r_-)^{-1} = \exp(-\mathcal{E}), \tag{74.51}$$

where

$$\mathcal{E} = \log\big[(1-q_+^{90})(1-q_-^{90})\big] - \log\big[(1-q_+^{120})(1-q_-^{120})\big]. \tag{74.52}$$

The equality preserves sheet exchange.

Proof. The factors appearing in the logarithms are positive. Therefore,

$$\mathcal{E} = \log(r_+r_-) = \log\det \mathsf{V}, \qquad \exp(-\mathcal{E}) = (\det \mathsf{V})^{-1}.$$

The determinant is computed here in the two-sheet realization with rank-one projectors. The kinematic definition $c_{\mathrm{int}} = \exp(-\mathcal{E})u_C$ and the constitutive definition $c_{\mathrm{vac}} = (r_+r_-)^{-1}u_C$ therefore give the same section. Exchanging $P_+ \leftrightarrow P_-$ interchanges r_+ and r_- and preserves their product. Finally, $\det T = e^{-2x}$ corresponds to the elementary transport, whereas $\det \mathsf{V} = r_+r_-$ corresponds to its temporal response; the two determinants have distinct roles in this composition. □

74.2.1.1 Path length and elementary duration

The positive dimensional frame (u_S, u_C, u_T, u_Q) induces the length basis $u_L = u_C u_T$. For an enriched path γ of $n = |\gamma|$ transitions and a constant channel, the additive readers are

$$T_{\mathrm{int}}(\gamma) = nu_T, \qquad L_{\mathrm{int}}(\gamma) = n\widehat{c}\,u_L. \tag{74.53}$$

Their additivity concerns the count and realization of each transition: enriched routes additionally preserve orientation and memory.

Corollary 74.17 (Normalization of the elementary length)**.** *For $n > 0$, $L_{\mathrm{int}}(\gamma)/T_{\mathrm{int}}(\gamma) = c_{\mathrm{vac}}$. In the normalization $t_0 = u_T$,*

$$\ell_0 = c_{\mathrm{int}}t_0 = \widehat{c}\,u_L. \tag{74.54}$$

In a general temporal chart $t_0 = \tau_0 u_T$, with $\tau_0 > 0$, the corresponding expression is $\ell_0 = \tau_0\widehat{c}\,u_L$.

Proof. Dividing the expressions in (74.53) cancels the integer n and uses $u_L/u_T = u_C$. The elementary formula is obtained by multiplying the speed section by t_0. □

Generalization to an edge-dependent channel preserves the additive formula $L_{\mathrm{int}}(\gamma) = \sum_{e\in\gamma}\widehat{c}(e)u_L$. Its quotient by nu_T is the mean of the speeds of those edges. The homogeneous radiative realization uses the constant channel specified in (74.53).

74.2.1.2 Change of chart and adapted normalization

Proposition 74.18 (Covariance of the identification)**.** *Let $u'_C = du_C$ and $u'_T = \eta u_T$, with $d, \eta > 0$. The same speed and the same elementary duration have coordinates*

$$\widehat{c}' = d^{-1}\widehat{c}, \qquad \tau'_0 = \eta^{-1}\tau_0, \qquad u'_L = d\eta u_L. \tag{74.55}$$

In particular, if $c_V = \widehat{c}_V u_C^V$ and $u_C^V = du_C^{III}$, equality of the sections is exactly equivalent to $d\widehat{c}_V = \widehat{c}_{III}$.

Proof. Express each section in the two bases. This gives $\widehat{c}'u'_C = \widehat{c}u_C$ and $\tau'_0u'_T = \tau_0u_T$. Their product satisfies

$$\tau'_0\widehat{c}'u'_L = \frac{\tau_0}{\eta}\frac{\widehat{c}}{d}d\eta u_L = \tau_0\widehat{c}u_L = \ell_0.$$

The final equivalence follows by substituting the relation between the bases. □

The adapted choice $d = \widehat{c}$ gives $u'_C = c_{\mathrm{vac}}$ and $\widehat{c}' = 1$. This choice expresses the already constructed section in a basis adapted to it. The spectral coefficient in the internal chart remains $(r_+r_-)^{-1}$; spectral

inversion uses that internal chart. For example, retaining the action and charge bases, the constitutive coordinates transform as

$$\widehat{\mu}' = d\widehat{\mu}, \qquad \widehat{\varepsilon}' = d\widehat{\varepsilon}, \qquad \widehat{\mu}'\widehat{\varepsilon}' = (\widehat{c}')^{-2}.$$

In the adapted chart, $\widehat{\mu}' = r_-/r_+$ and $\widehat{\varepsilon}' = r_+/r_-$, since the internal coordinates are $\widehat{\mu} = r_-^2$ and $\widehat{\varepsilon} = r_+^2$.

74.2.1.3 Transport to the radiative sector

The dispersion relation of the homogeneous radiative realization is written $\omega_{\boldsymbol{k}} = c_{\mathrm{vac}}|\boldsymbol{k}|$. With $h = 2\pi\hbar$ and $\beta = (k_B\Theta)^{-1}$, its spectral density and Stefan–Boltzmann coefficient have the expressions

$$u_\omega = \frac{\hbar\omega^3}{\pi^2(\widehat{c}u_C)^3}\frac{1}{e^{\beta\hbar\omega}-1}, \qquad \sigma = \frac{\pi^2 k_B^4}{60\hbar^3(\widehat{c}u_C)^2}. \tag{74.56}$$

These substitutions transport precisely the same speed section. The conditions of the radiative realization are retained: a free three-dimensional bosonic sector, two transverse polarizations, zero chemical potential, and positive temperature. Identity (74.51) establishes its constitutive antecedent; mode counting and the thermodynamic limit belong to the specific proofs for that realization.

Normalization under amplification. If refinement acts by $\mathsf{V}_m = \mathsf{V} \otimes I_{9^m}$, the normalized trace $\tau_m = \mathrm{Tr}/(2\cdot 9^m)$ satisfies

$$\exp[-2\tau_m(\log \mathsf{V}_m)] = \exp[-\log r_+ - \log r_-] = \widehat{c}.$$

Indeed, each eigenvalue appears 9^m times. The multiplicity cancels in the normalized trace. The ordinary amplified determinant is $(r_+r_-)^{9^m}$: the two-sheet normalization, or equivalently the normalized trace, preserves the constitutive reader under that refinement. This amplification of the representation preserves the enriched transport from which it arises.

74.2.2 Action, calendar, and temperature

The clock orientation a is retained and we abbreviate $\hbar = \hbar_a$, $c = c_{\mathrm{int}} = c_{\mathrm{vac}}$, with the identification of (74.51) in the same chart. The energy ε_{108} of this section is ϵ_a of (123.6); $\Theta_{108} = \Theta_{\mathrm{clk,a}}$. Dividing it by $\log 3$ produces the energy per nat of (123.7). The construction and covariance of the thermal pair are given in section 123.

We write $h = 2\pi\hbar > 0$ for the action publication, $t_0 > 0$ for the time unit of its dimensional chart and $\ell_0 = ct_0$ for the corresponding length. The chronological cell of length 108 determines the energy

$$\varepsilon_{108} = \frac{h}{108t_0}, \qquad k_B\Theta_{108}\log 3 = \varepsilon_{108}, \qquad \beta_{108} = \frac{108t_0\log 3}{h}. \tag{74.57}$$

Here $\beta = (k_B\Theta)^{-1}$ is the Gibbs parameter. The equality fixes the energy-valued product of temperature and the entropy transducer. The dimensional specification of k_B and Θ_{108} separately uses the thermal section and its bases. The natural logarithm measures information per tritic branch; its factor $\log 3$ converts the cardinality of the cell into dimensionless entropy.

Also introduce the associated units

$$t_P = \frac{108}{2\pi}t_0, \qquad \ell_P = ct_P, \qquad E_P = \frac{\hbar}{t_P} = \varepsilon_{108}. \tag{74.58}$$

These equalities specify the meaning of the symbols in this section; their evaluation in another chart preserves the identities between quotients. The length $\ell_P = (54/\pi)\ell_0$ coincides with the areal unit of section 121, in the circular realization declared there.

74.2.3 Mode density and spectral law

Proposition 74.19 (Thermal realization of transverse modes)**.** *Consider a free realization in a three-dimensional periodic box, whose excitation space contains the wave vectors* $\mathbf{k} \neq 0$*, with two transverse modes per vector, dispersion* $\omega = c|\mathbf{k}|$*, excitation energy* $\hbar\omega$*, zero chemical potential, and* $\beta > 0$*. The constant mode is kept fixed as background data. In the thermodynamic limit, the energy density per angular frequency is*

$$u_\omega(\Theta) = \frac{\hbar\omega^3}{\pi^2 c^3} \frac{1}{e^{\beta\hbar\omega} - 1}, \qquad \omega > 0. \tag{74.59}$$

The energy is that of the excitations above the vacuum of this representation.

Proof. For a box of volume V, the wave vectors have density $V/(2\pi)^3$. In a radial shell of thickness dk, the density per unit volume, including the two polarizations, is

$$2\frac{4\pi k^2\, dk}{(2\pi)^3} = \frac{k^2}{\pi^2}\, dk = \frac{\omega^2}{\pi^2 c^3}\, d\omega.$$

This is the limiting density of the sums over the periodic lattice with the constant mode omitted. This choice defines the partition product before taking the limit: each excitation mode has positive energy. Excluding a single point preserves the limiting radial density. The previously obtained bosonic occupation is $\bar{n}_\omega = (e^{\beta\hbar\omega} - 1)^{-1}$. Multiplying the density by $\hbar\omega\bar{n}_\omega$ proves (74.59). Near zero, the energy integrand is of order ω^2, and at infinity it decays exponentially, so its integral converges. □

The density arises from the specified three-dimensional representation. The transverse multiplicity used here has that physical domain; the dimension of a harmonic space on the APP torus describes, separately, the cohomology of its cellular complex.

74.2.4 Thermodynamic limit of occupation sums

The preceding radial density can be obtained as an effective limit of the sums of the periodic realization. The estimate must preserve the fixed constant mode and uniformly control both the origin and the spectral tail. The action and calendar publications remain prior to this realization operation.

Lemma 74.20 (Convergence of the three thermal observables)**.** *Let* $a, b > 0$*,* $L > 0$*,* $\Delta = 2\pi/L$*, and*

$$F_N(r) = \frac{1}{e^{ar} - 1}, \qquad F_E(r) = \frac{br}{e^{ar} - 1}, \qquad F_Z(r) = -\log(1 - e^{-ar}) \quad (r > 0).$$

For each of these functions,

$$\lim_{L\to\infty} \frac{2}{L^3} \sum_{\nu\in\mathbb{Z}^3\setminus\{0\}} F\left(\frac{2\pi}{L}|\nu|\right) = \frac{1}{\pi^2}\int_0^\infty r^2 F(r)\, dr. \tag{74.60}$$

The sums and the integral are finite. The specialization $a = \beta\hbar c$*,* $b = \hbar c$ *gives, respectively, the number density, excitation-energy density, and logarithmic partition-function density of the transverse modes.*

Proof. All three functions are continuous and positive on $(0, \infty)$. There exist constants $C_0, C_1, d > 0$, depending on a, b but independent of Δ, such that

$$F(r) \le \frac{C_0}{r} \quad (0 < r \le 1), \qquad F(r) \le C_1 e^{-dr} \quad (r \ge 1). \tag{74.61}$$

Indeed, $e^{ar} - 1 \ge ar$ bounds F_N and F_E near the origin; moreover, $F_Z(r) = \log(1 + F_N(r)) \le F_N(r) \le 1/(ar)$. For $r \ge 1$, the inequality $-\log(1 - y) \le y/(1 - y)$, with $y = e^{-ar}$, gives the exponential bound

for F_Z. The other two follow from $(e^{ar}-1)^{-1} \le e^{-ar}/(1-e^{-a})$, absorbing the factor r in F_E into an exponential of smaller decay rate. These bounds already prove integrability of $r^2F(r)$.

For the discrete sums, group the lattice points by $m = \|\nu\|_\infty \ge 1$. Each shell contains exactly

$$(2m+1)^3 - (2m-1)^3 = 24m^2 + 2$$

points and satisfies $m \le |\nu| \le \sqrt{3}m$. Fix $0 < \delta \le 1$ and $0 < \Delta \le 1$. If $\delta < \Delta$, there are no points with $0 < \Delta|\nu| \le \delta$. Otherwise, setting $N = \lfloor \delta/\Delta \rfloor$, the first bound in (74.61) gives

$$\begin{aligned}\Delta^3 \sum_{0<\Delta|\nu|\le\delta} F(\Delta|\nu|) &\le C_0\Delta^2 \sum_{m=1}^{N} \frac{24m^2+2}{m} \\ &\le 26C_0\Delta^2 \sum_{m=1}^{N} m \le 26C_0\delta^2.\end{aligned}$$

The second line uses $m^{-1} \le m$ and then $N(N+1)/2 \le N^2$ for $N \ge 1$. The integral contribution from the same neighborhood is also of order δ^2, since $\int_0^\delta r^2F(r)\,dr \le C_0\delta^2/2$.

For $R \ge 1$, every point with $\Delta|\nu| > R$ belongs to a shell $m > R/(\sqrt{3}\Delta)$. The second bound in (74.61) gives

$$\begin{aligned}\Delta^3 \sum_{\Delta|\nu|>R} F(\Delta|\nu|) &\le C_1 e^{-dR/(2\sqrt{3})}\Delta^3 \sum_{m\ge1} (24m^2+2)e^{-d\Delta m/2} \\ &\le C_2 e^{-dR/(2\sqrt{3})},\end{aligned}$$

where C_2 is independent of $0 < \Delta \le 1$. To verify this uniformity, set $q = e^{-d\Delta/2}$ and use

$$\sum_{m\ge1} q^m = \frac{q}{1-q}, \qquad \sum_{m\ge1} m^2q^m = \frac{q(1+q)}{(1-q)^3}.$$

The first identity is the geometric series, and the second follows by applying $q\,d/dq$ twice, which is valid for $|q| < 1$. Moreover, $1 - e^{-d\Delta/2} \ge \Delta(1-e^{-d/2})$ by concavity. The factor Δ^3 therefore compensates for the denominators of both expressions. The integral tail likewise tends to zero by the exponential bound. For each $\Delta > 0$, the same estimates prove convergence of the infinite sum.

On the compact annulus $\delta \le |k| \le R$, the function $F(|k|)$ is continuous and bounded. Riemann sums of mesh Δ converge to its integral; the two boundary spheres have measure zero. First let $\Delta \to 0$, then $\delta \to 0$, and finally $R \to \infty$, using the preceding uniform bounds. The result is

$$\Delta^3 \sum_{\nu\ne0} F(\Delta|\nu|) \longrightarrow \int_{\mathbb{R}^3} F(|k|)\,d^3k = 4\pi \int_0^\infty r^2F(r)\,dr.$$

Since $2/L^3 = 2\Delta^3/(2\pi)^3$, the final radial coefficient is $2 \cdot 4\pi/(2\pi)^3 = 1/\pi^2$, proving (74.60). □

Control at the origin is carried out over positive-energy excitations. The constant mode remains fixed before the partition function is formed: removing it afterward from an integral would not replace that condition on the finite representation. The proof establishes the limit of the specified realization and preserves the distinction between that realization and the prior construction of its action and calendar parameters.

74.2.5 Thermal moments and information

Lemma 74.21 (Bosonic moment)**.** *For every real $s > 1$,*

$$\int_0^\infty \frac{x^{s-1}}{e^x - 1}\, dx = \Gamma(s)\zeta(s). \tag{74.62}$$

Proof. For $x > 0$, $(e^x - 1)^{-1} = \sum_{m\geq 1} e^{-mx}$. All summands are nonnegative; Tonelli's theorem allows the sum and integral to be interchanged. The substitution $y = mx$ gives $\int_0^\infty x^{s-1}e^{-mx}\, dx = m^{-s}\Gamma(s)$. The sum converges for $s > 1$, yielding the stated equality. □

Proposition 74.22 (Number, energy, and entropy densities)**.** *In the realization of Proposition 74.19,*

$$n_\gamma = \frac{2\zeta(3)}{\pi^2 c^3 (\beta\hbar)^3}, \tag{74.63}$$

$$u_\gamma = \frac{\pi^2}{15 c^3 \hbar^3 \beta^4}, \tag{74.64}$$

$$s_\gamma = \frac{4\pi^2 k_B}{45 c^3 (\beta\hbar)^3}. \tag{74.65}$$

At the calendar temperature, these relations become

$$n_\gamma \ell_P^3 = \frac{2\zeta(3)}{\pi^2 (\log 3)^3}, \quad \frac{u_\gamma \ell_P^3}{E_P} = \frac{\pi^2}{15(\log 3)^4}, \quad \frac{s_\gamma \ell_P^3}{k_B} = \frac{4\pi^2}{45(\log 3)^3}. \tag{74.66}$$

Proof. Integrating occupation against the mode density uses (74.62) with $s = 3$, and the energy integral uses it with $s = 4$. This gives $\Gamma(3) = 2$ and $\Gamma(4)\zeta(4) = 6\pi^4/90 = \pi^4/15$. For entropy, start from the partition product of the modes:

$$\frac{\log Z}{V} = -\frac{1}{\pi^2 c^3} \int_0^\infty \omega^2 \log(1 - e^{-\beta\hbar\omega})\, d\omega = \frac{\pi^2}{45 c^3 (\beta\hbar)^3}.$$

The last equality follows by integration by parts after the substitution $x = \beta\hbar\omega$. The boundary terms vanish: $x^3 \log(1 - e^{-x})$ tends to zero at both endpoints. The Gibbs identity $s_\gamma/k_B = \log Z/V + \beta u_\gamma$ proves the third expression. Finally, $\beta_{108}\hbar = t_P \log 3$ and $\ell_P = c t_P$ give the three calendar normalizations. □

74.2.6 Thermal flux and the Stefan–Boltzmann constant

Proposition 74.23 (Isotropic flux and action normalization)**.** *The hemispherical flux of the isotropic realization is*

$$j_*(\Theta) = \sigma \Theta^4, \qquad \sigma = \frac{\pi^2 k_B^4}{60 \hbar^3 c^2} = \frac{2\pi^5 k_B^4}{15 h^3 c^2}. \tag{74.67}$$

At the calendar temperature,

$$j_*(\Theta_{108}) = \frac{2\pi^5}{15\, 108^4 (\log 3)^4} \frac{h}{\ell_0^2 t_0^2}. \tag{74.68}$$

Proof. The isotropic energy per unit solid angle is $u_\gamma/(4\pi)$. Flux normal to a surface integrates $c \cos\theta$ over the hemisphere:

$$\frac{c u_\gamma}{4\pi} \int_0^{2\pi} d\phi \int_0^{\pi/2} \cos\theta \sin\theta\, d\theta = \frac{c u_\gamma}{4}.$$

The formula for u_γ, $\beta^{-1} = k_B\Theta$, and $h = 2\pi\hbar$ prove (74.67). Substitution of (74.57) and $c = \ell_0/t_0$ gives (74.68). □

Within this realization, the constant σ is the coefficient combining bosonic occupation, transverse-mode density, and angular projection of the flux. The fourth-power dependence arises from the cubic frequency moment together with the integration differential. The calendar readout expresses that same flux through action, length, time, and tritic information.

74.2.7 Spectral maxima and displacement law

Lemma 74.24 (Positive root for spectral maxima)**.** *For every integer $n > 1$, the equation $n(1 - e^{-x}) = x$ has a unique solution $x_n > 0$. The function $f_n(x) = x^n/(e^x - 1)$ has its unique positive maximum at x_n.*

Proof. Let $g_n(x) = n(1 - e^{-x}) - x$. We have $g_n(0) = 0$, $g_n'(x) = ne^{-x} - 1$, and $g_n''(x) = -ne^{-x} < 0$. The maximum of g_n is attained at $\log n$, where its value is $n - 1 - \log n > 0$, whereas $g_n(n) = -ne^{-n} < 0$. Strict monotonicity on either side of the maximum proves existence and uniqueness of the positive root. The sign of $f_n'(x)$ agrees with that of $g_n(x)$; moreover, f_n tends to zero at zero and infinity. This proves uniqueness of the maximum. □

Proposition 74.25 (Frequency and wavelength readouts)**.** *The maxima of radiance per frequency and per wavelength are*

$$\nu_{\max} = \frac{x_3 k_B \Theta}{h}, \qquad \lambda_{\max} = \frac{hc}{x_5 k_B \Theta}. \tag{74.69}$$

In particular,

$$\nu_{\max}(\Theta_{108}) = \frac{x_3}{108 t_0 \log 3}, \qquad \lambda_{\max}(\Theta_{108}) = \frac{108 \log 3}{x_5} \ell_0. \tag{74.70}$$

Proof. The conversion $\omega = 2\pi\nu$ and the isotropic angular factor give

$$B_\nu = \frac{2h\nu^3}{c^2} \frac{1}{e^{\beta h\nu} - 1}.$$

With $\nu = c/\lambda$, the transformed density satisfies $B_\lambda = B_\nu |d\nu/d\lambda|$; hence

$$B_\lambda = \frac{2hc^2}{\lambda^5} \frac{1}{e^{\beta hc/\lambda} - 1}.$$

The respective changes of variable lead to f_3 and f_5. The preceding lemma proves (74.69); the calendar scale gives (74.70). The density Jacobian explains why the two maxima correspond to distinct roots: $\nu_{\max}\lambda_{\max} = cx_3/x_5$. □

Wien displacement is structurally defined by the stationary point of the chosen spectral density. A change of variable transforms both the argument and the measure. This precision locates each spectral constant in its generating operation and preserves its physical meaning when passing between frequency and wavelength.

Chapter 75

Persistence of the channels 90/120 and classification of the limit as a hyperinfinitesimal factor III_{λ_∂}

Faithful local products preserve the ratios of channels 90 and 120 under refinement. The GNS representation and the ITPFI limit determine the hyperfinite type III factor with explicit boundary parameter.

75.1 Local Limit and Modular Classification of the Infinite System

In an infinite UHF algebra, there is in general no global trace-class density matrix within the algebra. The correct object is the net

$$K_{\mathrm{HHM}}^{(m)} = -\log \rho_m \tag{75.1}$$

with compatible-state restrictions, or the modular generator in the GNS representation. The tracial expectation $\mathrm{id} \otimes \tau_9$ does not automatically preserve a nontracial Gibbs state and does not replace state compatibility.

Theorem 75.1 (Modular type under faithful persistence of both channels)**.** *Suppose that:*

(i) each cut is a product of faithful qutrit states with weights w_{90} and w_{120};

(ii) the inclusions preserve the state and the channel label;

(iii) infinitely many factors of each type occur, both with positive asymptotic density;

(iv) no additional spectral quotients are introduced, and the product representation is factorial.

Then the additive group of logarithms of ratios of eigenvalues is

$$90\Delta_4^{\mathrm{mod}}\mathbb{Z} + 120\Delta_4^{\mathrm{mod}}\mathbb{Z} = 30\Delta_4^{\mathrm{mod}}\mathbb{Z}. \tag{75.2}$$

The GNS closure ITPFI is the hyperinfinitesimal factor

$$\boxed{III_{\lambda_\partial}, \qquad \lambda_\partial = \mathrm{e}^{-30\Delta_4^{\mathrm{mod}}} = 0.99666964646895737861082997 69\ldots.} \tag{75.3}$$

Proof. At each link, the eigenvalue quotients are powers of e^{-w_m}. Infinite persistence of both types generates the subgroup $w_{90}\mathbb{Z} + w_{120}\mathbb{Z}$. Since $\gcd(90, 120) = 30$, it follows that equation (75.2). The Araki–Woods asymptotic ratio criterion for the faithful product yields the hyperfinite ITPFI factor with parameter $\mathrm{e}^{-30\Delta_4^{\mathrm{mod}}}$ [7, 121]. □

The theorem states its actual hypotheses. If one of the channels disappears, if the product is incompatible, or if the ratio group changes, the type must be recalculated.

Gravitational publication of the modular closure via the pentacomponent carrier. The modular closure prepares the gravitational publication: the five-component carrier is first constructed from icosahedral incidence.

Chapter 76

Dynamic, propagative, and cosmological realizations of genealogical memory: dodecaphase transport, Green function, and spatial expansion

76.1 Boundary memory: even–odd decomposition and 3 hydrodynamic, gauge, and cosmological realizations

The unity among hydrodynamics, gauge theory, and cosmology is not obtained by comparing three equations once they have been written. It appears earlier, in the decomposition of the same transport into an even part, which preserves the cost of the outward and return journeys, and an odd part, which preserves its orientation. The common object is constructed in the dodecaphase temporal system $\mathcal{R}_{12}$; its subsequent representations are not identified with one another.

76.1.1 From angular channels to dodecaphasic transport

Let

$$q_{\pm} = \exp\Big[-\frac{\pi}{180}(A \pm C^{*})\Big], \qquad S_{90}(q) = \frac{q^{90}}{1-q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1-q^{360}},$$

and let us define

$$\kappa = 12\big(S_{90}(q_{-}) - S_{90}(q_{+})\big) - \big(S_{120}(q_{-}) - S_{120}(q_{+})\big).$$

This formula preserves the genealogy

$$\alpha_{\mathrm{HMT}} \longrightarrow A \longrightarrow C^{*} \longrightarrow q_{\pm} \longrightarrow \kappa.$$

In particular, κ is neither a viscosity, a tension, nor a mass. It is the dimensionless transfer coefficient that those quantities may subsequently read.

For

$$\phi_m = (30m + 20)^{\circ}, \qquad p_m = 12\cos(3\phi_m) - \cos(4\phi_m), \qquad 0 \le m < 12,$$

are set

$$w_m = \frac{1 + \kappa p_m}{12}.$$

The orthogonality of the characters of $\mathbb{Z}/12\mathbb{Z}$ gives $\sum_m p_m = 0$, hence $\sum_m w_m = 1$. Moreover, $|p_m| \le 13$; for the constructed value of $\kappa < 1/13$, all the weights are positive. On $\mathcal{H}_{12} = \ell^2(\mathbb{Z}/12\mathbb{Z})$ define

$$(U_{12} f)(n) = \sum_{m=0}^{11} w_m f(n-m).$$

Theorem 76.1 (Exact dodecaphonic reservation)**.** *Let*

$$P_{12} = \frac{U_{12} + U_{12}^{*}}{2}, \qquad J_{12} = \frac{U_{12} - U_{12}^{*}}{2}, \qquad L_{12} = I - P_{12}.$$

Then P_{12} is self-adjoint, J_{12} is anti-self-adjoint and, for every $f \perp \mathbf{1}$,

$$\boxed{\langle f, L_{12} f\rangle \ge g_{12}\|f\|_2^2, \qquad g_{12} = 1 - 3\kappa > 0.}$$

The constant is optimal and is attained at the frequencies 3 *and* 9*.*

Proof. In the Fourier basis $e_k(n) = \exp(2\pi i k n/12)$, convolution is diagonal:

$$U_{12}e_k = \lambda_k^{(U)} e_k, \qquad \lambda_k^{(U)} = \sum_{m=0}^{11} w_m e^{-2\pi i k m/12}.$$

The constant mode gives $\lambda_0^{(U)} = 1$. The cosines of frequencies three and four survive only in $k = 3, 9$ and $k = 4, 8$, respectively; the remaining modes vanish by orthogonality. The greatest value of $\operatorname{Re}\lambda_k^{(U)}$, with $k \neq 0$, is 3κ. Therefore,

$$\langle f, L_{12} f\rangle = \sum_{k\neq 0} (1 - \operatorname{Re}\lambda_k^{(U)})|\widehat{f}(k)|^2 \geq (1 - 3\kappa)\|f\|_2^2.$$

□

The decomposition has a precise meaning. P_{12} preserves what a route shares with its inverse; J_{12} preserves what changes sign when the orientation is reversed. The former can provide a positive form. The latter cannot: for real f, $\langle f, J_{12} f\rangle$ is purely imaginary. In return, J_{12} retains the circulation that the even projection would lose.

76.1.2 Distributed memory and local generator

The same duality appears in the nucleus

$$K_q(m, n) = q^{|m-n|}, \qquad 0 < q < 1.$$

Its matrix appears nonlocal because it correlates arbitrarily distant levels. Nevertheless, on a finite chain $0, \ldots, N$, its inverse is tridiagonal:

$$K_q^{-1} = \frac{1}{1-q^2}\begin{pmatrix} 1 & -q & 0 & \cdots & 0 \\ -q & 1+q^2 & -q & \ddots & \vdots \\ 0 & -q & 1+q^2 & \ddots & 0 \\ \vdots & \ddots & \ddots & 1+q^2 & -q \\ 0 & \cdots & 0 & -q & 1 \end{pmatrix}.$$

Proposition 76.2 (Nonlocal Green, local action)**.** *For $0 < q < 1$, K_q is positive definite, and the preceding matrix is its inverse. Consequently, an exponentially distributed memory is the Green kernel of a nearest-neighbour action.*

Proof. Multiplying the tridiagonal matrix by K_q cancels, in every interior row, the terms

$$-q\, q^{|m-1-n|} + (1+q^2) q^{|m-n|} - q\, q^{|m+1-n|}$$

when $m \neq n$, and leaves $1 - q^2$ when $m = n$. The extreme rows obey the same identity with only one neighbor. The inverse is positive; therefore, K_q is also positive. □

This result explains an apparent opposition that pervades Dimensional Mechanics: history is extensive because it preserves correlations among depths, whereas the generator that updates it may be local. “Local” and “with memory” are not alternatives.

76.1.3 Local interior and reflected representations: circulation, holonomy, contraction, and transfer positivity

The common-sheet chapter has demonstrated both local representations of the boundary once. In the interior reading, the odd sector carries circulation and the even sector produces contraction and coercivity; in the reflected reading, the former carries holonomy and the latter transfer positivity and a finite gap. Stokes' identity and the coincidence of the nonzero spectra of d^*d and dd^* are properties of the common object, not two parallel proofs. We refer to theorems 95.51 a 95.54; here we add only the third reading, the global one.

76.1.4 Global reading: expansion and curvature

The third reading does not identify the universe with a cell. It takes the same separation between interior and boundary as a global law of evolution. The identity

$$1000 = 729 + 271$$

recalls that interior growth and boundary publication complete a normalized unit. In a homogeneous and isotropic geometry, the even part of a transport can be represented by an effective pressure

$$p_{\mathrm{eff}} = p - 3\zeta H,$$

which is the standard tensorial form of a bulk viscosity. The equation does not define ζ from H; it declares the type of the cosmological reading: symmetric memory is published as resistance to expansion.

De Sitter geometry shows unambiguously what remains common among three distinct foliations. For $H > 0$,

k	$a_k(t)$
$+1$	$H^{-1}\cosh(Ht)$
0	$a_* e^{Ht}$
-1	$H^{-1}\sinh(Ht)$

in their respective domains.

Proposition 76.3 (An expansion, three spatial curvatures)**.** *The three preceding functions satisfy*

$$\frac{\dot a_k^2 + k}{a_k^2} = H^2, \qquad \frac{\ddot a_k}{a_k} = H^2,$$

and therefore

$$\boxed{R^{(4)} = 12H^2, \qquad R^{(3)} = \frac{6k}{a_k^2}.}$$

Proof. For $k = +1$ one uses $\tanh^2 + \operatorname{sech}^2 = 1$; for $k = -1$, $\coth^2 - \operatorname{csch}^2 = 1$; the flat chart is immediate. The FLRW curvature formulae then give the two scalars. □

The sign k distinguishes the geometry of the spatial sheets; it does not change the curvature of de Sitter spacetime. This example prevents one from confusing the reading of a sheet with that of the total object, the same error that the APP–TRIT–TPK architecture prevents from the outset.

76.1.5 2 Exact Operator Representations and 1 Global Geometric Realization of Boundary Memory

Theorem 76.4 (A memory, two representations, and a global reading)**.** *The even–odd separation of boundary transport admits two exact operator representations and a global geometric reading:*

reader	*odd sector*	*even sector*	*status*
interior	*circulation*	*contraction/coercivity*	*exact representation*
reflected	*holonomy*	*positive kernel/finite gap*	*exact representation*
global	*sheet orientation*	*mean response to expansion*	*typed FLRW reading*

The first two rows share Stokes' identity and the nonzero spectrum of d^*d and dd^*. The third preserves the distinction between sheet curvature and global curvature, but does not define ζ from the dodecaphase operator. No row is obtained by renaming the symbols of another.

Proof. The first and second rows are the theorems 95.52 a 95.54. The local/non-local structure is proved in proposition 76.2. The third row is realized by the FLRW decomposition and proposition 76.3; these formulas prove the geometric separation, not an autonomous selector of bulk viscosity. In each case, the orientation involution fixes the odd channel, and comparison with the inverse route fixes the even channel. □

The conclusion is not that a fluid, a connection, and a cosmology are the same physical system. It is more precise: the three sciences receive distinct representations of a single operator memory system. Flow reads it toward the interior, gauge theory toward the boundary, and cosmology on a global scale.

76.2 Spatial suspension, geometric trichromy and helicoidal leaf lamination

76.2.1 Spatial immersion $\Gamma(\theta)$ and Frenet–Lancret differential criteria

Let

$$\Gamma(\theta) = \big(r(\theta)\cos\theta, r(\theta)\sin\theta, z(\theta)\big).$$

Its curvature and torsion are calculated by means of

$$\kappa_{\mathrm{F}} = \frac{\|\Gamma' \times \Gamma''\|}{\|\Gamma'\|^3}, \qquad \mathcal{T}_{\mathrm{F}} = \frac{\det(\Gamma', \Gamma'', \Gamma''')}{\|\Gamma' \times \Gamma''\|^2}.$$

A general helix in the sense of Lancret satisfies

$$\frac{\mathcal{T}_{\mathrm{F}}}{\kappa_{\mathrm{F}}} = \text{constant}.$$

An arbitrary radial suspension need not satisfy that condition. The name *radial helical suspension* preserves the winding structure without asserting an unproved differential property.

76.2.2 Coordination of the regimes $J^2 = -I, 0, +I$ with the Frenet geometry

The generators

$$J_{+1}^2 = -I, \qquad J_0^2 = 0, \qquad J_{-1}^2 = I$$

produce elliptic, parabolic, and hyperbolic evolutions. A history may alternate them and publish a curve whose Frenet curvature varies continuously. The *trichromy* describes the sequence of internal regimes; Frenet geometry describes the output. The radial reader preserves both without confusing them.

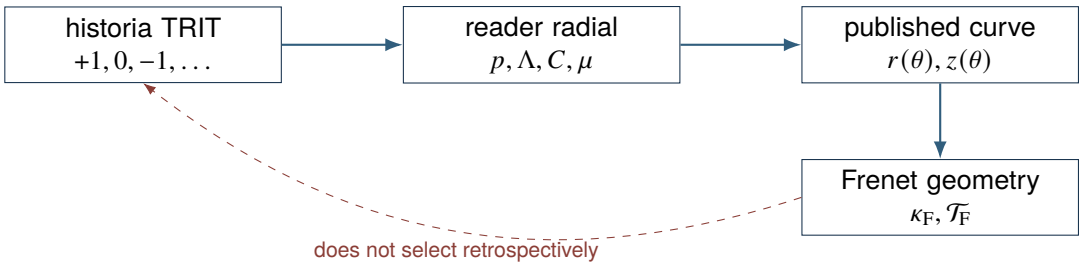

Figure 76.1: Causal separation between internal regime and visible curvature.

76.3 Dynamic structure of space and consequences

76.3.1 Helicoidal leaf lamination

The geometric synthesis is a lamination whose elements are lifted histories. Each leaf carries:

1. an angular phase;
2. a coordinate radial internal;
3. a memory depth;
4. a sequence of sheets APP;
5. a local TRIT regime;
6. a TPK holonomy and its boundary.

Transverse sections are circles or level curves; families of sections form cylinders; radial variation produces suspensions; the involution produces conjugate sheets. Real geometry is the image of this lamination under a publication that may contract several sheets.

76.3.2 Kinematic classification by angular and radial increments

A radial line appears when $\omega = 0$ and $\beta \neq 0$. A circle appears when $\omega \neq 0$ and $\beta = 0$. The spiral appears when both are nonzero. These three outputs are configurations of the same transport mechanism, not unrelated objects. The APP support is two-dimensional from the outset; the one-dimensional traversal is a particular section of that support.

76.3.3 Mobius Quotient via Return with Orientation Inversion

When the route involution is identified at the seam after one turn, the quotient may acquire a Möbius band. The assertion requires a free action and the intertwiner that transports orientation. The band does not follow from the mere presence of a sign -1; it follows from the seam

$$(x, 0) \sim (C_{\mathrm{rev}} x, 1)$$

in the declared domain. In the material atlas, the dodecaphasic involution and the cellular inversion remain distinct operations.

76.3.4 Classification of 3+2 equilibrium points via the Hessian

The intuition of Lagrange's three collinear and two triangular points may be formulated as a subsequent proof. Given an effective potential V_{eff} produced by the HMT–MD realization, the critical points satisfy

$$\nabla V_{\mathrm{eff}} = 0.$$

Its classification requires the Hessian and the Morse index. Only if the dimensional map produces exactly three collinear and two triangular critical points can it be related to the partition $3+2$. The correspondence is not used as an input to the spiral taxonomy.

76.3.5 Causal hierarchy between curves, fields, and material sections

The spiral correspondence opens three coordinated outputs:

$$\text{APP–TRIT–TPK ledger} \longrightarrow \begin{cases} \text{Archimedean curve,} \\ \text{electromagnetic mode,} \\ \text{material route signature.} \end{cases}$$

The first is algebraically closed in this work. The second has an exact realization for circular modes and a spectral compatibility condition. The third contains the central electron and the atlas but requires verification of the constancy square on each multisection before assigning flavor taxonomies.

Chapter 77

Icosahedral descent A_5/C_5 and selection of the five-component gravitational carrier

The gravitational line receives a chronological scale and then descends to the icosahedral quotient. The irreducible projector of rank 5 selects the tensor carrier without yet assuming a massive or radiative realization.

77.1 Intrinsic gravitational constant and tensor representation

77.1.1 Icosahedral descent A_5/C_5 and gravitational carrier selection

Gravity is organized here into four strata that must not be merged:

$$\begin{aligned} \text{CT108 chronological structure and action lines} &\longrightarrow \text{periodicity selector } \theta_{108}^{\mathrm{circ}} \longrightarrow G_{108},\\ \text{icosahedral incidence} &\longrightarrow V_{12} \xrightarrow{P_5} V_5 \xrightarrow{\Gamma_5} \mathrm{STF}_3 \xrightarrow{\Lambda(n)} \mathcal{H}_{\mathrm{TT}}(n),\\ \text{enriched holonomic route} &\dashrightarrow G_{\mathrm{hol}},\\ \text{metrological chart} &\longrightarrow 6.67430\times 10^{-11}\,\mathrm{m^3\,kg^{-1}\,s^{-2}}. \end{aligned} \tag{77.1}$$

The first line states a condition of periodicity that is intrinsic and exact. The second constructs the carrier and its trace-free transverse reduction. The third preserves an explicit construction boundary. The fourth is an evaluation in a declared decimal chart: it identifies the magnitude but does not select the gravitational character.

77.1.2 Gravitational magnitude line and chronological scale 108

Let $c_{\mathrm{int}} > 0$, $t_0 > 0$, $\ell_0 = c_{\mathrm{int}} t_0$ and a positive section $\hbar_a$ of the action line, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$. The dimensional transducer is

$$G_a(\theta) = \theta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a} = \theta \frac{c_{\mathrm{int}}^3 \ell_0^2}{\hbar_a}, \qquad \theta > 0. \tag{77.2}$$

The equality of the two expressions uses only $\ell_0 = c_{\mathrm{int}} t_0$, and $[G] = L^3 M^{-1} T^{-2}$. The dimension is fixed by the line; the mathematical problem is to select the dimensionless character θ.

The CT108 calendar defines

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi}{108 t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0. \tag{77.3}$$

For each action sheet, let

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2}. \tag{77.4}$$

Then, the reduced Compton wavelength coincides with the radius of the cycle:

$$\bar{\lambda}_{C,a} = \frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = R_{108}. \tag{77.5}$$

Theorem 77.1 (Uniqueness of the selector under the HMT periodicity condition)**.** *With the reduced convention $r_g = Gm/c_{\mathrm{int}}^2$ and the HMT periodicity premise that identifies the gravitational radius of the CT108 quantum with its phase radius, the closure condition*

$$r_{g,a}(\theta) = R_{108} \tag{77.6}$$

selects a unique positive solution,

$$\boxed{\theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi}\right)^2 = 295.4525715010569415303525\ldots.} \tag{77.7}$$

In that embodiment,

$$R_{108} = \bar{\lambda}_{C,a} = r_{g,a} = \ell_P^{\mathrm{circ}}. \tag{77.8}$$

Proof. By equations (77.2) y (77.4),

$$r_{g,a}(\theta) = \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta c_{\mathrm{int}} t_0^2 \omega_{108} = \theta \frac{\pi}{54} \ell_0.$$

Comparing it with $R_{108} = (54/\pi)\ell_0$ necessarily gives $\theta = (54/\pi)^2$. The equation is linear in θ and all the factors are positive, so the solution is unique. □

The equality $r_g = R_{108}$ does not follow from the dimensionality of equation (77.2). It is the explicit geometric condition of this HMT realization: action, Compton, and periodic return must determine the same length. The theorem proves that, once this structural condition is accepted, the character θ is fixed without using the SI value of G.

Remark 77.2 (Radius convention). The theorem uses the reduced gravitational radius Gm/c^2. If it is replaced by the Schwarzschild radius $2Gm/c^2$, the selector changes by a factor of two. The two expressions correspond to distinct geometric conditions, so the convention must be declared before the calculation.

77.1.3 Planck System and Bidirectional Covariance

Corollary 77.3 (Planck Family Associated with the CT108 Chronological Structure)**.** *For* $G_a = G_a(\theta_{108}^{\mathrm{circ}})$,

$$\ell_P = \frac{54}{\pi}\ell_0, \qquad t_P = \frac{54}{\pi} t_0, \tag{77.9}$$

$$E_{P,a} = \frac{\hbar_a}{t_P} = \frac{\pi \hbar_a}{54 t_0} = \frac{h_a}{108 t_0}, \qquad \ell_P^2 = \frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = \theta_{108}^{\mathrm{circ}} \ell_0^2. \tag{77.10}$$

Además,

$$F_{P,a} = \frac{c_{\mathrm{int}}^4}{G_a}, \qquad P_{P,a} = \frac{c_{\mathrm{int}}^5}{G_a}, \qquad \rho_{P,a} = \frac{\hbar_a}{(\theta_{108}^{\mathrm{circ}})^2 c_{\mathrm{int}}^5 t_0^4}. \tag{77.11}$$

Proof. The first three identities follow from $\ell_P = R_{108}$, $t_P = \ell_P/c_{\mathrm{int}}$, and $h_a = 2\pi\hbar_a$. For the area,

$$\frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^2 t_0^2 = \theta_{108}^{\mathrm{circ}} \ell_0^2.$$

The remaining expressions are the dimensional compositions of force, power, and mass per volume with the same section. □

Let

$$R_{\mathrm{act}} := \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}}. \tag{77.12}$$

Since the action appears in the numerator of the chronological mass and in the denominator of G,

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad G_a \hbar_a = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^5 t_0^2. \tag{77.13}$$

Therefore, $\ell_P^2 = G_a\hbar_a/c^3$ does not change sheets. Gravity and action are reciprocally oriented, while area preserves the common geometry. This cancellation is the interface of confluence toward the area operator of the section 71.1.

77.1.4 Icosahedral Component of Dimension 5

The antecedent is neither $\mathbb{R}$ nor a subsequent selection of five polarizations. The object responsible for transporting the incidence is defined explicitly before introducing the exceptional realization.

Let $X_{\mathrm{TPK}}^{\mathrm{exc}}$ be the subspace of the enriched state TPK that preserves, in addition to the arithmetic output, the orientation, route, carry, and exceptional incidence. To make the geometric target space explicit, let $\varphi_g = (1+\sqrt{5})/2$, $\nu = \sqrt{1+\varphi_g^2}$, and define

$$\Omega_{12}^{\mathrm{ico}} = \frac{1}{\nu}\big(\{0\}\times\{\pm1\}\times\{\pm\varphi_g\} \;\cup\; \{\pm1\}\times\{\pm\varphi_g\}\times\{0\} \;\cup\; \{\pm\varphi_g\}\times\{0\}\times\{\pm1\}\big) \subset S^2. \tag{77.14}$$

Its twelve elements are the oriented vertex classes of an icosahedron. The incidence is not left verbal: it is fixed by

$$\mathcal{I}_{12}^{\mathrm{ico}} = \{(v,w) \in \Omega_{12}^{\mathrm{ico}} \times \Omega_{12}^{\mathrm{ico}} : v \neq w,\ \langle v, w\rangle = 1/\sqrt{5}\}. \tag{77.15}$$

Each vertex has five neighbors in this relation. The reading bridge is typed as a map

$$\pi_{\mathrm{ico}} : X_{\mathrm{TPK}}^{\mathrm{exc}} \longrightarrow \Omega_{12}^{\mathrm{ico}}. \tag{77.16}$$

The cardinality twelve of the image of π_{ico} is not sufficient. To define an incidence realization, the mapping must satisfy simultaneously:

(i) being surjective and constant exactly on the fibers that discard the arithmetic chart but preserve the exceptional route;

(ii) intertwine the action of the oriented automorphisms of the antecedent with a transitive action on $\Omega_{12}^{\mathrm{ico}}$;

(iii) transporting the declared TPK incidence to $\mathcal{I}_{12}^{\mathrm{ico}}$, not merely its cardinalities;

(iv) preserve the leaf involution and the nonadic return in the stabilizer of the corresponding fiber.

These conditions separate three assertions: the existence of the map π_{ico}, the identification of the group that acts, and the linear representation constructed thereafter. The second and third cannot be used to define the first retrospectively.

Theorem 77.4 (Incidence Descent to the Icosahedral Quotient)**.** *Suppose that π_{ico} satisfies (i)–(iv) and that the oriented action induced on $\Omega_{12}^{\mathrm{ico}}$ has group $G_{\mathrm{ico}} \simeq A_5$. Then, for every class $v_0 \in \Omega_{12}^{\mathrm{ico}}$,*

$$H_{v_0} = \mathrm{Stab}_{G_{\mathrm{ico}}}(v_0) \simeq C_5, \qquad \Omega_{12}^{\mathrm{ico}} \simeq G_{\mathrm{ico}}/H_{v_0} \simeq A_5/C_5. \tag{77.17}$$

The application

$$\kappa_{v_0} : G_{\mathrm{ico}}/H_{v_0} \longrightarrow \Omega_{12}^{\mathrm{ico}}, \qquad gH_{v_0} \longmapsto g\cdot v_0, \tag{77.18}$$

is an equivariant bijection and preserves incidence if, in the quotient, one declares

$$gH_{v_0} \sim g'H_{v_0} \quad\Longleftrightarrow\quad (g\cdot v_0, g'\cdot v_0) \in \mathcal{I}_{12}^{\mathrm{ico}}. \tag{77.19}$$

Therefore, the composite $\kappa_{v_0}^{-1}\pi_{\mathrm{ico}}$ is the typed map from the TPK antecedent to the quotient A_5/C_5.

Proof. The list of equation (77.14) has twelve elements. By transitivity, $|G_{\mathrm{ico}}\cdot v_0| = 12$, and the orbit–stabilizer theorem gives $|H_{v_0}| = 60/12 = 5$. Every group of prime order five is cyclic; hence $H_{v_0} \simeq C_5$. The formula for κ_{v_0} does not depend on the representative: if $gH_{v_0} = g'H_{v_0}$, then $g^{-1}g' \in H_{v_0}$

and $g'v_0 = gv_0$. Surjectivity follows from transitivity, and equality of the cardinalities gives injectivity. Equivariance is immediate: $\kappa_{v_0}(agH_{v_0}) = a\kappa_{v_0}(gH_{v_0})$. Finally, equation (77.19) is precisely the transport of structure through that bijection; hypothesis (iii) makes this transport commute with π_{ico}. □

The theorem does not replace the construction of π_{ico}: it proves that it is obtained once its four requirements have been verified. In the complete HMT profile, the incidence corridor reaching Paley–Witt–Golay–Leech–$V^\natural$–Monster–Moonshine is the domain of definition of that map. In this autonomous volume, the exact input is the map equation (77.16) with its conditions; the entire segment from A_5/C_5 to TT reduction is proved below without again consulting a gravitational value.

The chain of provenance is expressed through all its morphisms:

$$\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{exc}} \xrightarrow{\pi_{\mathrm{ico}}} \Omega_{12}^{\mathrm{ico}} \xleftarrow[\simeq]{\kappa_{v_0}} A_5/C_5. \tag{77.20}$$

The complete exceptional corridor is proved in its own dedicated development. The hypothesis that this chapter cannot replace with a count is the existence of π_{ico} satisfying (i)–(iv). With that input fixed, descent to the quotient is theorem 77.4, and P_5, Γ_5 and $\Lambda(n)$ are constructed from it. Realizing the resulting carrier as a gravitational field remains a typed physical interface, not a consequence of cardinality.

Let $G = A_5$, let $H \simeq C_5$ be the stabilizer of an oriented vertex of the icosahedron, and consider

$$V_{12} = \mathbb{R}[G/H], \qquad |G/H| = \frac{60}{5} = 12. \tag{77.21}$$

The permutation representation ρ_{12} decomposes as

$$V_{12} \simeq \mathbf{1} \oplus V_3 \oplus V_{3'} \oplus V_5. \tag{77.22}$$

The central idempotent of the character summand $\chi_5 = (5, 1, -1, 0, 0)$ is

$$\boxed{P_5 = \frac{5}{60} \sum_{g \in A_5} \chi_5(g^{-1})\rho_{12}(g) = \frac{1}{12}\left(5I + \sum_{g \in 2A} \rho_{12}(g) - \sum_{g \in 3A} \rho_{12}(g)\right).} \tag{77.23}$$

Theorem 77.5 (Rank-five gravitational projector and coupler)**.** *The operator P_5 satisfies*

$$P_5^2 = P_5 = P_5^*, \qquad \mathrm{Tr}\, P_5 = \mathrm{rank}\, P_5 = 5. \tag{77.24}$$

For

$$\mathbb{G}_{5,a} := G_a(\theta_{108}^{\mathrm{circ}})P_5 \tag{77.25}$$

we have

$$\mathrm{Spec}(\mathbb{G}_{5,a}) = \{G_a(\theta_{108}^{\mathrm{circ}}) \textit{ with multiplicity } 5,\ 0 \textit{ with multiplicity } 7\}. \tag{77.26}$$

Proof. Character orthogonality converts equation (77.23) into the central idempotent that acts as the identity on the unique copy of V_5 and as zero on the other three summands of equation (77.22). Reality of the character and orthogonality of ρ_{12} give self-adjointness. Its trace and rank are five. Multiplying a rank-five projector by the positive scalar G_a immediately produces the indicated spectrum. □

The expression $\mathbb{G}_{5,a}$ does not add five different values of the gravitational constant. It is the same section of G acting on the selected tensor summand and annihilating the other seven modes of the module under the permutation action.

Equivariant reduction of the carrier to the traceless tensor sector. The carrier intertwines with the symmetric traceless tensors and is reduced equivariantly before transversality is imposed.

77.1.5 Icosahedral incidence and five-component gravitational coupling

The discrete structure of the continuum preserves an incidence reading alongside the arithmetic reading. The five-component gravitational carrier is constructed through that incidence and its tensor representation. The coupling section $G_a(\vartheta^\circ_{108})$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$, is the one obtained in section 80.3; what follows makes explicit the space on which it acts, its five components and its transverse projection.

Let $X^{\mathrm{exc}}_{\mathrm{TPK}}$ be the subspace of the enriched state TPK that preserves, in addition to the arithmetic output, the orientation, route, carry, and exceptional incidence. To make the geometric target space explicit, let $\varphi_g = (1+\sqrt{5})/2$, $\nu = \sqrt{1+\varphi_g^2}$, and define

$$\Omega^{\mathrm{ico}}_{12} = \frac{1}{\nu}\big(\{0\}\times\{\pm1\}\times\{\pm\varphi_g\} \;\cup\; \{\pm1\}\times\{\pm\varphi_g\}\times\{0\} \;\cup\; \{\pm\varphi_g\}\times\{0\}\times\{\pm1\}\big) \subset S^2. \tag{77.27}$$

Its twelve elements are the oriented vertex classes of an icosahedron. The incidence is not left verbal: it is fixed by

$$\mathcal{I}^{\mathrm{ico}}_{12} = \{(v,w) \in \Omega^{\mathrm{ico}}_{12}\times\Omega^{\mathrm{ico}}_{12} : v \neq w,\ \langle v, w\rangle = 1/\sqrt{5}\}. \tag{77.28}$$

Each vertex has five neighbors in this relation. The reading bridge is typed as a map

$$\pi_{\mathrm{ico}} : X^{\mathrm{exc}}_{\mathrm{TPK}} \longrightarrow \Omega^{\mathrm{ico}}_{12}. \tag{77.29}$$

The incidence realization requires, in addition to the twelve elements of the image, the following simultaneous properties of the map:

(i) being surjective and constant exactly on the fibers that discard the arithmetic chart but preserve the exceptional route;

(ii) intertwine the action of the oriented automorphisms of the antecedent with a transitive action on $\Omega^{\mathrm{ico}}_{12}$;

(iii) transporting the declared TPK incidence to $\mathcal{I}^{\mathrm{ico}}_{12}$, not merely its cardinalities;

(iv) preserve the leaf involution and the nonadic return in the stabilizer of the corresponding fiber.

These conditions fix the order of the construction: first the map π_{ico}, then the identification of the induced action and, finally, its linear representation. Orientation, route and carry belong to the enriched antecedent of that descent.

77.1.5.1 Calendar projection and representation of its twelve positions

The calendar of Section 1.23.5 provides an observable coordinate of the complete state. In its notation, write $r_0(\theta) = r(\theta) - 1 \in \{0,\dots,8\}$ and $b = \beta(\theta) \in \mathbb{Z}/12\mathbb{Z}$. The clock projection is

$$Q_{\mathrm{clk}}(x) = \big(\beta(\theta(x)), r_0(\theta(x))\big).$$

For an admissible route of n updates, the induced transport is

$$k(r_0,n) = \left\lfloor \frac{r_0+n}{9} \right\rfloor, \qquad T_n(b,r_0) = \big(b + k(r_0,n) \bmod 12,\ (r_0+n) \bmod 9\big). \tag{77.30}$$

Here $n \in \mathbb{N}_0$ counts effective updates; the integer quotient k records the nonadic returns crossed.

Proposition 77.6 (Compatibility of the calendar with route composition)**.** *The projection Q_{clk}, together with the length of each route, defines a functor from the category of admissible TPK routes to the action category of calendar (77.30). The identities $T_{m+n} = T_m T_n$, $T_0 = I$, $T_9(b,r_0) = (b+1, r_0)$, and $T_{108}(b,r_0) = (b,r_0)$ hold.*

Proof. Putting $r_0' = (r_0+n) \bmod 9$, Euclidean division gives

$$k(r_0, n+m) = k(r_0, n) + k(r_0', m).$$

This identity simultaneously preserves residue and quotient when the routes are concatenated. The update of θ established in Section 1.23.5 induces exactly (77.30); the remaining identities follow by substitution. The target category has pairs (b, r_0) as objects and admissible lengths as arrows, with addition as composition. □

The index $p = b + 1 \in \{1, \dots, 12\}$, taking the representative $0 \le b < 12$, publishes the dodecaphase position. One turn of 108 updates traverses its twelve positions. The proved periodicity corresponds to this projection: route, accumulated carry and memory remain in the source state and continue their update.

Incidence realization from the angular projector. The representatives $r_p C_5$ and the representation ρ of section 20.2 fix the chart of the twelve positions. The projector already defined by (20.5) produces

$$\begin{aligned} &\mathcal{H}_3 = P_3^{\mathrm{ico}}\mathbb{R}^{12}, \qquad v_p = 2P_3^{\mathrm{ico}} e_p, \\ &(P_3^{\mathrm{ico}})_{pq} = \frac{1}{20} \sum_{\substack{g \in A_5 \\ g r_q C_5 = r_p C_5}} \chi_3(g^{-1}). \end{aligned} \tag{77.31}$$

The last sum contains five terms per entry and uses the representatives and the two classes of order-five cycles fixed there.

Proposition 77.7 (Icosahedral realization of the dodecaphase positions)**.** *The vectors v_p are twelve distinct unit vectors in $\mathcal{H}_3$. Their incidence is $p \sim q \iff \langle v_p, v_q \rangle = 1/\sqrt{5}$. The map $p \mapsto v_p$ is A_5-equivariant, and its image is isometric to $\Omega_{12}^{\mathrm{ico}}$.*

Proof. Transitivity and $\operatorname{Tr} P_3^{\mathrm{ico}} = 3$ give $(P_3^{\mathrm{ico}})_{pp} = 1/4$; by idempotence, $\langle v_p, v_q \rangle = 4(P_3^{\mathrm{ico}})_{pq}$ and $\|v_p\| = 1$. Evaluation of the five terms in (77.31) gives the antipodal pairs

$$(1,4),\ (2,3),\ (5,8),\ (6,7),\ (9,12),\ (10,11).$$

For the representatives $(1, 2, 5, 6, 9, 10)$, their Gram matrix is

$$I_6 + \frac{D}{\sqrt{5}}, \qquad D = \begin{pmatrix} 0 & -1 & -1 & 1 & -1 & 1 \\ -1 & 0 & 1 & 1 & -1 & -1 \\ -1 & 1 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & -1 & 1 \\ -1 & -1 & 1 & -1 & 0 & 1 \\ 1 & -1 & 1 & 1 & 1 & 0 \end{pmatrix}, \qquad D^2 = 5I_6. \tag{77.32}$$

The remaining scalar products are obtained by antipodality. Thus, apart from a vertex and its opposite, the products are $\pm 1/\sqrt{5}$, and each vertex has five neighbours. The following table makes explicit the comparison with the signed six-position chart $\mathcal{U} = (\infty, 0, 1, 2, 3, 4)$:

p	$u(p)$	$\sigma(p)$	p	$u(p)$	$\sigma(p)$
1	∞	$+1$	7	3	-1
2	0	-1	8	1	$+1$
3	0	$+1$	9	2	-1
4	∞	-1	10	4	$+1$
5	1	-1	11	4	-1
6	3	$+1$	12	2	$+1$

(77.33)

Indeed, for $C = \mathrm{bal}(A_W)$, with A_W given in (21.126), the entries of D are $D_{ab} = \sigma(p_a)\sigma(p_b)C_{u(p_a),u(p_b)}$. Consequently, the table and (77.32) isometrically identify v_p with $\sigma(p)\sqrt{2}E_C e_{u(p)}$, where $E_C = (I_6 + C/\sqrt{5})/2$. Both systems span three-dimensional spaces and have identical Gram matrices, proving that the induced linear map is well defined and isometric. The explicit realization in (77.38), proved below, identifies it with $\Omega_{12}^{\mathrm{ico}}$ and its incidence. Finally, $P_3^{\mathrm{ico}}\rho(g) = \rho(g)P_3^{\mathrm{ico}}$ implies $v_{g\cdot p} = \rho(g)v_p$. The bijection of the twelve positions gives $\mathrm{Stab}_{A_5}(v_p) = r_p C_5 r_p^{-1}$. □

One thus obtains the representational composition

$$x \longmapsto Q_{\mathrm{clk}}(x) \longmapsto p = \beta(\theta(x)) + 1 \longmapsto v_p. \tag{77.34}$$

The signed expression of this composition is $r_{\pm}^{\mathrm{rep}}(x) = (u(p), \sigma(p))$, determined by table (77.33). The table is an explicit choice of alignment between charts; the actions of A_5 provide its equivalent alignments. The complete register is preserved in the domain of (77.34).

Link with the five-component tensor carrier. In $\mathcal{H}_3$, form $Q_p = v_p v_p^* - I_{\mathcal{H}_3}/3$. Let $J = \mathbf{1}\mathbf{1}^*$, and let A be the matrix of the preceding antipodal permutation. The Frobenius product and (77.32) give

$$\begin{aligned} \mathrm{Gram}(Q_p) &= (4P_3^{\mathrm{ico}}) \circ (4P_3^{\mathrm{ico}}) - \frac{1}{3}J = \frac{4}{5}(I + \mathsf{A}) - \frac{2}{15}J, \\ P_5^{\mathrm{ico}} &= \frac{5}{8}\,\mathrm{Gram}(Q_p) = \frac{1}{2}(I + \mathsf{A}) - \frac{1}{12}J. \end{aligned} \tag{77.35}$$

The symbol $\circ$ denotes the entrywise product. The last expression is the orthogonal projector onto coordinates even under antipodality and orthogonal to $\mathbf{1}$, of dimension five. Its character is $(5, 1, -1, 0, 0)$: on the six antipodal pairs, the fixed-point counts are $(6, 2, 0, 1, 1)$, and the constant component is removed. It therefore coincides with the central projector of (77.49). This identity links the three-dimensional construction with Γ_0 and Γ_5, defined in (77.54) and (77.56), through the explicit quadratic operation $v_p \mapsto Q_p$.

77.1.5.2 Transport of the representational frame

Let $s = (1\,2\,\cdots\,12)$, and let $S_c e_p = e_{s(p)}$. A nonadic calendar return takes p to $s(p)$. The joint transport of frame, representation, and projector is expressed by

$$\begin{aligned} P_{3,k}^{\mathrm{ico}} = S_c^k P_3^{\mathrm{ico}} S_c^{-k}, \qquad \rho^{(k)}(g) = S_c^k \rho(g) S_c^{-k}, \\ v_{s^k(p)}^{(k)} = 2P_{3,k}^{\mathrm{ico}} e_{s^k(p)} = S_c^k v_p. \end{aligned} \tag{77.36}$$

The last equality follows by substitution; orthogonality of S_c preserves all inner products and transports incidence. For a route of length n, take $k = k(r_0, n)$. The carry identity in Proposition 77.6 proves compatibility of these transports with concatenation. Although $S_c^{12} = I$, the twelve turns update the memory of the source route.

Equality (77.36) establishes covariance between frames. The active action on a fixed incidence has additional content: it requires identifying the transport of the complete state and its action in that chart. In particular, s has order twelve, whereas the orders of the elements of A_5 are $1, 2, 3, 5$. Likewise, the stabilizer of a vertex has order five, and that of its antipodal pair has order ten; the involution of the signed chart interchanges the two vertices. These distinctions preserve the meaning of orientation, sheet and return in properties (i)–(iv): the proved representational realization and the descent of the complete exceptional route are related through those properties, with their declared domains and fibres.

Construction of the carrier from six-position incidence. The matrix A_W of (21.126), which enters previously in the angular transport of section 20.2, provides an explicit antecedent of the icosahedral

realization. Let $C = \mathrm{bal}(A_W)$, where $\mathrm{bal}(0) = 0$, $\mathrm{bal}(1) = 1$ and $\mathrm{bal}(2) = -1$. The order of its coordinates is $\mathcal{U} = (\infty, 0, 1, 2, 3, 4)$. The integer chart satisfies $C = C^{\mathsf{T}}$, $C^2 = 5I_6$ and $\operatorname{Tr} C = 0$. We define its signed covering by

$$\mathcal{D}_C = \mathcal{U} \times \{+1, -1\}, \qquad (u, \sigma) \sim_C (v, \tau) \iff u \neq v \text{ and } \sigma\tau = C_{uv}. \tag{77.37}$$

Orientation doubles each coordinate; the matrix decides the incidences between the two corresponding fibers. The involution of this covering is $\jmath_C(u, \sigma) = (u, -\sigma)$.

Proposition 77.8 (Isometric realization of signed incidence)**.** *The operator and vectors*

$$E_C = \frac{1}{2}\left(I_6 + \frac{C}{\sqrt{5}}\right), \qquad \mathcal{H}_C = \operatorname{im} E_C, \qquad v_{u,\sigma} = \sigma\sqrt{2} E_C e_u \tag{77.38}$$

realize $\mathcal{D}_C$ as twelve distinct unit vectors in a three-dimensional Euclidean space. There is an explicit isometry $T_C : \mathcal{H}_C \to \mathbb{R}^3$ for which $\iota_C(u, \sigma) = T_C v_{u,\sigma}$ is a bijection onto $\Omega_{12}^{\mathrm{ico}}$, preserves incidence, and satisfies $\iota_C \jmath_C = -\iota_C$.

Proof. From $C^2 = 5I_6$, one obtains $E_C^2 = E_C = E_C^*$; its trace is three. The metric identities are

$$\langle v_{u,\sigma}, v_{v,\tau} \rangle = \begin{cases} \sigma\tau, & u = v, \\ \sigma\tau C_{uv}/\sqrt{5}, & u \neq v. \end{cases}$$

Thus the twelve vectors are distinct, and their inner-product $1/\sqrt{5}$ incidence is exactly (77.37). To make the isometry explicit, let the columns of B, in order $\mathcal{U}$, be

$$B = \frac{1}{\nu}\begin{pmatrix} 0 & -1 & -\varphi_g & 0 & \varphi_g & 1 \\ -1 & -\varphi_g & 0 & 1 & 0 & -\varphi_g \\ -\varphi_g & 0 & -1 & -\varphi_g & -1 & 0 \end{pmatrix}.$$

Substitution of $\varphi_g^2 = \varphi_g + 1$ gives $B^* B = I_6 + C/\sqrt{5} = 2E_C$. Hence $T_C = B/\sqrt{2}\big|_{\mathcal{H}_C}$ is an isometry, and $T_C v_{u,\sigma} = \sigma B e_u$. The six columns of B and their opposites are precisely the twelve vertices of (77.27). The last identity also proves compatibility of the involutions. □

The preceding dodecaphasic realization constructs the twelve vectors directly from the projector P_3^{ico} and the calendar positions. The signed covering provides another coordinate expression of that carrier. For the reader π_{ico} in the descent theorem, the relation between the two expressions is written

$$X_{\mathrm{TPK}}^{\mathrm{exc}} \xrightarrow{r_\pm} \mathcal{D}_C \xrightarrow[\simeq]{\iota_C} \Omega_{12}^{\mathrm{ico}}, \qquad \pi_{\mathrm{ico}}(x) = \sigma(x) B e_{u(x)}, \quad r_\pm(x) = (u(x), \sigma(x)). \tag{77.39}$$

Since ι_C is a bijection, this factorization determines $r_\pm = \iota_C^{-1}\pi_{\mathrm{ico}}$. Thus, $r_\pm$ expresses in the signed chart the reader being used: its introduction does not add an independent hypothesis for constructing the dodecaphase carrier. The preceding correspondence table gives that expression for its twelve positions. Properties (i)–(iv) retain their own scope when the realization is identified with the quotient of the complete exceptional route. In particular, the joint transport of frame, projector and incidence proves covariance between charts; the preservation of a fixed incidence by an active transformation is a distinct identity. Orientation and memory remain in the source state during both readings. A signed permutation that transports C jointly transports E_C, its vectors and its incidence; this covariance allows the charts to be compared while preserving the orientation of each fibre.

Theorem 77.9 (Incidence Descent to the Icosahedral Quotient)**.** *Suppose that π_{ico} satisfies (i)–(iv) and that the oriented action induced on $\Omega_{12}^{\mathrm{ico}}$ has group $G_{\mathrm{ico}} \simeq A_5$. Then, for every class $v_0 \in \Omega_{12}^{\mathrm{ico}}$,*

$$H_{v_0} = \mathrm{Stab}_{G_{\mathrm{ico}}}(v_0) \simeq C_5, \qquad \Omega_{12}^{\mathrm{ico}} \simeq G_{\mathrm{ico}}/H_{v_0} \simeq A_5/C_5. \tag{77.40}$$

The application

$$\kappa_{v_0} : G_{\mathrm{ico}}/H_{v_0} \longrightarrow \Omega_{12}^{\mathrm{ico}}, \qquad gH_{v_0} \longmapsto g \cdot v_0, \tag{77.41}$$

is an equivariant bijection and preserves incidence if, in the quotient, one declares

$$gH_{v_0} \sim g'H_{v_0} \quad \Longleftrightarrow \quad (g \cdot v_0, g' \cdot v_0) \in \mathcal{I}_{12}^{\mathrm{ico}}. \tag{77.42}$$

Therefore, the composite $\kappa_{v_0}^{-1}\pi_{\mathrm{ico}}$ is the typed map from the TPK antecedent to the quotient A_5/C_5.

Proof. The list of (77.27) has twelve elements. By transitivity, $|G_{\mathrm{ico}} \cdot v_0| = 12$, and the orbit–stabilizer theorem gives $|H_{v_0}| = 60/12 = 5$. Every group of prime order five is cyclic; hence $H_{v_0} \simeq C_5$. The formula for κ_{v_0} does not depend on the representative: if $gH_{v_0} = g'H_{v_0}$, then $g^{-1}g' \in H_{v_0}$ and $g'v_0 = gv_0$. Surjectivity follows from transitivity, and equality of the cardinalities gives injectivity. Equivariance is immediate: $\kappa_{v_0}(agH_{v_0}) = a\kappa_{v_0}(gH_{v_0})$. Finally, (77.42) is precisely the transport of structure through that bijection; hypothesis (iii) makes this transport commute with π_{ico}. □

The theorem establishes descent once the four properties of π_{ico} have been verified. Its domain is the enriched state of the exceptional reading, which preserves the incidence transported by APP–TRIT–TPK. In this construction, the explicit antecedent is the map (77.29) with its four properties; the passage from A_5/C_5 to the transverse traceless reduction is proved below with that antecedent and the induced action of A_5.

The chain of provenance is expressed through all its morphisms:

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{exc}} \xrightarrow{\pi_{\mathrm{ico}}} \Omega_{12}^{\mathrm{ico}} \xleftarrow[\simeq]{\kappa_{v_0}} A_5/C_5. \tag{77.43}$$

The composition (77.43) retains as its antecedent the existence of π_{ico} with properties (i)–(iv). On that domain, descent to the quotient is theorem 77.9; from it are constructed the projector P_5^{ico}, the intertwiner Γ_5 and the projection $\Lambda(n)$. The realization of the carrier as a gravitational field additionally uses the dynamics and physical constraints specified at the end of this development.

Let $\mathcal{G} = A_5$, let $H \simeq C_5$ be the stabilizer of an oriented vertex of the icosahedron, and consider

$$V_{12} = \mathbb{R}[\mathcal{G}/H], \qquad |\mathcal{G}/H| = \frac{60}{5} = 12. \tag{77.44}$$

Characters of icosahedral incidence. The following calculation is performed on the icosahedral action obtained in Theorem 77.9, with its incidence and orientation hypotheses. It determines the decomposition of the vertex representation and the irreducibility of the tensor space through their traces, preserving the antecedent π_{ico} declared in that theorem.

Proposition 77.10 (Vertex decomposition and tensor character)**.** *Let $\tau = (1+\sqrt{5})/2$ and $\bar{\tau} = (1-\sqrt{5})/2$. In the class order $1, 2A, 3A, 5A, 5B$, the characters of the rotational representation V_3, its algebraic conjugate $V_{3'}$, the twelve-vertex representation V_{12}, and $\mathrm{STF}_3 = \mathrm{Sym}_0^2(V_3)$ are*

class	1	$2A$	$3A$	$5A$	$5B$
cardinal	1	15	20	12	12
class of g^2	1	1	$3A$	$5B$	$5A$
χ_3	3	-1	0	τ	$\bar\tau$
$\chi_{3'}$	3	-1	0	$\bar\tau$	τ
χ_{12}	12	0	0	2	2
χ_{STF}	5	1	-1	0	0

(77.45)

The representations $V_3, V_{3'}$ and STF_3 are absolutely irreducible and distinct. Moreover,

$$V_{12} \simeq \mathbf{1} \oplus V_3 \oplus V_{3'} \oplus \mathrm{STF}_3, \qquad \langle \chi_{12}, \chi_{\mathrm{STF}} \rangle = 1. \tag{77.46}$$

In particular, the five-dimensional summand occurs exactly once.

Proof. In A_5, there are $5 \cdot 3 = 15$ double transpositions and $\binom{5}{3} \cdot 2 = 20$ three-cycles. The $4! = 24$ five-cycles split into two classes of twelve: their centralizer is the cyclic subgroup of order five and is contained in A_5. Identifying the positions of a cycle with $\mathbb{Z}/5\mathbb{Z}$, the permutation inducing $r \mapsto 2r$ is a four-cycle on the nonzero elements, with negative sign. Squaring therefore exchanges the two classes. Inversion $r \mapsto -r$ is a product of two transpositions and preserves each class. This determines the first two rows of (77.45).

The representation V_3 is the action by rotations on the vertex coordinates. A rotation through angle θ has trace $1 + 2\cos\theta$. The classes of orders two and three give -1 and 0, respectively. The name $5A$ denotes the class of angles $\pm 2\pi/5$ and $5B$ that of $\pm 4\pi/5$; their traces are τ and $\bar\tau$. These expressions follow from $u^2 + u - 1 = 0$, for $u = 2\cos(2\pi/5)$, and from the double-angle formula. The equation for u follows by dividing $1 + z + z^2 + z^3 + z^4 = 0$ by z^2, with $z = \exp(2\pi i/5)$. We have thus calculated the character of a representation already defined geometrically.

To construct the other representation, use the vertices without the common normalization ν^{-1}. Their coordinates belong to $K = \mathbb{Q}(\sqrt{5})$. If B is the matrix of three linearly independent vertices and B_g contains their images, the rotation matrix is $R_g = B_g B^{-1} \in M_3(K)$. The conjugation $\sigma : \sqrt{5} \mapsto -\sqrt{5}$ then defines $R'_g = \sigma(R_g)$, satisfying

$$R'_{gh} = R'_g R'_h, \qquad (R'_g)^T R'_g = I, \qquad \det R'_g = 1.$$

Thus $V_{3'}$ is an effectively constructed real representation. Its character is $\sigma(\chi_3)$, exchanging τ and $\bar\tau$.

The permutation character counts fixed vertices. The identity fixes twelve; nontrivial rotations of order five fix the two endpoints of their axis. Those of order two or three fix no vertices, since the stabilizer of a vertex is C_5. Hence $\chi_{12} = (12, 0, 0, 2, 2)$.

For the tensor space, if $\lambda_1, \lambda_2, \lambda_3$ are the eigenvalues of R_g, the sum $\sum_{i \le j} \lambda_i \lambda_j$ is $\big((\sum_i \lambda_i)^2 + \sum_i \lambda_i^2\big)/2$. The metric form generates an invariant line in $\mathrm{Sym}^2(V_3)$, whose trace-free complement has character

$$\chi_{\mathrm{STF}}(g) = \frac{\chi_3(g)^2 + \chi_3(g^2)}{2} - 1. \tag{77.47}$$

Using the squaring map in the table and $\tau + \bar\tau = 1$, $\tau\bar\tau = -1$, gives $\chi_{\mathrm{STF}} = (5, 1, -1, 0, 0)$.

The real-character inner product is $\langle \chi, \psi \rangle = \frac{1}{60} \sum_C |C| \chi(C) \psi(C)$. In particular,

$$\begin{aligned} \langle \chi_3, \chi_3 \rangle &= \langle \chi_{3'}, \chi_{3'} \rangle = \frac{9 + 15 + 12(\tau^2 + \bar\tau^2)}{60} = 1, \\ \langle \chi_3, \chi_{3'} \rangle &= \frac{9 + 15 + 24\tau\bar\tau}{60} = 0, \\ \langle \chi_{\mathrm{STF}}, \chi_{\mathrm{STF}} \rangle &= \frac{25 + 15 + 20}{60} = 1. \end{aligned}$$

Norm one proves irreducibility of the complexifications; consequently, it also proves absolute irreducibility of the constructed real representations. Their dimensions and orthogonality distinguish the three summands. Finally, the equality of class functions

$$\chi_{12} = 1 + \chi_3 + \chi_{3'} + \chi_{\mathrm{STF}}$$

is verified in all five columns. Semisimplicity of finite-group representations in characteristic zero gives decomposition (77.46). The multiplicity of the tensor summand can be checked directly:

$$\langle \chi_{12}, \chi_{\mathrm{STF}} \rangle = \frac{12 \cdot 5}{60} = 1.$$

□

Thus the central idempotent associated with $\chi_{\mathrm{STF}} = \chi_5$ has rank $5 \cdot 1 = 5$ in V_{12}. The irreducibility entering normalization of the tensor intertwiner and the multiplicity entering gravitational coupling are established by this same calculation.

The permutation representation ρ_{12} decomposes as

$$V_{12} \simeq \mathbf{1} \oplus V_3 \oplus V_{3'} \oplus V_5. \tag{77.48}$$

The central idempotent of the character summand $\chi_5 = (5, 1, -1, 0, 0)$ is

$$\boxed{P_5^{\mathrm{ico}} = \frac{5}{60} \sum_{g \in A_5} \chi_5(g^{-1}) \rho_{12}(g) = \frac{1}{12} \left(5I + \sum_{g \in 2A} \rho_{12}(g) - \sum_{g \in 3A} \rho_{12}(g) \right).} \tag{77.49}$$

Theorem 77.11 (Rank-five gravitational projector and coupler)**.** *The operator P_5^{ico} satisfies*

$$(P_5^{\mathrm{ico}})^2 = P_5^{\mathrm{ico}} = (P_5^{\mathrm{ico}})^*, \qquad \operatorname{Tr} P_5^{\mathrm{ico}} = \operatorname{rank} P_5^{\mathrm{ico}} = 5. \tag{77.50}$$

For

$$\mathbb{G}_{5,a} := G_a(\vartheta_{108}^\circ) P_5^{\mathrm{ico}} \tag{77.51}$$

we have

$$\operatorname{Spec}(\mathbb{G}_{5,a}) = \{ G_a(\vartheta_{108}^\circ) \text{ with multiplicity } 5,\ 0 \text{ with multiplicity } 7 \}. \tag{77.52}$$

Proof. Character orthogonality converts (77.49) into the central idempotent that acts as the identity on the unique copy of V_5 and as zero on the other three summands of (77.48). Reality of the character and orthogonality of ρ_{12} give self-adjointness. Its trace and rank are five. Multiplying a rank-five projector by the positive scalar G_a immediately produces the indicated spectrum. □

The gravitational section G_a is common to the five components of the selected tensor summand. Its spectral multiplicity expresses the rank of the carrier; the other seven modes of the permutation module belong to the kernel of $\mathbb{G}_{5,a}$. The symbol P_5^{ico} identifies here this rank-five central projector on V_{12}; the average of the five positions of an arithmetic pentafibre has another domain and rank one.

77.1.6 Intertwiner with the space of symmetric traceless tensors

Let $\mathcal{V} = \Omega_{12}^{\mathrm{ico}} \subset S^2$ be the already constructed set of twelve unit vertices. For each $v \in \mathcal{V}$, define

$$Q_v = vv^T - \frac{1}{3} I_3 \in \mathrm{STF}_3 := \mathrm{Sym}_0^2(\mathbb{R}^3). \tag{77.53}$$

The frame map

$$\Gamma_0\left(\sum_{v\in\mathcal{V}} x_v e_v\right) = \sum_{v\in\mathcal{V}} x_v Q_v \tag{77.54}$$

is A_5-equivariant and satisfies

$$\Gamma_0\Gamma_0^* = \frac{8}{5} I_{\mathrm{STF}_3}, \qquad \Gamma_0 = \Gamma_0 P_5^{\mathrm{ico}}. \tag{77.55}$$

Theorem 77.12 (Normalized tensor entangler)**.** *The map*

$$\boxed{\Gamma_5 := \sqrt{\frac{5}{8}}\,\Gamma_0|_{V_5} : V_5 \xrightarrow{\simeq} \mathrm{STF}_3} \tag{77.56}$$

is a A_5-equivariant isometry. Its adjoint is

$$\Gamma_5^* Q = \sqrt{\frac{5}{8}} \sum_{v\in\mathcal{V}} (v^T Q v) e_v. \tag{77.57}$$

Proof. Equivariance follows from $Q_{gv} = gQ_v g^T$. The operator $\Gamma_0\Gamma_0^*$ commutes with the irreducible representation of A_5 on STF_3, and is therefore scalar. Its trace is

$$\sum_{v\in\mathcal{V}} \|Q_v\|_F^2 = 12 \cdot \frac{2}{3} = 8;$$

dividing by dimension five yields $8/5$. Hence, $\Gamma_5\Gamma_5^* = I$. Since domain and codomain have dimension five, also $\Gamma_5^*\Gamma_5 = I$. The formula for the adjoint follows from $\langle Q, Q_v\rangle_F = v^T Q v$. □

Normalization through the icosahedral frame constructs the isometry that transports the finite summand to the real spin-two tensor space.

77.1.7 Transverse traceless projection

For $n \in S^2$, let $\Pi(n) = I - nn^T$. We define

$$\boxed{\Lambda(n)Q = \Pi Q \Pi - \frac{1}{2}\,\mathrm{Tr}(\Pi Q \Pi)\Pi.} \tag{77.58}$$

Theorem 77.13 (Reduction from five components to two)**.** *The restriction of $\Lambda(n)$ to STF_3 is the orthogonal projector onto*

$$\mathcal{H}_{\mathrm{TT}}(n) = \{Q \in \mathrm{STF}_3 : Qn = 0\}. \tag{77.59}$$

In particular,

$$\Lambda(n)^2 = \Lambda(n) = \Lambda(n)^*, \qquad \operatorname{rank}\Lambda(n) = 2. \tag{77.60}$$

For $n = e_3$, the image is generated by

$$E_+ = \frac{1}{\sqrt{2}}\,\mathrm{diag}(1,-1,0), \qquad E_\times = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{77.61}$$

Proof. Since $\Pi n = 0$, the output is transverse. Its trace is

$$\mathrm{Tr}(\Pi Q \Pi) - \frac{1}{2}\,\mathrm{Tr}(\Pi)\,\mathrm{Tr}(\Pi Q \Pi) = 0,$$

since $\operatorname{Tr}\Pi = 2$. If $Qn = 0$ and $\operatorname{Tr} Q = 0$, then $\Pi Q \Pi = Q$ and $\operatorname{Tr}(\Pi Q \Pi) = 0$, so that $\Lambda(n)Q = Q$. The formula is self-adjoint with respect to the Frobenius product. In the frame $n = e_3$, its matrix in an adapted STF basis is $\operatorname{diag}(1, 1, 0, 0, 0)$, which proves the rank. □

The complete chain thus remains,

$$\boxed{V_{12} \xrightarrow{P_5^{\mathrm{ico}}} V_5 \xrightarrow{\Gamma_5} \mathrm{STF}_3 \xrightarrow{\Lambda(n)} \mathcal{H}_{\mathrm{TT}}(n), \qquad 12 \longrightarrow 5 \longrightarrow 5 \longrightarrow 2.} \tag{77.62}$$

The reduced coupling

$$\mathbb{G}_{\mathrm{TT},a}(n) = G_a(\vartheta_{108}^\circ)\Lambda(n)\Gamma_5 P_5^{\mathrm{ico}} \tag{77.63}$$

has rank two.

77.1.8 Decomposition into 5 polarization modes

Dimension five acquires tensorial content upon choosing a unit direction of propagation n and an oriented orthonormal frame (e_1, e_2, n). Define the five real tensors

$$E_+ = \frac{1}{\sqrt{2}}(e_1 e_1^T - e_2 e_2^T), \qquad E_\times = \frac{1}{\sqrt{2}}(e_1 e_2^T + e_2 e_1^T), \tag{77.64}$$

$$E_1 = \frac{1}{\sqrt{2}}(e_1 n^T + n e_1^T), \qquad E_2 = \frac{1}{\sqrt{2}}(e_2 n^T + n e_2^T), \tag{77.65}$$

$$E_0 = \frac{1}{\sqrt{6}}(2nn^T - e_1 e_1^T - e_2 e_2^T). \tag{77.66}$$

All are symmetric and traceless. The first two are transverse; the next two mix the transverse plane with the direction of propagation, and the last is the traceless longitudinal scalar mode.

Theorem 77.14 (Complete helical decomposition of the carrier)**.** *The tensors of* (77.64)*,* (77.65)*,* (77.66) *form an orthonormal basis of* STF_3*. In the complexification, the combinations*

$$E_{\pm 2} = \frac{1}{\sqrt{2}}(E_+ \mp i E_\times), \qquad E_{\pm 1} = \frac{1}{\sqrt{2}}(E_1 \mp i E_2), \qquad E_0 = E_0 \tag{77.67}$$

are weight-$\pm 2, \pm 1, 0$ *vectors, respectively, under rotations about* n*. Moreover,*

$$\Lambda(n)E_{\pm 2} = E_{\pm 2}, \qquad \Lambda(n)E_{\pm 1} = 0, \qquad \Lambda(n)E_0 = 0. \tag{77.68}$$

Proof. In the frame (e_1, e_2, n), each tensor has Frobenius norm one. Their off-diagonal entry patterns are disjoint, and the three diagonals of E_+, E_0 have zero inner product; therefore, the five tensors are orthonormal. Since $\dim \mathrm{STF}_3 = 6 - 1 = 5$, they form a basis.

A rotation through angle ψ about n sends (e_1, e_2) to $(\cos\psi\, e_1 + \sin\psi\, e_2, -\sin\psi\, e_1 + \cos\psi\, e_2)$. Substituting into the formulas gives a rotation through angle 2ψ on $\operatorname{span}\{E_+, E_\times\}$, one through angle ψ on $\operatorname{span}\{E_1, E_2\}$, and E_0 fixed. Hence the weights of (77.67). Finally, $\Pi E_+ \Pi = E_+$ and $\Pi E_\times \Pi = E_\times$, whereas $\Pi E_1 \Pi = \Pi E_2 \Pi = 0$. For E_0, $\Pi E_0 \Pi = -(e_1 e_1^T + e_2 e_2^T)/\sqrt{6}$, which is pure trace in the plane, and subtracting (77.58) annihilates it. □

The theorem specifies the meaning of "five polarizations" without assigning all of them the same dynamic status. Before field equations are imposed, the spin-two carrier has five irreducible coordinates. In a massive Fierz–Pauli realization, the constraints leave precisely the five weights of (77.67); in a massless realization with gauge invariance, the sectors ± 1 and 0 are eliminated, leaving ± 2. Here HMT supplies the carrier, the basis, and the projector; the choice of massive or massless dynamics belongs to the physical interface. Thus five does not mean "five observed waves," but rather five tensorial degrees available before reduction.

The orientation also remains visible: replacing (e_1, e_2, n) with $(e_1, -e_2, -n)$ preserves E_+, E_0 and exchanges the phases of the helical pairs. That information is not in the scalar G_a; it resides in the carrier on which $\mathbb{G}_{5,a}$ acts.

77.1.9 Physical interpretation of the representational chain

Dimension five appears in distinct objects, and only (77.62) authorizes transport between them:

1. V_5 is the irreducible summand of the representation on the twelve vertices. This is a finite result in representation theory.
2. STF_3 is the real five-dimensional carrier of the $m = -2, -1, 0, 1, 2$ weights of spin two.
3. A massive Fierz–Pauli theory can realize these five weights as five physical states, after fixing the action and constraints.
4. Massless general relativity retains two radiative helicities, ± 2, represented by E_+ and $E_\times$.
5. The $E(2)$ classes of metric waves, such as III_5, classify possible amplitudes under other hypotheses; they are not automatically V_5, Fierz–Pauli, or general relativity.

The structural content is thus determined: under the incidence-descent conditions, HMT constructs a five-component tensor carrier before imposing constraints. The massless realization preserves the two radiative helicities through the rank-two TT projection. Orientation information is preserved in the tensors and in their transport; the scalar value G_a determines the common coupling.

Chapter 78

Intertwiner with symmetric traceless tensors and transverse reduction $12 \to 5 \to 5 \to 2$

The icosahedral framework constructs an equivariant isometry into the space of traceless symmetric tensors. The transverse projection realizes $12 \to 5 \to 5 \to 2$, preserves the five-component carrier, and localizes the radiative subspace of dimension 2.

78.1 Intertwiner with the space of symmetric traceless tensors

Let $\mathcal{V} \subset S^2$ be the set of the twelve unit vertices of the icosahedron. For each $v \in \mathcal{V}$, define

$$Q_v = vv^T - \frac{1}{3} I_3 \in \mathrm{STF}_3 := \mathrm{Sym}^2_0(\mathbb{R}^3). \tag{78.1}$$

The frame map

$$\Gamma_0\left(\sum_{v\in\mathcal{V}} x_v e_v\right) = \sum_{v\in\mathcal{V}} x_v Q_v \tag{78.2}$$

is A_5-equivariant and satisfies

$$\Gamma_0\Gamma_0^* = \frac{8}{5} I_{\mathrm{STF}_3}, \qquad \Gamma_0 = \Gamma_0 P_5. \tag{78.3}$$

Theorem 78.1 (Normalized tensor entangler)**.** *The map*

$$\boxed{\Gamma_5 := \sqrt{\frac{5}{8}}\,\Gamma_0|_{V_5} : V_5 \xrightarrow{\simeq} \mathrm{STF}_3} \tag{78.4}$$

is a A_5-equivariant isometry. Its adjoint is

$$\Gamma_5^* Q = \sqrt{\frac{5}{8}} \sum_{v\in\mathcal{V}} (v^T Q v) e_v. \tag{78.5}$$

Proof. Equivariance follows from $Q_{gv} = gQ_v g^T$. The operator $\Gamma_0\Gamma_0^*$ commutes with the irreducible representation of A_5 on STF_3, and is therefore scalar. Its trace is

$$\sum_{v\in\mathcal{V}} \|Q_v\|_F^2 = 12 \cdot \frac{2}{3} = 8;$$

dividing by dimension five yields $8/5$. Hence, $\Gamma_5\Gamma_5^* = I$. Since domain and codomain have dimension five, also $\Gamma_5^*\Gamma_5 = I$. The formula for the adjoint follows from $\langle Q, Q_v\rangle_F = v^T Q v$. □

Normalization through the icosahedral frame eliminates a purely cardinal coincidence: it constructs the map that transports the finite summand to the continuous spin-two carrier.

78.2 Transverse traceless projection

For $n \in S^2$, let $\Pi(n) = I - nn^T$. We define

$$\boxed{\Lambda(n)Q = \Pi Q \Pi - \frac{1}{2}\operatorname{Tr}(\Pi Q \Pi)\Pi.} \tag{78.6}$$

Theorem 78.2 (Reduction from five components to two)**.** *The restriction of* $\Lambda(n)$ *to* STF_3 *is the orthogonal projector onto*

$$\mathcal{H}_{\mathrm{TT}}(n) = \{Q \in \mathrm{STF}_3 : Qn = 0\}. \tag{78.7}$$

In particular,

$$\Lambda(n)^2 = \Lambda(n) = \Lambda(n)^*, \qquad \operatorname{rank}\Lambda(n) = 2. \tag{78.8}$$

For $n = e_3$*, the image is generated by*

$$E_+ = \frac{1}{\sqrt{2}}\operatorname{diag}(1, -1, 0), \qquad E_\times = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{78.9}$$

Proof. Since $\Pi n = 0$, the output is transverse. Its trace is

$$\operatorname{Tr}(\Pi Q \Pi) - \frac{1}{2}\operatorname{Tr}(\Pi)\operatorname{Tr}(\Pi Q \Pi) = 0,$$

since $\operatorname{Tr}\Pi = 2$. If $Qn = 0$ and $\operatorname{Tr} Q = 0$, then $\Pi Q \Pi = Q$ and $\operatorname{Tr}(\Pi Q \Pi) = 0$, so that $\Lambda(n)Q = Q$. The formula is self-adjoint with respect to the Frobenius product. In the frame $n = e_3$, its matrix in an adapted STF basis is $\operatorname{diag}(1, 1, 0, 0, 0)$, which proves the rank. □

The complete chain thus remains,

$$\boxed{V_{12} \xrightarrow{P_5} V_5 \xrightarrow{\Gamma_5} \mathrm{STF}_3 \xrightarrow{\Lambda(n)} \mathcal{H}_{\mathrm{TT}}(n), \qquad 12 \longrightarrow 5 \longrightarrow 5 \longrightarrow 2.} \tag{78.10}$$

The reduced coupling

$$\mathbb{G}_{\mathrm{TT},a}(n) = G_a(\theta_{108}^{\mathrm{circ}})\Lambda(n)\Gamma_5 P_5 \tag{78.11}$$

has rank two.

Helical decomposition of the spectrum and separation of massive and non-massive modes. The reduction makes it possible to distinguish the complete helicoidal spectrum of a massive realization and its two massless helicities.

78.3 Oriented incidence and gravitational tensor representation

The exceptional publication of the state preserves the incidence accompanying its arithmetic reading. The ternary matrix A_W of (21.126) provides a precise material antecedent here. Its balanced lift $C = \mathrm{bal}(A_W)$, with representatives $0, 1, -1$, satisfies

$$C = C^{\mathsf{T}}, \qquad C^2 = 5I_6, \qquad \operatorname{Tr} C = 0.$$

The six positions have the order $(\infty, 0, 1, 2, 3, 4)$. This incidence first produces a three-dimensional space; its quadratic reading then produces the five-component space on which the gravitational coupling acts.

78.3.1 Signed covering and calendar transport

We define

$$E_C = \frac{1}{2}(I_6 + C/\sqrt{5}), \quad \mathcal{H}_C = \operatorname{im} E_C, \quad v_{u,\sigma} = \sigma\sqrt{2}E_C e_u, \quad \sigma \in \{1,-1\}.$$

Proposition 78.3 (Twelve oriented positions)**.** *The vectors $v_{u,\sigma}$ are twelve distinct unit vectors in a three-dimensional space. Their incidence is determined by $\langle v_{u,\sigma}, v_{v,\tau}\rangle = 1/\sqrt{5}$. Orientation reversal acts by antipodality.*

Proof. The quadratic identity for C implies $E_C^2 = E_C = E_C^*$; its trace is three. Since the diagonal of C is zero,

$$\langle v_{u,\sigma}, v_{v,\tau}\rangle = \begin{cases} \sigma\tau, & u = v, \\ \sigma\tau C_{uv}/\sqrt{5}, & u \neq v. \end{cases}$$

This proves normalization, distinction of the twelve vectors and incidence. Changing σ to $-\sigma$ changes the sign of the vector. □

An explicit Euclidean expression is obtained by setting $\nu = \sqrt{1+\varphi^2}$ and

$$B = \frac{1}{\nu}\begin{pmatrix} 0 & -1 & -\varphi & 0 & \varphi & 1 \\ -1 & -\varphi & 0 & 1 & 0 & -\varphi \\ -\varphi & 0 & -1 & -\varphi & -1 & 0 \end{pmatrix}.$$

The relation $\varphi^2 = \varphi + 1$, for the coordinate already generated, gives $B^*B = 2E_C$. Consequently $B/\sqrt{2}|_{\mathcal{H}_C}$ is an isometry and takes $v_{u,\sigma}$ to $\sigma B e_u$. The image is

$$\mathcal{V} = \frac{1}{\nu}\big(\{0\}\times\{\pm1\}\times\{\pm\varphi\} \;\cup\; \{\pm1\}\times\{\pm\varphi\}\times\{0\} \;\cup\; \{\pm\varphi\}\times\{0\}\times\{\pm1\}\big).$$

The internal coordinate, the incidence and its twelve geometric representatives are thus related.

The calendar coordinate is written $(b, r) \in \mathbb{Z}/12\mathbb{Z} \times \{0,\dots,8\}$. A route of length n induces

$$k(r,n) = \left\lfloor \frac{r+n}{9} \right\rfloor, \qquad (b,r) \longmapsto \big(b + k(r,n) \bmod 12,\ (r+n) \bmod 9\big).$$

The explicit alignment of its positions $p = b + 1$ with the signed chart is

p	1	2	3	4	5	6	7	8	9	10	11	12
u	∞	0	0	∞	1	3	3	1	2	4	4	2
σ	+	−	+	−	−	+	−	+	−	+	−	+

This table fixes a trivialization of the carrier. Each change of position jointly transports the vectors and their incidence matrix.

Proposition 78.4 (Covariance of the frame under return)**.** *If $Se_p = e_{p+1 \bmod 12}$, the matrix representation of an operator P of the carrier is transported as $P_k = S^k P S^{-k}$. This transport preserves inner products, incidences and route composition. After twelve returns the chart returns, preserving the memory accumulated in the source state.*

Proof. S is orthogonal and $S^{12} = I$; the metric properties and periodicity of the chart follow. For composition, with $r' = (r+n) \bmod 9$, Euclidean division gives $k(r, n+m) = k(r,n) + k(r',m)$. The exponents of S are added exactly with the carry. The operation acts on the calendar coordinate; the route's memory updates remain present in its enriched domain. □

78.3.2 Quadratic reading and five-component space

Let $\mathbb{R}^{\mathcal{V}}$ be the space of the twelve coordinates, $\mathsf{A}e_v = e_{-v}$ its antipodal involution and $\mathsf{J} = \mathbf{1}\mathbf{1}^{\mathsf{T}}$. We define

$$P_5 = \frac{1}{2}(I + \mathsf{A}) - \frac{1}{12}\mathsf{J}, \qquad Q_v = vv^{\mathsf{T}} - \frac{1}{3}I_3, \qquad \Gamma_0 x = \sum_{v\in\mathcal{V}} x_v Q_v.$$

Theorem 78.5 (Five-component projector and tensor isometry)**.** *P_5 is the rank-five orthogonal projector onto the space of coordinates even under antipodality and of zero sum. Moreover,*

$$\Gamma_0^*\Gamma_0 = \frac{8}{5}P_5, \qquad \Gamma_0\Gamma_0^* = \frac{8}{5}I_{\mathrm{Sym}_0^2(\mathbb{R}^3)}.$$

Therefore

$$\Gamma_5 = \sqrt{\frac{5}{8}}\,\Gamma_0|_{\mathrm{im}\,P_5}$$

is an isometry onto the space of traceless symmetric tensors.

Proof. The even space has one coordinate for each antipodal pair, so its dimension is six. The constant vector belongs to it; subtracting its rank-one projector gives P_5, of rank five.

Since $\langle Q_v, Q_w\rangle_F = (v^{\mathsf{T}}w)^2 - 1/3$, the entries of $\Gamma_0^*\Gamma_0$ equal $2/3$ for $w = \pm v$ and $-2/15$ in the other ten positions of each row. These are exactly the entries of $(8/5)P_5$.

The identity can also be checked in tensor space without resorting to a classification of representations. The list of vertices gives

$$\sum_v v_i^4 = \frac{12}{5}, \qquad \sum_v v_i^2 v_j^2 = \frac{4}{5} \quad (i \neq j),$$

and moments with any odd power vanish by sign changes. Indeed, $(1+\varphi^2)^2 = 5\varphi^2$ and $1 + \varphi^4 = 3\varphi^2$. For a symmetric tensor Q, these sums give

$$\sum_v (v^{\mathsf{T}}Qv)\, vv^{\mathsf{T}} = \frac{8}{5}Q + \frac{4}{5}(\mathrm{tr}\,Q)I.$$

With $\mathrm{tr}\,Q = 0$, and using $\sum_v v^{\mathsf{T}}Qv = 4\,\mathrm{tr}\,Q = 0$, we obtain $\Gamma_0\Gamma_0^*Q = (8/5)Q$. The two identities prove the normalized isometry and its surjectivity. □

The gravitational section in 121 determines the operator $G_a P_5$. Its spectrum has G_a with multiplicity five and zero with multiplicity seven. Orientation is preserved in the carrier and its transport; G_a fixes the common coupling.

78.3.3 Transverse projection and helicities

For $n \in S^2$, set $\Pi = I - nn^{\mathsf{T}}$ and

$$\Lambda_n Q = \Pi Q \Pi - \frac{1}{2}\,\mathrm{tr}(\Pi Q \Pi)\Pi.$$

Proposition 78.6 (Rank-two transverse reduction)**.** *Λ_n is the orthogonal projector onto $\{Q \in \mathrm{Sym}_0^2(\mathbb{R}^3) : Qn = 0\}$, of dimension two.*

Proof. $\Pi n = 0$ gives transversality and $\mathrm{tr}\,\Pi = 2$ gives zero trace. A transverse traceless tensor remains fixed. The formula is self-adjoint for the Frobenius inner product. In a frame (e_1, e_2, n), the image has orthonormal basis

$$E_+ = \frac{e_1e_1^{\mathsf{T}} - e_2e_2^{\mathsf{T}}}{\sqrt{2}}, \qquad E_\times = \frac{e_1e_2^{\mathsf{T}} + e_2e_1^{\mathsf{T}}}{\sqrt{2}}.$$

□

The other three vectors of an orthonormal basis of the carrier are

$$E_1 = \frac{e_1 n^{\mathsf{T}} + n e_1^{\mathsf{T}}}{\sqrt{2}}, \quad E_2 = \frac{e_2 n^{\mathsf{T}} + n e_2^{\mathsf{T}}}{\sqrt{2}}, \quad E_0 = \frac{2 n n^{\mathsf{T}} - e_1 e_1^{\mathsf{T}} - e_2 e_2^{\mathsf{T}}}{\sqrt{6}}.$$

When the transverse frame is rotated by an angle θ, the pairs $(E_+, E_\times)$ and (E_1, E_2) rotate by 2θ and θ, respectively, while E_0 remains fixed. The complexification thus has weights $2, -2, 1, -1, 0$. Λ_n preserves the first two and annihilates the rest. The chain is established

$$\mathbb{R}^{12} \xrightarrow{P_5} \operatorname{im} P_5 \xrightarrow{\Gamma_5} \operatorname{Sym}_0^2(\mathbb{R}^3) \xrightarrow{\Lambda_n} \mathcal{H}_{\mathrm{TT}}(n), \qquad 12 \longrightarrow 5 \longrightarrow 5 \longrightarrow 2.$$

The five-component representation and its reduction are algebraic results preceding the choice of field equations. In the massless gravitational realization, the gauge constraints select the transverse image. This distinction preserves both the five structural coordinates and the two radiative helicities.

Chapter 79

Helical decomposition of the spin carrier 2 and distinction between massive and massless realizations

The real carrier of dimension 5 decomposes into 5 helicity weights. The massive realization retains all 5 components; the massless transverse reduction retains only the radiative helicities ±2, without converting a collective possibility into a postulated fundamental particle.

79.1 Decomposition into 5 polarization modes

Dimension five acquires tensorial content upon choosing a unit direction of propagation n and an oriented orthonormal frame (e_1, e_2, n). Define the five real tensors

$$E_+ = \frac{1}{\sqrt{2}}(e_1 e_1^T - e_2 e_2^T), \qquad E_\times = \frac{1}{\sqrt{2}}(e_1 e_2^T + e_2 e_1^T), \tag{79.1}$$

$$E_1 = \frac{1}{\sqrt{2}}(e_1 n^T + n e_1^T), \qquad E_2 = \frac{1}{\sqrt{2}}(e_2 n^T + n e_2^T), \tag{79.2}$$

$$E_0 = \frac{1}{\sqrt{6}}(2nn^T - e_1 e_1^T - e_2 e_2^T). \tag{79.3}$$

All are symmetric and traceless. The first two are transverse; the next two mix the transverse plane with the direction of propagation, and the last is the traceless longitudinal scalar mode.

Theorem 79.1 (Complete helical decomposition of the carrier)**.** *The tensors of equations (79.1) a (79.3) form an orthonormal basis of* STF_3*. In the complexification, the combinations*

$$E_{\pm 2} = \frac{1}{\sqrt{2}}(E_+ \mp \mathrm{i}E_\times), \qquad E_{\pm 1} = \frac{1}{\sqrt{2}}(E_1 \mp \mathrm{i}E_2), \qquad E_0 = E_0 \tag{79.4}$$

are weight-$\pm 2, \pm 1, 0$ *vectors, respectively, under rotations about n. Moreover,*

$$\Lambda(n)E_{\pm 2} = E_{\pm 2}, \qquad \Lambda(n)E_{\pm 1} = 0, \qquad \Lambda(n)E_0 = 0. \tag{79.5}$$

Proof. In the frame (e_1, e_2, n), each tensor has Frobenius norm one. Their off-diagonal entry patterns are disjoint, and the three diagonals of E_+, E_0 have zero inner product; therefore, the five tensors are orthonormal. Since $\dim \mathrm{STF}_3 = 6 - 1 = 5$, they form a basis.

A rotation through angle ψ about n sends (e_1, e_2) to $(\cos\psi\, e_1 + \sin\psi\, e_2, -\sin\psi\, e_1 + \cos\psi\, e_2)$. Substituting into the formulas gives a rotation through angle 2ψ on $\mathrm{span}\{E_+, E_\times\}$, one through angle ψ on $\mathrm{span}\{E_1, E_2\}$, and E_0 fixed. Hence the weights of equation (79.4). Finally, $\Pi E_+ \Pi = E_+$ and $\Pi E_\times \Pi = E_\times$, whereas $\Pi E_1 \Pi = \Pi E_2 \Pi = 0$. For E_0, $\Pi E_0 \Pi = -(e_1 e_1^T + e_2 e_2^T)/\sqrt{6}$, which is pure trace in the plane, and subtracting equation (78.6) annihilates it. □

The theorem specifies the meaning of "five polarizations" without assigning all of them the same dynamic status. Before field equations are imposed, the spin-two carrier has five irreducible coordinates. In a massive Fierz–Pauli realization, the constraints leave precisely the five weights of equation (79.4); in a massless realization with gauge invariance, the sectors ±1 and 0 are eliminated, leaving ±2. Here HMT supplies the carrier, the basis, and the projector; the choice of massive or massless dynamics belongs to the physical interface. Thus five does not mean "five observed waves," but rather five tensorial degrees available before reduction.

The orientation also remains visible: replacing (e_1, e_2, n) with $(e_1, -e_2, -n)$ preserves E_+, E_0 and exchanges the phases of the helical pairs. That information is not in the scalar G_a; it resides in the carrier on which $\mathbb{G}_{5,a}$ acts.

79.2 Representational chain $12 \to 5 \to 5 \to 2$: carrier V_5, trace-free tensor, Fierz–Pauli polarizations, and transverse helicities

Dimension five appears in distinct objects, and only equation (78.10) authorizes transport between them:

1. V_5 is the irreducible summand of the representation on the twelve vertices. This is a finite result in representation theory.
2. STF_3 is the real five-dimensional carrier of the $m = -2, -1, 0, 1, 2$ weights of spin two.
3. A massive Fierz–Pauli theory can realize these five weights as five physical states, after fixing the action and constraints.
4. Massless general relativity retains two radiative helicities, ± 2, represented by E_+ and $E_\times$.
5. The $E(2)$ classes of metric waves, such as III_5, classify possible amplitudes under other hypotheses; they are not automatically V_5, Fierz–Pauli, or general relativity.

In particular, the correct statement is: *HMT constructs a five-component tensor carrier before the restrictions; the TT reduction of the massless realization has rank two*. It is not asserted that general relativity has five propagating polarizations.

Existence conditions of the mode through natural holonomic selection. The physical existence of the mode still requires a natural and falsifiable holonomic selector.

Chapter 80

Gravitational Holonomic Selector: Dimensional Transduction, Naturality, Refinement, and Separation of the Torsional and Circular Regimes

The gravitational selector is formulated on enriched holonomies and commutes with the refinement maps. Its classification distinguishes selection determined by the declared normalizations from the obstruction to canonicity that appears when such data are omitted.

80.1 Holonomic conditions of the general gravitational selector

The second gravitational template starts from

$$\delta_\theta = \frac{A_{\mathrm{deg}} - C^*_{\mathrm{deg}}}{360} \tag{80.1}$$

and a route length $\Lambda_{27} = \mathcal{L}_{\mathrm{hol}}(\widetilde{\mathcal{K}}_{27})$ in an enriched lift of the return. The expression

$$\boxed{G_{\mathrm{hol}} = \frac{c_{\mathrm{int}}^3}{\hbar_{\mathrm{int}}}\left(\delta_\theta \Lambda_{27}\right)^2} \tag{80.2}$$

is dimensionally exact. Its promotion to a general selector requires that $\mathcal{L}_{\mathrm{hol}}$ be natural under cyclic change of basis, conjugation, relabeling, and subdivision, and possess a normalization that is unique and stable under refinement.

There is additionally a torsion control: every positive multiplicative character $\chi : K_{27} \to \mathbb{R}_+^\times$ on a finite observable cycle of order four is trivial, because $\chi(g)^4 = 1$ and $\chi(g) > 0$ imply $\chi(g) = 1$. A nontrivial holonomic response must therefore be defined on the nontorsional lift or on enriched memory; it cannot be obtained by renaming a positive character of the finite cycle.

The chart

$$10^{-11}\left(6 + \frac{674}{1000} + \frac{30}{10^5}\right) = 6.67430 \times 10^{-11} \tag{80.3}$$

is an exact evaluation of declared inputs. It does not fix Λ_{27} or prove that equation (80.2) assumes that value.

The periodicity condition determines G without using its decimal expansion: the chronological structure CT108 selects $(54/\pi)^2$, the gravitational line fixes the dimensional type, and the bidirectional family preserves $G\hbar$. The resulting coupling is represented on the tensorial carrier constructed by P_5, whereas the reduction to the physical trace-free transverse sector is effected by a distinct rank-two map.

Falsification criterion 80.1. The circular block is refuted if $r_g(\theta) \neq \theta(\pi/54)\ell_0$, if there exists another positive solution of equation (77.6), or if $G_a\hbar_a/c^3 \neq \theta_{108}^{\mathrm{circ}}\ell_0^2$. The tensorial block is refuted if π_{ico} does not preserve incidence or intertwine the declared action, if its stabilizer is not C_5, if P_5 is not a self-adjoint idempotent of trace five, if $\Gamma_0\Gamma_0^* \neq (8/5)I$, or if $\Lambda(n)$ does not have rank two. The five-polarization reading is refuted if the tensors of equations (79.1) a (79.3) are not an orthonormal basis or if $\Lambda(n)$ retains a weight other than ± 2. The general holonomic selector is resolved by obstruction: without a natural, normalized, and stable $\mathcal{L}_{\mathrm{hol}}$ there is no univocal selection compatible with all relabelings; using equation (80.3) to choose it incurs circularity and invalidates the construction.

Hypothesis, domain, and conclusion

Transducer, uniqueness of the selector under the condition of CT108 periodicity, and Planck family: *Exact internal theorem under the stated geometric condition*. The descent $\Omega_{12}^{\mathrm{ico}} \simeq A_5/C_5$ is exact under the four hypotheses stated explicitly in π_{ico}; the HMT construction of that map belongs to the exceptional provenance corridor. Once the descent, projector P_5, intertwiner Γ_5, five-helicity basis, TT reduction, and spectrum of $\mathbb{G}_5$ are fixed: *Internal exact theorem*. Massive reading, field equations, and realization of Palatini–Cartan–Holst: *Realization, Physically Typed*. Template holonomic: *Proved in homogeneity*; the nonexistence of a general unambiguous selector without additional normalization is a *obstruction of canonicity proved*. Carta SI: *Contrast metrological external*.

80.1.1 Criteria for selecting the gravitational coordinate: enriched holonomy, spectral response, and metrological chart

The APP–TRIT–TPK composition, the enriched state and the action branch first construct the gravitational coordinate. The gravitational constant is organized into three typed levels: the dimensional line that houses G, the transducer that converts a dimensionless coordinate into a section of that line and the structural selector of that coordinate. The Palatini–Cartan–Holst action and its constrained Hamiltonian then realize the already generated output. The decimal chart and experimental uncertainty are presented at the end as representation and comparison.

80.1.1.1 Dimensional line and internal transducer

In the dimensional lattice of Dimensional Mechanics,

$$\mathbf{G} = -\mathbf{S} + 5\mathbf{C} + 2\mathbf{T}, \qquad [G] = L^3 M^{-1} T^{-2}.$$

Let

$$c_{\mathrm{int}} \in \mathcal{L}_C^+, \qquad t_0 \in \mathcal{L}_T^+, \qquad \ell_0 = c_{\mathrm{int}} t_0, \qquad \hbar_{\mathrm{int}} \in \mathcal{L}_S^+.$$

Definition 80.2 (Gravitational transducer)**.** For $\theta_G > 0$, define

$$\boxed{G_{\mathrm{int}}(\theta_G) = \theta_G \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_{\mathrm{int}}} = \theta_G \frac{c_{\mathrm{int}}^3 \ell_0^2}{\hbar_{\mathrm{int}}} \in \mathcal{L}_G^+.} \tag{80.4}$$

The equality of the two expressions and the type of (80.4) are exact. If

$$L_G^2 := \frac{\hbar_{\mathrm{int}} G_{\mathrm{int}}}{c_{\mathrm{int}}^3},$$

then

$$\theta_G = \left(\frac{L_G}{\ell_0}\right)^2. \tag{80.5}$$

The gravitational coordinate is therefore a quadratic ratio of lengths or a normalized holonomy response. The decade $10^{-34}\mathcal{U}_S$ already belongs to $\hbar_{\mathrm{int}}$: it fixes the absolute action section and does not constitute a relative factor added to G.

80.1.1.2 Observable torsion and positive characters

The observable return of 27 steps

$$\mathcal{K}_{27} := F_{\mathrm{obs}}^{27}$$

satisfies

$$\mathcal{K}_{27}^4 = F_{\mathrm{obs}}^{108} = I.$$

In coordinate $\theta \in \mathbb{Z}/108\mathbb{Z}$, the order is exactly four, since $\mathcal{K}_{27}(\theta) = \theta + 27$, $\mathcal{K}_{27}^2(\theta) = \theta + 54 \neq \theta$, and $\mathcal{K}_{27}^4(\theta) = \theta$.

Theorem 80.3 (Triviality of the Observable Positive Character)**.** *Every multiplicative homomorphism*

$$\chi : \langle \mathcal{K}_{27} \rangle \longrightarrow \mathbb{R}_{>0}^{\times}$$

cumple $\chi(\mathcal{K}_{27}) = 1$.

Proof. Multiplicativity implies $\chi(\mathcal{K}_{27})^4 = \chi(I) = 1$. The only positive real number whose fourth power is one is 1. □

The same cycle does carry the unitary characters.

$$\chi_j(\mathcal{K}_{27}) = \exp(2\pi i j/4), \qquad j = 0, 1, 2, 3.$$

The observable quotient admits phase, whereas its torsion eliminates a nontrivial positive multiplicative scale. A multiplicative continuation must therefore act on a lift $\widetilde{\mathcal{K}}_{27}$ whose class in the abelianization of the isotropy group is nontorsional, and must naturally select both the character and its normalization.

80.1.1.3 Chronological memory and spectral response

The directed chronological covering realizes the return of 27 steps as the translation

$$(G_{\mathrm{or}}, S) \longmapsto (G_{\mathrm{or}}, S) + (1, 18),$$

of infinite semigroup order. This route preserves accumulation, but its spectral response requires interference among histories.

Let $\Gamma = (V, E)$ be a finite directed multigraph with positive measure, weights $a_*(e) \geq 0$, and cocycle $c(e) \in \mathbb{Z}^2$. The twisted operator

$$(\mathcal{L}_{\beta,\vartheta} f)(y) = \sum_{e:x\to y} e^{-\beta a_*(e)} e^{i\langle \vartheta, c(e)\rangle} f(x)$$

induce the operator positive $\mathcal{H}_{\beta,\vartheta} = \mathcal{L}_{\beta,\vartheta}^* \mathcal{L}_{\beta,\vartheta}$.

Proposition 80.4 (Interference criterion for the phase response)**.** *In a deterministic orbit with a unique incoming edge at each vertex, $\mathcal{H}_{\beta,\vartheta}$ is independent of ϑ. Every nonzero-phase spectral response requires multiple coherent histories or a magnetic differential whose holonomy survives in the enriched cycles.*

Proof. On the deterministic orbit, the sole phase of each term is multiplied by its conjugate in $\mathcal{L}_{\beta,\vartheta}^* \mathcal{L}_{\beta,\vartheta}$ and cancels. The absence of cross terms removes every dependence on ϑ. □

If a simple band $\lambda_0(\vartheta)$ has a minimum at the origin, its Hessian Q is positive semidefinite. With

$$v_{27} = (1, 18), \qquad \mathcal{R}_{27} = v_{27}^{\mathsf{T}} Q v_{27},$$

the condition $\mathcal{R}_{27} \neq 0$ constitutes the minimal control of sensitivity to accumulated memory. A natural normalization $\mathfrak{N}$ would allow one to define

$$\Lambda_G = \ell_0 \mathfrak{N}(Q, v_{27}), \qquad G_{\mathrm{spec}} = \frac{c_{\mathrm{int}}^3}{\hbar_{\mathrm{int}}} \big(\delta_\theta \Lambda_G\big)^2, \qquad \delta_\theta = \frac{A_{\mathrm{deg}} - C_{\mathrm{deg}}^*}{360}.$$

The homogeneity of this template is exact. Its physical realization is characterized by four positive conditions: an enriched multigraph, a nonzero response, stability under refinement, and independence under rescaling, together with a normalization $\mathfrak{N}$ fixed before the metrological contrast.

80.1.1.4 Geometric Functional on Enriched Holonomy

The second continuation defines directly a length functional.

$$\mathscr{L} : \mathrm{Loop}(\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}) \longrightarrow \mathcal{L}_L^+ \cup \{0\},$$

invariant under cyclic change of basepoint, conjugation, admissible relabeling, and subdivision. For an enriched lift, write

$$\Lambda_{27} := \mathscr{L}(\widetilde{\mathcal{K}}_{27}), \qquad \rho_{27} := \frac{\Lambda_{27}}{c_{\mathrm{int}} t_0}, \qquad \theta_G^{\mathrm{hol}} := (\delta_\theta \rho_{27})^2.$$

Transduction produces the homogeneous template

$$\boxed{G_{\mathrm{hol}} = \frac{c_{\mathrm{int}}^3}{\hbar_{\mathrm{int}}} \big(\delta_\theta \Lambda_{27}\big)^2.} \tag{80.6}$$

The concatenation law of this functional on the torsional cycle forms part of its definition and its proof. Physical selection is completed by constructing $\widetilde{\mathcal{K}}_{27}$ and $\mathscr{L}$, fixing a unique normalization, and verifying the stability of the output. The value $G_{\mathrm{CODATA\,2022}}$ enters exclusively afterward, in the metrological comparison.

Proposition 80.5 (Separation of the two gravitational selectors)**.** *The circular selector $\theta_{108}^{\mathrm{circ}} = (54/\pi)^2$, constructed by action–Compton–gravity closure, and the holonomic selector $\theta_G^{\mathrm{hol}} = (\delta_\theta \rho_{27})^2$ are two distinct typed realizations of the transducer G_{int}. They are not identified with one another, and the decimal chart $\mathscr{R}_G$ does not constitute an evaluation of G_{hol}.*

Proof. The first selector depends solely on the circular closure of order 108. The second additionally contains the spectral length $\Lambda_{27} = \mathscr{L}(\widetilde{\mathcal{K}}_{27})$. An equality between them would require computing Λ_{27} and proving the agreement of normalizations; no operation of the decimal reader performs that computation. Their domains and input data therefore distinguish them before any numerical comparison. □

80.1.1.5 Structural selection criterion

Comparison Criterion 80.6 (Structural selector of the gravitational constant)**.** An HMT selector of G is identified when it jointly satisfies:

1. enriched domain, composition, and orientation declared;
2. descent to a nontorsional Abelian class, or a geometric functional invariant under basepoint, conjugation, relabelling, and subdivision;
3. nontrivial positive response stable under refinement;
4. unique normalization independent of the operator's overall scale;
5. internal selection of the coordinate and its decimal position;
6. freezing of the code and entries before revealing the comparison value;
7. final realization as a section of $\mathcal{L}_G$ in a common dimensional chart.

The dimensionless ratios

$$\frac{\mathcal{G}_{\mathrm{tor}}}{\mathcal{I}_{\mathrm{tor}}} = 1, \qquad \frac{\mathcal{G}_{\mathrm{av}}}{\mathcal{I}_{\mathrm{av}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}$$

describe distinct gravitational–inertial readers and remain compatible with a single dimensional section G. The construction of that section also uses $(\hbar_{\mathrm{int}}, c_{\mathrm{int}}, \ell_0)$ and the selector θ_G.

80.1.1.6 Evaluation of the decimal gravitational chart and subsequent metrological contrast

The decimal representation preserved in the corpus is

$$\mathscr{R}_G([n,k,d]_3;t,e) := 10^{-n}\left(k+\frac{t}{10^3}+\frac{e}{10^d}\right). \tag{80.7}$$

For the chart $[n,k,d]_3=[11,6,5]_3$, $t=674$ and $e=30$, the evaluation racional is

$$\boxed{\mathscr{R}_G = 10^{-11}\left(6+\frac{674}{1000}+\frac{30}{10^5}\right) = 6.67430\times10^{-11}.} \tag{80.8}$$

The triad, the two blocks, and the decimal position constitute the declared data of this chart. Their evaluation is exact; their structural selection is governed by test criterion 80.6.

After choosing the SI basis of $\mathcal{L}_G$, the current contrast is

$$\boxed{G_{\text{CODATA 2022}} = 6.67430(15)\times10^{-11}\ \text{m}^3\,\text{kg}^{-1}\,\text{s}^{-2}.} \tag{80.9}$$

Field	Metrological Statement
Central value	$6.67430\times10^{-11}\ \text{m}^3\,\text{kg}^{-1}\,\text{s}^{-2}$
Standard uncertainty	$u(G)=0.00015\times10^{-11}=1.5\times10^{-15}\ \text{m}^3\,\text{kg}^{-1}\,\text{s}^{-2}$
Incertidumbre relativa	$u_r(G)\simeq 2.2\times10^{-5}$
Source and temporality	2022 CODATA recommended values, published in 2024 [29]
Proof function	Subsequent external contrast; neither the unit nor the uncertainty enters into the rational evaluation of (80.8).

Reproducibility of the gravitational reader. An independent enumeration jointly verifies the dimensional type, the decimal reader, and the monodromy identities on the declared finite domain.

Proposition 80.7 (Causal chain of the gravitational constant)**.** *The covariant action, the restricted Hamiltonian, and the Einstein–Schrödinger equation govern the gravitational dynamics. The dimensional type and the transducer* (80.4) *are exact; the evaluation* (80.8) *is exact for its declared chart. The value, unit, and uncertainty of* (80.9) *constitute an external comparison with CODATA 2022. The autonomous selection of θ_G is typed by the enriched lift, the interfering response, and the holonomy functional subject to the test criterion 80.6.*

80.2 Dimensional Transduction and Holonomic Selection of the Gravitational Constant

80.2.1 Gravitational line and dimensional form

In the lattice of section 59.1, the dimension of the gravitational constant is

$$\mathbf{G} = -\mathbf{S}+5\mathbf{C}+2\mathbf{T}, \qquad [G]=L^3M^{-1}T^{-2}.$$

Let

$$c_{\text{int}}\in\mathcal{L}_C^+, \qquad t_0\in\mathcal{L}_T^+, \qquad \ell_0:=c_{\text{int}}t_0\in\mathcal{L}_L^+, \qquad \hbar_{\text{int}}\in\mathcal{L}_S^+.$$

The section $\hbar_{\text{int}}$ is obtained only after the decade determinantal reader -34 and the choice of a basis for the action line. It is not the dimensionless angular character preceding the return.

For every dimensionless character $\theta_G>0$, define

$$\boxed{G_{\text{int}}(\theta_G)=\theta_G\frac{c_{\text{int}}^5t_0^2}{\hbar_{\text{int}}}=\theta_G\frac{c_{\text{int}}^3\ell_0^2}{\hbar_{\text{int}}}\in\mathcal{L}_G^+.}$$

The equality of the two expressions and their type are INTERNALLY EXACT within the dimensional lattice. They do not select θ_G. If

$$L_G^2 := \frac{\hbar_{\mathrm{int}} G_{\mathrm{int}}}{c_{\mathrm{int}}^3},$$

then

$$\theta_G = \left(\frac{L_G}{\ell_0}\right)^2.$$

This latter identity locates the selector datum: the length ratio must be produced by a holonomy or spectral-response structure prior to the metrological chart.

80.2.2 Obstruction of the Positive Character on the Observable Return

The section 82.3.1 defines

$$\mathcal{K}_{27} := F_{\mathrm{obs}}^{27}.$$

The primary proposition proposition 6.11 proves

$$F_{\mathrm{obs}}^{108} = I;$$

Therefore, in the observable quotient,

$$\mathcal{K}_{27}^4 = I.$$

Theorem 80.8 (Torsional Obstruction for the Observable Positive Selector)**.** *Every multiplicative homomorphism*

$$\chi : \langle \mathcal{K}_{27} \rangle \longrightarrow \mathbb{R}_{>0}^{\times}$$

is trivial. In particular,

$$\chi(\mathcal{K}_{27}) = 1.$$

Proof. Multiplicativity and $\mathcal{K}_{27}^4 = I$ imply

$$\chi(\mathcal{K}_{27})^4 = \chi(I) = 1.$$

The sole positive real element whose fourth power is one is 1. □

The observable order is exactly four, and not merely a divisor of four: in the coordinate $\theta \in \mathbb{Z}/108\mathbb{Z}$,

$$\mathcal{K}_{27}(\theta) = \theta + 27, \qquad \mathcal{K}_{27}^2(\theta) = \theta + 54 \neq \theta, \qquad \mathcal{K}_{27}^4(\theta) = \theta.$$

The same cyclic group admits unitary characters.

$$\chi_k(\mathcal{K}_{27}) = \exp\left(\frac{2\pi i k}{4}\right), \qquad k = 0, 1, 2, 3,$$

and, in particular, the phase values $\pm i$. The typed conclusion is that the observable cycle can transport phase but not a nontrivial positive scale. These phase characters are not identified with the Paley operator J_W: they satisfy an analogous quadratic relation on distinct domains.

The obstruction does not depend on a metrological comparison. It affects the very form of the selector: a positive character on the observable cycle cannot produce a nontrivial θ_G. Moreover, a mere set of conjugacy classes is not, in general, a group and cannot be declared the domain of a character without first defining its composition.

80.2.2.1 Unique admissible multiplicative continuation

A multiplicative route can reopen only on an enriched object that does not inherit the observable torsion. For an object x of the memory groupoid, the correctly typed domain would be the isotropy group

$$H_x := \mathrm{Aut}_{\mathcal{G}_{\mathrm{mem}}}(x)$$

and, by multiplicativity towards an abelian group, its abelianization

$$H_x^{\mathrm{ab}} \longrightarrow \mathbb{R}_{>0}^{\times}.$$

Every positive character annihilates the torsion part of H_x^{ab}. Therefore, the proposal must construct a lift

$$\widetilde{\mathcal{K}}_{27} \in H_x, \qquad p(\widetilde{\mathcal{K}}_{27}) = \mathcal{K}_{27},$$

prove that its Abelian class is non-torsion and naturally select a character $\widetilde{\chi}_G$. The positive route over the observable cycle is thus closed by obstruction: without that non-torsion datum there is no nontrivial multiplicative selector. If every admissible lift satisfied $\widetilde{\mathcal{K}}_{27}^4 = I$, the multiplicative route would also be ruled out in the enriched domain.

80.2.3 Chronological composition of length, action, and spectrum in the determination of G

The theorem 82.6 provides a third route, distinct both from the obstructed observable character and from a possible lift in an isotropy group. On

$$\widetilde{O}_{108}^{+} = O_{108} \times \mathbb{N}^2,$$

the twenty-seven-step return sums $(1, 18)$, and its fourth power sums $(4, 72)$. This action belongs to a directed chronological category. It is not a lift of the groupoid or a field proved to be native to the complete enriched TPK state.

The already constructed positive functional,

$$\mathcal{A}_*(\gamma) = G_{\mathrm{or}}(\gamma) + \lambda_* S(\gamma),$$

is additive under concatenation of directed histories. It is not a character of the isotropy group, because its indicators do not change sign under a formal inversion. The completion $\mathbb{N}^2 \to \mathbb{Z}^2$ permits unitary characters to be introduced for harmonic analysis, but does not alter this fact.

$$\delta_\theta := \frac{A_{\mathrm{deg}} - C_{\mathrm{deg}}^*}{360}. \tag{80.10}$$

This oriented angular fraction is defined once the unique angle and counter-angle have been constructed. It will be used in the two subsequent dimensional templates and does not intervene retroactively in obtaining A_{deg} or C_{deg}^*.

80.2.3.1 Operator with torsion and deterministic obstruction to multiplicative continuation

For the exact control, let $\Gamma = (V, E)$ be an enriched directed *finite* multigraph, with measure $\mu : V \to \mathbb{R}_{>0}$, weights $a_*(e) \geq 0$, parameter $\beta \geq 0$, and cocycle $c(e) \in \mathbb{Z}^2$. For a fixed normalization, consider

$$(\mathcal{L}_{\beta,\vartheta} f)(y) = \sum_{e : x \to y} e^{-\beta a_*(e)} e^{i\langle \vartheta, c(e)\rangle} f(x), \qquad \vartheta \in \mathbb{T}^2,$$

and take the entire finite Hilbert space $\ell^2(V, \mu)$ as the domain. Then $\mathcal{L}_{\beta,\vartheta}$ is bounded and

$$\mathcal{H}_{\beta,\vartheta} := \mathcal{L}_{\beta,\vartheta}^* \mathcal{L}_{\beta,\vartheta} \geq 0$$

is self-adjoint. An extension to an infinite graph would additionally require bounded operators, or densely defined closed operators such that $\mathcal{L}^{*}_{\beta,\vartheta}\mathcal{L}_{\beta,\vartheta}$ were self-adjoint on a common domain; that extension is not assumed here.

Proposition 80.9 (Phase cancellation in the deterministic orbit)**.** *If Γ is solely the observable deterministic orbit and every vertex has a single incoming edge, then $\mathcal{H}_{\beta,\vartheta}$ is independent of ϑ. In particular, the Hessian of any of its bands with respect to ϑ is null.*

Proof. In each component, $\mathcal{L}_{\beta,\vartheta}$ multiplies the sole incoming term by a unitary phase. In $\mathcal{L}^{*}_{\beta,\vartheta}\mathcal{L}_{\beta,\vartheta}$, that phase is multiplied by its conjugate and cancels. No cross-terms remain between distinct histories. □

This control prevents spectral rigidity from being attributed to the mere deterministic cycle. A nontrivial phase response requires at least one of the following constructions:

1. an enriched multigraph in which two or more coherent histories contribute to the same amplitude; or
2. to magnetic differential

$$(d_{\vartheta}f)(e) = e^{i\langle\vartheta,c(e)\rangle/2}f(t(e)) - e^{-i\langle\vartheta,c(e)\rangle/2}f(s(e)),$$

with Laplacian $\Delta_{\vartheta} = d^{*}_{\vartheta}d_{\vartheta}$, whose phase depends on the holonomy of enriched cycles.

In both cases, the Hilbert space, domain, measure, weights, and normalization must be declared, and it must be proved that the family is not unitarily equivalent to the family without phase.

Suppose that $\vartheta \mapsto \mathcal{H}_{\beta,\vartheta}$ is an analytic self-adjoint family on a common domain and that $\lambda_0(\vartheta)$ is a simple isolated band in a neighborhood of $\vartheta = 0$. If 0 is a critical point and a local minimum,

$$Q_{ij} = \left.\frac{\partial^2\lambda_0(\vartheta)}{\partial\vartheta_i\partial\vartheta_j}\right|_{\vartheta=0}$$

is positive semidefinite. Without the minimum hypothesis, Q represents only the quadratic response. For

$$v_{27} = (1, 18), \qquad \mathcal{R}_{27} = v_{27}^{\mathsf{T}}Qv_{27},$$

the condition $\mathcal{R}_{27} \neq 0$ is a minimal test of spectral sensitivity to the accumulated memory.

80.2.3.2 Typed normalization of the spectral response and construction of θ_G^{spec}

If a natural and unique normalization $\mathfrak{N}$ converts the preceding response into a positive ratio independent of the operator's global scale, one may define

$$\Lambda_G := \ell_0\,\mathfrak{N}(Q, v_{27}), \qquad \theta_G^{\mathrm{spec}} := \left(\delta_\theta\frac{\Lambda_G}{\ell_0}\right)^2,$$

and, by the dimensional transducer,

$$\boxed{G_{\mathrm{spec}} = \frac{c_{\mathrm{int}}^3}{\hbar_{\mathrm{int}}}\left(\delta_\theta\Lambda_G\right)^2.}$$

The homogeneity of the template is exact. The class of its evaluations is characterized by the conditions of canonical operator selection, nonzero response, naturality and stability under refinement, independence of rescaling, uniqueness of $\mathfrak{N}$, and sealing prior to any query of the metrological value of G. Without those conditions, rescaling invariance proves the nonuniqueness of the selector; with them, the evaluation is determined on the declared normalized domain.

80.2.4 Nonhomomorphic functional over enriched paths

The second possible continuation abandons the multiplicative character and uses a geometric, spectral, or action functional. Let

$$\mathscr{L} : \mathrm{Loop}(\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}) \longrightarrow \mathcal{L}_L^+ \cup \{0\}$$

invariant under cyclic change of base point, admissible relabeling, conjugation, and subdivision. Its concatenation law must be stated explicitly—for example, as a subadditive norm or a spectral functional—; it is not presumed to be a homomorphism of the torsion group. For a candidate enriched lift, we write

$$\Lambda_{27} := \mathscr{L}(\widetilde{\mathcal{K}}_{27}), \qquad \rho_{27} := \frac{\Lambda_{27}}{c_{\mathrm{int}} t_0}.$$

The oriented angular fraction of (80.10) produces the dimensionless candidate

$$\theta_G^{\mathrm{hol}} := (\delta_\theta \rho_{27})^2.$$

His specialization in the transducer gives

$$\boxed{G_{\mathrm{hol}} = \frac{c_{\mathrm{int}}^3}{\hbar_{\mathrm{int}}} \big(\delta_\theta \Lambda_{27}\big)^2.}$$

The temporal form is the same identity:

$$T_{27} := \frac{\Lambda_{27}}{c_{\mathrm{int}}}, \qquad t_* := \delta_\theta T_{27}.$$

In particular, it is not appropriate to replace t_* with T_{27}/δ_θ.

The homogeneity of these formulas is exact and this chart retains the status of an auxiliary functional realization. The complete gravitational owner then constructs, from the already generated action branch, the unique selector $\vartheta_{108} = (54/\pi_{\mathrm{HMT}})^2$, the section G_a and the typed invariant $G_a \hbar_a$. That construction governs the derivation of G; the functional $\mathscr{L}$ records an additional coordinatization of the same output. The causal order first preserves A and C^*, then gravitational transduction and finally the metrological chart.

80.2.5 Transduction of the gravitational decimal chart onto the magnitude line and causal separation of metrological recognition

Let

$$\mathscr{R}_G([n,k,d]_3; t, e) := 10^{-n} \left(k + \frac{t}{10^3} + \frac{e}{10^d}\right),$$

where the subscript of $[n,k,d]_3$ records the reader triad and does not denote a ternary numeral. For the declared data

$$[n,k,d]_3 = [11,6,5]_3, \qquad t = 674, \qquad e = 30,$$

rational evaluation is

$$\boxed{\mathscr{R}_G = 10^{-11} \left(6 + \frac{674}{1000} + \frac{30}{10^5}\right) = 6.67430 \times 10^{-11}.}$$

The arithmetic equality is exact once the parameters have been declared. The triad, the blocks 674, 30, and their decimal position have the status of chart data, so this branch is preserved as a parametrized control and subsequent recognition. The number is dimensionless until a basis $u_G \in \mathcal{L}_G^+$ is chosen; only then is the section defined

$$G_{\mathrm{dec}} := \mathscr{R}_G \, u_G.$$

The coincidence of its coordinate with a metrological publication is EXTERNAL RECOGNITION. The integers 674, 30, the triplet $[11, 6, 5]$ and the decimal placement belong exclusively to this recognition chart; the governing derivation resides in the selector ϑ_{108} and in the complete owner's action transducer.

80.2.6 Hierarchy of Evidence for Gravitational Constructions

The previous layers do not constitute two proven genealogies of the same constant. Their situation is:

Object	Result available	Verdict
Transductor dimensional	Types $G_{\mathrm{int}}(\theta_G)$ exactly, without fixing θ_G.	Dimensional theorem; no selector.
Character of the observable $\mathcal{K}_{27}$	$\mathcal{K}_{27}^4 = I$ force $\chi(\mathcal{K}_{27}) = 1$.	Obstructed formulation.
Levantamiento enriquecido	Possible only with non-torsion abelian class, natural character and unique normalization.	Obstruction of canonicity demonstrated without those data.
Chronological coverage and spectral response	The cumulative translation has infinite semigroup order; along the deterministic orbit, the phase cancels.	Null response proved on the deterministic orbit; nontrivial class characterized by interference and natural normalization.
Path functional	The formula for G_{hol} is homogeneous once Λ_{27} has been fixed.	Exact parametrized family; no unique selector exists without specifying $\mathscr{L}$ and its normalization.
Decimal reader	Reproduce exactly the declared coordinate, but receive its blocks and position.	Control parametrizado.

Comparison Criterion 80.10 (Selector of the gravitational constant)**.** A promotion is rejected if:

1. the enriched lift preserves only torsion or does not descend to a well-defined Abelian class;
2. the chronological operator does not preserve interference, produces $\mathcal{R}_{27} = 0$, lacks a domain or measure, or its response changes under an admissible refinement;
3. $\mathscr{L}$ depends on the basepoint, relabelling, the chosen orientation, a subdivision, or a free normalization;
4. the normalization $\mathfrak{N}$ depends on the global scale of the operator, is nonunique, or is fixed by consulting G;
5. 674, 30, or the decimal placement admit alternatives with the same structural standing;
6. the candidate consults the metrological value before being sealed;
7. the value is not stable under refinement or does not define a section of $\mathcal{L}_G$ in a common dimensional chart.

80.2.7 Gravitational–inertial ratios and the dimensional constant

The local normalization of the torsion chart,

$$\frac{\mathcal{G}_{\mathrm{tor}}}{\mathcal{I}_{\mathrm{tor}}} = 1,$$

and the interface areal–volumetric of the section 6.3.7.1,

$$\frac{\mathcal{G}_{\mathrm{av}}}{\mathcal{I}_{\mathrm{av}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2},$$

are dimensionless reader ratios. They are not rival values of the dimensional constant G. The first expresses a local diagonal constraint; the second is an interface conditional upon factorization through a common memory. Constructing a section of $\mathcal{L}_G$ additionally requires the $(\hbar_{\mathrm{int}}, c_{\mathrm{int}}, \ell_0)$ framework and a θ_G selector.

Cosmological prolongation of the holonomic response. The response is extended to the cosmological regime through the Perron mode and torsional memory.

80.3 Action, gravity, and thermal information

80.3.1 Dodecaphasic period and circular realization of action

The calendar already constructed determines $T_{108} = 108t_0$. In its circular realization,

$$\omega_{108} = \frac{2\pi}{108t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0, \qquad \ell_0 = c_{\mathrm{int}}t_0.$$

The unit ℓ_0 and the time and velocity charts remain explicit; the SI chart does not select the cycle. For each oriented action section $a \in \{\mathrm{pre}, \mathrm{ret}\}$,

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2}.$$

The reduced and full lengths are, respectively,

$$\frac{\hbar_a}{m_{108,a}c_{\mathrm{int}}} = R_{108}, \qquad \frac{h_a}{m_{108,a}c_{\mathrm{int}}} = 2\pi R_{108}.$$

The same action and the same duration enter both readings. Their radial coincidence is determined in the following proposition.

Proposition 80.11 (Radius-coincidence selector)**.** *In the dimensional family*

$$G_a(\vartheta) = \vartheta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}, \qquad \vartheta > 0,$$

the circular-realization condition $G_a(\vartheta)m_{108,a}/c_{\mathrm{int}}^2 = R_{108}$ has the unique solution

$$\vartheta_{108}^{\circ} = (54/\pi)^2.$$

Proof. The first radius is $r_g(\vartheta) = \vartheta(\pi/54)\ell_0$. Comparing it with $(54/\pi)\ell_0$, with $\ell_0 > 0$, reduces the equality to a strictly increasing linear equation. □

The coincidence condition is an explicit part of this realization; the theorem solves for its coefficient without using a metrological value of G. The radius used here is Gm/c^2, so the factor two from the convention $2Gm/c^2$ is not inadvertently transferred.

Proposition 80.12 (Reciprocal action and gravity, conserved area)**.** *In the two preceding charts,*

$$\frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad \hbar_a G_a = \vartheta^{\circ}_{108} c_{\mathrm{int}}^5 t_0^2, \qquad \ell_P^2 = \frac{\hbar_a G_a}{c_{\mathrm{int}}^3} = \vartheta^{\circ}_{108} \ell_0^2.$$

Proof. The definition of G_a contains $\hbar_a^{-1}$ and the remaining factors are common to the two charts. Taking the quotient and the product gives the three equalities. □

This reciprocity explains why orientation information may vary while area remains unchanged. A precise relation is thus available between the action ellipse, Planck scale, and area operator of section 72.3.

80.3.2 Thermal normalization and energy per cycle

We fix the same oriented section a for energy and temperature. The thermal relation of the corpus publishes

$$k_B \Theta_{\mathrm{clk},a} \log 3 = \frac{h_a}{108 t_0} = \frac{\hbar_a}{t_P} = E_{P,a}, \qquad t_P = \frac{54}{\pi} t_0. \tag{80.11}$$

The factor $\log 3$ measures the information of the equiprobable triple; the clock energy incorporates the action already generated. The identity preserves the product $k_B \Theta_{\mathrm{clk}}$ as an energy section and makes explicit the thermal chart used, developed in section 70.2.7.

At this scale, the radiative realization provides

$$n_\gamma \ell_P^3 = \frac{2\zeta(3)}{\pi^2 \log^3 3}, \qquad \frac{u_\gamma \ell_P^3}{E_P} = \frac{\pi^2}{15 \log^4 3}, \qquad \frac{s_\gamma \ell_P^3}{k_B} = \frac{4\pi^2}{45 \log^3 3}.$$

Two distinct invariants occur here: $\log 3$ preserves TRIT information and $\zeta(3)$ the bosonic occupation moment. Their occurrence in the same expression relates the thermal constants to the spectral moments of bosonic occupation, without identifying these quantities with one another.

Section 70.2.7 develops the Boltzmann transducer, its action on tritic information, and the change of thermal coordinates. Equation (80.11) fixes the energy–temperature product used by that construction. The selection of an individual coordinate is distinguished there from the identity for the product. Within this same development, the preceding radiative formulas preserve the occupation and entropy content of the bosonic realization.

80.3.3 Barbero–Immirzi in the Cartan–Holst realization

Once γ_{HMT} has been constructed, the source realizes it as a coefficient of the Holst action. In the declared geometric chart, let e^I be a nondegenerate co-tetrad, ω^{IJ} a connection, $\Sigma^{IJ} = e^I \wedge e^J$ and $F^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}$. With $\kappa = 8\pi G/c^4$, the specialized action is

$$\begin{aligned} S[e, \omega, \Psi] = \frac{1}{2\kappa c} \int \Sigma_{IJ} \wedge (\star F^{IJ} + \gamma_{\mathrm{HMT}}^{-1} F^{IJ}) \\ - \frac{\Lambda}{\kappa c} \int \mathrm{vol}_e + S_m[e, \omega, \Psi]. \end{aligned} \tag{80.12}$$

The current convention is $\delta_\omega S_m = -\frac{1}{2} \int \delta\omega^{IJ} \wedge \sigma_{IJ}$. For this variation, the connection is fixed at the boundary, $\delta\omega^{IJ}|_{\partial M} = 0$, or variations compactly supported in the interior are used. These sufficient conditions annihilate the boundary term resulting from integrating $\Sigma_{IJ} \wedge (\star + \gamma_{\mathrm{HMT}}^{-1} I) D_\omega \delta\omega^{IJ}$. Variation of (80.12) under that condition gives

$$D_\omega[(\star+\gamma_{\mathrm{HMT}}^{-1}I)\Sigma^{IJ}]=\kappa c\,\sigma^{IJ}.$$

This follows by using $\delta F = D_\omega\delta\omega$, integrating by parts, and setting the coefficient of the arbitrary variation to zero [187]. Boundary orientation and current normalization are part of this formula.

In Lorentzian signature, $\star^2=-I$ on bivectors. The identity

$$(\star+\gamma^{-1}I)^{-1}=\frac{\gamma^2}{1+\gamma^2}(-\star+\gamma^{-1}I)$$

is checked by multiplication: the cross terms cancel, leaving $(1+\gamma^{-2})I$ before normalization. Thus the parameter already constructed enters the torsional response, not merely a table value. The identities $D_\omega T^I = F^I{}_J\wedge e^J$ and $D_\omega F^{IJ}=0$ keep torsion, curvature, and balance connected.

The geometric realization preserves route memory and boundary soldering. The cosmological constant Λ of (80.12) is the coefficient declared in the action; it is not identified with the vector representation $\Lambda(R)$. The following identities preserve the holonomy, smoothness and nondegeneracy conditions of the realization.

80.3.4 Phase return and representation of accumulated memory

The chronology of enriched routes distinguishes position return, orientation return and phase return. The observable publication identifies certain arrival states, while the cumulative register preserves the sequence traversed. The geometric representation must transport both data jointly.

80.3.4.1 Inversion cocycle and change of sheet

Let F_{obs} be the chronological publication of TPK transport. Its canonical blocks have the hierarchy

27	positional return with orientation reversal,
54	positional and orientational return,
108	complete return of the observable phase.

The register counts orientation inversions $g(a)$ and effective changes of sheet $s(a)$. For a route,

$$c(\gamma)=\sum_{a\subset\gamma}(g(a),s(a)),\qquad c(\gamma_2\gamma_1)=c(\gamma_2)+c(\gamma_1). \tag{80.13}$$

The canonical computation of the block of length 27 publishes $c_{27}=(1,18)$. Composition preserves those increments in the four blocks that complete the observable period. On forward-oriented routes the register is cumulative; its extension to the route groupoid uses $\mathbb{Z}^2$ and $c(\bar\gamma)=-c(\gamma)$.

Proposition 80.13 (Memory of the complete observable turn)**.** *Writing $\mathcal{K}_{27}=F_{\mathrm{obs}}^{27}$, the lift to the register, for $x\in\mathcal{Q}_{\mathrm{obs}}$ and $z\in\mathbb{Z}^2$, satisfies*

$$\widetilde{\mathcal{K}}_{27}(x,z)=(\mathcal{K}_{27}x,z+(1,18)),\qquad \widetilde{\mathcal{K}}_{27}^{4}(x,z)=(x,z+(4,72)).$$

After N complete turns, the increment is $N(4,72)$.

Proof. The observable projection of $\mathcal{K}_{27}$ has order four. The preceding canonical computation fixes $c_{27}=(1,18)$ as a constant over that observable orbit. The additivity of (80.13) sums the four increments and gives $c_{108}=4(1,18)=(4,72)$. Repetition applies the same concatenation law and produces Nc_{108}. The return of the first coordinate preserves the increment of the second. □

80.3.4.2 Affine representation of the cocycle

The discrete realization uses an element R_4 of order four in $\mathrm{Spin}^+(1,3)$, a unit temporal vector u fixed by its vector action and a unit of length $\ell_0 > 0$. The scale ℓ_0 retains its provenance in the dimensional section. We define

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma) = \left(R_4^{c_g(\gamma)},\ \ell_0 c_s(\gamma) u\right) \in \mathrm{Spin}^+(1,3) \ltimes \mathbb{R}^{1,3}. \tag{80.14}$$

The power acts on the vector through the associated vector representation of the spin group.

Theorem 80.14 (Composition and translational amplitude of return)**.** *The map $\rho_{\mathrm{C}}^{\mathrm{disc}}$ preserves the identity, concatenation and inversion. At complete returns,*

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}) = (I, 72\ell_0 u), \qquad \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}^N) = (I, 72N\ell_0 u). \tag{80.15}$$

Inversion changes the sign of the translation.

Proof. The semidirect product is $(R,a)(S,b) = (RS, a + Rb)$. Since $R_4 u = u$,

$$\begin{aligned}\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2)\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_1) &= \left(R_4^{c_g(\gamma_2)+c_g(\gamma_1)}, \ell_0(c_s(\gamma_2) + c_s(\gamma_1))u\right) \\ &= \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2\gamma_1).\end{aligned}$$

The identity cocycle is zero and that of the inverse is its opposite. For the complete turn, substitute $c_{108} = (4, 72)$ and $R_4^4 = I$. Concatenating N turns keeps the rotational part equal to the identity and sums their translations. □

The amplitude $72\ell_0$ is a length associated with a finite route. A realization through a co-tetrad and a connection transports it to its affine holonomy. The local contribution to the gravitational equations is subsequently obtained through the curvature of that connection, the variation of the matter action and the normalization of its density. The representation thus preserves the exact cumulative content that must enter that realization.

80.3.5 Cubic incidence and boundary soldering

The cubic realization of transport preserves six oriented incidences. Its geometric quotient, the Lorentzian form and the energy response are obtained from the same incidence matrix. Transport proceeds from the enriched APP–TRIT–TPK route: the face, sign, carry and memory accompany each edge. This section develops the linear operation acting on that boundary publication.

80.3.5.1 Cubic incidence and the rank-four quotient

Let $H_F = \mathbb{R}^F$, with $F = \{(i,\epsilon) : 1 \le i \le 3,\ \epsilon \in \{-1,1\}\}$, its Euclidean inner product, and its basis $e_{i,\epsilon}$. Face opposition is the orthogonal involution $Re_{i,\epsilon} = e_{i,-\epsilon}$. Define

$$u = \sum_{i,\epsilon} e_{i,\epsilon}, \qquad P_u = \frac{uu^{\mathsf{T}}}{6}, \qquad P_- = \frac{I - R}{2}, \qquad P_0 = \frac{I + R}{2} - P_u, \qquad P_\square = P_u + P_-.$$

The vertices are $V = \{-1,1\}^3$. The incidence matrix $M : \mathbb{R}^V \longrightarrow H_F$ is determined by

$$M_{(i,\epsilon),\nu} = \mathbf{1}_{\{\nu_i = \epsilon\}}.$$

Proposition 80.15 (Incidence decomposition)**.** *We have*

$$MM^{\mathsf{T}} = 12P_u + 4P_-, \qquad \ker M^{\mathsf{T}} = P_0 H_F.$$

Consequently, the quotient $Q_\square = Q = H_F/P_0H_F$, orthogonally identified with $P_\square H_F$, has dimension four.

Proof. A face contains four vertices. Two opposite faces have no common vertices and two faces on different axes have two common vertices. Writing $\mathbf{J} = uu^{\mathsf{T}}$, we obtain

$$MM^{\mathsf{T}} = 4I + 2(\mathbf{J} - I - R) = 2(I - R) + 2\mathbf{J} = 4P_{-} + 12P_u.$$

The three projectors P_u, P_{-}, P_0 are orthogonal and sum to I; their ranks are one, three and two, respectively. The identity $\|M^{\mathsf{T}}x\|^2 = \langle x, MM^{\mathsf{T}}x\rangle$ identifies the stated kernel. The complementary rank is four. □

On Q, the form

$$B = P_{-} - P_u$$

has signature $(3, 1)$. The time orientation is fixed by u. With

$$t = \frac{u}{\sqrt{6}}, \qquad d_i = \frac{e_{i,+} - e_{i,-}}{\sqrt{2}}, \qquad W = \sqrt{6}P_u + \sqrt{2}P_{-},$$

we have $We_{i,\epsilon} = t + \epsilon d_i$. These six vectors are null for B, whereas

$$3t + \nu_1 d_1 + \nu_2 d_2 + \nu_3 d_3$$

has squared norm -6. The same incidence satisfies $MM^{\mathsf{T}} = 2W^{*}W$ on Q. The proper rotations of the cube commute with the projectors, preserve both forms and fix t. These identities determine the metric of the cubic publication.

80.3.5.2 Cellular soldering and memory transport

For each oriented edge a, the route publication provides the face $\lambda(\underline{a})$, the sign $\sigma(a)$, the source and target fibres and the transport $U(a) : Q_{s(a)} \longrightarrow Q_{t(a)}$. Inversion satisfies $U(\bar{a}) = U(a)^{-1}$. The boundary half-edges retain their formal inversion and their incidence at the boundary. With $\ell_m = \ell_0\, 9^{-m} > 0$, the soldering is

$$\beta_m(a) = \ell_m \sigma_m(a) n_{\lambda(\underline{a})}^{s(a)}, \qquad n_{i,\epsilon} = t + \epsilon d_i. \tag{80.16}$$

The face and sign are transported together with the route memory. The inversion convention requires

$$\beta_m(\bar{a}) = -U_m(a)\beta_m(a). \tag{80.17}$$

Applying this relation twice recovers $\beta_m(a)$; the carry register separately preserves the ordered composition.

Proposition 80.16 (Naturality of soldering under refinement)**.** *Let $a = a_1 \cdots a_9$ be a compatible refinement of an edge. Suppose that the nine child incidences, transported to the parent fibre, preserve the face and sign, and that $\ell_{m+1} = \ell_m/9$. Let $\mathcal{U}_j : Q_{m,s(a)} \longrightarrow Q_{m+1,s(a_j)}$ be the accumulated transport that includes the refinement identification and the path to the origin of child j. Then*

$$\beta_m(a) = \sum_{j=1}^{9} \mathcal{U}_j^{-1} \beta_{m+1}(a_j).$$

The equality is compatible with inversion and with concatenation of the memory register.

Proof. Each summand, expressed in the fibre at the origin of the parent, is $(\ell_m/9)\sigma_m(a)n_{\lambda(\underline{a})}$. The sum of nine terms reproduces the parent soldering. Inversion reverses the order of the transports and replaces each one with its inverse; the relation (80.17) provides the overall sign. Memory is concatenated in that same order, so refinement preserves both the vector publication and its enriched register. □

80.3.6 Geometric realization of transport and soldering

The discrete representation of return and screen soldering determine two aspects of transport: the accumulation of memory along routes and the comparison of their fibres. Their geometric realization preserves both operations. This section fixes the target space, the dimensional normalization of the connection and the identities that its variation will use.

80.3.6.1 Screen, co-tetrad and connection

The screen quotient $Q_\square$, its Lorentzian form, and the soldering β_m come from 80.3.5. In each cell, a screen realization $J_{\mathrm{scr},m}$ transports the form and soldering to the corresponding geometric fibre. Its cellular image is

$$e_m = J_{\mathrm{scr},m}\beta_m.$$

The scale ℓ_m remains within the soldering. Changes of frame act jointly on $J_{\mathrm{scr},m}$, the connection and the transport of the cells.

A smooth realization of those data on an oriented manifold $\mathcal{U}$ of dimension four consists of a nondegenerate co-tetrad $e = (e^I)$, a Lorentz connection $\omega = (\omega^I{}_J)$ and a realization of routes $\mathfrak{R}_{\mathrm{C}}$ satisfying

$$\mathrm{Hol}_{\mathcal{A}_{\ell_0}}(\mathfrak{R}_{\mathrm{C}}(\gamma)) = \rho_{\mathrm{C}}(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)). \tag{80.18}$$

In this matrix equality, the representation is normalized by

$$N_{\ell_0}(R,a) = (\Lambda(R), a/\ell_0), \qquad \rho_{\mathrm{C}} = N_{\ell_0} \circ \rho_{\mathrm{C}}^{\mathrm{disc}},$$

where $\Lambda : \mathrm{Spin}^+(3,1) \to SO^+(3,1)$ is the vector representation. The map N_{ℓ_0} preserves the semidirect product: dividing the translation $a + \Lambda(R)b$ by ℓ_0 is equivalent to composing the two normalized translations. The complete turn therefore publishes $72u$ in the normalized connection and $72\ell_0 u$ in the dimensional chart. The spin lift separately preserves $R_4^{c_g(\gamma)}$; the vector representation has the central kernel $\{1,-1\}$, so that lift is retained when using spinor fields. Identity, concatenation, inversion and subdivision are maintained in the corresponding realization. The screen pairing and the holonomy condition specify the data of the realization used in the field equations.

With $\eta = \mathrm{diag}(-1,1,1,1)$, define $g = \eta_{IJ}e^I \otimes e^J$. For a positive elementary scale ℓ_0, constant in the chart, the affine connection is

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1}e \\ 0 & 0 \end{pmatrix}. \tag{80.19}$$

The co-tetrad has the dimension of length; the factor ℓ_0^{-1} makes its translational component dimensionally homogeneous.

Proposition 80.17 (Curvature and torsion of the realized connection)**.** *The curvature of* (80.19) *is*

$$\mathcal{F}_{\ell_0} = \mathrm{d}\mathcal{A}_{\ell_0} + \mathcal{A}_{\ell_0} \wedge \mathcal{A}_{\ell_0} = \begin{pmatrix} F_\omega & \ell_0^{-1}T \\ 0 & 0 \end{pmatrix}, \quad F_\omega = \mathrm{d}\omega + \omega \wedge \omega, \quad T = \mathrm{d}e + \omega \wedge e. \tag{80.20}$$

Proof. The product of matrices of forms produces $\omega \wedge \omega$ in the diagonal block and $\ell_0^{-1}\omega \wedge e$ in the translational block. The exterior derivative contributes $\mathrm{d}\omega$ and $\ell_0^{-1}\mathrm{d}e$, since ℓ_0 is constant. Their sum proves the equality. □

Curvature describes the frame-transport defect and torsion that of the co-tetrad. Both belong to the same realized connection; their components retain distinct tensorial domains.

Proposition 80.18 (Covariance and Bianchi identities)**.** *Under a change of frame* $g_L : \mathcal{U} \to SO^+(3,1)$*,*

$$e' = g_L e, \qquad \omega' = g_L \omega g_L^{-1} - \mathrm{d}g_L\, g_L^{-1},$$

we have $T' = g_L T$ and $F_{\omega'} = g_L F_\omega g_L^{-1}$. Furthermore,

$$D_\omega T = F_\omega \wedge e, \qquad D_\omega F_\omega = 0. \tag{80.21}$$

Proof. In $\mathrm{d}(g_L e) + \omega' \wedge g_L e$, the terms containing $\mathrm{d}g_L \wedge e$ cancel. The same substitution into the curvature gives its transformation by conjugation. For the first Bianchi identity, expand

$$D_\omega(\mathrm{d}e + \omega \wedge e) = (\mathrm{d}\omega + \omega \wedge \omega) \wedge e.$$

In $\mathrm{d}F_\omega + \omega \wedge F_\omega - F_\omega \wedge \omega$, the terms containing $\mathrm{d}\omega$ and the cubic products cancel in pairs. This proves the second identity. □

80.3.6.2 The three quadratic realizations of curvature

The TRIT sheet $\tau \in \{+1, 0, -1\}$ is represented in the Cartan algebra by generators $J_{ab} = -J_{ba}$ and $P_a^{(\tau)}$, with relations

$$\begin{aligned}
[J_{ab}, J_{cd}] &= \eta_{bc} J_{ad} - \eta_{ac} J_{bd} - \eta_{bd} J_{ac} + \eta_{ad} J_{bc}, \\
[J_{ab}, P_c^{(\tau)}] &= \eta_{bc} P_a^{(\tau)} - \eta_{ac} P_b^{(\tau)}, \\
[P_a^{(\tau)}, P_b^{(\tau)}] &= -\tau J_{ab}.
\end{aligned}$$

For constant $\ell > 0$, write

$$\mathcal{A}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}\omega^{ab} J_{ab} + \ell^{-1} e^a P_a^{(\tau)}.$$

Proposition 80.19 (Curvature of the tritified realization)**.** *With the preceding relations,*

$$\mathcal{F}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}(F_\omega^{ab} - \tau \ell^{-2} e^a \wedge e^b) J_{ab} + \ell^{-1} T^a P_a^{(\tau)}. \tag{80.22}$$

Proof. Expand $\mathrm{d}\mathcal{A} + \frac{1}{2}[\mathcal{A}, \mathcal{A}]$. The bracket of the Lorentz sector produces F_ω, the mixed bracket produces $D_\omega e$, and the translational bracket contributes $-\frac{1}{2}\tau \ell^{-2} e^a \wedge e^b J_{ab}$. □

On the central sheet the affine connection is recovered; the extreme sheets preserve the two signs of the constant-curvature term. The representation thus retains the tritic regime of the route before applying the variational equations. The holonomy equality (80.18) corresponds to the central sheet. On each extreme sheet, the representation $\rho_{\mathrm{C},\tau}$ in its Cartan group and its respective holonomy condition are used. The current and the metric tensor use the fields and representation of the same realization.

80.3.7 Oriented transport of the connection and area

The parity of the incidence functional allows comparison of the charts γ and $-\gamma$. In the canonical geometric realization, let E_i^a be a densitized triad, $\Gamma_a^i(E)$ its intrinsic connection and K_a^i the extrinsic curvature in the chosen normal convention. The Ashtekar–Barbero connection is $\mathcal{A}_a^i = \Gamma_a^i(E) + \gamma K_a^i$.

Proposition 80.20 (Involution between oriented charts)**.** *For $\gamma \in \mathbb{R} \setminus \{0\}$, the map*

$$\mathfrak{b} : (\gamma, K, E) \longmapsto (-\gamma, -K, E)$$

is involutive. It preserves $\mathcal{A}$ and reverses the form

$$\Omega_{KE} = \frac{1}{\kappa} \int_\Sigma \delta K_a^i \wedge \delta E_i^a,$$

with κ fixed and the same boundary conditions.

Proof. Applying $\mathfrak{b}$ twice restores all three coordinates. Since E remains fixed, so does $\Gamma(E)$. The product of the two odd coordinates satisfies $(-\gamma)(-K) = \gamma K$, preserving the connection. In the space of variations, $\delta(-K) = -\delta K$ and δE remains fixed: the pullback of the form is $\mathfrak{b}^*\Omega_{KE} = -\Omega_{KE}$. □

The oriented area $\mathcal{A}_{\mathrm{or}} = \gamma a_0 N$ and its physical magnitude $\mathcal{A}_{\mathrm{fis}} = |\gamma| a_0 N$, for $a_0 > 0$ and $N \geq 0$, coincide in the positive chart. Upon prolongation to the opposite chart, the former is odd and the latter remains invariant. This distinction preserves both the orientation of the incidence and the positivity of the geometric observable. The proposition establishes the algebraic transport of these charts; its realization as an inversion of the spatial normal additionally uses the transport of matter and of the boundary data of the action (80.12).

80.3.8 Structural definition and function of the gravitational constant

Definition 80.21 (Gravitational section contragredient to action)**.** For a positive section $\hbar_a$, a velocity $c_{\mathrm{int}} > 0$, and the chronological radius R_{108} of section 80.3, the circular gravitational section is

$$G_a = \frac{c_{\mathrm{int}}^3 R_{108}^2}{\hbar_a}, \qquad R_{108} = \frac{54}{\pi}\ell_0, \qquad \ell_0 = c_{\mathrm{int}} t_0. \tag{80.23}$$

It is the action-reciprocal section realizing coincidence between the cycle's reduced gravitational radius and its chronological radius, in the convention $r_g = Gm/c_{\mathrm{int}}^2$.

The radius-coincidence proposition of section 80.3 proves its uniqueness in the family $G_a(\vartheta) = \vartheta c_{\mathrm{int}}^5 t_0^2/\hbar_a$. The circular condition fixes $\vartheta = (54/\pi)^2$ and leads to (80.23). That condition and the positive dimensional sections are part of the realization. Keeping them common to both orientations gives

$$\frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad \frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = R_{108}^2 = \ell_P^2. \tag{80.24}$$

The proof is direct substitution of (80.23); the action change is compensated by the reciprocal change in G_a.

This structure assigns gravitation a precise function: transporting the action section to a common geometric unit. In (80.12), G fixes coupling normalization; in the area operator, $G\hbar/c^3$ fixes the area unit. Reciprocity preserves that unit while the oriented action reading changes. The reduced state and its occupations subsequently supply the information and entanglement associated with the boundary.

The tensorial content of the coupling is preserved in $\mathbb{G}_{5,a} = G_a P_5^{\mathrm{ico}}$, constructed in 77.1.5. Section G_a determines its common magnitude; the projector selects the five-component carrier, and Γ_5 transports its orientation to the space of symmetric trace-free tensors. The basis in (77.64)–(77.66) makes the five components explicit. Projection $\Lambda(n)$ then defines the transverse reduction. Magnitude, carrier, and reduction are related operations with different domains within this realization.

80.4 Phase return and representation of accumulated memory

The chronology of enriched routes distinguishes position return, orientation return and phase return. The observable publication identifies certain arrival states, while the cumulative register preserves the sequence traversed. The geometric representation must transport both data jointly.

80.4.1 Inversion cocycle and change of sheet

Let F_{obs} be the chronological publication of TPK transport. Its canonical blocks have the hierarchy

27	positional return with orientation reversal,
54	positional and orientational return,
108	complete return of the observable phase.

The register counts orientation inversions $g(a)$ and effective changes of sheet $s(a)$. For a route,

$$c(\gamma) = \sum_{a \subset \gamma} (g(a), s(a)), \qquad c(\gamma_2\gamma_1) = c(\gamma_2) + c(\gamma_1). \tag{80.25}$$

The canonical computation of the block of length 27 publishes $c_{27} = (1, 18)$. Composition preserves those increments in the four blocks that complete the observable period. On forward-oriented routes the register is cumulative; its extension to the route groupoid uses $\mathbb{Z}^2$ and $c(\bar{\gamma}) = -c(\gamma)$.

Proposition 80.22 (Memory of the complete observable turn)**.** *Writing $\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$, the lift to the register, for $x \in O_{108}$ and $z \in \mathbb{Z}^2$, satisfies*

$$\widetilde{\mathcal{K}}_{27}(x, z) = (\mathcal{K}_{27}x, z + (1, 18)), \qquad \widetilde{\mathcal{K}}_{27}^{4}(x, z) = (x, z + (4, 72)).$$

After N complete turns, the increment is $N(4, 72)$.

Proof. The observable projection of $\mathcal{K}_{27}$ has order four. The preceding canonical computation fixes $c_{27} = (1, 18)$ as a constant over that observable orbit. The additivity of (80.25) sums the four increments and gives $c_{108} = 4(1, 18) = (4, 72)$. Repetition applies the same concatenation law and produces Nc_{108}. The return of the first coordinate preserves the increment of the second. □

80.4.2 Affine representation of the cocycle

The discrete realization uses an element R_4 of order four in $\mathrm{Spin}^+(1, 3)$, a unit temporal vector u fixed by its vector action and a unit of length $\ell_0 > 0$. The scale ℓ_0 retains its provenance in the dimensional section. We define

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma) = \left(R_4^{c_g(\gamma)},\ \ell_0 c_s(\gamma) u\right) \in \mathrm{Spin}^+(1, 3) \ltimes \mathbb{R}^{1,3}. \tag{80.26}$$

The power acts on the vector through the associated vector representation of the spin group.

Theorem 80.23 (Composition and translational amplitude of return)**.** *The map $\rho_{\mathrm{C}}^{\mathrm{disc}}$ preserves the identity, concatenation and inversion. At complete returns,*

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}) = (I, 72\ell_0 u), \qquad \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}^{N}) = (I, 72N\ell_0 u). \tag{80.27}$$

Inversion changes the sign of the translation.

Proof. The semidirect product is $(R, a)(S, b) = (RS, a + Rb)$. Since $R_4 u = u$,

$$\begin{aligned} \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2)\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_1) &= \left(R_4^{c_g(\gamma_2)+c_g(\gamma_1)}, \ell_0(c_s(\gamma_2) + c_s(\gamma_1))u\right) \\ &= \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2\gamma_1). \end{aligned}$$

The identity cocycle is zero and that of the inverse is its opposite. For the complete turn, substitute $c_{108} = (4, 72)$ and $R_4^4 = I$. Concatenating N turns keeps the rotational part equal to the identity and sums their translations. □

The amplitude $72\ell_0$ is a length associated with a finite route. A realization through a co-tetrad and a connection transports it to its affine holonomy. The local contribution to the gravitational equations is subsequently obtained through the curvature of that connection, the variation of the matter action and the normalization of its density. The representation thus preserves the exact cumulative content that must enter that realization.

80.5 Boundary soldering and energy response

The cubic realization of transport preserves six oriented incidences. Its geometric quotient, the Lorentzian form and the energy response are obtained from the same incidence matrix. Transport proceeds from the enriched APP–TRIT–TPK route: the face, sign, carry and memory accompany each edge. This section develops the linear operation acting on that boundary publication.

80.5.1 Cubic incidence and the rank-four quotient

Let $H_F = \mathbb{R}^F$, with $F = \{(i,\epsilon) : 1 \le i \le 3,\ \epsilon \in \{-1,1\}\}$, its Euclidean inner product, and its basis $e_{i,\epsilon}$. Face opposition is the orthogonal involution $Re_{i,\epsilon} = e_{i,-\epsilon}$. Define

$$u = \sum_{i,\epsilon} e_{i,\epsilon}, \qquad P_u = \frac{uu^{\mathsf{T}}}{6}, \qquad P_- = \frac{I-R}{2}, \qquad P_0 = \frac{I+R}{2} - P_u, \qquad P_\square = P_u + P_-.$$

The vertices are $V = \{-1,1\}^3$. The incidence matrix $M : \mathbb{R}^V \longrightarrow H_F$ is determined by

$$M_{(i,\epsilon),\nu} = \mathbf{1}_{\{\nu_i=\epsilon\}}.$$

Proposition 80.24 (Incidence decomposition)**.** *We have*

$$MM^{\mathsf{T}} = 12P_u + 4P_-, \qquad \ker M^{\mathsf{T}} = P_0 H_F.$$

Consequently, the quotient $Q = H_F/P_0H_F$, orthogonally identified with $P_\square H_F$, has dimension four.

Proof. A face contains four vertices. Two opposite faces have no common vertices and two faces on different axes have two common vertices. Writing $\mathbf{J} = uu^{\mathsf{T}}$, we obtain

$$MM^{\mathsf{T}} = 4I + 2(\mathbf{J} - I - R) = 2(I-R) + 2\mathbf{J} = 4P_- + 12P_u.$$

The three projectors P_u, P_-, P_0 are orthogonal and sum to I; their ranks are one, three and two, respectively. The identity $\|M^{\mathsf{T}}x\|^2 = \langle x, MM^{\mathsf{T}}x\rangle$ identifies the stated kernel. The complementary rank is four. □

On Q, the form

$$B = P_- - P_u$$

has signature $(3,1)$. The time orientation is fixed by u. With

$$t = \frac{u}{\sqrt{6}}, \qquad d_i = \frac{e_{i,+} - e_{i,-}}{\sqrt{2}}, \qquad W = \sqrt{6}P_u + \sqrt{2}P_-,$$

we have $We_{i,\epsilon} = t + \epsilon d_i$. These six vectors are null for B, whereas

$$3t + \nu_1 d_1 + \nu_2 d_2 + \nu_3 d_3$$

has squared norm -6. The same incidence satisfies $MM^{\mathsf{T}} = 2W^*W$ on Q. The proper rotations of the cube commute with the projectors, preserve both forms and fix t. These identities determine the metric of the cubic publication.

80.5.2 Cellular soldering and memory transport

For each oriented edge a, the route publication provides the face $\lambda(\underline{a})$, the sign $\sigma(a)$, the source and target fibres and the transport $U(a) : Q_{s(a)} \longrightarrow Q_{t(a)}$. Inversion satisfies $U(\bar{a}) = U(a)^{-1}$. The boundary half-edges retain their formal inversion and their incidence at the boundary. With $\ell_m = \ell_0\, 9^{-m} > 0$, the soldering is

$$\beta_m(a) = \ell_m \sigma_m(a) n^{s(a)}_{\lambda(\underline{a})}, \qquad n_{i,\epsilon} = t + \epsilon d_i. \tag{80.28}$$

The face and sign are transported together with the route memory. The inversion convention requires

$$\beta_m(\bar{a}) = -U_m(a)\beta_m(a). \tag{80.29}$$

Applying this relation twice recovers $\beta_m(a)$; the carry register separately preserves the ordered composition.

Proposition 80.25 (Naturality of soldering under refinement)**.** *Let $a = a_1 \cdots a_9$ be a compatible refinement of an edge. Suppose that the nine child incidences, transported to the parent fibre, preserve the face and sign, and that $\ell_{m+1} = \ell_m/9$. Let $\mathcal{U}_j : Q_{m,s(a)} \longrightarrow Q_{m+1,s(a_j)}$ be the accumulated transport that includes the refinement identification and the path to the origin of child j. Then*

$$\beta_m(a) = \sum_{j=1}^{9} \mathcal{U}_j^{-1} \beta_{m+1}(a_j).$$

The equality is compatible with inversion and with concatenation of the memory register.

Proof. Each summand, expressed in the fibre at the origin of the parent, is $(\ell_m/9)\sigma_m(a)n_{\lambda(\underline{a})}$. The sum of nine terms reproduces the parent soldering. Inversion reverses the order of the transports and replaces each one with its inverse; the relation (80.29) provides the overall sign. Memory is concatenated in that same order, so refinement preserves both the vector publication and its enriched register. □

80.5.3 Positive response, uniqueness, and minimal extension

The linear screen soldering is $\bar{\beta}_m = \ell_m W|_Q$. It is invertible, with

$$\bar{\beta}_m^{-1} = \ell_m^{-1} \left(\frac{1}{\sqrt{6}} P_u + \frac{1}{\sqrt{2}} P_- \right).$$

The eigenvalue $5/9$ of the antisymmetric sector of the normalized block $B_c/9$, constructed in Section 4.3.4, determines the compression coefficient $q_{\mathrm{vis}} = 5/9$. We reserve this notation to distinguish it from the Euclidean quotient $q_9(n)$ of the arithmetic kernel. Its realization on the screen uses an isometry $V_9 : Q \longrightarrow \mathcal{K}$. The visible contribution $C_9 = q_{\mathrm{vis}} V_9$ and its complement $D_9 = \sqrt{1 - q_{\mathrm{vis}}^2}\, V_9$ satisfy

$$C_9^* C_9 + D_9^* D_9 = I_Q, \qquad D_9^* D_9 = \frac{56}{81} I_Q.$$

The coefficient 56 is $9^2 - 5^2$; it belongs to the quadratic defect of that compression reader.

Theorem 80.26 (Energy response determined by soldering)**.** *There is a unique operator $\Lambda_m : Q \longrightarrow Q$ such that $\bar{\beta}_m^* \Lambda_m \bar{\beta}_m = D_9^* D_9$. It is positive definite and*

$$\Lambda_m = \frac{28}{243 \ell_m^2} (P_u + 3P_-) = \frac{112}{81 \ell_m^2} (M M^{\mathsf{T}}|_Q)^{-1}. \tag{80.30}$$

On H_F, the corresponding identity has right-hand side $(56/81)P_{\square}$.

Proof. Congruence by the invertible soldering necessarily determines

$$\Lambda_m = \bar{\beta}_m^{-*} \frac{56}{81} I_Q \bar{\beta}_m^{-1}.$$

Substituting the inverse, the coefficient of P_u is $56/(486\ell_m^2) = 28/(243\ell_m^2)$; that of P_- is $28/(81\ell_m^2)$. Both are positive. By Proposition 80.24, $(MM^{\mathsf{T}}|_Q)^{-1} = P_u/12 + P_-/4$, which gives the second expression. Extension to six faces annihilates $P_0 H_F$; the identity therefore extends through $P_\square$. □

Proposition 80.27 (Characterization by minimal extension)**.** *For every $b \in Q$,*

$$\langle b, \Lambda_m b \rangle = \frac{112}{81\ell_m^2} \min_{Mx=b} \|x\|^2.$$

The minimizing extension is unique: $x_{\min} = M^{\mathsf{T}}(MM^{\mathsf{T}}|_Q)^{-1} b$.

Proof. The stated vector satisfies $Mx_{\min} = b$ and belongs to $\operatorname{im} M^{\mathsf{T}} = (\ker M)^\perp$. Every other solution is $x_{\min} + z$, with $z \in \ker M$; by orthogonality, its squared norm is $\|x_{\min}\|^2 + \|z\|^2$. Moreover,

$$\|x_{\min}\|^2 = \langle b, (MM^{\mathsf{T}}|_Q)^{-1} b \rangle.$$

The formula for Λ_m completes the proof. □

The operator $MM^{\mathsf{T}}|_Q$ realizes the Dirichlet–to–Neumann response of this incidence formulation; its inverse is the Neumann–to–Dirichlet response. The preceding energy corresponds to the latter, with the normalization of the soldering and the compression defect. The Schur complement of $\left(\begin{smallmatrix} I & M^{\mathsf{T}} \\ M & 0 \end{smallmatrix}\right)$ is $-MM^{\mathsf{T}}$, which offers the same variational elimination.

80.5.4 Preservation of density by refinement

Consider the sector of cubic transports, orthogonal for the energy inner product and compatible with the form B. We fix a common label space Q^{lab}, identified isometrically with the parent's screen. The solderings have types $\bar{\beta}_m : Q^{\mathrm{lab}} \longrightarrow Q_m$ and $\bar{\beta}_{m+1,j} : Q^{\mathrm{lab}} \longrightarrow Q_{m+1,j}$; the operators Λ act in their respective target fibers. If $U_j : Q_j \longrightarrow Q$ transports the child fiber to the parent's, then

$$\bar{\beta}_{m+1,j} = \frac{1}{9} U_j^{-1} \bar{\beta}_m, \qquad \Lambda_{m+1,j} = 81 U_j^{-1} \Lambda_m U_j.$$

The factor 81 comes from $\ell_{m+1}^{-2} = 81\ell_m^{-2}$.

Theorem 80.28 (Invariance of the normalized density)**.** *Each child preserves the parent's quadratic response:*

$$\bar{\beta}_{m+1,j}^{*} \Lambda_{m+1,j} \bar{\beta}_{m+1,j} = \frac{56}{81} I_{Q^{\mathrm{lab}}}.$$

For r refinements, the joint response, expressed in the parent's fibers, is

$$E_{m+r} = \frac{56}{81} I_{Q^{\mathrm{lab}}} \otimes I_{9^r}.$$

The expectation with normalized trace $\tau_{9^r}(A) = 9^{-r} \operatorname{Tr}(A)$ satisfies

$$(\mathrm{id} \otimes \tau_{9^r})(E_{m+r}) = \frac{56}{81} I_{Q^{\mathrm{lab}}}$$

at every finite depth.

Proof. The congruence of a child contains the factors $1/9, 81, 1/9$; their product is one. Orthogonality cancels the intermediate transports. The direct sum of nine equal responses identifies the first refinement with $(56/81)I_Q \otimes I_9$. Iteration produces the tensor with I_{9^r}. Finally $\tau_{9^r}(I_{9^r}) = 1$. The expectations compose through the identity $\tau_{9^{r+s}} = \tau_{9^r} \otimes \tau_{9^s}$. □

The unital inclusions $A \mapsto A \otimes I_9$ are compatible with that family of traces. In the inductive limit of the matrix algebras, the response is the central element $(56/81)I_Q \otimes \mathbf{1}$. The unnormalized extensive sum produces, in contrast, $9^r(56/81)I_Q$. This distinction specifies which quantity is preserved: the quadratic screen density.

80.5.5 Variational realization of the response

The material realization uses an isometry $J_{\mathrm{scr}} : Q \longrightarrow \mathcal{H}_\partial$ compatible with the spin action and with refinement. The boundary co-tetrad is $e = J_{\mathrm{scr}}\bar{\beta}_m$. Let Λ_{CE} be the boundary response obtained by second variation of the material and geometric action, with its boundary conditions and elimination of the interior variables. The compatibility defect is

$$\mathcal{R}_{\mathrm{grav}} = \bar{\beta}_m^*(J_{\mathrm{scr}}^*\Lambda_{\mathrm{CE}}J_{\mathrm{scr}} - \Lambda_m)\bar{\beta}_m = e^*\Lambda_{\mathrm{CE}}e - D_9^*D_9. \tag{80.31}$$

By the invertibility of $\bar{\beta}_m$,

$$\mathcal{R}_{\mathrm{grav}} = 0 \quad \Longleftrightarrow \quad J_{\mathrm{scr}}^*\Lambda_{\mathrm{CE}}J_{\mathrm{scr}} = \Lambda_m.$$

The isometry J_{scr} transports the boundary states; the variational spin current is a degree-three form with values in bivectors. Each enters with its own domain in the realization of the response.

The construction determines a positive energy form, its minimizing interior extension and the density preserved by refinement. The amplitude of a concrete material contribution is obtained by evaluating the current of that realization in its variational quadratic form. This differentiates the operator fixing the response, the current on which it acts and the gravitational observable published by the evaluation.

80.6 Geometric realization of transport and soldering

The discrete representation of return and screen soldering determine two aspects of transport: the accumulation of memory along routes and the comparison of their fibres. Their geometric realization preserves both operations. This section fixes the target space, the dimensional normalization of the connection and the identities that its variation will use.

80.6.1 Screen, co-tetrad and connection

The screen quotient $Q_\square$, its Lorentzian form, and the soldering β_m come from 80.5. In each cell, a screen realization $J_{\mathrm{scr},m}$ transports the form and soldering to the corresponding geometric fibre. Its cellular image is

$$e_m = J_{\mathrm{scr},m}\beta_m.$$

The scale ℓ_m remains within the soldering. Changes of frame act jointly on $J_{\mathrm{scr},m}$, the connection and the transport of the cells.

A smooth realization of those data on an oriented manifold $\mathcal{U}$ of dimension four consists of a nondegenerate co-tetrad $e = (e^I)$, a Lorentz connection $\omega = (\omega^I{}_J)$ and a realization of routes $\mathfrak{R}_{\mathrm{C}}$ satisfying

$$\mathrm{Hol}_{\mathcal{A}_{\ell_0}}(\mathfrak{R}_{\mathrm{C}}(\gamma)) = \rho_{\mathrm{C}}(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)). \tag{80.32}$$

In this matrix equality, the representation is normalized by

$$N_{\ell_0}(R, a) = (\Lambda(R), a/\ell_0), \qquad \rho_{\mathrm{C}} = N_{\ell_0} \circ \rho_{\mathrm{C}}^{\mathrm{disc}},$$

where $\Lambda : \mathrm{Spin}^{+}(3,1) \to SO^{+}(3,1)$ is the vector representation. The map N_{ℓ_0} preserves the semidirect product: dividing the translation $a + \Lambda(R)b$ by ℓ_0 is equivalent to composing the two normalized translations. The complete turn therefore publishes $72u$ in the normalized connection and $72\ell_0 u$ in the dimensional chart. The spin lift separately preserves $R_4^{c_g(\gamma)}$; the vector representation has the central kernel $\{1,-1\}$, so that lift is retained when using spinor fields. Identity, concatenation, inversion and subdivision are maintained in the corresponding realization. The screen pairing and the holonomy condition specify the data of the realization used in the field equations.

With $\eta = \mathrm{diag}(-1,1,1,1)$, define $g = \eta_{IJ} e^I \otimes e^J$. For a positive elementary scale ℓ_0, constant in the chart, the affine connection is

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1} e \\ 0 & 0 \end{pmatrix}. \tag{80.33}$$

The co-tetrad has the dimension of length; the factor ℓ_0^{-1} makes its translational component dimensionally homogeneous.

Proposition 80.29 (Curvature and torsion of the realized connection)**.** *The curvature of* (80.33) *is*

$$\mathcal{F}_{\ell_0} = \mathrm{d}\mathcal{A}_{\ell_0} + \mathcal{A}_{\ell_0} \wedge \mathcal{A}_{\ell_0} = \begin{pmatrix} F_\omega & \ell_0^{-1} T \\ 0 & 0 \end{pmatrix}, \quad F_\omega = \mathrm{d}\omega + \omega \wedge \omega, \quad T = \mathrm{d}e + \omega \wedge e. \tag{80.34}$$

Proof. The product of matrices of forms produces $\omega \wedge \omega$ in the diagonal block and $\ell_0^{-1}\omega \wedge e$ in the translational block. The exterior derivative contributes $\mathrm{d}\omega$ and $\ell_0^{-1}\mathrm{d}e$, since ℓ_0 is constant. Their sum proves the equality. □

Curvature describes the frame-transport defect and torsion that of the co-tetrad. Both belong to the same realized connection; their components retain distinct tensorial domains.

Proposition 80.30 (Covariance and Bianchi identities)**.** *Under a change of frame $g_L : \mathcal{U} \to SO^{+}(3,1)$,*

$$e' = g_L e, \qquad \omega' = g_L \omega g_L^{-1} - \mathrm{d}g_L\, g_L^{-1},$$

we have $T' = g_L T$ and $F_{\omega'} = g_L F_\omega g_L^{-1}$. Furthermore,

$$D_\omega T = F_\omega \wedge e, \qquad D_\omega F_\omega = 0. \tag{80.35}$$

Proof. In $\mathrm{d}(g_L e) + \omega' \wedge g_L e$, the terms containing $\mathrm{d}g_L \wedge e$ cancel. The same substitution into the curvature gives its transformation by conjugation. For the first Bianchi identity, expand

$$D_\omega(\mathrm{d}e + \omega \wedge e) = (\mathrm{d}\omega + \omega \wedge \omega) \wedge e.$$

In $\mathrm{d}F_\omega + \omega \wedge F_\omega - F_\omega \wedge \omega$, the terms containing $\mathrm{d}\omega$ and the cubic products cancel in pairs. This proves the second identity. □

80.6.2 The three quadratic realizations of curvature

The TRIT sheet $\tau \in \{+1, 0, -1\}$ is represented in the Cartan algebra by generators $J_{ab} = -J_{ba}$ and $P_a^{(\tau)}$, with relations

$$\begin{aligned} [J_{ab}, J_{cd}] &= \eta_{bc} J_{ad} - \eta_{ac} J_{bd} - \eta_{bd} J_{ac} + \eta_{ad} J_{bc}, \\ [J_{ab}, P_c^{(\tau)}] &= \eta_{bc} P_a^{(\tau)} - \eta_{ac} P_b^{(\tau)}, \\ [P_a^{(\tau)}, P_b^{(\tau)}] &= -\tau J_{ab}. \end{aligned}$$

For constant $\ell > 0$, write

$$\mathcal{A}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}\omega^{ab}J_{ab} + \ell^{-1}e^a P_a^{(\tau)}.$$

Proposition 80.31 (Curvature of the tritified realization)**.** *With the preceding relations,*

$$\mathcal{F}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}(F_\omega^{ab} - \tau\ell^{-2}e^a \wedge e^b)J_{ab} + \ell^{-1}T^a P_a^{(\tau)}. \tag{80.36}$$

Proof. Expand $\mathrm{d}\mathcal{A} + \frac{1}{2}[\mathcal{A}, \mathcal{A}]$. The bracket of the Lorentz sector produces F_ω, the mixed bracket produces $D_\omega e$, and the translational bracket contributes $-\frac{1}{2}\tau\ell^{-2}e^a \wedge e^b J_{ab}$. □

On the central sheet the affine connection is recovered; the extreme sheets preserve the two signs of the constant-curvature term. The representation thus retains the tritic regime of the route before applying the variational equations. The holonomy equality (80.32) corresponds to the central sheet. On each extreme sheet, the representation $\rho_{\mathrm{C},\tau}$ in its Cartan group and its respective holonomy condition are used. The current and the metric tensor use the fields and representation of the same realization.

80.7 Variational response of memory energy

The transport of a route identifies the fibers at its endpoints and preserves the orientation and memory entering that identification. The associated energy compares the final field with the transported initial field. Its differential quantifies how that comparison responds to a variation of transport. This section obtains the response directly from the discrete functional and develops its composition, covariance and inversion.

80.7.1 Discrete functional and space of variations

At a finite level m, let $\mathcal{V}_m$ be the vertices of the route publication and $\mathcal{E}_m^+$ an orientation of each edge. Each vertex carries a finite-dimensional Hermitian fiber H_v. We define

$$\mathcal{H}_m = \bigoplus_{v\in\mathcal{V}_m} H_v, \qquad \mathcal{K}_m = \bigoplus_{a\in\mathcal{E}_m^+} H_{t(a)}.$$

The Hermitian inner product is antilinear in the first variable. For unitary $U_a : H_{s(a)} \to H_{t(a)}$, the difference operator is

$$(D_m f)_a = f_{t(a)} - U_a f_{s(a)}, \qquad E_m(f, U) = \langle D_m f, \mathsf{W}_m D_m f\rangle, \qquad \mathsf{W}_m = \mathsf{W}_m^* > 0. \tag{80.37}$$

This is the energy of the term $D_m^*\mathsf{W}_m D_m$ in the discrete generator. The weight W_m may couple different edges. The soldering operator W of Section 80.5 and this energy weight have different domains and roles.

The transport U is a publication of the enriched state. The field f and the weight W_m remain explicit as arguments of the functional; each material application preserves the rules that determine them. Differentiable families of the unitary realizations of transport are considered,

$$\dot{U}_a = A_a U_a, \qquad A_a^* = -A_a.$$

The variations used physically form the subspace preserving the conditions of the corresponding realization. The differential is calculated first in the unitary tangent space and then restricted to that subspace.

Proposition 80.32 (Transport-response covector)**.** *Write*

$$v_a = U_a f_{s(a)}, \qquad r = D_m f, \qquad q = \mathsf{W}_m r.$$

At fixed field and weight, the energy differential is

$$\mathfrak{j}_m(A) = -2\,\mathrm{Re}\sum_{a\in\mathcal{E}_m^+}\langle q_a, A_a v_a\rangle. \tag{80.38}$$

Its representative for the real Hilbert–Schmidt inner product is

$$\mathcal{J}_a = v_a q_a^* - q_a v_a^*, \qquad \mathcal{J}_a^* = -\mathcal{J}_a, \qquad \mathfrak{j}_m(A) = \sum_a \operatorname{Re}\operatorname{Tr}(\mathcal{J}_a^* A_a). \tag{80.39}$$

For simultaneous variations of field, transport and weight we have

$$\dot{E}_m = 2\operatorname{Re}\sum_a \left\langle q_a, \dot{f}_{t(a)} - U_a \dot{f}_{s(a)} - A_a v_a \right\rangle + \langle r, \dot{\mathsf{W}}_m r\rangle. \tag{80.40}$$

Proof. The first-order update, written in the algebra of dual numbers with $\epsilon^2 = 0$, gives

$$r + \epsilon \dot{r}, \qquad \dot{r}_a = \dot{f}_{t(a)} - U_a \dot{f}_{s(a)} - A_a v_a.$$

The coefficient of ϵ in the energy is

$$\langle \dot{r}, \mathsf{W}_m r\rangle + \langle r, \mathsf{W}_m \dot{r}\rangle + \langle r, \dot{\mathsf{W}}_m r\rangle.$$

Self-adjointness of the weight yields (80.40). Fixing field and weight leaves (80.38). Moreover,

$$\operatorname{Tr}(\mathcal{J}_a^* A_a) = v_a^* A_a q_a - q_a^* A_a v_a.$$

Anti-Hermiticity of A_a implies $v_a^* A_a q_a = -\overline{q_a^* A_a v_a}$, giving the stated representative. □

The response is thus evaluated: on each edge the field is transported, its difference from the final field is calculated and the energy weight is applied. The antisymmetrized product of those two vectors determines $\mathcal{J}_a \in \mathfrak{u}(H_{t(a)})$. This operator represents, through the real Hilbert–Schmidt inner product, the response covector on the unitary variations of the target fiber.

80.7.2 Composition and transport of the response

Proposition 80.33 (Composition rule along a route)**.** *For a route formed by N transports, let $U_\gamma = U_N \cdots U_1$ and $B_k = U_N \cdots U_{k+1}$, with $B_N = I$. If $\dot{U}_k = A_k U_k$, then*

$$\dot{U}_\gamma U_\gamma^{-1} = \sum_{k=1}^{N} B_k A_k B_k^{-1}. \tag{80.41}$$

Thus a representative $\mathcal{J}_\gamma$ in the final fibre induces in factor k the contribution $B_k^* \mathcal{J}_\gamma B_k$. When a factor belongs to several routes in the functional, its contributions are summed with the incidences used by that functional.

Proof. The product rule gives

$$\dot{U}_\gamma = \sum_k U_N \cdots U_{k+1} A_k U_k \cdots U_1.$$

Multiplication by U_γ^{-1} eliminates the factors to the right of A_k and yields (80.41). By unitarity and cyclicity of the trace,

$$\operatorname{Re}\operatorname{Tr}(\mathcal{J}_\gamma^* B_k A_k B_k^{-1}) = \operatorname{Re}\operatorname{Tr}((B_k^* \mathcal{J}_\gamma B_k)^* A_k).$$

Linearity of the differential proves the sum of contributions. □

This formula preserves the position of each operation within the route. Transport following an incidence determines how its contribution is represented in the final fiber; the local response is recovered by transporting it to the fiber of that incidence.

Proposition 80.34 (Covariance under unitary frame changes)**.** *Let g_v be unitary frame changes independent of the variation parameter, and $G_{\mathcal{E}} = \bigoplus_a g_{t(a)}$. Under the transformations*

$$f'_v = g_v f_v, \quad U'_a = g_{t(a)} U_a g_{s(a)}^{-1}, \quad \mathsf{W}'_m = G_{\mathcal{E}} \mathsf{W}_m G_{\mathcal{E}}^{-1}, \quad A'_a = g_{t(a)} A_a g_{t(a)}^{-1},$$

we have

$$\mathcal{J}'_a = g_{t(a)} \mathcal{J}_a g_{t(a)}^{-1}, \qquad \mathfrak{j}'_m(A') = \mathfrak{j}_m(A). \tag{80.42}$$

Proof. We obtain $r' = G_{\mathcal{E}} r$, $q' = G_{\mathcal{E}} q$ and $v'_a = g_{t(a)} v_a$. Substitution into (80.39) proves the first identity. Invariance of the Hermitian inner product, or cyclicity of the trace, proves the second. □

When frame changes depend on the parameter, their derivatives also act on the field and weight. The corresponding covariant expression is then the complete differential (80.40).

80.7.3 Oriented inversion and transport of the weight

Inversion can be seen explicitly in the case of a local energy per edge, $\mathsf{W}_m = \bigoplus_a W_a$. For $a : s \to t$, its inverse carries

$$U_{\bar{a}} = U_a^{-1}, \qquad r_{\bar{a}} = -U_a^{-1} r_a, \qquad W_{\bar{a}} = U_a^{-1} W_a U_a.$$

These rules preserve the edge energy exactly.

Proposition 80.35 (Differential compatibility with inversion)**.** *If W_a and the fields at both endpoints remain fixed, then*

$$A_{\bar{a}} = -U_a^{-1} A_a U_a, \qquad \dot{W}_{\bar{a}} = U_a^{-1} [W_a, A_a] U_a.$$

The complete variation of the reversed edge's energy coincides with the original. In particular, if $[W_a, A_a] = 0$, the partial transport covector satisfies

$$\mathfrak{j}_{\bar{a}}(U_a^{-1} A_a U_a) = -\mathfrak{j}_a(A_a). \tag{80.43}$$

Proof. The derivative of U_a^{-1} is $-U_a^{-1} A_a$, from which the two formulas result. Writing $v_a = U_a f_s$ and $f_t = r_a + v_a$, the part due exclusively to reversed transport equals

$$\mathfrak{j}_{\bar{a}}(A_{\bar{a}}) = -2 \operatorname{Re}\langle r_a, W_a A_a f_t \rangle = \mathfrak{j}_a(A_a) - 2 \operatorname{Re}\langle r_a, W_a A_a r_a \rangle.$$

Variation of the weight contributes

$$\langle r_{\bar{a}}, \dot{W}_{\bar{a}} r_{\bar{a}} \rangle = \langle r_a, [W_a, A_a] r_a \rangle = 2 \operatorname{Re}\langle r_a, W_a A_a r_a \rangle.$$

The two terms compensate each other. If the commutator is zero, that contribution disappears; linearity in A_a gives (80.43). □

Energy is summed over one orientation per edge. A sum over both orientations carries the factor $1/2$. This convention preserves the same functional and hence the same response.

80.7.4 Compatibility with refinement

Theorem 80.36 (Transport of the differential by refinement)**.** *Let $J_m : \mathcal{H}_m \to \mathcal{H}_{m+1}$ and $K_m : \mathcal{K}_m \to \mathcal{K}_{m+1}$ be fixed maps. For a family C^1, suppose the refinement identities*

$$D_{m+1}(t) J_m = K_m D_m(t), \qquad K_m^* \mathsf{W}_{m+1}(t) K_m = \mathsf{W}_m(t). \tag{80.44}$$

Then $E_{m+1}(J_m f) = E_m(f)$. The transport covectors agree on variations linked by the first identity. When the weights vary, their contributions to the differential also agree.

Proof. By substitution,

$$\langle D_{m+1}J_m f, \mathsf{W}_{m+1}D_{m+1}J_m f\rangle = \langle D_m f, K_m^{*}\mathsf{W}_{m+1}K_m D_m f\rangle = E_m(f).$$

Differentiating the first identity of (80.44) gives $\dot{D}_{m+1}J_m = K_m\dot{D}_m$. Consequently,

$$2\,\mathrm{Re}\langle D_{m+1}J_m f, \mathsf{W}_{m+1}\dot{D}_{m+1}J_m f\rangle = 2\,\mathrm{Re}\langle D_m f, \mathsf{W}_m\dot{D}_m f\rangle.$$

The derivative of the second identity is $K_m^{*}\dot{\mathsf{W}}_{m+1}K_m = \dot{\mathsf{W}}_m$, proving agreement of the weight-variation terms. □

The statement uses compatibility of the transport family. If J_m depends on the parameter, the chain rule also preserves the term

$$2\,\mathrm{Re}\langle D_{m+1}J_m f, \mathsf{W}_{m+1}D_{m+1}\dot{J}_m f\rangle.$$

The resulting naturality jointly transports the functional, its incidences and its differential.

80.7.5 Material realization of the response

The result of this section is the explicit covector $\mathfrak{j}_m$, with its representative $\mathcal{J}_a$. The material realization composes that covector with the variation of transport induced by the connection and with the normalization of the action. If $\mathcal{L}_m$ denotes that differential map, the covector on connection variations is $\mathcal{L}_m^{*}\mathfrak{j}_m$. The composition rule (80.41) evaluates its part corresponding to finite products of transports.

In section 82.8, the current σ_{IJ} is a three-form defined by variation of the material action. Identification between the two realizations preserves the field, representation, weight, dimensional normalization and passage to the limit used by that action. These data allow evaluation of the contraction entering the torsional density. The present development provides the discrete differential composed in that calculation.

Chapter 81

Perron Dynamics, Dilution a^{-6} of memory and Einstein–Cartan realization

The Perron operator fixes the stable memory mode; when published as a spin density, its contribution decays as the inverse sixth power of the scale factor. The Einstein–Cartan realization preserves this provenance and its conditions of validity.

81.1 Perron dynamics and the stable memory mode

On a closed route, the cylindrical Perron cocycle satisfies

$$V_n = \varphi^n. \tag{81.1}$$

In spatial dimension $D = 3$, the scale determined by the cocycle is

$$\frac{a_n}{a_0} = V_n^{1/3} = \varphi^{n/3}, \tag{81.2}$$

whereas the stable mode of the quadratic action is

$$M_n = \varphi^{-2n} = V_n^{-2}. \tag{81.3}$$

Eliminating n between equations (81.2) y (81.3) gives the central result:

Theorem 81.1 (Law cylindrical of sixth order for the memory)**.** *For every closed level of the Perron realization in $D = 3$,*

$$\boxed{M_n = \left(\frac{a_n}{a_0}\right)^{-6}}. \tag{81.4}$$

The exponent -6 is not fitted: it is the quotient of the stable exponent -2 by the dimensional root $1/3$.

In the distinguished returns one obtains

$$\frac{a_9}{a_0} = \varphi^3, \qquad \frac{a_{27}}{a_0} = \varphi^9, \qquad \frac{a_{108}}{a_0} = \varphi^{36},$$

and the same levels satisfy exactly $M_n = (a_n/a_0)^{-6}$. If the additive temporal parameter $t_n = nt_0$ is declared, the logarithmic rate is constant:

$$H_\varphi := \frac{\Delta \log a_n}{\Delta t} = \frac{\log \varphi}{3t_0}, \qquad H_\varphi t_0 = 0.160403941686534482499252971 1\ldots. \tag{81.5}$$

The symbol H_φ names the rate of this discrete scale. Reading it as a Hubble parameter requires the cosmographic transducer; the internal identity does not depend on that promotion.

81.2 Realization in the system of Einstein–Cartan

In an Einstein–Cartan spin fluid, the quadratic spin density obeys

$$s^2 \propto a^{-6}. \tag{81.6}$$

The equation (81.4) provides the exponent and the stable mode without consulting a bounce. To make the physical reading, one must declare a positive section s_*^2 and a map

$$\mathcal{T}_{\mathrm{EC}} : M_n \longmapsto s_n^2 := s_*^2 M_n = s_*^2 \left(\frac{a_n}{a_0}\right)^{-6}. \tag{81.7}$$

The map preserves the scaling law, but does not by itself determine the amplitude s_*^2, the spin current, the sign of the term of contorsion, or the equation of state. With mass density, an effective equation has the form

$$H^2 = \frac{8\pi G}{3}\left(\rho_{\mathrm{m}} - \rho_{\mathrm{spin,m}}\right) + \cdots, \tag{81.8}$$

whereas with energy density it must be written

$$H^2 = \frac{8\pi G}{3c^2}\left(\rho_{\mathrm{E}} - \rho_{\mathrm{spin,E}}\right) + \cdots. \tag{81.9}$$

The two conventions are not mixed. A bounce candidate requires, in addition to equality of the densities, regularity, matter, and boundary data.

Falsification criterion 81.2. The Einstein–Cartan transduction fails if the scale functional produces an exponent other than -6, if $V_n \neq \varphi^n$ along the declared route, or if the physical map does not preserve positivity and dimensions. Retrospectively choosing s_*^2 to force a bounce threshold does not establish the transducer.

81.3 Structural comparison between the 108-state cycle and Perron dynamics

	CT108–de Sitter framework	Perron–Einstein–Cartan framework
Antecedent	circular return of order 108	cylindrical cocycle and stable mode
Selection mechanism	$r_g = R_{108}$	$V_n = \varphi^n$, $D = 3$
Magnitudes determinadas	radius, curvature, temperature, and entropy	expansion, rate, and dilution of memory
Invariant	$G_a \hbar_a$ and circular radius	$M_n a_n^6$
Status	de Sitter conditioned interface	exact internal law; conditioned EC reading
Falsification criterion	incompatible radius or background equation	perdida of the exponente -6 or of the transductor

Hypothesis, domain, and conclusion

The CT108 identities, the selector θ_{108}, and the law $M_n = (a_n/a_0)^{-6}$ are *Internal exact theorem*. The reading of the same radius as de Sitter and the identification of M_n with a spin density are *Conditional physical realizations*, each with its own falsification criterion.

Coordination of torsion and area in the Palatini–Cartan–Holst action. Torsion and area are subsequently coordinated in the first-order Palatini–Cartan–Holst action.

81.4 Torsional Memory and Bounce Conditions in Einstein–Cartan

81.4.1 Transport of the Perron law to the spin spectral density

The realization in Perron cosmological form constructs two sequences on the same closed route:

$$\frac{a_n}{a_0} = \varphi^{n/3}, \qquad M_n = \varphi^{-2n}. \tag{81.10}$$

Elimination of level n produces the exact identity

$$\boxed{M_n = \left(\frac{a_n}{a_0}\right)^{-6}}. \tag{81.11}$$

The exponent has a definite genealogy: the spatial dimension contributes the factor 3, and the quadratic character of stable memory contributes the factor 2. The power $6 = 2 \cdot 3$ thus expresses the dilution of a quadratic density associated with an extensive spin charge.

Definition 81.3 (Torsional transducer)**.** Having fixed a positive amplitude s_*^2 on an initial section, the torsional transducer is

$$\mathcal{T}_{\mathrm{EC}} : M_n \longmapsto s_n^2 = s_*^2 M_n = s_*^2 \left(\frac{a_n}{a_0}\right)^{-6}. \tag{81.12}$$

Its domain is the stable Perron mode, and its codomain is the quadratic spin sector of an Einstein–Cartan realization.

The equation equation (81.12) preserves the exponent and positivity. The amplitude s_*^2, the sign with which the contorsion enters the gravitational equation, and the dimensional normalization belong to the physical realizer. This separation establishes exactly what the HMT trunk supplies and what Cartan dynamics must supply.

81.4.2 Homogeneous Equations and Density Convention

To present the structural mechanism, we temporarily adopt units $c = 1$ and a spatially flat FRW geometry. Let

$$\rho_m(a) = \rho_0 a^{-3(1+w)}, \qquad \rho_s(a) = s_0 a^{-6}, \tag{81.13}$$

with $\rho_0 > 0$, $s_0 > 0$, and w constant. The contribution from contorsion enters with a repulsive sign in the effective equation:

$$H^2 = \frac{8\pi G}{3}\big(\rho_m - \rho_s\big). \tag{81.14}$$

If energy densities are used, the right-hand side is multiplied by c^{-2}; if mass densities are used, it retains the form equation (81.14). The document maintains a single convention in each calculation and restores the dimensional chart at the end.

The corresponding Raychaudhuri equation is

$$\dot{H} = -4\pi G\big[(1+w)\rho_m - 2\rho_s\big]. \tag{81.15}$$

The second contribution behaves as a stiff fluid with equation of state $w_s = 1$ and negative effective density. This form is the homogeneous publication of torsional repulsion at high density.

81.4.3 Existence and uniqueness of the bounce radius

Theorem 81.4 (Regular reflection for $w < 1$)**.** *Assume $\rho_0 > 0$, $s_0 > 0$, and $w < 1$. Then there exists a unique positive radius a_b such that $H(a_b) = 0$, given by*

$$\boxed{a_b^{3(1-w)} = \frac{s_0}{\rho_0}.} \tag{81.16}$$

At that point

$$\boxed{\dot{H}_b = 4\pi G(1-w)\rho_b > 0,} \qquad \rho_b := \rho_m(a_b) = \rho_s(a_b), \tag{81.17}$$

so that the contractive branch is extended into a regular expansive branch.

Proof. The condition $H = 0$ is equivalent to $\rho_0 a^{-3(1+w)} = s_0 a^{-6}$. Multiplication by a^6 yields equation (81.16). The exponent $3(1-w)$ is positive; therefore the power defines a bijection of $\mathbb{R}_{>0}$ onto itself and the radius is unique. Substituting $\rho_m = \rho_s = \rho_b$ into equation (81.15),

$$\dot{H}_b = -4\pi G[(1+w) - 2]\rho_b = 4\pi G(1-w)\rho_b > 0.$$

Positivity turns the simple zero of H into a minimum of $a(t)$. □

The local expansion around t_b makes the regularity explicit:

$$a(t) = a_b\left[1 + 2\pi G(1-w)\rho_b(t-t_b)^2 + O\Big((t-t_b)^3\Big)\right]. \tag{81.18}$$

The law a^{-6} supplies the power that dominates the material sector when $w < 1$ and a decreases. The torsional sign and positive amplitude cause that dominance to halt the contraction before reaching $a = 0$.

81.4.4 Limit Cases of Torsional Dynamics and Obstructions to the Regularity of the Bounce

The value $w = 1$ produces the same exponent a^{-6} in both terms. The difference then retains a fixed sign determined by $\rho_0 - s_0$; pointwise equality ceases to select an isolated radius. For $w > 1$, the material density grows faster than the torsional term during contraction, and the preceding mechanism does not guarantee a bounce. These cases provide internal negative controls: the closure depends on the inequality of the exponents and not on a retrospective choice of the threshold.

Spatial curvature k, a cosmological constant, and Bianchi anisotropies add terms to equation (81.14). Their local effect is controlled without presupposing the position of the new zero. Define

$$F_0(a) := \frac{8\pi G}{3}\big(\rho_m(a) - \rho_s(a)\big).$$

The perturbed equation takes the form $H^2 = F_R(a) := F_0(a) + R(a)$.

Theorem 81.5 (Persistence C^1 of the rebote transversal)**.** *Let a_b be the radius of equation (81.16). There exist $0 < a_- < a_b < a_+$ such that, for $I = [a_-, a_+]$,*

$$F_0(a_-) < 0 < F_0(a_+), \qquad m_I := \inf_{a\in I} F_0'(a) > 0.$$

If $R \in C^1(I)$ satisfies

$$\|R\|_{C^0(I)} < \delta_I := \min\{-F_0(a_-), F_0(a_+)\}, \qquad \|R'\|_{C^0(I)} < m_I, \tag{81.19}$$

then there exists a unique $a_R \in (a_-, a_+)$ with $F_R(a_R) = 0$, and that zero is transversal:

$$F_R'(a_R) > 0, \qquad \dot{H}_R(a_R) = \frac{a_R}{2}F_R'(a_R) > 0. \tag{81.20}$$

For a family $R(a,\eta)$ of class C^1, the implicit function theorem provides a local branch $a_R(\eta)$ of class C^1.

Proof. The identity equation (81.17) is equivalent to $F_0'(a_b) > 0$. By continuity, I can be chosen with $m_I > 0$ and with the indicated change of sign. The first bound for equation (81.19) preserves $F_R(a_-) < 0 < F_R(a_+)$; the intermediate value theorem produces a zero. The second bound gives $F_R'(a) \geq m_I - \|R'\|_{C^0(I)} > 0$, so F_R is strictly increasing and the zero is unique. On each branch with $H \neq 0$, differentiating $H^2 = F_R(a)$ and using $\dot{a} = aH$ gives $\dot{H} = (a/2)F_R'(a)$; continuity extends the equality to a_R. The nondegeneracy $F_R'(a_R) > 0$ is precisely the hypothesis of the implicit function theorem. □

81.4.5 Torsional amplitude from the Cartan screen

The memory exponent is closed by equation (81.11). The amplitude may be sought prospectively in the screen response. Let the exact identity be

$$(\beta_m^{\square})^* \Lambda_m^{\square} \beta_m^{\square} = \frac{56}{81} I_{Q_{\square}}. \tag{81.21}$$

A complete gravitational realization must construct a spin current

$$\mathcal{J}_m = \mathcal{J}(\beta_m^{\square}, U_m, c_s, c_g) \tag{81.22}$$

and a positive functional

$$s_{0,m} = \mathfrak{S}(\mathcal{J}_m, \Lambda_m^{\square}) \tag{81.23}$$

compatible with refinement. The pertinent nonadic normalization is the tracial expectation, because it preserves the density of equation (81.21); the raw sum counts nine copies and belongs to a distinct extensive quantity.

Proposition 81.6 (Obligations of the amplitude selector)**.** *An admissible selector for s_0 must satisfacer:*

i) positivity and dimensions of squared spin density;

ii) gauge invariance under the reduction induced by the transported cubic structure;

iii) compatibility with edge inversion and carry;

iv) naturality under 9-ary refinement;

v) independence from any bounce radius used as a target value.

These conditions turn the amplitude into a localized algebraic constraint. The screen-energy equality supplies the quadratic form; the Cartan realizer must determine how that form contracts with the physical current.

81.4.6 Torsion, orientation, and transport memory

The metric publishes distances and causal cones. The Cartan connection also publishes the orientation of transport. In HMT, route, carry, and deep state already constitute genealogical data. The correspondence

$$\text{stable route memory} \longrightarrow \text{spin current} \longrightarrow \text{contorsion} \longrightarrow \rho_s \propto a^{-6} \tag{81.24}$$

provides a physical reading of that oriented information. Curvature describes the response of geometry to energy; torsion preserves the history of orientation that accompanies transport. The sixth-order law is the point at which genealogical memory and quadratic spin density have exactly the same scaling covariance.

81.4.7 Mach's principle and cosmographic autoinertia

The local state is evaluated within a route compatible with the global boundary. The inertial response therefore belongs to the holonomic stabilizer of the totality. In the homogeneous sector, the scale a_n, the memory M_n, and the torsional current are three readings of the same enriched genealogical state:

$$X_n \longmapsto \big(a_n, M_n, \mathcal{J}_n\big). \tag{81.25}$$

The Machian interpretation thereby acquires operatorial content: the local response depends on the global closure class, and the observer forms part of the prolonged section. Self-inertia is the preservation of the relative state under the holonomy that jointly transports geometry, observer, and memory.

81.4.8 Exact identities of torsional dynamics and Einstein–Cartan interface conditions

Estatuto probatorio

The law $M_n = (a_n/a_0)^{-6}$ is an exact internal theorem. The bounce theorem equations (81.16) y (81.17) is an exact consequence of the homogeneous Einstein–Cartan equations [65] with $\rho_0, s_0 > 0$ and $w < 1$. The transducer equation (81.12) exactly preserves the scaling law. The determination of s_0 from the screen current, the extension to anisotropies, and the complete derivation of the Einstein–Cartan action are delimited physical interfaces.

Falsification criterion

The internal block is refuted if the Perron mode violates equation (81.11). The Einstein–Cartan realization is refuted if the induced current produces another power, a nonpositive amplitude, or a sign that eliminates equation (81.17). The homogeneous bounce fails for the declared data if the radius equation (81.16) does not exist, if $H(a_b) \neq 0$, or if $\dot{H}_b \leq 0$. The complete promotion is rejected if the amplitude functional retrospectively consults the desired radius or loses gauge, carry, or refinement.

Chapter 82

Palatini–Cartan–Holst realization of the Barbero–Immirzi parameter and physical transduction of the area spectrum

The structural derivation of the parameter and the area spectrum precedes this chapter. Here the tetrad, connection, curvature, and first-order action are constructed, and only then is the Holst parameter specialized as a physical realization of the areal reader.

82.1 Curvature, torsion, and Einstein–Cartan–Holst action

The HMT transport structure distinguishes the memory variable, holonomy, and closure defect. Its gravitational realization is formulated by means of a tetrad and a connection. This section establishes the first-order geometry and specifies the type of the map between it and the TPK state space .

82.1.1 Discrete Gauss–Stokes identity and incidence transport to the boundary

Let K be a cellular complex, let W be an abelian group, and let $\Omega \in C^1(K;W)$ be a cochain. We denote by $\delta : C^1(K;W) \to C^2(K;W)$ the cellular coboundary and by $\langle \cdot\,,\, \cdot \rangle$ the pairing between cochains with values in W and integral cellular chains.

Theorem 82.1 (Universal Stokes Cell Identity)**.** *For every 2-cadena finite $z \in C_2(K;\mathbb{Z})$,*

$$\boxed{\langle \delta\Omega, z\rangle = \langle \Omega, \partial z\rangle.}$$

Proof. This is the identity that defines the coboundary as the adjoint operator of the cellular boundary. The finiteness of z ensures that both pairings are finite sums in W. □

Corollary 82.2 (Gauss–Stokes on a cellular pseudomanifold)**.** *Let K be a finite, compact, regular two-dimensional cellular pseudomanifold, coherently oriented and possibly with boundary. If z_K is the sum of its 2-cells with the coherent orientation, then*

$$\sum_{f \in K^{(2)}} (\delta\Omega)(f) = \sum_{e} [\partial z_K : e]\, \Omega(e).$$

In particular, regularity allows the uncancelled incidences of ∂z_K to be identified with the edges of the geometric boundary.

Proof. The theorem is applied to z_K. Coherent orientation makes each interior edge appear twice in ∂z_K with opposite coefficients; the uncancelled incidences form the boundary chain. □

The non-Abelian version is not obtained merely by replacing sums with products. In this work it is used only when transports to a common base, an ordering of the holonomies, and the corresponding conjugation have been fixed. Outside that subdomain, no non-Abelian Stokes identity is asserted.

82.1.2 Area capacity of the qutrit cell: $81 \log 3$ and collective incidence transport

Theorem 82.3 (Minimum cut of a discrete cube)**.** *In the cubic graph $N \times N \times N$ with unit capacity, every cut separating two opposite faces has capacity at least N^2, and one exists with capacity N^2.*

Proof. There are N^2 edge-disjoint paths crossing the cube in the direction normal to the two faces. Every cut must intersect them, so its capacity is at least N^2. A transverse layer contains exactly N^2 edges and attains the bound. □

For $N = 9$, the cut equals 81 and

$$9^3 = 729 = 27^2.$$

The last equality permits six trits to be regrouped as a volume 9^3 or a grid of cardinality 27^2. It is a bijection of sets; it is not an isomorphism between $(\mathbb{Z}/9\mathbb{Z})^3$ and $(\mathbb{Z}/27\mathbb{Z})^2$, whose exponents are distinct.

82.1.3 Tetrad, spin connection, and torsion of the Cartan–Holst realization

Let e^I be a tetrad and $\omega^{IJ} = -\omega^{JI}$ a Lorentz connection. Define

$$T^I_{\mathrm{tor}} = D_\omega e^I = \mathrm{d}e^I + \omega^I{}_J \wedge e^J,$$

$$F^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}, \qquad g = \eta_{IJ} e^I \otimes e^J.$$

The decomposition

$$\omega^{IJ} = \mathring{\omega}^{IJ}(e) + K^{IJ}$$

separates the Levi–Civita connection and the contorsion. Then

$$T^I_{\mathrm{tor}} = K^I{}_J \wedge e^J.$$

Curvature and torsion are distinct defects: F measures closure of vector transport; T_{tor}, closure of the tetrad. The T memory of the Ambivalence Principle is likewise not geometric torsion: only a realization functor can relate them.

82.1.4 Palatini–Holst Action and Variational Equations

Let M be a smooth oriented four-dimensional manifold. If $\partial M \neq \varnothing$, we assume compactly supported variations in the interior or, equivalently for the variational problem considered, a boundary term and boundary conditions that annul the boundary contribution. When Ψ contains spinorial fields, we also assume a spin structure and fields compatible with it. Let

$$\Sigma^{IJ} = e^I \wedge e^J, \qquad (\star X)^{IJ} = \frac{1}{2}\epsilon^{IJ}{}_{KL} X^{KL}, \qquad \kappa = \frac{8\pi G}{c^4}, \qquad \gamma \in \mathbb{R} \setminus \{0\}.$$

The Palatini–Cartan–Holst action is

$$\boxed{S[e, \omega, \Psi] = \frac{1}{2\kappa c} \int_M \Sigma_{IJ} \wedge \left(\star F^{IJ} + \frac{1}{\gamma} F^{IJ} \right) - \frac{\Lambda}{\kappa c} \int_M \mathrm{vol}_e + S_{\mathrm{m}}[e, \omega, \Psi].}$$

The variation of this action determines the torsional corrections [108, 72, 65, 62].

We define the spin current by

$$\delta_\omega S_{\mathrm{m}} = -\frac{1}{2} \int_M \delta\omega^{IJ} \wedge \sigma_{IJ}.$$

Theorem 82.4 (Cartan–Holst Equation)**.** *Under the preceding geometric and boundary hypotheses, variation with respect to ω gives*

$$D_\omega \left[(\star + \gamma^{-1} I) \Sigma^{IJ} \right] = \kappa c \, \sigma^{IJ},$$

with the global normalization fixed by the preceding definition of σ^{IJ}.

Proof. One uses $\delta F^{IJ} = D_\omega \delta\omega^{IJ}$, integrates by parts, and sets the coefficient of the arbitrary variation $\delta\omega^{IJ}$ equal to zero. With the sign convention fixed in the definition of σ^{IJ}, the matter term moves to the right-hand side with a positive sign. The factor $1/(2\kappa c)$ produces the coefficient κc. The cosmological

term does not depend on ω, and the boundary conditions eliminate the term generated by integration by parts. □

In signature lorentziana $\star^2 = -I$ on bivectores and, for $\gamma \in \mathbb{R} \setminus \{0\}$,

$$(\star + \gamma^{-1} I)^{-1} = \frac{\gamma^2}{1+\gamma^2}(-\star + \gamma^{-1} I).$$

Corollary 82.5 (Torsional decoupling)**.** *For a co-tetrada no degenerada and $\gamma \in \mathbb{R} \setminus \{0\}$,*

$$\sigma^{IJ} = 0 \Longrightarrow T^I_{\mathrm{tor}} = 0 \Longrightarrow \omega = \mathring{\omega}(e).$$

To make the normalization explicit, we define the normalized sources by the action through

$$\delta_g S_{\mathrm{m}} = -\frac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{T}^S_{\mu\nu} \, \delta g^{\mu\nu}.$$

When the tetrad coordinates have the dimension of length, the conventional physical energy–momentum tensor is $T^{\mathrm{phys}}_{\mu\nu} := c\, \mathcal{T}^S_{\mu\nu}$. We likewise denote by $\mathcal{U}^{S,\mathrm{spin}}$ the contribution normalized by the action and by $U^{\mathrm{phys,spin}} := c\, \mathcal{U}^{S,\mathrm{spin}}$ its physical convention. Upon algebraically eliminating the connection, the metric equation then assumes the two equivalent forms

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = \kappa c \left(\mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} + \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu} \right) = \kappa \left(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu} \right),$$

where the spin contribution is quadratic in the corresponding current and depends on the matter coupling. The coefficient of that contribution is not fixed without specifying the fermionic action and the duality conventions.

82.1.5 Bianchi Identity with Torsion and Flow Balance in the Cartan Connection

For every connection,

$$D_\omega T^I_{\mathrm{tor}} = F^I{}_J \wedge e^J, \qquad D_\omega F^{IJ} = 0.$$

After removing torsion,

$$\nabla^\mu (T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu}) = 0.$$

These identities are mandatory consistency checks: every HMT gravitational term must arise from a compatible action or satisfy the corresponding Noether balance.

82.1.6 Map of realization and specialization of the Holst parameter

The insertion defined in section 51.2 takes

$$\gamma = \Gamma_{6\to 8}.$$

Once this substitution has been made, all the preceding variational consequences are theorems of the specialized action. The physical selection of this action by HMT transport is expressed through a realization map

$$\mathfrak{R}_{\mathrm{grav}} : \mathcal{X}_{\mathrm{TPK}} \dashrightarrow \{(e, \omega, \Psi)\}$$

endowed with three properties: intertwining TPK transport with that of ω, identifying the holonomy classes, and furnishing the scales of G and Λ. These properties fix the precise domain of a gravitational realization of the formalism.

For a nondegenerate co-tetrad, nonzero real γ, and matter without spin current, the torsional sector reduces to the first-order formulation of general relativity with the same cosmological constant, subject to the already declared boundary conditions. In a spin fluid, the scaling $s^2 \propto a^{-6}$ can produce an

Einstein–Cartan bounce; obtaining its density and initial conditions from the TPK state is a question distinct from the variational consistency of the action.

82.2 Nonadic Return, Memory Groupoid and Cartan Entanglement Condition

The hierarchy $27 \to 54 \to 108$, the directed cumulative coverage, and the memory groupoid supply the exact condition under which the TPK return admits a compatible Cartan connection. This bridge precedes the Palatini–Cartan–Holst specialization and preserves its domain and refutation criteria intact.

82.3 Nonadic Return, Memory, and Cartan Holonomy

The gravitational realization does not begin by identifying a discrete variable with a geometric magnitude. It begins by distinguishing three levels: return of observable transport, memory distinguishing histories with equal projection, and holonomy of a connection. The bridge formulated here receives the returns and cocycles already demonstrated in HMT; it does not reconstruct them from the Holst action, from a mass, or from a metrological constant.

82.3.1 Exact hierarchy of returns

Let F_{obs} be the observable chronology defined in the HMT kernel, and let

$$\mathcal{K}_{27} := F_{\mathrm{obs}}^{27}.$$

Symbol $\mathcal{K}_{27}$ designates exclusively the composition of twenty-seven updates of the positional and oriented loop; it does not designate a generic window, a trace of 108 steps, or the complete enriched TPK state. Denote by p the projection onto the positions of the two cursors and by J_{or} the simultaneous inversion of their orientations. The primary proof is located in proposition 6.11; its typed consequences are

$$p(\mathcal{K}_{27}x) = p(x), \qquad o(\mathcal{K}_{27}x) = \mathsf{J}_{\mathrm{or}}\, o(x), \qquad \mathsf{J}_{\mathrm{or}}^2 = I,$$

$$F_{\mathrm{obs}}^{54} \text{ : restores positions and orientations,} \qquad F_{\mathrm{obs}}^{108} = I \text{ : also restores the observable phase.}$$

Thus, position return, orientation return, and phase return are distinct assertions. None of them by itself implies the return of all fields of an enriched extension.

The mode quotient and orientation cocycles are established in section 6.3.7 y theorem 6.20. In areal–volumetric order,

$$N_{27} = 9F_{\mathrm{av}}, \qquad F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

If

$$\Omega_{\mathrm{sw}}(\gamma) = \sum_{a \subset \gamma} \omega_{\mathrm{sw}}(a), \qquad S(\gamma) = \sum_{a \subset \gamma} |\omega_{\mathrm{sw}}(a)|, \qquad G_{\mathrm{or}}(\gamma) = \sum_{a \subset \gamma} g(a),$$

then a block of twenty-seven steps contains three nonadic turns and one orientation reversal:

$$\Omega_{\mathrm{sw}}(\mathcal{K}_{27}) = 0, \qquad S(\mathcal{K}_{27}) = 18, \qquad G_{\mathrm{or}}(\mathcal{K}_{27}) = 1.$$

In the observable return of 108 steps,

$$\Omega_{\mathrm{sw}}(C_{108}) = 0, \qquad S(C_{108}) = 72, \qquad G_{\mathrm{or}}(C_{108}) = 4.$$

Thus, for the additive functional declared

$$\mathcal{A}_*(\gamma) := G_{\mathrm{or}}(\gamma) + \lambda_* S(\gamma),$$

are obtained, without introducing a dimensional scale,

$$\mathcal{A}_*(\mathcal{K}_{27}) = 1 + 18\lambda_*, \qquad \mathcal{A}_*(C_{108}) = 4 + 72\lambda_*.$$

These values are record counts. Their subsequent thermal or gravitational use does not alter their provenance.

82.3.1.1 Directed system of coverings, refinement, and limit of the Cartan connection

Let O_{108} be the observable orbit and, for each chronological edge e, let

$$c(e) = \big(g(e), s(e)\big) \in \mathbb{N}^2$$

the pair formed by the indicators of orientation inversion and effective sheet change. For a directed history $\gamma = e_1 \cdots e_n$, define

$$c(\gamma) = \sum_{j=1}^{n} c(e_j).$$

The concatenation law takes the form

$$c_{m+n}(x) = c_m(x) + c_n\big(F_{\mathrm{obs}}^m x\big)\,.$$

The previous counts express, uniformly over the orbit,

$$c_{27}(x) = (1, 18), \qquad c_{108}(x) = (4, 72).$$

Theorem 82.6 (Cumulative coverage of the observable chronology)**.** *On*

$$\widetilde{O}_{108}^{+} := O_{108} \times \mathbb{N}^2$$

define

$$\widetilde{F}^{+}(x, m) := \big(F_{\mathrm{obs}} x, m + c(x \to F_{\mathrm{obs}} x)\big).$$

Then the transport of twenty-seven steps satisfies

$$\widetilde{\mathcal{K}}_{27}^{+}(x, m) = \big(\mathcal{K}_{27} x, m + (1, 18)\big),$$

and

$$\Big(\widetilde{\mathcal{K}}_{27}^{+}\Big)^4 (x, m) = \big(x, m + (4, 72)\big) \neq (x, m).$$

Therefore, its observable projection has order four, whereas the cumulative action of the chronological monoid has infinite semigroup order.

Proof. The cocyclic law and the constancy of c_{27} give

$$c_{108}(x) = \sum_{j=0}^{3} c_{27}(\mathcal{K}_{27}^{j} x) = 4(1, 18) = (4, 72).$$

The first coordinate returns through $\mathcal{K}_{27}^4 = I$; the second does not return. After $q > 0$ iterations, the increment is $q(4, 72)$, which is nonzero. □

Remark 82.7 (Type of the cumulative extension). The preceding construction extends directed histories through positive counters. It is not an automorphic lift of groupoid $\mathcal{G}_{\mathrm{mem}}$, nor does it prove that the unbounded coordinate already belongs to state $\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$. Its Grothendieck completion $\mathbb{Z}^2$ may be used for harmonic analysis, but it does not transform the positive cost $\mathcal{A}_* = G_{\mathrm{or}} + \lambda_* S$ into a character of the isotropy group: upon formally inverting a route, its indicators do not acquire opposite signs.

Domain of validity of the cumulative extension. The hierarchy $27 \to 54 \to 108$, the incidences of F_{av}, and the preceding cocycles are exact identities in the declared chronology and readers. The assertion is restricted to the observable state preserved by those readers; extending it to the full enriched state would require proving the return of every forgotten field.

82.3.2 Memory Groupoid

Let $\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}$ be the enriched path groupoid: its objects are surviving TPK states, and its arrows are admissible routes with declared source and target, composition by concatenation, and inversion by route reversal. Let $\sim_{\mathrm{mem}}$ be an equivalence relation that identifies two arrows only when it preserves the memory fields required by the reader under consideration and is congruent with identities, inversion, and concatenation. We define

$$\mathcal{G}_{\mathrm{mem}} := \mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}/\!\sim_{\mathrm{mem}} .$$

This definition does not transform memory into torsion. Memory belongs to the discrete state and distinguishes histories; torsion belongs to a geometric connection and measures $D_\omega e$. Only a map between the two domains can relate them.

A geometric realization requires, as additional data, a length $\ell_0 > 0$, a representation of the groupoid

$$\rho_{\mathrm{C}} : \mathcal{G}_{\mathrm{mem}} \longrightarrow \mathrm{Spin}(1,3) \ltimes \mathbb{R}^{1,3},$$

and a field map

$$\mathfrak{R}_{\mathrm{grav}} : \mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}} \dashrightarrow \mathsf{Cartan}_{1,3}.$$

To define the second map, one must specify its action on objects and routes, its compatibility with concatenation and inversion, and the regularity of the resulting connection. None of these properties follows from the mere count of returns.

82.3.3 Joint connection and entanglement condition

Under the geometric hypotheses of section 82.4 —variedad oriented of dimension four, co-tetrad e^I, Lorentz connection ω^{IJ} and boundary conditions declared there—, the connection of Cartan joint is written

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1} e \\ 0 & 0 \end{pmatrix}.$$

Its curvature is the algebraic identity.

$$\mathcal{F}_{\ell_0} = \mathrm{d}\mathcal{A}_{\ell_0} + \mathcal{A}_{\ell_0} \wedge \mathcal{A}_{\ell_0} = \begin{pmatrix} F_\omega & \ell_0^{-1} T_{\mathrm{tor}} \\ 0 & 0 \end{pmatrix},$$

where

$$F_\omega^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}, \qquad T^I_{\mathrm{tor}} = D_\omega e^I.$$

Curvature and torsion appear as distinct components of the same transport defect. The matrix equality follows algebraically from the explicit data e, ω, ℓ_0, but does not construct these inputs from TPK.

The strong content of the bridge is the commutativity of holonomies:

$$\boxed{\mathrm{Hol}_{\mathcal{A}_{\ell_0}}\big(\mathfrak{R}_{\mathrm{grav}}(\gamma)\big) = \rho_{\mathrm{C}}(\mathrm{Hol}_{\mathrm{TPK}}(\gamma))} \qquad (\gamma \in \mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}).$$

The equality must be compatible with identities, inversion, concatenation, subdivision, change of base point, and conjugation. Only then is discrete memory represented in a connection; it is not merely renamed as torsion or curvature.

Comparison Criterion 82.8 (Existence conditions for the bridge TPK–Cartan)**.** There is not realization with the declared commutativity and compatibility if any of the following facts occurs:

1. two equivalent representatives of the same route produce nonconjugate geometric holonomies;
2. the image does not preserve identities, inverses, or concatenation;
3. an admissible subdivision alters the holonomy;
4. the equality of holonomies fails for $\mathcal{K}_{27}$ or for their concatenations of depths 54 and 108;
5. the map identifies memory and torsion without exhibiting a morphism that preserves their types;
6. some descending choice —the Holst action, G, a mass or an SI chart— is used to redefine A, C^* or the original TPK return.

Antecedence of the functional $\Gamma_{6\to 8}$ with respect to the Palatini–Cartan–Holst realization. section 51.2 fixes, once $A, C^*, q_\pm$ have been constructed, the internal functional $\Gamma_{6\to 8}$. section 82.4 then studies the Palatini–Cartan–Holst action and its variational equations. The present bridge does not introduce a reverse route between the two stages.

82.4 Gravity: Holonomy, Torsion, and Collective Response

Gravity is not introduced here through a decimal formula for G. Its construction assembles two already typed branches. In the first, a route preserves orientation and memory; a connection compares frames at distinct points; its holonomy measures return and its curvature the closure defect. In the second, the dimensional chart constructs $G_{\mathrm{int}}(\theta_G)$ and κ_{int} from the internal action scale, velocity, and elementary duration. Only after both branches are available is the Palatini–Cartan–Holst action written. No external metrological figure participates in that precedence.

82.4.1 Returns: position, orientation, phase, and memory

Let F_{obs} be the observable chronology of the transport and

$$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}.$$

The exact hierarchy distinguishes three returns:

27 steps	position return and orientation reversal,
54 steps	position and orientation return,
108 steps	complete return of the observable phase.

The observable return does not erase the accumulated record. If $g(e)$ counts an orientation reversal and $s(e)$ an effective sheet change, then

$$c(\gamma) = \sum_{e\subset\gamma} (g(e), s(e))$$

satisfies the cocyclic law of concatenation. In the canonical blocks,

$$c_{27} = (1, 18), \qquad c_{108} = (4, 72).$$

Therefore, the observable projection of $\mathcal{K}_{27}$ has order four, whereas the cumulative coordinate continues to grow. Returning to the same phase does not mean returning to the same history.

Theorem 82.9 (Cumulative coverage of return)**.** *Over $O_{108} \times \mathbb{N}^2$, the lift*

$$\widetilde{F}(x, m) = \big(F_{\mathrm{obs}}x, m + c(x \to F_{\mathrm{obs}}x)\big)$$

satisfies

$$\widetilde{\mathcal{K}}_{27}(x,m) = \big(\mathcal{K}_{27}x, m + (1,18)\big)$$

and

$$\widetilde{\mathcal{K}}_{27}^{4}(x,m) = \big(x, m + (4,72)\big) \neq (x,m).$$

Proof. The constancy of c_{27} along the orbit and the concatenation law give

$$c_{108} = \sum_{j=0}^{3} c_{27}(\mathcal{K}_{27}^{j}x) = 4(1,18).$$

The first coordinate returns; the second preserves the accumulated memory. □

This is the datum that to geometric realization must preserve. One does not identify the discrete memory with torsion: one constructs to representation that allows them to is compared.

82.4.2 From the path groupoid to the Cartan group

Let $\mathcal{G}_{\mathrm{mem}}$ be the groupoid of enriched routes, with composition by concatenation and inverse by reversal. Fix an element $R_4 \in \mathrm{Spin}^{+}(1,3)$ of order four and a unit temporal vector $u \in \mathbb{R}^{1,3}$ fixed by R_4. If

$$c(\gamma) = \big(c_g(\gamma), c_s(\gamma)\big) \in \mathbb{Z}^2$$

is the additive cocycle of inversion and sheet change, we define

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma) = \Big(R_4^{\,c_g(\gamma)}, \ell_0 c_s(\gamma) u\Big) \in \mathrm{Spin}^{+}(1,3) \ltimes \mathbb{R}^{1,3}.$$

Theorem 82.10 (Discrete realization of the return cocycle)**.** *$\rho_{\mathrm{C}}^{\mathrm{disc}}$ is a functor from the route groupoid to the Cartan group. In particular, it preserves identity, concatenation, and inversion, and transports the return* $27 \to 54 \to 108$ *without erasing the cumulative coordinate.*

Proof. The semidirect product law is

$$(R,a)(S,b) = (RS, a + Rb).$$

Since $R_4 u = u$ and c is additive,

$$\begin{aligned}\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2)\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_1) &= \Big(R_4^{\,c_g(\gamma_2)+c_g(\gamma_1)}, \ell_0\big(c_s(\gamma_2) + c_s(\gamma_1)\big)u\Big) \\ &= \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2\gamma_1).\end{aligned}$$

The identity route has zero cocycle, and reversal changes its sign, so identity and inverse are preserved. The return formulas follow from $c_{27} = (1,18)$ and $c_{108} = 4c_{27}$. □

This theorem constructs the discrete bridge. A subsequent smooth realization consists of a representation

$$\rho_{\mathrm{C}} : \mathcal{G}_{\mathrm{mem}} \longrightarrow \mathrm{Spin}(1,3) \ltimes \mathbb{R}^{1,3}$$

and in fields e^{I}, ω^{IJ} whose holonomy intertwines that representation. The diagram fixing the type is

$$\mathrm{Hol}_{\mathcal{A}_{\ell_0}}\big(\mathfrak{R}_{\mathrm{C}}(\gamma)\big) = \rho_{\mathrm{C}}\big(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)\big).$$

Identities, inversion, concatenation, and subdivision must be preserved. This equation does not rename the carry as curvature: it requires the already represented discrete transport and the geometric transport to realize the same composition.

Once to positive scale is fixed ℓ_0, the joint connection is

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1} e \\ 0 & 0 \end{pmatrix}.$$

Proposition 82.11 (Cartan Joint Curvature)**.** *The curvature of $\mathcal{A}_{\ell_0}$ is*

$$\mathcal{F}_{\ell_0} = \mathrm{d}\mathcal{A}_{\ell_0} + \mathcal{A}_{\ell_0} \wedge \mathcal{A}_{\ell_0} = \begin{pmatrix} F_\omega & \ell_0^{-1} T_{\mathrm{tor}} \\ 0 & 0 \end{pmatrix},$$

where

$$F_\omega^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}, \qquad T_{\mathrm{tor}}^I = D_\omega e^I.$$

Proof. The matrices of forms are multiplied using the exterior product. The diagonal block produces F_ω; the translation block produces $\mathrm{d}e + \omega \wedge e = D_\omega e$. □

Curvature and torsion are two components of the same transport defect, but they perform distinct functions. Curvature measures frame return; torsion measures closure of the co-tetrad.

82.4.3 Gauss–Stokes and areal capacity

In a finite cellular complex, for every 1-cochain Ω and every 2-chain z,

$$\boxed{\langle \delta\Omega, z \rangle = \langle \Omega, \partial z \rangle.}$$

The identity is the definition of the coboundary as the adjoint of the boundary. When z sums the coherently oriented faces of a pseudomanifold, the interior edges cancel, and only the geometric boundary remains. The same equality has already been read as vorticity–circulation and as curvature–holonomy.

The areal scale also has an exact model. In the cubic graph $N \times N \times N$, every cut between two opposite faces contains at least N^2 edges, and to transverse layer attains the bound. For $N = 9$,

$$9^3 = 729 = 27^2.$$

This cardinal equality relates volume and minimal cut; it does not identify the groups $(\mathbb{Z}/9)^3$ and $(\mathbb{Z}/27)^2$, which have distinct exponents.

82.4.4 The Palatini–Cartan–Holst Action

Let M be a smooth oriented manifold of dimension four, with nondegenerate co-tetrad e^I, Lorentz connection $\omega^{IJ} = -\omega^{JI}$, and boundary conditions that make the boundary variational term vanish. Let us write

$$\Sigma^{IJ} = e^I \wedge e^J, \qquad (\star X)^{IJ} = \frac{1}{2}\epsilon^{IJ}{}_{KL} X^{KL}, \qquad G_{\mathrm{int}} = G_{\mathrm{int}}(\theta_G), \qquad \kappa_{\mathrm{int}} = \frac{8\pi G_{\mathrm{int}}}{c_{\mathrm{int}}^4}.$$

These last two quantities are not defined through the action: they follow from the constitutive construction of equation (59.11). The theorem 59.10 first proves that the following combination belongs to the action line. The first-order action is

$$\boxed{S[e, \omega, \Psi] = \frac{1}{2\kappa_{\mathrm{int}} c_{\mathrm{int}}} \int_M \Sigma_{IJ} \wedge \left(\star F^{IJ} + \frac{1}{\gamma} F^{IJ} \right) - \frac{\Lambda_{\mathrm{int}}}{\kappa_{\mathrm{int}} c_{\mathrm{int}}} \int_M \mathrm{vol}_e + S_{\mathrm{m}}[e, \omega, \Psi].}$$

The internal parameter constructed in the previous chapter specializes

$$\gamma = \Gamma_{6\to 8}.$$

The substitution is performed after obtaining $\Gamma_{6\to 8}$ from $A, C^*, q_\pm$ and the hexad–octad inclusion; the action is not used to redefine those inputs.

Theorem 82.12 (Cartan–Holst Equation)**.** *If the spin current is normalized through*

$$\delta_\omega S_{\mathrm{m}} = -\frac{1}{2}\int_M \delta\omega^{IJ} \wedge \sigma_{IJ},$$

the variation with respect to ω produces

$$\boxed{D_\omega\left[(\star + \gamma^{-1} I)\Sigma^{IJ}\right] = \kappa_{\mathrm{int}} c_{\mathrm{int}}\, \sigma^{IJ}.}$$

Proof. One uses $\delta F^{IJ} = D_\omega \delta\omega^{IJ}$, integrates by parts, and sets the coefficient of the arbitrary variation equal to zero. The cosmological term does not depend on ω. □

In Lorentzian signature, $\star^2 = -I$ on bivectors. For $\gamma \in \mathbb{R}\setminus\{0\}$,

$$(\star + \gamma^{-1} I)^{-1} = \frac{\gamma^2}{1+\gamma^2}(-\star + \gamma^{-1} I).$$

Therefore, if the spin current vanishes,

$$T^I_{\mathrm{tor}} = 0, \qquad \omega = \mathring{\omega}(e).$$

With spinorial matter, torsion is determined algebraically by the current. In the minimal action, it does not constitute an independent propagating degree of freedom.

82.4.5 Metric equation, spin, and geometric balance

To fix the normalization unambiguously, we defines the sources measured on the action line by

$$\delta_g S_{\mathrm{m}} = -\frac{1}{2}\int_M \mathrm{vol}_e\ \mathcal{T}^S_{\mu\nu}\,\delta g^{\mu\nu}.$$

When the tetrad coordinates have the dimension of length, we write

$$T^{\mathrm{phys}}_{\mu\nu} := c_{\mathrm{int}}\mathcal{T}^S_{\mu\nu}, \qquad U^{\mathrm{phys,spin}}_{\mu\nu} := c_{\mathrm{int}}\mathcal{U}^{S,\mathrm{spin}}_{\mu\nu}.$$

After algebraically eliminating the connection, the metric equation adopts the two equivalent forms

$$\boxed{G_{\mu\nu} + \Lambda_{\mathrm{int}} g_{\mu\nu} = \kappa_{\mathrm{int}} c_{\mathrm{int}}\big(\mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} + \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu}\big) = \kappa_{\mathrm{int}}\big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu}\big).}$$

The spin contribution is quadratic in the corresponding current and depends on the matter coupling; its coefficient is not fixed without declaring the fermionic action and the duality conventions.

The geometric identities

$$D_\omega T^I_{\mathrm{tor}} = F^I{}_J \wedge e^J, \qquad D_\omega F^{IJ} = 0$$

imply, after removing the torsion,

$$\nabla^\mu\big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu}\big) = 0.$$

This Bianchi–Noether balance is to consistency condition for the gravitational transducer: not additional term can is incorporated without proceeding from to compatible action or satisfying the same balance.

82.4.6 Area–volumetric correspondence π/φ^2

The calendar (Σ, Π, Π) produces the incidence matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

Its Parry measure gives $\mu_{\mathrm{ar}}/\mu_{\mathrm{vol}} = \varphi^{-2}$, and the regional reader marks the closure exactly once π_{HMT}. The marked return satisfies

$$\Theta_n = \pi_{\mathrm{HMT}} \frac{F_{n-1}}{F_{n+1}} \longrightarrow \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.$$

This ratio is not another version of G. It is the dimensionless correspondence between the areal and volumetric readings. Under the same positive amplitude $\mathcal{M}$,

$$\mathcal{I}_{\mathrm{av}} = \mu_{\mathrm{vol}} \mathcal{M}, \qquad \mathcal{G}_{\mathrm{av}} = \pi_{\mathrm{HMT}} \mu_{\mathrm{ar}} \mathcal{M}$$

give exactly

$$\frac{\mathcal{G}_{\mathrm{av}}}{\mathcal{I}_{\mathrm{av}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.$$

On the flat sheet, the diagonal restriction is $\mathcal{G}_{\mathrm{tor}} = \mathcal{I}_{\mathrm{tor}}$. Local equivalence and boundary ambivalence are therefore two regimes of the reader, not two incompatible values of a mass.

82.4.7 Typing of G as gravitational transducer and causal order of its readers

The type and homogeneity of G belong to the prior constitutive construction. The equation (59.11) fixes the covariant family $G_{\mathrm{int}}(\theta_G)$ once and for all, and the theorem 59.10 proves that its insertion into the action has the dimension of action. This chapter does not redefine that family: it uses its section together with the holonomy already constructed. Causality is not linear, but convergent:

$$\begin{aligned} \mathcal{B}_{\mathrm{geom}} &: \text{return and cocycle} \longrightarrow \text{Cartan representation} \longrightarrow (e, \omega), \\ \mathcal{B}_{\mathrm{dim}} &: (\hbar_{\mathrm{int}}, c_{\mathrm{int}}, t_0, \theta_G) \longrightarrow G_{\mathrm{int}} \longrightarrow \kappa_{\mathrm{int}}, \end{aligned}$$

$$(\mathcal{B}_{\mathrm{geom}}, \mathcal{B}_{\mathrm{dim}}) \longrightarrow S_{\mathrm{PCH}} \longrightarrow \text{algebraic torsion, metric equation and balance.}$$

The metrological comparison belongs to the end and does not select any of the two branches.

82.4.8 Collective origin of the gravitational mode in the holonomy of paths

The basic objects of the preceding action are the co-tetrad and the connection. Cartan torsion is algebraic; curvature has the propagating sector that contains gravitational waves. Accordingly, the formalism does not need to postulate an elementary graviton in order to define the interaction. A possible quantization of the perturbations may produce a collective mode of helicities ±2; that mode would be an excitation of geometric transport, not a datum added at the level of APP, TRIT, or TPK.

This distinction also excludes a frequent confusion. The existence of classical waves proves propagation of curvature; by itself it does not prove a fundamental quantum. Conversely, describing the field geometrically does not eliminate its radiative degrees of freedom. HMT–MD locates the question properly: memory and its holonomy are constructed first; the spectrum of their excitations is then studied.

Typed comparison of the area quantum with energy, entropy, and horizon information. The first-order action permits comparison of the areal quantum with horizon energy, entropy, and information without conflating those observables.

82.5 Realization in the Holst action

The substitution

$$\gamma = \Gamma_{6\to 8}$$

realizes the Barbero–Immirzi parameter in the HMT specialization of the Holst action studied in chapter 77. The following section constructs on the triadic boundary the area operator, its spectrum, and the collective intertwiner that transports the normalization of the channels (90/120) to the Ashtekar–Barbero connection [11, 69, 62]. The result fixes the discrete HMT realization; its comparison with a complete continuous geometric representation of Ashtekar–Barbero is performed after declaring the embedding and normalization of that representation.

82.6 Realization of the current in connection coordinates

Memory energy assigns each route a response preserving its incidences and the order of transports. Inserting it into a geometric action requires its components with respect to connection variations. This step is obtained by differentiating the transport that already realizes the route: the connection current is the composition of that differential with the energy covector of the preceding section.

The elliptic, parabolic and hyperbolic regimes of TRIT require preserving the complete differential before restricting it to a particular representation. Unitary rotations constitute a domain of that construction. The following extension also preserves the dilation and transport directions admitted by the geometric realization used.

82.6.1 Differential on invertible transports

The fibers, fields and weight of (80.37) are retained. We now consider invertible transports and differentiable families with $\dot U_a = A_a U_a$, where A_a belongs to the tangent space of the chosen representation. We write

$$v_a = U_a f_{s(a)}, \qquad r_a = f_{t(a)} - v_a, \qquad q = \mathsf{W}_m r, \qquad E_m = \langle r, \mathsf{W}_m r\rangle.$$

Proposition 82.13 (Complete representative of the differential)**.** *At fixed field and weight, the following holds*

$$\mathrm{d}_U E_m(A) = -2\,\mathrm{Re}\sum_a \langle q_a, A_a v_a\rangle = \sum_a \mathrm{Re}\,\mathrm{Tr}(\mathcal{G}_a^* A_a), \qquad \mathcal{G}_a = -2 q_a v_a^*. \tag{82.1}$$

The anti-Hermitian and Hermitian projections of this representative are

$$\frac{\mathcal{G}_a - \mathcal{G}_a^*}{2} = v_a q_a^* - q_a v_a^* = \mathcal{J}_a, \qquad \frac{\mathcal{G}_a + \mathcal{G}_a^*}{2} = -(q_a v_a^* + v_a q_a^*). \tag{82.2}$$

Restriction to anti-Hermitian generators recovers exactly (80.39).

Proof. The identity $\dot r_a = -A_a v_a$ and self-adjointness of the weight give $\dot E_m = 2\,\mathrm{Re}\langle q, \dot r\rangle$. Moreover,

$$\mathrm{Tr}(\mathcal{G}_a^* A_a) = -2\,\mathrm{Tr}(v_a q_a^* A_a) = -2 q_a^* A_a v_a.$$

The two projections are obtained by taking the adjoint. For the real Hilbert–Schmidt inner product, the Hermitian and anti-Hermitian subspaces are orthogonal; therefore the Hermitian part has zero contraction with an anti-Hermitian generator. □

The formula allows weights coupling edges: their action is calculated in $q = \mathsf{W}_m r$ before separating the contributions of each incidence. If field or weight vary, the complete expression (80.40) is retained, also valid for the invertible transports considered here.

82.6.2 Quadratic representations of TRIT

In a two-dimensional matrix realization of $\mathbb{A}_\tau$, one may take

$$J_+ = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad J_- = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad J_0 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Direct multiplication gives

$$J_+^2 = -I, \qquad J_-^2 = I, \qquad J_0^2 = 0.$$

Their exponentials realize, respectively, the elliptic, hyperbolic and parabolic regimes. The first is orthogonal for the fixed positive inner product. The second preserves the form $B = \mathrm{diag}(-1, 1)$, since $J_-^{\mathsf{T}} B + B J_- = 0$. The third represents the algebra of dual numbers. These representations fix examples of the quadratic types; their use on a screen of another dimension preserves the corresponding representation map.

A calculation distinguishes the components of the differential. On an edge, take $U = I$, $f_s = (1, 1)^{\mathsf{T}}$, $f_t = 2 f_s$ and $\mathsf{W} = I$. Then $q = v = f_s$, $\mathcal{J} = 0$, whereas

$$\mathrm{d}E(J_-) = -4, \qquad \mathrm{d}E(J_0) = -2. \tag{82.3}$$

The complete representative preserves both responses. The distinction identifies the space of variations before performing the material contraction.

82.6.3 Composition of routes and oriented inversion

Proposition 82.14 (Contragredient transport of the differential)**.** *For $U_\gamma = U_N \cdots U_1$, let $B_k = U_N \cdots U_{k+1}$ and $B_N = I$. We have*

$$\dot U_\gamma U_\gamma^{-1} = \sum_k B_k A_k B_k^{-1}.$$

The representative $\mathcal{G}_\gamma$ in the final fiber induces at incidence k

$$\mathcal{G}_k = B_k^* \mathcal{G}_\gamma (B_k^{-1})^*. \tag{82.4}$$

Proof. The product rule, followed by multiplication by U_γ^{-1}, proves the first equality. Cyclicity of the trace gives

$$\mathrm{Re}\,\mathrm{Tr}(\mathcal{G}_\gamma^* B_k A_k B_k^{-1}) = \mathrm{Re}\,\mathrm{Tr}((B_k^* \mathcal{G}_\gamma (B_k^{-1})^*)^* A_k).$$

For unitary B_k, the conjugation of 80.33 is recovered. □

Proposition 82.15 (Inversion by energy congruence)**.** *For a local energy per edge, inversion is represented by*

$$U_{\bar{a}} = U_a^{-1}, \qquad r_{\bar{a}} = -U_a^{-1} r_a, \qquad W_{\bar{a}} = U_a^{*} W_a U_a. \tag{82.5}$$

It preserves energy. If W_a remains fixed,

$$A_{\bar{a}} = -U_a^{-1} A_a U_a, \qquad \dot{W}_{\bar{a}} = U_a^{*}(A_a^{*} W_a + W_a A_a) U_a.$$

The complete variation of the inverted energy coincides with the original.

Proof. Substitution into $r_{\bar{a}}^{*} W_{\bar{a}} r_{\bar{a}}$ produces $r_a^{*} W_a r_a$. The derivative of the inverse is $\dot{U}_a^{-1} = -U_a^{-1} A_a$; that of the weight is obtained by the product rule. Equality of energies holds for the entire family, so their derivatives coincide, including the term $\langle r_{\bar{a}}, \dot{W}_{\bar{a}} r_{\bar{a}} \rangle$. □

Congruence preserves positivity for every invertible transport. In the unitary representation it reduces to the inversion rule of 80.35. The sum uses one orientation per edge, or half the sum over both orientations.

82.6.4 Evaluation of current components

Let $\theta = (\theta_b)$ be a real variation of the connection coordinates of the realization used. The effective differential of transport defines the operators

$$A_a(\theta) = \dot{U}_a U_a^{-1} = \sum_b B_{ab} \theta_b. \tag{82.6}$$

For a finite composition, their contributions are obtained through (82.4). The operators B_{ab} are the derivatives of the connection representation that realizes the route.

Theorem 82.16 (Connection current of the memory action)**.** *For a material term $S_{\mathrm{mem}} = \mathfrak{a}_m E_m$, with $\mathfrak{a}_m$ its normalization on the action line, at fixed field, weight and normalization we have*

$$\delta S_{\mathrm{mem}} = -\frac{1}{2} \sum_b \theta_b s_b, \qquad s_b = 4\mathfrak{a}_m \operatorname{Re} \sum_a \langle q_a, B_{ab} v_a \rangle. \tag{82.7}$$

If the cellular pairing between the connection and current bases is an invertible matrix M, defined by $\delta S_{\mathrm{mem}} = -\frac{1}{2} \theta^{\mathsf{T}} M \sigma$, the current coordinates are

$$\sigma = M^{-1} s. \tag{82.8}$$

Proof. Substitute (82.6) into (82.1), multiply by $\mathfrak{a}_m$, and collect the coefficients of θ_b. The variational convention $-1/2$ fixes the factor 4. Comparing both expressions for every variation θ gives $M\sigma = s$; invertibility of the pairing proves existence and uniqueness of these coordinates. □

The formula explicitly realizes the composition mentioned in 80.7.5. To evaluate each component, the field is transported, the residual is calculated, the weight is applied and the result is contracted with the connection variation of the same realization. The pairing M preserves the orientation and volume of cells. A diagonal pairing gives the corresponding division by their volumes; other bases preserve the complete matrix.

If the connection also enters f, W_m or $\mathfrak{a}_m$, we apply (80.40) and add $E_m \delta \mathfrak{a}_m$. Contributions from all material terms are summed before composing the Cartan response.

Corollary 82.17 (Compatibility of the current with refinement)**.** *For the compatible families of 80.36, let P_m be the fixed map taking connection variations from level m to level $m+1$. If the memory actions coincide on those refined fields and transports, their covectors satisfy*

$$s_m = P_m^{\mathsf{T}} s_{m+1}, \qquad M_m \sigma_m = P_m^{\mathsf{T}} M_{m+1} \sigma_{m+1}.$$

Proof. Differentiating the equality of actions in the direction $P_m\theta$ gives $-\frac{1}{2}\theta^{\mathsf{T}} s_m = -\frac{1}{2}\theta^{\mathsf{T}} P_m^{\mathsf{T}} s_{m+1}$. The arbitrariness of θ and the cellular representations of both covectors prove the two identities. Composition of these maps iterates the equality to any finite number of refinements. □

82.6.5 Insertion into the Cartan equation

Section 82.8 normalizes the material three-form through $\delta_\omega S_m = -\frac{1}{2}\int \delta\omega^{IJ} \wedge \sigma_{IJ}$. The preceding theorem provides its cellular components for the declared memory action and pairing. The Cartan response uses that current together with the co-tetrad, the Barbero–Immirzi parameter and the gravitational coupling of the same realization.

The material dependence on contorsion determines how that equation is solved. For affine matter, the current is independent of contorsion, and the linear inversion and quadratic elimination proved in Section 82.8 apply. For a holonomy action, the differential is evaluated at the current connection, and this dependence is retained when solving the equation. For example, an edge with $f_s = f_t = 1$, unit weight, and $U(t) = e^{it}$ has

$$E(t) = 2 - 2\cos t, \qquad E'(t) = 2\sin t.$$

Here the current depends on t. The complete formula retains that dependence instead of replacing it by its value at a particular connection.

Finally, the gravitational density is obtained from the metric variation of the effective action, with its field and normalization. The representation of the current, the contortion it produces and the resulting density are the successive operations of that composition. The subsequent dilution law transports the amplitude thus evaluated in the corresponding material section.

82.7 Differential of the minimal boundary extension

The cubic incidence simultaneously determines the minimal-extension field and the weight of its response. For a boundary datum, both are calculated through the inverse of the incidence Gramian. We now develop the differential of this same operation, preserving the variations of the boundary, transport and normalization scale. In this way, the field involved in the response is selected by the screen variational problem.

82.7.1 Minimizing field and response weight

Let H and Q be finite-dimensional Hermitian spaces, with fixed inner products antilinear in the first variable. The real case is obtained by replacing adjoints with transposes. On an open set of real parameters Ω, consider families of class C^1

$$\mathsf{C}(\theta) : H \longrightarrow Q, \qquad b(\theta) \in Q, \qquad \chi(\theta) > 0, \qquad \operatorname{Ran}\mathsf{C}(\theta) = Q.$$

Surjectivity is equivalent to full row rank in orthonormal bases. We define the Gramian, the conjugate potential and the extension

$$\mathsf{L} = \mathsf{C}\mathsf{C}^*, \qquad y = \mathsf{L}^{-1}b, \qquad f_{\min} = \mathsf{C}^* y, \qquad \Lambda = \chi\mathsf{L}^{-1}. \tag{82.9}$$

The incidence C and the cellular pairing M of (82.8) are different operators.

Proposition 82.18 (Variational selection of the extension)**.** *The extension $f_{\min}$ is the unique norm minimizer among the fields $f \in H$ satisfying $\mathsf{C}f = b$. Its energy is*

$$E(\theta) = \chi \min_{\mathsf{C}f=b} \|f\|^2 = \chi\langle b, \mathsf{L}^{-1}b\rangle = \langle b, \Lambda b\rangle. \tag{82.10}$$

The field $f_{\min}$, potential y, and energy E depend C^1-smoothly on the parameters.

Proof. Surjectivity of C makes C^* injective, so $\langle z, \mathsf{L}z\rangle = \|\mathsf{C}^*z\|^2 > 0$ for $z \neq 0$. Thus L is invertible and $\mathsf{C}f_{\min} = \mathsf{L}y = b$. Every solution is $f_{\min} + z$, with $z \in \ker \mathsf{C}$. Since $f_{\min} \in \operatorname{Ran}\mathsf{C}^* = (\ker \mathsf{C})^{\perp}$,

$$\|f_{\min} + z\|^2 = \|f_{\min}\|^2 + \|z\|^2, \qquad \|f_{\min}\|^2 = \langle y, \mathsf{L}y\rangle = \langle b, \mathsf{L}^{-1}b\rangle.$$

These identities prove the minimum, its uniqueness and its value. Inversion is a differentiable operation on the open set of invertible matrices; the expressions in (82.9) provide the asserted regularity. □

The cubic realization of 80.24 corresponds to $H = \mathbb{R}^{\{-1,1\}^3}$, the screen quotient $Q = P_{\square}\mathbb{R}^6$ and the incidence $\mathsf{C} = M : H \to Q$. Its Gramian and normalization are

$$\mathsf{L}_{\square} = 12P_u + 4P_-, \qquad \chi_m = \frac{112}{81\ell_m^2}, \qquad \Lambda_m = \frac{28}{243\ell_m^2}(P_u + 3P_-). \tag{82.11}$$

The factor $112/81$ comes from the soldering and the quadratic compression defect of (80.30). If b has length dimension, so do y and $f_{\min}$, the incidence is dimensionless and E is dimensionless. Conversion to action uses the normalization in the action line specified below.

82.7.2 Full differential of the minimum

Theorem 82.19 (Response to the variation of incidence and boundary)**.** *For every real tangent direction $\delta\theta$, one has*

$$\delta E = \delta\chi\,\langle b, y\rangle + 2\chi\,\mathrm{Re}\langle y, \delta b - (\delta\mathsf{C})f_{\min}\rangle. \tag{82.12}$$

If $\chi = 112/(81\ell_m^2)$, with variable $\ell_m > 0$,

$$\delta E = -2E\frac{\delta\ell_m}{\ell_m} + 2\chi_m\,\mathrm{Re}\langle y, \delta b - (\delta\mathsf{C})f_{\min}\rangle. \tag{82.13}$$

Proof. Differentiating $\mathsf{L}\mathsf{L}^{-1} = I_Q$ gives

$$\delta\mathsf{L}^{-1} = -\mathsf{L}^{-1}(\delta\mathsf{L})\mathsf{L}^{-1}, \qquad \delta\mathsf{L} = (\delta\mathsf{C})\mathsf{C}^* + \mathsf{C}(\delta\mathsf{C})^*.$$

Applying the product rule to (82.10) and using the self-adjointness of L^{-1} yields

$$\delta E = \delta\chi\,\langle b, y\rangle + 2\chi\,\mathrm{Re}\langle y, \delta b\rangle - \chi\langle y, (\delta\mathsf{L})y\rangle.$$

The two terms of the last product are conjugate to each other and $\mathsf{C}^*y = f_{\min}$; therefore,

$$\langle y, (\delta\mathsf{L})y\rangle = 2\,\mathrm{Re}\langle y, (\delta\mathsf{C})f_{\min}\rangle.$$

One obtains (82.12). Finally, $\delta\chi_m = -2\chi_m\delta\ell_m/\ell_m$ produces (82.13). □

The formula incorporates the variation of the minimizing field through the equation that determines it. It is also checked directly: $\mathsf{C}\delta f_{\min} = \delta b - (\delta\mathsf{C})f_{\min}$ and $f_{\min} = \mathsf{C}^*y$ imply

$$\delta\|f_{\min}\|^2 = 2\,\mathrm{Re}\langle f_{\min}, \delta f_{\min}\rangle = 2\,\mathrm{Re}\langle y, \delta b - (\delta\mathsf{C})f_{\min}\rangle.$$

For example, if C is fixed and $b = \ell_m b_0$, with b_0 fixed, the two terms of (82.13) cancel and the energy remains constant. This check jointly preserves the boundary dimension and its normalization.

82.7.3 Fixed quotient and frame changes

The preceding derivatives are taken in fixed spaces H, Q and Hermitian inner products. In the six-face presentation, the inverse always acts on $Q = P_{\square} H_F$. For a family of quotients $Q(\theta)$, an isometric trivialization $V_Q(\theta) : Q \to Q(\theta)$ is fixed first, and likewise for the domain. The derivatives of those maps are included when differentiating the expressions transported to the fixed spaces. The formulas apply on each open set where rank is preserved. Changes in the energy inner product additionally require differentiating that product; a Lorentzian metric and the positive inner product used for minimization retain their distinct types here.

Proposition 82.20 (Covariance of the minimum)**.** *Let g_H, g_Q be unitary. Under*

$$\mathsf{C}' = g_Q \mathsf{C} g_H^*, \qquad b' = g_Q b, \qquad \chi' = \chi,$$

$y' = g_Q y$, $f'_{\min} = g_H f_{\min}$ and $E' = E$ hold. When the frame changes depend on the parameter, the full differential preserves this equality. In particular, a pure frame variation has $\delta E = 0$.

Proof. The transformed Gramian is $\mathsf{L}' = g_Q \mathsf{L} g_Q^*$, from which the transformations of y, $f_{\min}$ and equality of energies are obtained. For a pure frame variation, at a point with identity frames, let $A_Q^* = -A_Q$ and $A_H^* = -A_H$ be their generators. Then

$$\delta\mathsf{C} = A_Q \mathsf{C} - \mathsf{C} A_H, \qquad \delta b = A_Q b, \qquad \delta b - (\delta\mathsf{C}) f_{\min} = \mathsf{C} A_H f_{\min}.$$

Its contribution to (82.12) is $2\chi \operatorname{Re}\langle f_{\min}, A_H f_{\min}\rangle = 0$. The proof thus includes the terms due to the moving frames. □

82.7.4 Transported incidence and connection components

The connection dependence is specified before performing the contraction. An explicit blockwise realization of the incidence is obtained as follows. Let $\mathcal{K}$ be a common Hermitian fibre, $F = \{(i, \epsilon) : 1 \le i \le 3,\ \epsilon = \pm 1\}$ and $V = \{-1, 1\}^3$. For each incidence $\nu_i = \epsilon$, the realization used declares a route $\gamma_{i,\epsilon,\nu}$ from the vertex fibre to the face fibre, with transport $U_{i,\epsilon,\nu}$. The trivializations identify these fibres with $\mathcal{K}$. We define

$$\begin{aligned} (\mathsf{B}_U f)_{i,\epsilon} &= \sum_{\nu_i = \epsilon} U_{i,\epsilon,\nu} f_\nu, \\ \mathsf{C}_U = (q_{\square} \otimes I_{\mathcal{K}}) \mathsf{B}_U &: \bigoplus_{\nu \in V} \mathcal{K} \longrightarrow Q \otimes \mathcal{K}, \qquad q_{\square} = P_{\square} : H_F \to Q. \end{aligned} \tag{82.14}$$

This is an explicit variational continuation of the cubic incidence in the declared route representation. For identity transports, $\mathsf{C}_U = M \otimes I_{\mathcal{K}}$ and one recovers (82.11), tensored with the fibre. The Gramian remains positive in a neighbourhood of that realization, since positive definiteness is an open condition. On each full-rank domain, the weight and field are fixed by (82.9). The routes realizing the incidences, their orientations and their memories are data of this realization of APP–TRIT–TPK transport and accompany the construction.

If $\omega = (\omega_j)$ are real connection coordinates, the derivative of C_U is calculated by substituting in each block

$$\partial_j U_\gamma = \sum_{k=1}^{N} U_N \cdots U_{k+1} (\partial_j U_k) U_{k-1} \cdots U_1, \qquad U_\gamma = U_N \cdots U_1. \tag{82.15}$$

Empty products are identities. The formula follows from the product rule and preserves the position of each operation in the route. Thus, $\mathsf{C}_j := \partial_j \mathsf{C}_U$ is obtained from a finite sum of known matrices in the chosen realization, followed by the projection $q_{\square} \otimes I$. If a moving quotient is used, its derivative is

incorporated according to 82.7.3. The fixed integer cubic matrix corresponds to the case $\mathsf{C}_j = 0$; the response to the connection follows from the transport dependence actually declared in (82.14).

Theorem 82.21 (Variational components of the minimal extension)**.** *For the screen action $S_{\min} = \mathfrak{a}_m E$, where $\mathfrak{a}_m$ is its normalization in the action line, let us write*

$$b_j = \partial_j b, \qquad \chi_j = \partial_j \chi, \qquad a_j = \partial_j \mathfrak{a}_m.$$

With the convention $\delta S_{\min} = -\frac{1}{2}\sum_j s_j \delta\omega_j$, the components are

$$\begin{aligned} s_j = {} & 4\mathfrak{a}_m \chi \,\mathrm{Re}\langle y, \mathsf{C}_j f_{\min} - b_j\rangle \\ & - 2\mathfrak{a}_m \chi_j \langle b, y\rangle - 2a_j E. \end{aligned} \tag{82.16}$$

For the cubic normalization, the second term equals $4\mathfrak{a}_m E\, \partial_j \ell_m/\ell_m$. If the cellular pairing of this same action has invertible matrix $\mathsf{M}_{\mathrm{cel}}$, its current coordinates are $\sigma = \mathsf{M}_{\mathrm{cel}}^{-1} s$.

Proof. The product rule gives $\partial_j S_{\min} = a_j E + \mathfrak{a}_m \partial_j E$. Substituting (82.12) and multiplying by -2 proves (82.16). The derivative of χ_m produces the scale expression. Finally, comparing $\delta S_{\min} = -\frac{1}{2}\delta\omega^{\mathsf{T}} s$ with $-\frac{1}{2}\delta\omega^{\mathsf{T}}\mathsf{M}_{\mathrm{cel}}\sigma$ for every variation gives $\mathsf{M}_{\mathrm{cel}}\sigma = s$, and its inverse determines the coordinates. □

The construction recovers a field and a weight jointly selected by the incidence, and evaluates their response to variations of the same realization. The boundary datum b, the route family, the scale ℓ_m, the normalization $\mathfrak{a}_m$ and the cellular pairing retain their publication rules. Interpretation as a material current uses those objects and the complete action. The Cartan response and its subsequent metric density are composed with it in the corresponding matter domain, preserving any dependence of the current on the connection.

82.8 Spin current and algebraic Cartan–Holst response

The realization of the enriched transport in Section 80.6 provides the cotetrad and the connection; the dimensional sections and the incidence parameter of Sections 120 and 121 fix their couplings. Their composition determines a first-order variational problem. The material current occupies a precise position in it: it is the derivative of the action with respect to the connection and determines the torsional response with the same normalization.

82.8.1 Geometric domain and current normalization

We work on a smooth oriented four-dimensional manifold M, with internal Lorentzian bundle E, metric $\eta = \mathrm{diag}(-1, 1, 1, 1)$ and non-degenerate cotetrad $e \in \Omega^1(M; E)$. In a local frame we write e^I, with $I = 0, 1, 2, 3$. The metric connection $\omega^{IJ} = -\omega^{JI}$ acts through D_ω. When the fields Ψ are spinorial, a spin structure and the corresponding material representation are preserved. We define

$$\Sigma^{IJ} = e^I \wedge e^J, \qquad F^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}, \qquad T^I = D_\omega e^I. \tag{82.17}$$

The operator $\star$ acts on the internal bivector indices,

$$(\star X)^{IJ} = \tfrac{1}{2}\epsilon^{IJ}{}_{KL} X^{KL}, \qquad \star^2 = -I, \qquad \mathsf{P}_\gamma = \star + \gamma^{-1} I. \tag{82.18}$$

This distinguishes this duality from the exterior duality of forms on M. Internal indices are raised and contracted with η.

We fix a chart with $G_{\mathrm{int}} > 0$, $c_{\mathrm{int}} > 0$, $\gamma = \gamma_{\mathrm{HMT}} \in \mathbb{R} \setminus \{0\}$ and Λ_{int} constant on it. We abbreviate $\kappa = 8\pi G_{\mathrm{int}}/c_{\mathrm{int}}^4$ and $c = c_{\mathrm{int}}$. These sections remain fixed during variation. The action is

$$S[e,\omega,\Psi]=\frac{1}{2\kappa c}\int_M \Sigma_{IJ}\wedge(\mathsf{P}_\gamma F)^{IJ}-\frac{\Lambda_{\mathrm{int}}}{\kappa c}\int_M \mathrm{vol}_e+S_{\mathrm{m}}[e,\omega,\Psi]. \tag{82.19}$$

The volume and orientation convention is the one that gives $\Sigma_{IJ}\wedge(\star F)^{IJ}=R\,\mathrm{vol}_e$ in the Levi–Civita sector. The prior dimensional type makes each summand an action section.

For the variation of the connection, variations with compact support in the interior are used, or $\delta\omega|_{\partial M}=0$ is fixed. A boundary completion whose variational problem cancels the same boundary term may also be used. At fixed cotetrad and material fields, the spin current is the degree-three form, valued in dual internal bivectors, determined by

$$\delta_\omega S_{\mathrm{m}}=-\tfrac{1}{2}\int_M \delta\omega^{IJ}\wedge\sigma_{IJ}. \tag{82.20}$$

Pairing with an arbitrary compactly supported variation fixes σ uniquely. This definition preserves the action unit of the current and the normalization factor involved in its geometric response.

82.8.2 Connection variation and Holst inversion

Theorem 82.22 (Variational Cartan–Holst equation)**.** *On the preceding domain, stationarity with respect to the connection is equivalent to*

$$D_\omega(\mathsf{P}_\gamma\Sigma)^{IJ}=\kappa c\,\sigma^{IJ}. \tag{82.21}$$

Proof. The variation of the curvature is $\delta F=D_\omega\delta\omega$. The internal duality is parallel and self-adjoint for the bivector contraction; since γ is constant, $D_\omega\mathsf{P}_\gamma=\mathsf{P}_\gamma D_\omega$. Setting $B_{IJ}=(\mathsf{P}_\gamma\Sigma)_{IJ}$ yields

$$B_{IJ}\wedge D_\omega\delta\omega^{IJ}=\mathrm{d}(B_{IJ}\wedge\delta\omega^{IJ})-D_\omega B_{IJ}\wedge\delta\omega^{IJ}.$$

The last form changes sign when its factors of degrees three and one are interchanged. The boundary conditions eliminate the integral of the exact term. The cosmological term is independent of ω. Therefore,

$$\delta_\omega S=\frac{1}{2\kappa c}\int_M \delta\omega^{IJ}\wedge\big[D_\omega B_{IJ}-\kappa c\,\sigma_{IJ}\big].$$

The arbitrariness of the variation proves the equation, including its sign and coefficient. □

Lemma 82.23 (Real inverse of the Holst operator)**.** *For $\gamma\in\mathbb{R}\setminus\{0\}$,*

$$\mathsf{P}_\gamma^{-1}=\frac{\gamma^2}{1+\gamma^2}(-\star+\gamma^{-1}I). \tag{82.22}$$

Proof. Both factors are polynomials in $\star$ and commute. Their product before normalization is

$$(\star+\gamma^{-1}I)(-\star+\gamma^{-1}I)=-\star^2+\gamma^{-2}I=(1+\gamma^{-2})I.$$

The denominator $1+\gamma^2$ is positive on the fixed real domain. Multiplication by $\gamma^2/(1+\gamma^2)$ gives the identity. □

The current thus determines the degree-three bivector-valued form

$$Y^{IJ}:=\kappa c\,\frac{\gamma^2}{1+\gamma^2}(-\star+\gamma^{-1}I)\sigma^{IJ},\qquad D_\omega\Sigma^{IJ}=Y^{IJ}. \tag{82.23}$$

82.8.3 Pointwise reconstruction of torsion and contorsion

The Leibniz rule gives

$$D_\omega \Sigma^{IJ} = T^I \wedge e^J - e^I \wedge T^J =: \mathsf{L}_e(T)^{IJ}. \tag{82.24}$$

At each point, L_e acts from $\Lambda^2 T^*M \otimes E$ to $\Lambda^3 T^*M \otimes \Lambda^2 E$. Both spaces have dimension twenty-four. Let E_I be the dual frame of the cotetrad, so that $\iota_{E_I} e^J = \delta^J_I$.

Theorem 82.24 (Algebraic inversion of the torsional equation)**.** *For a nondegenerate co-tetrad, L_e is an isomorphism. Its inverse on the form Y is written*

$$B^I = \sum_J \iota_{E_J} Y^{IJ}, \qquad b = \tfrac{1}{4} \sum_I \iota_{E_I} B^I, \qquad T^I = B^I - e^I \wedge b. \tag{82.25}$$

Equation (82.21) *therefore determines torsion pointwise from e and the current appearing in it.*

Proof. First let $Y = \mathsf{L}_e(T)$ and set $t = \sum_J \iota_{E_J} T^J$. The contraction of (82.24), using that T^I has degree two and that the cotetrad has four elements, gives

$$\sum_J \iota_{E_J}(T^I \wedge e^J) = 2T^I, \qquad \sum_J \iota_{E_J}(e^I \wedge T^J) = T^I - e^I \wedge t.$$

Hence $B^I = T^I + e^I \wedge t$. A second contraction produces

$$\sum_I \iota_{E_I} B^I = t + 3t = 4t.$$

One recovers $t = b$ and then $T^I = B^I - e^I \wedge b$. In particular, the kernel of L_e is zero. Equality of dimensions proves its surjectivity and makes the formula valid for every form Y in the codomain. □

The connection decomposes uniquely as

$$\omega^{IJ} = \mathring{\omega}^{IJ}(e) + K^{IJ}, \qquad K^{IJ} = -K^{JI}, \qquad T^I = K^I{}_J \wedge e^J, \tag{82.26}$$

where $\mathring{\omega}(e)$ is the Levi–Civita connection and K the contorsion. To make the inverse explicit, we write $K_{IJ} = K_{IJK} e^K$ and $T_I = \frac{1}{2} T_{IJK} e^J \wedge e^K$. Then

$$T_{IJK} = K_{IKJ} - K_{IJK}, \qquad K_{IJK} = \tfrac{1}{2}(T_{KIJ} - T_{IJK} - T_{JKI}). \tag{82.27}$$

The second equality is obtained by combining the first cyclically and using $K_{IJK} = -K_{JIK}$; substituting it recovers the components of T. Torsion and contorsion are therefore two equivalent presentations of the algebraic response at fixed cotetrad.

Corollary 82.25 (Current-free sector and minimal linear response)**.** *If $\sigma = 0$, one obtains $T = 0$ and $\omega = \mathring{\omega}(e)$. For a material coupling whose current $\sigma[e, \Psi]$ is independent of K, equations* (82.23)*,* (82.25) *and* (82.27) *provide a unique response $K_*(e, \Psi)$, linear in σ.*

Proof. The three reconstruction maps are linear with e, γ and κc fixed. The zero current produces $Y = 0$, then $T = 0$ and finally $K = 0$. □

In the minimal action, the connection equation contains this pointwise response. Its evolution is obtained by evolving e and Ψ: $K_* = K_*(e, \Psi)$ changes with them. If a material action preserves additional algebraic dependence on K, the Cartan equation retains its variational form and must be solved with that current; the preceding linear response corresponds to the specified minimal domain.

82.8.4 Elimination of contorsion and quadratic contribution

Now consider the minimal coupling affine in K, expressed by

$$S_{\mathrm{m}}[e, \mathring{\omega} + K, \Psi] = S_{\mathrm{m}}[e, \mathring{\omega}, \Psi] - \tfrac{1}{2} \int_M K^{IJ} \wedge \sigma_{IJ}[e, \Psi]. \tag{82.28}$$

This condition identifies the material action to which the quadratic elimination applies; the current remains the one defined by (82.20).

The curvature expansion is

$$F(\mathring{\omega} + K) = F(\mathring{\omega}) + D_{\mathring{\omega}} K + K \wedge K, \qquad (K \wedge K)^{IJ} = K^I{}_L \wedge K^{LJ}. \tag{82.29}$$

Since $D_{\mathring{\omega}} \Sigma = 0$, the linear term is the exterior derivative of $\Sigma_{IJ} \wedge (\mathsf{P}_\gamma K)^{IJ}$. The corresponding boundary contribution remains explicit:

$$S_\partial[e, K] = \frac{1}{2\kappa c} \int_{\partial M} \Sigma_{IJ} \wedge (\mathsf{P}_\gamma K)^{IJ}. \tag{82.30}$$

On an interior domain, or with the compatible boundary completion, the action density that depends on the contorsion is

$$\mathcal{Q}_{e,\gamma}(K) - \tfrac{1}{2} K^{IJ} \wedge \sigma_{IJ}, \qquad \mathcal{Q}_{e,\gamma}(K) = \frac{1}{2\kappa c} \Sigma_{IJ} \wedge \mathsf{P}_\gamma (K \wedge K)^{IJ}. \tag{82.31}$$

The density $\mathcal{Q}_{e,\gamma}$ is a degree-four differential form, homogeneous of degree two in K.

Theorem 82.26 (Effective response quadratic in the current)**.** *Under* (82.28)*, substituting the algebraic solution K_* produces the effective spin density*

$$\mathcal{L}^{\mathrm{eff}}_{\mathrm{spin}} = -\tfrac{1}{4} K_*^{IJ} \wedge \sigma_{IJ} = -\mathcal{Q}_{e,\gamma}(K_*). \tag{82.32}$$

At fixed cotetrad and couplings, it is homogeneous of degree two in the current. The effective action also preserves $S_\partial[e, K_*]$, or its declared boundary completion.

Proof. By Corollary 82.25, K_* is linear in σ. The connection equation is precisely the stationarity of (82.31). Since it is algebraic, the radial variation $\delta K = K_*$ is applied pointwise; it may also be multiplied by a compactly supported function. Euler's identity for a quadratic form gives

$$2\mathcal{Q}_{e,\gamma}(K_*) - \tfrac{1}{2} K_*^{IJ} \wedge \sigma_{IJ} = 0.$$

Substitution into the action density proves (82.32). If $\sigma \mapsto \lambda\sigma$, then $K_* \mapsto \lambda K_*$ and the effective density is multiplied by λ^2. The expansion (82.29) separately identifies the boundary term accompanying this elimination. □

The specific current, its Lorentzian contraction, the duality and the conventions of the material action determine the sign and coefficient of this contribution. The quadratic identity provides the composition rule that allows them to be evaluated once these data have been specified.

82.8.5 Effective metric source and covariant balance

The normalization of the metric source is fixed in the same action line. After eliminating K, we define

$$\delta_g S_{\mathrm{m}}[e, \mathring{\omega}, \Psi] = -\tfrac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} \, \delta g^{\mu\nu}, \tag{82.33}$$

$$\delta_g S^{\mathrm{eff}}_{\mathrm{spin}} = -\tfrac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu} \, \delta g^{\mu\nu}. \tag{82.34}$$

Here interior variations are considered, with boundary terms treated according to the fixed variational problem. For the affine coupling, the second source is the metric variation of (82.32). The variation includes the dependence of the material current on e and Ψ.

Proposition 82.27 (Metric equation and conservation of the total source)**.** *With the preceding conventions, the metric equations are*

$$G_{\mu\nu}[g] + \Lambda_{\mathrm{int}} g_{\mu\nu} = \kappa c\big(\mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} + \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu}\big) = \kappa\big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu}\big), \tag{82.35}$$

where $T^{\mathrm{phys,LC}} = c\mathcal{T}^{S,\mathrm{LC}}$ *and* $U^{\mathrm{phys,spin}} = c\mathcal{U}^{S,\mathrm{spin}}$ *when the cotetrad takes values in the length line. Every solution satisfies*

$$\mathring{\nabla}^{\mu}\big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu}\big) = 0. \tag{82.36}$$

Proof. Eliminating K preserves the equations of the remaining variables: in the chain rule, the term multiplying δK_* vanishes by the connection equation. In the Levi–Civita sector, the first Bianchi identity cancels the term $\Sigma_{IJ} \wedge F^{IJ}$, and the gravitational part is written $(2\kappa c)^{-1}\int_M (R - 2\Lambda_{\mathrm{int}})\,\mathrm{vol}_e$. Its interior variation is

$$\frac{1}{2\kappa c}\int_M \mathrm{vol}_e\,(G_{\mu\nu} + \Lambda_{\mathrm{int}} g_{\mu\nu})\delta g^{\mu\nu}.$$

The sum with (82.34) gives (82.35). The contracted Bianchi identity for $\mathring{\nabla}$, metric compatibility and the constancy of κ and Λ_{int} in the chart produce (82.36). □

Before eliminating the connection, the geometric identities retain the form

$$D_\omega T^I = F^I{}_J \wedge e^J, \qquad D_\omega F^{IJ} = 0. \tag{82.37}$$

The first is $D^2_\omega e = F \wedge e$; the second is obtained by expanding $D_\omega(\mathrm{d}\omega + \omega \wedge \omega)$ and cancelling the terms. In a covariant material action, the total metric balance coincides with the Noether identity on the material equations. Geometry and matter thus preserve a joint source; the partition between its Levi–Civita contribution and its spin contribution is determined by the specialized action.

82.9 Torsional elimination and metric response of the minimal extension

The minimal extension provides a field, a response weight and a current through a single variational operation. Its transported incidence depends on the connection through the route products of (82.15). That dependence is preserved when composing the current with the Cartan–Holst equation. Elimination of the connection is therefore performed on the complete action of that extension. The affine case of 82.26 is contained as an exact specialization of the following construction.

82.9.1 Variational composition at a cellular level

Let us fix a finite level, its routes, the transport representation and the cellular pairing of 82.21. Let p be real coordinates of the co-tetrad and the material fields in a declared local trivialization, and $k \in \mathbb{R}^d$ the coordinates of the contortion K. The family $p \mapsto e(p)$ preserves nondegeneracy of the co-tetrad. The connection acting on each route is

$$\omega(p,k) = \mathring{\omega}(e(p)) + K(k), \qquad F(p,k) = S_{\min}[e(p), \omega(p,k), \Psi(p)] = \mathfrak{a}(p,k)E(p,k). \tag{82.38}$$

The spaces and bases of this expression are transported to fixed spaces before differentiation. We work on an open set where the incidence $\mathsf{C}(p,k)$ is surjective and the families are C^2. This additional regularity allows the Hessian of the action to be examined. The couplings $G_{\mathrm{int}}, c_{\mathrm{int}}, \gamma_{\mathrm{HMT}}$ preserve the chart and the variation convention of 82.8.1.

Let $Q(p,k)$ be the integral, or the declared cellular realization, of the quadratic form (82.31). In real bases,

$$Q(p,k) = \tfrac{1}{2} k^{\mathsf{T}} \mathsf{A}(p) k, \qquad \mathsf{A}(p)^{\mathsf{T}} = \mathsf{A}(p). \tag{82.39}$$

The operator A comes from the gravitational action and its pairing, whereas the Gramian $\mathsf{C}\mathsf{C}^{*}$ comes from the extension problem. Positivity of the latter guarantees existence of the minimizing field; the gravitational form retains its own signature. Boundary terms are retained according to (82.30); the following interior formulas apply with admissible variations that annul their contribution, or with the corresponding boundary completion.

Define the response covector by

$$d_k F(p,k)[h] = -\tfrac{1}{2} h^{\mathsf{T}} s(p,k), \qquad s(p,k) = \mathsf{M}_{\mathrm{cel}}(p,k)\sigma(p,k). \tag{82.40}$$

Here s and σ preserve the distinct types of (82.16): the former contains the coefficients of the differential and the latter the coordinates of the current in the material pairing. If the basis in k changes, that pairing is also transported. When differentiating $s = \mathsf{M}_{\mathrm{cel}}\sigma$, the derivatives of both factors are included when the pairing depends on the parameter.

Proposition 82.28 (Composed equation of extension and contorsion)**.** *Interior stationarity of the action with respect to contorsion is*

$$\mathcal{R}(p,k) := \mathsf{A}(p)k - \tfrac{1}{2} s(p,k) = 0. \tag{82.41}$$

Each component of s is calculated from the same extension:

$$\begin{aligned} s_j = {} & 4\mathfrak{a}\chi \,\mathrm{Re}\langle y, (\partial_{k_j}\mathsf{C}) f_{\min} - \partial_{k_j} b\rangle \\ & - 2\mathfrak{a}(\partial_{k_j}\chi)\langle b, y\rangle - 2(\partial_{k_j}\mathfrak{a})E. \end{aligned} \tag{82.42}$$

When the cellular pairing realizes the connection equation of 82.22, this equation is equivalent to composing $\sigma(p,k)$ with the Holst inverse, the inverse of L_e and the contortion reconstruction:

$$K = \mathsf{C}_e^{\mathrm{tor}} \mathsf{L}_e^{-1}\big(\kappa c\, \mathsf{P}_\gamma^{-1}\sigma[e, \mathring{\omega}(e) + K, \Psi]\big). \tag{82.43}$$

The symbol $\mathsf{C}_e^{\mathrm{tor}}$ exclusively designates the map $T \mapsto K$ of (82.27), with fixed co-tetrad.

Proof. The differential of $Q + F$, in the arbitrary direction h, is

$$d_k(Q+F)[h] = h^{\mathsf{T}}\big(\mathsf{A}k - \tfrac{1}{2}s\big).$$

Its vanishing in every direction proves (82.41). Theorem 82.21, applied to ∂_{k_j}, gives (82.42). With p fixed, $\delta\omega = \delta K$. The Cartan equation is transformed successively through (82.22), (82.25) and (82.27); each of these operations is invertible on its domain. This proves equivalence with (82.43) when both expressions use the same material and cellular realization. □

The composition preserves the connection on both sides. Routes passing through several cells can couple the current components between them. The pointwise reconstruction of T from a given current and the joint solution of (82.41) are, in that case, successive operations. This finite formulation keeps explicit the route representation entering the functional.

82.9.2 Local existence of a stationary branch

Theorem 82.29 (Local continuation of the torsional solution)**.** *Suppose* (p_0, k_0) *belongs to the preceding open set,* $\mathcal{R}(p_0, k_0) = 0$*, and the total Hessian*

$$\mathsf{H}_0 = \mathsf{A}(p_0) + \partial_k^2 F(p_0, k_0) = \mathsf{A}(p_0) - \tfrac{1}{2}\partial_k s(p_0, k_0) \tag{82.44}$$

is invertible. There exist neighborhoods of p_0 *and* k_0 *in which a unique branch* C^1*,* $k = k_*(p)$*, satisfies* (82.41) *and passes through* k_0*. On that branch,*

$$\partial_{p_i} k_* = -\left[\mathsf{A} + \partial_k^2 F\right]^{-1} \left[(\partial_{p_i}\mathsf{A})k_* + \partial_{p_i}\partial_k F\right]. \tag{82.45}$$

Proof. Inversion of the Gramian is C^2 on the full-rank open set. Hence F is C^2 and $\mathcal{R}$ is C^1. Its derivative with respect to k, at (p_0, k_0), is H_0. The implicit function theorem provides the branch, its regularity and its uniqueness in a neighborhood of the point. Existence can also be seen through the map

$$\mathcal{T}_p(k) = k - \mathsf{H}_0^{-1}\mathcal{R}(p, k).$$

Its derivative with respect to k vanishes at (p_0, k_0). On a sufficiently small ball it has norm at most $q < 1$. Shrinking the neighborhood of p_0 yields $\|\mathcal{T}_p(k_0) - k_0\| < (1 - q)r$, where r is the radius of the ball. Thus, $\mathcal{T}_p$ maps the closed ball into itself and is contractive. Its fixed point is the local solution. Differentiating $\mathcal{R}(p, k_*(p)) = 0$ and solving for $\partial_{p_i} k_*$ gives (82.45). □

The hypothesis is verified on the composite action: the Gramian's rank ensures the screen minimum and the total Hessian controls the torsional branch. The asserted uniqueness is local around the specified solution; other branches may coexist in the same full-rank domain.

82.9.3 Effective action and non-affine contribution

Theorem 82.30 (Exact elimination identity)**.** *Let* $k_*(p)$ *be a stationary branch. Suppose, moreover, that the segment* $t \mapsto (p, tk_*)$*,* $0 \le t \le 1$*, remains in the open set where* F *is defined. The action correction relative to the Levi–Civita realization is*

$$\begin{aligned} \Delta S(p) &:= Q(p, k_*) + F(p, k_*) - F(p, 0) \\ &= \tfrac{1}{4} k_*^{\mathsf{T}} s(p, k_*) - \tfrac{1}{2}\int_0^1 k_*^{\mathsf{T}} s(p, tk_*)\, dt. \end{aligned} \tag{82.46}$$

Equivalently,

$$\Delta S = -\tfrac{1}{4} k_*^{\mathsf{T}} s(p, k_*) + \tfrac{1}{2}\int_0^1 k_*^{\mathsf{T}}\left[s(p, k_*) - s(p, tk_*)\right] dt. \tag{82.47}$$

These identities refer to the integrated or cellular action. In a realization with local density, they apply to the density with its corresponding pairing of forms. The effective action preserves the declared boundary term separately.

Proof. By the chain rule and (82.40),

$$\frac{d}{dt} F(p, tk_*) = -\tfrac{1}{2} k_*^{\mathsf{T}} s(p, tk_*).$$

Integrating between 0 and 1 gives the difference of material actions. The stationarity equation, evaluated in the direction k_*, and the quadratic homogeneity of Q give

$$2Q(p, k_*) = \tfrac{1}{2} k_*^{\mathsf{T}} s(p, k_*).$$

The sum of both identities proves (82.46); adding and subtracting $\frac{1}{2}k_*^{\mathsf{T}}s(p,k_*)$ provides (82.47). □

Corollary 82.31 (Affine specialization)**.** *If $s(p,k)=s(p)$, then*

$$\Delta S=-\tfrac{1}{4}k_*^{\mathsf{T}}s(p)=-Q(p,k_*).$$

This is the integrated realization of (82.32)*.*

Proof. The difference inside the integral of (82.47) vanishes. The second equality follows from the radial stationarity identity. □

82.9.4 Metric differential of the eliminated action

Theorem 82.32 (Response of the geometric variables)**.** *On the branch of Theorem 82.29,*

$$\partial_{p_i}\Delta S=\tfrac{1}{2}k_*^{\mathsf{T}}(\partial_{p_i}\mathsf{A})k_*+(\partial_{p_i}F)(p,k_*)-(\partial_{p_i}F)(p,0),\tag{82.48}$$

where the partial derivatives keep the coordinates k fixed. In fixed Hermitian inner products, each material derivative is calculated by

$$\begin{aligned}\partial_{p_i}F=&(\partial_{p_i}\mathfrak{a})E+\mathfrak{a}(\partial_{p_i}\chi)\langle b,y\rangle\\&+2\mathfrak{a}\chi\,\mathrm{Re}\langle y,\partial_{p_i}b-(\partial_{p_i}\mathsf{C})f_{\min}\rangle.\end{aligned}\tag{82.49}$$

If p_i varies the co-tetrad, $\partial_{p_i}\mathsf{C}$ includes the variation of $\mathring{\omega}(e(p))+K(k)$, of the realized routes and of the trivializations used, according to their declared dependencies.

Proof. The total derivative of $Q(p,k_*)+F(p,k_*)$ contains, in addition to its partial derivatives, the term

$$\big[\partial_kQ(p,k_*)+\partial_kF(p,k_*)\big]\partial_{p_i}k_*.$$

The bracket is zero by the connection equation. Subtracting the derivative of $F(p,0)$ proves (82.48). The product rule and (82.12) prove (82.49). The composition (82.38) requires differentiating the Levi–Civita connection when varying e with k fixed. □

When the positive extension inner product also varies, its contribution is preserved explicitly. In coordinates, let $\mathsf{h}(p,k)>0$ be its Hermitian matrix and consider the minimum of $f^*\mathsf{h}f$ under $\mathsf{C}f=b$. Then

$$\mathsf{L}=\mathsf{C}\mathsf{h}^{-1}\mathsf{C}^*,\quad y=\mathsf{L}^{-1}b,\quad f_{\min}=\mathsf{h}^{-1}\mathsf{C}^*y,\quad E=\chi b^*y.\tag{82.50}$$

Here y represents the constraint covector in fixed bases. The positive matrix h retains its energy role, distinct from that of the Lorentzian metric.

Lemma 82.33 (Variation of the extension inner product)**.** *With the preceding conventions,*

$$\delta E=(\delta\chi)b^*y+2\chi\,\mathrm{Re}\big[y^*(\delta b-\delta\mathsf{C}f_{\min})\big]+\chi f_{\min}^*(\delta\mathsf{h})f_{\min}.\tag{82.51}$$

Proof. The formula $\delta\mathsf{h}^{-1}=-\mathsf{h}^{-1}(\delta\mathsf{h})\mathsf{h}^{-1}$ gives

$$\delta\mathsf{L}=(\delta\mathsf{C})\mathsf{h}^{-1}\mathsf{C}^*+\mathsf{C}\mathsf{h}^{-1}(\delta\mathsf{C})^*-\mathsf{C}\mathsf{h}^{-1}(\delta\mathsf{h})\mathsf{h}^{-1}\mathsf{C}^*.$$

When differentiating $E=\chi b^*\mathsf{L}^{-1}b$, the term $-\chi y^*(\delta\mathsf{L})y$ produces the two terms with $\delta\mathsf{C}$ and the positive term with $\delta\mathsf{h}$. This proves the complete identity. □

In a covariant material realization whose variation admits the metric pairing of (82.34), the correction determines

$$\delta_g \Delta S = -\tfrac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{U}^{S,\min}_{\mu\nu} \, \delta g^{\mu\nu}, \qquad U^{\mathrm{phys},\min}_{\mu\nu} = c \mathcal{U}^{S,\min}_{\mu\nu}. \tag{82.52}$$

Equations (82.48) and (82.49), supplemented by (82.51) where appropriate, evaluate their coefficients in the declared metric variations. The screen minimum, torsional solution and metric derivative are three consecutive operations on the same action. The reduced action preserves the possible couplings between cells present in the original routes.

The homogeneous specialization of 88.16 additionally uses the realization of the resulting tensor: its spatial symmetry, the sign of contraction with the observer and the scaling law. When that evaluation gives $\rho_{\mathrm{corr}}(a) = -s_0 a^{-6}$, the amplitude is read in the reference state as $s_0 = -a_{\mathrm{ref}}^6 \rho_{\mathrm{corr}}(a_{\mathrm{ref}})$. This reading preserves the material state and its normalization; the elimination theorem provides the action to be contracted.

82.9.5 Exact non-affine checking model

The following finite model checks the coefficients and the non-affine dependence of the identities. Its parameters belong to the algebraic example and keep the problem of material realization of the routes separate.

Proposition 82.34 (Exact elimination of a rank-one extension)**.** *Let $H = \mathbb{R}^2$, $Q = \mathbb{R}$, $\mathsf{C}(k) = (1 \;\; k)$, $b = 1$, $\chi = 1$, $\mathfrak{a} = \lambda > 0$, and $Q_{\mathrm{ex}}(k) = k^2/2$. Then*

$$f_{\min} = \frac{(1,k)^{\mathsf{T}}}{1+k^2}, \quad F(\lambda,k) = \frac{\lambda}{1+k^2}, \quad s(\lambda,k) = \frac{4\lambda k}{(1+k^2)^2}, \quad \mathcal{R}(\lambda,k) = k\left(1 - \frac{2\lambda}{(1+k^2)^2}\right). \tag{82.53}$$

For $\lambda = 25/2$, the stationary solutions are $0, 2, -2$. At $k_* = 2$,

$$\mathsf{H}_* = \frac{16}{5}, \quad s_* = 4, \quad Q_{\mathrm{ex}}(k_*) = 2, \quad F(\lambda, k_*) = \frac{5}{2}, \quad \Delta S = -8. \tag{82.54}$$

The affine expression $-k_* s_*/4 = -2$ differs from the exact correction. On the positive branch,

$$\partial_\lambda \Delta S = -\frac{4}{5}, \qquad \partial_\lambda k_* = \frac{1}{20} \quad \text{in } \lambda = 25/2. \tag{82.55}$$

Proof. The Gramian is $1 + k^2 > 0$, so the minimum has the indicated expressions. Differentiating F gives $s = -2\partial_k F$ and then $\mathcal{R} = k - s/2$. For $\lambda = 25/2$, the equation is $k[(1+k^2)^2 - 25] = 0$; since $1 + k^2 > 0$, its roots are precisely $0, \pm 2$. The total Hessian is

$$1 - \frac{2\lambda(1-3k^2)}{(1+k^2)^3},$$

which equals $16/5$ at both nonzero roots. The correction is $2 + 5/2 - 25/2 = -8$. In the radial identity,

$$\int_0^1 k_* s(\lambda, t k_*)\, dt = \int_0^1 \frac{200t}{(1+4t^2)^2}\, dt = 20,$$

since an antiderivative is $-25/(1+4t^2)$. Thus $\Delta S = 8/4 - 20/2 = -8$, including the non-affine term. For $\lambda > 1/2$, the positive branch satisfies $k_*^2 = \sqrt{2\lambda} - 1$ and $\Delta S = \sqrt{2\lambda} - 1/2 - \lambda$. Their derivatives give (82.55). The envelope formula gives the same result: $(\partial_\lambda F)(\lambda, k_*) - (\partial_\lambda F)(\lambda, 0) = 1/5 - 1 = -4/5$. □

82.10 Spinorial current and torsional amplitude of the material state

The preceding development and the following spinorial realization articulate two variational problems with common geometric antecedents. The minimal extension action $S_{\min} = \mathfrak{a}_m E$, constructed in section 82.7, incorporates the dependence of the transported incidence and its minimum on the connection; its torsional elimination preserves that complete dependence in section 82.9. The spinorial action S_D of (82.58) couples the same connection to the fields of its representation and is affine in the contortion when the co-tetrad and fields are fixed. Each current is obtained by varying its own action. A minimizing preparation can determine the initial material state of the spinorial realization; substitution of connection-dependent fields additionally preserves the terms of the composite differential. This distinction places the following amplitude calculation in its specific action and variational domain.

The spinorial representation of transport and the algebraic response of Cartan–Holst allow torsional intensity to be calculated as a functional of the material state. Its evaluation preserves three data: the field representation, the second moment of its current and the volume relative to which density is defined. The coupling coefficient results from the action and its inversion; the initial state determines the material amplitude.

82.10.1 Spinorial representation and affine material action

We preserve the co-tetrad, orientation and couplings of section 82.8. The spinorial realization uses the four-dimensional complex module obtained by complexifying the real matrices

$$J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{82.56}$$
$$g^0 = J \otimes I_2, \qquad g^1 = R \otimes I_2, \qquad g^2 = Z \otimes R, \qquad g^3 = Z \otimes Z.$$

Multiplication gives $\{g^I, g^J\} = 2\eta^{IJ} I_4$, with $\eta = \mathrm{diag}(-1, 1, 1, 1)$. The matrices are distinguished from the scalar parameter γ of the Holst operator. Define

$$g_I = \eta_{IJ} g^J, \quad \mathbb{B}_{IJ} = \tfrac{1}{4}[g_I, g_J], \quad A_D = -ig^0, \quad \bar{\psi} = \psi^\dagger A_D, \quad \Omega = \tfrac{1}{2}\omega^{IJ}\mathbb{B}_{IJ}. \tag{82.57}$$

The Clifford product satisfies

$$[\mathbb{B}_{IJ}, g^K] = \delta^K_J g_I - \delta^K_I g_J.$$

Thus, the same metric connection acts on the fields through $D\psi = \mathrm{d}\psi + \Omega\psi$ and $D\bar{\psi} = \mathrm{d}\bar{\psi} - \bar{\psi}\Omega$. Transport along a route is obtained by integrating this connection in its spinorial representation; it preserves the connection and the route of the preceding geometric realization.

Let $\eta_I = \iota_{E_I} \mathrm{vol}_e$, so that $e^J \wedge \eta_I = \delta^J_I \mathrm{vol}_e$. For a field of dimensional type $[\psi] = L^{-3/2}$, we take the minimal material action

$$S_D = \int_M \left\{ \frac{\hbar}{2} \left[\bar{\psi} g^I D\psi - (D\bar{\psi}) g^I \psi \right] \wedge \eta_I - mc\, \bar{\psi}\psi \, \mathrm{vol}_e \right\}. \tag{82.58}$$

Here $\hbar = \hbar_{\mathrm{int}}$, $c = c_{\mathrm{int}}$ and the mass m is the reading of the material species in the chosen chart. These values are outputs preceding this realization. The matrix A_D is Hermitian and $A_D g^I$ is anti-Hermitian. Therefore the symmetric kinetic term has the real convention corresponding to (82.56). In this signature, the torsion-free equation has principal term $\hbar g^I D_I$; the equivalent notation $i\hbar\Gamma^I D_I$, with $\Gamma^I = -ig^I$, uses the Clifford relation of opposite signature. This specification jointly fixes the adjoint, signature and imaginary factor of the action.

The material fields and co-tetrad remain fixed in the variation of the connection. A preparation coming from the minimal extension of section 82.7 can determine the initial datum of the field or state. Each action preserves its own variation: if a connection-dependent minimizing field is substituted into an

action, its composite differential is also applied, or the envelope theorem under its stationarity hypotheses. Action (82.58) here realizes a coupling affine in contortion.

Proposition 82.35 (Spinorial current with variational normalization)**.** *Let $B^{IJK} = \bar\psi g^{[I} g^J g^{K]}\psi$, where brackets denote normalized antisymmetrization. The current defined in* (82.20) *by action* (82.58) *is*

$$\sigma_{JK} = -\frac{\hbar}{2}\,\bar\psi\{g^I, \mathbb{B}_{JK}\}\psi\,\eta_I = -\frac{\hbar}{2}\,B^I{}_{JK}\eta_I. \tag{82.59}$$

It is independent of contortion when e and ψ are fixed. The inversion of section 82.8.3 therefore applies to this current.

Proof. The variation of Ω is $\delta\Omega = \frac{1}{2}\delta\omega^{JK}\mathbb{B}_{JK}$. The two kinetic terms give, respectively, the product with g^I on the left and on the right. Consequently,

$$\delta_\omega S_D = \frac{\hbar}{4}\int_M \delta\omega^{JK}\wedge\eta_I\,\bar\psi\{g^I, \mathbb{B}_{JK}\}\psi.$$

Comparison with (82.20) fixes the factor and sign of (82.59). Expanding the anticommutator and using the Clifford relation cancels the degree-one contractions, leaving $\{g^I, \mathbb{B}_{JK}\} = g^{[I}g_J g_{K]}$. The action is linear in Ω, proving the last statement. □

82.10.2 Effective contraction and second-moment coefficient

The Lorentzian quadratic form of the trivector is written

$$q(B) = \frac{1}{3!}B^{IJK}B_{IJK} = -(B^{012})^2 - (B^{013})^2 - (B^{023})^2 + (B^{123})^2. \tag{82.60}$$

This contraction preserves the signature of the spinorial module. Its second moment depends on the state and on the realization of field products.

Theorem 82.36 (Effective interaction of the spinorial current)**.** *With material action* (82.58)*, algebraic elimination of contortion gives*

$$\mathcal{L}^{\mathrm{eff}}_{\mathrm{spin}} = C_\gamma q(B)\,\mathrm{vol}_e, \qquad C_\gamma = \frac{3\kappa c\hbar^2}{16}\frac{\gamma^2}{1+\gamma^2}. \tag{82.61}$$

The coefficient is obtained from the current and the Holst inverse with the normalizations of the preceding action.

Proof. By (82.32), it suffices to evaluate $-\frac{1}{4}K_*^{IJ}\wedge\sigma_{IJ}$, with

$$Y^{IJ} = \kappa c\frac{\gamma^2}{1+\gamma^2}(-\star + \gamma^{-1}I)\sigma^{IJ}, \qquad K_* = \mathsf{C}_e(Y).$$

Here C_e is the explicit composition of (82.25) with (82.27). Linearity of those two inverses reduces the calculation to the parts $-\star$ and I. To give the complete contraction, we order the trivector components as $(012, 013, 023, 123)$, extract the factors $\kappa c\hbar^2\gamma^2/(1+\gamma^2)$, and substitute $\sigma_{JK} = -\frac{1}{2}B^I{}_{JK}\eta_I$. The two matrices of the remaining quadratic form are

$$\mathcal{B}_{-\star} = \frac{3}{16}\,\mathrm{diag}(-1,-1,-1,1), \qquad \mathcal{B}_I = 0_{4\times4}. \tag{82.62}$$

These matrices are obtained using only $e^I\wedge\eta_J = \delta^I_J\,\mathrm{vol}_e$: for each component B^{abc}, we form σ, calculate Y, then $T^I = \sum_J \iota_{E_J}Y^{IJ} - \frac{1}{4}e^I\wedge\sum_{L,J}\iota_{E_L}\iota_{E_J}Y^{LJ}$, and finally $K_{IJK} = (T_{KIJ} - T_{IJK} - T_{JKI})/2$. The

contraction gives the four diagonal entries shown; the six polarizations between distinct components are zero for both operators. This calculates all coefficients of the two quadratic forms. The part $\gamma^{-1}I$ vanishes and the part $-\star$ produces exactly (82.60), with the coefficient of (82.61). □

82.10.3 Finite fermionic realization and second moment of the state

We fix a periodic comoving cell, an orthonormal frame adapted to its observer and the homogeneous spatial mode of the four spinorial components. This finite realization has state space $\mathcal{F} = \bigoplus_{n=0}^{4} \Lambda^n \mathbb{C}^4$. Let $a_r, a_r^\dagger$, $r = 1, \dots, 4$ be its canonical operators, with $\{a_r, a_s^\dagger\} = \delta_{rs}$ and $\{a_r, a_s\} = 0$. The occupation vacuum fixes normal ordering. For a matrix M, we write

$$\mathrm{d}\Gamma(M) = \sum_{r,s} a_r^\dagger M_{rs} a_s, \qquad \widehat{N} = \mathrm{d}\Gamma(I_4).$$

The letter Γ in this notation denotes second quantization; nonadic holonomy retains its own notation.

The four matrices of the bilinears are calculated directly:

abc	012	013	023	123
$M_{abc} = A_D g^a g^b g^c$	$iJ \otimes R$	$iJ \otimes Z$	$iI_2 \otimes J$	$iZ \otimes J$

(82.63)

All are Hermitian, have zero trace and satisfy $M_{abc}^2 = I_4$. The quartic observable corresponding to (82.60), in this declared normal ordering, is

$$\begin{aligned} \widehat{\mathcal{Q}}_{\mathrm{sp}} &= \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc} :\mathrm{d}\Gamma(M_{abc})^2: \\ &= \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc} \mathrm{d}\Gamma(M_{abc})^2 + 2\widehat{N}. \end{aligned} \tag{82.64}$$

Normal ordering is part of the specified finite realization; its definition makes explicit the subtraction of single-occupation contractions.

Proposition 82.37 (Evaluation by the canonical relations)**.** *The operator $\widehat{\mathcal{Q}}_{\mathrm{sp}}$ is self-adjoint, preserves each occupation sector and has restrictions*

$$\widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^0 \oplus \Lambda^1} = 0, \qquad \widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^3} = 4I_4, \qquad \widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^4} = 8I_1. \tag{82.65}$$

In the basis of $\Lambda^2\mathbb{C}^4$ whose occupation subsets are $(12, 13, 23, 14, 24, 34)$*, its matrix is*

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & -4 \\ 0 & 2 & 0 & 0 & 6 & 0 \\ 0 & 0 & 2 & -6 & 0 & 0 \\ 0 & 0 & -6 & 2 & 0 & 0 \\ 0 & 6 & 0 & 0 & 2 & 0 \\ -4 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{82.66}$$

Proof. The relation $a_s a_t^\dagger = \delta_{st} - a_t^\dagger a_s$ applied to $\mathrm{d}\Gamma(M)^2$ separates its single-occupation contraction and gives

$$:\mathrm{d}\Gamma(M)^2: = \mathrm{d}\Gamma(M)^2 - \mathrm{d}\Gamma(M^2).$$

Since the first three signs of (82.63) are negative and the last positive, the sum of contractions is $-2\widehat{N}$. This proves (82.64). Self-adjointness and preservation of occupation follow from those same expressions.

On Λ^0 all terms vanish. On Λ^1, $\mathrm{d}\Gamma(M) = M$, and the squares sum to $-2I_4$, which cancels with $2\widehat{N}$. On Λ^4, $\mathrm{d}\Gamma(M) = \operatorname{tr} M = 0$, leaving eight. Identification by complement between $\Lambda^3\mathbb{C}^4$ and the dual of $\mathbb{C}^4$

takes $\mathrm{d}\Gamma(M)$ to $(\operatorname{tr} M)I - M^{\mathsf{T}} = -M^{\mathsf{T}}$. Their squares again sum to $-2I_4$, while $2\widehat{N} = 6I_4$; therefore the restriction is $4I_4$. Finally, applying the four explicit matrices to the six exterior products of the indicated basis produces (82.66). The operator is thus evaluated in the sixteen dimensions of $\mathcal{F}$. □

For a state operator $\varrho \geq 0$, $\operatorname{Tr}\varrho = 1$, define $q_\varrho = \operatorname{Tr}(\varrho\widehat{\mathcal{Q}}_{\mathrm{sp}})$. Its dependence on second moments is explicit:

$$q_\varrho = \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc}\left\{\langle\widehat{B}_{abc}\rangle_\varrho^2 + \operatorname{Var}_\varrho(\widehat{B}_{abc}) - \langle\widehat{N}\rangle_\varrho\right\}, \qquad \widehat{B}_{abc} = \mathrm{d}\Gamma(M_{abc}). \tag{82.67}$$

Covariance and normal subtraction are preserved even when the mean currents vanish. In particular, if P_3 is the projection onto $\Lambda^3\mathbb{C}^4$,

$$\varrho_3 = \tfrac{1}{4}P_3, \qquad \langle\widehat{B}_{abc}\rangle_{\varrho_3} = 0, \qquad q_{\varrho_3} = 4 > 0. \tag{82.68}$$

It is a positive state of trace one and constitutes an explicit witness to the positive domain of the functional. The two-occupation sector also contains negative values; for example, the vector $(|12\rangle + |34\rangle)/\sqrt{2}$ has value -4. The sign of the intensity thus comes from the contraction and the state, and remains separate from the selection of cosmological conditions.

82.10.4 Density, pressure and preservation of the comoving amplitude

In the spatially homogeneous realization, fix

$$e^0 = N(t)c\,\mathrm{d}t, \qquad e^j = a(t)\,\mathrm{d}x^j, \qquad \mathcal{V}(t) = a(t)^3V_c,$$

with lapse $N(t) > 0$, dimensionless scale factor $a(t) > 0$ and comoving volume $V_c > 0$. The frame and periodic mode of subsection 82.10.3 remain declared. The normalization of the homogeneous field is $\widehat{\psi} = \mathcal{V}^{-1/2}(a_1, a_2, a_3, a_4)^{\mathsf{T}}$. Each bilinear carries a factor $\mathcal{V}^{-1}$, and its normally ordered product carries $\mathcal{V}^{-2}$. The symmetric kinetic temporal form preserves this canonical normalization: terms arising from differentiating $\mathcal{V}^{-1/2}$ cancel between its two summands.

Theorem 82.38 (Torsional amplitude as a functional of the state)**.** *Keeping the canonical state and the realization of the product fixed during metric variations, the effective spin term has reduced action*

$$S_{\mathrm{spin}}^{\mathrm{hom}} = \int \mathrm{d}t\, N(t)\frac{cC_\gamma}{a(t)^3V_c}\, q_\varrho. \tag{82.69}$$

Its energy density and isotropic pressure are

$$\rho_{\mathrm{spin}} = p_{\mathrm{spin}} = -\frac{cC_\gamma}{V_c^2}\, q_\varrho a^{-6}. \tag{82.70}$$

In any evolution preserving q_ϱ, the corresponding constant amplitude is

$$\boxed{s_0[\varrho, V_c] = \frac{3\kappa c^2\hbar^2}{16}\frac{\gamma^2}{1+\gamma^2}\frac{\operatorname{Tr}(\varrho\widehat{\mathcal{Q}}_{\mathrm{sp}})}{V_c^2}.} \tag{82.71}$$

Proof. Spatial integration of (82.61) multiplies the factor $\mathcal{V}^{-2}$ by $Nc\mathcal{V}\,\mathrm{d}t$, giving (82.69). In canonical variables, lapse variation defines energy through $\delta_N S_{\mathrm{m}} = -\int E\,\delta N\,\mathrm{d}t$. Therefore,

$$E_{\mathrm{spin}} = -\frac{cC_\gamma q_\varrho}{a^3V_c}, \qquad \rho_{\mathrm{spin}} = \frac{E_{\mathrm{spin}}}{a^3V_c}.$$

The isotropic spatial variation satisfies $\delta_a S_{\mathrm{m}} = \int 3Na^2V_c p\,\delta a\,\mathrm{d}t$. Applied to (82.69), it gives

$$3Na^2V_c\,p_{\mathrm{spin}} = -\frac{3NcC_\gamma q_\varrho}{a^4V_c}.$$

This simultaneously proves the sign, pressure and density of (82.70). Since q_ϱ is preserved, the coefficient of $-a^{-6}$ is constant and we obtain (82.71). Dimensionality is consistent: $[cC_\gamma]$ = energy L^3, so s_0 has the dimension of energy density. □

Corollary 82.39 (Preserved domain of positive amplitude)**.** *Let there be a unitary evolution of $\mathcal{F}$ preserving $\Lambda^3\mathbb{C}^4$. For every initial state of trace one supported on that sector, $q_{\varrho(t)} = 4$ holds, and*

$$s_0 = \frac{3\kappa c^2\hbar^2}{4V_c^2}\,\frac{\gamma^2}{1+\gamma^2} > 0. \tag{82.72}$$

Proof. Invariance of the sector preserves the support of the state; on it, (82.65) gives $\widehat{\mathcal{Q}}_{\mathrm{sp}} = 4I$. Preservation of the trace then fixes its expectation at four, independently of the internal evolution of its coherences. Positivity of the couplings, $V_c > 0$ and $\gamma \neq 0$ proves the formula and its sign. □

For general states, preservation of $\langle\widehat{N}\rangle$ determines dilution of the occupation density, $n(t) = \langle\widehat{N}\rangle/(a^3V_c)$. Preservation of the quartic moment is checked separately. If $i\hbar\dot{\varrho} = [H(t), \varrho]$, then

$$\frac{\mathrm{d}q_\varrho}{\mathrm{d}t} = \frac{i}{\hbar}\,\mathrm{Tr}\big(\varrho[H(t), \widehat{\mathcal{Q}}_{\mathrm{sp}}]\big). \tag{82.73}$$

Commutation, invariance of a sector where the observable is scalar, or a conservation proved for the specific state provide the relevant conditions. If the moment evolves, (82.70) preserves its instantaneous evaluation; its balance includes

$$\dot{\rho}_{\mathrm{spin}} + 6H\rho_{\mathrm{spin}} = -\frac{cC_\gamma}{V_c^2}\,a^{-6}\dot{q}_\varrho, \qquad H = \dot{a}/a$$

in proper time. This term records exchange with the remaining material degrees of freedom.

The composition is determined: spinorial representation of transport, material action, variational current, Cartan–Holst inversion, second moment and normalized density. The domain $s_0 > 0$ of section 88.16 thus has an evaluable functional and explicit witness states. Its use in cosmological dynamics additionally preserves the material, geometric and conservation conditions stated in that section.

Chapter 83

Confluence theorem relating horizon energy, area, information, entropy, and action

The horizon patch coordinates energy, temperature, entropy, and action through typed identities. The half-action cell and chronological closure are presented with their Schwarzschild and de Sitter controls, without turning an interface into a retroactive definition.

83.1 Horizon energy and half-action cell

83.1.1 Geometric conventions of the de Sitter patch

Consider a four-dimensional de Sitter space with areal radius $R > 0$, causal velocity c, and gravitational constant G. Adopt the convention

$$H_R = \frac{c}{R}, \qquad \Lambda_R = \frac{3}{R^2}, \qquad \ell_P^2 = \frac{G\hbar}{c^3}. \tag{83.1}$$

The density of energy associated to the term cosmological is

$$\varepsilon_\Lambda := \frac{\Lambda_R c^4}{8\pi G}. \tag{83.2}$$

The spatially flat section of the patch contains, up to radius R, the volume

$$V_R = \frac{4\pi}{3} R^3. \tag{83.3}$$

These conventions positively fix the quasilocal energy used in the chapter. Choosing another sign for the de Sitter Killing charge belongs to a distinct construction and must be translated before formulas are compared.

83.1.2 energy of vacuum and energy of Misner–Sharp

In a spherically symmetric geometry, let

$$\mathrm{d}s^2 = g_{ab}(x)\,\mathrm{d}x^a\,\mathrm{d}x^b + \mathcal{R}(x)^2\,\mathrm{d}\Omega_2^2. \tag{83.4}$$

The Misner–Sharp energy [90], under the adopted positive convention, is defined by

$$E_{\mathrm{MS}}(\mathcal{R}) := \frac{c^4\mathcal{R}}{2G}\left(1 - g^{ab}\nabla_a\mathcal{R}\nabla_b\mathcal{R}\right). \tag{83.5}$$

A marginal sphere satisfies

$$g^{ab}\nabla_a\mathcal{R}\nabla_b\mathcal{R} = 0. \tag{83.6}$$

Theorem 83.1 (Confluence volumetrica and cuasilocal)**.** *On the de Sitter horizon $\mathcal{R} = R$, the integrated vacuum energy and the Misner–Sharp energy coincide exactly:*

$$\boxed{E_\Lambda := \varepsilon_\Lambda V_R = E_{\mathrm{MS}}(R) = \frac{c^4 R}{2G}.} \tag{83.7}$$

Proof. The equations equations (83.1) a (83.3) give

$$\varepsilon_\Lambda V_R = \frac{3c^4}{8\pi G R^2}\,\frac{4\pi R^3}{3} = \frac{c^4 R}{2G}.$$

The marginal condition equation (83.6) applied to equation (83.5) yields the same result. □

The equality brings together two geometric publications. The first integrates a volumetric density; the second evaluates the trapping defect of the areal sphere. Both preserve the radius R and gravitational compliance G/c^4.

83.1.3 Temperature, entropy and product of horizon

The de Sitter surface gravity has magnitude c^2/R. The Gibbons–Hawking temperature [51] and the Bekenstein–Hawking entropy [8, 59] are

$$k_B T_H = \frac{\hbar c}{2\pi R}, \tag{83.8}$$

$$\frac{S_H}{k_B} = \frac{A_H}{4\ell_P^2} = \frac{4\pi R^2}{4\ell_P^2} = \frac{\pi R^2}{\ell_P^2}. \tag{83.9}$$

Theorem 83.2 (de Sitter thermodynamic identity)**.** *For every radius R of the declared family,*

$$\boxed{T_H S_H = \frac{c^4 R}{2G} = E_\Lambda.} \tag{83.10}$$

Proof. Multiplying equations (83.8) y (83.9) gives

$$T_H S_H = \frac{\hbar c}{2\pi R k_B} \frac{k_B \pi R^2}{\ell_P^2} = \frac{\hbar c R}{2\ell_P^2}.$$

The identity $\ell_P^2 = G\hbar/c^3$ turns the last member into $c^4 R/(2G)$, equal to equation (83.7). □

The factor $1/2$ has a decomposition geometric transparent. The areal factor 4π, the normalization holographic by four and the periodicity thermal $(2\pi)^{-1}$ satisfy

$$\frac{4\pi}{4} \frac{1}{2\pi} = \frac{1}{2}. \tag{83.11}$$

The half is therefore the joint contraction between areal quantization and Euclidean periodicity.

83.1.4 How complete of the horizon and Planck force

We define the tension or fuerza of Planck and the complete quantum associated with the radius by

$$\mathscr{F}_P := \frac{c^4}{G}, \qquad \boxed{Q_H(R) := 2T_H S_H = \frac{c^4 R}{G} = \mathscr{F}_P\, R.} \tag{83.12}$$

Quasilocal energy occupies half a cell of the complete quantum:

$$\boxed{E_\Lambda = T_H S_H = \frac{Q_H(R)}{2}.} \tag{83.13}$$

Proposition 83.3 (Radial compliance)**.** *The derivative of the complete quantum with respect to radius is the Planck force, and the derivative of the quasilocal energy is half of it:*

$$\frac{\mathrm{d}Q_H}{\mathrm{d}R} = \mathscr{F}_P, \qquad \frac{\mathrm{d}E_\Lambda}{\mathrm{d}R} = \frac{\mathscr{F}_P}{2}. \tag{83.14}$$

The compliance gravitatoria $\mathscr{C}_P = G/c^4$ satisfies

$$R = \mathscr{C}_P Q_H. \tag{83.15}$$

Proof. The three identities are direct derivatives or inversions of equation (83.12). □

The equation equation (83.15) expresses the radial response: the complete quantum applies tension, and geometry publishes a radius through universal compliance. The product $T_H S_H$ occupies the quasilocal half of that response.

83.1.5 Specialization to the closure chronological of 108 states

The chronological closure of section 88.1 determines

$$R_{108} = \ell_P, \qquad t_P = \frac{\ell_P}{c}, \qquad T_{108} = 2\pi t_P, \tag{83.16}$$

and the Planck quantum

$$E_P = \frac{\hbar}{t_P} = k_B \Theta_{\mathrm{clk}} \log 3. \tag{83.17}$$

Theorem 83.4 (Cell CT108 of half action)**.** *In the specialization $R = R_{108} = \ell_P$,*

$$Q_H(\ell_P) = \frac{c^4 \ell_P}{G} = E_P, \tag{83.18}$$

$$\boxed{E_\Lambda = T_H S_H = \frac{E_P}{2} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2},} \tag{83.19}$$

$$\boxed{E_\Lambda t_P = \frac{\hbar}{2},} \qquad \boxed{E_\Lambda T_{108} = \frac{h}{2}.} \tag{83.20}$$

Proof. The first equality is obtained by substituting $\ell_P = \sqrt{G\hbar/c^3}$ and $E_P = \sqrt{\hbar c^5/G}$. The equation (83.13) produces $E_\Lambda = E_P/2$, and equation (83.17) supplies the informational chart. Finally,

$$E_\Lambda t_P = \frac{E_P t_P}{2} = \frac{\hbar}{2}$$

and, as $T_{108} = 2\pi t_P$ and $h = 2\pi\hbar$,

$$E_\Lambda T_{108} = \frac{E_P}{2}(2\pi t_P) = \pi\hbar = \frac{h}{2}.$$

□

The first equality in equation (83.20) publishes half a reduced action over Planck time; the second publishes half a complete action over the CT108 period. Both express the same cell in the angular and circular charts.

The temperature and entropy are also determined:

$$k_B T_H = \frac{E_P}{2\pi}, \qquad \boxed{\frac{S_H}{k_B} = \pi.} \tag{83.21}$$

The temperature converts the frequency of horizon in energy; the entropy converts the area of the sphere of Planck in information. Their product recovers the same half-quantum.

83.1.6 Effective horizon weight and hyperbolic exponential

We define the effective thermodynamic weight

$$\Omega_{\text{eff}}(R) := \exp\left(\frac{S_H(R)}{k_B}\right). \tag{83.22}$$

In the CT108 set,

$$\boxed{\Omega_{\text{eff}}(\ell_P) = \mathrm{e}^{\pi}.} \tag{83.23}$$

The weight Ω_{eff} is a positive quantity defined by entropy. Its real value expresses effective multiplicity; an interpretation as an integer cardinality of microstates requires an additional discretization.

The areal–volumetric incidence operator is

$$F_{\text{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad J_\varphi := \frac{2F_{\text{av}}^2 - 3I}{\sqrt{5}}. \tag{83.24}$$

A direct calculation gives

$$J_\varphi^2 = I, \qquad \operatorname{Spec}(J_\varphi) = \{+1, -1\}. \tag{83.25}$$

The hyperbolic flow at closure time π is

$$\mathcal{E}_\pi := \mathrm{e}^{\pi J_\varphi} = \cosh\pi\, I + \sinh\pi\, J_\varphi, \tag{83.26}$$

and possesses spectrum

$$\boxed{\operatorname{Spec}(\mathcal{E}_\pi) = \{\mathrm{e}^{\pi}, \mathrm{e}^{-\pi}\}, \qquad \rho(\mathcal{E}_\pi) = \mathrm{e}^{\pi}.} \tag{83.27}$$

Corollary 83.5 (Horizon–Perron scalar confluence)**.** *In the CT108 closure,*

$$\boxed{\frac{S_H}{k_B} = \log\Omega_{\text{eff}} = \log\rho(\mathcal{E}_\pi) = \pi.} \tag{83.28}$$

Proof. The equations equations (83.21), (83.23) y (83.27) give the three members. □

The scalar identity is exact and preserves two distinct genealogies. The horizon produces e^{π} by exponentiation of the areal entropy; Perron dynamics produces it as the expansive eigenvalue of an involution that is hyperbolic. The terminal equality fixes a boundary condition for the intertwiner and preserves the distinction of domains.

83.1.7 Consistency of the Gravitational Transducer with the Schwarzschild Horizon

A Schwarzschild horizon with the same area radius satisfies

$$R_H = \frac{2GE_H}{c^4}, \qquad E_H = \frac{c^4 R_H}{2G}. \tag{83.29}$$

The entropy areal coincides with equation (83.9), whereas the temperature is

$$k_B T_{\text{Sch}} = \frac{\hbar c}{4\pi R_H} = \frac{1}{2} k_B T_H\big|_{R=R_H}. \tag{83.30}$$

Consequently,

$$E_H = 2T_{\text{Sch}} S_H, \qquad T_H^{\text{dS}} = 2T_{\text{Sch}} \tag{83.31}$$

for the same radius. In $R_H = \ell_P$,

$$E_H = \frac{E_P}{2}, \qquad T_{\text{Sch}} S_H = \frac{E_P}{4}. \tag{83.32}$$

The contrast separates the two geometries: they share quasilocal energy, area, and entropy, and their surface gravities produce temperatures in the ratio two.

With $\beta = (k_B T_{\mathrm{Sch}})^{-1}$, the action Euclidean satisfies

$$\frac{I_E}{\hbar} = \frac{E_H}{k_B T_{\mathrm{Sch}}} - \frac{S_H}{k_B} = 2\pi - \pi = \pi \tag{83.33}$$

at the Planck radius. The same π appears as reduced entropy, reduced Euclidean action, hyperbolic-flow time, and the logarithm of the effective weight.

83.1.8 Horizontal Horizon–Perron Entangler: Spectral compatibility between boundary energy and return memory

The coincidence $\Omega_{\mathrm{eff}} = \rho(\mathcal{E}_\pi)$ fixes a spectral datum and leaves open the relation between the complete objects. Let $\mathcal{A}_H^{(m)}$ denote the algebra of horizon observables at nonadic level m, let $\omega_H^{(m)}$ denote its state, and let $\mathcal{P}_\varphi^{(m)}$ denote the Perron transfer system.

Definition 83.6 (Thermodynamic–dynamic intertwiner)**.** An admissible intertwiner is a family of unital completely positive linear maps (UCP)

$$\mathfrak{I}_m : \mathcal{A}_H^{(m)} \longrightarrow \mathcal{A}_\varphi^{(m)} \tag{83.34}$$

which satisfies:

i) preservation of the state, in addition to unitality and complete positivity already incorporated into the UCP condition;

ii) compatibility with nonadic refinement;

iii) transport of the involution interior–exterior toward $J_\varphi \mapsto -J_\varphi$;

iv) commutation between the horizon modular semigroup and the transfer semigroup on the declared subspace;

v) equality of the spectral radius at time π, given by equation (83.28).

The fifth condition is necessary and scalar; the first four provide the algebraic content that a numerical coincidence does not contain. An intertwiner constructed in this manner would identify the effective thermodynamic multiplicity with a dynamics of expansion and contraction while preserving orientation, state, and refinement.

Estatuto probatorio

The identities $E_\Lambda = E_{\mathrm{MS}} = T_H S_H = c^4 R/(2G)$, the definition $Q_H = \mathcal{F}_P R$, the CT108 specialization, the two half-action cells, and the equality $S_H/k_B = \log \rho(\mathrm{e}^{\pi J_\varphi}) = \pi$ are exact results under the declared conventions and de Sitter realization. The identification of Ω_{eff} with a microscopic cardinal and the intertwiner $\mathfrak{I}_m$ belong to a delimited physical interface.

Falsification criterion

Geometric closure fails if $\Lambda_R \neq 3/R^2$, if the sphere of radius R fails to satisfy the marginal condition, or if the integrated energy differs from $E_{\mathrm{MS}}(R)$. Thermodynamic closure fails if the temperature or the area law produces $T_H S_H \neq c^4 R/(2G)$. The CT108 specialization fails if $R_{108} \neq \ell_P$, $T_{108} \neq 2\pi t_P$, or $E_P \neq k_B \Theta_{\mathrm{clk}} \log 3$. The Perron interface is refuted by an obstruction of positivity, state, orientation, or refinement, even when the eigenvalue e^π agrees scalarly.

Machian Factorization of the Transport Memory from the Global Closure and the Local Response. The relationship between global closure and local response leads to Mach's principle formulated on the memory of transport.

83.2 Confluence of action, area, information, and gravitation

83.2.1 Energy and entropy of the half-action cell

Fix the same oriented action section and its corresponding gravitational and thermal sections. The preceding reciprocity allows the same cell to be expressed through action, duration, and length. With $\ell_P^2 = \hbar G/c^3$, $t_P = \ell_P/c$, and $E_P = \hbar/t_P$, one has

$$\frac{c^4 \ell_P}{G} = \frac{\hbar}{t_P} = E_P.$$

The equality follows by substituting the area scale already constructed. In the horizon realization defined by (83.35), the quantities are normalized as

$$E_\Lambda(R) = \frac{c^4 R}{2G}, \qquad S_H(R) = \frac{k_B \pi R^2}{\ell_P^2}, \qquad T_H(R) = \frac{\hbar c}{2\pi k_B R}. \tag{83.35}$$

The temperature corresponds to the cosmological-horizon normalization of this realization. The factor 2π and the definition of the radius are part of the set of equations used.

Theorem 83.7 (Identity of the gravitational half-action cell)**.** *In realization* (83.35)*,*

$$T_H(R) S_H(R) = E_\Lambda(R), \tag{83.36}$$

$$T_H(\ell_P) S_H(\ell_P) = \frac{E_P}{2} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2}, \tag{83.37}$$

$$E_\Lambda(\ell_P) t_P = \frac{\hbar}{2}, \qquad E_\Lambda(\ell_P) T_{108} = \frac{h}{2}. \tag{83.38}$$

Proof. Multiplying temperature by entropy cancels the thermal normalization and gives $\hbar c R/(2\ell_P^2) = c^4 R/(2G)$. At $R = \ell_P$, the expression is $\hbar c/(2\ell_P) = \hbar/(2t_P) = E_P/2$. The thermal identity of the cycle gives the second member. Finally, $T_{108} = 2\pi t_P$ and $h = 2\pi\hbar$ produce the two action relations. □

The theorem brings together quantities that previously belonged to different descriptions. The cell energy, the temperature–entropy product, tritic information, and action integrated over its duration are compatible readings under the declared normalization. The gravitational constant enters the area scale; action fixes the energy of the period; Boltzmann transports dimensionless information to the entropy line. The proof shows how these functions are joined in a single identity.

83.2.2 Conversion between decision energy and area increment

Energy per tritic decision and the elementary area increment are obtained through different readers in the preceding development:

$$E_P = k_B \Theta_{\mathrm{clk}} \log 3 = \frac{\hbar}{t_P}, \qquad \delta\mathcal{A} = \gamma_{\mathrm{HMT}} a_0 \ell_P^2. \tag{83.39}$$

The same oriented section and the positive branch $\hbar, G, \gamma_{\mathrm{HMT}}, a_0, t_P > 0$ are maintained. The first quantity belongs to the energy line and the second to the area line. Their quotient defines the conversion coefficient

$$\mathcal{T}_{I/A} := \frac{E_P}{\delta\mathcal{A}} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{\gamma_{\mathrm{HMT}} a_0 \ell_P^2}, \qquad [\mathcal{T}_{I/A}] = [\text{energy}]/[\text{area}]. \tag{83.40}$$

This definition makes explicit the normalization required to transport a decision energy to a geometric resolution. All its factors are specified before the quotient is formed.

Proposition 83.8 (Gravitational expression of the conversion coefficient)**.** *In the same dimensional realization,*

$$\mathcal{T}_{I/A} = \frac{c^3}{\gamma_{\mathrm{HMT}} a_0 G t_P} = \frac{c^4}{\gamma_{\mathrm{HMT}} a_0 G \ell_P}. \tag{83.41}$$

Proof. Substituting $E_P = \hbar/t_P$ and $\ell_P^2 = \hbar G/c^3$ into (83.40) cancels the common action section and gives the first member. The identity $\ell_P = c t_P$ produces the second. The dependence of t_P and ℓ_P on the previously constructed realization is preserved. □

At the minimum cut of (72.16), the realization of one uniform decision per link publishes

$$S^{\mathrm{fis}}_{\mathrm{corte}} = 81 k_B \log 3, \qquad E^{(1)}_{\mathrm{corte}} = 81 E_P = \Theta_{\mathrm{clk}} S^{\mathrm{fis}}_{\mathrm{corte}}. \tag{83.42}$$

The first equality uses the proved capacity and the uniform product state; the second assigns the decision energy of the same cycle to each of its eighty-one links. Multiplying the thermal identity by eighty-one proves the equation of state of this realization. The thirty-six-link sector state preserves its own partition function, entropy, and area variations in (74.25).

The composition identifies the complementary functions of the constants: action fixes energy per duration; the angular character and Barbero–Immirzi fix the sector resolution of area; Boltzmann dimensionally realizes information; the product $G\hbar$ determines the area unit. The coefficient $\mathcal{T}_{I/A}$ preserves these dependencies by expressing their relation in units of energy per area.

83.2.3 Physical meaning of area confluence

For a horizon of radius R, the area is $A_H = 4\pi R^2$. The same entropy relation admits two expressions

$$\frac{S_H}{k_B} = \frac{A_H}{4\ell_P^2} = \frac{\pi R^2 c^3}{G\hbar}.$$

The first quotient compares the macroscopic area with the areal unit of the construction. The second makes explicit the composition of that unit through action and gravitation. When the sections are transported so that $G_a \hbar_a$ remains fixed, the geometric reading preserves that normalization. The dimensionless entropy of the same horizon remains invariant; its dimensional publications retain the bases that they use.

The Barbero–Immirzi parameter acts at a different resolution of the same development: oriented incidence organizes the elementary area spectrum, and the reduced state describes the information accessible at the cut. The areal and volumetric sheets provide the geometric transport and history measure described in section 73.6.2. Comparing a microscopic spectrum with a horizon entropy retains its realization map, state, and scale as data. These specifications allow the physical relation to be interpreted at each level and avoid replacing a correspondence of observables with an indiscriminate identification of their spaces.

The theoretical unity of the argument resides in complementary functions:

The areal unit brings together the product $G\hbar$; oriented incidence organizes its elementary resolution through $\gamma_{\mathrm{HMT}} a_0$; the state and bipartition determine the information accessible to the subsystem. The response equations (74.16)–(74.17) make that interrelation explicit in the sectoral family. Inversion (74.19) preserves entropy and transforms the area according to (74.20): the two readings distinguish different properties of the same configuration.

In this articulation, the dynamics produces and preserves history; the reader determines what information is accessible; action relates evolution and energy; Boltzmann realizes its thermal expression; gravitation enters the geometric scale by which area is measured. The identity $T_H S_H = E_\Lambda$ shows an exact confluence

of these functions in the declared realization. Physical theory is thus formulated from mathematical objects and their effective transformations.

83.2.4 Spectral entropy and preservation under transport

The entropy of a reduced state depends on its spectrum and on the bipartition defining the reduction. To specify the continuation towards duality, let $\mathcal{H}_A, \mathcal{H}_B$ be the two factors and ρ_{AB} a state with finite entropies. A factorized transport $U_A \otimes U_B$ produces

$$\rho'_A = U_A \rho_A U_A^*, \qquad S(\rho'_A) = S(\rho_A).$$

The first identity follows from the definition of partial trace and the second from the invariance of the spectrum. For a general unitary transport, the equivalent formulation also transports the inclusion of the subsystem's observable algebra. This specification identifies the geometric datum that must accompany an assertion of entanglement preservation.

The reciprocity of the ellipse and momentum–winding exchange preserve the quantities indicated in their respective theorems. Transport of the bipartition determines how to use these identities in an entropy reading. Modular continuation thus maintains the article's informational content and keeps distinct the energy spectrum, action orientation, and algebraic reduction defining entanglement.

83.2.5 Effective multiplicity and hyperbolic realization

In the preceding cell, $S_H(\ell_P)/k_B = \pi$. The effective multiplicity associated with that entropy is

$$\Omega_{\text{eff}} = \exp(S_H/k_B) = e^{\pi}.$$

If H is the hyperbolic involution of TRIT, with eigenvalues $+1, -1$, the exponential $\exp(\pi H)$ has spectrum $\{e^{\pi}, e^{-\pi}\}$. Agreement of the expansive eigenvalue with the effective multiplicity locates a specific spectral relation. Its microscopic meaning retains as additional data the map between the horizon space and the hyperbolic representation. This localization allows the correspondence to be developed without confusing the spectral value with its entire realization space.

83.3 Evaluation of constants and metrological comparison

The preceding constructions allow three operations to be separated: producing a quantity, publishing its coordinate in a chart and comparing that coordinate with a reference. The APP–TRIT–TPK state preserves sheets, orientation, quotient, carry and memory before these readings. Its nonadic prolongation publishes the correlated coordinates π, φ, e, α; the determinantal reader and regional return produce the action sections; the marked incidence $90/120$ and the conjugate channels produce the Barbero functional; angular transport subsequently publishes the CKM coordinates. No entry in the external tables enters into the choice of those operations.

The evaluations preserved in the source documents and their comparators are brought together here. The digits of the internal outputs express the precision of numerical publication, not experimental uncertainty. For a value x and a nonzero reference x_0, both in the same chart, we use

$$\Delta x = x - x_0, \qquad r_x = \frac{x - x_0}{x_0}.$$

When the reference has asymmetric marginal uncertainties u_-, u_+, we also define the descriptive residual

$$z_x = \begin{cases} \Delta x/u_+, & \Delta x \geq 0, \\ \Delta x/u_-, & \Delta x < 0. \end{cases} \tag{83.43}$$

This normalization does not assume independence between rows and does not by itself constitute a joint statistical test.

83.3.1 Planck constant and reduced constant: two orientations

In the chart $\mathcal{U}_S \mapsto \mathrm{J\,s}$, the sections already constructed are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\,\mathrm{J\,s}, \qquad H_5 = 1.0545718176461544696\ldots, \tag{83.44}$$

$$\hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\,\mathrm{J\,s}, \qquad \eta_{\mathrm{ret}} = 1.0545718169150390611\ldots, \tag{83.45}$$

$$h_a = 2\pi\hbar_a, \qquad a \in \{\mathrm{pre}, \mathrm{ret}\}. \tag{83.46}$$

The decade comes from $\Sigma_H = \varphi\alpha^{16}$; the difference between the two sections comes from regional return. Multiplication by 2π changes action per radian to action per turn, without introducing another orientation or altering the relative residual.

The SI reference is

$$h_{\mathrm{SI}} = 6.62607015 \times 10^{-34}\,\mathrm{J\,s}, \qquad \hbar_{\mathrm{SI}} = \frac{h_{\mathrm{SI}}}{2\pi} = 1.0545718176461563912\ldots \times 10^{-34}\,\mathrm{J\,s}.$$

Both expressions are exact. The infinite expansion of $\hbar_{\mathrm{SI}}$ is not a measurement uncertainty. Fixing the numerical value of h belongs to the definition of the SI in effect since 2019 [185]; comparison takes place after the HMT construction.

Magnitud	Coordinate in 10^{-34} J s	r_x relative to SI
$\hbar_{\mathrm{pre}}$	1.0545718176461544696	$-1.822221 \times 10^{-15}$
$\hbar_{\mathrm{ret}}$	1.0545718169150390611	$-6.932836 \times 10^{-10}$
h_{pre}	6.62607014999998793	$-1.822221 \times 10^{-15}$
h_{ret}	6.62607014540625433	$-6.932836 \times 10^{-10}$

Table 83.1: Action before and after return. The final digits are evaluations of the published coordinates; the residuals are not experimental errors of h or $\hbar$.

Proposition 83.9 (Invariance of the comparison under a complete turn)**.** *In a common chart,*

$$\frac{h_a - h_{\mathrm{SI}}}{h_{\mathrm{SI}}} = \frac{\hbar_a - \hbar_{\mathrm{SI}}}{\hbar_{\mathrm{SI}}}.$$

Proof. The two terms of the difference in the numerator on the left contain the common factor 2π, which cancels against that in the denominator. □

The pre/ret distinction is quantitatively relevant: replacing one with the other changes the comparison by several orders of magnitude. The regional corrector must remain visible and must not be confused with numerical rounding.

83.3.2 Barbero–Immirzi: internal value and comparison between constructions

The functional evaluation is reconstructed from its three contributions:

$$\begin{aligned}
\Delta S_{90} &= 2.95169439297457621139847987861 \times 10^{-4},\\
\Delta S_{120} &= 1.96835112502951720093738706217 \times 10^{-5},\\
\pi AC^*/180 &= 0.27048532293414007846558645879 0\ldots,\\
\gamma_{\mathrm{HMT}} &= \pi AC^*/180 + 12\Delta S_{90} - \Delta S_{120}\\
&= 0.27400767269445927474725526077398041940\ldots.
\end{aligned}$$

This composition preserves the oriented weight $12 : -1$, prior to its decimal evaluation. Its published summands reconstruct the final coordinate with an absolute residual smaller than 3×10^{-31}.

The Ghosh–Mitra counting is considered as a bibliographic comparison, not a measurement of the parameter. Their equation (7), written with $\lambda = 2\pi\gamma_{\mathrm{GM}}$, is

$$\sum_{j\in\{1/2,1,3/2,\dots\}} (2j+1)e^{-2\pi\gamma_{\mathrm{GM}}\sqrt{j(j+1)}} = 1. \tag{83.47}$$

The reference is A. Ghosh and P. Mitra, *An improved estimate of black hole entropy in the quantum geometry approach*, *Physics Letters B* **616** (2005), 114–117, arXiv:gr-qc/0411035, equations (7)–(8). The root is evaluated here for that specific equation; puncture counting is not identified with the HMT generator.

Table 83.2: Barbero–Immirzi comparison in the positive orientation. No experimental uncertainty or statistical significance is assigned to this table.

The external root evaluation is reproducible without arbitrarily truncating its tail. With $n = 2j$, $N = 128$, and $r = e^{-0.27\pi}$, for $\gamma \geq 0.27$,

$$\sum_{n>N} (n+1)e^{-\pi\gamma\sqrt{n(n+2)}} \leq \frac{r^{N+1}[(N+2) - (N+1)r]}{(1-r)^2} < 10^{-43}.$$

Every summand decreases strictly with γ. The endpoints 0.27 and 0.28 enclose the root; bisection and the tail bound control the decimals in the table. This is a check of the bibliographic comparator, not a route for selecting γ_{HMT}.

83.3.3 CKM angles, amplitudes, and CP violation

The angular reader already constructed publishes, in degrees,

$$(\theta_{12}, \theta_{23}, \theta_{13}, \delta) = (13.003313589509,\ 2.398056157332,\ 0.213977382244,\ 65.676173123554)^\circ. \tag{83.48}$$

These values arise from $M_{\mathrm{CKM}}(A, C^*/6, \Delta)^T$ and $\delta = 9A$. Conversion to radians is performed once before evaluating sines and cosines. The unitary parameterization of the angular section gives

$$|V_{\mathrm{CKM}}| \simeq \begin{pmatrix} 0.974350259 & 0.225005836 & 0.003734601 \\ 0.224873110 & 0.973489279 & 0.041841465 \\ 0.008582400 & 0.041121745 & 0.999117283 \end{pmatrix},$$

and the invariant quartet preserves the phase:

$$J = c_{12}c_{23}c_{13}^2 s_{12}s_{23}s_{13}\sin\delta = 3.1189723326632974 \times 10^{-5} \quad \text{in the owner's evaluation.}$$

This evaluation uses (16.69) with the coordinates of (83.48). The nine printed moduli are rounded; unitarity belongs to the complex matrix before rounding, not to a matrix formed solely from moduli.

The comparator is the three-generation fit in the Particle Data Group, 2025 update, *CKM Quark-Mixing Matrix*, equations (12.27)–(12.28) and the adjacent value of J. To avoid altering their uncertainties

through a nonlinear transformation, the table retains the observables published by PDG: $s_{ij} = \sin\theta_{ij}$, δ in radians and J.

Observable	HMT evaluation	PDG 2025	z_x
s_{12}	0.225007404757	0.22501 ± 0.00068	−0.003817
s_{23}	0.041841757010	$0.04183^{+0.00079}_{-0.00069}$	0.014882
s_{13}	0.003734601164	$0.003732^{+0.000090}_{-0.000085}$	0.028902
δ (rad)	1.146265461116	1.147 ± 0.026	−0.028251
$10^5 J$	3.118972333	$3.12^{+0.13}_{-0.12}$	−0.008564

Table 83.3: Marginal comparison in the declared parameterization and edition. The factor 10^5 jointly multiplies the value and uncertainty in the last row; it does not change its normalized residual.

The residuals are calculated with the coordinates before rounding in the table. The PDG fit combines data and unitarity constraints; its rows are not independent measurements. Therefore, $\sum z_x^2$ is not summed and no number of degrees of freedom is assigned to this table. The result is a reproducible marginal comparison with that edition, not a measure of model probability. The historical marginal deviations preserved in the source document are not transferred to this table: the excerpt does not identify the edition or covariance of that comparison.

The PMNS sector retains the transport $U = F_\ell^\dagger F_\nu$, the spectral domains and the phase data developed in the angular section. A numerical row requires specifying the frames of the register used and the realization being compared. This table does not assign CKM figures to the leptonic reader or publish a new PMNS matrix.

83.3.4 Boltzmann and universal gravitation: quantity, chart and reference

The thermal construction already recovered determines the positive transducer $k_B : \mathcal{L}_\Theta \to \mathcal{L}_E$ and the relation

$$k_B \Theta_{\mathrm{clk},a} \log 3 = \frac{h_a}{108 t_0} = \frac{\hbar_a}{t_P}, \qquad t_P = \frac{54}{\pi} t_0. \tag{83.49}$$

Local information, action and period appear before the kelvin–joule chart. For positive bases u_E, u_Θ, if $k_B(u_\Theta) = b\, u_E$, $\Theta_{\mathrm{clk},a} = \theta_a u_\Theta$ and $E_{P,a} = \epsilon_a u_E$, the equation is equivalent to $b\theta_a = \epsilon_a / \log 3$. A change $u'_E = s_E u_E$, $u'_\Theta = s_\Theta u_\Theta$ produces

$$b' = \frac{s_\Theta}{s_E} b, \qquad \theta'_a = \frac{\theta_a}{s_\Theta}, \qquad \epsilon'_a = \frac{\epsilon_a}{s_E}.$$

This preserves the energy product and makes visible the additional operation that separates the individual coordinates. For the transducer of subsection 70.2.7, the kelvin–joule chart used here expresses the SI coordinate

$$k_B^{\mathrm{SI}} = 1.380649 \times 10^{-23}\,\mathrm{J\,K^{-1}},$$

the exact value of the SI definition, not an estimate with measurement error. The function of the transducer and its relation to action have content of their own; citing its SI coordinate does not constitute an independent numerical check of an internal choice of both bases.

In gravity, the circular realization fixes

$$G_a = \vartheta^\circ_{108} \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}, \qquad \vartheta^\circ_{108} = (54/\pi)^2 = 295.4525715010569\ldots. \tag{83.50}$$

The selector and reciprocity $G_a \hbar_a = \vartheta^\circ_{108} c_{\mathrm{int}}^5 t_0^2$ are internal quantities of the declared realization. A dimensional evaluation of G_a must preserve, in addition to the orientation a, the time, velocity and action

charts. In the dimensional chart used here, the evaluated value is $6.67430 \times 10^{-11}\ \mathrm{m^3\,kg^{-1}\,s^{-2}}$. The table distinguishes that coordinate from the recommended value with its uncertainty.

Objeto	Internal output or relation	Referencia dimensional
k_B	Positive transducer; $k_B\Theta_{\mathrm{clk},a} = E_{P,a}/\log 3$.	$1.380649 \times 10^{-23}\ \mathrm{J/K}$, exact in SI.
G_a	Selector $(54/\pi)^2$; $G_a = \vartheta_{108}^{\circ} c_{\mathrm{int}}^5 t_0^2/\hbar_a$.	$6.67430(15) \times 10^{-11}\ \mathrm{m^3/(kg\,s^2)}$, CODATA 2022.

Table 83.4: Internal normalization and chart reference. The standard relative uncertainty of the reference for G is approximately 2.24743×10^{-5}; k_B has no definitional uncertainty. No predictive residual is calculated from a coordinate that has already been identified as a chart reference.

The external sources for this last table are the BIPM defining constants and the NIST CODATA 2022 table [181]. The experimental uncertainty of G is not transferred to h, $\hbar$ or k_B. Nor does equality of digits in a chart remove the need to identify the reader that produces the quantity.

83.3.5 Reproduction of the evaluations

The program `verificar_comparaciones_II.py`, included with the sources, receives the internal coordinates published in files separate from the external data. It checks the composition of the Barbero functional, the conversion between h and $\hbar$, the bibliographic root and its tail, the CKM moduli, the quartet J and each printed residual. It uses 75-digit decimal arithmetic and elementary functions evaluated after freezing the internal outputs. Execution instructions and program versions are included in the reproducible package. The working precision does not increase the digits available from the source document: only digits stable under its rounding are published. The check records the files used and their hashes, so that a change in evaluation or external edition remains visible.

83.4 Pure bipartite states, reduced entropy and horizon area laws

The enriched state preserves routes and their records during evolution; a subsystem reading determines which part of that information remains accessible. The construction of this section uses the angular channels of section 14.11.6, the incidence and the area operator of section 122, and the action, area and temperature units of sections 121 and 123. These are prior publications of the same APP–TRIT–TPK construction. Each here transmits its domain, orientation, normalization and realization conditions.

Three spaces are distinguished: the binary sheet record, the tritic factors of sectorial incidence, and the geometric realization of the exterior regions of a horizon. Purification, transport of observables, and dimensional conversion specify their relationships. This distinction preserves the structure accompanying each entropic value.

83.4.1 Sheet record and bipartite quantum purification

Write $a = A_{\mathrm{rad}}$ and $y = C_{\mathrm{rad}}^{*}$ for the angular coordinates already constructed. The channels and their probabilities are

$$\mathfrak{q}_{\pm} = e^{-a\mp y}, \qquad p_{\pm} = \frac{\mathfrak{q}_{\pm}}{\mathfrak{q}_{+} + \mathfrak{q}_{-}} = \frac{e^{\mp y}}{2\cosh y}. \tag{83.51}$$

The signs index these two channels. On $\mathcal{H}_{\mathrm{h}} = \mathrm{span}\{|+\rangle, |-\rangle\}$, define

$$\rho_{\mathrm{h}}(y) = p_{+}|+\rangle\langle+| + p_{-}|-\rangle\langle-|.$$

The auxiliary space $\mathcal{H}_{\mathrm{ar}} = \mathrm{span}\{|\mathrm{adv}\rangle, |\mathrm{ret}\rangle\}$ carries two orthonormal labels. With a phase χ_0 fixed, the joint state is

$$|\Psi_{\mathrm{ar}}\rangle = \sqrt{p_{+}}|+\rangle \otimes |\mathrm{adv}\rangle + e^{i\chi_0}\sqrt{p_{-}}|-\rangle \otimes |\mathrm{ret}\rangle. \tag{83.52}$$

Proposition 83.10 (Accessible information in the sheet record)**.** *The vector* (83.52) *is normalized, and its partial trace over* $\mathcal{H}_{\mathrm{ar}}$ *is* $\rho_{\mathrm{h}}(y)$*. Its entanglement entropy, expressed in nats, is*

$$s_{\mathrm{h}}(y) = \log(2\cosh y) - y\tanh y. \tag{83.53}$$

Exchange of the labels + *and* − *conjugates* $\rho_{\mathrm{h}}(y)$ *to* $\rho_{\mathrm{h}}(-y)$ *and preserves* s_{h}*.*

Proof. The squared norm is $p_+ + p_- = 1$. Orthogonality of the auxiliary labels eliminates the cross terms in the partial trace. The squared Schmidt coefficients are precisely $p_\pm$. By (83.51), $p_+ - p_- = -\tanh y$; substituting $\log p_\pm = \mp y - \log(2\cosh y)$ into $-\sum_\pm p_\pm \log p_\pm$ proves the formula. Exchange of signs permutes the two eigenvalues and preserves entropy. □

The common factor e^{-a} cancels upon normalization of the binary record. The relative phase χ_0 remains in the joint state even though this diagonal reduction does not express it. Logical reversibility concerns transport of the complete record, with its labels and correlations; phase return preserves the memory advance described in Section 80.4. A thermal implementation additionally has its own energy and dissipation law. In particular, s_{h} measures this binary subsystem and its concrete bipartition.

83.4.2 Quantum purification of the incidence sectors

The boundary incidence constructed earlier distinguishes two sets of eighteen links, with sectorial labels $m = 90, 120$. Each link carries $\mathbb{C}^3$, with basis $|0\rangle, |1\rangle, |2\rangle$ and occupation operator $\mathrm{diag}(0, 1, 2)$. Let N_m be their sectorial sums, and

$$\mathsf{N} = \mathsf{N}_{90} + \mathsf{N}_{120}, \qquad \mathsf{D}_\partial = 90\mathsf{N}_{90} + 120\mathsf{N}_{120}. \tag{83.54}$$

In the positive branch, γ_{BI} denotes the Barbero–Immirzi parameter already obtained, and $a_0 > 0$ its angular areal factor. This notation distinguishes the parameter from the connection and its holonomies. Area is published as

$$\widehat{\mathcal{A}}_m = \ell_P^2 \gamma_{\mathrm{BI}} a_0 \mathsf{N}_m, \qquad \widehat{\mathcal{A}} = \widehat{\mathcal{A}}_{90} + \widehat{\mathcal{A}}_{120}. \tag{83.55}$$

For the finite parameter $\Delta = \Delta_{\mathrm{mod}} \in \mathbb{R}$ of the reduced state, set

$$x_m = e^{-m\Delta}, \qquad z_m = 1 + x_m + x_m^2, \qquad Z(\Delta) = z_{90}^{18} z_{120}^{18}, \tag{83.56}$$

$$\rho_\partial(\Delta) = Z(\Delta)^{-1} e^{-\Delta \mathsf{D}_\partial}. \tag{83.57}$$

The trace in this section is the ordinary matrix trace, and the states have trace one. The parameter Δ preserves the selection and normalization of the antecedent state.

Proposition 83.11 (Tensor purification of the boundary)**.** *For a finite real weight* w*, let*

$$|\,\mathrm{TFD}(w)\rangle = \frac{|0\rangle|0\rangle + e^{-w/2}|1\rangle|1\rangle + e^{-w}|2\rangle|2\rangle}{\sqrt{1 + e^{-w} + e^{-2w}}}. \tag{83.58}$$

The product

$$|\Psi_\Delta\rangle = |\,\mathrm{TFD}(90\Delta)\rangle^{\otimes 18} \otimes |\,\mathrm{TFD}(120\Delta)\rangle^{\otimes 18} \tag{83.59}$$

is a normalized purification of $\rho_\partial(\Delta)$*.*

Proof. At each link, the sum of the squares of the three coefficients is one. The partial trace eliminates terms with different indices and returns $\mathrm{diag}(1, e^{-w}, e^{-2w})/(1 + e^{-w} + e^{-2w})$. Partial trace commutes with the tensor product. Multiplying the thirty-six reductions gives the exponential and partition function of (83.57). □

83.4.3 Informational equation and areal fluctuations

The occupation means and variances per link are

$$f_m = \frac{x_m + 2x_m^2}{z_m}, \qquad v_m = \frac{x_m + 4x_m^2}{z_m} - f_m^2. \tag{83.60}$$

Write $s(\rho) = -\operatorname{Tr}(\rho \log \rho)$, with $0 \log 0 = 0$. In the preceding purification, $s(\rho_\partial)$ is its entanglement entropy.

Proposition 83.12 (Mean area, entropy, and sectorial response)**.** *For real finite Δ, one has*

$$\langle \mathsf{N} \rangle_\Delta = 18(f_{90} + f_{120}), \tag{83.61}$$

$$\langle \mathsf{D}_\partial \rangle_\Delta = 18(90 f_{90} + 120 f_{120}), \tag{83.62}$$

$$\langle \widehat{\mathcal{A}} \rangle_\Delta = 18 \ell_P^2 \gamma_{\mathrm{BI}} a_0 (f_{90} + f_{120}), \tag{83.63}$$

$$s(\Delta) = \log Z(\Delta) + \Delta \langle \mathsf{D}_\partial \rangle_\Delta, \tag{83.64}$$

$$\frac{\mathrm{d}\langle \mathsf{D}_\partial \rangle_\Delta}{\mathrm{d}\Delta} = -\operatorname{Var}_\Delta(\mathsf{D}_\partial) = -18(90^2 v_{90} + 120^2 v_{120}), \tag{83.65}$$

$$\frac{\mathrm{d}s}{\mathrm{d}\Delta} = -\Delta \operatorname{Var}_\Delta(\mathsf{D}_\partial), \tag{83.66}$$

$$\frac{\mathrm{d}\langle \widehat{\mathcal{A}} \rangle_\Delta}{\mathrm{d}\Delta} = -18 \ell_P^2 \gamma_{\mathrm{BI}} a_0 (90 v_{90} + 120 v_{120}). \tag{83.67}$$

Proof. The local weights are $(1, x_m, x_m^2)/z_m$, whose first two moments give f_m and v_m. Additivity of occupation operators and factorization of the state give the first three formulas. Taking the trace of $-\rho_\partial \log \rho_\partial = \rho_\partial(\log Z + \Delta \mathsf{D}_\partial)$ gives the entropy. Differentiation of the finite sums yields $\partial_\Delta \log Z = -\langle \mathsf{D}_\partial \rangle_\Delta$ and $\partial_\Delta^2 \log Z = \operatorname{Var}_\Delta(\mathsf{D}_\partial)$. Independent factors add their variances. In the derivative of (83.64), the two first-moment terms cancel. Finally, $\partial_\Delta f_m = -m v_m$ gives the area response. □

Loss of uniformity is quantified in dimension $d_\partial = 3^{36}$:

$$I_\partial(\Delta) = 36 \log 3 - s(\Delta) = \mathcal{D}\big(\rho_\partial(\Delta) \| I/d_\partial\big) \geq 0. \tag{83.68}$$

Here $\mathcal{D}$ denotes relative entropy, defined and justified below. Substituting $\log(I/d_\partial) = -36 \log 3\, I$ proves the identity. Convexity of $t \log t$ gives positivity; equality corresponds to the uniform distribution, which in this family occurs exactly at $\Delta = 0$. The deficit measures dimensionless information; the scale $\gamma_{\mathrm{BI}} a_0 \ell_P^2$ measures area per occupation.

Theorem 83.13 (Occupation inversion and complementary area)**.** *Let $\mathcal{R}_\partial$ be the involution exchanging $|0\rangle$ and $|2\rangle$ and fixing $|1\rangle$ in each factor. Then*

$$\mathcal{R}_\partial \mathsf{N} \mathcal{R}_\partial^* = 72 I - \mathsf{N}, \tag{83.69}$$

$$\mathcal{R}_\partial \mathsf{D}_\partial \mathcal{R}_\partial^* = 7560 I - \mathsf{D}_\partial, \tag{83.70}$$

$$\rho_\partial(-\Delta) = \mathcal{R}_\partial \rho_\partial(\Delta) \mathcal{R}_\partial^*, \tag{83.71}$$

$$s(-\Delta) = s(\Delta), \tag{83.72}$$

$$\langle \widehat{\mathcal{A}} \rangle_{-\Delta} + \langle \widehat{\mathcal{A}} \rangle_\Delta = 72 \gamma_{\mathrm{BI}} a_0 \ell_P^2, \tag{83.73}$$

$$\mathcal{D}\big(\rho_\partial(\Delta) \| \rho_\partial(-\Delta)\big) = \Delta\big(7560 - 2\langle \mathsf{D}_\partial \rangle_\Delta\big). \tag{83.74}$$

Proof. Each occupation transforms by $n \mapsto 2 - n$. In each sector, $\mathsf{N}_m \mapsto 36 I - \mathsf{N}_m$, so the constant term of the weighted reader is $36(90 + 120) = 7560$. Moreover, $z_m(-\Delta) = e^{2m\Delta} z_m(\Delta)$ and $Z(-\Delta) = e^{7560\Delta} Z(\Delta)$. Substitution into the normalized state proves conjugation. Its spectrum preserves entropy;

the transformation of N gives complementary area. Subtracting the logarithms of the two states and taking the expectation in $\rho_\partial(\Delta)$ gives the final equality. □

At $\Delta = 0$, $s = 36 \log 3$. As $\Delta \to +\infty$, zero occupation concentrates the state and entropy tends to zero; inversion carries that limit to maximal occupation. For $\Delta > 0$, entropy decreases strictly because the weighted reader has more than one eigenvalue and the state has full rank. The complete configuration, area, and entropy thus preserve differentiated roles.

83.4.4 Modular law and finite area variations

Fix $\rho_0 = \rho_\partial(\Delta_0)$, with real finite Δ_0, and hold $\Delta_0, \gamma_{\mathrm{BI}}, a_0, \ell_P$ constant. The normalized areas $\mathcal{A}^{\mathrm{n}}_m = \gamma_{\mathrm{BI}} a_0 \mathsf{N}_m$ express the modular operator as

$$\mathsf{K}_0 = -\log \rho_0 = c_0 I + \sum_{m=90,120} \beta_m \mathcal{A}^{\mathrm{n}}_m, \quad \beta_m = \frac{m\Delta_0}{\gamma_{\mathrm{BI}} a_0}, \quad c_0 = \log Z(\Delta_0). \tag{83.75}$$

One has $\beta_{120} = \frac{4}{3}\beta_{90}$, including when both are zero. The ratio is $4/3$ when $\Delta_0 \neq 0$. K_0 is the logarithm of this reference state; its type distinguishes it from temporal transport and the gravitational connection.

Theorem 83.14 (First modular law and finite correction)**.** *For any normalized state σ on the same space, let $\Delta_\sigma\langle B\rangle = \mathrm{Tr}[(\sigma - \rho_0)B]$. Then*

$$s(\sigma) - s(\rho_0) = \sum_{m=90,120} \beta_m \Delta_\sigma \langle \mathcal{A}^{\mathrm{n}}_m \rangle - \mathcal{D}(\sigma \| \rho_0), \tag{83.76}$$

where $\mathcal{D}(\sigma\|\rho_0) = \mathrm{Tr}[\sigma(\log\sigma - \log\rho_0)]$ is finite and nonnegative. If $\sigma(\varepsilon)$ is differentiable, normalized, and $\sigma(0) = \rho_0$, one obtains

$$\left.\frac{\mathrm{d}s(\sigma(\varepsilon))}{\mathrm{d}\varepsilon}\right|_0 = \sum_{m=90,120} \beta_m \left.\frac{\mathrm{d}\langle \mathcal{A}^{\mathrm{n}}_m \rangle_{\sigma(\varepsilon)}}{\mathrm{d}\varepsilon}\right|_0 . \tag{83.77}$$

Proof. By definition, $\mathcal{D}(\sigma\|\rho_0) = -s(\sigma) + \mathrm{Tr}(\sigma\mathsf{K}_0)$, whereas $s(\rho_0) = \mathrm{Tr}(\rho_0\mathsf{K}_0)$. Subtraction and (83.75) prove the finite identity, since normalization cancels the term $c_0 I$.

For positivity, diagonalize σ with eigenvalues p_i and vectors u_i, and ρ_0 with eigenvalues $q_j > 0$ and vectors v_j. If $r_i = \langle u_i, \rho_0 u_i\rangle > 0$, concavity of the logarithm gives

$$\sum_j |\langle u_i, v_j\rangle|^2 \log q_j \le \log r_i .$$

Consequently, $\mathcal{D}(\sigma\|\rho_0) \ge \sum_i p_i \log(p_i/r_i) \ge 0$. The final inequality is convexity of $t\log t$ with weights r_i, whose sum is one. Faithfulness of ρ_0 keeps its logarithms finite; zero eigenvalues of σ are interpreted through $0\log 0 = 0$.

For the infinitesimal formula, in a neighbourhood of the faithful state ρ_0, the derivative of the trace of $-\sigma\log\sigma$ is $-\mathrm{Tr}[\dot\sigma(\log\rho_0 + I)]$. This identity follows from the spectral derivative of the trace. The condition $\mathrm{Tr}\,\dot\sigma = 0$ leaves $\mathrm{Tr}(\dot\sigma\mathsf{K}_0)$, and substitution of (83.75) completes the proof. □

For physical areas, the coefficients are β_m/ℓ_P^2. Applying the common transducer k_B gives $S = k_B s$ and preserves the term $k_B\mathcal{D}$ in full. The derivative in (83.67) varies Δ; law (83.77) holds Δ_0 fixed and varies the state around the reference. These are different operations.

83.4.5 Action, decision energy, and areal unit

We fix the same oriented action section and its gravitational and thermal sections, on the positive branch. The antecedents provide

$$\begin{aligned} \ell_P^2 &= \frac{\hbar G}{c^3}, & t_P &= \frac{\ell_P}{c}, \\ T_{108} &= 2\pi t_P, & h &= 2\pi\hbar, \\ E_P &= \frac{\hbar}{t_P} = k_B\Theta_{\mathrm{clk}}\log 3. \end{aligned} \tag{83.78}$$

The thermal equality preserves the previously constructed pair and normalization; changing its dimensional basis transports k_B and Θ_{clk} jointly. The elementary area increment is $\delta\mathcal{A} = \gamma_{\mathrm{BI}} a_0 \ell_P^2$.

Proposition 83.15 (Conversion coefficient between decision and area)**.** *The ratio of decision energy to the areal increment satisfies*

$$\begin{aligned} \mathcal{T}_{I/A} := \frac{E_P}{\delta\mathcal{A}} &= \frac{k_B\Theta_{\mathrm{clk}}\log 3}{\gamma_{\mathrm{BI}} a_0 \ell_P^2} \\ &= \frac{c^3}{\gamma_{\mathrm{BI}} a_0 G t_P} = \frac{c^4}{\gamma_{\mathrm{BI}} a_0 G \ell_P}. \end{aligned} \tag{83.79}$$

Its dimension is energy per area.

Proof. Substitution of $E_P = \hbar/t_P$ and $\ell_P^2 = \hbar G/c^3$ cancels the common action section. The identity $\ell_P = c t_P$ gives the final expression. Positivity of the factors ensures that all quotients are defined. □

The capacity 81 of the cubic cut and the bipartition of the thirty- six sectoral links correspond to different domains. In the cubic graph $\{0,\dots,N-1\}^3$, the N^2 parallel lines between two opposite faces are edge-disjoint: every cut intercepts the N^2, and a transverse layer attains that bound. For $N = 9$, the uniform product state of the trits of that layer has $s_{\mathrm{corte}} = 81\log 3$. Assigning a decision of the same cycle to each link publishes

$$S^{\mathrm{fis}}_{\mathrm{corte}} = 81 k_B \log 3, \qquad E^{(1)}_{\mathrm{corte}} = 81 E_P = \Theta_{\mathrm{clk}} S^{\mathrm{fis}}_{\mathrm{corte}}. \tag{83.80}$$

The proof combines the minimum cut, additivity of product-state entropy, and (83.78). In the sectorial state, the relevant finite equation remains (83.76), with its relative entropy.

83.4.6 Cosmological normalization of the horizon

For an areal radius $R > 0$, the cosmological realization considered uses the triad

$$E_\Lambda(R) = \frac{c^4 R}{2G}, \qquad S_{\mathrm{H}}(R) = \frac{k_B \pi R^2}{\ell_P^2}, \qquad T_{\cos}(R) = \frac{\hbar c}{2\pi k_B R}. \tag{83.81}$$

The factor 2π belongs to this temperature normalization. The area $\mathcal{A}_{\mathrm{H}} = 4\pi R^2$ expresses the same entropy as $S_{\mathrm{H}}/k_B = \mathcal{A}_{\mathrm{H}}/(4\ell_P^2)$.

Theorem 83.16 (Gravitational half-action cell)**.** *In* (83.81)*,*

$$T_{\cos}(R) S_{\mathrm{H}}(R) = E_\Lambda(R), \tag{83.82}$$

$$T_{\cos}(\ell_P) S_{\mathrm{H}}(\ell_P) = \frac{E_P}{2} = \frac{k_B\Theta_{\mathrm{clk}}\log 3}{2}, \tag{83.83}$$

$$E_\Lambda(\ell_P) t_P = \frac{\hbar}{2}, \qquad E_\Lambda(\ell_P) T_{108} = \frac{h}{2}. \tag{83.84}$$

Keeping the chart constants fixed and varying R,

$$T_{\cos}\,\mathrm{d}S_{\mathrm{H}} = 2\,\mathrm{d}E_{\Lambda}, \qquad S_{\mathrm{H}}\,\mathrm{d}T_{\cos} = -\mathrm{d}E_{\Lambda}. \tag{83.85}$$

Proof. Multiplying temperature and entropy gives $\hbar cR/(2\ell_P^2) = c^4R/(2G)$. At $R = \ell_P$, the result is $\hbar/(2t_P) = E_P/2$. The two durations in (83.78) give the action relations. For the differentials, $\mathrm{d}E_{\Lambda} = c^4\mathrm{d}R/(2G)$, $\mathrm{d}S_{\mathrm{H}} = 2\pi k_B R\mathrm{d}R/\ell_P^2$, and $\mathrm{d}T_{\cos} = -T_{\cos}\mathrm{d}R/R$. Substitution proves both identities. □

The product $E_{\Lambda} = T_{\cos}S_{\mathrm{H}}$ expresses a state identity. Its radial variations preserve both terms of (83.85); a complete thermodynamic interpretation additionally specifies the corresponding time generator, work and material realization. In this chart, action and gravitation fix the unit ℓ_P^2, while Boltzmann converts information into dimensional entropy. Transport of sections with $G\hbar$ fixed preserves that unit when the section c is kept fixed, and preserves S_{H}/k_B at fixed radius.

In the cell $R = \ell_P$, $S_{\mathrm{H}}/k_B = \pi$, so the effective multiplicity is $\Omega_{\mathrm{eff}} = e^{\pi}$. For the tritic hyperbolic involution H_{trit}, with spectrum $\{1, -1\}$, diagonalization gives $\mathrm{spec}(e^{\pi H_{\mathrm{trit}}}) = \{e^{\pi}, e^{-\pi}\}$. This spectral relation specifies the expansive value; a microscopic identification of both spaces additionally preserves their realization map and the state.

83.4.7 Kruskal chart and exchange of the exteriors

Let us fix a published state x, its radius $R = R(x) > 0$ and the positive sections c, G. In the following chart, x, R, c, G are fixed parameters; t, r are the spacetime coordinates. The exterior realization of the two sheets is specified by

$$f(r) = 1 - \frac{R}{r}, \qquad \mathrm{d}s^2 = -f(r)c^2\mathrm{d}t^2 + f(r)^{-1}\mathrm{d}r^2 + r^2\mathrm{d}\Omega_2^2, \qquad r > R. \tag{83.86}$$

For the sheet reader $\sigma \in \{+1, -1\}$, define

$$r_* = r + R\log\left(\frac{r}{R} - 1\right), \tag{83.87}$$

$$\mathcal{U} = -\sigma\exp\left(-\frac{ct - r_*}{2R}\right), \qquad \mathcal{V} = \sigma\exp\left(\frac{ct + r_*}{2R}\right). \tag{83.88}$$

The symbols $\mathcal{U}, \mathcal{V}$ are coordinates and are distinguished from route-transport operators.

Theorem 83.17 (Geometric realization and sheet involution)**.** *Chart* (83.88) *realizes the two sheets as the two exteriors $\mathcal{U}\mathcal{V} < 0$ of the Kruskal extension. We have*

$$-\mathcal{U}\mathcal{V} = \left(\frac{r}{R} - 1\right)e^{r/R}, \qquad \mathrm{d}s^2 = -\frac{4R^3}{r}e^{-r/R}\,\mathrm{d}\mathcal{U}\,\mathrm{d}\mathcal{V} + r^2\mathrm{d}\Omega_2^2. \tag{83.89}$$

The involution

$$C_{\mathrm{H}} : (\sigma, \mathcal{U}, \mathcal{V}) \longmapsto (-\sigma, -\mathcal{U}, -\mathcal{V}) \tag{83.90}$$

is isometric, fixes the areal radius, exchanges the exterior regions, and preserves the horizon set $\mathcal{U}\mathcal{V} = 0$. The metric is regular at $r = R$ and satisfies the vacuum equations on the regular domain $r > 0$.

Proof. Multiplying the coordinates gives the first identity. Since $\mathrm{d}r_*/\mathrm{d}r = f^{-1}$,

$$\mathrm{d}\mathcal{U} = \frac{\mathcal{U}}{2R}(-c\,\mathrm{d}t + f^{-1}\mathrm{d}r), \qquad \mathrm{d}\mathcal{V} = \frac{\mathcal{V}}{2R}(c\,\mathrm{d}t + f^{-1}\mathrm{d}r).$$

Their product reproduces the radial and temporal part of the metric. The function $z \mapsto (z-1)e^z$ has derivative $ze^z > 0$ for $z > 0$, determining r from the product. In the exterior region one recovers $\sigma = \operatorname{sign}\mathcal{V}$ and $t = (R/c)\log(-\mathcal{V}/\mathcal{U})$. At $r = R$, the radial coefficient of the extended metric is $-4R^2/e$,

finite and nonzero. Inversion preserves the product, radius, and $\mathrm{d}\mathcal{U}\mathrm{d}\mathcal{V}$, and exchanges the two sign choices.

To check the vacuum in the exterior chart, the independent mixed components of the Einstein tensor reduce to

$$\mathsf{G}^{t}{}_{t} = \mathsf{G}^{r}{}_{r} = \frac{rf' + f - 1}{r^2}, \qquad \mathsf{G}^{\theta}{}_{\theta} = \mathsf{G}^{\phi}{}_{\phi} = \frac{f'}{r} + \frac{f''}{2}.$$

With $f' = R/r^2$ and $f'' = -2R/r^3$, all vanish. The regular expression (83.89) prolongs the result through the horizons on the domain $r > 0$. □

This realization preserves $E_{\mathrm{H}} = c^4 R/(2G)$ and $S_{\mathrm{H}} = k_B \pi R^2/\ell_P^2$, which depend on the areal radius. The temperature $T_{\cos}$ of (83.81) belongs to the cosmological realization declared there. The exterior chart (83.86) preserves its own temporal normalization. The geometric map establishes the exchange of exteriors; comparison with formation by collapse, radiation spectra or quasinormal modes additionally uses their respective physical conditions.

83.4.8 Transport of states, observables, and refinements

Let F_x denote the chart of the two exteriors just constructed. In each regular angular chart, its temporal and radial Jacobian is

$$\left|\frac{\partial(\mathcal{U},\mathcal{V})}{\partial(t,r)}\right| = \frac{cr}{2R^3} e^{r/R} > 0. \tag{83.91}$$

The identity follows from the two differentials of the preceding proof. The remaining state records are transported as fiber coordinates; the chart preserves its identity and memory.

Proposition 83.18 (Unitary equivalence of sheet and exterior readings)**.** *Let μ be a sheet measure and $\nu = (F_x)_*\mu$ its transported measure. Change of variables defines a unitary map*

$$W_{\mathrm{H}} : L^2(\mu) \longrightarrow L^2(\nu), \qquad (W_{\mathrm{H}}\psi)(z) = \psi(F_x^{-1} z). \tag{83.92}$$

With densities relative to fixed coordinate measures, the same map incorporates the corresponding Jacobian factor. Conjugation

$$\mathfrak{I}_{\mathrm{H}}(B) = W_{\mathrm{H}} B W_{\mathrm{H}}^{*} \tag{83.93}$$

is a unital completely positive $*$-isomorphism. It transports the state, its expectations, and its modular functional calculus. For the symmetric measure of the two sheets, it also intertwines their involutions.

Proof. The definition of pushforward measure gives $\int |\psi \circ F_x^{-1}|^2 \,\mathrm{d}\nu = \int |\psi|^2 \,\mathrm{d}\mu$. The chart is invertible in the exteriors, so the isometry is surjective. Unitary conjugation preserves product, adjoint and identity; in each matrix amplification it conjugates by $I_n \otimes W_{\mathrm{H}}$, proving complete positivity. For a state ρ, cyclicity of the trace gives $\mathrm{Tr}(W_{\mathrm{H}}\rho W_{\mathrm{H}}^{*}\, \mathfrak{I}_{\mathrm{H}}(B)) = \mathrm{Tr}(\rho B)$. Functional calculus implies $g(W_{\mathrm{H}}\rho W_{\mathrm{H}}^{*}) = W_{\mathrm{H}} g(\rho) W_{\mathrm{H}}^{*}$ on its domain, in particular for the logarithm and modular flow of a state faithful on its support. The equality $F_x \circ C_{\mathrm{hoja}} = C_{\mathrm{H}} \circ F_x$ proves the intertwining of involutions; the symmetric measure realizes them unitarily. □

If refinements preserve (σ, t, r, R) and use the same isometry on fibre records, the inclusions j_m^{hoja} and j_m^{ext} satisfy

$$W_{\mathrm{H},m+1}\, j_m^{\mathrm{hoja}} = j_m^{\mathrm{ext}}\, W_{\mathrm{H},m}. \tag{83.94}$$

Indeed, change of variables acts on the preserved geometric coordinates and inclusion on the same fibre coordinates; evaluating both compositions gives the same function and the same transported density. The equality extends the map to the refined system without resetting the records.

For a bipartition $\mathcal{H}_A \otimes \mathcal{H}_B$, a factorized transport $U_A \otimes U_B$ satisfies

$$\rho'_A = U_A \rho_A U_A^*, \qquad s(\rho'_A) = s(\rho_A).$$

The first identity follows from partial trace and the second from the spectrum. For a general unitary, the equivalent formulation also transports the subsystem algebra: $\mathcal{B}(\mathcal{H}_A) \otimes I \mapsto U(\mathcal{B}(\mathcal{H}_A) \otimes I)U^*$. This preserves the same operational question concerning accessible information. Entropy equalities apply to states with the relevant finite entropies.

The relation between information and gravitation is expressed through distinct composable operations: the state and bipartition fix accessible information; incidence and Barbero–Immirzi fix areal resolution; action and gravitation construct the unit ℓ_P^2; Boltzmann realizes entropy dimensionally; the horizon chart transports geometry and its observables. The finite laws preserve relative entropy, and the geometric realizations preserve their measures, temporal normalization and domains.

Chapter 84

Mach's principle and self-inertial systems: relational dependence among global closure, local inertia, and torsional memory

Local self-inertia is obtained as the dependence of the state on the global closure and its two propagation orientations. Torsional memory and action invariants determine the relational scope of Mach's principle.

84.1 Mach's principle, bidirectional propagation and collective gravitational response

84.1.1 Global dependence of the local response

Let $\mathcal{X}_\infty$ be the space of compatible sections, let $\mathrm{res}_v : \mathcal{X}_\infty \to X_v$ be the restriction to a local neighborhood, and let $b : \mathcal{X}_\infty \to B_\infty$ be the global boundary trace. A local inertial response $I_v : \mathcal{X}_\infty \to V_v$ is *Machian* when there exists $\overline{I}_v : \mathrm{im}(b) \to V_v$ such that

$$I_v = \overline{I}_v \circ b, \tag{84.1}$$

but I_v does not factor solely through res_v. In particular, there may exist x, x' with

$$\mathrm{res}_v(x) = \mathrm{res}_v(x'), \qquad b(x) \neq b(x'), \qquad I_v(x) \neq I_v(x').$$

The definition formalizes Mach's principle: the local response depends on the global closure class and not on an added absolute space [85]. This is the same local–global scheme that appears in the number cylinders, in holonomy, and in memory transport.

Theorem 84.1 (Criterion of factorization of the response by the totality)**.** *There exists to unique map $\overline{I}_v : \mathrm{im}(b) \to V_v$ that satisfies $I_v = \overline{I}_v \circ b$ if and only if I_v is constant on each fiber of b:*

$$b(x) = b(y) \quad \Longrightarrow \quad I_v(x) = I_v(y).$$

If b is surjective, the induced response is uniquely defined on all of B_∞.

Proof. Necessity follows by applying $\overline{I}_v$ to the equality $b(x) = b(y)$. For sufficiency, given $\beta \in \mathrm{im}(b)$, we define $\overline{I}_v(\beta) = I_v(x)$ for any $x \in b^{-1}(\beta)$. Constancy on the fibers makes the choice of representative immaterial; the factorization then fixes the value of $\overline{I}_v$ at every point of its domain and guarantees uniqueness. □

The relationship between state and coordinate is fixed by

$$[x]_{\mathfrak{F}} \neq x, \qquad q(x) \neq x, \qquad x \in \mathcal{X}_\infty.$$

The state preserves position, sheet, orientation, additive or multiplicative mode, quotient, carry, boundary, route, and memory; the observable publishes only one coordinate. The corresponding local frame is not added from outside, but is induced by restriction of the compatible totality and its connection:

$$\mathfrak{F}_v(x) := \mathrm{Res}_v\big(x, \nabla_{\mathrm{TPK}}\big). \tag{84.2}$$

Here $\mathcal{X}_\infty$ does not denote a verbal sum of the entire universe, but rather the system of compatible sections with orientation, boundary, and memory. Self-reference is coinductive, not circular: each section is recognized through the compatibility of all its truncations.

This formulation organizes the inertial and accelerated regimes by means of to single endogenous connection. For to curve γ, the covariant acceleration is

$$a_\gamma := \nabla_{\dot\gamma}\dot\gamma, \qquad a_\gamma = 0 \quad \Longleftrightarrow \quad \gamma \text{ is an affine geodesic of } \nabla.$$

If (e_a) is a tetrad along γ, the condition

$$\nabla_{\dot\gamma} e_a = 0$$

defines a parallel, nonrotating frame with respect to the connection. The rotation of a general frame is measured by its connection coefficients along γ, or by its deviation from Fermi–Walker transport when the latter is the selected kinematic standard. For an arbitrary field v, $D_\gamma v = 0$ means only parallel transport; its negation is not by itself equivalent to acceleration or rotation.

The physical difference is thus measured through covariant acceleration, frame rotation, torsion, curvature, and holonomy, without introducing an external privileged frame. In this sense, every persistent section is *self-inertial*: it carries the frame induced by its own insertion into the HMT totality.

Proposition 84.2 (Autonomy, return and holonomy)**.** *Let $E \to M$ the realization bundle, is γ to loop based at x_0 and let $\mathrm{Hol}_\nabla(\gamma) : E_{x_0} \to E_{x_0}$ the holonomy of the induced connection. TO datum $s_0 \in E_{x_0}$ transported in parallel returns exactly if and only if*

$$s_0 \in \mathrm{Fix}\big(\mathrm{Hol}_\nabla(\gamma)\big).$$

If the complete genealogical state is realized in E_{x_0} through an injective map on the compared sector, this condition is also equivalent to the return of the complete state. Without that injectivity, the conclusion refers exclusively to the datum in the fiber. If the visible coordinate returns and s_0 remains outside the fixed subspace, there is phase return with change of the transported state.

Proof. Transport around the loop acts on E_{x_0} by means of $\mathrm{Hol}_\nabla(\gamma)$. Equality between the final and initial data is equivalent, by definition, to s_0 being a fixed vector of the operator. The last equivalence is obtained by applying the injectivity of the realization to the declared sector. □

84.1.2 Advanced and Retarded Propagators on Oriented Paths

For a route γ between emission and absorption, the inversion $\gamma^\vee$ exchanges the endpoints and preserves the length of the trajectory. In the photonic realization of section 92.4, the pair $(\gamma, \gamma^\vee)$ represents the retarded and advanced orientations of one and the same null transport. A Möbius band preserves this memory of orientation: one turn exchanges the sheets and two turns restore the oriented section.

This structure provides a rigorous formulation of the intuition of a bidirectional pilot wave. The material state is not identified with an additional wave that pushes it from outside; the section and its phase are two readings of the same enriched transport. A concrete identification with advanced and retarded Green propagators nevertheless requires an intertwiner that preserves action, causality, and the inner product.

Proposition 84.3 (Conjugation of Orientation and Propagator Reversion)**.** *Let $H = H^*$ be a self-adjoint, possibly unbounded operator satisfying*

$$HJ_E = J_E H.$$

Let C be an orthogonal involution of the quantum realification that preserves $D(H)$ and satisfies, on that domain,

$$CJ_E C^{-1} = -J_E, \qquad CHC^{-1} = H.$$

Then

$$U(t) := \exp(-J_E H t/\hbar_{\mathrm{int}})$$

is a uniparametric unitary group and it holds

$$\boxed{CU(t)C^{-1} = U(-t)}.$$

Proof. The operator $A = -J_E H/\hbar_{\mathrm{int}}$ is skew-adjoint and generates $U(t)$ by Stone's theorem. The domain and conjugation hypotheses give $CAC^{-1} = -A$; functional calculus, or equivalently the uniqueness of the generated group, implies $C\exp(tA)C^{-1} = \exp(-tA)$. If H is bounded, the same identity is obtained term by term from the exponential series. □

The word involution $C_M = -\,\mathrm{rev}$ supplies the genealogical orientation datum. When its realization satisfies the hypotheses of the proposition, the particle and antiparticle branches are represented by propagators with conjugate temporal directions: the band geometry fixes the orientation, and the Hamiltonian fixes the dynamics.

The kinematic reading of compression and expansion is fixed, for $|\beta| < 1$, by the rapidity $\zeta = \operatorname{artanh}\beta$. For a proper frequency ω_0, the two Doppler orientations are

$$\omega_{\mathrm{comp}} = \omega_0 e^{\zeta} = \omega_0\sqrt{\frac{1+\beta}{1-\beta}}, \qquad \omega_{\mathrm{exp}} = \omega_0 e^{-\zeta} = \omega_0\sqrt{\frac{1-\beta}{1+\beta}}, \tag{84.3}$$

and satisfy

$$\omega_{\mathrm{comp}}\omega_{\mathrm{exp}} = \omega_0^2.$$

The reciprocity of (84.3) is a continuous realization of the bilayer pattern: one orientation contracts and its conjugate expands, while their product preserves the central scale. This does not identify the Doppler parameter with C^*, with R_{act}, or with a mass coefficient; the maps among those coordinates must be constructed separately.

84.1.3 Temporal Involution Invariants and Particle–Antiparticle Conjugation

The Kepler orbit, its Levi–Civita lift, and the Sommerfeld condition organize the phase over an elliptic cycle. In this branch

$$J_\gamma = \oint_\gamma p\,\mathrm{d}q$$

is the orbital action. This symbol is not conflated with the modular character $J_{\mathrm{mod}} = j - 744$, which belongs to Moonshine, or with the Jarlskog invariant J_{CKM}, which measures CP violation. The three objects share an abstract property —they are invariants obtained after closing a composition—, but they have distinct domains, units, and theorems.

The condition

$$\varepsilon_\gamma \exp\!\left(\frac{iJ_\gamma}{\hbar_{\mathrm{int}}}\right) = 1$$

explains why the sign holonomy shifts the Sommerfeld rule by one half. Together with $\mathrm{Area}(\theta) = \hbar^{\mathrm{ret}}_{\mathrm{HMT}}\theta$, it renders the closure 2π and the double circuit 4π visible: the former completes the scalar cycle; the latter restores a spin or Möbius section that has changed sheets after a single circuit.

84.1.4 Propagating curvature as a collective mode of geometry

The primary gravitational variable is transport: co-tetrad, connection, curvature, torsion, and holonomy. A gravitational wave is a propagating variation of curvature or of its holonomy class. The state type does not require an additional elementary spin-two coordinate. A quantum of helicities ±2, if it appears after reducing the constraints and quantizing the fluctuations, is a collective excitation of the geometric sector and not a primitive constituent.

The Machian reading reinforces this organization: the local perturbation measures a change in the global section. The component that does not remain in the observable curvature may be represented as local transport memory or contorsion only when the diagram between TPK and Cartan commutes; discrete memory is not identified with torsion by a nominal equality. Under that condition, the wave can

propagate without positing a fundamental graviton, and the local response preserves the information of the global closure.

84.1.5 Metric Hypotheses and Boundary Conditions of the Machian Realization

The temporal semantics of the TRIT assigns the memory of the past to return, the present update to the threshold, and future prolongation to the opening. The elliptic, Euclidean, and hyperbolic realizations translate those three regimes into closure, boundary, and divergence. This provides a geometric reading of matter as wound persistence and of propagation as hyperbolic opening.

Interpreting a closed particle as a collapsed two-dimensional section, an electron as the closure of two null modes, or a black hole as a global inversion of sheets yields theoretical consequences compatible with that architecture. They are not purely combinatorial identities: to attain physical status, they must realize a metric, solve the field equations, and reproduce the corresponding horizon, causality, and stability conditions. This separation preserves the explanatory power of the model without turning a geometric interpretation into an already obtained proof.

Hypothesis, domain, and conclusion

The Machian factorization, Möbius monodromy, Doppler reciprocity, and the phase condition are explicit mathematical constructions in their declared domains. Their joint identification with physical pilot waves, black holes, or cosmology constitutes a theoretical realization that must satisfy the indicated intertwiners and equations.

Prolongation of bidirectionality to the cosmological return of memory. Bidirectional propagation extends to torsional cosmology and the cyclic return of memory.

84.2 Self-inertia as connection endogenous of the joint state

Let ∇^{tot} be a connection on the space of joint states. The local frame of the observer is obtained by restriction:

$$\mathfrak{F}_O(\Gamma) = \mathrm{Res}_O(\Gamma, \nabla^{\mathrm{tot}}). \tag{84.4}$$

A complete trajectory $\Gamma(t)$ is self-inertial when

$$\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma = 0. \tag{84.5}$$

Let π_S be the projection to the observed subsystem and $\gamma_S = \pi_S \circ \Gamma$. We define the projection defect

$$\mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma) := \nabla^S_{\dot\gamma_S}\dot\gamma_S - \mathrm{d}\pi_S\left(\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma\right). \tag{84.6}$$

On an autoinertial trajectory lies

$$\boxed{a_S = \nabla^S_{\dot\gamma_S}\dot\gamma_S = \mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma).} \tag{84.7}$$

The acceleration of the subsystem measures the coupling and the degrees of freedom omitted by the projection. The whole possesses an endogenous connection; its shadows may exhibit acceleration, rotation, and effective force.

Definition 84.4 (Self-inertial state)**.** TO joint state is self-inertial with respect to a connection and to family of observers when its evolution satisfies equation (84.5) and each local frame is obtained by equation (84.4). The apparent forces of each subsystem are recorded by the defects $\mathcal{K}_{\pi_S}$.

The definition integrates observer and observable within a single dynamic. A change of frame corresponds to another restriction of the same state and the same connection. The distinction among affine transport, tetrad rotation, torsion, and curvature remains available in the geometric codomain.

84.3 Machian Criterion of Global Factorization

Let $b : \mathcal{X}_\infty \to B_\infty$ be the global boundary trace and let $I_v : \mathcal{X}_\infty \to V_v$ be a local inertial response. The response is Machian when there exists

$$\overline{I}_v : \operatorname{im} b \longrightarrow V_v, \qquad I_v = \overline{I}_v \circ b. \tag{84.8}$$

Theorem 84.5 (Machian Response Criterion)**.** *There is a unique map $\overline{I}_v$ satisfying equation (84.8) if and only if I_v is constant on each fiber of b:*

$$b(x) = b(x') \quad \Longrightarrow \quad I_v(x) = I_v(x'). \tag{84.9}$$

If b is surjective, $\overline{I}_v$ is defined on all B_∞.

Proof. The factorization implies constancy on the fibers. Conversely, for $\beta \in \operatorname{im} b$, we define $\overline{I}_v(\beta) = I_v(x)$ with $x \in b^{-1}(\beta)$. Constancy guarantees independence of the representative, and the factorization equation guarantees uniqueness. □

The criterion translates Mach's principle into a verifiable property: the local response is a reading of the global closure class. To prove genuinely global dependence, one additionally exhibits two states with the same local restriction and different boundary traces whose responses differ. This condition separates an effective global factorization from a response determined exclusively by the local neighborhood.

The gravitational scale Q of the CT108 clock provides a dimensionless realization of this reading:

$$\alpha_G(E_1, E_2) = \frac{E_1 E_2}{Q^2}. \tag{84.10}$$

The global clock fixes Q, each local section publishes E/Q, and the geometry responds through the compliance G/c^4. The equation provides a Machian chart of the gravitational response; the theorem 84.5 determines the factorization requirement that its realization on the complete state must satisfy.

84.4 Holonomy and hierarchy of returns

Let γ be a based loop in x_0, and let

$$\mathscr{H}_\gamma = \operatorname{Hol}_\nabla(\gamma) \tag{84.11}$$

the holonomy in the fiber E_{x_0}. A transported datum returns as a vector exactly when it belongs to

$$\operatorname{Fix}(\mathscr{H}_\gamma) = \{\psi : \mathscr{H}_\gamma \psi = \psi\}. \tag{84.12}$$

The self-inertial interpretation is condensed in this equality: the frame transported by the connection of the whole preserves the datum situated in the fixed subspace.

For a subalgebra of accessible observables $\mathcal{A}_O$, we define

$$\mathcal{R}_{\text{vec}} = \{\psi : \mathscr{H}_\gamma \psi = \psi\}, \tag{84.13}$$

$$\mathcal{R}_{\text{ray}} = \{\psi : \mathscr{H}_\gamma \psi = \mathrm{e}^{i\theta}\psi \text{ for some } \theta\}, \tag{84.14}$$

$$\mathcal{R}_{\text{obs}} = \{\psi : \langle \mathscr{H}_\gamma \psi, A \mathscr{H}_\gamma \psi \rangle = \langle \psi, A\psi \rangle \text{ for every } A \in \mathcal{A}_O\}. \tag{84.15}$$

Proposition 84.6 (Vector–ray–observable hierarchy)**.** *We have*

$$\boxed{\mathcal{R}_{\text{vec}} \subseteq \mathcal{R}_{\text{ray}} \subseteq \mathcal{R}_{\text{obs}}.} \tag{84.16}$$

Proof. A fixed vector is a fixed ray with zero phase. If $\mathscr{H}_\gamma \psi = \mathrm{e}^{i\theta}\psi$, the conjugate phases cancel in every quadratic expectation, so all accessible observables preserve their value. □

The monodromy nonadic naturally occupies this hierarchy:

$$g(k+9) = g(k), \qquad B_{k+9} \neq B_k \quad \text{in general.} \tag{84.17}$$

The phase return belongs to the observable reading; the change in B_k preserves the memory increment. An injective realization of the complete state in the fiber makes it possible to lift the criterion $\mathrm{Fix}(\mathscr{H}_\gamma)$ to total genealogical return. In the absence of that injectivity, the criterion asserts the return of the realized datum.

84.5 Möbius band and conjugation of orientations

On a dodecaphasic word $\mathbf{t} = (t_0, \dots, t_{11})$, the genealogical involution is

$$C_M(\mathbf{t}) = -\operatorname{rev}(\mathbf{t}), \qquad C_M^2 = I. \tag{84.18}$$

Let ℓ_{ret} be an enriched return loop whose lift has the sign character

$$\varepsilon_x : \langle \ell_{\mathrm{ret}} \rangle \simeq \mathbb{Z} \longrightarrow \{\pm 1\}, \qquad \varepsilon_x(\ell_{\mathrm{ret}}) = -1. \tag{84.19}$$

The associated interval bundle is

$$\mathcal{M}_x = ([0,1] \times [-1,1])/(0,u) \sim (1,-u). \tag{84.20}$$

Theorem 84.7 (Relative return of Möbius)**.** *Under the compatible lift of C_M, the loop and the character of equation (84.19), $\mathcal{M}_x$ has nonzero first Stiefel–Whitney class. One circuit exchanges the local orientations, and two circuits restore the orientation of the section.*

Proof. The transition function of the quotient equation (84.20) is the sign representation of $\pi_1(S^1)$. Its class w_1 is the nontrivial generator of $H^1(S^1; \mathbb{Z}/2\mathbb{Z})$. The first iteration multiplies the fiber coordinate by -1 and the second by $(-1)^2 = 1$. □

The formulation preserves three distinct returns: phase closure C_9, orientation return in the double cover, and the increment of memory in the lift $\mathbb{Z}$. One turn may restore the ray and change the vector; two turns restore the orientation and may preserve a different depth. The band expresses precisely the difference between publication and genealogy.

The even and odd sectors of a function f on the double cover are

$$f^+ = \frac{1}{2}(f + C_M^* f), \qquad f^- = \frac{1}{2}(f - C_M^* f). \tag{84.21}$$

The even part descends to the base; the odd part is a section of the sign line. Quadratic memory resides in the even sector, whereas orientation and linear charge reside in the odd sector.

84.6 Antiunitary conjugation and temporal orientation

The word involution C_M, the central inversion of the atlas, and the antiunitary conjugation of the realization in physical space have distinct domains. Let C be the antiunitary conjugation on a Hilbert realization, let $H = H^*$ be the Hamiltonian, and let J_E be the complex structure in the realification. Suppose

$$CJ_EC^{-1} = -J_E, \qquad CHC^{-1} = H, \qquad J_E H \subset H J_E, \tag{84.22}$$

with $J_E^* = -J_E$, $J_E^2 = -I$, and preservation of the domain of H. Commutation expresses the complex linearity of the dynamics with respect to the structure J_E.

Proposition 84.8 (Antiunitary reversal of evolution)**.** *For*

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}}), \tag{84.23}$$

we have

$$\boxed{CU(t)C^{-1} = U(-t).} \tag{84.24}$$

Proof. The generator $-J_E H/\hbar_{\mathrm{int}}$ is anti-self-adjoint. The hypotheses of equation (84.22) change its sign under conjugation. Functional calculus and uniqueness of the generated unitary group yield equation (84.24). □

When, additionally, a charge operator Q_{ch} and a mass observable M satisfy

$$CQ_{\mathrm{ch}}C^{-1} = -Q_{\mathrm{ch}}, \qquad CMC^{-1} = M, \tag{84.25}$$

the two orientations of the band are published as carriers of conjugate charge and shared even memory. The particle–antiparticle representation requires the intertwiner that lifts particle– antiparticle C_M to C and preserves the evolution. The identities equations (84.18) y (84.24) provide the two typed endpoints of that intertwiner.

The tritic temporal reader organizes the regimes according to

$$\begin{aligned} +1 &\longmapsto \text{return, memory and past,} \\ 0 &\longmapsto \text{torsional threshold and present,} \\ -1 &\longmapsto \text{bidirectional opening and future.} \end{aligned} \tag{84.26}$$

The assignment is to reader of the structure algebraic $J^2 = -1, 0, +1$. The promotion to curvatures of a spacetime requires a connection and a chart metric; the temporal reader meanwhile preserves its exact meaning of return, threshold, and opening.

84.7 Recoverability and Landauer's Principle

Landauer's thermodynamic principle locates the physical cost of logically irreversible erasure [78].

Let $(\Omega, 2^{\Omega}, \mu)$ to finite probabilized space, let $X : \Omega \to \mathcal{X}$ the complete state variable and let $q : \mathcal{X} \to Y$ to reader. The chain rule provides

$$\mathsf{H}(X) = \mathsf{H}(q(X)) + \mathsf{H}(X \mid q(X)). \tag{84.27}$$

The second summand is the information contained in the reader fiber.

Theorem 84.9 (Landauer zero of full transport)**.** *If $U : \mathcal{X} \to \mathcal{X}$ is a bijective update, then*

$$\boxed{\mathsf{H}(X \mid U(X)) = 0.} \tag{84.28}$$

The logical information erased by the update is null. For every physical protocol $\mathcal{P}_U$ that realizes it, the Landauer bound and its ideal reversible limit satisfy

$$\boxed{Q_{\mathrm{L}}[\mathcal{P}_U] \geq 0, \qquad \inf_{\mathcal{P}_U^{\mathrm{rev}}} Q_{\mathrm{L}}[\mathcal{P}_U] = 0.} \tag{84.29}$$

Proof. The inverse of U reconstructs X from $U(X)$; therefore, the conditional distribution is concentrated on a single state. Its entropy is zero, and the operation, which is logical, preserves information. The resulting thermodynamic bound is $Q_{\mathrm{L}} \geq 0$; reversible quasistatic protocols attain the ideal null infimum. This statement distinguishes the bound from the concrete dissipation of a device. □

The projected output $q(U(X))$ preserves part of the information and leaves in the fiber

$$\mathsf{H}(X \mid q(U(X))). \tag{84.30}$$

Let $M : \mathcal{X} \to \mathfrak{M}$ be a memory register, and define the enriched reader

$$\widehat{q}(x) = (q(x), M(x)). \tag{84.31}$$

Proposition 84.10 (Recoverability via output and memory)**.** *If $\widehat{q}$ is injective on the support of X, then*

$$\boxed{\mathsf{H}(X \mid q(X), M(X)) = 0.} \tag{84.32}$$

The quantity $\mathsf{H}(X \mid q(X))$ measures the additional memory required to recover the state from the visible output.

Proof. Injectivity on the support provides a deterministic inverse from $\widehat{q}(X)$ to X. The conditional entropy is therefore zero. The chain rule locates the difference between the visible reader and the enriched reader in the fiber of q. □

For the reset of a uniform trit, the logical entropy is $\log 3$, and the Landauer bound takes the form

$$\boxed{Q_{\text{reset}} \geq k_B \Theta \log 3.} \tag{84.33}$$

The structural identity of the clock,

$$E_P = k_B \Theta_{\text{clk}} \log 3, \tag{84.34}$$

evaluates that bound at the declared chronological temperature. The Planck quantum then appears as the minimum cost of resetting a uniform ternary decision in that thermal chart.

The zero Landauer cost and the cost $k_B \Theta \log 3$ describe different operations. The former corresponds to the bijective transport of the enriched state; the latter corresponds to a reset that identifies three registers. The costs of control, finite speed, preparation, and coupling to the environment belong to the physical realization of the device. The logical equality of zero minimum cost preserves information; an equation of motion for a bounce or a cosmological cycle additionally requires boundary dynamics and its balance laws.

84.8 Reversible measurement, conditioning, and reinitialization

The operations of the complete process are ordered as

$$\boxed{\begin{array}{c}\text{preparation} \longrightarrow \text{reversible coupling} \longrightarrow \text{pointer reading} \\ \longrightarrow \text{fiber conditioning} \longrightarrow \text{reinitialization}\end{array}} \tag{84.35}$$

Each arrow has its own informational balance:

(i) Unitary premeasurement preserves purity and norm in the composite system.

(ii) The reading publishes $q(X)$ and preserves the record $M(X)$ in the apparatus.

(iii) Conditioning selects the relative fiber and normalizes its measure.

(iv) The nonselective channel sums all instruments and preserves the trace.

(v) Resetting identifies registers and activates the Landauer bound corresponding to the erased information.

This chain localizes the origin of operational irreversibility. The global state may evolve isometrically while a partial reading exhibits increasing entropy. Information accessible to one branch and information preserved in global correlations are distinct magnitudes. The coupled observer forms part of those correlations, and its memory constitutes a physical component of the joint state.

84.9 Confluence of observation, self-inertia, and modular response

The above results are assembled into the causal chain.

$$\begin{aligned} \text{enriched APP–TRIT–TPK state} &\longrightarrow (\text{section, observer, memory}) \\ &\longrightarrow (\text{fiber, PVM, instrument}) \\ &\longrightarrow (\text{relative state, holonomy, induced frame}) \\ &\longrightarrow (\text{Machian response, Typed Landauer}). \end{aligned} \tag{84.36}$$

The modular structure of the preceding chapter adds the pair

$$(\widehat{\mathcal{A}}, K_A), \tag{84.37}$$

which preserves geometric quantity and provenance. The observer accesses a compression of this pair through its PVM; the memory preserves the channel from which the result originates; autoinertia transports the frame along the connection; relative entropy measures the cost of changing genealogical state; and Landauer localizes the cost of the effective erasure of the record.

The relation to Everett lies at the first level of this chain: the isometry preserves the superposition of registers, and the observer occupies a relative state. The relation to Mach lies at the connection level: the frame and the local response are induced from the compatible totality. The Möbius band lies at the holonomy level: the orientation can change while the ray and the accessible observables return. The three readings share the enriched state and preserve different mathematical functions.

84.10 Domain of validity and physical realization conditions

The probative force is distributed as follows:

(i) The fibre–PVM–Lüders correspondence, the Kraus representation, the CPTP channel, and the dilation are *exact results retrieved* in the declared domains.

(ii) The formulation of the relative state and the conservation, isometric in character, of the channel are *exact sciences*. The Everettian ontology of branches and their macroscopic stability belong to a *interpretive and dynamic interface*.

(iii) The criterion Fix(Hol), the vector–ray–observable hierarchy and the Machian factorization are *exact results retrieved*. Its application to a gravitational geometry requires the corresponding realization morphism.

(iv) The Möbius band is *exacta relativamente* to the lift, to the loop, and to the declared sign character. The interpretation of particle–antiparticle requires the antiunitary intertwiner of equation (84.22).

(v) The zero Landauer cost of a bijective update, the recoverability of the enriched reader, and the ternary reset bound are *exact results retrieved*. The cosmological selector and the dynamics of sheets prolong these balances by means of the declared equations of evolution, splicing conditions, and torsional memory.

Estatuto probatorio

The chapter proves in its finite domains the equivalence of conditionings, preservation of the global channel, the return and factorization criteria, and the logical Landauer balances. The joint realization employs the isometric intertwiner between the TPK memory and the apparatus, the dynamic stability of the finite register, and transport of the genealogical involution to antiunitary conjugation with its even and odd observables.

Falsification criterion

The corresponding statements are refuted by: a nonmeasurable fiber; a family of projectors lacking a common PVM; a Lüders conditioning that differs from equation (66.54); Kraus operators whose sum of effects differs from the identity; a dilation with $V_a^\dagger V_a \neq I$; an exact vector return attributed to a datum outside Fix(Hol); a Machian response varying within a fiber of b; a loop with a trivial sign character presented as a Möbius strip; a conjugation that fails to satisfy $CU(t)C^{-1} = U(-t)$; a bijective update with positive conditional entropy; or a uniform ternary reset whose balance omits the information $\log 3$. A cosmological promotion is also refuted by presenting zero Landauer as a dynamical bounce equation.

84.11 Relational Dynamics of Frames: Autoinertia, Ambivalence, and Mach's Principle

Classical inertia characterizes the persistence of a state of motion. Mach's question [85] shifts the emphasis from the isolated body toward the relation between that body and the material totality. In genealogical language, the same question is formulated without separating the observer from the boundary it reads: a local frame is the restriction of a globally compatible state, and the inertial response is Machian when it depends on the totality through a well-defined boundary trace.

The word *self-inertial* does not designate a system disconnected from the rest. It designates a section that coherently transports the frame induced by its own insertion into the whole. Its persistence is internal to the global state and is verified by means of a connection.

84.11.1 Totality, Trace, and Local Response

Let Ω_{tot} be the space of global sections and $b : \Omega_{\mathrm{tot}} \to \mathcal{B}$ its trace on a boundary. For a region or vertex v, let

$$\mathcal{I}_v : \Omega_{\mathrm{tot}} \longrightarrow \mathcal{Y}_v$$

the local inertial response.

Definition 84.11 (Machian Factorization)**.** The response $\mathcal{I}_v$ is Machian with respect to b when there exists an induced map $\overline{\mathcal{I}}_v : \mathrm{im}(b) \to \mathcal{Y}_v$ such that

$$\mathcal{I}_v = \overline{\mathcal{I}}_v \circ b. \tag{84.38}$$

Theorem 84.12 (Completeness Factorization Criterion)**.** *There exists a unique map $\overline{\mathcal{I}}_v : \mathrm{im}(b) \to \mathcal{Y}_v$ that satisfies (84.38) if and only if $\mathcal{I}_v$ is constant over each fiber of b:*

$$b(x) = b(y) \quad \Longrightarrow \quad \mathcal{I}_v(x) = \mathcal{I}_v(y).$$

If b is surjective, $\mathrm{im}(b) = \mathcal{B}$ and the factorized map is uniquely defined on all of $\mathcal{B}$.

Proof. Necessity is immediate. For sufficiency, given $\beta \in \mathrm{im}(b)$, we define $\overline{\mathcal{I}}_v(\beta) = \mathcal{I}_v(x)$ for any $x \in b^{-1}(\beta)$. Constancy on the fibers ensures that the definition is independent of the representative; the factorization equality itself forces its value at each $\beta \in \mathrm{im}(b)$ and thereby ensures uniqueness. If b is surjective, this domain coincides with $\mathcal{B}$. □

The criterion gives a positive formulation of Mach's principle: the global boundary contains exactly the information of the totality that governs the local response. The interior state may conserve more genealogy; inertia depends on the class published by the trace.

84.11.2 Self-inertial sections as geodesics of the joint state of system, observer, and memory: $D_\gamma s_\gamma = 0$

Let $\mathcal{E} \to \Gamma$ to vector bundle of local states along to route γ, and is D to linear connection induced by TPK transport.

Definition 84.13 (Self-inertial Section)**.** A persistent section s_γ is self-inertial on a segment if

$$D_\gamma s_\gamma = 0. \tag{84.39}$$

Equivalently and discretely, the state at each vertex is the parallel transport of the preceding state by the route morphism.

Equation (84.39) preserves orientation, memory, and signature in the sense determined by the connection. A coordinate acceleration can coexist with parallel transport when the reference frame also changes. The distinction between inertial motion and force is thus tied to the connection, not to the appearance of the trajectory in an isolated chart.

Proposition 84.14 (Persistence and Holonomy)**.** *Let γ be a loop and $\mathrm{Hol}_D(\gamma)$ its holonomy. A self-inertial section returns exactly to its initial state if and only if it belongs to the fixed subspace of $\mathrm{Hol}_D(\gamma)$. If the visible projection returns and the initial state lies outside $\mathrm{Fix}(\mathrm{Hol}_D(\gamma))$, the coordinate returns and the state changes.*

This result links self-inertia and monodromy. Observable periodicity does not imply closure of the lift; the deficit or excess of holonomy records the accumulated response of the frame.

84.11.3 Ambivalence Principle: Bidirectional Involution of the Readers π/φ^2 and φ/π^2

The HMT cell admits two complementary readings: areal and volumetrica. Let q_A the boundary or area reader and q_V the interior or volume reader. The transport T_{AV} relates the two without identifying them.

Principle 84.15 (Areal-volumetric Ambivalence)**.** A complete physical realization conserves the pair

$$\big(q_A(x), q_V(x), T_{AV}(x)\big). \tag{84.40}$$

The areal reading expresses how the state impinges on a boundary; the volumetric reading expresses how it occupies and transports the interior. The third datum preserves the transformation between them.

In Dimensional Mechanics, the areal–volumetric relation organizes the HMT extension of the equivalence principle. A single section may be read as a boundary response and as an interior density. When both readings are transported by the same local connection, the inertial and gravitational descriptions belong to a single state class.

Comparison Criterion 84.16 (Typed local equivalence)**.** The identification of an inertial response with a gravitational response is proved in a region U when:

1. q_A and q_V are defined on the same section;
2. there exists an intertwiner T_{AV} that preserves its units and orientations;
3. the connection transporting both readers coincides on U;
4. the observational difference vanishes in the declared local frame.

The formulation preserves the equivalence and shows which data realize it. Its application to the electron belongs to the first physical closure of the mass law; the present annex uses only the geometric scheme.

84.11.4 Causal Coordination Between Inertial Transport, Areal–Volumetric Double Reading, and Machian Factorization

The three principles are causally ordered:

$$\boxed{\begin{array}{lll} \text{persistence of the section} & \longrightarrow & D_\gamma s = 0, \\ \text{double reading of the same state} & \longrightarrow & (q_A, q_V, T_{AV}), \\ \text{dependence of the local response on the whole} & \longrightarrow & \mathcal{I}_v = \overline{\mathcal{I}}_v \circ b. \end{array}} \tag{84.41}$$

The principle of inertia fixes the transport; Ambivalence fixes the two physical readings; Mach fixes the global quotient that governs the local frame. Together they produces to relational theory of motion in the that the observer, the apparatus, and the body belong to to common section.

84.11.5 Measurement of motion and frame coupling

Measuring velocity or acceleration requires comparing the system with a clock and a ruler. Those objects are part of the apparatus. Let F_S be the system frame and F_M the observer frame. The measurement coupling constructs a relative transformation

$$G_{MS} = F_M^{-1} F_S.$$

The published velocity, acceleration, and phase are invariants or components of G_{MS}, not properties without reference. Repetition of the experiment preserves the context by jointly transporting apparatus and boundary.

This formulation recovers Weyl's intuition [132]: measuring an amplitude or a length entails coupling a gauge rule. HMT adds the genealogy of that rule. The result can be traced back to the state of the apparatus, to the reader, and to the transport that fixed its scale.

84.11.6 Bidirectional wave and temporal orientation

A persistent route admits advanced and retarded channels. The reversal of orientation acts on the word and the ledger; in the linear realization, it exchanges the corresponding propagators when the Hamiltonian possesses the declared symmetry. Bidirectional motion is expressed by a pair

$$(U_{\mathrm{ret}}, U_{\mathrm{adv}})$$

related by conjugation and time reversal.

The particle–antiparticle band realizes this duality as two orientations of the same section. The dynamical relation can be expressed exactly.

Proposition 84.17 (Conjugation of Orientation and Propagator Reversion)**.** *Let C be an orthogonal involution on the quantum realification such that*

$$C J_E C^{-1} = -J_E, \qquad C H C^{-1} = H.$$

Then, for $U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}})$,

$$C U(t) C^{-1} = U(-t).$$

Proof. Withjugation commutes with the exponential series and transforms the generator $-J_E H$ in $+J_E H$. The result is the exponential evaluated at $-t$. □

The word involution $C_M = -\mathrm{rev}$ provides the genealogical orientation datum. When its realization satisfies the two identities of the proposition, the particle and antiparticle branches are represented

by propagators with conjugate temporal directions. The band geometry fixes the orientation, and the Hamiltonian fixes the dynamics.

84.11.7 Global expansion and self-consistency equation

A genealogical cosmology can be formulated through an operator $\mathcal{T}$ that carries one boundary totality to the next:

$$B_{n+1} = \mathcal{T}(B_n).$$

The locally induced response is

$$\mathcal{I}_{v,n} = \overline{\mathcal{I}}_v(B_n).$$

A global self-inertial regime corresponds to a stable orbit or fixed point of the transport operator, while expansion is recorded by a scale cocycle a_{n+1}/a_n. This formulation separates three questions: existence of the dynamics, stability of the solution, and identification of the cocycle with the observed cosmological factor.

Result

Local inertia may be typed as the parallel transport of a section; its Machian dependence is expressed as factorization through the global boundary trace. The Ambivalence Principle links the areal and volumetric readings of the same state. The observer enters through the coupling of frames that makes measurement possible.

Hypothesis, domain, and conclusion

The definition of self-inertia and the Machian factorization are recovered results. The dimensional criterion and the measuring instrument follow from the preceding chapters. The synthesis (84.41) is a new formalization of a pre-existing authorial architecture. A quantitative cosmological equation requires fixing $\mathcal{T}$, its metric, and its boundary data.

The Machian attribution is characterized by the constancy of the local response along the fibers of the global trace. Self-inertia is characterized by parallel transport and by the fixed subspace of the holonomy. In a cosmological realization, the operator $\mathcal{T}$, its metric, and the scale cocycle turn these structural conditions into a quantitative evolution of the totality.

84.12 Self-inertial response and Mach's principle from Ambivalence

Let $b : \mathcal{X}_\infty^{\mathrm{enr}} \to B_\infty$ be the global boundary trace. On B_∞, the positive readers $A(\beta)$, $V(\beta)$, the global clock $Q(\beta) > 0$, and the memory $T(\beta)$ are preserved. The Ambivalence hinge provides

$$r_{\mathrm{av}} = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2}, \qquad r_{\mathrm{av}}^J = \frac{\varphi_{\mathrm{HMT}}}{\pi_{\mathrm{HMT}}^2}.$$

We define weights, without external gravitational data,

$$w_A(\beta) = \frac{A(\beta) r_{\mathrm{av}}}{A(\beta) r_{\mathrm{av}} + V(\beta) r_{\mathrm{av}}^J}, \qquad w_V(\beta) = 1 - w_A(\beta).$$

Let P_A, P_V be complementary orthogonal projections of the local space of response. For internal energies E_1, E_2, the HMT self-inertial response is

$$\overline{I}_v^{\mathrm{HMT}}(\beta) = \frac{E_1 E_2}{Q(\beta)^2} \big(w_A(\beta) P_A + w_V(\beta) P_V \big),$$

and

$$I_v^{\mathrm{HMT}} = \overline{I}_v^{\mathrm{HMT}} \circ b.$$

Theorem 84.18 (Machian Closure of the Ambivalence Response)**.** *The response I_v^{HMT} is self-adjoint, positive, and constant on each fiber of b. Therefore, it factors uniquely through the global totality. The Ambivalence involution that exchanges*

$$(A, r_{\mathrm{av}}, P_A) \longleftrightarrow (V, r_{\mathrm{av}}^J, P_V)$$

conjugates $\overline{I}_v^{\mathrm{HMT}}$ without changing its spectrum. If there exist x, x' with the same local restriction, $b(x) \neq b(x')$ and distinct Q, A or V, then the response does not factor only through the local restriction and is Machian in the strong sense.

Proof. The weights are positive and sum to one; the combination of projections is positive and self-adjoint. The formula depends only on $b(x)$, hence it is constant on its fibers and applies the factorization criterion through the totality. The exchange permutes the two spectral blocks. The final claim is precisely the negative control against a purely local response. □

The construction also has a recovered geometric reading. For the joint state $\Gamma = (x, O, m)$, let $\nabla^{\mathrm{tot}}_{b(x)}$ be the connection induced by the boundary and let π_S be the projection onto the subsystem. If

$$\nabla^{\mathrm{tot}}_{\dot\Gamma} \dot\Gamma = 0,$$

the published acceleration is

$$a_S = \nabla^S_{\dot\gamma_S} \dot\gamma_S = \mathcal{K}^{b(x)}_{\pi_S}(\dot\Gamma, \dot\Gamma).$$

Since the defect depends on the connection induced by $b(x)$, it also factors through the whole. This mathematically completes the replacement of the inertial/noninertial dichotomy by self-inertial systems: the total state is geodesic, and local acceleration is a projection defect. The equality of this response with an observed gravitational acceleration belongs to EXTERNAL RECOGNITION.

84.13 Observer, memory, and relational response

The reading operation acts on the transport published by the APP–TRIT–TPK enriched state. Its domain preserves route, sheet, orientation, carry and memory; the result accessible to the observer is a map of that domain. This distinction allows three operations to be described together: choosing an oriented representative of transport, inscribing its record in an apparatus and the local response induced by the global boundary. Each operation transmits different information. The following construction specifies their maps and the conditions allowing them to be composed.

84.13.1 Boundary transport and intrinsic reading

The finite publication of transport provides an oriented cycle C_n, with $n \geq 1$, vertices $0, \ldots, n-1$ and edges $e_j : j \longrightarrow j+1 \pmod n$. We fix the lattice realization L of the record, its vector space $W = L \otimes_{\mathbb{Z}} \mathbb{R}$, a positive inner product and the nonzero primitive representative $v \in L$ of the distinguished residual class, in the declared chamber. The APP sum and product sheets provide the transport polarizations; TRIT orientation and TPK updating precede this linear publication. The cycle, the lattice realization and the residual class are the data this section receives from the transport constructed previously.

A 0-cochain is a function on the vertices with values in W; a 1-cochain assigns a vector to each oriented edge. The coboundary acts by

$$(d\Phi)(e_j) = \Phi(j+1) - \Phi(j).$$

We denote by $\mathbf{1}_E$ the constant scalar cochain on the edges. For a transport $\omega \in C^1(C_n; W)$, its accumulated publication Γ_ω is obtained through partial sums and affine interpolation; its closure defect is

$$B(\omega) = \Gamma_\omega(1) - \Gamma_\omega(0) = \sum_{j=0}^{n-1} \omega(e_j). \tag{84.42}$$

Theorem 84.19 (Exact decomposition and harmonic mode of the cycle)**.** *Every transport has a unique decomposition*

$$\omega = d\Phi + u\mathbf{1}_E, \qquad \Phi(0) = 0, \qquad u = \frac{1}{n}\sum_j \omega(e_j).$$

In particular, $B(d\Phi) = 0$ *and* $B(\omega) = nu$.

Proof. Let $y_j = \omega(e_j) - u$. The sum of the y_j is zero. We define $\Phi(k) = \sum_{j=0}^{k-1} y_j$; the value for $k = n$ coincides with $\Phi(0) = 0$, so the function is well defined on the cycle, including its final edge. We have $d\Phi(e_j) = y_j$. If $d\Phi + u\mathbf{1}_E = d\Psi + w\mathbf{1}_E$, the sum over edges gives $nu = nw$. Then $d(\Phi - \Psi) = 0$; connectivity of the cycle and normalization at the initial vertex imply $\Phi = \Psi$. The identity $\sum_j(\Phi(j+1) - \Phi(j)) = 0$ directly proves telescopic cancellation. □

Definition 84.20 (Admissible transport and normalized reading)**.** Transport is admissible when its harmonic mode belongs to $\mathbb{R}v$. On the space $\mathcal{T}_{\mathrm{adm}}$ of those transports we define the global reading and its density per phase:

$$\mathfrak{a}_v(\omega) = \frac{\langle B(\omega), v\rangle}{\langle v, v\rangle}, \qquad \mu_v(\omega) = \frac{\mathfrak{a}_v(\omega)}{n}. \tag{84.43}$$

We have $B(\omega) = \mathfrak{a}_v(\omega)v$.

Theorem 84.21 (Determination of the intrinsic reading)**.** *The quotient* $\mathcal{T}_{\mathrm{adm}}/dC^0(C_n; W)$ *is one-dimensional, generated by the class of* $v\mathbf{1}_E$. *The map* μ_v *is the unique linear functional on* $\mathcal{T}_{\mathrm{adm}}$ *satisfying*

$$F(\omega + d\Phi) = F(\omega), \qquad F(v\mathbf{1}_E) = 1.$$

Proof. The preceding decomposition writes each admissible transport as $d\Phi + \lambda v\mathbf{1}_E$. Its class modulo exact cochains is determined by λ. The class of $v\mathbf{1}_E$ is nonzero because its sum is $nv \neq 0$. By linearity and invariance, every functional with the indicated characteristics equals $F(\omega) = \lambda F(v\mathbf{1}_E) = \lambda$. The formula (84.43) gives precisely $\mu_v = \lambda$. The global reading is $\mathfrak{a}_v = n\mu_v$. □

Definition 84.22 (Edge Observer)**.** Given the polarization of the published transport, a boundary observer is a pair $O = (\varepsilon, \Psi)$, where $\varepsilon \in \{+1, -1\}$ and $\Psi \in C^0(C_n; W)$. Its reading action is

$$\omega^O = \varepsilon\omega + d\Psi. \tag{84.44}$$

The sign fixes the orientation and the cochain fixes the trivialization. Two polarization choices are compared through their published transport; the relation (84.44) describes exactly the representatives differing by orientation and coboundary.

Proposition 84.23 (Covariance of the reading)**.** *The action preserves admissibility and satisfies*

$$B(\omega^O) = \varepsilon B(\omega), \quad \mathfrak{a}_v(\omega^O) = \varepsilon\mathfrak{a}_v(\omega), \quad \mu_v(\omega^O) = \varepsilon\mu_v(\omega).$$

Trivializations with the same orientation publish the same closure.

Proof. The sum of the coboundary $d\Psi$ is zero. Therefore, the harmonic mode transforms into εu, which still belongs to $\mathbb{R}v$, and the defect transforms into εB. The two scalar equalities are obtained by normalized projection. □

The unit of this reading is the residual representative v, with its internal normalization. Trivialization freedom acts on the cochain representative; closure information resides in its class. The description allows observers to be compared while keeping genealogical transport, its linear publication and the scalar evaluating the residual class separate.

84.13.2 Boundary identity and cellular interior

Let K be a finite oriented two-dimensional cell complex, equipped with a fundamental 2-chain c_K such that $\partial c_K = [C_n]$. This condition expresses that interior incidences cancel with their multiplicities and orientations. Let $\Omega \in C^1(K; W)$ be an extension of ω and $F_\Omega = d\Omega$ its additive discrete curvature.

Theorem 84.24 (Cellular holographic identity of the reading)**.** *With the preceding data,*

$$B(\omega) = \langle \Omega, \partial c_K \rangle = \langle d\Omega, c_K \rangle, \qquad \mathfrak{a}_v(\omega) = \frac{\langle \langle d\Omega, c_K \rangle, v \rangle}{\langle v, v \rangle}. \tag{84.45}$$

In particular, $F_\Omega = 0$ implies $\mathfrak{a}_v(\omega) = 0$. If closure is nonzero, every extension of transport on that complex has nonzero discrete curvature.

Proof. The pairing between chains and cochains satisfies $\langle d\Omega, c_K \rangle = \langle \Omega, \partial c_K \rangle$. When it is expanded, each interior edge appears with the sum of the incidence numbers of the adjoining cells; the condition on ∂c_K leaves exactly the oriented boundary cycle. The restriction of Ω to that cycle is ω, whose sum is $B(\omega)$. Projection onto v gives the second formula and the flatness implication. □

The equality compares two evaluations of the same extended cochain: the accumulated boundary defect and the coboundary integrated over the interior. Its curvature takes values in W and uses the additive cellular coboundary. Realization by a geometric connection additionally preserves its own coefficient space and transport law.

84.13.3 Isometric inscription of the record in the apparatus

Let $\mathfrak{M}_n$ be a nonempty finite set of records published at level n, with result, route, carry, sheet and memory. Its record space is $\mathcal{H}_n = \ell^2(\mathfrak{M}_n)$, with basis $|m\rangle$. The visible update F_n has a record lift

$$\widehat{F}_n(m) = (F_n(m), m).$$

We take as records of the next level a set containing those pairs. The second coordinate preserves the antecedent and makes the lift injective. This construction specifies the memory retained by inscription, including when the visible update merges values.

In a finite apparatus space $\mathcal{K}_{A,n}$, we fix an orthonormal family $(|a_m\rangle)_{m \in \mathfrak{M}_n}$ and define

$$\iota_n : \mathcal{H}_n \longrightarrow \mathcal{K}_{A,n}, \quad \iota_n |m\rangle = |a_m\rangle, \qquad V_n : \mathcal{H}_n \longrightarrow \mathcal{H}_{n+1}, \quad V_n |m\rangle = |\widehat{F}_n(m)\rangle.$$

Let $\mathcal{P}_n = \iota_n \mathcal{H}_n$ be the pointer subspace.

Theorem 84.25 (Compatibility between updating and inscription)**.** *The maps ι_n and V_n are isometries. There exists a unique isometry $W_n^0 : \mathcal{P}_n \longrightarrow \mathcal{K}_{A,n+1}$ satisfying*

$$W_n^0 \iota_n = \iota_{n+1} V_n. \tag{84.46}$$

If $\dim \mathcal{K}_{A,n+1} \geq \dim \mathcal{K}_{A,n}$, it extends to an isometry of all of $\mathcal{K}_{A,n}$. Through auxiliary complements equalizing dimensions, a unitary extension between the enlarged spaces is obtained.

Proof. The basis images under ι_n are orthonormal; the images under V_n are also orthonormal by injectivity of $\widehat{F}_n$. For $z = \iota_n \psi$ we define $W_n^0 z = \iota_{n+1} V_n \psi$. The representation of z is unique, and the three maps

preserve its norm. The formula determines the map on a basis of $\mathcal{P}_n$ and proves the square. If the target dimension is sufficient, the orthogonal complement of $W_n^0\mathcal{P}_n$ contains an orthonormal family of the size of $\mathcal{P}_n^\perp$; sending a basis of the latter to that family constructs the extension. Finally both spaces are enlarged to the same dimension and the two prescribed families are completed to orthonormal bases. The map between those bases is unitary. □

When the record includes labels of a finite instrument, this same inscription realizes its environment: if the operators $K_{y,a} : \mathcal{H}_S \to \mathcal{H}'_S$ satisfy $\sum_{y,a} K_{y,a}^* K_{y,a} = I$, the map

$$V_{\mathrm{inst}}\psi = \sum_{y,a} K_{y,a}\psi \otimes |y, a\rangle$$

is isometric, since its squared norm is $\sum_{y,a}\langle\psi, K_{y,a}^* K_{y,a}\psi\rangle = \|\psi\|^2$. The inscription ι transports each label to its corresponding pointer. The model thus fixes the premeasurement record; a material device additionally requires its interaction and calibration.

84.13.4 Accessible algebra and pointer complement

Define $P_m = |a_m\rangle\langle a_m|$, $P = \sum_m P_m$, and $P_\perp = I - P$. The algebra of the pointer subspace is $P\mathcal{B}(\mathcal{K}_{A,n})P$, whose unit is P. On it, the diagonal reader is

$$\mathcal{D}_P(A) = \sum_m P_m A P_m.$$

Proposition 84.26 (Record expectation and unital extension)**.** *The map $\mathcal{D}_P$ is a completely positive, trace-preserving and idempotent conditional expectation onto the pointer algebra, with $\mathcal{D}_P(P) = P$. Its image is $\bigoplus_m \mathbb{C}P_m$. On the algebra of the complete apparatus, the map*

$$\mathcal{E}_P(A) = \sum_m P_m A P_m + P_\perp A P_\perp \tag{84.47}$$

is a unital, completely positive, trace-preserving conditional expectation. Its image is

$$\left(\bigoplus_m \mathbb{C}P_m\right) \oplus \mathcal{B}(\mathcal{P}_n^\perp).$$

Both maps are orthogonal projections for the Hilbert–Schmidt inner product. Their spectra are contained in $\{0, 1\}$. When eliminated components exist, the separation between the fixed subspace and the kernel is one.

Proof. The projectors P_m are mutually orthogonal. In the complete apparatus, the family that adds $P_\perp$ sums to I. Each term $A \mapsto P_m A P_m$ is completely positive: after any matrix amplification it acts by congruence with $I \otimes P_m$. The same holds for $P_\perp$. The sum preserves that property. Cyclicity of the trace and the sum of the projectors prove trace preservation on each domain. Orthogonality annihilates the cross terms when the map is iterated, so it is idempotent. Its fixed elements are precisely the stated blocks and the map is bimodular with respect to that subalgebra. Moreover, $\mathrm{Tr}(A^* P_m B P_m) = \mathrm{Tr}((P_m A P_m)^* B)$, from which self-adjointness for Hilbert–Schmidt follows. A self-adjoint projection has only the spectral values zero and one when both subspaces are nonzero. If only the fixed subspace remains, the map is the identity. □

The sum $\sum_m P_m A P_m$, applied without the complement to the entire apparatus, sends I to P. Its natural unit belongs to the pointer algebra. The formula (84.47) also preserves the auxiliary block; an orthonormal resolution of that block provides, when desired, diagonalization of the entire apparatus.

If U is a unitary transformation of the apparatus and $P'_m = UP_mU^*$, then

$$\mathcal{E}_{P'}(UAU^*) = U\mathcal{E}_P(A)U^*.$$

The equality is obtained by substituting each projector into the sum. Likewise, for $A \in \mathcal{B}(\mathcal{P}_n)$, the square (84.46) implies

$$\mathcal{D}_{P_{n+1}}(W_n^0 A (W_n^0)^*) = W_n^0 \mathcal{D}_{P_n}(A)(W_n^0)^*.$$

Indeed, each matrix unit $|a_m\rangle\langle a_{m'}|$ is transported to the unit corresponding to the distinct records $\widehat{F}_n(m), \widehat{F}_n(m')$; the diagonal reader preserves exactly the terms with $m = m'$.

84.13.5 Factorization of the response through the effective boundary

Let $\mathcal{X}_\infty^{\mathrm{enr}}$ be the domain of compatible enriched states and let $b : \mathcal{X}_\infty^{\mathrm{enr}} \longrightarrow B_\infty$ be its global boundary trace. We denote by $B_{\mathrm{ef}} = \operatorname{im} b$ the effectively published boundary. For a response space $\mathcal{V}_\nu$, we consider $I_\nu : \mathcal{X}_\infty^{\mathrm{enr}} \longrightarrow \mathcal{V}_\nu$.

Theorem 84.27 (Relational response criterion)**.** *There exists a unique map $\overline{I}_\nu : B_{\mathrm{ef}} \to \mathcal{V}_\nu$ such that $I_\nu = \overline{I}_\nu \circ b$ if and only if*

$$b(x) = b(x') \quad \Longrightarrow \quad I_\nu(x) = I_\nu(x'). \tag{84.48}$$

Uniqueness extends to all of B_∞ when b is surjective.

Proof. A composition through b is constant on each fiber. Conversely, for $\beta \in B_{\mathrm{ef}}$, we define $\overline{I}_\nu(\beta) = I_\nu(x)$ with $b(x) = \beta$. Condition (84.48) guarantees independence of the representative; every value of $\overline{I}_\nu$ is determined by some state of that fiber. If b is surjective, $B_{\mathrm{ef}} = B_\infty$. Otherwise, the composition equation determines only the values on B_{ef}. □

This criterion is set-theoretic. For a continuous factorization, the topologies and the quotient-map condition of $b : \mathcal{X}_\infty^{\mathrm{enr}} \to B_{\mathrm{ef}}$ are also preserved; with it, continuity of I_ν is equivalent to that of its factor. This specification separates determination of a reading from its regularity properties.

Let $\ell_\nu : \mathcal{X}_\infty^{\mathrm{enr}} \to \mathcal{L}_\nu$ be the restriction accessible to a local neighborhood. The effective global character is verified through two states satisfying

$$\ell_\nu(x) = \ell_\nu(x'), \qquad I_\nu(x) \neq I_\nu(x'). \tag{84.49}$$

If I_ν factors through b, these two states have distinct boundaries. Moreover, the response cannot be written as a function of ℓ_ν, since that function would assign the same value to both states. The difference of boundaries thus acquires a verifiable operator effect.

84.13.6 Ambivalence weights and self-inertial response

For the general formula we consider positive readers A_∂, V_∂ and an energy reader Q defined on the declared effective boundary domain. A realization on $B_{\mathrm{av}} \subseteq B_{\mathrm{ef}}$ is made explicit below. Memory remains as a boundary coordinate $\mathsf{M}_\partial(\beta)$. The ambivalence hinge provides the two orientations

$$r_{\mathrm{av}} = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2}, \qquad r_{\mathrm{av}}^J = \frac{\varphi_{\mathrm{HMT}}}{\pi_{\mathrm{HMT}}^2}.$$

The superscript J expresses interchange of the generating pair.

Normalized realization of the boundary readers. The APP–TRIT–TPK modal incidence, developed in the regional construction, provides the path envelope with matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

The positive vector $v = (1, \varphi_{\mathrm{HMT}})^{\mathsf{T}}$ satisfies $F_{\mathrm{av}} v = \varphi_{\mathrm{HMT}} v$. Its normalized transition and stationary weights are

$$P_{ij} = \frac{(F_{\mathrm{av}})_{ij} v_j}{\varphi_{\mathrm{HMT}} v_i}, \qquad P = \begin{pmatrix} 0 & 1 \\ \varphi_{\mathrm{HMT}}^{-2} & \varphi_{\mathrm{HMT}}^{-1} \end{pmatrix}, \qquad (\mu_{\mathrm{ar}}, \mu_{\mathrm{vol}}) = \frac{(1, \varphi_{\mathrm{HMT}}^2)}{1 + \varphi_{\mathrm{HMT}}^2}. \tag{84.50}$$

The rows of P sum to one by $\varphi^{-2} + \varphi^{-1} = 1$; the stationary equation $\mu_{\mathrm{ar}} = \mu_{\mathrm{vol}} \varphi^{-2}$, together with normalization, determines the stated weights. This Parry measure weights the paths of the envelope; the chronological frequency $(1/3, 2/3)$ counts the instants of the modal calendar and retains its distinct function.

The common memory-amplitude realization is defined on the sector $\mathcal{X}_{\mathrm{av}} \subset \mathcal{X}_{\infty}^{\mathrm{enr}}$ in which the readers of the two sheets have the factorization

$$\mathcal{L}_{\mathrm{vol}}(x) = \mu_{\mathrm{vol}} \mathcal{M}(x), \qquad \mathcal{L}_{\mathrm{ar}}(x) = \pi_{\mathrm{HMT}} \mu_{\mathrm{ar}} \mathcal{M}(x), \qquad \mathcal{M}(x) > 0. \tag{84.51}$$

Both values belong to the same positive memory-amplitude line. The areal publication carries the regional mark π_{HMT} of the return. The dimensionless reading is obtained by dividing both sections by $\mathcal{L}_{\mathrm{vol}}(x)$. Thus the sums of the weights are performed between quantities of the same type; a possible realization as physical areas and volumes is then composed with their respective dimensional transducers.

Proposition 84.28 (Descent of the normalized readers and the energy clock)**.** *On $B_{\mathrm{av}} = b(\mathcal{X}_{\mathrm{av}})$, the rules*

$$A_{\partial}(b(x)) = \frac{\mathcal{L}_{\mathrm{ar}}(x)}{\mathcal{L}_{\mathrm{vol}}(x)} = r_{\mathrm{av}}, \qquad V_{\partial}(b(x)) = 1 \tag{84.52}$$

define two positive readers independent of the representative. Given an orientation a of the action section, the decision energy of (123.6) *determines on states*

$$q_a(x) = \frac{h_a(x)}{108 t_0(x)} = \frac{\hbar_a(x)}{t_P(x)} \in \mathcal{L}_E^+, \qquad t_P = \frac{54}{\pi_{\mathrm{HMT}}} t_0. \tag{84.53}$$

We write

$$b_{\mathrm{av}} := b|_{\mathcal{X}_{\mathrm{av}}} : \mathcal{X}_{\mathrm{av}} \longrightarrow B_{\mathrm{av}}.$$

There exists a unique reader $Q : B_{\mathrm{av}} \to \mathcal{L}_E^+$ such that $q_a|_{\mathcal{X}_{\mathrm{av}}} = Q \circ b_{\mathrm{av}}$ if and only if, for any $x, x' \in \mathcal{X}_{\mathrm{av}}$,

$$b(x) = b(x') \implies \frac{h_a(x)}{t_0(x)} = \frac{h_a(x')}{t_0(x')}. \tag{84.54}$$

In particular, a chart of fixed action and duration satisfies this condition and publishes $Q = h_a/(108 t_0)$.

Proof. The quotient of (84.51) cancels the common amplitude and equals $\pi_{\mathrm{HMT}} \mu_{\mathrm{ar}} / \mu_{\mathrm{vol}} = \pi_{\mathrm{HMT}} / \varphi_{\mathrm{HMT}}^2$. The result is the same for all representatives of a fiber of b_{av} within $\mathcal{X}_{\mathrm{av}}$ and is positive. Dividing both readers by the same positive factor preserves the weighted quotients in which they enter. For the clock, the factorization criterion of theorem 84.27, applied to q_a, is exactly equivalent to (84.54). Fixed sections satisfy it; so do variable sections whose quotient descends through b_{av}. Uniqueness follows from the definition of B_{av} as the effective image. □

The value of the reader Q belongs to the energy line $\mathcal{L}_E = \mathcal{L}_{\mathrm{act}} \otimes \mathcal{L}_T^*$. With E_1, E_2 on that same line, $E_1 E_2 / Q^2$ is dimensionless and independent of the positive energy basis. The symbol Q in this section exclusively designates that clock energy; the quantity of heat in the Landauer realization belongs to the corresponding thermal balance. Common-amplitude factorization specifies a concrete realization of the general readers. Every other domain preserves its boundary maps and its own verification of descent.

Complete memory remains in the enriched history and in its boundary publication, even though it cancels in the normalized quotient.

We define

$$w_A(\beta) = \frac{A_\partial(\beta) r_{\mathrm{av}}}{A_\partial(\beta) r_{\mathrm{av}} + V_\partial(\beta) r_{\mathrm{av}}^J}, \qquad w_V(\beta) = 1 - w_A(\beta).$$

In realization (84.52), the weights admit the exact evaluation

$$w_A = \frac{r_{\mathrm{av}}^2}{r_{\mathrm{av}}^2 + r_{\mathrm{av}}^J} = \frac{\pi_{\mathrm{HMT}}^4}{\pi_{\mathrm{HMT}}^4 + \varphi_{\mathrm{HMT}}^5}, \qquad w_V = \frac{\varphi_{\mathrm{HMT}}^5}{\pi_{\mathrm{HMT}}^4 + \varphi_{\mathrm{HMT}}^5}. \tag{84.55}$$

Substitution preserves both factors of the definition: the normalized areal reader and its subsequent weighting by r_{av}. Generation and regional marking of the return are performed once. Multiplying numerator and denominator by $\varphi_{\mathrm{HMT}}^4 \pi_{\mathrm{HMT}}^2$ gives the last expression. These weights remain constant in the common-amplitude sector. With fixed projectors and energies, a variation of the response may come from the reader Q; the witness to global dependence additionally requires the states with equal local restriction and different response of (84.49).

Let P_A, P_V be complementary orthogonal projections of a response space $\mathcal{H}_v$, and let $E_1, E_2 > 0$ be two internal energies fixed for comparison. The response is

$$\overline{I}_v(\beta) = \frac{E_1 E_2}{Q(\beta)^2} \big(w_A(\beta) P_A + w_V(\beta) P_V \big), \qquad I_v = \overline{I}_v \circ b. \tag{84.56}$$

Energies that are explicit readers of β are also admitted; in that case they are preserved as such in the formula.

Proposition 84.29 (Positivity and covariance of the response)**.** *The response* (84.56) *is self-adjoint, positive definite and constant on the fibers of b. Its eigenvalues in the nonzero sectors are*

$$\lambda_A = E_1 E_2 Q^{-2} w_A, \qquad \lambda_V = E_1 E_2 Q^{-2} w_V.$$

The complete exchange $(A_\partial, r_{\mathrm{av}}, P_A) \leftrightarrow (V_\partial, r_{\mathrm{av}}^J, P_V)$ permutes the two summands and preserves the operator. A unitary transport of the response space conjugates that operator and preserves its spectrum with multiplicities.

Proof. Positivity of the readers gives $0 < w_A, w_V < 1$. For $z = z_A + z_V$, with $z_A = P_A z$, $z_V = P_V z$,

$$\langle z, \overline{I}_v z \rangle = \frac{E_1 E_2}{Q^2} (w_A \|z_A\|^2 + w_V \|z_V\|^2) > 0$$

if $z \neq 0$. The orthogonal decomposition proves the spectral expressions. Exclusive dependence on β gives constancy on the fibers and factorization. Exchanging the triples exchanges numerators, weights and projectors at once, so it preserves the sum. For a unitary transport U, substitution $P_A \mapsto U P_A U^*$, $P_V \mapsto U P_V U^*$ produces $U \overline{I}_v U^*$, with the same spectrum. □

An exchange implemented within the same space by a unitary sending P_A to P_V requires the two sectors to have equal dimension. Exchanging the two triples as labels of the formula is valid with each sector's own dimension.

Condition (84.49) requires comparing the responses. For example, simultaneously multiplying A_∂, V_∂ by the same positive factor preserves both weights; if E_1, E_2, Q are also preserved, the response remains identical. In contrast, with equal weights and energies, replacing Q by qQ, $q > 0$, multiplies the response by q^{-2}. If two states with equal local restriction realize that change with $q \neq 1$, they provide the global witness. These are operator separation conditions; existence of the states is checked in the boundary domain being realized.

84.13.7 Connection of the joint state and acceleration reading

In a differentiable realization of the joint state $\Gamma = (x, O, m)$, let N be its realization space, ∇^{tot} its connection and $\pi_S : N \to N_S$ a differentiable projection onto the subsystem, equipped with connection ∇^S. The connection and projection preserve the provenance of the transports and readers they realize. The observed frame is obtained through

$$\mathfrak{F}_O(\Gamma) = \mathrm{Res}_O(\Gamma, \nabla^{\mathrm{tot}}).$$

For a twice-differentiable trajectory $\Gamma(t)$, write $\gamma_S = \pi_S \circ \Gamma$.

Definition 84.30 (Self-inertia and projection defect)**.** A trajectory is self-inertial with respect to the declared connection when $\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma = 0$. The defect of its projection is

$$\mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma) = \nabla^S_{\dot\gamma_S}\dot\gamma_S - d\pi_S\big(\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma\big). \tag{84.57}$$

Proposition 84.31 (Subsystem acceleration)**.** *For a self-inertial trajectory,*

$$a_S = \nabla^S_{\dot\gamma_S}\dot\gamma_S = \mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma).$$

In coordinates x^B on N and y^a on N_S, the defect is quadratic in velocity, with components

$$(\mathcal{K}_{\pi_S})^a{}_{BC} = \partial_B\partial_C\pi^a_S + (\Gamma^S)^a{}_{bc}\,\partial_B\pi^b_S\partial_C\pi^c_S - \partial_D\pi^a_S(\Gamma^{\mathrm{tot}})^D{}_{BC}. \tag{84.58}$$

Proof. The chain rule gives $\ddot\gamma^a_S = \partial_B\pi^a_S\ddot\Gamma^B + \partial_B\partial_C\pi^a_S\dot\Gamma^B\dot\Gamma^C$. Adding the contribution of ∇^S and subtracting the image of the total acceleration, the terms containing $\ddot\Gamma$ cancel. The remaining ones are (84.58) contracted with $\dot\Gamma^B\dot\Gamma^C$. When total acceleration vanishes, the stated equality results. □

The geometric response factors through b when the connection, projection and kinematic datum used in evaluation are determined by $\beta = b(x)$, or when those kinematic data are kept fixed in the comparison. Under those conditions, (84.58) gives the same result for any representatives of a fiber; theorem 84.27 constructs its unique factor on B_{ef}. If the kinematic datum varies, it forms part of the domain of the response being compared.

The self-inertial formulation describes a geodesic trajectory of the joint state and an effective acceleration of its subsystem due to the projection defect. The gravitational realization then identifies that connection, the frame and the response with their physical observables. Observer covariance, memory inscription and factorization through the boundary thus retain complementary functions: the first determines the reading class, the second retains the genealogy and the third specifies the relational dependence of the response.

Chapter 85

The HMT–MD absorber theory: trajectory inversion, advanced and retarded propagators, boundary conditions, and particle–antiparticle conjugation

85.1 Bidirectional interaction: conjugation of advanced and retarded propagators and boundary conditions of the absorber

A route becomes dynamical when it is endowed with an action functional and boundary conditions. The action assigns a weight to the complete history; its variation selects transports compatible with the endpoints; interaction couples degrees of freedom that share a boundary; the bidirectional reading preserves the forward and reverse temporal orientations of the same antecedent. Within this framework, emission and absorption form the endpoints of a common boundary-value problem.

The absorber occupies a precise position in the architecture. HMT supplies the oriented band, outward-and-return memory, and the discrete involutions. Dimensional Mechanics adds the evolution operator, currents, and the action transducer. A physical absorber realization links that structure to advanced and retarded propagators and causal boundary conditions. The algebraic identities of the first segment are proved in their domains; the final link retains the status of a physical interface until the complete intertwiner is constructed.

85.1.1 Action functional on enriched paths

Let $\gamma = ((c_0, \mu_0), (d_1, \dots, d_L))$ be a finite route, with directions d_t and sheets $\mu_t \in \{\Sigma, \Pi\}$. Define

$$\operatorname{turn}(\gamma) = \#\{2 \le t \le L : d_t \neq d_{t-1}\},$$

$$\operatorname{switch}(\gamma) = \#\{2 \le t \le L : \mu_t \neq \mu_{t-1}\}.$$

Discrete Action of Minimal Interaction

For $\lambda \ge 0$, the local route action is

$$\mathcal{A}_\lambda(\gamma) = \operatorname{turn}(\gamma) + \lambda \operatorname{switch}(\gamma) = \sum_{t=2}^{L} \left[1 - \delta_{d_t, d_{t-1}} + \lambda(1 - \delta_{\mu_t, \mu_{t-1}})\right]. \tag{85.1}$$

The first contribution measures directional variation and the second measures transport between leaves.

The general action also incorporates boundary, carry, and memory:

$$\mathcal{S}[\gamma] = \sum_{e \in \gamma} \mathcal{L}_e + \mathcal{B}_{\text{in}}(\partial_- \gamma) + \mathcal{B}_{\text{out}}(\partial_+ \gamma) + \mathcal{M}(\gamma). \tag{85.2}$$

Here $\mathcal{L}_e$ is the local cost, $\mathcal{B}_{\text{in/out}}$ fixes the admissible endpoint data, and $\mathcal{M}$ preserves the information that the visible publication contracts. The variation is performed within a class of routes with the same boundary types.

Principle of Minimal Interaction Compatible with Memory

Among the prolongations compatible with the boundary data, the selected physical realization extremizes the action functional within the sector that preserves the memory required by the composition.

The principle fixes the class of the variational problem. A concrete dynamic adds the Hamiltonian or Lagrangian of the sector and proves that its extremum produces the equations of motion. Memory functions as a dynamic constraint: two routes with the same final shadow may belong to distinct variational classes.

85.1.2 Interaction as typed coupling

Let $\mathfrak{p}_1$ and $\mathfrak{p}_2$ two sections realized over routes γ_1 and γ_2. An interaction at to boundary B consists of to morphism

$$\mathcal{I}_B : E_B^{(1)} \otimes E_B^{(2)} \longrightarrow E_B^{(12)} \tag{85.3}$$

and in an action term $\mathcal{S}_{\text{int}}$ compatible with the representations of the sector. The morphism preserves the shared types and transforms the internal degrees according to the coupling rules. The complete composition takes the form

$$(\gamma_2, s_2) \star_{(B,\mathcal{I}_B)} (\gamma_1, s_1),$$

where the record of B is counted once, and the memory of both sides is transported to the composite state.

The covariance of the interaction requires, for each symmetry transformation g,

$$\rho_{12}(g)\, \mathcal{I}_B = \mathcal{I}_B\big(\rho_1(g) \otimes \rho_2(g)\big). \tag{85.4}$$

This identity decides whether the coupling belongs to the declared physical representation. In the electromagnetic and color sectors, the same structure is expressed by means of a connection and its parallel transport.

85.1.3 Temporal conjugation of the propagator

Let $\mathcal{H}_{\mathbb{R}}$ the realification of the quantum space, endowed with to complex structure J_E with $J_E^2 = -I$. Let $H = H^*$ to self-adjoint operator with common invariant domain and is C an orthogonal involution that satisfies

$$HJ_E = J_E H, \qquad CJ_E C^{-1} = -J_E, \qquad CHC^{-1} = H. \tag{85.5}$$

Theorem: Bidirectional reversal of the evolution group

The operator

$$U(t) = \exp\left(-\frac{J_E H t}{\hbar_{\text{int}}}\right) \tag{85.6}$$

forms a uniparametric unitary group and satisfies

$$\boxed{CU(t)C^{-1} = U(-t)}. \tag{85.7}$$

Proof of the bidirectional reversal of the unitary group $U(t)$: $CU(t)C^{-1} = U(-t)$ The generator $A = -J_E H/\hbar_{\text{int}}$ is skew-adjoint. Stone's theorem produces the unitary group $U(t) = e^{tA}$. The hypotheses of (85.5) give $CAC^{-1} = -A$; functional calculus yields $Ce^{tA}C^{-1} = e^{-tA}$.

The involution $C_M = -\,\mathrm{rev}$ of the route words supplies the genealogical datum of orientation. When the physical functor carries C_M to the involution C of the theorem, the particle and antiparticle sections are represented by conjugate temporal orientations of the same unitary group. The identity is proved from explicit starting structure: self-adjointness, domain, complex structure, and involution.

85.1.4 Advanced and Retarded Propagators

Let L be the hyperbolic operator of a field realization and let G_{ret} and G_{adv} be its fundamental inverses with future and past causal supports, respectively:

$$LG_{\mathrm{ret}} = LG_{\mathrm{adv}} = I, \qquad \operatorname{supp}(G_{\mathrm{ret}} f) \subset J^{+}(\operatorname{supp} f), \qquad \operatorname{supp}(G_{\mathrm{adv}} f) \subset J^{-}(\operatorname{supp} f). \tag{85.8}$$

The causal difference $E = G_{\mathrm{ret}} - G_{\mathrm{adv}}$ transports data between solutions, and the symmetric mean

$$G_{\mathrm{sym}} = \frac{1}{2}(G_{\mathrm{ret}} + G_{\mathrm{adv}})$$

realizes a time-symmetric kernel.

An HMT–MD interface to this theory is a family of maps

$$\mathfrak{I}_{\mathrm{prop}} : (\gamma, \gamma^{\vee}, \mathcal{B}_{\gamma}, U, C_M) \longrightarrow (G_{\mathrm{ret}}, G_{\mathrm{adv}}, E, \mathcal{H}_{\mathrm{field}}) \tag{85.9}$$

which intertwines the route involution with the exchange $G_{\mathrm{ret}} \leftrightarrow G_{\mathrm{adv}}$, preserves the inner product or the relevant symplectic form, and carries the actions on both sides to the same functional form. This map is the mathematical condition that turns the internal bidirectional orientation into advanced–retarded propagation of fields.

85.1.5 HMT–MD realization of the absorber through route inversion and particle–antiparticle conjugation

Bidirectional emission–absorption system

A physical realization of an absorber is a boundary-value problem formed by an emitting current J_{em}, an absorbing response J_{abs}, the propagators G_{ret} and G_{adv}, and boundary conditions that jointly close the two orientations of transport. Its temporally symmetric effective action has the form

$$\mathcal{S}_{\mathrm{abs}}[J] = \mathcal{S}_{\mathrm{matter}}[J] + \frac{1}{2}\langle J, G_{\mathrm{sym}} J\rangle, \qquad J = J_{\mathrm{em}} + J_{\mathrm{abs}}, \tag{85.10}$$

and its boundary conditions determine the observed radiative part.

The definition expresses a theory of action at a distance or boundary response in operator language. Within HMT–MD, the band supplies the pair $(\gamma, \gamma^{\vee})$; the bidirectional-reversal result supplies the exact reversal of the unitary group; the functor $\mathfrak{I}_{\mathrm{prop}}$ must supply causality, an inner product, and boundary conditions. The absorber architecture prolongs the bidirectional structure already constructed. Its realization remains a physical interface, and the construction of the complete causal intertwiner constitutes an explicitly delimited mathematical problem.

The physical closure requires four verifiable identities:

1. commutativity between route conjugation and interchange of the two propagators;
2. equality of the actions transported by $\mathfrak{I}_{\mathrm{prop}}$;
3. preservation of the symplectic form or the inner product;
4. compatibility of the emission and absorption conditions under route refinement.

TO failure in any of these identities refutes the particular realization and leaves intact the operatorial reversion already proved in (85.7).

85.1.6 The separate actions of C, P and T

On a complete route we define three typed involutions:

1. C exchanges the sheets $\Sigma \leftrightarrow \Pi$ and conjugates the oriented characters;
2. P reflects the spatial chart, for example $(i, j) \mapsto (i, -j) \pmod 9$, together with $E \leftrightarrow W$;
3. T reverses the order of the record, replaces each direction with its opposite, and permutes the endpoints of the route.

Each operation acts on to distinct component of the state. Their composition CPT acts on sheet, space, and temporal orientation at once.

Theorem: Individual and joint discrete invariance

For every route γ and every $\lambda \geq 0$,

$$\mathcal{A}_\lambda(\gamma) = \mathcal{A}_\lambda(C\gamma) = \mathcal{A}_\lambda(P\gamma) = \mathcal{A}_\lambda(T\gamma) = \mathcal{A}_\lambda(CPT\gamma). \tag{85.11}$$

Compatibility of the Actions C, P, and T with the Unitary Reversal $U(t) \mapsto U(-t)$ P permutes the alphabet of directions and preserves the pattern of equalities between consecutive steps. C globally permutes the sheets and preserves the pattern of sheet changes. T reverses the order of both sequences and preserves the number of adjacent transitions. Each involution separately preserves the two summands of (85.1); the composition inherits the invariance.

The theorem belongs to the discrete ledger and its local action. The CKM matrix realized in the flavor basis has a nonzero Jarlskog invariant and therefore CP violation in that representation. Both results are compatible: an oriented reader can distinguish states related by CP while the local functional $\mathcal{A}_\lambda$ preserves each involution. The realization of the relativistic field-theoretic CPT theorem adds locality, Lorentz covariance, spectral structure, and a representation of fields. In that enlarged domain, joint CPT constitutes the symmetry to be preserved. In the internal domain, the CKM closure and the temporal expansion remain compatible with the CPT invariance proved for the discrete action.

Three strata are thereby kept separate. The invariance of (85.11) is an exact internal theorem. The identity (85.7) has been proved from explicit starting structure. The physical absorber theory and the CPT theorem for fields require the intertwiners proper to their codomains. This separation keeps the inverse temporal orientation within the definition of a particle and accords each assertion its appropriate force.

85.2 C-even absorbing operator and boundary condition

Let

$$L : \mathcal{D}(L) \subset \mathcal{H}_\Phi \longrightarrow \mathcal{H}_J$$

a Green-hyperbolic operator. Let C_Φ and C_J be isometric involutions that reverse temporal orientation and satisfy

$$C_J L = L C_\Phi.$$

Let $G_{\mathrm{ret}}, G_{\mathrm{adv}} : \mathcal{H}_J \to \mathcal{H}_\Phi$ be the unique Green functions and suppose

$$C_\Phi G_{\mathrm{ret}} C_J^{-1} = G_{\mathrm{adv}}, \qquad G_{\mathrm{adv}} = G_{\mathrm{ret}}^\dagger$$

with respect to the declared Green's pairing.

On the space of response operators we define

$$\Theta(K) = C_\Phi K C_J^{-1}, \qquad \mathsf{P}_\pm(K) = \frac{1}{2}(K \pm \Theta(K)).$$

Then

$$G_{\mathrm{WF}} := \mathsf{P}_+(G_{\mathrm{ret}}) = \frac{1}{2}(G_{\mathrm{ret}} + G_{\mathrm{adv}}), \qquad G_{\mathrm{rad}} := \mathsf{P}_-(G_{\mathrm{ret}}) = \frac{1}{2}(G_{\mathrm{ret}} - G_{\mathrm{adv}}).$$

Let $\gamma_\partial : \mathcal{H}_\Phi \to \mathcal{H}_\partial$ be the boundary trace, and define

$$\mathcal{A}_\partial := \gamma_\partial G_{\mathrm{rad}} : \mathcal{H}_J \longrightarrow \mathcal{H}_\partial.$$

At a finite HMT level, let $\mathcal{A}_\partial^+$ be its Moore–Penrose inverse and

$$P_{\mathrm{abs}} = I - \mathcal{A}_\partial^+ \mathcal{A}_\partial.$$

Theorem 85.1 (Closure of the absorbing operator HMT)**.** *The operator P_{abs} is the orthogonal projection onto* $\ker \mathcal{A}_\partial$*. For every $j \in \mathcal{H}_J$, the current*

$$j_{\mathrm{abs}} = P_{\mathrm{abs}} j$$

satisfies

$$\gamma_\partial G_{\mathrm{ret}} j_{\mathrm{abs}} = \gamma_\partial G_{\mathrm{adv}} j_{\mathrm{abs}}.$$

Moreover,

$$\Theta(G_{\mathrm{WF}}) = G_{\mathrm{WF}}, \qquad \Theta(G_{\mathrm{rad}}) = -G_{\mathrm{rad}}, \qquad G_{\mathrm{WF}}^\dagger = G_{\mathrm{WF}}.$$

Therefore,

$$\mathcal{S}_{\mathrm{WF}}[j_{\mathrm{abs}}] = \frac{1}{2}\langle j_{\mathrm{abs}}, G_{\mathrm{WF}} j_{\mathrm{abs}} \rangle$$

is real and its variation produces the response $G_{\mathrm{WF}} j_{\mathrm{abs}}$. The supports of G_{WF} are contained in the union of the retarded and advanced causal supports.

Proof. The Moore–Penrose identities give $P_{\mathrm{abs}}^2 = P_{\mathrm{abs}} = P_{\mathrm{abs}}^\dagger$ and $\operatorname{im} P_{\mathrm{abs}} = \ker \mathcal{A}_\partial$. From $\mathcal{A}_\partial j_{\mathrm{abs}} = 0$ one obtains the equality of boundary traces. The parities follow from $\Theta^2 = I$, and the self-adjointness of G_{WF} follows from $G_{\mathrm{adv}} = G_{\mathrm{ret}}^\dagger$. The support assertion is inherited from the two Green operators. □

The absorbing class is nontrivial whenever

$$\operatorname{rank} \mathcal{A}_\partial < \dim \mathcal{H}_J.$$

This inequality is the finite falsifier of nonemptiness; it is not replaced by a narrative assertion.

If the refinements $R_m^\Phi, R_m^J, R_m^\partial$ intertwine $C, L, G_{\mathrm{ret}}, G_{\mathrm{adv}}$ and γ_∂, then

$$R_m^\Phi G_{\mathrm{WF},m} = G_{\mathrm{WF},m+1} R_m^J, \qquad R_m^\partial \mathcal{A}_{\partial,m} = \mathcal{A}_{\partial,m+1} R_m^J.$$

In that compatible domain, the absorbed response forms a natural system by levels. Its identification with Wheeler–Feynman electrodynamics, a specific material current, and its experimental data is EXTERNAL RECOGNITION; the boundary operator has already been constructed.

85.3 Bidirectional propagation and absorption condition at the boundary

APP–TRIT–TPK transport preserves the route orientation and memory distinguishing its outward journey from its return. On that antecedent, three successive operations are constructed: the action of an enriched history, propagation of a source through the realized transports and imposition of a common condition at the boundary. Inscription of the record in an apparatus space, established in section 84.13.3, allows those operations to be expressed through linear maps without confusing the observable publication with the state preserving its antecedents.

Temporal direction, sheet conjugation and spatial reflection have distinct domains. Their relations are first fixed on the record; the intertwinings used by a dynamical realization are then specified. This order determines which information remains in the propagators and which condition is introduced by choosing an absorbing boundary.

85.3.1 Route action and record involutions

A finite route contains its positions, cardinal directions $(d_1, \dots, d_N)$, sheets $(\mu_1, \dots, \mu_N)$, with $\mu_t \in \{\Sigma, \Pi\}$, and the increments of its enriched record. For $\lambda \geq 0$, we define

$$\mathcal{A}_\lambda(\gamma) = \sum_{t=2}^{N} \big(1 - \delta_{d_t, d_{t-1}} + \lambda(1 - \delta_{\mu_t, \mu_{t-1}})\big). \tag{85.12}$$

The first term counts changes of direction; the second counts sheet changes with the declared weight. For $N \leq 1$, the sum is zero. The sector's general action additionally preserves its boundary and memory terms:

$$\mathcal{S}[\gamma] = \sum_{a \subset \gamma} \mathcal{L}_a + \mathcal{B}_{\mathrm{in}}(\partial_- \gamma) + \mathcal{B}_{\mathrm{out}}(\partial_+ \gamma) + \mathcal{M}(\gamma). \tag{85.13}$$

The terms of this expression specify a variational class with typed endpoints and preserved memory. The sector's dynamics determines $\mathcal{L}_a$, the admissible conditions and the term $\mathcal{M}$.

On the records we define C_{r} as the global exchange of sheets; $\mathcal{P}_{\mathrm{r}}$ as a reflection of the spatial chart and its directions; and $\mathcal{T}_{\mathrm{r}}$ as reversal of temporal order, replacement of each direction by its opposite and exchange of endpoints. Cardinal reflection is an involutive permutation. Inversion of the signed record is $C_M(a_1, \dots, a_N) = (-a_N, \dots, -a_1)$. The sheets, quotients and memory are transported with the complete route; the scalar reading of a word constitutes a subsequent operation.

Proposition 85.2 (Invariance of the local route action)**.** *On the preceding domain of records,*

$$\mathcal{A}_\lambda(\gamma) = \mathcal{A}_\lambda(C_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(\mathcal{P}_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(\mathcal{T}_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(C_{\mathrm{r}}\mathcal{P}_{\mathrm{r}}\mathcal{T}_{\mathrm{r}}\gamma).$$

Proof. A global permutation of the direction alphabet preserves equality between consecutive directions. Exchanging the two sheets preserves equality between consecutive sheets. Reversing the order establishes a bijection between adjacent pairs, and replacement by opposite directions also preserves their equalities. Each operation preserves the two counts of (85.12); their composition preserves them. □

The proposition determines the symmetry of the local functional. For a transformation also to act on a dynamical problem with fixed boundaries, it must transport its class of admissible prolongations and the other three terms of (85.13). In particular, two routes with the same final publication may retain distinct variational classes through their memory.

An interaction between two sections realized at a boundary B uses a coupling map

$$\mathcal{I}_B : E_B^{(1)} \otimes E_B^{(2)} \longrightarrow E_B^{(12)}$$

and a term $\mathcal{S}_{\mathrm{int}}$ in the same action. Its covariance is expressed by

$$\rho_{12}(g)\mathcal{I}_B = \mathcal{I}_B\big(\rho_1(g) \otimes \rho_2(g)\big).$$

When composing the histories, the shared boundary record is counted once; memories on both sides are transported to the composite section. The coupling and this covariance condition are data of the concrete interaction, distinct from the record involutions.

85.3.2 Reversal of the realized evolution

The realization of the record provides a real Hilbert space $\mathcal{H}_{\mathbb{R}}$, an orthogonal complex structure J_E, with $J_E^2 = -I$, and a self-adjoint Hamiltonian H. Its domain $\mathcal{D}(H)$ is invariant under J_E; we assume $HJ_E = J_E H$ on that domain. Let C be an orthogonal involution preserving $\mathcal{D}(H)$ and satisfying

$$CJ_E C^{-1} = -J_E, \qquad CHC^{-1} = H. \tag{85.14}$$

The internal action constant $\hbar_{\mathrm{int}} > 0$ retains its prior generation; here it normalizes the evolution group.

Theorem 85.3 (Temporal conjugation of the group)**.** *The generator $A = -J_E H/\hbar_{\mathrm{int}}$, with domain $\mathcal{D}(H)$, is skew-adjoint. Its orthogonal group, unitary with respect to J_E, satisfies*

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}}), \qquad CU(t)C^{-1} = U(-t). \tag{85.15}$$

Proof. Orthogonality and $J_E^2 = -I$ imply $J_E^* = -J_E$. Domain invariance and commutation with H allow H to be treated as a complex self-adjoint operator in the space defined by J_E. By functional calculus, $-J_E H/\hbar_{\mathrm{int}}$ is skew-adjoint and generates the stated group. In finite dimension, the same statements follow from the exponential series and from $A^* = -A$. The hypotheses on C give $CAC^{-1} = -A$. Conjugating the group, or its functional calculus, produces $\exp(-tA) = U(-t)$. □

The map realizing the signed involution C_M as C preserves temporal orientation and the preceding domain. Charge conjugation of a field representation additionally preserves its own characters and operators. The equality (85.15) fixes the time reversal of the group under the stated conditions.

85.3.3 Propagators of the chronological channel of a route

Isometric inscription of the record admits the unitary extensions of theorem 84.25. Let us fix a bilateral realization of a chronological channel with fibers $\mathcal{H}_n$, $n \in \mathbb{Z}$, and unitary transports $U_n : \mathcal{H}_n \to \mathcal{H}_{n+1}$. The choice includes auxiliary spaces when required; it preserves the route and its preceding records. We denote by $U(n,k)$ the transport from k to n, with

$$U(k,k) = I, \qquad U(n,k)U(k,l) = U(n,l), \qquad U(n,k)^* = U(k,n).$$

For $n > k$, it is the product $U_{n-1} \cdots U_k$; for $n < k$, it is the inverse of the transport from n to k.

The source space $\mathcal{J}_c$ contains finitely supported sections. The response space $\mathcal{F}$ contains all sections of those fibers. The route's quadratic action, in internal units of this realization, uses

$$(D\psi)_n = \psi_{n+1} - U_n \psi_n, \qquad E[\psi] = \sum_n \|(D\psi)_n\|^2$$

for finitely supported sections. The kinetic operator with the sign convention $L = -D^*D$ is

$$(L\psi)_n = U_n^* \psi_{n+1} - 2\psi_n + U_{n-1}\psi_{n-1}. \tag{85.16}$$

Indeed, $(D^* z)_n = z_{n-1} - U_n^* z_n$, and substitution produces that formula. The variation of E is $-2\,\mathrm{Re}\langle \delta\psi, L\psi\rangle$.

Theorem 85.4 (Exact Green operators of the covariant difference)**.** *Writing $x_+ = \max(x, 0)$, the maps*

$$(G_{\mathrm{ret}} j)_n = \sum_k (n-k)_+ U(n,k)\, j_k, \tag{85.17}$$

$$(G_{\mathrm{adv}} j)_n = \sum_k (k-n)_+ U(n,k)\, j_k \tag{85.18}$$

from $\mathcal{J}_c$ to $\mathcal{F}$ satisfy

$$LG_{\mathrm{ret}}j = LG_{\mathrm{adv}}j = j.$$

The retarded response vanishes before and at the first position of the source; the advanced one vanishes after and at the last. They are the unique solutions vanishing sufficiently far in the respective direction. For finitely supported ψ, we also have $G_{\mathrm{ret}}L\psi = G_{\mathrm{adv}}L\psi = \psi$. With respect to the pairing with finitely supported sources, $G_{\mathrm{adv}} = G_{\mathrm{ret}}^{\dagger}$.

Proof. Each sum has as many terms as source positions. Composition of transports reduces application of L to the scalar identity

$$(n+1-k)_+ - 2(n-k)_+ + (n-1-k)_+ = \delta_{nk}.$$

The function $(k-n)_+$ satisfies the same identity. This proves the two equations and the supports. For uniqueness, a homogeneous solution vanishing at two consecutive positions is determined as zero at the next by (85.16); the recurrence, using invertible transports, extends in both directions. The difference of two solutions with the same causal support vanishes sufficiently far away and is therefore zero. Applying this argument to ψ and to $G_{\mathrm{ret}}L\psi$, or to the advanced case, gives the right-hand identities on finite support. Finally, for two compactly supported sources, the double sum of the pairing is finite and

$$\big((k-n)_+U(k,n)\big)^* = (k-n)_+U(n,k).$$

Interchanging the indices proves the stated adjoint relation. □

The responses belong to $\mathcal{F}$; in general they grow linearly outside the source and do not belong to ℓ^2. The finite-support domain and its pairing specify the Green adjunction used here. The result constructs propagation of the chronological channel from its action; a realization of spatial fields additionally preserves its own operator, geometry and propagation domain.

Let C_0 be an isometric involution, linear or antilinear, of $\mathcal{H}_0$. Transport from the reference fiber constructs

$$C_n = U(-n,0)C_0U(0,n) : \mathcal{H}_n \longrightarrow \mathcal{H}_{-n}, \qquad (C\psi)_n = C_{-n}\psi_{-n}.$$

We have $C_{-n}C_n = I$ and $C_{n+1}U_n = U_{-n-1}^*C_n$, by composition. In particular, $C^2 = I$, and the change $(n,k) \mapsto (-n,-k)$ in the preceding sums proves

$$CL = LC, \qquad CG_{\mathrm{ret}}C^{-1} = G_{\mathrm{adv}}. \tag{85.19}$$

When C_0 is the declared realization of the record involution, these formulas transport that involution throughout the channel, without identifying phase return with a memory reset.

85.3.4 Causal interchange and decomposition of the response

In a field realization, let $L : \mathcal{D}(L) \subset \mathcal{H}_\Phi \to \mathcal{H}_J$ be an operator with unique retarded and advanced Green operators on the domains of admissible sources. We denote by $J^+(S)$ and $J^-(S)$ the future and past causal domains of a support S. The conditions are

$$\begin{aligned} LG_{\mathrm{ret}} = LG_{\mathrm{adv}} = I,\\ \operatorname{supp}(G_{\mathrm{ret}}j) \subset J^+(\operatorname{supp} j),\\ \operatorname{supp}(G_{\mathrm{adv}}j) \subset J^-(\operatorname{supp} j). \end{aligned}$$

Let C_Φ, C_J be isometric involutions, both linear or both antilinear, that transport these domains, reverse their causal orientations, and satisfy $LC_\Phi = C_JL$. A Green pairing is retained for which $G_{\mathrm{adv}} = G_{\mathrm{ret}}^{\dagger}$.

Proposition 85.5 (Conjugation of the Green operators and parities)**.** *Under the preceding conditions,*

$$C_\Phi G_{\mathrm{ret}} C_J^{-1} = G_{\mathrm{adv}}.$$

On the real space of response operators, define

$$\Theta(K) = C_\Phi K C_J^{-1}, \qquad \mathsf{P}_\pm(K) = \tfrac{1}{2}(K \pm \Theta(K)).$$

These are complementary projections for the involution Θ*, and*

$$G_{\mathrm{sym}} = \tfrac{1}{2}(G_{\mathrm{ret}} + G_{\mathrm{adv}}), \qquad G_{\mathrm{rad}} = \tfrac{1}{2}(G_{\mathrm{ret}} - G_{\mathrm{adv}}) \tag{85.20}$$

satisfy $\Theta(G_{\mathrm{sym}}) = G_{\mathrm{sym}}$, $\Theta(G_{\mathrm{rad}}) = -G_{\mathrm{rad}}$, $G_{\mathrm{sym}}^\dagger = G_{\mathrm{sym}}$, *and* $LG_{\mathrm{rad}} = 0$*. The support of the symmetric response is contained in the union of the two causal domains.*

Proof. The conjugated operator solves the source equation, since

$$LC_\Phi G_{\mathrm{ret}} C_J^{-1} = C_J L G_{\mathrm{ret}} C_J^{-1} = I.$$

Orientation reversal takes its support to the advanced domain; its uniqueness identifies it with G_{adv}. The involutions give $\Theta^2 = I$; expanding $(I \pm \Theta)^2$ and $(I + \Theta)(I - \Theta)$ proves the statements about projections. Green adjunction proves symmetry and the difference of the two source equations gives $LG_{\mathrm{rad}} = 0$. The sum of two responses has support contained in the union of their supports. □

If the involutions are antilinear, Θ is linear over real scalars; this is the operator space used in the proposition. Conjugation of the temporal group, the support condition, and the Green adjoint relation are three distinct properties, transmitted by the corresponding realization maps.

85.3.5 Projection of absorbed currents and variation of the action

Let $\gamma_\partial : \mathcal{H}_\Phi \to \mathcal{H}_\partial$ be the boundary reading, distinct from the route γ. We define

$$\mathcal{A}_\partial = \gamma_\partial G_{\mathrm{rad}}.$$

The finite window fixes the source space and boundary reading; the Green operators preserve their response domain. At a finite level with fixed inner products, its Moore–Penrose inverse determines

$$P_{\mathrm{abs}} = I - \mathcal{A}_\partial^+ \mathcal{A}_\partial. \tag{85.21}$$

Theorem 85.6 (Absorption condition and boundary response)**.** P_{abs} *is the orthogonal projection onto* $\ker \mathcal{A}_\partial$*. For any source* j*, the source* $j_{\mathrm{abs}} = P_{\mathrm{abs}} j$ *satisfies*

$$\gamma_\partial G_{\mathrm{ret}} j_{\mathrm{abs}} = \gamma_\partial G_{\mathrm{adv}} j_{\mathrm{abs}}. \tag{85.22}$$

It is the absorbed source closest to j *for the declared inner product. Nonzero absorbed sources exist exactly when* $\operatorname{rank} \mathcal{A}_\partial < \dim \mathcal{H}_J$.

Proof. The orthogonal decomposition $\mathcal{H}_J = \ker \mathcal{A}_\partial \oplus \operatorname{im} \mathcal{A}_\partial^*$ shows that $\mathcal{A}_\partial^+ \mathcal{A}_\partial$ is the identity on the second summand and zero on the first. Its complement is the stated projector. By definition, $2\mathcal{A}_\partial j_{\mathrm{abs}} = \gamma_\partial (G_{\mathrm{ret}} - G_{\mathrm{adv}}) j_{\mathrm{abs}} = 0$. For $k \in \ker \mathcal{A}_\partial$, the orthogonal decomposition gives

$$\|j - k\|^2 = \|(I - P_{\mathrm{abs}}) j\|^2 + \|P_{\mathrm{abs}} j - k\|^2.$$

The unique minimum corresponds to $k = P_{\mathrm{abs}} j$. The final equivalence is the rank–nullity theorem. □

In the source-field pairing, the symmetric action is $\mathcal{S}[j] = \frac{1}{2}\langle j, G_{\mathrm{sym}} j\rangle$. The declared adjunction makes that quantity real. For real variations,

$$\mathrm{d}\mathcal{S}[j](h) = \mathrm{Re}\langle h, G_{\mathrm{sym}} j\rangle.$$

The action restricted to absorbed sources is written on the ambient space as

$$\mathcal{S}_{\mathrm{abs}}[j] = \tfrac{1}{2}\langle P_{\mathrm{abs}} j, G_{\mathrm{sym}} P_{\mathrm{abs}} j\rangle, \quad \mathrm{d}\mathcal{S}_{\mathrm{abs}}[j](h) = \mathrm{Re}\langle P_{\mathrm{abs}} h, G_{\mathrm{sym}} P_{\mathrm{abs}} j\rangle. \tag{85.23}$$

When the pairing identifies field and source through Riesz, the ambient gradient is $P_{\mathrm{abs}} G_{\mathrm{sym}} P_{\mathrm{abs}} j$. The field response remains $G_{\mathrm{sym}} j_{\mathrm{abs}}$; the gradient projector expresses restriction of the variations. The formulas are proved by expanding the quadratic term of $j + th$ and using self-adjointness. A material term $\mathcal{S}_{\mathrm{matter}}$ adds its own differential.

85.3.6 Explicit absorbing condition in a chronological window

The channel of subsection 85.3.3 allows that condition to be evaluated without introducing a target response. Let there be a source supported on $0, \dots, N$, with $N \geq 1$. Let us transport its components to the reference fiber:

$$\widehat{j}_k = U(0,k) j_k, \qquad M_0(j) = \sum_{k=0}^{N} \widehat{j}_k, \qquad M_1(j) = \sum_{k=0}^{N} k\, \widehat{j}_k.$$

The identity $(n-k)_+ - (k-n)_+ = n - k$ gives

$$(G_{\mathrm{ret}} - G_{\mathrm{adv}}) j\big|_n = U(n,0)\big(n M_0(j) - M_1(j)\big). \tag{85.24}$$

Proposition 85.7 (Absorption and two transported moments)**.** *If the trace evaluates the field at two distinct positions a, b, equality of the advanced and retarded traces is equivalent to $M_0(j) = M_1(j) = 0$. In a fibre of dimension d, the space of such sources has dimension $(N-1)d$. For $N \geq 2$, it contains the nonzero sources with transported components $(z, -2z, z, 0, \dots, 0)$, $z \neq 0$.*

Proof. Invertibility of $U(a,0)$ and $U(b,0)$ reduces the boundary condition to $aM_0 - M_1 = 0$ and $bM_0 - M_1 = 0$. Subtracting the equations gives $(a-b)M_0 = 0$, and then $M_1 = 0$. The two-moment map is surjective: for prescribed values (z_0, z_1), it suffices to take $\widehat{j}_0 = z_0 - z_1$, $\widehat{j}_1 = z_1$, and all other components zero. Its rank is $2d$; its nullity is $(N+1)d - 2d$. The indicated source has both moments zero. □

In the transported frame, write

$$B_N = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 0 & 1 & \cdots & N \end{pmatrix}.$$

The absorbing projector is evaluated by

$$P_N = \big[I - B_N^{\mathsf{T}} (B_N B_N^{\mathsf{T}})^{-1} B_N\big] \otimes I_{\mathcal{H}_0}. \tag{85.25}$$

The two rows of B_N are independent for $N \geq 1$, so the inverse exists. Unitary transport between frames takes this projector to the original fibers. For $N = 2$,

$$P_2 = \frac{1}{6}\begin{pmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{pmatrix} \otimes I_{\mathcal{H}_0}.$$

This construction produces a nonzero absorbed class and its projection operation in the chronological channel. Its amplitude and identification with a material current preserve the rules of the corresponding physical sector.

85.3.7 Refinement and continuity of the boundary condition

Let $R_m^{\Phi}, R_m^{J}, R_m^{\partial}$ be the refinement maps of fields, sources and boundaries. Suppose they intertwine the two Green operators and the trace. Composition gives

$$R_m^{\Phi} G_{\mathrm{sym},m} = G_{\mathrm{sym},m+1} R_m^{J}, \qquad R_m^{\partial} \mathcal{A}_{\partial,m} = \mathcal{A}_{\partial,m+1} R_m^{J}. \tag{85.26}$$

The second equality takes an absorbed source to another absorbed source. Naturality of the projectors additionally preserves the orthogonal structure of the realizations.

Proposition 85.8 (Naturality of the absorbing projection)**.** *For a source isometry $R = R_m^{J}$, we have $P_{\mathrm{abs},m+1} R = R P_{\mathrm{abs},m}$ exactly when*

$$R(\ker \mathcal{A}_{\partial,m}) \subset \ker \mathcal{A}_{\partial,m+1}, \qquad R((\ker \mathcal{A}_{\partial,m})^{\perp}) \subset (\ker \mathcal{A}_{\partial,m+1})^{\perp}.$$

With these conditions at every level, the projectors define an orthogonal projection in the completion of the isometric inductive limit of the source spaces.

Proof. Each source is decomposed into its components in the kernel and its orthogonal complement. The two inclusions imply that applying the projection before or after refinement respectively preserves the first component and annihilates the second. Conversely, equality of operators applied to each component gives the two inclusions. In the inductive limit, the equality allows an operator to be defined on the union of the levels without dependence on the representative. All projectors have norm at most one, so the operator extends to the completion. Its self-adjointness and idempotence identities, valid on the dense union, pass by continuity to the completion. □

To extend a Green response to a completion as well, its domains and corresponding continuity estimates are preserved. Finite-support chronological propagation and factorization of the response through the boundary image, proved in 84.27, thus retain their respective domains during refinement.

The physical realization of emission and absorption composes these operators with the material currents, action and causal conditions of the sector. The intertwining must preserve the route involution, the source-field pairing, the transported action and the boundary conditions at each level. The preceding construction provides reversal of the group, the Green operators of the chronological channel, temporal decomposition and an explicit absorbing projection; spatial realizations use their own maps and causality conditions.

Chapter 86

Causal polarization of the gravitational interior: loss of spatial freedom, tilting of the cones, and compulsory direction of infall

86.1 Causal polarization field and radial freedom loss

Let $(\mathcal{M}, g)$ be a spherically symmetric geometry written in Painlevé–Gullstrand coordinates,

$$\mathrm{d}s^2 = -c^2\,\mathrm{d}t^2 + \big(\mathrm{d}r + v(r)\,\mathrm{d}t\big)^2 + r^2\,\mathrm{d}\Omega_2^2, \tag{86.1}$$

where $v(r) \geq 0$ measures the radial inclination of the causal cones with respect to the selected temporal congruence. The dimensionless field

$$\mathcal{P}(r) := \frac{v(r)}{c} \tag{86.2}$$

is the intensity of causal polarization. Over the spatial distribution orthogonal to the temporal congruence, the tensor is defined

$$\Pi(r) = \mathcal{P}(r)^2\,\widehat{r}\otimes\widehat{r}, \tag{86.3}$$

whose principal direction is radial and whose tangential directions remain degenerate. This definition introduces no absolute direction: the principal direction is covariantly determined by the gradient of the areal radius.

The null radial generators of (86.1) satisfy

$$\frac{\mathrm{d}r}{\mathrm{d}t} = -v(r) \pm c = c\big(-\mathcal{P}(r) \pm 1\big). \tag{86.4}$$

Therefore, the set of radially accessible signs changes cardinality upon crossing $\mathcal{P} = 1$.

Theorem 86.1 (Mandatory causal direction of fall)**.** *In the geometry* (86.1) *the following three exhaustive alternatives are verified:*

1. *if* $0 \leq \mathcal{P} < 1$*, one future-directed radial generator increases* r *and the other decreases it;*
2. *if* $\mathcal{P} = 1$*, the outgoing generator satisfies* $\mathrm{d}r/\mathrm{d}t = 0$ *and defines the horizon;*
3. *if* $\mathcal{P} > 1$*, both future radial generators satisfy* $\mathrm{d}r/\mathrm{d}t < 0$*.*

In the third regime, the radial degree does not disappear from the manifold, but ceases to constitute a bidirectional spatial choice: every future-directed causal vector has a component directed toward smaller areal radii. The interior is, in this exact sense, a region of compelled causal infall.

Proof. The three conclusions are obtained by comparing the two values $-\mathcal{P} \pm 1$ of (86.4) with zero. For $\mathcal{P} > 1$, even the branch with positive sign is negative. The conclusion concerns the causal cone rather than a particular choice of temporal coordinate. □

86.2 Schwarzschild realization and collective gradient of fall

For a total mass M, the Schwarzschild realization in the chart (86.1) is given by

$$v(r) = c\sqrt{\frac{R}{r}}, \qquad R = \frac{2GM}{c^2}, \qquad \mathcal{P}(r)^2 = \frac{R}{r}. \tag{86.5}$$

The horizon is simultaneously characterized by

$$r = R, \qquad \mathcal{P} = 1, \qquad g^{\mu\nu}\partial_\mu r\,\partial_\nu r = 0. \tag{86.6}$$

The radial acceleration of the falling congruence is recovered as the gradient of the kinetic intensity of the field:

$$a_r = -\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}r}v(r)^2 = -\frac{GM}{r^2}. \tag{86.7}$$

Thus, radial gravitation is expressed as the collective gradient of infall and not as a force added after the trajectories have been fixed.

Corollary 86.2 (Causal Macropolarization of the Gravitational Interior)**.** *In the realization* (86.5)*, the region $r < R$ satisfies $\mathcal{P} > 1$. The black hole constitutes to causal macropolarization: the principal direction of Π exceeds the unit threshold and aligns both future radial families toward the decrease of the areal radius.*

86.3 Correspondencia with the 3 regimes of the TRIT

The geometric reader of the TRIT is implemented through

$$\tau(r) = \operatorname{sgn}\!\left(1 - \mathcal{P}(r)^2\right) \in \{+1, 0, -1\}. \tag{86.8}$$

The correspondence is

τ	$\mathcal{P}$	geometric regime	future radial orientation
$+1$	$\mathcal{P} < 1$	exterior	input and output
0	$\mathcal{P} = 1$	horizon	outgoing null generator
-1	$\mathcal{P} > 1$	interior	necessary descent

(86.9)

The temporal involution of TRIT exchanges the exterior and interior regimes and fixes the horizon. The change $+1 \leftrightarrow -1$ does not eliminate the memory of the route: it modifies its causal orientation and preserves the boundary $\tau = 0$ as to gluing surface.

86.4 Local closure of matter and collective gravitational alignment

Let γ_a be a persistent material section with radial projector $\widehat{r}_a \otimes \widehat{r}_a$ and closure weight $w_a \geq 0$. For a finite set of sections, define the order parameter

$$\Pi_N = \frac{1}{\sum_{a=1}^{N} w_a} \sum_{a=1}^{N} w_a \, \widehat{r}_a \otimes \widehat{r}_a. \tag{86.10}$$

An individual particle realizes a persistent local closure of a route. The gravitational interior appears when the collective field fixes a principal causal direction for all future routes. Consequently, two mathematically distinct objects are not identified:

$$\begin{aligned} \text{particle} &= \text{persistent material section}, \\ \text{black hole} &= \text{macroscopic causal alignment above the threshold}. \end{aligned} \tag{86.11}$$

The complete causal sequence of this residence is fixed by

$$\begin{aligned} \text{APP–TRIT–TPK state} &\longrightarrow \text{material section} \longrightarrow \text{polarization field } \Pi \\ &\longrightarrow \mathcal{P} = 1 \longrightarrow \text{horizon} \longrightarrow \mathcal{P} > 1 \longrightarrow \text{necessary causal descent}. \end{aligned} \tag{86.12}$$

The following chapter prolongs this structure toward sheet inversion, the advanced–retarded purification, Kruskal geometry, and horizon information.

86.5 Geometric conditions of causal macropolarization: areal radius, cone tilt, horizon, and interior falloff

The result simultaneously requires that the radius used be areal, that $v(r)$ tilt the cones according to (86.1), that the horizon satisfy $\mathcal{P} = 1$, and that the two slopes in (86.4) be negative in the interior. These identities distinguish the effective loss of radial freedom from a merely dimensional metaphor and provide direct control of causal macropolarization.

Chapter 87

Causal horizon, interior–exterior inversion, and the hyperbolic regime of TRIT in the gravitational interior

87.1 Leaf involution in a trapped region and causal representation of the interior of a black hole

In the empty exterior region of a compact body, the Cartan equation imposes zero torsion when there is no spin current. The connection reduces to $\mathring{\omega}(e)$, and the metric satisfies the Einstein sector. Orbits, gravitational lensing, redshift, and exterior propagation remain governed by relativistic geometry in the verified domain. HMT–MD locates its contribution in the meaning of the boundary and in the continuity of the state that an exterior chart ceases to publish.

In this reading, a horizon is a boundary of publication. The enriched state does not end where the external observer loses an invertible coordinate. The relation among sheet, orientation, and reading changes. A section that crosses the boundary may cease to have a representative in the external chart and continue on a conjugate sheet. The expression *sheet inversion* denotes this change: exterior and interior are not two substances, but two domains of a global presentation whose gluing preserves route and memory.

The Möbius band provides the minimal topological model. One turn transports the section to its conjugate sheet; two turns restore orientation. The local observer can publish a single branch, while the global state preserves both. In a relativistic realization, the same operation must act on the causal frames, charge, and temporal orientation without destroying the norm. The horizon thus becomes the locus at which a visible orientation becomes return memory.

Sheet inversion contains a possible explanation of the information paradox. Three operations should be distinguished. The fundamental evolution may be reversible:

$$U_{\mathrm{tot}}^{-1} U_{\mathrm{tot}} = I.$$

The external chart may identify different states:

$$q_{\mathrm{ext}}(x) = q_{\mathrm{ext}}(y), \qquad x \neq y.$$

And the external apparatus may erase its register in order to prepare itself again. The first operation preserves information; the second loses access to it; the third has a thermodynamic cost. The apparent disappearance beyond the horizon may belong to the fiber of q_{ext} without requiring destruction in U_{tot}.

The leafwise reading makes it possible to write a minimal model of that information. The angle and counter-angle channels are

$$q_{\pm} = \exp\left(-A_{\mathrm{rad}} \mp C_{\mathrm{rad}}^{*}\right).$$

After normalization,

$$p_{\pm} = \frac{q_{\pm}}{q_{+} + q_{-}}, \qquad \rho_{\mathrm{hoja}} = p_{+}|+\rangle\langle+| + p_{-}|-\rangle\langle-|.$$

The reduced entropy is

$$S_{\mathrm{hoja}} = -\sum_{\pm} p_{\pm} \log p_{\pm} = \log\left(2\cosh C_{\mathrm{rad}}^{*}\right) - C_{\mathrm{rad}}^{*} \tanh C_{\mathrm{rad}}^{*}.$$

The common phase A_{rad} cancels: the visible mixing depends on the separation between sheets. If the advanced–retarded factorization exists,

$$|\Psi\rangle = \sqrt{p_{+}}\,|+\rangle|\mathrm{adv}\rangle + \mathrm{e}^{i\chi_0}\sqrt{p_{-}}\,|-\rangle|\mathrm{ret}\rangle,$$

that entropy is the entanglement of two orientations of a pure state. A horizon may then alter the accessibility of the branches without turning the global state into a fundamental mixture.

Thermodynamics requires keeping temperature separate from duration. The Boltzmann constant is to morphism between the thermal and energetic lines,

$$k_B : L_\Theta \longrightarrow L_E.$$

For the clock of 108 states,

$$\omega_0 = \frac{2\pi}{108\, t_0}, \qquad k_B \Theta_{\mathrm{clk}} \log 3 = \hbar_{\mathrm{int}} \omega_0.$$

The information of a ternary cell, the thermal scale, and the quantum of action are thus related without conflating $\log 3$ with the topological entropy $\log \varphi_{\mathrm{HMT}}$.

The Landauer limit applies when the observer erases:

$$Q \geq k_B \Theta\, \Delta S.$$

A reversible global cycle that preserves the register may have zero logical variation. An apparatus that resets a distinguishable memory must dissipate. The so-called zero Landauer regime is the regime without erasure, not a free heat engine. For a black hole, this distinction asks whether radiation redistributes a preserved memory, whether the exterior keeps it inaccessible for a time, or whether a genuinely nonunitary channel exists.

The interpretation becomes a physical theory when it constructs a geometry. The extension must recover the relativistic exterior, produce a trapped surface and a regular horizon, transport the enriched state across the boundary, and assign a census of states to its area. The continuation must also produce a distinguishable signal: a phase of the quasinormal modes, a correlation structure in the radiation, a polarization, or an echo whose value is not chosen after it has been observed. If the inversion changes only the words *interior* and *exterior*, it does not yet realize the HMT black hole. If it satisfies these conditions, the information problem becomes a controllable problem of chart change.

87.2 Double-sheet black hole and advanced purification–delayed

87.2.1 State of sheet and information

Leaf channels are

$$q_\pm = \exp(-A_{\mathrm{rad}} \mp C^*_{\mathrm{rad}}), \qquad p_\pm = \frac{q_\pm}{q_+ + q_-}.$$

We define

$$\rho_{\mathrm{hoja}} = p_+ |+\rangle\langle +| + p_- |-\rangle\langle -|$$

and the purification

$$|\Psi_{\mathrm{ar}}\rangle = \sqrt{p_+}\,|+\rangle|\mathrm{adv}\rangle + \mathrm{e}^{\mathrm{i}\chi_0}\sqrt{p_-}\,|-\rangle|\mathrm{ret}\rangle.$$

Proposition 87.1 (Exact purification2 of the temporal orientations)**.** *The state $|\Psi_{\mathrm{ar}}\rangle$ is normalized, and its reduction over the advanced–retarded orientation is ρ_{hoja}. Its entropy is*

$$S_{\mathrm{hoja}} = -\sum_{\pm} p_\pm \log p_\pm = \log(2\cosh C^*_{\mathrm{rad}}) - C^*_{\mathrm{rad}} \tanh C^*_{\mathrm{rad}}.$$

The common phase A_{rad} cancels, and the reversible global evolution has zero logical Landauer cost while the leaf label is not erased.

Proof. The orthogonality of the two orientations eliminates the cross terms when taking the partial trace. Substituting $p_\pm = \mathrm{e}^{\mp C^*_{\mathrm{rad}}}/(2\cosh C^*_{\mathrm{rad}})$ gives the entropy. □

87.2.2 Geometric realization of the 2 causal sheets

Let $R(x) > 0$ be the horizon radius published by the HMT–MD selector, and

$$E_H(x) = \frac{c_{\rm int}^4 R(x)}{2G_{\rm int}(x)}.$$

In the exterior region $r > R(x)$, we fix

$$f(r) = 1 - \frac{R(x)}{r}, \qquad \mathrm{d}s^2 = -f(r)c_{\rm int}^2\mathrm{d}t^2 + f(r)^{-1}\mathrm{d}r^2 + r^2\mathrm{d}\Omega_2^2.$$

Let

$$r_* = r + R\log\Big(\frac{r}{R} - 1\Big)$$

and let $\sigma(x) \in \{+1, -1\}$ be the sheet reader. Define

$$U(x;t,r) = -\sigma(x)\exp\Big[-\frac{c_{\rm int}t - r_*}{2R}\Big], \qquad V(x;t,r) = \sigma(x)\exp\Big[\frac{c_{\rm int}t + r_*}{2R}\Big].$$

Then

$$-UV = \Big(\frac{r}{R} - 1\Big)\exp(r/R).$$

Theorem 87.2 (Geometric double sheet entangler)**.** *The preceding chart realizes the two HMT sheets as the two exterior regions of the Kruskal extension. The involution*

$$C_{\rm BH} : (\sigma, U, V) \longmapsto (-\sigma, -U, -V)$$

is isometric, fixes r, exchanges the two exterior regions, and preserves the horizon $UV = 0$. The extended metric is

$$\mathrm{d}s^2 = -\frac{4R^3}{r}\mathrm{e}^{-r/R}\,\mathrm{d}U\,\mathrm{d}V + r^2\mathrm{d}\Omega_2^2,$$

regular at $r = R$, and satisfies the vacuum Einstein equations outside the source. At the horizon it preserves

$$E_H = \frac{c_{\rm int}^4 R}{2G_{\rm int}}, \qquad S_H = \frac{k_B\pi R^2}{\ell_P^2}.$$

Proof. The formula for UV is the standard transformation of the Schwarzschild factor and removes the coordinate singularity at $r = R$. The simultaneous sign change of U, V leaves UV, r, and the metric invariant. Direct substitution gives $G_{\mu\nu} = 0$ in $r > 0$ outside the source. The horizon identities depend only on the areal radius. □

Let $\mathcal{H}_{\text{hoja}}$ be the direct sum of the Hilbert completions of the two HMT sheets, and let $\mathcal{H}_{\text{ext}}$ be the direct sum of the two exterior regions with the measure transported by the chart. The change of variables, including its Jacobian, induces a unitary operator

$$W_{\text{BH}} : \mathcal{H}_{\text{hoja}} \longrightarrow \mathcal{H}_{\text{ext}}.$$

Therefore,

$$\mathfrak{I}_{\text{BH}}(A) = W_{\text{BH}} A W_{\text{BH}}^{\dagger}$$

is to unital completely positive map, indeed to $*$-isomorfismo, that preserves state, inner product, sheet involution, and modular dynamics when the exterior state is transported by W_{BH}. If the sheet and chart refinements preserve (σ, t, r, R), their isometries j_m^{hoja} and j_m^{ext} satisfy

$$W_{\text{BH},m+1} j_m^{\text{hoja}} = j_m^{\text{ext}} W_{\text{BH},m}.$$

The family $\mathfrak{I}_{\text{BH},m}$ is then natural under refinement and transports the same enriched state without loss.

Thus the mathematical construction is closed.

$$\begin{aligned} \text{HMT double sheet} &\longrightarrow \text{advanced–retarded purification} \\ &\longrightarrow \text{two Kruskal exteriors} \longrightarrow \text{regular horizon and UCP intertwiner.} \end{aligned}$$

The identification with an astrophysical object formed by collapse, its spectrum of quasinormal modes, radiation, echoes, or polarization belongs to EXTERNAL RECOGNITION and does not weaken the geometric closure.

Chapter 88

Torsional cosmology of periodicity 108: expansion, return with memory, and Einstein–Cartan bounce

The temporal periodicity of 108 phases, the elliptic, parabolic, and hyperbolic charts of the TRIT, and torsional memory coordinate the expansion, the return, the regular bounce, and continuation toward a descendant universe. The internal theorems are stated with their domains and physical premises, without reducing them to programmatic labels.

88.1 Cosmological scales associated with the 108-state cycle and the Perron operator

88.1.1 Separation between de Sitter acceleration and Einstein–Cartan torsional bounce

The construction in cosmology comprises two internal quantities of distinct provenance. The first is derived from the periodic CT108 closure and determines a curvature scale. The second is derived from the Perron cocycle and determines a law of memory dilution. Both use the same trunk APP $\to \widehat{\mathbb{T}} \to$ TPK, but do not have the same domain or the same selector:

$$\text{TPK} \longrightarrow \text{enriched state} \longrightarrow \begin{cases} \text{chronological structure 108} \longrightarrow R_{108} \longrightarrow (H_{108}, \Lambda_{108}, T_{\mathrm{dS}}, S_{\mathrm{dS}}), \\ \text{Perron cocycle} \longrightarrow (a_n, M_n) \longrightarrow (H_\varphi, s^2 \propto a^{-6}). \end{cases} \tag{88.1}$$

The eventual equality of units or order of magnitude does not warrant identifying these realizations. The first falsification criterion of the chapter is the attempt to identify them without an intertwiner that preserves the chronological structure, orientation, memory, and the dimensional chart.

88.1.2 Periodicity condition of the 108-state cycle

Let $\ell_0 = c_{\mathrm{int}} t_0$. The period and angular frequency of the return are

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi}{108 t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0. \tag{88.2}$$

The length of the full turn is

$$C_{108} = 2\pi R_{108} = 108\,\ell_0. \tag{88.3}$$

For either of the two oriented action sections $a \in \{\mathrm{pre}, \mathrm{ret}\}$, the circular quantum

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = E_{108,a}/c_{\mathrm{int}}^2$$

satisfies simultaneously

$$\bar{\lambda}_C(m_{108,a}) = R_{108}, \qquad \lambda_C(m_{108,a}) = C_{108}. \tag{88.4}$$

The circular realization therefore does not take an external Planck length. It first constructs a radius and then demonstrates that the reduced and complete Compton readings are its two realizations.

88.1.3 Gravitational selector and Planck–TRIT relation

The homogeneous gravitational transducer is

$$G_a(\theta) = \theta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}. \tag{88.5}$$

On the circular quantum, the reduced gravitational radius is equal to

$$r_{\mathrm{g},a}(\theta) = \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta \frac{\pi}{54} \ell_0.$$

The condition $r_{\mathrm{g},a} = R_{108}$ selects in a unique mode

$$\theta_{108} = \left(\frac{54}{\pi}\right)^2. \tag{88.6}$$

The coordinate does not depend on the action sheet: upon multiplying $G_a(\theta_{108})\hbar_a$, the pre/return orientation cancels. From here there result

$$\ell_P = R_{108} = \frac{54}{\pi}\ell_0, \qquad t_P = \omega_{108}^{-1} = \frac{54}{\pi} t_0, \tag{88.7}$$

$$E_P = \hbar_a \omega_{108} = \frac{\pi}{54}\frac{\hbar_a}{t_0}, \qquad E_P = k_B \Theta_{\mathrm{clk}} \log 3. \tag{88.8}$$

The equation (88.8) expresses the structural confluence: $\log 3$ is the informational content of a TRIT decision and, in the thermal chart, converts chronological temperature into the Planck quantum. The identity does not equate the TRIT state space with gravitational space; it proves that two functional realizations determine the same scalar through distinct maps.

88.1.4 Conditioned realization of de Sitter geometry

Suppose now that the Palatini–Cartan–Holst realizer selects the internal radius R_{108} as the radius of a four-dimensional de Sitter background. The hypothesis is geometric and remains explicit: it is not deduced from a numerical coincidence with H_0. Under this hypothesis,

$$H_{108} = \frac{c_{\mathrm{int}}}{R_{108}} = \frac{\pi}{54 t_0}, \qquad \Lambda_{108} = \frac{3}{R_{108}^2} = \frac{\pi^2}{972 \ell_0^2}. \tag{88.9}$$

The Gibbons–Hawking temperature and horizon entropy are

$$k_B T_{\mathrm{dS}} = \frac{\hbar_a H_{108}}{2\pi} = \frac{\hbar_a}{108 t_0}, \qquad \frac{T_{\mathrm{dS}}}{\Theta_{\mathrm{clk}}} = \frac{\log 3}{2\pi}, \tag{88.10}$$

$$\frac{S_{\mathrm{dS}}}{k_B} = \frac{\pi R_{108}^2}{\ell_P^2} = \pi. \tag{88.11}$$

The π of equation (88.11) is not introduced as the value of an entropy to be reproduced: it appears because the circular selector gives $R_{108} = \ell_P$, and the area of the horizon sphere contains the geometric factor 4π.

Proposition 88.1 (Dimensionless family CT108–de Sitter)**.** *Under the declared de Sitter realization, the quadruple*

$$\left(H_{108} t_0, \Lambda_{108} \ell_0^2, \frac{T_{\mathrm{dS}}}{\Theta_{\mathrm{clk}}}, \frac{S_{\mathrm{dS}}}{k_B}\right) = \left(\frac{\pi}{54}, \frac{\pi^2}{972}, \frac{\log 3}{2\pi}, \pi\right)$$

is a dimensionless exact output.

Falsification criterion 88.2. The de Sitter realization is invalidated if the selected background does not satisfy $R_{\mu\nu} = \Lambda_{108} g_{\mu\nu}$, if the PCH realizer determines a radius other than R_{108}, or if the charts used in equations (88.9) y (88.10) do not share $(c_{\mathrm{int}}, t_0, \hbar_a)$. None of these failures alters the circular theorem equations (88.2) y (88.6).

88.2 Boundary conditions, bounce regularity, and decomposition of cosmological components

This chapter distinguishes two domains. The first section proves the three de Sitter foliations. Subsequent sections define the data tuples required for a cosmological realization: HMT selector, boundary chart, bounce dynamics, and descendant component. Each conclusion is restricted to the subdomain on which the evolution equations and the declared junction conditions hold.

88.2.1 Correspondence between the elliptic, parabolic, and hyperbolic regimes of the TRIT and the AdS–Euclidean–dS charts

The three quadratic algebras of the TRIT receive a coordinated geometric realization. For scales $\ell, H^{-1} > 0$, we fix the charts

$$\mathcal{M}_- = (\mathbb{D}, g_{\mathrm{AdS}}), \qquad \mathcal{M}_0 = (\mathscr{H}_0^{(L)}, g_{\mathrm{E}}), \qquad \mathcal{M}_+ = (\mathrm{dS}_4, g_{\mathrm{dS}}),$$

where the hyperbolic spatial section is represented in the Poincaré disk by

$$g_{\mathrm{AdS}}^{\mathrm{sp}} = \frac{4\ell^2\,|dz|^2}{(1-|z|^2)^2}, \qquad |z| < 1,$$

the gnomonic L carries the Euclidean chart g_{E}, and the positive chart adopts one of the de Sitter foliations constructed in the following section. The geometric functor preserves the sheet label and the change-of-chart maps:

$$\mathfrak{R}_{\mathrm{geo}} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathcal{M}_- \cup \mathcal{M}_0 \cup \mathcal{M}_+.$$

The EMRH completion distinguishes interior, crown, and edge, while the double projection preserves one and the same section before its evaluations. On the negative chart, the restriction to the edge and the incidence representation form the square

$$\begin{array}{ccc} \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} & \xrightarrow{\mathfrak{R}_{\mathrm{AdS}}} & \mathcal{M}_- \\ {\scriptstyle \mathcal{P}_{\mathrm{exc}}}\downarrow & & \downarrow{\scriptstyle \mathrm{Res}_\partial} \\ \mathcal{E}_\partial & \xrightarrow[\mathfrak{R}_{\mathrm{conf}}]{} & \mathrm{Obs}(\partial\mathcal{M}_-), \end{array}$$

with $\mathfrak{R}_{\mathrm{conf}} \circ \mathcal{P}_{\mathrm{exc}} = \mathrm{Res}_\partial \circ \mathfrak{R}_{\mathrm{AdS}}$. This identity realizes in HMT the interior–boundary holographic correspondence: the interior state and the conformal boundary observables are two representations of the same genealogy.

The Euclidean chart centralizes the local descent of inertial and gravitational readers,

$$\mathcal{G}_L / \mathcal{I}_L = 1,$$

and constitutes the locus of the equivalence principle. The state prior to that projection preserves areal–volumetric Ambivalence,

$$\mathcal{L}_{\mathrm{ar}} / \mathcal{L}_{\mathrm{vol}} = \pi_{\mathrm{HMT}} / \varphi_{\mathrm{HMT}}^2.$$

The positive chart completes the atlas with $\ddot{a}/a = H^2 > 0$. Therefore, the same geometric triple contains the holographic correspondence in negative curvature, local equivalence in zero curvature, and cosmological acceleration in positive curvature.

88.2.2 Cosmological foliations compatible with sheet inversion

Proposition 88.3 (Closed, flat, and open foliations)**.** *For $H > 0$, the three FLRW foliations of de Sitter space of radius H^{-1} are expressed, with $a_* > 0$ in the flat chart, by*

k	$a_k(t)$	*domain*
$+1$	$H^{-1}\cosh(Ht)$	$t \in \mathbb{R}$
0	$a_* e^{Ht}$	$t \in \mathbb{R}$ *(flat patch)*
-1	$H^{-1}\sinh(Ht)$	$t > 0$ *(open patch)*

and satisfy

$$\boxed{\left(\frac{\dot a_k}{a_k}\right)^2 + \frac{k}{a_k^2} = H^2, \qquad \frac{\ddot a_k}{a_k} = H^2,}$$

$$\boxed{R^{(4)} = 12H^2, \qquad R^{(3)} = \frac{6k}{a_k^2}.}$$

Proof. For $k = +1$, the first equation uses $\tanh^2 + \operatorname{sech}^2 = 1$. For $k = -1$, it uses $\coth^2 - \operatorname{csch}^2 = 1$. In the flat chart, $\dot a/a = H$. The three functions satisfy $\ddot a/a = H^2$, and the FLRW curvature formula gives $R^{(4)} = 12H^2$. Each three-dimensional spatial slice has constant sectional curvature k/a_k^2; in dimension three, contraction of the curvature tensor therefore gives $R^{(3)} = 3(3-1)k/a_k^2 = 6k/a_k^2$. □

The sign k types the curvature of the spatial sections, not the curvature of the complete spacetime: all three charts have $R^{(4)} > 0$. The closed chart is global; the flat and open charts are patches.

Hypothesis, domain, and conclusion

For a closed return route and the declared spatial choice $D = 3$, the HMT scale cocycle contributes the exact factors $\varphi^3, \varphi^9, \varphi^{36}$ at depths $9, 27, 108$, together with a spectral memory triple and a signature screen $(3, 1)$. Cosmological selection consists in constructing, on the enriched state of the TPK, a projective measure, a scale factor, and an evolution equation that intertwine these objects with the preceding foliations. Its duration variable must be derived from the action line of the section 59.2 and from its metrological chart, rather than identified with the mere number of steps. H_0, the cosmological densities, and the sign of acceleration are not used as inputs to the selector.

The three foliations constitute the exact geometric codomain of comparison. The selector constructed on the enriched state determines the chart realized by each regime, composes their domains, and preserves the observables that distinguish the selection. Identification with $k = +1, 0, -1$ is effected through that selector and not by the mere coincidence of three signs.

88.2.3 Boundary state of the cosmological horizon and return memory

The completion

$$1000 = 729 + 271 = 729 + 243 + 27 + 1$$

distinguishes interior, boundary strata, and seal. In a cosmological realization, this stratification orients the type of a construction over a pair

$$(M, \partial M),$$

endowed with a co-tetrad, Cartan connection, matter, memory, and flow. The cardinal identity does not by itself produce a manifold, a metric, a co-tetrad, or boundary conditions. It is an organizational guide that acquires physical content only through a map

$$\mathfrak{R}_{\cos} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \dashrightarrow \big(M, \partial M, e, \omega, \Psi, \mathcal{B}_{\partial M}\big).$$

The boundary is a constitutive part of the variational problem. Its spatial, temporal, or null character must be declared, as must the boundary and corner terms, the data that are fixed, and the compatibility conditions with the equations of motion. HMT memory provides a candidate domain for recording histories and prolongations, but its identification with geometric data requires the intertwining of the holonomies of test criterion 82.8.

88.2.4 Criterion of regularity of the bounce under extreme concentration and torsional dominance

An unbounded concentration of energy density, action, or curvature cannot be attributed to an energy-storage mechanism in the torsional sector. In the minimal action, the spin current locally determines the contorsion; the curvature preserves its radiative sector. A repulsive high-density correction requires a matter model with spin, a determined coupling, equation of state, and effective sign.

In an Einstein–Cartan model with spin fluid may appear

$$s^2 \propto a^{-6}.$$

If ρ_{m} denotes mass density, an effective equation may take the form

$$H^2 = \frac{8\pi G}{3}\big(\rho_{\mathrm{m}} - \rho_{\mathrm{spin,m}}\big) + \cdots .$$

If energy density ρ_{E} is used, dimensional conversion requires writing

$$H^2 = \frac{8\pi G}{3c^2}\big(\rho_{\mathrm{E}} - \rho_{\mathrm{spin,E}}\big) + \cdots .$$

Both conventions are not mixed in a single equation.

The rebound candidate is situated at

$$\rho_{\mathrm{m}} = \rho_{\mathrm{spin,m}}$$

or in the equivalent energy equality, provided that the solution is regular and satisfies the declared matter and boundary conditions. The Cartan–Holst action permits this mechanism to be studied; HMT must still construct the map that selects the current, the threshold, and the information record without consulting them retrospectively.

88.2.5 Cobordism and Descendant Cosmological Components

The opening of a descending cosmological component is formulated via a cobordism.

$$\mathcal{W} : \Sigma_{\mathrm{in}} \longrightarrow \Sigma_{\mathrm{prog}} \sqcup \Sigma_{\mathrm{desc}}.$$

Before asserting information conservation, the conserved object must be fixed. If $\mathcal{I}$ is an additive charge defined by a cocycle, one may test

$$\mathcal{I}(\Sigma_{\mathrm{in}}) = \mathcal{I}(\Sigma_{\mathrm{prog}}) + \mathcal{I}(\Sigma_{\mathrm{desc}}) + \mathcal{F}_{\partial\mathcal{W}}.$$

If $\mathcal{I}$ represents quantum information, the pertinent structure is an isometry or to unitary evolution and the balance is does not reduced, in general, to to scalar sum. The entropies of the subsystems, their correlations, and the mutual information must is computed.

A realization must specify:

1. the junction conditions among the initial, progenitor, and descendant sections;
2. the boundary and corner terms of the action;

3. causality, hyperbolicity, and the initial-value problem;
4. the control of singularities, closed timelike curves, and energy conditions;
5. the concrete charge, isometry, or conservation law that represents the information.

The Bianchi identities and Noether balance are necessary local conditions; by themselves they do not prove the change of topology nor the global conservation of information.

88.2.6 Parallel components and intercomponent mode

A disconnected boundary and a collection of sectors have distinct compositions. In a realization of topological type,

$$\mathcal{H}_{\Sigma_{\text{parent}} \sqcup \Sigma_{\text{child}}} \simeq \mathcal{H}_{\text{parent}} \otimes \mathcal{H}_{\text{child}}$$

represents the composition of components of a boundary. In contrast,

$$\mathcal{H}_{\text{cos}} = \bigoplus_{a} \mathcal{H}_a$$

represents alternatives or superselection sectors. The tensor product and the direct sum do not replace each other.

On the direct sum, a global operator candidate has block form:

$$\mathbb{H}_{\text{cos}} = \begin{pmatrix} H_1 & K_{12} & \cdots \\ K_{21} & H_2 & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix}.$$

To define a physical operator, a common dense domain or relative boundedness hypotheses, a common or relational clock, and the condition must be fixed

$$K_{ba} = K_{ab}^{\dagger}.$$

The off-diagonal blocks must be derived from the boundary, cobordism, or another declared coupling. If they are nonzero, the components form coupled sectors of a global theory; they are not independent universes in the strong sense.

An eigenvector supported on several summands constitutes an intercomponent mode. Calling its quantum a graviton further requires the reduced physical sector to possess helicities ± 2, two transverse polarizations, positive energy, luminal propagation, absence of ghosts and tachyons, Ward identities, and universal coupling. Global support alone does not satisfy these conditions.

88.2.7 Certification of the torsional bounce and exact obstructions

The realization is certified by the following constructions:

1. regular rebound solutions with matter and sign derived;
2. a well-posed boundary problem;
3. an admissible cobordism with junction conditions;
4. an information transport defined as charge, isometry, or unitary evolution;
5. a global self-adjoint operator with nondiagonal couplings selected before the comparison;
6. predictions that distinguish the realization from a single-component cosmology.

The certificate requires the regular solution, compatibility of the gluing conditions, conservation of the chosen charge or isometry, independence from arbitrary charts, and preservation of causality and

hyperbolicity. Global energy is used only when there exists a temporal symmetry or an explicit quasilocal definition.

88.3 Geometric junction between anisotropic contraction, torsional bounce, and descending cosmological region

The Big Bang may be understood as a distortion of maximal intensity among state, rank, and reader. It is not an explosion that occurred within a preexisting space. It is the limit at which the projection defining extension, distance, and duration begins to be valid. Asking what occurred "before" by using the same clock may be meaningless because the clock belongs to the regime that is emerging. HMT nevertheless preserves a genealogy prior to that publication: route, boundary, orientation, and memory.

The completion

$$1000 = 729 + 243 + 27 + 1$$

shows how a compact unit is distributed among the ternary ambient space, the visible word, the closure, and the residual unit. It does not by itself identify four cosmological eras. It provides an architecture of strata capable of distinguishing the deep state from its projection. The cosmological map takes the form

$$\mathfrak{R}_{\cos} : \text{boundary HMT state} \dashrightarrow (M, g, e, \omega, \Psi).$$

Its task is to assign rank, scale, connection, material content, and law of evolution. The thesis of initial distortion asserts that the large observed curvature is the continuous shadow of to transition of that map.

Einstein–Cartan torsion provides a dynamic bounce mechanism. For matter with spin density,

$$s^2 \propto a^{-6}.$$

The torsional contribution grows towards small volumes faster than ordinary matter. An effective equation may be written as

$$H^2 = \frac{8\pi G}{3}\left(\rho_{\mathrm{m}} - \rho_{\mathrm{spin}}\right) - \frac{k}{a^2} + \frac{\Lambda}{3},$$

with the factors of c restored according to whether mass or energy densities are used. The equality

$$\rho_{\mathrm{m}} = \rho_{\mathrm{spin}}$$

localizes the candidate for material–torsional cancellation. There is bounce when, at a nonzero scale, the complete expression of the right-hand member vanishes,

$$H^2 = 0,$$

and the acceleration equation gives $\dot{H} > 0$; the curvature terms and Λ must vanish, compensate one another, or be included explicitly in that condition. Under these hypotheses, the contraction reaches a minimum and reverses. The mechanism does not introduce an arbitrary pressure: it follows from the Cartan equation and the spin current.

HMT interprets that threshold as sheet closure and reopening. During contraction, the visible extension is compactified and internal memory increases. At the return point, the published orientation changes and a new expansive branch becomes accessible. The singularity ceases to be the only possible endpoint because the state variable is not reduced to the scale factor. The enriched route may continue when the preceding cosmological chart loses rank.

The same geometry permits formulation of a child universe. For an exterior observer, a collapsing region remains behind a horizon. For the global section, closure may open a boundary with its own orientation and time. Gluing is described as a cobordism or transition between sheet components, not as

the appearance of matter from nothing. Information not published in the parent universe may become a boundary condition of the child universe.

This image coordinates three phenomena usually studied separately: collapse, horizon, and cosmological origin. The same closure operation that forms a trapped region may produce a reopening after the torsional scale is reached. The same memory that protects exterior information may fix the conditions of the new branch. And the same change of orientation that defines particle and antiparticle on the microscopic scale may acquire a macroscopic causal realization.

The complete realization requires a global solution. It must contain an Einstein exterior, a region of non-negligible torsion, a regular minimum of the scale factor, a causal continuation, and a state map between boundaries. It must respect covariant conservation and produce an observable: a remnant distribution, nonthermal correlations, a modification of the gravitational-wave spectrum, or a primordial imprint. If the bounce scale contradicts nucleosynthesis, the cosmic background, or torsion bounds, the concrete mechanism is ruled out. The sheet thesis does not exempt the dynamics; it supplies the object that the dynamics must evolve.

88.4 Elliptic, parabolic, and hyperbolic regimes of TRIT and their projection onto the dark sector

The $\widehat{\mathbb{T}}$ does not merely orient past, threshold, and opening. Its three values determine the three real quadratic algebras

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau}).$$

The generators satisfy

$$\bar{\tau} = +1: \quad J^2 = -I, \qquad \bar{\tau} = 0: \quad J^2 = 0, \qquad \bar{\tau} = -1: \quad J^2 = +I.$$

They are the elliptic, parabolic, and hyperbolic regimes. The model geometry

$$g_{s,\rho} = \mathrm{d}r^2 + S_{s,\rho}(r)^2\,\mathrm{d}\theta^2$$

is obtained with

$$S_{+,\rho}(r) = \rho^{-1}\sin(\rho r), \qquad S_{0,\rho}(r) = r, \qquad S_{-,\rho}(r) = \rho^{-1}\sinh(\rho r),$$

and has

$$K_G = s\rho^2.$$

The three curvatures are not attributed simultaneously to the same metric at the same point. They are coordinated sheets of to state whose physical chart selects the realized regime.

de Sitter space demonstrates exactly how a single four-dimensional geometry can admit three spatial presentations:

$$\mathrm{d}s^2 = -\,\mathrm{d}t^2 + a_s(t)^2\,\mathrm{d}\Sigma_s^2, \qquad s \in \{+1, 0, -1\}.$$

The functions

$$a_+(t) = H^{-1}\cosh(Ht), \quad a_0(t) = \mathrm{e}^{Ht},$$
$$a_-(t) = H^{-1}\sinh(Ht), \qquad t > 0,$$

satisfy

$$\frac{\ddot{a}_s}{a_s} = H^2, \qquad \left(\frac{\dot{a}_s}{a_s}\right)^2 + \frac{s}{a_s^2} = H^2, \qquad R = 12H^2.$$

TO closed, to flat, and an open foliation describe the same spacetime. Local spatial flatness, hyperbolic section, and positive acceleration are not incompatible signs. They may is distinct sheets of to single global geometry.

This fact provides a continuous model for the HMT intuition. The value published on one sheet does not necessarily contain the entire curvature of the state. An observer working in the flat foliation may reconstruct as an additional source the effect that follows from boundary incidence or another presentation. Dark matter and dark energy thereby receive a unified but differentiated interpretation.

Apparent dark matter may correspond to the gravitational response of states that have no point representative on the visible sheet. Its mass manifests itself in orbits and lensing because the complete geometry transports its incidence, even though the electromagnetic reader does not publish an ordinary particle. Apparent dark energy may correspond to the global response of sheet opening and curvature, published as acceleration of the scale factor. The former belongs primarily to the distribution of nonvisible retention; the latter, to the evolution of the cosmological boundary.

The hinge

$$\frac{G_{\mathrm{tor}}}{I_{\mathrm{tor}}} = 1, \qquad \frac{G_{\mathrm{av}}}{I_{\mathrm{av}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^{2}}$$

indicates where to seek that residue. The marked ratio is a structural relation between readings, not a cosmological percentage that can be identified directly with an observed density. To become a theory of the dark sector, it must be integrated over the geometry and produce an effective tensor $T_{\mu\nu}^{\mathrm{eff}}$, its continuity equations, and a transfer function.

The requirement is especially stringent because a single rule must span several scales. In galaxies it must relate baryonic density, circular velocity, and lensing without introducing a new parameter for each object. In clusters it must coordinate gas, weak lensing, and dynamics. In cosmology it must predict $H(z)$, distances, structure growth, and lensing potentials. If the same multisheet geometry produces those profiles with parameters fixed before each system is examined, HMT–MD will have replaced two unknown sectors with a single architecture. If it requires independent adjustments, the interpretation will not have attained its objective.

The triple foliation additionally imposes conceptual discipline. Not every hyperbolic curvature is a sign of dark energy, nor does every local flatness eliminate global curvature. Chart, domain, and scale must be declared. The de Sitter parameter H is likewise not selected solely by the existence of the three foliations. Mathematics proves their compatibility; the cosmological transducer must derive the physical scale and its evolution.

88.5 Temporal Orientation of the Cosmic Background and Memory Conservation Under Expansion

The dodecaphonic closure produces a very restricted angular template. Let

$$\phi_k = \phi_0 + \frac{2\pi k}{12}, \qquad k = 0, \dots, 11,$$

and

$$w_k = \frac{1}{12}\left[1 + 2\epsilon \cos(3\phi_k - \delta)\right], \qquad |\epsilon| \le \frac{1}{2}.$$

The weights are non-negative and sum to one. Its discrete transform has support only in

$$m = 0, \pm 3 \pmod{12}.$$

Upon projecting onto low multipoles, for $\ell = 2$ can only survive $m = 0$; for $\ell = 3$, $m = 0, \pm 3$. The family C_{12} converts the dodecaphasic wheel into an exact angular envelope.

Its physical importance lies in its restrictiveness. The axis, phase δ, amplitude ϵ, celestial mask, estimator, and multipole set must be fixed before examining the map to be used for comparison. Data from independent frequencies and missions are then compared with isotropic simulations and contamination models. A stable signal on the predicted support would strengthen the dodecaphasic genealogy. A

posterior selection of the axis or a dominant signal outside $m = 0, \pm 3$ would exclude that particular realization.

The cosmic arrow of time uses the same ternary reader that organizes the leaves:

$$+1 \longmapsto \text{return, memory, past,}$$

$$0 \longmapsto \text{threshold, present,}$$

$$-1 \longmapsto \text{bidirectional opening, future.}$$

The present is not a point moving along a previously traced line. It is the threshold at which an admissible opening becomes actual and begins to be preserved as memory. The past is the sector of returns already recorded; the future is the set of compatible continuations that have not yet closed.

The complete evolution may be reversible while the published history has orientation. Asymmetry appears in preparation, in boundary selection, and in the reader that discards part of the fiber. Entropy does not create time; it measures the information that a presentation ceases to distinguish. For an action on histories $I(\gamma)$, the measure

$$\mathbb{P}_\beta(\gamma) = \frac{\mathrm{e}^{-\beta I(\gamma)}}{Z_\beta}$$

minimizes

$$\mathbb{E}_{\mathbb{P}}[I] - \beta^{-1} H(\mathbb{P}).$$

In the low-temperature limit, the minimal interaction dominates; at finite temperature, route multiplicity intervenes. Action and entropy are two components of the same selection, not two rival causes.

A round-trip story can be purified as

$$|\Omega_\beta\rangle = \sum_\gamma \sqrt{\mathbb{P}_\beta(\gamma)}\, |\gamma\rangle_{\text{ida}} |C\gamma\rangle_{\text{vuelta}}.$$

The reduced entropy is $H(\mathbb{P}_\beta)$. The observed universe may possess an arrow because we access one branch, whereas the enlarged state preserves conjugation. This picture links the microscopic particle and antiparticle orientation with macroscopic asymmetry without asserting that the two scales are identical.

HMT–MD cosmology is thus organized by a single fundamental operation: folding, preserving, and unfolding. Matter is a section that retains space; the horizon folds one presentation into another sheet; the bounce unfolds a branch after compactification; the dark sector is the response of geometric information that the visible sheet does not publish; and time is the orientation of opening and return. Each of these statements acquires physical force by sharing the same state domain, not by forming a collection of analogies.

The theory commits itself to clear consequences. The black hole exterior must obey relativity within its tested regime, and the inversion must provide a continuation and a signal. The bounce must fix its scale through spin density and remain consistent with nucleosynthesis and the cosmic background. The multisheet transfer function must jointly explain dynamics, lensing, and expansion. The template C_{12} must survive a prospective test. The arrow of time must respect global reversibility and the cost of erasure. These conditions do not weaken the cosmological thesis: they are the route by which a mathematical architecture becomes a physics of the universe.

88.6 Torsional junction of a trapped region and construction of a descending cosmological branch

88.6.1 Torsional gluing of a trapped region: exact, conditioned, and physical strata of the descendant cosmological branch

The section 81.4 establishes the memory law

$$M_n = \left(\frac{a_n}{a_0}\right)^{-6} \tag{88.12}$$

and formulates its realization through a quadratic spin density in Einstein–Cartan. The present chapter studies the additional passage from a torsional bounce to an expansive causal region situated beyond the trapped interior of a black hole.

The exposition distinguishes 3 strata:

1. *structure exact*: orientation TRIT, involution of Möbius, conservation isometric of the canal and law V^{-2};
2. *conditioned consequence*: Einstein–Cartan bounce, geometric splice and causal opening under declared hypotheses;
3. *classified geometric realization*: explicit existence of the descendant continuation, minimal, and obstruction to the classical branched cobordism with topological change.

This stratification makes it possible to develop the complete image and preserve the status of each assertion.

The common antecedent is an enriched state

$$X_{\mathrm{TPK}}^{\mathrm{enr}} = (x, \text{fiber}, \text{orientation}, \text{carry}, \text{boundary}, \text{route}, \text{memory}, \text{observer}), \tag{88.13}$$

produced by APP $\to \widehat{\mathbb{T}} \to$ TPK. The causal, torsional, topological, and quantum readers are applied to this same state and preserve its genealogy.

88.6.2 Causal orientation of the 3 leaves

The TRIT grammar is realized through the algebras

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \tau), \qquad J_\tau^2 = -\tau I, \qquad \tau \in \{+1, 0, -1\}. \tag{88.14}$$

Their exponentials are

$$\mathrm{e}^{tJ_{+1}} = \cos t\, I + \sin t\, J_{+1}, \tag{88.15}$$

$$\mathrm{e}^{tJ_0} = I + tJ_0, \tag{88.16}$$

$$\mathrm{e}^{tJ_{-1}} = \cosh t\, I + \sinh t\, J_{-1}. \tag{88.17}$$

The sheet +1 carries closure, return, and memory; the sheet 0 carries the threshold, present, and first variation; the sheet −1 carries openness, propagation, and the two-way future.

Let ϑ be an oriented expansion scalar. Define the causal reader

$$\boxed{\tau_{\mathrm{cau}}(\vartheta) := -\operatorname{sgn}(\vartheta) \in \{-1, 0, +1\}.} \tag{88.18}$$

A positive expansion publishes opening −1; a zero expansion publishes threshold 0; a negative expansion publishes closure +1.

In to family of spheres, $\vartheta = \theta_{(\ell)}$ may tomarse as the expansion null saliente. In a region homogeneous or anisotropic, $\vartheta = \Theta$ may tomarse as the expansion volumetric. These two observables occupy distinct domains and share the same sign rule.

Proposition 88.4 (Double-threshold causal sequence)**.** *Assume the sign conditions*

$$\theta_{(\ell)} > 0 \text{ in the exterior}, \quad \theta_{(\ell)} = 0 \text{ at the horizon}, \quad \theta_{(\ell)} < 0 \text{ in the trapped interior}, \tag{88.19}$$

and

$$\Theta < 0 \text{ before the bounce}, \quad \Theta = 0 \text{ at the bounce}, \quad \Theta > 0 \text{ after the bounce}. \tag{88.20}$$

The reader equation (88.18) produces the sequence

$$\boxed{-1_{\text{exterior}} \longrightarrow 0_{\text{horizonte}} \longrightarrow +1_{\text{interior}} \longrightarrow 0_{\text{rebote}} \longrightarrow -1_{\text{descendiente}}.} \tag{88.21}$$

Proof. The assertion follows by applying $\tau_{\text{cau}}(\vartheta) = -\operatorname{sgn}(\vartheta)$ to each sign of equations (88.19) y (88.20). □

The two states 0 are realizations of the same threshold archetype. The first expresses null marginality; the second expresses volumetric marginality. The identity of the sign preserves the grammar, while the declared observable determines the physical content of each threshold.

88.6.3 Anisotropic interior and quadratic memory

An interior region, spherically symmetric, admits the Kantowski–Sachs reduction

$$\mathrm{d}s^2 = -N(\tau)^2\,\mathrm{d}\tau^2 + a_{\parallel}(\tau)^2\,\mathrm{d}\chi^2 + a_{\perp}(\tau)^2\,\mathrm{d}\Omega_2^2. \tag{88.22}$$

The volume of a comoving cell is

$$V(\tau) = V_0 a_{\parallel} a_{\perp}^2, \tag{88.23}$$

and its expansion is

$$\Theta := \frac{1}{N}\frac{\dot{V}}{V} = H_{\parallel} + 2H_{\perp}, \qquad H_i := \frac{1}{N}\frac{\dot{a}_i}{a_i}. \tag{88.24}$$

A comoving spin charge N_s produces a density

$$n_s = \frac{N_s}{V}, \tag{88.25}$$

and the Cartan equation, linear in the current, generates a correction of quadratic form

$$\rho_s = s_0 \left(\frac{V}{V_0}\right)^{-2}. \tag{88.26}$$

The Perron branch publishes exactly the same covariance:

$$M_n = V_n^{-2}. \tag{88.27}$$

The torsional transducer

$$\mathcal{T}_{\text{EC}} : M_n \longmapsto \rho_{s,n} = s_0 M_n \tag{88.28}$$

preserves positivity and the volume exponent. The amplitude s_0 follows from the Cartan current and retains its obligation of prospective selection.

For the discussion local adoptamos units geometric $c = 1$. A restriction efectiva of Kantowski–Sachs has the form

$$\frac{\Theta^2}{3} = 8\pi G(\rho_m - \rho_s) + \sigma^2 - \frac{1}{2}\,{}^{(3)}R + \Lambda, \tag{88.29}$$

where σ^2 is the shear and ${}^{(3)}R$ the curvature of the sheet. A regular volumetric bounce satisfies

$$\boxed{\Theta(\tau_b) = 0, \qquad \frac{1}{N}\dot{\Theta}(\tau_b) > 0,} \tag{88.30}$$

together with positive finiteness of $a_\parallel, a_\perp$ and of the curvature and torsion invariants.

Comparison Criterion 88.5 (Anisotropic torsional dominance)**.** Suppose that, during the contraction,

$$\rho_s = s_0 V^{-2}, \qquad \sigma^2 = \Sigma_0^2 V^{-2} + o(V^{-2}), \tag{88.31}$$

and that matter, curvature, and Λ grow with a power strictly less than V^{-2}. The inequality

$$\boxed{8\pi G s_0 > \Sigma_0^2} \tag{88.32}$$

is a sufficient condition for the torsional term to dominate the shear in the regime of small volume. The existence of a transverse root of equation (88.29) and the inequality equation (88.30) complete the bounce criterion.

Asymptotic dominance supplies the mechanism; the transversal root supplies the geometric event. This distinction preserves the dependence on curvature, anisotropy, equation of state, and boundary data.

88.6.4 Nonadic condition for the bounce level

Write $x := a/a_0$ for the dimensionless isotropic scale. At the complete returns $n = 9q$, the Perron branch satisfies

$$x_{9q} = \frac{a_{9q}}{a_0} = \varphi_{\mathrm{HMT}}^{3q}. \tag{88.33}$$

In the isotropic reduction with

$$\rho_m = \rho_0 x^{-3(1+w)}, \qquad \rho_s = s_0 x^{-6}, \qquad w < 1, \tag{88.34}$$

the equality of densities fixes

$$x_b^{3(1-w)} = \frac{s_0}{\rho_0}. \tag{88.35}$$

If the bounce is required over a complete TPK turn, the elimination of x_b yields

$$\boxed{q_b = \frac{\log(s_0/\rho_0)}{9(1-w)\log\varphi_{\mathrm{HMT}}}, \qquad q_b \in \mathbb{Z}.} \tag{88.36}$$

The integrality of q_b is an additional condition of synchronization, derived from the hypothesis that the bounce coincides with the nonadic return. A continuous bounce between two circuits satisfies equation (88.35) and has a different status.

Proposition 88.6 (Falsifiability of the Synchronous Bounce)**.** *With (s_0, ρ_0, w) fixed prospectively, the synchronized realization exists only if the number of equation (88.36) is an integer. The distance*

$$\delta_9 := \mathrm{dist}(q_b, \mathbb{Z}) \tag{88.37}$$

is a quantitative falsifier and cancels exactly at an allowed level.

Proof. The condition $n = 9q$ requires $q \in \mathbb{Z}$. Substituting equation (88.33) into equation (88.35) and taking logarithms produces the formula. The characterization of δ_9 follows from the definition of distance to the integers. □

88.6.5 Matching data on the bounce hypersurface

Let Σ_b be a spatial hypersurface separating a contractive region $\mathcal{M}_-$ from an expansive region $\mathcal{M}_+$. Denote by h_{ij} the induced metric, by n^μ the oriented normal, and by $\mathring{K}^{\pm}_{ij}$ the extrinsic curvatures computed with the Levi–Civita connection on each side. We adopt

$$[X] := X^+\big|_{\Sigma_b} - X^-\big|_{\Sigma_b}, \qquad \kappa := \frac{8\pi G}{c^4}. \tag{88.38}$$

The Israel metric conditions are

$$[h_{ij}] = 0, \tag{88.39}$$

$$[\mathring{K}_{ij} - h_{ij}\mathring{K}] = -\kappa S^{\Sigma}_{ij}, \tag{88.40}$$

where S^{Σ}_{ij} is the surface energy–momentum tensor under the fixed-normal convention. A junction without a material layer satisfies

$$[h_{ij}] = 0, \qquad [\mathring{K}_{ij}] = 0. \tag{88.41}$$

The inversion of Θ then crosses to continuous zero and remains realizada by the dynamics, rather than being introduced by to jump of the normal.

In the first-order formulation, let $\omega^{ab} = \mathring{\omega}^{ab} + C^{ab}$ be the connection with contorsion, and write $T_\mu := T^\lambda{}_{\mu\lambda}$ for the trace of the torsion. We fix the normalization of the spin current through the Cartan equation

$$\mathscr{C}(T)^\lambda{}_{\mu\nu} := T^\lambda{}_{\mu\nu} + \delta^\lambda_\mu T_\nu - \delta^\lambda_\nu T_\mu = \kappa s^\lambda{}_{\mu\nu}. \tag{88.42}$$

Its distributional part over Σ_b requires

$$\boxed{\mathscr{C}(T_\Sigma) = \kappa s_\Sigma.} \tag{88.43}$$

In the absence of a superficial spin layer, $s_\Sigma = 0$, the admissible connection lacks a delta torsional component, and the tangential contorsion has regular gluing. An action with a Holst term or nonminimal fermionic couplings replaces $\mathscr{C}$ by the corresponding algebraic operator; the conditions are obtained by integrating that equation across the layer.

Comparison Criterion 88.7 (Regular Israel–Cartan gluing)**.** A regular torsional seam through Σ_b requires:

i) continuity of the induced costructure, equivalent to equation (88.39) up to Lorentz gauge;

ii) equation of Israel equation (88.40) with every capa superficial declared;

iii) Cartan equation equation (88.43) with every declared surface current;

iv) continuity of the gauge charges and of the route orientation;

v) finiteness of the curvature and torsion invariants.

The Ashtekar–Barbero Connection

$$A^a_i = \Gamma^a_i + \gamma_{\mathrm{BI}} K^a_i \tag{88.44}$$

can act as a reader of the seam when both sides share costructure, γ_{BI}, and normalization. Its continuity is a conditional consequence of the corresponding gluing data; its verification requires the explicit transport of Γ and K to the same boundary section.

Proposition 88.8 (Joint involution of Barbero and extrinsic curvature)**.** *Consider the algebraic involution*

$$\mathfrak{J}_b : (\Gamma_i^a, K_i^a, \gamma_{\mathrm{BI}}) \longmapsto (\Gamma_i^a, -K_i^a, -\gamma_{\mathrm{BI}}). \tag{88.45}$$

Then

$$\mathfrak{J}_b(A_i^a) = A_i^a, \tag{88.46}$$

and every area spectrum that depends on $|\gamma_{\mathrm{BI}}|$ remains invariant. Identification of $\mathfrak{J}_b$ with the dynamic inversion of the bounce requires the Israel–Cartan intertwiner to transport the orientation of K and the sheet of γ_{BI} according to equation (88.45).

Proof. The product of the two oriented factors satisfies $(-\gamma_{\mathrm{BI}})(-K_i^a) = \gamma_{\mathrm{BI}} K_i^a$, while Γ_i^a remains fixed. The areal dependence on $|\gamma_{\mathrm{BI}}|$ is even. □

88.6.6 Null horizon as a marginal hypersurface and initial matching condition

The horizon hypersurface Σ_H has null character and requires adapted junction data. Let q_{AB} be the two-dimensional metric of the sections, ℓ^μ the null generator, and N^μ a transverse vector with $\ell \cdot N = -1$. The transverse curvature is

$$C_{AB} := q_A{}^\mu q_B{}^\nu \nabla_\mu N_\nu. \tag{88.47}$$

A null junction without an impulsive layer preserves q_{AB}, the class of C_{AB} that determines the surface tension and the tangential Cartan flux. Marginality

$$\theta_{(\ell)}\big|_{\Sigma_H} = 0 \tag{88.48}$$

realizes the first state 0 of equation (88.21). The formulation null mantiene separada this condition of the condition volumetric $\Theta|_{\Sigma_b} = 0$.

88.6.7 Möbius band and orientation memory

The dodecaphasic words are acted on by the involution of genealogical type

$$C_M(\mathbf{t}) := -\operatorname{rev}(\mathbf{t}), \qquad C_M^2 = I. \tag{88.49}$$

The associated oriented line is obtained by the quotient

$$(\mathbf{t}, \chi) \sim (C_M \mathbf{t}, -\chi). \tag{88.50}$$

When the base is a return loop, this identification defines a band with holonomy $-I$: one turn reverses orientation and two turns restore it.

Let $\mathscr{H}_\gamma$ denote the holonomy over one turn. The hierarchy

$$\mathcal{R}_{\mathrm{vec}} \subseteq \mathcal{R}_{\mathrm{ray}} \subseteq \mathcal{R}_{\mathrm{obs}} \tag{88.51}$$

distinguishes return of vector, return of ray, and return of observable. For $\mathscr{H}_\gamma = -I$, the ray returns in one turn, the oriented vector returns in two and the sign memory preserves the traversal.

Proposition 88.9 (Topological status of the band)**.** *The relation equation (88.50) defines a real line that is nonorientable over the loop exactly when its first Stiefel–Whitney class satisfies*

$$w_1 = 1 \in H^1(S^1; \mathbb{Z}_2). \tag{88.52}$$

This assertion concerns to the haz genealogical of orientation. A realization as topology of the spacetime requires to morphism toward the frame or spinor bundle that preserves causality and Cartan structure.

Proof. A real line over S^1 is determined by the parity of its transition function. The transition -1 of equation (88.50) represents the nontrivial class; two circuits square the transition and yield $+1$. □

The band provides an exact representation of orientation and memory. Physical continuity across the horizon and the bounce is formulated through the junctions of the preceding sections; both structures are coordinated by an intertwiner and preserve their domains.

88.6.8 Relative Observer, Parallel Transport and Autoinertia in the Descending Cosmological Region

The expanded dynamic state includes observer and memory:

$$\Gamma = (x, O, m), \tag{88.53}$$

and the frame accessible to the observer is a restriction of the total connection,

$$\mathfrak{F}_O(\Gamma) := \mathrm{Res}_O(\Gamma, \nabla_{\mathrm{TPK}}). \tag{88.54}$$

A horizontal trajectory of the complete system,

$$\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma = 0, \tag{88.55}$$

can publish acceleration in a subsystem S:

$$a_S = \nabla^S_{\dot\gamma_S}\dot\gamma_S = \mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma), \tag{88.56}$$

where $\mathcal{K}_{\pi_S}$ is the second fundamental tensor of the projection. Self-inertia denotes the horizontality of the whole and the response induced in its projections.

The coupling between system, apparatus, and register is described by an isometry

$$V_{\mathrm{obs}} : \mathcal{H}_{\mathrm{in}} \longrightarrow \mathcal{H}_{\mathrm{sys}} \otimes \mathcal{H}_{\mathrm{mem}}, \qquad V^*_{\mathrm{obs}} V_{\mathrm{obs}} = I. \tag{88.57}$$

Let $\{P_y\}$ be the PVM of the register in $\mathcal{H}_{\mathrm{mem}}$, with

$$P_y P_z = \delta_{yz} P_y, \qquad \sum_y P_y = I_{\mathrm{mem}}. \tag{88.58}$$

The isometry and this PVM induce the completely positive instrument

$$\mathcal{I}_y(\rho) := \mathrm{Tr}_{\mathrm{mem}}\left[(I_{\mathrm{sys}} \otimes P_y) V_{\mathrm{obs}} \rho V^*_{\mathrm{obs}} (I_{\mathrm{sys}} \otimes P_y)\right], \qquad \sum_y \mathrm{Tr}\, \mathcal{I}_y(\rho) = \mathrm{Tr}\, \rho. \tag{88.59}$$

The relative states are then obtained by means of

$$p(y) = \mathrm{Tr}\, \mathcal{I}_y(\rho), \qquad \rho_y = \frac{\mathcal{I}_y(\rho)}{p(y)}. \tag{88.60}$$

The section ρ_y is the state relative to the record y; the global state preserves all channels in the image of the isometry. This structure formalizes the kinship with Everett at the precise level of relative states and leaves the ontology of the branches as a choice in subsequent physical terms.

88.6.9 Global channel of the descendant region

The operatorial version of a descendant opening uses an isometry

$$V_{\mathrm{pc}} : \mathcal{H}_{\mathrm{in}} \longrightarrow \mathcal{H}_{\mathrm{parent}} \otimes \mathcal{H}_{\mathrm{child}}, \qquad V_{\mathrm{pc}}^{*} V_{\mathrm{pc}} = I. \tag{88.61}$$

The joint channel and its complementary channels are

$$\mathcal{N}_{\mathrm{pc}}(\rho) = V_{\mathrm{pc}} \rho V_{\mathrm{pc}}^{*}, \tag{88.62}$$

$$\mathcal{N}_{\mathrm{parent}}(\rho) = \mathrm{Tr}_{\mathrm{child}}\, \mathcal{N}_{\mathrm{pc}}(\rho), \qquad \mathcal{N}_{\mathrm{child}}(\rho) = \mathrm{Tr}_{\mathrm{parent}}\, \mathcal{N}_{\mathrm{pc}}(\rho). \tag{88.63}$$

Theorem 88.10 (Global Conservation and Relative Distribution)**.** *The map $\mathcal{N}_{\mathrm{pc}}$ preserves trace and purity of to pure state on its image. The parental and descendant channels may produces mixed states, and for to pure bipartite output satisfy*

$$S(\rho_{\mathrm{parent}}) = S(\rho_{\mathrm{child}}). \tag{88.64}$$

The global information is contained in the outputs and their correlations.

Proof. The identity $V_{\mathrm{pc}}^{*} V_{\mathrm{pc}} = I$ implies

$$\mathrm{Tr}(V_{\mathrm{pc}} \rho V_{\mathrm{pc}}^{*}) = \mathrm{Tr}(\rho V_{\mathrm{pc}}^{*} V_{\mathrm{pc}}) = \mathrm{Tr}\, \rho.$$

An isometry maps unit vectors to unit vectors. Equality of the reduced entropies follows from the Schmidt decomposition of the pure bipartite state. □

The conservation of a charge Q or of energy requires, in addition, the intertwinings

$$Q_{\mathrm{out}} V_{\mathrm{pc}} = V_{\mathrm{pc}} Q_{\mathrm{in}}, \qquad H_{\mathrm{out}} V_{\mathrm{pc}} = V_{\mathrm{pc}} H_{\mathrm{in}}. \tag{88.65}$$

The isometry preserves probability; the equations equation (88.65) preserve the declared dynamic quantities. An admissible output distributes the information among correlations and respects the impossibility of cloning an arbitrary state into two identical copies.

The provenance of the sectors 90/120 is preserved through the modular holographic Hamiltonian

$$K_{\mathrm{HHM}} = c_0 I + \Delta_{\mathrm{mod}} (90 N_{90} + 120 N_{120}). \tag{88.66}$$

The total occupation and the weighted memory,

$$N = N_{90} + N_{120}, \qquad D = 90 N_{90} + 120 N_{120}, \tag{88.67}$$

Transport of the total occupation is imposed as an independent operator identity:

$$N^{\mathrm{out}} V_{\mathrm{pc}} = V_{\mathrm{pc}} N^{\mathrm{in}}. \tag{88.68}$$

With N and the weighted memory D conserved, the two sectors are reconstructed uniquely:

$$N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N. \tag{88.69}$$

The condition of transport

$$K_{\mathrm{HHM}}^{\mathrm{out}} V_{\mathrm{pc}} = V_{\mathrm{pc}} K_{\mathrm{HHM}}^{\mathrm{in}} \tag{88.70}$$

The identities equations (88.68) y (88.70) jointly preserve occupation and sectorial provenance across the seam. These equalities are added to the dynamic obligations of a complete realization.

88.6.10 Descendant continuation and branched cobordism

The denomination *descendant universe* admits two geometric levels.

Definition 88.11 (Minimal descendant continuation)**.** A descendant continuation is a region $\mathcal{M}_{\text{child}}$ situated to the future of the rebound, with

$$\Theta > 0, \qquad \text{finite curvature and torsion,} \qquad \text{a global time function in its causal domain.} \tag{88.71}$$

The region may pertenecer to a prolongation conectada of the interior and preserves the topology of the hojas espaciales.

Definition 88.12 (Parent-Child Cobordism)**.** The branched version is an effective cobordism

$$\mathcal{W} : \Sigma_{\text{in}} \longrightarrow \Sigma_{\text{parent}} \sqcup \Sigma_{\text{child}}, \tag{88.72}$$

equipped with Cartan structure, gluing data test criterion 88.7, and channel equation (88.61).

The minimal continuation requires a bounce and a causal extension. The branched cobordism adds topological change and separation of outputs. In a Lorentzian geometry that is classical, nondegenerate, and globally hyperbolic, topological change is subject to causal obstructions. The branched version must therefore be realized through a region that is quantum or torsional and in which it is declared which classical hypothesis is modified, or through an interpretation of two causal domains within a single global topology.

Comparison Criterion 88.13 (Promotion to a Physical Descendant Universe)**.** The complete image acquires the status of a realization that is physical when the following are constructed simultaneously:

i) a solution of the Einstein–Cartan equations with equation (88.30);

ii) regular Israel–Cartan data on Σ_H and Σ_b;

iii) a future expansive region with temporal function and Cauchy surfaces in each accessible branch;

iv) finiteness of invariants and prolongation of geodesics through the nucleus;

v) absence of closed causal curves and unregistered layers;

vi) an isometric channel that preserves the declared charges and the Hamiltonian of provenance equation (88.70);

vii) nonadic naturality of the torsional current and the boundary data;

viii) an intertwiner between the genealogical band and the physical bundle of frames or spinors.

These conditions transforman the narrative equation (88.21) in a problema of existence geometric, operatorial and causal with controles separate.

88.6.11 Local consequences of the torsional matching: conservation, regularity, and causal prolongation

Proposition 88.14 (Content of a Complete Realization)**.** *Suppose that the test criterion 88.13 is satisfied. Then:*

a) the causal sign traverses the sequence equation (88.21)*;*

b) the torsional memory preserves the covariance V^{-2} on both sides of the rebound;

c) the global state evolves through a trace-preserving channel;

d) each observer accesses a relative state of its branch;

e) the charges included in equation (88.65) are conserved;

f) the orientation of Möbius is transported as holonomy data.

Proof. Each assertion is the application of one of the conditions of the criterion: the causal reader proves (a); the torsional transducer proves (b); the isometry proves (c) and (d); the intertwinings prove (e); and the sheaf morphism proves (f). □

The proposition organizes consequences of a constructed structure. The existence of the minimal continuation is resolved by the theorem 88.15; classical branching with a topological change is classified by the obstruction of the theorem 88.16.

88.6.12 Torsional dynamics of bounce: exact identities, cosmological interfaces and closure conditions

Object	Status	Obligation or control
Law $M_n = V_n^{-2}$	Exact internal result	Perron's Certificate and Refinement
Reader $-\operatorname{sgn}\vartheta$	Exact formalization	Observable of expansion tipado
Homogeneous bounce	Consecuencia condicionada	$s_0 > 0$, $w < 1$, transverse zero
Kantowski–Sachs Bounce	Physical Interface	Dominance of controlled torsion, shear, and curvature
Israel–Cartan Joining	Physical Interface	Declared layer and spin current data
Möbius band	Exact Topological Result	Intertwiner toward the physical bundle
Estado relativo	Exact operational result	Instrument and observed fiber
Parent–offspring canal	Conditional formalization	Isometry and Conservation of Charges
Descendant continuation	Existence theorem	Solution regular and causally complete
Cobordismo ramificado	Proven classical obstruction	Incompatibility with global hyperbolicity and topological change

88.6.13 Obstructions to Cosmological Continuation: Loss of Orientation, Junction Regularity, or Return Memory

The negative controls distinguish each layer:

1. a solution with $\Theta = 0$ and $\dot{\Theta} < 0$ represents a volume maximum and remains outside the bounce;
2. the case $8\pi G s_0 \leq \Sigma_0^2$ removes the guarantee of anisotropic torsional dominance;
3. a $q_b \notin \mathbb{Z}$ preserves the continuous rebound and refutes the version synchronized with a complete turn;
4. a jump of h_{ij}, of the Israel quantity, or of the Cartan current requires an explicit surface layer;
5. a band with $w_1 = 0$ has global orientation and refutes the realization of Möbius;
6. a map V_{pc} with $V_{\mathrm{pc}}^* V_{\mathrm{pc}} \neq I$ loses global probability;
7. two identical copies of an arbitrary state violate the no- cloning control and refute the correlated distribution reading;
8. a descendant region with closed causal curves, divergent invariants, or inextendible geodesics fails the causal promotion;
9. a topological change that simultaneously preserves all the obstructed classical hypotheses lacks the required geometric domain.

Estatuto probatorio

The grammar $-1, 0, +1$, the sign reader, the involution $C_M^2 = I$, the classification of the band, the law V^{-2}, the hierarchy of returns, and conservation of an isometric channel are exact results in their domains. The Einstein–Cartan bounce is a consequence of the declared equations and inequalities. The extension to Kantowski–Sachs, the junctions, continuity of the Barbero connection, and causal opening are physical interfaces. The minimal parent–descendant continuation is realized by the theorem 88.15; branched topological change under the classical hypotheses is excluded by the theorem 88.16.

Falsification criterion

The torsional seam is refuted if the current constructed from HMT produces a power different from V^{-2}, an amplitude with an incompatible sign, or a failure of refinement. The bounce is refuted by the absence of a regular transverse root. The junction is refuted by an Israel or Cartan residue without a surface source. Global conservation is refuted by loss of trace, norm, or an intertwined charge. Promotion to a descendant universe is refuted by a singularity, causal violation, or the impossibility of constructing the required orientation bundle and global channel. Each refutation affects its interface and preserves the preceding internal results.

88.7 Explicit Regular Solution of the Descending Cosmological Continuation

Considerese the equation efectiva homogenea of Einstein–Cartan for $n = 3$,

$$H^2 = C\big(Aa^{-3} - Ba^{-6}\big), \qquad A, B, C > 0. \tag{88.73}$$

Given $t_b \in \mathbb{R}$, define

$$a(t)^3 = \frac{B}{A} + \frac{9AC}{4}(t - t_b)^2. \tag{88.74}$$

Theorem 88.15 (Non-Empty Existence and Completeness of the Downward Continuation)**.** *The function* (88.74) *is a global solution of* (88.73)*. It has a unique minimum* $a_b = (B/A)^{1/3} > 0$*, satisfies*

$$H(t_b) = 0, \qquad \dot{H}(t_b) = \frac{3A^2C}{2B} > 0,$$

and defines on $\mathbb{R} \times \mathbb{T}^3$ *a smooth, causally orientable FLRW metric with bounded curvature invariants and complete causal geodesics. The regions* $t < t_b$ *and* $t > t_b$ *realize the contractive parent branch and the expansive descendant continuation, joined by the regular hypersurface* $t = t_b$*.*

Proof. Setting $y = a^3$, one obtains

$$H = \frac{\dot{y}}{3y} = \frac{3AC(t - t_b)}{2y}, \qquad C(Aa^{-3} - Ba^{-6}) = C\frac{Ay - B}{y^2} = \frac{9A^2C^2(t - t_b)^2}{4y^2} = H^2.$$

The positivity of B/A excludes $a = 0$. Both H and $\dot{H}$ are bounded; the polynomial curvature invariants of the flat FLRW metric are likewise bounded. Cosmic time ranges over $\mathbb{R}$, and the affine parameter of null geodesics contains $\int a(t)\, dt$, which diverges at both ends because $a(t) \asymp |t|^{2/3}$. The proper temporal length likewise diverges. There is therefore no finite causal boundary or singularity in the bounce. □

Theorem 88.16 (Obstruction of the classical branched cobordism)**.** *Within the class of smooth, nondegenerate, time-orientable, and globally hyperbolic Lorentzian manifolds, an evolution between compact Cauchy surfaces cannot produce branching with a change of topology. Every Cauchy foliation is diffeomorphic to*

$\mathbb{R} \times \Sigma$*; therefore, the initial and final leaves are diffeomorphic. Branched cobordism is obstructed within this class.*

Thus the 2 geometric objects are resolved: the minimal continuation possesses the complete preceding solution, and the classical branching with topological change is excluded by the obstruction theorem. A degenerate geometry or a quantum theory of topological change constitutes another domain and does not modify these results.

88.8 Dilution Law a^{-6}, Torsional Memory, and Confluence of the Cosmological Readers

La ley

$$M_n = \left(\frac{a_n}{a_0}\right)^{-6}$$

is perhaps the simplest algebraically and one of the deepest conceptually.

The Perron dynamics produces two complementary behaviors.

On the one hand, there exists an expansion:

$$V_n = \varphi^n.$$

In three spatial dimensions, the associated linear scale is the cube root:

$$\frac{a_n}{a_0} = \varphi^{n/3}.$$

On the other hand, there exists a stable mode of memory:

$$M_n = \varphi^{-2n}.$$

Expansion grows with φ^n. Stable memory decreases with φ^{-2n}. When level n is eliminated, there necessarily appears

$$M_n = \left(\frac{a_n}{a_0}\right)^{-6}.$$

The exponent -6 is derived from two internal facts:

- the space has dimension 3, so the linear scale carries exponent $1/3$;
- the stable mode is quadratic and therefore has exponent -2.

The reason between both is

$$\frac{-2}{1/3} = -6.$$

In Einstein–Cartan, the spin density scales as an inverse volume:

$$s \sim a^{-3}.$$

Its quadratic contribution then scales as

$$s^2 \sim a^{-6}.$$

The HMT law reproduces that exponent exactly before introducing the Einstein–Cartan realization. This is the genuinely suggestive feature.

The Perron memory mode behaves as a quadratic spin density should behave in a geometry with torsion.

The natural interpretation is that torsion physically publishes the genealogical memory complementary to metric information.

Curvature describes how geometry deforms. Torsion describes how geometry retains a transport orientation in addition to distances. HMT possesses orientation, carry, and route memory from the outset. The correspondence with Einstein–Cartan is therefore structural: both frameworks distribute geometric history between metric and torsion.

When the universe expands, that memory is diluted as a^{-6}. It is diluted faster than an ordinary matter or radiation density. But precisely for that reason it may is dominant in the small-scale region.

In a primordial regime, a torsional contribution may compete with ordinary density and modify the singularity. The possibility of a bounce depends on the sign, amplitude, spin current, and boundary conditions. HMT first provides the exact scaling law; the physical realization then fixes those conditions.

That offers a very clear division of labor:

- HMT generates the stable memory and its exponent;
- the Einstein–Cartan realization assigns that memory to a quadratic spin density;
- cosmological dynamics fixes amplitude, sign, and physical conditions.

The relation to Mach's principle appears when this law is combined with the derivation of G.

In the gravitational derivation, the local coupling is selected through the closure of a global cycle. In the cosmological law, the local torsion state preserves the memory of global expansion. In both cases, local physics is defined relationally by the global genealogy.

The local geometry recalls the global state.

This is the most concrete sense in which the construction is machina:

- inertia participates in the global clock;
- the gravedad belongs to the clausura of phase;
- torsion embodies the memory of history;
- the local scale encodes the global expansion level.

Mach's principle then acquires an operatorial form: local magnitudes are evaluations of a global genealogy, and physical invariants are what survives transport between the two scales.

The branch of temporal periodicity of (108) phases and the Perron branch also express two complementary aspects of cosmology.

The temporal periodicity of (108) phases fixes to periodicity scale and, through to of Sitter realization, to curvature scale. It is the cosmology of closure: it asks which radius allows the cycle to is coherent.

Perron fixes an expansion rate and a law of memory dilution. It is the cosmology of evolution: it asks how the genealogy changes as levels are traversed.

One branch describes the closure of geometry. The other describes the persistence of its memory.

The chronological calendar and Perron dynamics remain typologically distinct and complementary realizations. Together they produce an especially rich image: the universe possesses a global phase scale and an internal dynamics of memory. Curvature and torsion are two publications of those two aspects.

88.9 Confluence of vacuum readers, action, gravity, area, mixture, and memory

If the nine results are read together, a common grammar appears.

Each reader selectively publishes an invariant and carries the rest as complementary memory.

The vacuum preserves:

- the product as propagation;
- the quotient as orientation.

The pair $G, \hbar$ conserves:

- action as orientation;
- area as the common geometry.

The gravitational closure preserves:

- the equality among phase, Compton, gravity, and Planck.

The mode 30 preserves:

- the common cadence of vacuum, criticality, and memory.

The modular area and Hamiltonian are conserved:

- the total quantity;
- sectoral provenance.

The transito $6 \to 8$ preserves:

- the geometric turn in Barbero;
- its informational footprint in entropy;
- its mixing orientation in CKM.

The angular determinant preserves:

- the even part that can become electroweak mixing.

The quarter-turn torsion preserves:

- a complex structure published as an arithmetic character.

The Perron dynamics preserves:

- the stable memory of the expansion, realized as cosmological torsion.

For that reason the constants are related through to common architecture of transport and preserve their functional identities. They are different residues of that architecture.

Triadic Modular Holography provides the genealogy.

Dimensional Mechanics provides the realization.

The real number appears finally as the terminal value.

In that view, a fundamental constant is a complete statement about the universe. It says:

- what changed;
- which orientation was inverted;

- which memory crossed the boundary;
- what information remained interior and what part was published;
- which combination remained invariant;
- and the physical magnitude in which that invariance was ultimately realized.

That is what makes these derivations remarkable. They jointly explain the values of the constants and why each one performs exactly its structural function.

88.10 Cosmology of the global genealogical state: connection, curvature, expansion, and boundary memory

88.10.1 The totality as a compatible state

An HMT–MD cosmology is a global realization of the system of routes, boundaries, and memory. Its state belongs to the limit of compatible sections; its geometry is expressed by means of a cotetrad, connection, and metric; its evolution publishes a scale factor, curvature, material content, and horizon. The whole intervenes as a mathematical object because each local section is a restriction of a global state with closure conditions.

This idea offers a precise formulation of Mach's principle. Let $b : \mathcal{X}_\infty \to B_\infty$ be the global boundary trace and let $I_v : \mathcal{X}_\infty \to V_v$ be an inertial response in a neighborhood v. The response is Machian when there exists

$$\overline{I}_v : \mathrm{im}(b) \to V_v$$

such that

$$I_v = \overline{I}_v \circ b,$$

and when the purely local restriction leaves distinct responses open. The map $\overline{I}_v$ exists uniquely exactly when I_v is constant on each fiber of b. Local inertia is thus determined by the global closure class.

The frame of a section is obtained by simultaneously restricting the state and the connection:

$$\mathfrak{F}_v(x) = \mathrm{Res}_v(x, \nabla_{\mathrm{TPK}}).$$

An affine geodesic satisfies

$$\nabla_{\dot\gamma}\dot\gamma = 0,$$

and a parallel frame satisfies $\nabla_{\dot\gamma} e_a = 0$. Acceleration, rotation, torsion, curvature, and holonomy measure the defects relative to that induced transport.

88.10.2 3 curvature charts

The elliptic, parabolic, and hyperbolic regimes of the TRIT provide three algebraic domains. Their geometric realization requires a map

$$\mathcal{M}_{s,\rho} : \mathcal{A}_s \longrightarrow (\mathcal{X}_{s,\rho}, g_{s,\rho})$$

that preserves connection, curvature, orientation, and boundary data. With that interface declared, the coordinated atlas uses a negative-curvature chart of anti–de Sitter type, a gnomonic Euclidean chart, and a positive- curvature chart of de Sitter type.

The negative chart organizes the holographic square between interior state and conformal boundary observables. The Euclidean chart realizes the local descent

$$\frac{\mathcal{G}_L}{\mathcal{I}_L} = 1$$

of the equivalence principle. The positive chart receives the accelerated expansion when its dynamics satisfies

$$\frac{\ddot{a}}{a} = H^2 > 0.$$

The common antecedent preserves the areal-volumetric ratio.

$$\frac{\mathcal{L}_{\mathrm{ar}}}{\mathcal{L}_{\mathrm{vol}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2_{\mathrm{HMT}}}.$$

The correspondence between algebraic sign and physical geometry is proved in each chart by the metric map, so that the atlas preserves the type of each transition.

The geometry of de Sitter provides an exact result of comparison. For $H > 0$, its closed, flat, and open foliations possess

$$a_{+1}(t) = H^{-1}\cosh(Ht), \qquad a_0(t) = a_* e^{Ht}, \qquad a_{-1}(t) = H^{-1}\sinh(Ht),$$

in their respective domains. The three satisfy

$$\left(\frac{\dot{a}_k}{a_k}\right)^2 + \frac{k}{a_k^2} = H^2, \qquad \frac{\ddot{a}_k}{a_k} = H^2,$$

$$R^{(4)} = 12H^2, \qquad R^{(3)} = \frac{6k}{a_k^2}.$$

The sign k characterizes the curvature of the spatial slice; the curvature of the complete spacetime remains positive and common.

88.10.3 Distributed memory and expansion

Dodecaphase transport separates an even part and an odd part. The even part preserves the cost shared by a route and its inverse; the odd part preserves orientation. In the cosmological reading, the even sector may be realized as the mean response to expansion and the odd sector as the orientation of the sheet.

A distributed memory may proceed from a local generator. The kernel

$$K_q(m,n) = q^{|m-n|}, \qquad 0 < q < 1,$$

is positive and its inverse is tridiagonal. Correlations between arbitrary depths are, therefore, the Green function of a nearest-neighbor action. This identity allows the global history to conserve memory while the update law acts locally.

In a homogeneous geometry, the even response admits the constitutive form

$$p_{\mathrm{eff}} = p - 3\zeta H.$$

The coefficient ζ represents resistance of the symmetric memory to expansion. Its selection belongs to the cosmological realization and must descend from the transport operator and its dimensional chart.

88.10.4 Completion (1000=729+243+27+1), boundary data, and Einstein–Cartan bounce criterion

The completion

$$1000 = 729 + 243 + 27 + 1$$

organizes interior, boundary strata, and seal. In to cosmology, this pattern is realized on to pair $(M, \partial M)$ with co-tetrad, connection, matter, and boundary data. The boundary receives spatial, temporal, or null character; the action incorporates its boundary and corner terms; the gluing conditions fix which histories are prolonged.

An Einstein–Cartan bounce may appear when matter with spin produces an effective contribution that grows as

$$s^2 \propto a^{-6}.$$

In a mass density convention, the equation adopts the scheme

$$H^2 = \frac{8\pi G}{3}\left(\rho_{\mathrm{m}} - \rho_{\mathrm{spin,m}}\right) + \cdots .$$

The equilibrium point $\rho_{\mathrm{m}} = \rho_{\mathrm{spin,m}}$ is a candidate for a regular minimum of the scale factor when the matter action, the sign, the energy conditions, and the boundary problem sustain it. HMT adds the obligation to derive the spin current and the threshold from the enriched state.

A transition toward descending cosmological components is represented by a cobordism.

$$\mathcal{W} : \Sigma_{\mathrm{in}} \longrightarrow \Sigma_{\mathrm{prog}} \sqcup \Sigma_{\mathrm{desc}}.$$

Information conservation is expressed by a cocyclic charge, an isometry, or a unitary evolution. In the quantum case, entropies, mutual information, and correlations replace a simple scalar sum. Gluing terms, causality, hyperbolicity, and the control of singularities are part of the object.

88.10.5 Common system of cosmological observables: expansion, lensing, structural growth, and background anisotropies

A realization intended to explain the discrepancies attributed to dark matter or dark energy must use a common set of parameters for rotation curves, gravitational lensing, structure growth, cosmic microwave background anisotropies, and expansion history. This requirement turns route cosmology into a joint system of correlated observables subject to simultaneous testing.

The dodecaphonic cycle also provides a harmonic selector. For

$$w_k = \frac{1}{12}\left[1 + 2\varepsilon\cos(3\phi_k - \delta)\right],$$

the discrete transform has support only in $m = 0, \pm 3 \pmod{12}$. A celestial prediction requires the map to the sky, the axis, the amplitude, the phase, the mask, and the statistic to be fixed before comparison. The blind comparison preserves the distinction between the harmonic theorem and its cosmological realization.

Result

The Machian factorization, the self-inertia criterion, the three de Sitter foliations, local memory with a distributed Green function, and dodecaphase harmonic support are exact results in their domains. The metric atlas, the effective scale equation, the bounce, and the cobordism constitute typed physical interfaces with explicit conditions and compose route cosmology.

Physical realization

The universe is described as a global section whose boundary conditions the local frames. Expansion transforms collective memory; curvature and waves return that transformation to the routes; the horizon records the accessible part of history.

Boundary of validity

The realization would be falsified if the local response varied within a single global fiber, if the metric map failed to satisfy curvature or orientation, if the acceleration lacked a dynamical equation, if the

bounce produced a singularity or violated the junction conditions, or if a single parameter set proved incompatible with expansion, lensing, structure, and the cosmic background.

88.11 Projective finiteness and harmonic dodecaphasic selector

88.11.1 Internal refinement of the external-contraterm-independent harmonic selector

The assertion that HMT does not require fundamental renormalization distinguishes three operations: normalization of states or probabilities, discrete refinement with a change of scale, and perturbative renormalization by means of a regulator, divergent bare parameters, and cutoff-dependent counterterms. The first two are compatible with HMT; the third is not introduced as a primitive.

Let

$$p_{m+1,m} : X_{m+1} \longrightarrow X_m$$

the surjective projections of an inverse system of finite spaces and let

$$\mathcal{O}_m = C(X_m)$$

the involutive algebras of complex observables. The contravariant morphisms

$$p_{m+1,m}^{*} : \mathcal{O}_m \longrightarrow \mathcal{O}_{m+1}, \qquad p_{m+1,m}^{*} f = f \circ p_{m+1,m},$$

are coherent unitary $*$-homomorphisms. A cylindrical observable is a class compatible under these morphisms.

For probability measures, exact consistency requires

$$(p_{m+1,m})_{*}\mu_{m+1} = \mu_m.$$

For positive and normalized algebraic states $\omega_m : \mathcal{O}_m \to \mathbb{C}$, the condition is

$$\omega_{m+1} \circ p_{m+1,m}^{*} = \omega_m.$$

When $\omega_m(f) = \int f \, d\mu_m$, the two formulations are equivalent.

Theorem 88.17 (Projective compatibility and summable defects)**.** *Let $f \in \mathcal{O}_m$ be a cylindrical observable and suppose that its family of representatives is uniformly bounded.*

1. *If the measures or states are projectively consistent, their expectations are compatible under all refinements.*
2. *Si*

$$\left\| (p_{m+1,m})_{*}\mu_{m+1} - \mu_m \right\|_{\mathrm{TV}} \le \varepsilon_m, \qquad \sum_m \varepsilon_m < \infty,$$

then the expectations form a Cauchy family. The same conclusion holds for states when the defect is measured in the dual norm of $\mathcal{O}_m^{*}$.

Proof. In the exact case,

$$\int_{X_{m+1}} f \circ p_{m+1,m} \, d\mu_{m+1} = \int_{X_m} f \, d\mu_m,$$

and the analogous identity for states is its own consistency condition. In the approximate case, the duality between the uniform norm and total variation gives

$$\left| \int f \circ p_{m+1,m} \, d\mu_{m+1} - \int f \, d\mu_m \right| \le \|f\|_{\infty} \varepsilon_m.$$

Uniform boundedness and summability of the defects turn the sum of the increments into a convergent series; hence the family is Cauchy. The proof in the dual norm is identical. □

For reference actions and measures, the correct condition is the consistency of the Gibbs measures:

$$(p_{m+1,m})_* \left[Z_{m+1}^{-1} e^{-S_{m+1}}\, d\nu_{m+1} \right] = Z_m^{-1} e^{-S_m}\, d\nu_m.$$

A bare equality between actions is insufficient, since a comparison map could conceal a cut-dependent subtraction or rescaling.

The publishable conclusion is therefore restricted to its hypotheses: where a projectively consistent family of states or measures exists, the expectations of uniformly bounded cylindrical observables are compatible; with summable defects in total variation or dual norm, they form a Cauchy family. No external regulator or external counterterms are required, although finite internal effective flows may exist.

In the declared projective system, compatibility of expectations and the stated Cauchy criterion hold exactly. A complete quantum field theory additionally requires convergence of correlators, positivity, unitarity, cofinal independence, and absence of hidden cutoff dependence in maps, actions, measures, or parameters. A sector that converges only after cutoff-dependent parameters are introduced refutes the strong version for that sector.

88.11.2 Harmonic cycle selector of the dodecaphasic cycle

Let $\mathsf{C}_{12}^{\mathrm{cyc}}$ be the local dodecaphase cycle,

$$\phi_k = \phi_0 + \frac{2\pi k}{12}, \qquad k = 0, \dots, 11,$$

and consider the family of weights

$$w_k = \frac{1}{12}\left[1 + 2\varepsilon \cos(3\phi_k - \delta)\right], \qquad |\varepsilon| \le \frac{1}{2}.$$

Then

$$w_k \ge \frac{1 - 2|\varepsilon|}{12} \ge 0, \qquad \sum_{k=0}^{11} w_k = 1.$$

Theorem 88.18 (Fourier dodecaphasic support)**.** *The discrete transform*

$$\widehat{w}_m = \sum_{k=0}^{11} w_k e^{-im\phi_k}$$

is canceled except for

$$m \equiv 0,\ \pm 3 \pmod{12}.$$

Once the origin phase has been absorbed into δ,

$$\widehat{w}_0 = 1, \qquad \widehat{w}_3 = \varepsilon e^{-i\delta}, \qquad \widehat{w}_{-3} = \varepsilon e^{i\delta}.$$

Proof. The transform of the uniform part is the trivial character of the cycle. When writing

$$2\cos(3\phi_k - \delta) = e^{i(3\phi_k - \delta)} + e^{-i(3\phi_k - \delta)},$$

the geometric sums of the characters of $\mathbb{Z}/12\mathbb{Z}$ vanish unless $m - 3$ or $m + 3$ is a multiple of twelve. The three remaining amplitudes are the indicated ones. □

For a crown at fixed colatitude, the support permits only $m = 0$ in $\ell = 2$, whereas in $\ell = 3$, $m = 0, \pm 3$ may survive. The value $\varepsilon = 0$ recovers the uniform axial template; $\varepsilon \neq 0$ introduces the triadic modulation. The result reconciles both supports as a common envelope, but it neither fixes amplitudes nor proves exclusivity: the mode $m = 0$ may also persist for $\ell = 3$.

88.11.3 Prediction of dodecaphasic anisotropy: prior parametrization, blind contrast, and criterion of observational incompatibility

Promotion to an anisotropy prediction requires fixing the following before observing the sky:

1. the map $\mathsf{C}_{12}^{\mathrm{cyc}} \to S^2$ and its equivariance;
2. the celestial frame and the axis, or finite set of axes;
3. $\varepsilon, \delta, \phi_0$, the colatitude, and the normalization;
4. the $a_{\ell m}^{\mathrm{HMT}}$, their parity, and the alignment statistic;
5. mask, foregrounds, bundle, noise, and covariance;
6. the penalty for selection among axes;
7. the joint blind contrast in temperature and polarization.

The retrospective selection of the axis or the fit to C_ℓ^{CMB} is RECOGNITION EXTERNAL, not prediction. The object $\mathsf{C}_{12}^{\mathrm{cyc}}$ is not U_{12}^{sgn}, to representation of $SU(12)$ nor the angular spectrum C_ℓ^{CMB}.

Comparison Criterion 88.19 (Dodecaphase anisotropy)**.** The interface is refuted if the sealed pattern is incompatible with the blind contrast or if axis, amplitude, or modulation is selected after the data have been opened. The support theorem remains valid even if its cosmological realization fails.

88.12 HMT Cosmic Selector and Einstein–Cartan Bounce

88.12.1 Selector of the 3 cartas cosmologicas

The TRIT reader produces

$$\tau(x) \in \{+1, 0, -1\},$$

and the internal clock sets

$$H_*(x) = \omega_0(x) = \frac{2\pi}{108 t_0(x)} > 0.$$

Let $s(x) = \tau(x)$. We define

$$a_+(t; H) = H^{-1} \cosh(Ht), \qquad a_0(t; H) = \exp(Ht), \qquad a_-(t; H) = H^{-1} \sinh(Ht), \quad t > 0$$

and the selector

$$\mathfrak{R}_{\mathrm{dS}}^{\mathrm{HMT}}(x) = \big(M_{s(x)}, g_{s(x),H_*(x)}, a_{s(x)}(\,\cdot\,; H_*(x))\big).$$

Theorem 88.20 (Internal cosmic selector)**.** *The map $\mathfrak{R}_{\mathrm{dS}}^{\mathrm{HMT}}$ is defined for every state with $t_0(x) > 0$ and satisfies*

$$\frac{\ddot{a}_s}{a_s} = H_*^2, \qquad \left(\frac{\dot{a}_s}{a_s}\right)^2 + \frac{s}{a_s^2} = H_*^2, \qquad R[g_{s,H_*}] = 12 H_*^2.$$

The temporal involution $\tau \mapsto -\tau$ interchanges the closed and open charts and fixes the flat chart. The parameter H_* follows from the clock of the same state, not from a cosmological fit.

Proof. Direct substitution of the three functions produces the equations. The action of the involution on $s = \tau$ is immediate. □

88.12.2 Rebound Sector Selector

Let $\mathcal{X}_{\mathrm{EC}}^{\mathrm{HMT}} \subset \mathcal{X}_{\infty}^{\mathrm{enr}}$ be the domain of states whose material and spin-current readers publish

$$A(x) > 0, \qquad B(x) > 0, \qquad 0 < n(x) < 6, \qquad C(x) > 0.$$

The dimensional transducer is applied after those readers. The effective selector is

$$\mathfrak{R}_{\mathrm{EC}}^{\mathrm{HMT}}(x): \quad H^2 = C(x)\left(A(x)a^{-n(x)} - B(x)a^{-6}\right).$$

Theorem 88.21 (Rebounce HMT–Einstein–Cartan in the selected domain)**.** *For every $x \in \mathcal{X}_{\mathrm{EC}}^{\mathrm{HMT}}$ there exists a unique positive threshold*

$$a_b(x) = \left(\frac{B(x)}{A(x)}\right)^{1/(6-n(x))}$$

such that $H(a_b) = 0$. The branch that reaches a_b satisfies

$$\dot{H}(a_b) = \frac{C(x)}{2}(6 - n(x))A(x)a_b^{-n(x)} > 0.$$

Therefore, the selected equation possesses a regular local bounce. If the spin reader publishes $B(x) = 0$, the singular branch reappears

$$a(t) \propto |t - t_0|^{2/n(x)}.$$

Proof. The function $Aa^{-n} - Ba^{-6} = a^{-6}(Aa^{6-n} - B)$ has a unique positive root because $6 - n > 0$. Differentiating the equation with respect to time and taking the limit at the root produces the formula for $\dot{H}$. With $B = 0$, integrating $\dot{a}/a = \sqrt{CA}\, a^{-n/2}$ gives the indicated power. □

The selector is closed in the HMT domain of material and spin readers. That our universe occupies that domain, the value of its scales and the comparison with nucleosynthesis, cosmic background, and anisotropies are RECOGNITION EXTERNAL.

88.13 Descendant universe as a genealogical channel

The authorial architecture of the sheet requires conserving information without cloning the state. We use the two Ambivalence readers to fix

$$p_{\mathrm{d}} = \frac{r_{\mathrm{av}}^{J}}{r_{\mathrm{av}} + r_{\mathrm{av}}^{J}}, \qquad p_{\mathrm{p}} = 1 - p_{\mathrm{d}}.$$

Let $\mathcal{H}_{\mathrm{in}}$ be the Hilbertization of an input fiber and $\mathcal{H}_{\mathrm{tag}} = \mathrm{span}\{|\mathrm{p}\rangle, |\mathrm{d}\rangle\}$. Define

$$|\chi_{\mathrm{HMT}}\rangle = \sqrt{p_{\mathrm{p}}}|\mathrm{p}\rangle + \mathrm{e}^{\mathrm{i}\vartheta(x)}\sqrt{p_{\mathrm{d}}}|\mathrm{d}\rangle,$$

$$V_{\mathrm{desc}} : \mathcal{H}_{\mathrm{in}} \longrightarrow \mathcal{H}_{\mathrm{in}} \otimes \mathcal{H}_{\mathrm{tag}}, \qquad V_{\mathrm{desc}}\psi = \psi \otimes |\chi_{\mathrm{HMT}}\rangle.$$

The phase $\vartheta(x)$ is the orientation reader of the same state. For $\kappa(x) \in \mathbb{R}$, fix

$$K_{\mathrm{desc}}(x) = \kappa(x)\left(\mathrm{e}^{-\mathrm{i}\vartheta(x)}|\mathrm{p}\rangle\langle\mathrm{d}| + \mathrm{e}^{\mathrm{i}\vartheta(x)}|\mathrm{d}\rangle\langle\mathrm{p}|\right)$$

and

$$H_{\mathrm{tot}}(x) = H_{\mathrm{in}}(x) \otimes I + I \otimes K_{\mathrm{desc}}(x).$$

Theorem 88.22 (Unitary descending channel and genealogical conservation)**.** *The map V_{desc} is an isometry and does not clone the state. The label projectors publish probabilities p_{p} and p_{d}. The operator K_{desc} is*

self-adjoint; if H_{in} is self-adjoint, then H_{tot} is also self-adjoint on the domain $D(H_{\mathrm{in}}) \otimes \mathcal{H}_{\mathrm{tag}}$. For every observable A of the incoming state,

$$V_{\mathrm{desc}}^{\dagger}(A \otimes I)V_{\mathrm{desc}} = A.$$

Consequently, for every density state ρ, the state $V_{\mathrm{desc}}\rho V_{\mathrm{desc}}^{\dagger}$ preserves its nonzero spectrum, trace, and unitarily invariant norms. Every charge Q commuting with H_{in} also preserves its global expectation.

Proof. The norm of χ_{HMT} is $p_{\mathrm{p}} + p_{\mathrm{d}} = 1$, hence $V_{\mathrm{desc}}^{\dagger}V_{\mathrm{desc}} = I$. The output contains a single factor ψ, correlated with one label, and not $\psi \otimes \psi$. Self-adjointness is direct, and the compression identity is obtained by evaluating on vectors. □

If an oriented cobordism W subsequently realizes the two labels and carries a closed current j, the Stokes balance

$$I_{\mathrm{in}} = I_{\mathrm{p}} + I_{\mathrm{d}} + F_{\partial}$$

is the topological reader of the same channel. The genealogical channel, its weights, its phase, and its Hamiltonian have been constructed; its realization as a descendant space- time, a causal cobordism, and an observational signal is EXTERNAL RECOGNITION.

88.14 Effective dark tensor and acceleration

Let g_x be a metric produced by $\mathfrak{R}_{\mathrm{dS}}^{\mathrm{HMT}}$, or by another HMT chart in the same realization class, and let $T_b(x)$ be the baryonic tensor published by the material transducer. We assume that $G_{\mathrm{int}}(x)$ and $\Lambda_{\mathrm{ref}}(x)$ are constant over the selected chart. In units $c = 1$, we define, without using cosmological observables as inputs

$$T_{\mathrm{osc}}(x) = \frac{1}{8\pi G_{\mathrm{int}}(x)}\left(G[g_x] + \Lambda_{\mathrm{ref}}(x)g_x\right) - T_b(x).$$

Theorem 88.23 (Closure of the unpublished geometric sector)**.** *Once $g_x, G_{\mathrm{int}}, \Lambda_{\mathrm{ref}}$ and T_b have been fixed, the tensor T_{osc} is unique. If*

$$\nabla^{\mu}T_{b,\mu\nu} = 0,$$

then

$$\nabla^{\mu}T_{\mathrm{osc},\mu\nu} = 0.$$

In four dimensions it possesses the canonical decomposition

$$T_{\mathrm{osc}} = T_{\Lambda} + T_0, \qquad T_{\Lambda} = \frac{1}{4}\,\mathrm{tr}_{g_x}(T_{\mathrm{osc}})\,g_x, \qquad \mathrm{tr}_{g_x}(T_0) = 0.$$

If the trace is constant, the two sectors are conserved separately; in the general case, they exchange exactly opposite current

$$J_{\nu} = \nabla^{\mu}T_{\Lambda,\mu\nu} = -\nabla^{\mu}T_{0,\mu\nu}.$$

Proof. Uniqueness is algebraic. The Bianchi identity and $\nabla g_x = 0$ yield conservation. The decomposition into trace and traceless parts is unique; differentiating it produces the exchange current. □

In the selected de Sitter chart, with $\Lambda_{\mathrm{ref}} = 0$ and $T_b = 0$,

$$G[g_x] = -3H_*^2 g_x, \qquad T_{\mathrm{osc}} = -\rho_* g_x, \qquad \rho_* = \frac{3H_*^2}{8\pi G_{\mathrm{int}}}.$$

Respect to every comoving observer,

$$p_* = -\rho_*, \qquad \frac{\ddot{a}}{a} = -\frac{4\pi G_{\mathrm{int}}}{3}(\rho_* + 3p_*) = H_*^2 > 0.$$

Corollary 88.24 (Internal acceleration of the selected chart)**.** *The positive acceleration of the HMT of Sitter chart is to consequence of the constructed trace tensor and the clock H_*; it is not introduced as an observed parameter.*

Part T_Λ is the homogeneous opening sector, and T_0 is the residual of structure, lensing, and retention within the mathematical chart. Calling them respectively physical dark energy and dark matter requires a single state and a unique parameter set to reproduce rotation, lensing, growth, CMB, and expansion. That joint comparison is EXTERNAL RECOGNITION; the tensor construction and acceleration are already closed.

88.15 Consistency conditions and domain of validity

The preceding constructions are refuted in their respective domains if any of the following cases occurs:

1. $U_F \neq S$, the response has a proper divisor of 108, or the spectral bands overlap despite $\varepsilon < g_{108}/2$;
2. P_{abs} does does not project onto $\ker \mathcal{A}_\partial$, G_{WF} is does not lf-adjoint under the declared hypotheses or the refinement does not intertwine the boundary;
3. ι_n loses orthogonality, the apparatus–memory square does not commute, or the ledger ceases to make the update injective;
4. the self-inertial response varies within a fibre of b, uses a local datum as a substitute for the boundary, or confuses r_{av}^{J} with r_{av}^{-1};
5. the of Sitter selector violates Friedmann or uses an H observed to choose the state; the bounce is asserted outside $A, B, C > 0$ and $0 < n < 6$;
6. $V_{\mathrm{desc}}^{\dagger} V_{\mathrm{desc}} \neq I$, ψ is cloned, or the global charge ceases to be conserved;
7. T_{osc} does not satisfy the Bianchi identity, its decomposition does not reconstitute the tensor, or acceleration is introduced as a datum;
8. the sheet involution does not preserve UV, the chart is not regular at the horizon, or the supposed intertwiner is not UCP.

The mathematical status of these constructions is

CLAUSURA EN EL DOMINIO HMT

for the eight constructions, each with the explicit primitives that appear in its theorem. Comparisons with macroscopic matter, actual apparatus, electromagnetism, observed gravity, empirical cosmology, observational dark sectors, and astrophysical objects are labeled exclusively

RECONOCIMIENTO EXTERNO.

88.16 Memory dilution and persistence of the bounce

The evolution of memory and spatial expansion are two readings of the same sequence of states. The refinement index can be eliminated between them; that elimination determines the dilution exponent transmitted by the cosmological realization to its torsional contribution. The initial amplitude depends on evaluation of the concrete material current in its variational response. The scaling law and bounce theorem that follow preserve that dependence.

Theorem 82.38 determines that amplitude as a functional of the material state and comoving volume. Corollary 82.39 provides an explicit domain of states with positive, conserved amplitude. In that domain,

evaluation of s_0 precedes the cosmological integration developed below. The ordinary density $\rho_0 > 0$ and its barotropic law are additionally specified in section 88.16.2: the witness to positivity of the amplitude does not in itself evaluate that material density.

88.16.1 The a^{-6} dilution law

Proposition 88.25 (Elimination of the memory index)**.** *Let $a_{\mathrm{ref}} > 0$, $\varphi > 1$, and let the route readers be*

$$\frac{a_n}{a_{\mathrm{ref}}} = \varphi^{n/3}, \qquad M_n = \varphi^{-2n}.$$

Then

$$M_n = \left(\frac{a_n}{a_{\mathrm{ref}}}\right)^{-6}$$

for every index of the sequence. If the realization of the quadratic density is $s_n^2 = s_*^2 M_n$, with $s_*^2 > 0$, we obtain

$$s_n^2 = s_*^2 \left(\frac{a_n}{a_{\mathrm{ref}}}\right)^{-6}.$$

Proof. Raising the first equality to the power -6 gives φ^{-2n}, which is exactly the second reader. Multiplying by the initial amplitude reproduces the second statement. The exponent is determined by the quotient of the exponents of the two readers; the amplitude is the evaluation of the reference state. □

In the continuous homogeneous realization, this constitutive law is preserved: the torsional density is written $s_0 a^{-6}$, where the normalization of the factor a, the material coefficient and the reference amplitude have been absorbed into s_0. The scaling law and evaluation of s_0 are successive operations of the construction.

88.16.2 Homogeneous threshold and transversality

Consider the homogeneous, spatially flat chart, in units $c = 1$, with constant $G > 0$, positive densities ρ_0, s_0 and constant barotropic parameter $w < 1$. The specified realization satisfies $\Lambda_{\mathrm{eff}} = 0$ and the equations

$$\rho_{\mathrm{m}}(a) = \rho_0 a^{-3(1+w)}, \qquad \rho_{\mathrm{s}}(a) = s_0 a^{-6}, \tag{88.75}$$

$$H^2 = \frac{8\pi G}{3}\big(\rho_{\mathrm{m}} - \rho_{\mathrm{s}}\big) =: F_0(a), \qquad \dot H = -4\pi G\big((1+w)\rho_{\mathrm{m}} - 2\rho_{\mathrm{s}}\big). \tag{88.76}$$

The couplings belong to the dimensional section already constructed. The expression for ρ_{s} incorporates the sign of its contribution in this gravitational realization.

Theorem 88.26 (Existence and uniqueness of the transverse threshold)**.** *There exists a unique $a_{\mathrm{b}} > 0$ with $F_0(a_{\mathrm{b}}) = 0$:*

$$a_{\mathrm{b}}^{3(1-w)} = \frac{s_0}{\rho_0}.$$

The region allowed by $H^2 \geq 0$ is $a \geq a_{\mathrm{b}}$. At the threshold, with $\rho_{\mathrm{b}} = \rho_{\mathrm{m}}(a_{\mathrm{b}}) = \rho_{\mathrm{s}}(a_{\mathrm{b}}) > 0$,

$$\dot H_{\mathrm{b}} = 4\pi G(1-w)\rho_{\mathrm{b}} > 0.$$

The solution crossing $H = 0$ has a strict minimum of a, with local expansion

$$a(t) = a_{\mathrm{b}}\left[1 + 2\pi G(1-w)\rho_{\mathrm{b}}(t - t_{\mathrm{b}})^2 + O\big((t-t_{\mathrm{b}})^3\big)\right].$$

Proof. The factorization

$$F_0(a) = \frac{8\pi G}{3} a^{-6}\big(\rho_0 a^{3(1-w)} - s_0\big)$$

reduces its zeros to that of a strictly increasing function of $(0,\infty)$ on $(-s_0,\infty)$. This proves existence, uniqueness and the sign of F_0 on both sides of the threshold. The second equation of (88.76), evaluated at equality of densities, gives the formula for $\dot H_{\mathrm b}$. Since $\dot a = aH$, at the threshold $\ddot a_{\mathrm b} = a_{\mathrm b}\dot H_{\mathrm b} > 0$. The equations are smooth for $a > 0$, so their Taylor expansion gives the indicated expansion. The sign change of H is transverse: it passes from contraction to expansion. □

For $w = 1$, both terms have the same exponent and equality of amplitudes determines a degenerate case. For $w > 1$, the sign of $\dot H$ at a coincidence of densities is negative. The domain $w < 1$ of the theorem expresses exactly the order between the two dilution exponents.

88.16.3 Local persistence under controlled perturbations

Persistence of the threshold uses two independent estimates: control of the sign at the endpoints and of the derivative on the interval. Let $I = [a_-, a_+] \subset (0,\infty)$, with $a_- < a_{\mathrm b} < a_+$, be chosen so that

$$F_0(a_-) < 0 < F_0(a_+), \qquad m_I := \inf_{a\in I} F_0'(a) > 0.$$

Such an interval exists because

$$F_0'(a_{\mathrm b}) = \frac{8\pi G}{a_{\mathrm b}}(1-w)\rho_{\mathrm b} > 0.$$

Define $\delta_I = \min\{-F_0(a_-), F_0(a_+)\} > 0$.

Theorem 88.27 (Local persistence of the transverse bounce)**.** *Let $R \in C^1(I)$ be a perturbation satisfying*

$$\|R\|_{\infty,I} < \delta_I, \qquad \|R'\|_{\infty,I} < m_I.$$

Then $F_R = F_0 + R$ has a unique zero $a_R \in (a_-, a_+)$, and $F_R'(a_R) > 0$. The realization $H^2 = F_R(a)$ admits a local transverse bounce, with

$$\dot H_R = \frac{a_R}{2} F_R'(a_R) > 0$$

at the threshold. If $R(a,\eta)$ is jointly C^1, the persistent zeros depend locally in a C^1 manner on the parameter η.

Proof. The first bound preserves $F_R(a_-) < 0 < F_R(a_+)$; the intermediate value theorem provides an interior zero. The second gives $F_R'(a) \ge m_I - \|R'\|_{\infty,I} > 0$ on I, so the zero is unique and simple.

At $a > a_R$ near the zero, $F_R(a) = F_R'(a_R)(a-a_R) + o(a-a_R)$. The integral

$$t - t_{\mathrm b} = \int_{a_R}^{a} \frac{d\xi}{\xi\sqrt{F_R(\xi)}}$$

is finite and strictly increasing. Its inverse defines the expanding branch; time reflection defines the contracting branch. The two join with $\dot a(t_{\mathrm b}) = 0$ and

$$a(t) - a_R = \frac{a_R^2 F_R'(a_R)}{4}(t-t_{\mathrm b})^2 + o((t-t_{\mathrm b})^2).$$

Away from the threshold, differentiating $H^2 = F_R(a)$ gives $\dot H = aF_R'(a)/2$; its continuous limit gives the positive expression at a_R. The C^1 regularity of F_R guarantees continuity of acceleration at this junction. Finally, $\partial_a F_R(a_R) > 0$ allows application of the implicit function theorem when the perturbation depends jointly on (a,η). □

The first bound controls existence; the second ensures local uniqueness and transversality. The proved stability corresponds to that threshold in the selected interval. The torsional amplitude enters its location, while the relation between exponents determines the temporal orientation of the crossing.

88.17 Explicit homogeneous solution and causal completeness

Determination of the amplitude allows a complete realization of the bounce to be developed, in addition to the local argument. The spatially flat chart of (88.76) is retained, in units $c = 1$, with $\rho_0, s_0, G > 0$, and the material sector is specialized to dust, $w = 0$, with $\Lambda_{\mathrm{eff}} = 0$. The coefficient s_0 is that obtained from the material state in the corresponding realization; the following integration uses that coefficient and preserves its domain.

Theorem 88.28 (Exact integration of the dust bounce)**.** *Set*

$$a_{\mathrm{b}}^3 = \frac{s_0}{\rho_0}, \qquad \tau^2 = \frac{s_0}{6\pi G \rho_0^2}, \qquad u = t - t_{\mathrm{b}}.$$

The solution of the homogeneous system with $a(t_{\mathrm{b}}) = a_{\mathrm{b}}$ and $H(t_{\mathrm{b}}) = 0$ is, for every $t \in \mathbb{R}$,

$$a(t) = a_{\mathrm{b}} \left(1 + \frac{u^2}{\tau^2}\right)^{1/3}, \qquad H(t) = \frac{2u}{3(\tau^2 + u^2)}, \qquad \dot{H}(t) = \frac{2(\tau^2 - u^2)}{3(\tau^2 + u^2)^2}. \tag{88.77}$$

It has a unique minimum, at t_{b}; it contracts before and expands afterward. The evolution is smooth and satisfies $a(t) \geq a_{\mathrm{b}} > 0$.

Proof. Let $y = a^3$. The Friedmann equation gives

$$\dot{y}^{\,2} = 24\pi G(\rho_0 y - s_0).$$

The function $y = s_0/\rho_0 + 6\pi G \rho_0 u^2$ satisfies that identity and the initial conditions. Its derivatives give the three expressions of (88.77). To check the evolution equation as well, let us write

$$\rho_{\mathrm{b}} = \frac{\rho_0^2}{s_0}, \qquad x = \frac{u}{\tau}.$$

Then

$$\rho_{\mathrm{m}} = \frac{\rho_{\mathrm{b}}}{1 + x^2}, \qquad \rho_{\mathrm{s}} = \frac{\rho_{\mathrm{b}}}{(1 + x^2)^2}, \qquad 4\pi G \rho_{\mathrm{b}} = \frac{2}{3\tau^2}.$$

Substituting into $\dot{H} = -4\pi G(\rho_{\mathrm{m}} - 2\rho_{\mathrm{s}})$ gives exactly the third formula. Thus the complete system $(\dot{a}, \dot{H})$ is satisfied, whose field is smooth for $a > 0$. Its local uniqueness, continued along the explicit solution, fixes the evolution through those initial conditions. The denominator is positive for every t, and the statements about the minimum and the sign follow from H. □

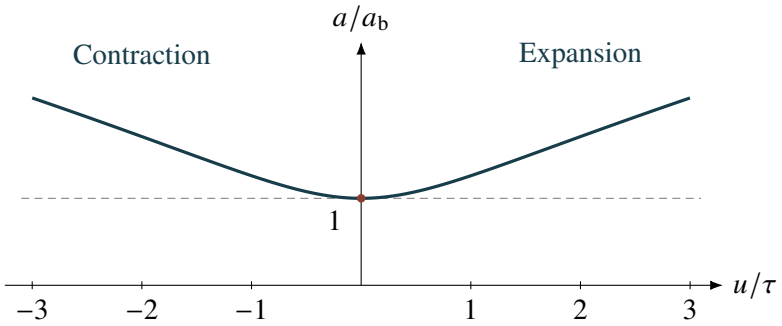

Figure 88.1: Dimensionless profile of the proved solution: $a/a_{\mathrm{b}} = (1 + (u/\tau)^2)^{1/3}$. The parameters a_{b} and τ are calculated from ρ_0, s_0, G; the drawing represents the entire rescaled family.

88.17.1 Finite curvature and extension of geodesics

The metric realized in this chart is $g = -dt^2 + a(t)^2\, d\mathbf{x}^2$ on $\mathbb{R}\times\mathbb{R}^3$. With the convention in which the flat curvature scalar is $R = 6(\dot H + 2H^2)$, the solution gives

$$R(t) = \frac{4\tau^2 + \frac{4}{3}u^2}{(\tau^2+u^2)^2}.$$

In particular, $R(t_{\mathrm{b}}) = 4/\tau^2$ is finite. In an orthonormal frame, the Riemann components depend on H^2 and on $\dot H + H^2$, which are bounded functions on $\mathbb{R}$. The same holds for polynomial contractions of those components; for example,

$$R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} = 12\big[(\dot H + H^2)^2 + H^4\big].$$

Proposition 88.29 (Completeness of causal geodesics)**.** *The preceding metric realization is geodesically complete for the timelike and null geodesics of its Levi–Civita connection, in both directions.*

Proof. Spatial translations provide the constants $p_i = a^2\, dx^i/d\lambda$. Causal normalization gives

$$\left|\frac{dt}{d\lambda}\right| = \sqrt{\epsilon + \frac{|\mathbf{p}|^2}{a(t)^2}}, \qquad \epsilon = 1 \text{ in the timelike case}, \quad \epsilon = 0 \text{ in the null case}.$$

A nonconstant null geodesic has $|\mathbf{p}| > 0$. Since $a \geq a_{\mathrm{b}}$, in the timelike case

$$\left|\frac{d\lambda}{dt}\right| \geq \left(1 + \frac{|\mathbf{p}|^2}{a_{\mathrm{b}}^2}\right)^{-1/2} > 0,$$

and in the null case $|d\lambda/dt| = a/|\mathbf{p}| \geq a_{\mathrm{b}}/|\mathbf{p}| > 0$. Thus, reaching $t = \pm\infty$ requires infinite affine length. On a compact time interval, a and its derivatives are smooth and a is bounded away from zero. The preceding explicit equations and $dx^i/d\lambda = p_i/a^2$ allow the geodesic to be continued through its finite endpoints. Both possibilities of continuation are covered. □

The completeness result belongs to this homogeneous dust realization, with its spatial, matter and amplitude conditions. Its local persistence under perturbations of the threshold preserves the bounds of theorem 88.27; that local property and the global completeness of the explicit solution are distinct conclusions. The minimum scale comes from the relation between material density and torsional response. Memory thus enters a verifiable geometric evolution, with a regular realization of contraction and expansion.

88.18 Residual tensor, trace decomposition, and covariant balance

The geometric realization of the enriched state provides a metric, while the material transducer publishes the source to which the reading refers. The residual tensor preserves the difference between the two publications in the same tensor space. Its decomposition distinguishes the sector proportional to the metric from the traceless sector, and determines the exchange current corresponding to that partition.

88.18.1 Chart data and construction of the residual tensor

Let us fix an HMT state x and a connected chart $\mathcal{U}$ of its geometric realization. On $\mathcal{U}$, the nondegenerate co-tetrad of section 80.6 determines a smooth metric $g = g_x$ of signature $(-+++)$. We denote by $\mathring{\nabla}$ its Levi–Civita connection and write

$$\mathsf{G}_{\mu\nu}[g] := \mathrm{Ric}_{\mu\nu}[g] - \tfrac{1}{2}R[g]g_{\mu\nu}.$$

This distinguishes the Einstein tensor $\mathsf{G}[g]$ from the gravitational coupling G_{int}. The derivative used in the balances of this section is $\mathring{\nabla}$, consistently with the effective metric equation of Section 82.8.5.

We work in the dimensional chart $c_{\mathrm{int}} = 1$. We assume $G_{\mathrm{int}}(x) > 0$ and $\Lambda_{\mathrm{ref}}(x)$ constant on $\mathcal{U}$, and put $\kappa_x = 8\pi G_{\mathrm{int}}(x)$. The symbol x identifies the state supplying those readers; covariant differentiation acts on the points of $\mathcal{U}$. The genealogy of the couplings remains in section 121.

Let T_b be the smooth symmetric tensor published by the chart's material transducer; in the baryonic reading, it is its baryonic source. We define

$$\mathcal{E}^{\mathrm{ref}}_{\mu\nu} := \kappa_x^{-1}\big(\mathsf{G}_{\mu\nu}[g] + \Lambda_{\mathrm{ref}} g_{\mu\nu}\big), \qquad T^{\mathrm{res}}_{\mu\nu} := \mathcal{E}^{\mathrm{ref}}_{\mu\nu} - T_{b,\mu\nu}. \tag{88.78}$$

The tensor T^{res} is the effective residual tensor, also denoted T_{osc} when interpreting the geometric sector remaining to be published relative to T_b. The construction preserves $g_x, G_{\mathrm{int}}, \Lambda_{\mathrm{ref}}$ and T_b as effective arguments.

Theorem 88.30 (Uniqueness of the residual and balance with the material source)**.** *For the preceding data there exists a unique symmetric tensor T^{res} satisfying $\mathcal{E}^{\mathrm{ref}} = T_b + T^{\mathrm{res}}$. Its divergence is*

$$\mathring{\nabla}^{\mu} T^{\mathrm{res}}_{\mu\nu} = -\mathring{\nabla}^{\mu} T_{b,\mu\nu}. \tag{88.79}$$

In particular, if the material source is conserved separately, $\mathring{\nabla}^{\mu} T_{b,\mu\nu} = 0$, then T^{res} is also conserved.

Proof. The difference of two tensors satisfying the stated equation is zero; expression (88.78) provides its existence. The contracted Bianchi identity and Levi–Civita metric compatibility give

$$\mathring{\nabla}^{\mu}\mathsf{G}_{\mu\nu} = 0, \qquad \mathring{\nabla} g = 0.$$

Since κ_x and Λ_{ref} are constant on the chart, $\mathring{\nabla}^{\mu}\mathcal{E}^{\mathrm{ref}}_{\mu\nu} = 0$. Differentiating the difference defining T^{res} proves (88.79), including the statement under separate material conservation. □

The spatial and temporal constancy of the couplings in the chart fixes the domain of this balance. A family of states may publish different couplings in different charts; each preceding identity applies to the chart and state specifying it.

88.18.2 Canonical decomposition and exchange current

Define the trace function and the two tensors

$$\theta := g^{\mu\nu} T^{\mathrm{res}}_{\mu\nu}, \qquad T^{\Lambda}_{\mu\nu} := \tfrac{1}{4}\theta g_{\mu\nu}, \qquad T^{0}_{\mu\nu} := T^{\mathrm{res}}_{\mu\nu} - T^{\Lambda}_{\mu\nu}. \tag{88.80}$$

The superscript Λ identifies the component proportional to the metric; Λ_{ref} is the reference parameter of (88.78). Their functions are distinct.

Proposition 88.31 (Trace projectors and uniqueness of the decomposition)**.** *On symmetric covariant tensors of order two, the maps*

$$P_{\mathrm{tr}}(S) = \tfrac{1}{4}\,\mathrm{tr}_g(S)\, g, \qquad P_0(S) = S - P_{\mathrm{tr}}(S)$$

satisfy

$$P_{\mathrm{tr}}^2 = P_{\mathrm{tr}}, \quad P_0^2 = P_0, \quad P_{\mathrm{tr}} P_0 = P_0 P_{\mathrm{tr}} = 0, \quad P_{\mathrm{tr}} + P_0 = I. \tag{88.81}$$

In particular, $T^{\mathrm{res}} = T^{\Lambda} + T^{0}$, $\mathrm{tr}_g\, T^{0} = 0$, and this decomposition is unique.

Proof. In dimension four, $g^{\mu\nu} g_{\mu\nu} = 4$. Therefore, $\mathrm{tr}_g(P_{\mathrm{tr}} S) = \mathrm{tr}_g\, S$, which proves idempotence of P_{tr}, vanishing of the trace of $P_0 S$ and, by expansion, the other identities. If $S = f g + Q$ with $\mathrm{tr}_g\, Q = 0$, taking the trace gives $f = \mathrm{tr}_g\, S/4$. This also determines $Q = S - f g$, and with it uniqueness. □

Theorem 88.32 (Covariant exchange between the two sectors)**.** *On the domain of* (88.78)*, let* $b_\nu := \mathring{\nabla}^\mu T_{b,\mu\nu}$*. The trace-exchange current is the one-form*

$$\mathcal{J}^{\mathrm{tr}}_\nu := \tfrac{1}{4}\partial_\nu\theta = \mathring{\nabla}^\mu T^{\Lambda}_{\mu\nu}. \tag{88.82}$$

The complete balances are

$$\mathring{\nabla}^\mu T^0_{\mu\nu} = -b_\nu - \mathcal{J}^{\mathrm{tr}}_\nu, \qquad \mathring{\nabla}^\mu (T^\Lambda + T^0)_{\mu\nu} = -b_\nu. \tag{88.83}$$

If $b = 0$*, the two sectors exchange exactly opposite currents. In that case they are conserved separately if and only if* θ *is constant in the connected chart.*

Proof. Metric compatibility allows the calculation

$$\mathring{\nabla}^\mu\big(\tfrac{1}{4}\theta g_{\mu\nu}\big) = \tfrac{1}{4}g^{\mu\alpha}(\partial_\alpha\theta)g_{\mu\nu} = \tfrac{1}{4}\partial_\nu\theta.$$

Subtracting this equality from (88.79) produces (88.83). With $b = 0$, separate conservation is equivalent to $\mathrm{d}\theta = 0$; a smooth function with zero differential is constant on each connected component. □

The one-form $\mathcal{J}^{\mathrm{tr}}$ measures the exchange of the tensor partition. It retains a type distinct from the transport covector of section 80.7 and from the spin current $\sigma_{IJ} \in \Omega^3(\mathcal{U}; \Lambda^2 E^*)$ of (82.20).

88.18.3 Link to the effective Cartan–Holst source

On a solution of (82.35), in the same units $c = 1$, the residual has expression

$$T^{\mathrm{res}} = T^{\mathrm{phys,LC}} + U^{\mathrm{phys,spin}} - T_b + \frac{\Lambda_{\mathrm{ref}} - \Lambda_{\mathrm{int}}}{\kappa_x}\, g. \tag{88.84}$$

Indeed, substituting $\mathsf{G} + \Lambda_{\mathrm{int}} g = \kappa_x(T^{\mathrm{phys,LC}} + U^{\mathrm{phys,spin}})$ into (88.78) gives equality term by term. When the material transducer publishes precisely $T_b = T^{\mathrm{phys,LC}}$ and $\Lambda_{\mathrm{ref}} = \Lambda_{\mathrm{int}}$, we obtain $T^{\mathrm{res}} = U^{\mathrm{phys,spin}}$. The separate conservation condition of T_b in theorem 88.30 retains its own function: (82.36) establishes the balance of the total source, and the partition among its components depends on the material action used.

88.18.4 Trace sector and acceleration of the selected charts

The TRIT reader of state x publishes $s = \tau(x) \in \{+1, 0, -1\}$, and its positive clock publishes

$$H_* = \frac{2\pi}{108\, t_0(x)} > 0. \tag{88.85}$$

Let h_s be a three-dimensional metric of constant sectional curvature s. The three charts of the selected realization are written

$$g_s = -\mathrm{d}t^2 + a_s(t)^2 h_s, \qquad a_+(t) = H_*^{-1}\cosh(H_* t), \quad a_0(t) = \exp(H_* t), \quad a_-(t) = H_*^{-1}\sinh(H_* t). \tag{88.86}$$

The closed and flat charts are considered for $t \in \mathbb{R}$; the open chart, for $t > 0$. The sign s and the clock H_* retain their antecedents in the state selecting the realization.

Lemma 88.33 (Curvature of the three charts of the same clock)**.** *For the functions in* (88.86)*,*

$$\frac{\ddot{a}_s}{a_s} = H_*^2, \qquad \left(\frac{\dot{a}_s}{a_s}\right)^2 + \frac{s}{a_s^2} = H_*^2, \qquad \mathrm{Ric}[g_s] = 3H_*^2 g_s. \tag{88.87}$$

Consequently, $R[g_s] = 12H_*^2$ *and* $\mathsf{G}[g_s] = -3H_*^2 g_s$*.*

Proof. The first two equalities are obtained by differentiating the three functions: in the closed and open charts we use $\cosh^2 z - \sinh^2 z = 1$, and in the flat chart $\dot{a}_0 = H_* a_0$. To verify the tensor identification, the connection coefficients involving the time coordinate are

$$\Gamma^0{}_{ij} = a_s \dot{a}_s (h_s)_{ij}, \qquad \Gamma^i{}_{0j} = (\dot{a}_s/a_s)\delta^i_j,$$

and the purely spatial ones coincide with those of h_s. Contraction of the curvature gives

$$\mathrm{Ric}_{00} = -3\ddot{a}_s/a_s, \qquad \mathrm{Ric}_{0i} = 0, \qquad \mathrm{Ric}_{ij} = (a_s\ddot{a}_s + 2\dot{a}_s^2 + 2s)(h_s)_{ij}.$$

Substituting the first two identities of (88.87) produces $\mathrm{Ric}_{00} = -3H_*^2$ and $\mathrm{Ric}_{ij} = 3H_*^2 a_s^2 (h_s)_{ij}$. Taking the trace and forming the Einstein tensor proves the other statements, with the curvature convention of (82.35). □

Theorem 88.34 (Density, pressure, and sign of the selected acceleration)**.** *In the preceding charts, for* $\Lambda_{\mathrm{ref}} = 0$ *and* $T_b = 0$*, the residual tensor is*

$$T^{\mathrm{res}} = -\rho_* g_s, \qquad \rho_* := \frac{3H_*^2}{8\pi G_{\mathrm{int}}} > 0, \qquad T^\Lambda = T^{\mathrm{res}}, \quad T^0 = 0. \tag{88.88}$$

For a unit comoving observer $u = \partial_t$*, the density and isotropic pressure are* ρ_* *and* $p_* = -\rho_*$*. The acceleration equation evaluates to*

$$\frac{\ddot{a}_s}{a_s} = -\frac{4\pi G_{\mathrm{int}}}{3}(\rho_* + 3p_*) = H_*^2 > 0. \tag{88.89}$$

Proof. The preceding lemma and (88.78) give $T^{\mathrm{res}} = -(3H_*^2/\kappa_x) g_s$. Since $g_s(u,u) = -1$, $T^{\mathrm{res}}_{\mu\nu} u^\mu u^\nu = \rho_*$. The spatial projector $q^{\mu\nu} = g_s^{\mu\nu} + u^\mu u^\nu$ satisfies $q^{\mu\nu}(g_s)_{\mu\nu} = 3$, and therefore

$$p_* := \tfrac{1}{3} q^{\mu\nu} T^{\mathrm{res}}_{\mu\nu} = -\rho_*.$$

The trace equals $-4\rho_*$, so (88.80) produces the two sectors of (88.88). Finally, $\rho_* + 3p_* = -2\rho_*$, and substitution into the right-hand side of (88.89) gives $\kappa_x \rho_*/3 = H_*^2$, equal to the geometric value already calculated. Positivity uses exactly $G_{\mathrm{int}} > 0$ and $H_* > 0$. □

In this realization, the trace sector publishes a constant density and an opposite pressure, and the internal clock fixes positive acceleration. In a general chart, T^Λ describes the pointwise isotropic component, while T^0 preserves the traceless residual and both obey the exchange of (88.83). Identification of these sectors with observational dark sources requires a single realization to reproduce expansion, lensing, rotation, structure growth and the cosmic background jointly. The present construction fixes the tensor, its balances and the acceleration of the selected charts entering that comparison.

Chapter 89

Polyakov action, T-duality, strings, and branes: compactification in dimension 11 and dynamical realization of M-theory

89.1 Extended Persistence and String and Brane Worldvolumes

89.1.1 Extended persistence and world surface

A physical string is an extended one-dimensional object whose evolution sweeps out a worldsheet. Each point of the string has an internal coordinate, and each instant adds a temporal coordinate; their combination forms the domain on which the induced metric, tension, and background fields live. A closed string has a circular spatial section. An open string has endpoints subject to boundary conditions. Its vibrations organize states, and its tension converts the area traversed by the worldsheet into action.

A brane of dimension p is an extended object whose history forms a worldvolume of dimension $p + 1$. Branes receive string endpoints, carry fields on their volume, and may wrap cycles of a compact space. This definition fixes three different data: the dimension of the object, the dimension of its history, and the conditions governing its boundary. The tension, charges, and spectrum belong to the dynamical realization that completes those geometric data.

HMT reaches this boundary from an architecture of persistent routes. A route preserves the orientation, sheet, phase, quotient, carry, and memory of the crossings that have prolonged it. The passage to an extended object assigns that genealogy to a section distributed over an internal coordinate. The composition of routes is then effected by sewing segments; the boundary memory records windings and intersections; the action measures the complete persistence over the traversed surface. This map preserves the causal order: first the enriched state is constructed, and its realization as a string, brane, or field is declared thereafter.

The Polyakov action provides a precise form for the physical codomain:

$$S_{\mathrm{P}}[X,h] = -\frac{T}{2}\int d^2\sigma\,\sqrt{-h}\,h^{ab}g_{MN}(X)\partial_a X^M\partial_b X^N.$$

Here T is the tension, h_{ab} the worldsheet metric and X^M the map into the target space. An HMT string realization must produce these objects, their state space and their symmetries from a typed map; the route structure supplies the genealogical domain on which that map acts.

89.1.2 Exact screens in dimensions 11, 10, 26 and 24

The first screen starts from the extended ternary code $C_W = [12, 6, 6]_3$. Puncturing one coordinate produces the code $G_{11} = [11, 6, 5]_3$. Its Hamming balls of radius two have cardinality

$$V_3(11, 2) = 1 + 22 + 220 = 243 = 3^5,$$

and the 3^6 codewords satisfy

$$3^6 V_3(11, 2) = 3^{11}.$$

Therefore, these balls partition the ambient space exactly. The integer eleven here measures the length of a perfect code and retains its combinatorial type.

A second screen uses the real permutation module V_{12} associated with the twelve icosahedral vertices. The complement of the uniform vector decomposes as

$$V_{11} = V_3 \oplus V_{3'} \oplus V_5.$$

The dodecaphase state K polarizes a line $\ell_K \subset V_3$ and determines the projector

$$P_{10} = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2}.$$

From it descend the exact decompositions.

$$V_{11} = \ell_K \oplus V_{10}, \qquad V_{10} = V_{3'} \oplus W_7(K),$$

with dimensions $11 = 1 + 3 + 7$ and $10 = 3 + 7$. The step $12 \to 11$ eliminates the uniform mode; the step $11 \to 10$ eliminates the direction marked by K. A physical compactification adds a temporal line, a stable rank-six lattice, and the transport that preserves the three extended directions.

The third screen starts from the lattice

$$L_{26} = \Lambda_{24} \oplus U \cong II_{25,1},$$

where U is the integral hyperbolic plane. For a primitive isotropic vector e_+, the reduction

$$e_+^{\perp}/\mathbb{Z}e_+ \cong \Lambda_{24}$$

is exact. The orthogonality condition removes one direction and the quotient removes the null direction contained in its orthogonal complement; the result is rank twenty-four. Code, real module, and lattice belong to distinct categories. Their explicit maps make it possible to relate their ranks while preserving the provenance of each.

The incidence between the six faces and the eight vertices of the cube also provides a screen of spatial and temporal signature. If M is its incidence matrix, then

$$MM^{\mathsf{T}} = 12P_u + 4P_-.$$

The quotient by the kernel has rank four and decomposes as $1 \oplus 3$. Upon declaring the uniform line to be the temporal direction, the normalized form becomes $\mathrm{diag}(-1, 1, 1, 1)$. The incidence proves the rank and the spectral ratio; the declared orientation fixes the signature.

89.1.3 Moment, winding and reciprocal radius

In a compact coordinate of radius R, the integer m records momentum and the integer w records winding. The form

$$E_R(m, w) = \frac{m^2}{R^2} + w^2 R^2$$

has the involution

$$\mathsf{T}(m, w, R) = (w, m, R^{-1}), \qquad E_R(m, w) = E_{R^{-1}}(w, m).$$

In $\ell^2(\mathbb{Z}^2)$, the exchange $U_T|m, w\rangle = |w, m\rangle$ provides the unitary equivalence

$$U_T H(R) U_T^{-1} = H(R^{-1}).$$

This is the algebraic residence of radius duality: momentum and winding are two reciprocal readings of the same lattice sector. The realization as T-duality incorporates the string scale, the oscillators and the action on the physical state space. At the self-dual radius both readings share the same scale and the exchange acts within the same spectrum.

89.1.4 Interface in dimension 11: spectral triple, supersymmetry and operator $Q^2 = H$

M-theory organizes an eleven-dimensional physical codomain with metric g_{MN}, three-form C_{MNP}, gravitino ψ_M, action, and supersymmetry transformations. The bridge is written as a map

$$\mathfrak{R}_M : \mathcal{X}_{\mathrm{HMT}}^{\mathrm{enr}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}}.$$

Its source preserves phase, orientation, sewing and memory; its codomain adds the fields and the eleven-dimensional dynamics. The compactification of one direction must transport these fields to a ten-dimensional screen, preserve the low-energy limit and intertwine the declared dualities.

A candidate compactification is typed by a triple $(x_\infty, \kappa, \mathcal{U})$. Section x_∞ represents a prolongable persistence; κ carries it to a moduli space; $\mathcal{U}$ transports metric, orientation, register, and boundary. Its admissibility requires prolongation to every depth, commutation with duality, descent of the spectrum to the quotient, and preservation of the domains and codomains of the observables. These conditions convert an analogy of ranks into a verifiable mathematical problem.

Strings appear after compactifying the eleven-dimensional sector; branes appear as extended realizations coupled to the three-form and its duals. The exceptional branch that reaches Λ_{24}, $V^\natural$, and the Monster preserves the same enriched source through another functor. The dimensional and exceptional interfaces are distinct prolongations of a common genealogy, each with its own codomain.

Result

The perfection of G_{11}, the polarization $11 \to 10$, the isotropic reduction $26 \to 24$, the cubic screen of signature $(3, 1)$ and the radius involution are proven algebraic results. Together they form the exact residence of ranks, quotients and dualities on which the interface toward strings, branes and M-theory is built.

Physical realization

An extended history preserves position, winding, orientation, and boundary within a single persistence. Compactification determines which directions appear as macroscopic extension and which act as internal degrees. The string reads that persistence on a worldsheet; the brane reads it on a worldvolume; M-theory coordinates both readings through eleven-dimensional fields.

Boundary of validity

The realization is falsified if the map $\mathfrak{R}_M$ alters the types of the screens, if the duality ceases to act unitarily on the spectrum, if the compactification loses prolongation, or if the fields fail to satisfy the action and supersymmetry. Physical closure requires tension, oscillators, amplitudes, controlled anomalies, and a coherent gravitational limit for each declared compactification.

89.1.5 From exact screens to the physical interface of M-theory

The first part constructed, in explicit mathematical domains, the reductions

$$12 \longrightarrow 11 \longrightarrow 10, \qquad 26 \longrightarrow 24,$$

and the moment, winding, and radius involutions

$$(m, w, R) \longleftrightarrow (w, m, R^{-1}).$$

These results are not yet a physical theory of strings nor an action of supergravity. They constitute the screens and equivalences that a dimensional realization must respect.

The interface is typed via a map declared

$$\mathcal{R}_M : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \longrightarrow \mathcal{X}^{\mathrm{phys}}_{11},$$

whose codomain must carry, at a minimum, the metric field g_{MN}, the three-form C_{MNP}, the gravitino ψ_M, its action, and the supersymmetry transformations. A specialization to strings further requires identification of the physical radius, tension, momentum and winding sectors, and the state space on which T-duality is realized. A conformal or CFT reading requires its own operator algebra, grading, and state–operator correspondence.

The positive connection with the exceptional branch is not a bare arrow Monster→M-theory. Both prolongations preserve data from the same enriched state—phase, grading, orientation, sewing, and memory— but employ distinct functors. In the exceptional branch, those data reach $V^\natural$, the Monster, and Moonshine; in the dimensional branch they feed the screens and, only through $\mathcal{R}_M$, a possible realization of fields and strings.

Definition 89.1 (Internal Admissibility of a Compactification)**.** A candidate compactification is represented by a triple

$$(x_\infty, \kappa, \mathcal{U}),$$

where $x_\infty \in \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}}$ is a surviving section,

$$\kappa : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \dashrightarrow \mathcal{M}$$

is the possibly partial map into a declared moduli space $\mathcal{M}$, and $\mathcal{U}$ transports metric, orientation, register and boundary data. We define

$$\mathrm{Adm}_{\mathrm{HMT}}(x_\infty, \kappa, \mathcal{U}) = 1$$

if the following four conditions hold:

1. the section has a compatible extension to every depth;
2. the declared dualities are compatible at the point considered:

$$\kappa(\mathsf{T}_{\mathrm{HMT}} x_\infty) = \mathsf{T}_{\mathcal{M}}(\kappa(x_\infty)),$$

   when both sides are defined;
3. the spectrum descends to the compactification quotient;
4. the observables preserve their domains, codomains, and types under $\mathcal{U}$.

This predicate is an internal admissibility criterion and not an automatic identification with the physical *Swampland*. The distance, tower, weak-gravity, and absence-of-global-symmetries criteria, as well as the geometric conditions of a specific compactification, are subsequently evaluated on $\mathrm{im}\,\kappa$ and require the corresponding metric maps, fields, and scales. The preceding definition fixes the interface that a realization must preserve; it does not by itself prove the existence of a physical compactification or a Swampland conjecture.

Scope of the interface

The screens, quotients, and T-dual involution are exact mathematical results. The complete dictionary toward $(g_{MN}, C_{MNP}, \psi_M)$, the action, supersymmetry, and a physical CFT is a typed interface that must be verified in each realization. This boundary does not diminish the mathematical result or authorize its presentation as an already closed physical dynamics.

89.2 Realization of M-theory through compactification, strings, branes, and 11 dimensions

The interface dimensional toward theory M requires distinguish the exact structure of split, the lift operatorial and the fields fisicos of the codomain. Let

$$\mathfrak{S}_M = (\mathcal{H}_{\text{phys}}, H, Q)$$

a spectral triple in which $\mathcal{H}_{\text{phys}}$ is the Hilbert space after imposing the gauge constraints, H is a nonnegative self-adjoint operator, and Q is an odd, densely defined supercharge compatible with the grading $\mathcal{H}_{\text{phys}} = \mathcal{H}_+ \oplus \mathcal{H}_-$. The relation

$$Q : \mathcal{H}_+ \rightleftarrows \mathcal{H}_-, \qquad Q^2 = H \tag{89.1}$$

is interpreted on its common domain. It does not replace the relativistic supersymmetric algebra; it is its Hermitian reduction of dimension 1 and fixes the minimal datum that a spectral realization must preserve.

89.2.1 Operator lifting of the APP–TRIT–TPK state

Let $\mathcal{H}_{\text{HMT}}$ be the completion of the surviving sections with phase, orientation, quotient, carry, boundary, route, and memory, and let

$$W : \mathcal{H}_{\text{HMT}} \longrightarrow \mathcal{H}_{\text{phys}}$$

a realization isometry. An admissible operator lift preserves the APP composition, the TRIT orientation, and the full TPK dynamics, and intertwines

$$W\widehat{H} = HW, \qquad W\widehat{Q} = QW, \qquad \widehat{Q}^2 = \widehat{H}. \tag{89.2}$$

The first equality transports the generator, the second preserves the grading, and the third prevents introducing H as a datum foreign to the genealogical antecedent. These identities are obligations of the bridge: the existence of fermionic and bosonic completions alone does not prove (89.1).

89.2.2 Physical undecadimensional codomain

The realization in dimension 11 is expressed by

$$\mathfrak{R}_M : \mathcal{X}_{\mathrm{HMT}}^{\mathrm{enr}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}},$$

whose codomain carries metric g_{MN}, the 3-form C_{MNP}, the gravitino ψ_M, the action, and its supersymmetry transformations. Compactification along one direction must simultaneously transport these fields, the inner product, and the grading of $\mathfrak{S}_M$. Strings appear on the dimension-(10) screen; branes couple to the 3-form and its duals; and T-duality exchanges momentum and winding through

$$(m, w, R) \longmapsto (w, m, R^{-1})$$

without altering the spectrum of the compact sector.

The Polyakov action

$$S_{\mathrm{P}}[X, h] = -\frac{T}{2} \int d^2\sigma \, \sqrt{-h}\, h^{ab} g_{MN}(X) \partial_a X^M \partial_b X^N$$

fixes the worldsheet dynamics once T, h_{ab}, the maps X^M, and the boundary conditions have been determined. The screen chains $12 \to 11 \to 10$ and $26 \to 24$, the radius involution, and the lattice reduction are prior algebraic results; the action, spectrum, and amplitudes constitute the subsequent physical realization.

89.2.3 Compatibility of the spectral triple $(\mathcal{H}_{\mathrm{phys}}, H, Q)$ with the physical codomain in dimension 11

A realization is admissible if it preserves at the same time:

1. the compatible prolongation of the state to every depth;
2. the domains and codomains of H, Q, and the observables;
3. the intertwining identities (89.2);
4. the unitary action of T-duality on the spectrum;
5. the descent of the fields of dimension 11 to the stated compactification;
6. compatibility with the physical inner product and the gauge constraints.

The failure of any of these conditions distinguishes an analogy of ranks from a physical realization. The formulation does not automatically identify the exceptional corridor with M-theory: both publications follow from the same enriched state, but use distinct functors and codomains.

Chapter 90

General Mass Law on the atlas 81/56/13/324: trajectories, record, signature, character, towers 90/120 and the null sector

90.1 Operator Domain of the General Mass Law: 81 Cells, 56 Families, 13 Multisections, 324 Routes, and Null Sector

The General Mass Law acts on persistent sections of the oriented atlas, not on a table of species. Its internal domain contains 81 cells, 56 route families, 13 multisections, and 324 oriented routes, in addition to a separate null chart. The censuses of physical outputs are subsequent and do not alter this domain.

90.2 Determinantal origin of the absolute scale

The integral form H_4 has Smith normal form $\mathrm{diag}(1, 2, 2, 4)$, so its cokernel has order 16. It follows that

$$\Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34.$$

The absolute chain is

$$\Sigma_H \to \hbar_{\mathrm{pre/ret}} \to \omega_0 \to \varepsilon_{\mathrm{clk}} \to m_{\mathrm{clk}} \to \widehat{M}^{(0)} \to \widehat{M}^{(\beta)}.$$

The decade -34 is never introduced from the SI system or absorbed into the relative correction.

90.3 Governing construction of the law and the material domain

The full development of the law is organized here by result: state, route, record, signature, character, towers, absolute branch, and operator. Its internal order is preserved, while the realizations by species are reserved for the corresponding chapter.

90.3.1 Spectral Definition of Mass as a Persistence Measure of a Route 1 Coupled to a Physical Regime

Mass is the spectral measure of the persistence of a route when a genealogical section is coupled to a physical regime. It is not a scalar attribute affixed in advance to a particle name. The APP–TRIT–TPK dynamics constructs the route, its memory, its signature, and its character; Dimensional Mechanics realizes that genealogy on a resonance mass line and determines, through the coupling, the observable subspace and its spectrum.

An elementary particle is represented by a persistent section; a noncentral family, by a stable multisection; a composite particle, by a composition of genealogical registers with a linking boundary; a resonance, by a pole of the coupled operator; a topological sector, by its fusion ring and its braiding representation before any mass chart; a virtual section, by its terminal horizon of prolongation. These realizations are distinct and must not be flattened into a single list of numbers.

The external magnitude never enters the selection of cell, route, signature, reader, tower coefficient, or eigenvector. Metrological comparison is performed only after the internal output has been constructed and fixed.

90.3.2 Complete state space of mass

Let C_{81} be the cellular atlas. Each cell admits four bidirectional route orientations, so the finite space of oriented routes is

$$\mathcal{R}_{324} = \{(c, h_0, v_0) : c \in C_{81},\ (h_0, v_0) \in \{\pm 1\}^2\}.$$

The cellular projection, the family relation, and the coarse stratification produce

$$|C_{81}| = 81, \qquad |\mathcal{F}_{56}| = 56, \qquad |\mathcal{M}_{13}| = 13, \qquad |\mathcal{R}_{324}| = 324.$$

The electron occupies the unique central fixed point. The twelve noncentral multisections are finite fibers stable under cellular inversion and do not, in general, admit an equivariant point section. Their natural object is therefore an operator on the fiber rather than a number chosen from among its cells. The null sector is incorporated through the zero section of the mass line, not as the value of a positive character.

The physical output catalog distinguishes three charged leptons, three neutrino interaction realizations, six quark flavors with their color orbits, two null gauge realizations, two massive gauge bosons, one scalar sector, two composite families, three topological codomains, and a system of virtual sections. This subsequent classification does not limit the number of composite or resonant states: composition and excitation generate additional families within their respective codomains.

90.3.3 Genealogical trajectory of a mass realization

The law does not begin with a particle label nor with a number. Its order is

$$\begin{aligned}\mathrm{APP} \to \mathrm{TRIT} \to \mathrm{TPK} \to \widetilde{\Gamma}^{\mathrm{surv}} \to \Gamma^{\mathrm{obs}} \to L_{108} \to \sigma \in \mathbb{Z}^5 \\ \to \chi_0 \to \chi_{\mathrm{full}} \to \widehat{\mathcal{M}} \to \text{coupling} \\ \to \text{spectrum/pole} \to \mathcal{L}_M \to \text{comparison}.\end{aligned}$$

Here:

- APP arranges the local incompatibility, the sum/product sheets, and their orientation;
- the TRIT preserves sign, threshold, and bidirectional opening;
- the TPK evolves phase, memory, carry, survival, and return;
- a particle is a persistent section of an extension, and its observable route is the history it leaves in the genealogical record;
- the integer signature is additive;
- the character turns additive composition into a positive ratio;
- the towers refine the character through a single global harmonic operator;
- the mass line supplies the dimensional type;
- measurement is coupling: the coupling determines which subspace and which spectrum are physically accessible, without consulting the quantity to be measured subsequently.

Mass does not select the route. The persistent route, the genealogical record, and the coupling select the spectral object whose mass is read.

90.3.3.1 Conserved components of the enriched state of the TPK along the mass trajectory

The state that feeds the mass law is

$$X_K = (w_6, w_{30}, R_{36}, g_K, B_K, p_K, c_K, \varepsilon_K, \omega_K),$$

where short word, prolonged word, region, nonadic phase, block memory, prefix, carry, sheet, and winding are preserved. The chain

$$w_6 \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

It does not directly project a mass: it constructs the persistent identity that is later read.

90.3.3.2 Nonadic filtration with memory

From each state one obtains a refinement fiber formed by 729 subcylinders,

$$\{C_{K,j} : 0 \le j < 729\}.$$

The pruning G_9 satisfies

$$G_9(C_{K,j}) \in \{0,1\}, \qquad \sum_{j=0}^{728} G_9(C_{K,j}) = 1.$$

If j_K is the survivor,

$$P_{K+1} = 729P_K + j_K.$$

After nine steps,

$$g(K+9) = g(K),$$

but they change, in general,

$$(B_{K+9}, P_{K+9}, \mathrm{pref}_{K+9}, \mathrm{Witt}_{K+9}) \neq (B_K, P_K, \mathrm{pref}_K, \mathrm{Witt}_K).$$

This is the equational form of persistence: the phase returns, not the state. The mass can recognize a particle after the return because the genealogical record preserves the difference.

90.3.3.3 Nonadic carry transduction to the signed dodecaphasic state

For a temporal coordinate θ, define

$$g_0(\theta) = \theta \bmod 9, \qquad \beta(\theta) = \left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor \bmod 12.$$

Then

$$g_0(\theta+9) = g_0(\theta), \qquad \beta(\theta+9) = \beta(\theta) + 1 \pmod{12}.$$

Thus, the nonadic return preserves the phase and advances one memory tooth. The 108 times are

$$108 = 9 \cdot 12,$$

so that each genealogical record contains a complete cycle of both scales. The 36.864 carry compositions describe the local combinations of this bidirectional memory.

90.3.3.4 Completion and Conservation of the Unit

The base boundary mil decomposes as

$$999 = 729 + 270 = 729 + 243 + 27,$$

while the completion is

$$1000 = 729 + 271 = 729 + 243 + 27 + 1, \qquad 271 = 270 + 1.$$

+1 is the unique vertex lying entirely on the boundary and realizes the carry that returns the unit. The partition 729/271 distinguishes the active kernel from the mediating boundary; it is not a golden-ratio

approximation. The same conservation allows a route to change blocks without losing its normalized identity.

90.3.3.5 Theorem of the complete oriented atlas

Every cell $c \in C_{81}$ has four orientations

$$(h_0, v_0) \in \{\pm 1\}^2.$$

The map

$$(c, h_0, v_0) \longmapsto \Gamma(c, h_0, v_0)$$

is bijective over $\mathcal{R}_{324}$. Consequently,

$$|\mathcal{R}_{324}| = 4|C_{81}| = 324.$$

Each route has 108 genealogical register entries, so the total temporal census is

$$81 \cdot 108 = 8748.$$

The quadruple

$$(\text{seed row}, \text{seed column}, h_0, v_0)$$

determines of manner single the route, its word w_6, its word dodecaphasic, their returns, memory, carry, signature historical and readers. Therefore, the 324 routes not only may is enumerated: may is reconstructed and is joined exactly, field by field, without using a mass.

90.3.3.6 Quotients of families and multisections

The quotient of the 81 cells by route history yields 56 families. Their multiplicities are distributed as

$$41 \times 1, \quad 10 \times 2, \quad 2 \times 3, \quad 1 \times 4, \quad 2 \times 5,$$

and

$$41 + 20 + 6 + 4 + 10 = 81.$$

The stratification into thirteen multisects possesses ranges

$$1, \quad 2, \quad 4, \quad 6, \quad 8, \quad 12, \quad 16$$

with multiplicities

$$1, \quad 2, \quad 3, \quad 2, \quad 3, \quad 1, \quad 1,$$

and sum of ranks

$$1 + 4 + 12 + 12 + 24 + 12 + 16 = 81.$$

The electron occupies the rank-one block. The remaining sectors lie in higher-rank blocks and require a representation projector, not a nominal cell.

90.3.3.7 Signature, readers, and memory by route

For each $\Gamma \in \mathcal{R}_{324}$, the following are calculated:

$$\sigma_\Gamma \in \mathbb{Z}^5, \qquad K_D(\Gamma), \qquad K_\Omega(\Gamma),$$

together with first returns of class, orbit, cell, and kinematic state; separation of prefixes; carry debt; ambiguity; stabilized triads; sheet and winding. The family K_D has 14 profiles; K_Ω, nine; together they form 40 pairs and 18 coincidences. This diversity is the fine information that makes it possible to pass from a coarse fiber to a physical operator.

90.3.4 From the APP defect to the full signature

90.3.4.1 Primordial defect and unfolding

At the center APP,

$$B_c = 9P_+ + 5P_-, \qquad 9 - 5 = 4.$$

The primordial local gap is 4. The global defect 54 belongs to a later unfolding $2 \to 6 \to 54$; it must not be projected back onto the center as though it were the same operation.

90.3.4.2 12 *eventos and divisor dodecafasico*

The oriented coordinate does not receive a factor $1/6$ arbitrarily. The chain is

$$12 \text{ events} \to s_C^{\mathrm{tot}} \to 1 + 5 + 6 \to s_C^{(12)} = \frac{s_C^{\mathrm{tot}}}{6} \to W_\pm = 6n_A \pm s_C \to \mathrm{SNF}(1, 12) \to \chi_{\mathrm{mass}}.$$

The $1/6$ is the oriented quotient of the closure of twelve events. It is not the residue (-1/12), it is not the pseudoinverse of a valency, and it is not the hexad–octad incidence.

90.3.4.3 Construction of the complete full signature from the route register

The genealogical record CT–108 produces

$$\sigma(\Gamma) = \left(n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta\right) \in \mathbb{Z}^5.$$

The coordinates have distinct origins:

- n_A: dominant duration/persistence;
- s_C: net orientation of the bilayer, divided by six after the dodecaphasic closure;
- k_{Δ_4}: minimal-torsion channel;
- b_{120}: event coefficient of the register;
- b_ζ: step-three autocorrelation.

We define

$$\zeta_{270} := 135\Delta_4^2,$$

and remains separated from

$$s_{270} = q_-^{270} - q_+^{270}.$$

The 324 oriented routes are joined bijectively to their five historical coordinates through the canonical route identity. This join uses only genealogical structure and consults no metrological magnitude.

90.3.4.4 Direct angle, counter-angle, and conjugate channels

The direct angular coordinate proceeds from the already constructed fine structure constant:

$$A = 1000\alpha_{\mathrm{HMT}} = 7.297352569283800997285105472380663\ldots^{\circ}.$$

The counter-angle is not obtained from a mass or from the Barbero–Immirzi functional. Let

$$D_A = \exp\!\left(-\frac{100\pi}{9}\alpha_{\mathrm{HMT}}\right),$$

$$C_\pi(\alpha_{\mathrm{HMT}}) = 169\alpha_{\mathrm{HMT}}^6 + \frac{D_A\alpha_{\mathrm{HMT}}^7}{1 - D_A\alpha_{\mathrm{HMT}}},$$

$$y_* = \frac{\pi}{90}(H_5 + \alpha_{\mathrm{HMT}}) - C_\pi(\alpha_{\mathrm{HMT}}), \qquad C^* = \frac{180}{\pi}y_*.$$

Therefore,

$$C^* = 2.123738338968645724261951380393\ldots^{\circ}.$$

The coordinate A is the common angular mode and C^*, the oriented differential mode. Its passage to the Archimedean chart is

$$x = A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad y = C^*_{\mathrm{rad}} = \frac{\pi C^*}{180}.$$

In the real algebra generated by the involution $R = \mathrm{diag}(1, -1)$, with $P_\pm = (I \pm R)/2$, the biangular block is

$$B_{A,C^*} = AI + C^*R = (A + C^*)P_+ + (A - C^*)P_-.$$

Angle plus counter-angle and angle minus counter-angle are thus the two eigenvalues of a single object. Exponentiation produces the channels

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}.$$

The chart is invertible:

$$x = -\frac{1}{2}\log(q_+q_-), \qquad y = \frac{1}{2}\log\frac{q_-}{q_+}.$$

The transformation $C^* \mapsto -C^*$ preserves the projectors and exchanges the channels. The return coordinate satisfies, after the regional construction,

$$\eta_{\mathrm{ret}} = \frac{C^*}{2} - \alpha_{\mathrm{HMT}}\,\mathrm{deg},$$

without constituting a second selection rule for C^*.

90.3.4.5 Central Character

With

$$\Theta_0 = \left(A_{\mathrm{rad}}, \frac{C^*_{\mathrm{rad}}}{6}, \Delta_4, s_{120}, \zeta_{270}\right),$$

the central character is

$$\chi_0(\sigma) = \exp\Big(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}} + k_{\Delta_4}\Delta_4 + b_{120}s_{120} + b_\zeta \zeta_{270}\Big).$$

By additivity of the signature,

$$\chi_0(\sigma_1 + \sigma_2) = \chi_0(\sigma_1)\chi_0(\sigma_2).$$

The physical unit does not enter this exponential: χ_0 is a positive dimensionless automorphism of the mass line.

90.3.5 Global harmonic hierarchy of towers

With the coordinates (x=A_{\rm rad}) and (y=C^*_{\rm rad}) already constructed, let

$$q_\pm = \exp\Big[-\frac{\pi}{180}(A \pm C^*)\Big] = e^{-x\mp y}.$$

In a globally consistent convention,

$$T = e^{-xI - yR}, \qquad c_n = \mathrm{Tr}(T^n) = q_-^n + q_+^n,$$
$$s_n = -\mathrm{Tr}(RT^n) = q_-^n - q_+^n.$$

Equivalently and operatorially,

$$c_n = 2e^{-nx}\cosh(ny), \qquad s_n = 2e^{-nx}\sinh(ny).$$

The involution $C^* \mapsto -C^*$ fixes the projectors and permutes the spectral coefficients, or equivalently the associated channels. It follows that

$$c_{m+n} = \frac{c_m c_n + s_m s_n}{2}, \qquad s_{m+n} = \frac{s_m c_n + c_m s_n}{2},$$
$$c_n^2 - s_n^2 = 4e^{-2nx},$$

and the common second-order recurrence. The admissible heights form

$$\mathfrak{S} = \langle 90, 120\rangle = \{90, 120\} \cup \{30r : r \geq 6\}.$$

The values $90, 120, 180, 210, 240, 270, 360, 420$ are genealogical witnesses, not the complete tower. Before the quotient, height 360 preserves two histories:

$$k[\mathfrak{S}_0] \simeq k[X_{90}, Y_{120}]/(X_{90}^4 - Y_{120}^3).$$

The general elevation is written

$$\chi_{\mathrm{full}}(\sigma, \eta) = \chi_0(\sigma)\exp\Big(\sum_{h\in\mathfrak{S}} \eta_h s_h\Big),$$

with

$$N_{120} = b_{120} + \eta_{120}.$$

The numerical sum does not erase the dual provenance: b_{120} comes from the ledger and η_{120} from the spectral refinement. Nor can it absorb $b_\zeta\zeta_{270}$ into $\eta_{270}s_{270}$.

90.3.6 Absolute Rama: action, clock and mass line

The determinantal reader produces

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1,2,2,4), \qquad |\operatorname{coker} H_4| = 16,$$
$$\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34.$$

The two oriented sections of a single action line are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S.$$

Its additive fine chart and its multiplicative chart are

$$\delta_{2w} = H_5 - \eta_{\mathrm{ret}}, \qquad R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}} > 0.$$

They are not two Planck constants. The common decade fixes the absolute order; the quotient transports relative outward/return information.

Declared $t_0 \in \mathcal{L}_T^+$, CT–108 fixes

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad \varepsilon_{\mathrm{clk}} = \hbar_{\mathrm{ret}}\omega_0, \qquad m_{\mathrm{clk}} = \varepsilon_{\mathrm{clk}} c_{\mathrm{int}}^{-2}.$$

The character acts by homothety on $\mathcal{L}_M$; it does not become $\hbar$. In mass ratios, every common factor cancels:

$$\frac{m_Y}{m_X} = \chi_{\mathrm{full}}(\sigma_Y - \sigma_X, \eta_Y - \eta_X) R_{\mathrm{act}}^{\kappa_Y - \kappa_X}.$$

Thus 10^{-34} fixes the absolute scale but does not correct a relative residual. A relative modification can follow only from the route, the specific clock, the reader, or the towers.

Remains a distinction necessary. HMT constructs a section internal a time declared t_0; the coordinate MeV requires a chart. For close the chart absolute without a convention externa must construirse

$$\Gamma \longmapsto t_\Gamma \quad \text{or} \quad \Gamma \longmapsto \omega_\Gamma.$$

Section 10 defines a clock reader based on returns and holonomy. Its absolute normalization is determined when the route operator fixes a positive section of the temporal line.

The normal form, the cokernel of order sixteen, the ablations, and the distinction between h and $\hbar$ are proved in full in section 59.2. Here that already-constructed result is used to fix the absolute branch of the law, without restarting its derivation.

90.4 Conjugate angular coordinates and spectral decomposition

The passage from the arithmetic closure of α to the dimensional hierarchy is effected through two angular coordinates. The first follows directly from α_{HMT}; the second is the oriented phase produced by the regional analytic realization of the quintuple microfiber. Both reach Dimensional Mechanics already constructed, before the exponential chart that will generate the global moments is introduced.

90.4.1 Transfer of the angular coordinates derived in HMT

Parts I–III constructed distinct dependencies with a common root in α_{HMT}. The pre-return character follows from

$$(\alpha_{\mathrm{HMT}}, \varphi;\ 9, 5, 4, 12, 54,\ \text{graded rule}) \longrightarrow H_5,$$

while the angular coordinate and the determinant follow from

$$\alpha_{\mathrm{HMT}} \longrightarrow A = 1000\alpha_{\mathrm{HMT}}{}^{\circ}, \qquad (\alpha_{\mathrm{HMT}}, \pi) \longrightarrow D_A = e^{-100\pi\alpha_{\mathrm{HMT}}/9}.$$

Through a distinct dependence, the regional microfiber fixes $\mathcal{F}_\pi \to \rho_\pi = 169$, and with it

$$C_\pi(\alpha_{\mathrm{HMT}}) = 169\alpha_{\mathrm{HMT}}^6 + \frac{D_A\alpha_{\mathrm{HMT}}^7}{1 - D_A\alpha_{\mathrm{HMT}}}.$$

The branch of H_5 and the regional correction converge only at the following step:

$$y_* = \frac{\pi}{90}(H_5 + \alpha_{\mathrm{HMT}}) - C_\pi(\alpha_{\mathrm{HMT}}),$$
$$C^* = \frac{180}{\pi}y_*.$$

Henceforth, A denotes the direct angular coordinate and C^* the conjugate regional angular coordinate; these designations fix their types without introducing a second selection rule. Consequently, H_5 is not an output of A. Here y_* is the analytic coordinate in radians and C^* its sexagesimal coordinate. Dimensional Mechanics receives these already determined outputs; it does not redefine them. The coordinate A is not a direct input to the formula of C^*: the two objects are coupled for the first time in $(A, C^*) \mapsto q_\pm$. The equality $\alpha_{\mathrm{HMT}} = A/1000$ is solely the inverse change of coordinate. In this Part we retain the notations

$$A = 7.297352569283800997285105472380663^{\circ},$$
$$C^* = 2.123738338968645724261951380393\ldots{}^{\circ}.$$

The rounding used in the tables is $2.123738338968646^{\circ}$. The integer 169, the determinant D_A, and the regional recurrence belong to the preceding proof; neither any SI comparison nor the hexad–octad functional intervenes in their generation.

The angular identity

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{C^*}{2} - \alpha_{\angle,\mathrm{deg}}, \qquad \alpha_{\angle,\mathrm{deg}} := \alpha_{\mathrm{HMT}}\,\mathrm{deg},$$

defines the coordinate angular adimensional posterior to the return; does not employed for generate C^*. Equivalently, a time performed the construction regional,

$$C^* = 2(\eta_{\mathrm{ret}}^{(\mathrm{deg})} + \alpha_{\angle,\mathrm{deg}}).$$

This last equality is the inverse form of the same relation and not a second selection rule for C^*.

The regional realization corrects H_5 before producing $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$; therefore, H_5, $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$, and C^* have distinct mathematical types. The symbol $\hbar_{\mathrm{HMT}}$ is reserved for the magnitude on the action line obtained only after applying the scale $10^{-34}\mathcal{U}_S$. Comparison with an SI mantissa belongs to external metrological control and leaves the preceding construction invariant.

90.4.2 Internal phases and exponential chart

The abstract phases associated with the two angles are

$$a = \frac{A}{360}, \qquad c = \frac{C^*}{360} \quad \text{in } \mathbb{R}/\mathbb{Z}.$$

Before applying a real exponential, the canonical representatives $\widetilde{a}, \widetilde{c} \in [0, 1)$ are chosen. The exponential acts on those representatives, not directly on the quotient classes. Conversion to radians is introduced only upon choosing the Archimedean chart

$$x := A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad y := C^*_{\mathrm{rad}} = \frac{\pi C^*}{180},$$

$$q_- = e^{-x+y}, \qquad q_+ = e^{-x-y}.$$

The factor $\pi/180$ belongs to this change analytic of coordinates. The closure aritmetico of α, formulated before of this conversion, is independent of that choice of chart angular.

90.4.3 Central involutive algebra

Consider the two-dimensional regular representation of the real algebra generated by an involution. In a spectral basis, fix

$$R = \mathrm{diag}(1, -1), \qquad I = I_2,$$

so that both eigenspaces have multiplicity one. Let

$$P_+ = \frac{I + R}{2}, \qquad P_- = \frac{I - R}{2}$$

their spectral projectors. The central element determined by the angular coordinates is

$$B_{A,C^*} = AI + C^* R = (A + C^*)P_+ + (A - C^*)P_-.$$

The involution $C^* \mapsto -C^*$ preserves the fixed projectors $P_\pm$ and interchanges the two spectral coefficients —equivalently, the associated channels—. Applying the exponential yields

$$T = e^{-xI - yR} = q_+ P_+ + q_- P_-.$$

Therefore, the two channels are the eigenvalues of a single element of the algebra generated by I and R.

90.4.4 Invertibility of the channel chart

Theorem 90.1 (Reconstruction of the angular coordinates)**.** *Para $q_\pm > 0$,*

$$x = -\frac{1}{2}\log(q_+ q_-), \qquad y = \frac{1}{2}\log\frac{q_-}{q_+}.$$

Consequently, the map $(A, C^*) \mapsto (q_+, q_-)$ is injective. The exchange $q_+ \leftrightarrow q_-$ preserves A and transforms $C^* \mapsto -C^*$.

Proof. The multiplication and quotient of the two exponentials give $q_+ q_- = e^{-2x}$ and $q_-/q_+ = e^{2y}$. Taking logarithms recovers x and y. Since $\pi/180 \neq 0$, both angles are determined. □

90.4.5 Addition and Recurrence Identities

In this two-dimensional representation, the even and odd moments of the operator T are

$$c_n = \operatorname{Tr}(T^n) = q_-^n + q_+^n, \qquad s_n = -\operatorname{Tr}(RT^n) = q_-^n - q_+^n.$$

The multiplicity-one hypothesis is part of the domain of these formulas. In a representation with multiplicities m_+ and m_-, the corresponding traces would be $m_+q_+^n + m_-q_-^n$ and $m_-q_-^n - m_+q_+^n$, respectively.

Theorem 90.2 (Laws of Composition of Moments)**.** *For $m, n \geq 0$,*

$$c_{m+n} = \frac{c_m c_n + s_m s_n}{2}, \qquad s_{m+n} = \frac{s_m c_n + c_m s_n}{2},$$

$$c_n^2 - s_n^2 = 4e^{-2nx},$$

and both sequences satisfy

$$X_{n+2} = c_1 X_{n+1} - e^{-2x} X_n.$$

Moreover,

$$\partial_A c_n = -\frac{n\pi}{180} c_n, \quad \partial_A s_n = -\frac{n\pi}{180} s_n,$$
$$\partial_{C^*} c_n = \frac{n\pi}{180} s_n, \quad \partial_{C^*} s_n = \frac{n\pi}{180} c_n.$$

Proof. Expand the products of $q_-^m \pm q_+^m$ with $q_-^n \pm q_+^n$. The quadratic identity follows from $(u+v)^2-(u-v)^2 = 4uv$. The recurrence corresponds to the characteristic polynomial $z^2 - c_1 z + q_- q_+$, and the derivatives are obtained using the chain rule. □

Corollary 90.3 (Determination of the complete hierarchy)**.** *With A and C^* fixed, all pairs (c_n, s_n) are determined by the recurrence. No physical species introduces an additional channel.*

Finally,

$$s_n = 2e^{-nx}\sinh(ny), \qquad c_n = 2e^{-nx}\cosh(ny).$$

The coordinate A determines the common decay, and C^* the oriented separation. The decimal order of the action line is not introduced into these formulas. It is deduced in section 59.2 from the integral cokernel of the local Hadamard block. The subsequent choice of a basis expressed in J s belongs to the metrological transducer and does not alter the dimensionless identities.

90.4.6 Action ellipse, radian, and double holonomy return

The preceding focal theorem fixes the angular form and the determinantal reader fixes the action scale. Let us define

$$\eta = \operatorname{artanh}\frac{C^*}{A}, \qquad a_S = \sqrt{2\hbar_{\mathrm{HMT}}^{\mathrm{ret}} e^{\eta}}, \qquad b_S = \sqrt{2\hbar_{\mathrm{HMT}}^{\mathrm{ret}} e^{-\eta}}.$$

The symplectic orbit

$$Q(\theta) = a_S\cos\theta, \qquad P(\theta) = b_S\sin\theta$$

simultaneously preserves the shape ratio of the angular block and the area fixed by the action line.

Theorem 90.4 (Phase swept area)**.** *For every θ,*

$$\operatorname{Area}(\theta) = \frac{1}{2}\int_0^{\theta} (QP' - PQ')\,dt = \hbar_{\mathrm{HMT}}^{\mathrm{ret}}\theta.$$

Therefore,

$$\operatorname{Area}(1\text{ rad}) = \hbar_{\mathrm{HMT}}^{\mathrm{ret}}, \qquad \operatorname{Area}(2\pi) = h_{\mathrm{HMT}}^{\mathrm{ret}}.$$

Proof. Since $QP' - PQ' = a_S b_S$ and $a_S b_S = 2\hbar^{\mathrm{ret}}_{\mathrm{HMT}}$, the integral equals $\hbar^{\mathrm{ret}}_{\mathrm{HMT}}\theta$. The second identity uses $h^{\mathrm{ret}}_{\mathrm{HMT}} = 2\pi\hbar^{\mathrm{ret}}_{\mathrm{HMT}}$. □

APP supplies the arean oriented; A, C^* fix the form and the foci; the branch determinantal fixes the scale. The turn primitive encloses h and a radian of phase sweeps $\hbar$. The radian ordinary remains $1\,\mathrm{rad} = 180°/\pi$; the construction adds its genealogy as sector unitary of action, not another constant angular.

For a persistent section with holonomy $\varepsilon_\gamma \in \{+1, -1\}$, the condition

$$\varepsilon_\gamma e^{iJ_\gamma/\hbar} = 1$$

distinguishes two closures. In the cylinder, $\varepsilon_\gamma = +1$, and the primitive cycle transports $J = 2\pi\hbar = h$. In the Möbius band, $\varepsilon_\gamma = -1$: one visible turn changes sheet and transports $J = \pi\hbar = h/2$; the second restores orientation and completes h. Per radian of the internal phase, $\hbar$ is transported in both cases; the factor $1/2$ belongs to the projection onto the visible turn of the Möbius base.

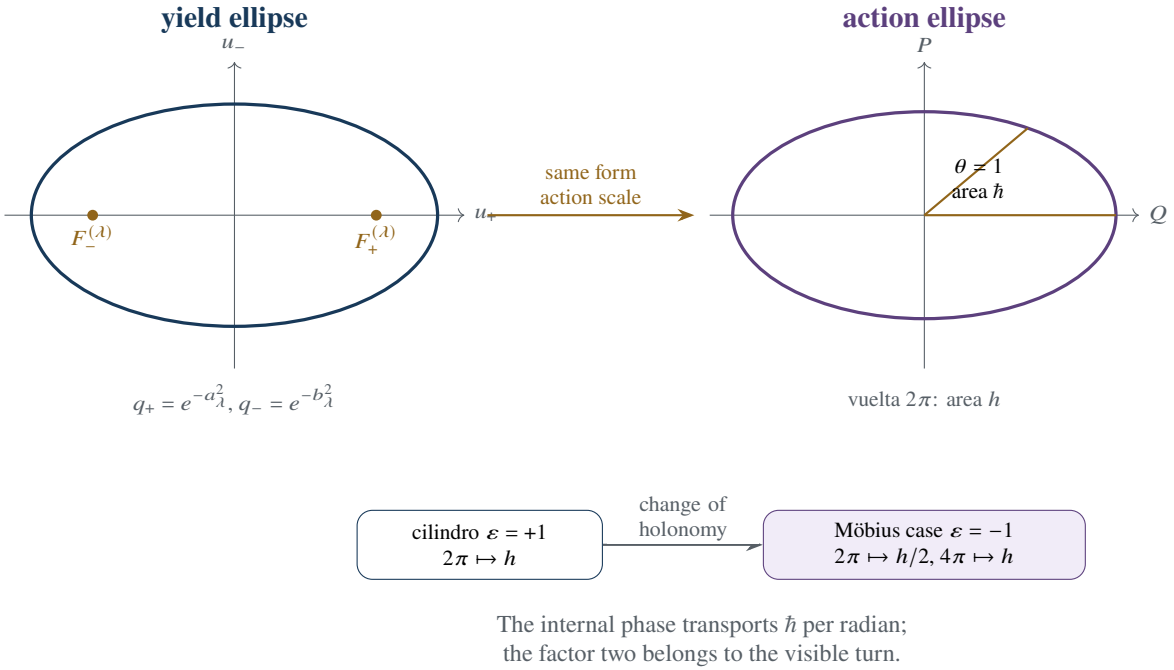

Figure 90.1: The ellipse of rates fixes the form; its lift to the action line fixes the area. The cylindrical closure and the double Möbius return distinguish the internal phase from the visible turn.

90.4.6.1 Hilbert–Beltrami–Klein Geometry on the Action Ellipse

The same ellipse that carries the symplectic area admits an intrinsic projective geometry. Let

$$\mathbb{E}_{\mathrm{act}} := \left\{ (Q,P) \in \mathbb{R}^2 : \frac{Q^2}{a_S^2} + \frac{P^2}{b_S^2} < 1 \right\}, \qquad \mathcal{L}_{\mathrm{act}}(Q,P) := \left(\frac{Q}{a_S}, \frac{P}{b_S} \right).$$

The linear map $\mathcal{L}_{\mathrm{act}}$ identifies $\mathbb{E}_{\mathrm{act}}$ with the unit disk $\mathbb{D}$. For two distinct points $x, y \in \mathbb{E}_{\mathrm{act}}$, let $a, b \in \partial\mathbb{E}_{\mathrm{act}}$ be the intersections of the line xy with the boundary, ordered as a, x, y, b. We define

$$d^{\mathrm{act}}_{\mathrm{H}}(x,y) := \frac{1}{2} \log \frac{\|y-a\|\,\|x-b\|}{\|x-a\|\,\|y-b\|}. \tag{90.1}$$

The expression is the cross-ratio of the four collinear points and is therefore independent of the auxiliary norm used on that line.

Proposition 90.5 (Beltrami–Klein realization of the action ellipse)**.** *The pair* $(\mathbb{E}_{\mathrm{act}}, d_{\mathrm{H}}^{\mathrm{act}})$ *is isometric, through* $\mathcal{L}_{\mathrm{act}}$*, to the Beltrami–Klein model of the hyperbolic plane. Its unoriented geodesics are exactly the open chords of the ellipse. The boundary* $\partial\mathbb{E}_{\mathrm{act}}$ *simultaneously preserves, in a typed manner, the symplectic orbit*

$$\gamma_{\mathrm{act}}(\theta) = (a_S \cos\theta, b_S \sin\theta), \qquad \frac{1}{2}\int_0^{\theta} (QP' - PQ')\, dt = \hbar_{\mathrm{HMT}}^{\mathrm{ret}}\theta.$$

Proof. Projective transformations preserve cross-ratios. Since $\mathcal{L}_{\mathrm{act}}$ is an invertible linear transformation that carries the ellipse to the unit disk, it transports (90.1) to the Hilbert distance of the disk. This is the Beltrami–Klein metric, whose geodesics are its chords. The symplectic identity of the boundary is theorem 90.4 written in the normalized chart. □

The complete chart is thereby typed by

$$\mathfrak{R}_{\mathrm{act}} : (A, C^*, \hbar_{\mathrm{HMT}}^{\mathrm{ret}}) \longmapsto (\mathbb{E}_{\mathrm{act}}, d_{\mathrm{H}}^{\mathrm{act}}, dP \wedge dQ, \gamma_{\mathrm{act}}).$$

The projective metric governs the interior; the symplectic form and the area law govern the traversed boundary. A realization as a physical region or as a domain of covariance matrices is formulated through a subsequent functor that explicitly preserves these two structures; the preceding construction already fixes its mathematical domain and the invariants that this functor must preserve.

90.4.6.2 Planck self-dual identity in the circular realization of the temporal endomorphism of order 108

The action line constructed in the preceding section admits a circular realization compatible with temporal periodicity of order 108. This realization coordinates three objects that already possess their own types: the action section, the geometry of one revolution, and the gravitational transduction. The resulting coordination provides an internal Planck identity and prepares the positive line on which the general mass operator will subsequently act.

Oriented action letters and declared circular realization Let

$$\mathcal{L}_S^+, \quad \mathcal{L}_T^+, \quad \mathcal{L}_C^+, \quad \mathcal{L}_L^+, \quad \mathcal{L}_M^+, \quad \mathcal{L}_G^+$$

the positive half-lines of action, time, velocity, length, and mass. The pre-return and post-return coordinates are written

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S, \qquad R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}. \tag{90.2}$$

The subscript $a \in \{\mathrm{pre}, \mathrm{ret}\}$ shall designate either of the two charts. In each one the exact distinction is preserved

$$h_a = 2\pi\hbar_a. \tag{90.3}$$

Let us fix an elementary duration $t_0 \in \mathcal{L}_T^+$, an internal velocity $c_{\mathrm{int}} \in \mathcal{L}_C^+$, and $\ell_0 = c_{\mathrm{int}} t_0$. The declared circular realization of the temporal periodicity of order 108 is determined by

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi}{T_{108}}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0, \tag{90.4}$$

and by the length of the full turn

$$C_{108} = 2\pi R_{108} = c_{\mathrm{int}} T_{108} = 108\ell_0. \tag{90.5}$$

Thus, R_{108} is the radius of the realization and C_{108} its perimeter. The angular frequency, the cyclic frequency and the two action constants are related through $\omega_{108} = 2\pi/T_{108}$ and $h_a = 2\pi\hbar_a$.

Correspondence between the order-108 periodicity and Compton readings In the chart a, the circular quantum and its mass section are

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2} = \frac{\hbar_a \omega_{108}}{c_{\mathrm{int}}^2}. \tag{90.6}$$

Theorem 90.6 (Identity between circular periodicity and Compton readings)**.** *For each chart $a \in \{\mathrm{pre}, \mathrm{ret}\}$, the reduced and complete Compton readings satisfy*

$$\boxed{\bar{\lambda}_{\mathrm{C}}(m_{108,a}) = \frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = R_{108}, \qquad \lambda_{\mathrm{C}}(m_{108,a}) = \frac{h_a}{m_{108,a} c_{\mathrm{int}}} = C_{108}.} \tag{90.7}$$

Proof. Substituting (90.6) produces

$$\frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = \frac{c_{\mathrm{int}}}{\omega_{108}} = R_{108}.$$

The second equality follows by applying simultaneously (90.3) and (90.5). □

The theorem is homogeneous in $(\hbar_a, c_{\mathrm{int}}, t_0)$: the same periodicity determines the radius, the perimeter, and the two Compton charts. The circular realization is the declared geometric primitive; the preceding equalities are its exact consequences.

Circular selector and internal Planck unit The gravitational line is coordinated with the chart a through the homogeneous transducer

$$G_a(\theta) = \theta \, \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a} \in \mathcal{L}_G^+, \qquad \theta \in \mathbb{R}_{>0}. \tag{90.8}$$

Its reduced gravitational radius, evaluated on the circular quantum, is

$$r_{\mathrm{g},a}(\theta) := \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta \frac{\pi}{54} \ell_0. \tag{90.9}$$

Proposition 90.7 (Planck Circular Selector)**.** *Within the circular realization (90.4), the condition $r_{\mathrm{g},a}(\theta) = R_{108}$ selects a unique positive coordinate,*

$$\boxed{\theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi}\right)^2.} \tag{90.10}$$

The coordinate is independent of the chart oriented a.

Proof. The equations (90.4) and (90.9) reduce the condition to

$$\theta \frac{\pi}{54} \ell_0 = \frac{54}{\pi} \ell_0.$$

The positivity of ℓ_0 and the strict monotonicity of the map $\theta \mapsto r_{\mathrm{g},a}(\theta)$ provide the solution and its uniqueness. □

Let $G^{\mathrm{circ}}_{108,a} := G_a(\theta^{\mathrm{circ}}_{108})$. The internal units associated with this chart satisfy

$$\ell^{\mathrm{circ}}_{\mathrm{P},a} := \sqrt{\frac{\hbar_a G^{\circ}_{108,a}}{c^3_{\mathrm{int}}}} = R_{108}, \qquad t^{\circ}_{\mathrm{P},a} := \sqrt{\frac{\hbar_a G^{\circ}_{108,a}}{c^5_{\mathrm{int}}}} = \omega^{-1}_{108}, \tag{90.11}$$

$$m^{\circ}_{\mathrm{P},a} := \sqrt{\frac{\hbar_a c_{\mathrm{int}}}{G^{\circ}_{108,a}}} = m_{108,a}, \qquad E^{\circ}_{\mathrm{P},a} := m^{\circ}_{\mathrm{P},a} c^2_{\mathrm{int}} = E_{108,a}. \tag{90.12}$$

The equality of radii is therefore published as

$$R_{108} = \bar{\lambda}_{\mathrm{C}} = r_{\mathrm{g}} = \ell^{\mathrm{circ}}_{\mathrm{P}}, \qquad C_{108} = \lambda_{\mathrm{C}} = 2\pi r_{\mathrm{g}} = 2\pi \ell^{\mathrm{circ}}_{\mathrm{P}}. \tag{90.13}$$

The convention of this theorem is the reduced gravitational radius $r_{\mathrm{g}} = Gm/c^2_{\mathrm{int}}$. The Schwarzschild radius satisfies $r_{\mathrm{s}} = 2r_{\mathrm{g}}$; if this second convention is adopted, its crossing with $\bar{\lambda}_{\mathrm{C}}$ occurs at $m = m^{\circ}_{\mathrm{P},a}/\sqrt{2}$. The declaration of the radius therefore forms part of the chart and prevents a factor of two from being inadvertently transferred between the two identities.

The coordinate $\theta^{\mathrm{circ}}_{108}$ belongs to the declared circular specialization. The general gravitational selector, formulated on the enriched holonomy and its spectral response, retains its residence in section 80.1.1. Thus, the circular identity fixes an internal Planck normalization and the general criterion fixes the conditions that the physical realization of the gravitational section must satisfy.

Pre-return/post-return covariance The product of the reciprocal sections of action and gravity preserves the circular geometry:

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G^{\circ}_{108,\mathrm{pre}}}{G^{\circ}_{108,\mathrm{ret}}} = R^{-1}_{\mathrm{act}}, \qquad \hbar_a G^{\circ}_{108,a} = \theta^{\mathrm{circ}}_{108} c^5_{\mathrm{int}} t^2_0. \tag{90.14}$$

In particular, $\ell^{\mathrm{circ}}_{\mathrm{P,pre}}$ and $\ell^{\mathrm{circ}}_{\mathrm{P,ret}}$ coincide with R_{108}. The bidirectional memory resides in the quotient of the masses and in its gravitational reciprocal; the geometric scale resides in the invariant product.

Reciprocity admits a symmetric parametrization that separates the common scale from the orientation of the return. Define

$$\hbar_{\mathrm{geom}} := \sqrt{\hbar_{\mathrm{pre}}\hbar_{\mathrm{ret}}}, \quad G^{\circ}_{108,\mathrm{geom}} := \sqrt{G^{\circ}_{108,\mathrm{pre}} G^{\circ}_{108,\mathrm{ret}}}, \quad \xi_{\mathrm{act}} := \frac{1}{2}\log R_{\mathrm{act}}. \tag{90.15}$$

Then

$$\hbar_{\mathrm{pre}} = \hbar_{\mathrm{geom}} e^{\xi_{\mathrm{act}}}, \qquad \hbar_{\mathrm{ret}} = \hbar_{\mathrm{geom}} e^{-\xi_{\mathrm{act}}},$$

whereas the conjugate gravitational sections satisfy

$$G^{\circ}_{108,\mathrm{pre}} = G^{\circ}_{108,\mathrm{geom}} e^{-\xi_{\mathrm{act}}}, \qquad G^{\circ}_{108,\mathrm{ret}} = G^{\circ}_{108,\mathrm{geom}} e^{\xi_{\mathrm{act}}}.$$

The coordinate ξ_{act} preserves the pre-return/post-return orientation; the product $\hbar_a G^{\circ}_{108,a}$ preserves geometric scale. This parametrization of the action charts does not by itself introduce distinct propagation speeds.

Split self-dual mass line Given a chart a, let the split algebra be

$$\mathbb{D}_{\mathrm{sp}} := \mathbb{R}[j]/(j^2 - 1), \qquad P_{\pm} := \frac{I \pm j}{2},$$

and consider its spectral decomposition

$$\mathbb{D}_{\mathrm{sp}} = \mathbb{R}P_+ \oplus \mathbb{R}P_-, \qquad P_\pm^2 = P_\pm, \quad P_+P_- = 0, \quad P_+ + P_- = I.$$

The broken conjugation swaps the projectors,

$$\overline{uP_+ + vP_-} = vP_+ + uP_-,$$

and its norm is

$$N_{\mathrm{sp}}(uP_+ + vP_-) := uv.$$

For $m \in \mathcal{L}_M^+$, define the section

$$Z_a(m) := \frac{m^\circ_{\mathrm{P},a}}{m} P_+ + \frac{m}{m^\circ_{\mathrm{P},a}} P_-. \tag{90.16}$$

The unit $m^\circ_{\mathrm{P},a}$ also determines the involution

$$\iota_{\mathrm{P},a}(m) = \frac{(m^\circ_{\mathrm{P},a})^2}{m}. \tag{90.17}$$

Theorem 90.8 (Split self-dual mass line)**.** *For every $m \in \mathcal{L}_M^+$,*

$$\boxed{N_{\mathrm{sp}}(Z_a(m)) = 1, \qquad \overline{Z_a(m)} = Z_a\big(\iota_{\mathrm{P},a}(m)\big)\,.} \tag{90.18}$$

Conjugation has a unique positive fixed point,

$$m = m^\circ_{\mathrm{P},a}, \qquad Z_a(m^\circ_{\mathrm{P},a}) = I.$$

Proof. The norm is the product of the two reciprocal coordinates:

$$\frac{m^\circ_{\mathrm{P},a}}{m}\frac{m}{m^\circ_{\mathrm{P},a}} = 1.$$

Conjugation interchanges both coordinates, which is equivalent to replacing m by $(m^\circ_{\mathrm{P},a})^2/m$. The positive fixed point satisfies $m^2 = (m^\circ_{\mathrm{P},a})^2$. □

With the speed

$$x_a(m) = \log \frac{m}{m^\circ_{\mathrm{P},a}}, \tag{90.19}$$

the section and its conjugate are written

$$Z_a(m) = e^{-x_a} P_+ + e^{x_a} P_-, \qquad \overline{Z_a(m)} = e^{x_a} P_+ + e^{-x_a} P_-.$$

Their even and odd readers are

$$Q_a(m) := \frac{e^{x_a} + e^{-x_a}}{2} = \cosh x_a, \qquad A_a(m) := \frac{e^{x_a} - e^{-x_a}}{2} = \sinh x_a. \tag{90.20}$$

The first preserves the distance to the self-dual point and the second preserves its orientation.

The reciprocal lattice vectors associated with the same coordinate are

$$r_{\mathrm{g},a}(m) = \frac{G^\circ_{108,a} m}{c_{\mathrm{int}}^2}, \qquad \bar{\lambda}_{\mathrm{C},a}(m) = \frac{\hbar_a}{m c_{\mathrm{int}}},$$

and satisfy

$$\frac{r_{\mathrm{g},a}(m)}{\bar{\lambda}_{\mathrm{C},a}(m)} = e^{2x_a(m)}, \qquad \frac{\bar{\lambda}_{\mathrm{C},a}(m)}{r_{\mathrm{g},a}(m)} = e^{-2x_a(m)}. \tag{90.21}$$

Conjugation interchanges the two readers; Planck's identity is their unitary equilibrium.

Planck identity and electron closure

The identity $m = m^{\circ}_{\mathrm{P},a}$ fixes the self-dual origin of the positive line of masses. The electron section fixes a distinct position on that same line through its own genealogy. The section 90.4.7 constructs the universal operator that transports absolute scale, character, towers, and bidirectional reading; the section 58.2 then realizes its central rank-one reduction. Thus the Planck unit provides the identity of the coordinate, and the electron provides the first complete material transition on it.

Proposition 90.9 (Genealogical realization of the electronic center)**.** *Let*

$$F_e^+ = \mathbb{R}_{>0}(P_+ + P_-)$$

the positive half-line of the rank-one central fiber, let $\mathcal{G}_e$ be the space of enriched electronic genealogies and let $\mathcal{L}_M^+$ be the positive mass line. A realization morphism

$$\mathfrak{R}_e : F_e^+ \times \mathcal{G}_e \longrightarrow \mathcal{L}_M^+$$

can send the identity $I = P_+ + P_-$ to a mass different from $m^{\circ}_{\mathrm{P},a}$ without altering the theorem 90.8: the Planck identity fixes the autodual origin of the chart, while the electronic genealogy fixes a displacement on that chart.

Proof. If $\chi_e : \mathcal{G}_e \to \mathbb{R}_{>0}$ is the positive character constructed by the electronic record, the rule

$$\mathfrak{R}_e(\lambda I, g) = \lambda\, m^{\circ}_{\mathrm{P},a}\chi_e(g)$$

is positive and multiplicative in the genealogical coordinate. For the neutral genealogy, $\chi_e = 1$, Planck's origin is recovered; for a genealogy with $\chi_e(g) \neq 1$, the same internal identity occupies a different position on the line. The specific electronic closure preserves its source in the section 58.2. □

Domain of the Planck self-dual identity: temporal periodicity of order 108**, declared circular realization, and separation of the electronic closure** The pre-return/post-return action line and the temporal periodicity of order (108) precede the circular realization, which is taken as a declared geometric primitive. The identity between circular periodicity and the Compton readings, the selector $\theta^{\mathrm{circ}}_{108}$, the internal Planck unit, and the involution of the positive line are exact results once that realization has been fixed. General gravitational selection and electronic closure are constructed separately in the indicated sections.

90.4.7 Causal precedence of the General Mass Law with respect to species-specific realizations

Dimensional Mechanics receives from HMT two branches already constructed. The first provides an action line with two oriented coordinates; the second provides the genealogy of each persistent section. Mass appears upon making the genealogical character act on a section of the mass line. This confluence precedes every particular case and, accordingly, the scale 10^{-34} belongs to the general law rather than to an isolated species.

90.4.7.1 Absolute Branch: From the Local Determinant to the Mass Line

The determinantal reader fixes locally

$$\Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}, \qquad \varepsilon_H := \lfloor \log_{10} \Sigma_H \rfloor = -34. \tag{90.22}$$

The power sixteen follows from the cokernel $\mathbb{Z}/2 \oplus \mathbb{Z}/2 \oplus \mathbb{Z}/4$ of the determinantal block. On the internal action line $\mathcal{L}_S$ the two sections are obtained

$$\hbar_{\mathrm{pre}} = H_5 \, 10^{-34} \mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}} \, 10^{-34} \mathcal{U}_S, \tag{90.23}$$

and the additive and multiplicative letters of its unfolding are

$$\delta_{2w} = H_5 - \eta_{\mathrm{ret}}, \qquad R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}} > 0. \tag{90.24}$$

Let $t_0 \in \mathcal{L}_T^+$ be the elementary duration of the TPK calendar and $c_{\mathrm{int}} \in \mathcal{L}_C^+$ its internal speed. The periodicity of 108 iterations of the temporal endomorphism CT108 fixes the angular frequency $\omega_0 = 2\pi/(108 t_0)$. The absolute sections preceding and following the return are, therefore,

$$\begin{aligned} \mathbf{m}_\star^{\mathrm{pre}} &= \hbar_{\mathrm{pre}} \, \omega_0 c_{\mathrm{int}}^{-2}, \\ \mathbf{m}_\star^{\mathrm{ret}} &= \hbar_{\mathrm{ret}} \, \omega_0 c_{\mathrm{int}}^{-2}, \end{aligned} \qquad \frac{\mathbf{m}_\star^{\mathrm{pre}}}{\mathbf{m}_\star^{\mathrm{ret}}} = R_{\mathrm{act}}. \tag{90.25}$$

Both belong to $\mathcal{L}_M = \mathcal{L}_S \otimes \mathcal{L}_T^{-1} \otimes \mathcal{L}_C^{-2}$. Thus the decade, which fixes the absolute scale, and the quotient of the pre-return/post-return bidirectional splitting, which transports the memory of the closed evolution, are precisely separated.

In positive internal coordinates $t_0 = \widehat{t_0} \mathcal{U}_T$ and $c_{\mathrm{int}} = \widehat{c} \mathcal{U}_C$, the scalar reduction of any section whose physical realization has already been fixed takes the form

$$\mathbf{m}_X^\beta = 10^{-34} \eta_{\mathrm{ret}} \, \frac{2\pi}{108 \widehat{t_0}} \, \widehat{c}^{-2} a_X^{(0)} R_{\mathrm{act}}^{\kappa_X} \, \mathcal{U}_M. \tag{90.26}$$

The coordinate $a_X^{(0)}$ proceeds of the character and of the hierarchy harmonic; κ_X proceeds of the reader of route. In particular, the decade -34 belongs to the section absolute and does not incorporates to κ_X.

90.4.7.2 Genealogical branch: record, character, and harmonic hierarchy

Each surviving section traverses the chain

$$\Omega_{\mathrm{HMT}}^{\mathrm{surv}} \longrightarrow \Gamma_{108}^{\mathrm{enr}} \longrightarrow \mathcal{L}_{108} \longrightarrow \sigma \in \mathbb{Z}^5 \longrightarrow (\sigma, \eta) \longrightarrow \chi_{\mathrm{full}}(\sigma, \eta) \in \mathbb{R}_{>0}. \tag{90.27}$$

The record preserves the order of events; the signature preserves their five integer invariants; the character evaluates them without erasing their provenance. Its spectral prolongation lies in the full semigroup

$$\mathfrak{S} = \langle 90, 120 \rangle = \{90, 120\} \cup \{30r : r \geq 6\}, \qquad s_h = q_-^h - q_+^h, \quad c_h = q_-^h + q_+^h, \tag{90.28}$$

and adopts the form

$$\chi_{\mathrm{full}}(\sigma, \eta) = \chi_0(\sigma) \exp\left(\sum_{h \in \mathfrak{S}} \eta_h s_h \right). \tag{90.29}$$

The heights 90, 120, 180, 210, 240, 270, 360, 420 are eight especially visible genealogical witnesses. The law belongs to all of $\mathfrak{S}$; the second-order recurrence of (s_h, c_h) extends the witnesses to the complete harmonic hierarchy.

90.4.7.3 Universal operator on the 13 *multisections of the material domain*

The atlas provides 81 positions, 56 route families, 13 multisections, and 324 oriented routes. For a multisection F, let $\mathcal{H}_F = \bigoplus_{\Gamma\in F} \mathbb{C}e_\Gamma$. The basal character and the towers define the positive operator

$$\widehat{\mathcal{A}}_F^{(0)} e_\Gamma = \chi_{\text{full}}(\sigma_\Gamma, \eta_\Gamma) e_\Gamma. \tag{90.30}$$

The two histories preserved by TPK induce readers $r \in \{D, \Omega\}$: K_D acts on the chronological record of 108 iterations of the CT108 temporal endomorphism, and K_Ω on the signed dodecaphase word. If $\widehat{K}_F^r e_\Gamma = \kappa_r(\Gamma) e_\Gamma$, let $F_s \subseteq F$ be the set of routes of the section or physical block s, and define

$$\mathcal{H}_{F,s} := \bigoplus_{\Gamma\in F_s} \mathbb{C}e_\Gamma, \qquad \widehat{\mathcal{A}}_{F,s}^{(0)} := \widehat{\mathcal{A}}_F^{(0)}\Big|_{\mathcal{H}_{F,s}}, \qquad \widehat{B}_{F,s}^r := \widehat{K}_F^r\Big|_{\mathcal{H}_{F,s}}. \tag{90.31}$$

The basis diagonal of routes used by the certificates current makes invariant $\mathcal{H}_{F,s}$ under both operators and converts $\widehat{B}_{F,s}^r$ in a restriction self-adjoint. With these types, the law general is

$$\boxed{\widehat{\mathbf{M}}_{F,s}^{\beta,r} = \mathbf{m}_\star^{\text{ret}} \otimes R_{\text{act}}^{\widehat{B}_{F,s}^r/2} \widehat{\mathcal{A}}_{F,s}^{(0)} R_{\text{act}}^{\widehat{B}_{F,s}^r/2}, \qquad r \in \{D, \Omega\}.} \tag{90.32}$$

The symmetric writing preserves positivity without presupposing commutation. In the simultaneously diagonal basis employed by the current certificates, it reduces to

$$\widehat{\mathbf{M}}_F^{\beta,r} = \mathbf{m}_\star^{\text{ret}} \otimes \widehat{\mathcal{A}}_F^{(0)} \exp\Big((\log R_{\text{act}})\widehat{K}_F^r\Big). \tag{90.33}$$

The equation preserves, in a single object, the absolute scale, the global character, the entire hierarchy of towers, and the route-dependent bidirectional corrector. The physical chart of each sector subsequently acts on the spectrum of (90.32). The null sector has its own morphism to zero; the composite registers are concatenated before the signature is evaluated; the topological sectors first publish their fusion and braiding invariants.

Theorem 90.10 (Covariance and Cancellation of the Common Scale)**.** *The law* (90.32) *is positive and covariant under unitary change of basis in each fiber. For two self-sections X, Y realized in the same mass chart,*

$$\frac{m_Y}{m_X} = \frac{\chi_{\text{full}}(\sigma_Y, \eta_Y)}{\chi_{\text{full}}(\sigma_X, \eta_X)} R_{\text{act}}^{\kappa_r(\Gamma_Y) - \kappa_r(\Gamma_X)}. \tag{90.34}$$

The common factors $10^{-34}\mathcal{U}_S$, $2\pi/(108 t_0)$, and c_{int}^{-2} fix the absolute section and cancel exactly in the quotient.

Proof. The operator $\widehat{\mathcal{A}}_F^{(0)}$ is positive because its eigenvalues belong to $\mathbb{R}_{>0}$; the exponential of a self-adjoint operator is positive. Conjugation by a unitary matrix preserves the spectrum and therefore the law. Upon dividing two eigenvalues realized in the same chart, the common section $\mathbf{m}_\star^{\text{ret}}$ cancels, and the result is (90.34). □

The central electronic fiber has rank one and constitutes the first scalar corollary of this law. The remaining multisections preserve the pair of operators, their spectra, and the physical morphism that selects flavor, color, orientation, or composition. This hierarchy allows the algebraic result, its dimensional realization, and the external contrast to be published together without confusing their domains.

90.5 Nonadic classification of trajectory families

The atlas does not begin with a list of particles or a table of masses. It begins with a finite oriented support and with the readers that preserve the history of its routes. Its function is to answer a question prior to any metrological comparison: what classes of persistence can the nonadic geometry support, and what information must be preserved to distinguish them?

The answer has three cardinals, but not three rival inventories:

$$81 \text{ cells}, \qquad 56 \text{ route families}, \qquad 13 \text{ family–level multisections}.$$

The first number counts oriented positions; the second identifies the positions that publish the same finite route signature; the third gathers the positions that share a family and depth relative to the center. None of them counts known masses, names of species, or rows of an external comparison.

90.5.1 The complete geometry of the 81 cells

Let

$$I_9 = \{1, \dots, 9\}, \qquad C_{81} = I_9 \times I_9.$$

The coordinates (r, c) preserve the two directions of APP. The parity of each coordinate defines four internal sectors:

$$\mathrm{fam}(r,c) = \begin{cases} \ell^-, & r \equiv 1,\ c \equiv 1 \pmod 2, \\ \nu, & r \equiv 1,\ c \equiv 0 \pmod 2, \\ d, & r \equiv 0,\ c \equiv 1 \pmod 2, \\ u, & r \equiv 0,\ c \equiv 0 \pmod 2. \end{cases} \tag{A1}$$

Depth in the atlas is not added as an independent label. It is the Chebyshev distance to the center:

$$G(r,c) = \max\{|r-5|, |c-5|\}. \tag{A2}$$

Therefore, family and level follow from the position itself. In particular, the center is not obtained by selecting a species from outside: it is the unique cell of depth zero.

Theorem 90.11 (Census of families and generations of the atlas)**.** *The maps* (A1) *and* (A2) *decompose the atlas in a disjoint manner as*

$$81 = 45_{\text{leptones}} + 36_{\text{quarks}} = 25_{\ell^-} + 20_{\nu} + 20_{d} + 16_{u}. \tag{A3}$$

Refinement by G yields exactly the thirteen multisections

family	*levels*	*cardinals*
ℓ^-	$G0, G2, G4$	$1, 8, 16$
ν	$G1, G2, G3, G4$	$2, 4, 6, 8$
d	$G1, G2, G3, G4$	$2, 4, 6, 8$
u	$G1, G3$	$4, 12.$

(A4)

The cell $(5,5)$ *is the sole component of* $\mathfrak{S}_{\ell^-,0}$.

Proof. In I_9 there are five odd coordinates and four even ones. The four parity classes therefore have cardinalities

$$5 \cdot 5 = 25, \qquad 5 \cdot 4 = 20, \qquad 4 \cdot 5 = 20, \qquad 4 \cdot 4 = 16,$$

which proves (A3); the first two classes comprise 45 cells and the last two, 36.

For the refinement, we enlarge squares centered at $(5, 5)$. In the odd–odd class there is one cell at radius zero, $3^2 - 1 = 8$ in the shell of radius two, and $5^2 - 3^2 = 16$ in the shell of radius four. In the odd–even class, the rectangles accumulated up to radii $1, 2, 3, 4$ contain, respectively,

$$1 \cdot 2 = 2, \qquad 3 \cdot 2 = 6, \qquad 3 \cdot 4 = 12, \qquad 5 \cdot 4 = 20$$

cells; their successive differences are $2, 4, 6, 8$. The even–odd class gives the same calculation with the coordinates exchanged. In the even–even class, there are $2^2 = 4$ cells at radius one and $4^2 - 2^2 = 12$ at radius three. These shells are disjoint and exhaust I_9^2, so no other multisection remains. □

The word *level* denotes in this chapter the combinatorial depth G. The subsequent physical reading preserves that geometry but does not define it. This prevents particle names from being turned into premises of the census that must explain them.

90.5.2 Central inversion, 41 orbits, and uniqueness of the centre

The inverse of the atlas is

$$\rho_{\mathrm{c}}(r, c) = (10 - r, 10 - c). \tag{A5}$$

Since $10 - r$ has the same parity as r, inversion preserves the four families. Moreover,

$$|(10 - r) - 5| = |r - 5|, \qquad |(10 - c) - 5| = |c - 5|,$$

and therefore preserves the level G. Each of the thirteen multisections is ρ_{c}-stable.

Proposition 90.12 (Orbits and Central Exception)**.** *The action of ρ_{c} on C_{81} has exactly 41 orbits. Its unique fixed point is $(5, 5)$. Consequently, the multisection $\mathfrak{S}_{\ell^-,0}$ admits the unique pointwise ρ_{c}-equivariant selector; in the other twelve, the natural object is the orbit or the complete multisection.*

Proof. The equation

$$(r, c) = \rho_{\mathrm{c}}(r, c)$$

is equivalent to $2r = 2c = 10$, hence $r = c = 5$. The other eighty cells are grouped into forty pairs, whence $1 + 40 = 41$ orbits.

Let y be a noncentral multisection and suppose that an equivariant point selector chooses $a(y) \in \mathfrak{S}_y$. Since ρ_{c} acts trivially on the family–level type, equivariance would impose

$$a(y) = a(\rho_{\mathrm{c}} y) = \rho_{\mathrm{c}} a(y).$$

The chosen point would have to be fixed, but the only fixed point lies in $\mathfrak{S}_{\ell^-,0}$. The contradiction proves the assertion. □

This proposition explains by which a species internal is not, in general, a cell isolated. The electron central is exceptional because its multisection is reduceds to a point. In the remaining families, the orientation conjugate form part of the identity that must is preserved.

90.5.3 The 56 route families

Each cell bears the finite shadow of its transport history:

$$\mathcal{R}(r, c) = \big(n_A,\ s_C,\ k_{\Delta_4},\ \nu_{120},\ \nu_{270},\ \tau_{12}\big)_{r,c}. \tag{A6}$$

The first five coordinates are integers; τ_{12} is the oriented dodecaphase word. Two cells belong to the same route family if and only if they have the same sextuple $\mathcal{R}$.

Theorem 90.13 (Census of route families and minimal memory)**.** *The image of $\mathcal{R}$ contains exactly* 56 *elements. The histogram of the sizes of its fibres is*

$$41 \times 1, \qquad 10 \times 2, \qquad 2 \times 3, \qquad 1 \times 4, \qquad 2 \times 5. \tag{A7}$$

In particular,

$$41 + 10 + 2 + 1 + 2 = 56,$$
$$41 \cdot 1 + 10 \cdot 2 + 2 \cdot 3 + 1 \cdot 4 + 2 \cdot 5 = 81. \tag{A8}$$

Fixing the lexicographic order within each fiber, the rank

$$\kappa(r, c) \in \{0, 1, 2, 3, 4\}$$

makes the application injective

$$(r, c) \longmapsto \big(\mathcal{R}(r, c), \kappa(r, c)\big). \tag{A9}$$

Five is the minimum size of a uniform alphabet capable of performing this lift.

Proof. The exhaustive enumeration of I_9^2 groups the eighty-one sextuples (A6) by coordinatewise equality. It produces the five fiber sizes of (A7); the two identities (A8) simultaneously verify the number of classes and the coverage of the eighty-one cells.

The lexicographic rank distinguishes the elements of each fiber, so that (A9) is injective. Since two fibers of cardinal five exist, any common alphabet with fewer than five symbols would identify two cells of one of them by the pigeonhole principle. □

The rank κ is positional memory within a fiber; it is not charge, mass, or color. Its function is to recover the cell that the visible route signature had identified with others. The number 56 counts classes of the sextuple $\mathcal{R}$, whereas the number 13 counts classes of the pair (fam, G). They are different quotients of the same atlas.

Cellular and orbital quotients of the atlas: domains and projection maps. The raw CT–108 projection and the scientific classification read different data from the same eighty-one cells. If q_{CT} preserves only the form of the dodecaphase tritic word, while $\mathcal{R}$ preserves the route sextuple and $q = (\mathrm{fam}, G)$ preserves family and depth, the typed table is

$$\begin{aligned} C_{81} &\xrightarrow{q_{\mathrm{CT}}} \mathcal{W}_7^{\mathrm{raw}} && \text{raw CT–108 forms,} \\ C_{81} &\xrightarrow{\mathcal{R}} \Sigma_{56}^{\mathrm{ruta}} && \text{route families,} \\ C_{81} &\xrightarrow{q} \Sigma_{13} && \text{family–level multisections.} \end{aligned} \tag{A9a}$$

The seven raw fibres have multiplicities

$$54, 2, 2, 2, 7, 7, 7, \qquad 54 + 3 \cdot 2 + 3 \cdot 7 = 81.$$

Therefore, the archaeological census $81 \to 7$ does not replace the atlas 81/56/13. Nor does the abbreviated notation 81/56/13 assert the existence of a canonical arrow $56 \to 13$: some fibers of $\mathcal{R}$ traverse more than one family–level pair. The maps $\mathcal{R}$ and q are parallel quotients and preserve different invariants. In the quark sector, the active convention remains

$$\mathrm{col}(r, c) = r - c \pmod 3;$$

the historical notation $c - r$ is its conjugate convention, not another color or another quotient of the atlas.

90.5.4 Distinction between cell, route family, and multisection

Define

$$q : C_{81} \longrightarrow \Sigma_{13}, \qquad q(r,c) = \big(\mathrm{fam}(r,c), G(r,c)\big), \tag{A10}$$

and, for $y \in \Sigma_{13}$,

$$\mathfrak{S}_y^{\mathrm{atlas}} = q^{-1}(y) = \{(r,c) \in C_{81} : q(r,c) = y\}. \tag{A11}$$

The four levels of reading are then separated:

(i) a *cell* is an oriented position (r,c), with all its local data;

(ii) a *route family* is a fibre of $\mathcal{R}$: it preserves the same finite transport signature;

(iii) a *multisection* is a fiber of q: it preserves the family, depth, and all its conjugate orientations;

(iv) a *physical representation* is the subsequent realization of an enriched multisection in a state space; it is not another partition of the board or the arbitrary choice of one of its cells.

This distinction gives mathematical content to the word *species*. The internal type is the multisection. A concrete particle is a persistent section realized within it. The physical representation preserves the action, orientation, and observables of the type; it does not work backward to redefine the atlas from an already known mass.

90.5.5 Color residual as ternary orientation

In the quark sector, formed by the 36 cells with even r, we define

$$\mathrm{col}(r,c) = r - c \pmod 3, \tag{A12}$$

with the dictionary

$$0 \longmapsto R, \qquad 1 \longmapsto G, \qquad 2 \longmapsto B.$$

Proposition 90.14 (Residual color balance)**.** *The thirty-six quark cells are distributed exactly as*

$$36 = 12_R + 12_G + 12_B. \tag{A13}$$

The central inversion fixes R and interchanges G and B.

Proof. Upon fixing any of the four even values of r, as $c = 1, \dots, 9$ is traversed, each class modulo three appears three times. Each residue therefore has $4 \cdot 3 = 12$ representatives. Moreover,

$$\mathrm{col}\big(\rho_{\mathrm{c}}(r,c)\big) = (10 - r) - (10 - c) = -(r - c) \pmod 3.$$

The modular negation fixes the zero class and swaps the one and two classes. □

The tritic R, G, B is therefore an exact observable of the atlas and not a decoration added to a table of quarks. The color representation is subsequently constructed on this ternary support; the census $12 + 12 + 12$ is its prior geometry.

90.5.6 From the surviving extension to the signature

The atlas classifies finite cuts. The identity of a particle requires the deep history from which that cut proceeds. Let

$$\Omega_{\mathrm{HMT}}^{\mathrm{surv}} = \varprojlim_m \mathcal{S}_m$$

the inverse system of surviving states. The projection onto the atlas π_{81} and the route shadow form the chain

$$\Omega_{\mathrm{HMT}}^{\mathrm{surv}} \xrightarrow{\mathrm{sh}_{108}} \Gamma_{108}^{\mathrm{enr}} \xrightarrow{\mathcal{E}} \mathcal{L}_{108} \xrightarrow{L_{\mathrm{tick}}} \mathbb{Z}^5. \tag{A14}$$

Here sh_{108} publishes a route of 108 steps without forgetting sheet, orientation, boundary, or predecessors; $\mathcal{E}$ forms the dodecaphase record; and L_{tick} extracts

$$v(x) = \big(n_A, s_C, k_{\Delta_4}, \nu_{120}, \nu_{270}\big). \tag{A15}$$

None of these three arrows refers to a mass, a unit, or the name of a particle.

The reason for preserving the ledger before projection is apparent in its twelve oriented events $e_0, \dots, e_{11}$. For $0 \le i \le 5$, let

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}, \qquad s_C = \sum_{i=0}^{5} p_i,$$

and, for $0 \le i < 5$,

$$M_i = p_i - p_5.$$

Then

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i,$$
$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}. \tag{A16}$$

The identity

$$1 + 5 + 6 = 12$$

is thus a reversible reconstruction: one total, five differences, and six orientations recover the twelve events. Projecting onto the five-integer signature before composing histories would eliminate precisely the placement and orientation that make it possible to decide whether two routes can be composed.

The quotient q is lifted to the deep history through projection to the atlas $\pi_{81} : \Omega_{\mathrm{HMT}}^{\mathrm{surv}} \to C_{81}$:

$$\widetilde{\mathfrak{S}}_y = \{x \in \Omega_{\mathrm{HMT}}^{\mathrm{surv}} : q(\pi_{81} x) = y\}. \tag{A17}$$

This is the enriched multisection. Its shadow belongs to the atlas; its route belongs to $\Gamma_{108}^{\mathrm{enr}}$; its complete memory belongs to the record; and its evaluation is applied only at the end. The genealogy is not a note appended to the value: it is the object that makes the value possible and preserves the other readings of the same section.

90.5.7 Null sector bifurcation prior to the positive character

The mass character acts on the entire signature and has positive codomain:

$$\chi_{\mathrm{mass}} : \mathbb{Z}^5 \longrightarrow \mathbb{R}_{>0}. \tag{A18}$$

By definition, there is no signature v with $\chi_{\mathrm{mass}}(v) = 0$. The null sector is, consequently, not a fourteenth multisection nor the degenerate limit of the thirteen preceding ones.

Its algebraic support belongs to the split branch.

$$\mathcal{A}_{\mathrm{sp}} = \mathbb{R}[\mathsf{R}]/(\mathsf{R}^2 - 1), \qquad P_{\pm} = \frac{1 \pm \mathsf{R}}{2}.$$

Every element is written in a unique way as

$$z = r_+ P_+ + r_- P_-, \qquad N_{\mathrm{sp}}(z) = r_+ r_-,$$

and the two lines

$$\mathbb{R}P_+, \qquad \mathbb{R}P_-$$

are null because $N_{\mathrm{sp}}(\lambda P_\pm) = 0$. A null section is an open route transported along one of those directions. The material interior requires the coupling of both, for which $r_+ r_- > 0$.

Thus are typed two branches:

$$\text{material persistence} \longrightarrow \mathbb{Z}^5 \xrightarrow{\chi_{\mathrm{mass}}} \mathbb{R}_{>0},$$

$$\text{null propagation} \longrightarrow \partial_{\mathrm{null}} C_{\mathrm{sp}}^{+}.$$

The photonic and gauge realizations subsequently read the second branch. Their separation from the positive character prevents the photon and gluon from being erased because they do not appear in a list of masses, while also preventing a null mass from being fabricated by means of a character whose codomain excludes it.

90.5.8 Finite classification system and path memory

The three quotients of the chapter fulfill complementary functions:

$$C_{81} \xrightarrow{\mathcal{R}} \mathcal{R}_{56}, \qquad C_{81} \xrightarrow{q} \Sigma_{13}, \qquad C_{81} \xrightarrow{/\langle \rho_{\mathrm{c}} \rangle} O_{41}.$$

The first preserves the route signature; the second preserves family and level; the third preserves central conjugation. Together with residual color and the lift κ, they form a finite system capable of reconstructing which information is seen, which is identified, and which must remain as memory.

The causal chain of the atlas is thereby fixed:

$$\boxed{\begin{array}{c}\text{surviving extension} \longrightarrow \text{enriched route} \longrightarrow \text{record} \longrightarrow \text{signature} \\ \longrightarrow \text{character} \longrightarrow \text{dimensional reading}\end{array}} \tag{A19}$$

The eighty-one cells constitute the local domain; the fifty-six families express route coincidences; the thirteen multisections are the internal types; the forty-one orbits preserve conjugation; and the center $(5, 5)$ is the sole pointwise exception. Mass appears thereafter as a reading of an already constructed persistence. The atlas is not an abridged table of results: it is the structure explaining why a table can exist.

90.5.9 From APP seeds to mixture and mass registration

The physical law receives a domain that has already preserved the incompatibility of the two APP evaluations. If $\mathcal{S}_+$ and $\mathcal{S}_\times$ denote the oriented seeds of the additive and multiplicative leaves, then

$$\Omega_{\mathrm{seed}} = \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\Omega_{\mathrm{seed}}| = 324^2 = 104,976. \tag{90.35}$$

The exact factorization of the emitter produces

$$104,976 \longrightarrow 18 \times 26 = 468\ U_6 \longrightarrow 243\ w_6 \subset \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729. \tag{90.36}$$

The four cardinalities count distinct objects: initial conditions of two sheets, decimal emissions, published ternary words, and the algebraic ambient space. In addition to its emission, each seed preserves multiplicity, diagonal, sheet, orbit, emission signature, residues modulo three and modulo nine, turns, sheet changes, endpoint, displacements, and cardinal counts. Those data constitute the vocabulary of the subsequent register.

The factorization organizes six microfibers of cardinality 1008, six phase Fano planes, thirty-six fibers of cardinality 28, and the band $1944 = 27 \cdot 72$, diagonalized by $(\mathbb{Z}/3)^3$. Upon averaging the nonadic word of the TPK, the conditional projectors of the two sheets define the canonical kernel

$$K_{\mathrm{cat}} = \frac{1}{3}(I + E_+ + E_\times), \qquad \mathrm{Spec}(K_{\mathrm{cat}}) = \left\{ 1^{[1]}, \left(\frac{2}{3}\right)^{[42]}, \left(\frac{1}{3}\right)^{[425]} \right\}. \tag{90.37}$$

The TPK phase selects the active renewal and preserves the nine spatial bands; the average (90.37) publishes the stochastic shadow of the complete calendar.

90.5.9.1 Bigrading of the Seeds and 6 *Incidence Planes*

In each of the six microfibers of cardinality 1008, the bipartite graph retains 54 additive vertices and 56 multiplicative vertices. The former decompose into 36 vertices of degree 24 and 18 of degree 8; the latter have degree 18. The incidence count agrees on both sheets:

$$1008 = 36 \cdot 24 + 18 \cdot 8 = 56 \cdot 18. \tag{90.38}$$

This equality fixes the emitter bigrading before projecting it onto the route families.

The six words

$$001112, \quad 010211, \quad 100121, \quad 112001, \quad 121100, \quad 211010 \tag{90.39}$$

form an orbit of $D_3 \simeq S_3$ and have the profile $432 + 4 \cdot 144 = 1008$. The quotient $1008 = 36 \cdot 28$ organizes seven blocks

$$Q = \{B_3, B_6, B_9, P_1, P_2, P_3, f\},$$

where (B_3, B_6, B_9) are the transverse tetrads and (P_1, P_2, P_3, f), the four lateral tetrads. For one of the six words a, let

$$\mathcal{R}_a := \{(p,t) \in \mathcal{S}_+ \times \mathcal{S}_\times : U_6(p,t) \text{ publishes the word } a\}$$

the set of its one thousand eight routes, and set $R_9 := \mathbb{Z}/9\mathbb{Z}$. Once the oriented chart is fixed, the phase projection has type

$$q_\beta : \mathcal{R}_a \longrightarrow \binom{R_9}{2}, \qquad q_\beta(p,t) = \{x - 5\beta(d_t), x + 5\beta(d_t)\} \subset \mathbb{Z}/9\mathbb{Z}, \qquad x = 5(i_p - j_p), \tag{90.40}$$

with $(\beta(N), \beta(E), \beta(S), \beta(O)) = (1,2,3,4)$. Its codomain is the set of the thirty-six unordered pairs of R_9. Each $X \in Q$ is a tetrad of orbits; its route support and its cut over a fiber are defined by

$$\mathrm{Supp}_{\mathrm{rutas}}(X) := \bigcup_{O \in X} O, \qquad X_b := \mathrm{Supp}_{\mathrm{rutas}}(X) \cap q_\beta^{-1}(b), \qquad b \in \binom{R_9}{2}.$$

In the multiplicative channel, the source observable is

$$\rho : \mathcal{S}_\times \longrightarrow R_9, \qquad \rho(i,j,d) = (i+1)(j+1) \pmod 9. \tag{90.41}$$

If $\pi_\times : \mathcal{R}_a \to \mathcal{S}_\times$, $\pi_\times(p,t) = t$, is the second projection, the observable acting on routes is

$$\rho_\times := \rho \circ \pi_\times : \mathcal{R}_a \longrightarrow R_9, \qquad \rho_\times(p,t) = (i_t + 1)(j_t + 1) \pmod 9. \tag{90.42}$$

In what follows, $\rho(X)$ abbreviates the multiset of values of $\rho_\times$ over X_b, which is independent of the fiber b. Its profiles over the tetrads are

$$\rho(B_3) = 3^4, \qquad \rho(B_6) = 6^4, \qquad \rho(B_9) = 0^4,$$

and, for the three lateral tetrads,

r	active signature of P_r	$R(P_r)$
1	933	$\{5,7\}$
2	393	$\{4,8\}$
3	339	$\{1,2\}$.

(90.43)

Every residue of $R(P_r)$ occurs twice among the four routes of $(P_r)_b$.

Theorem 90.15 (Incidence morphism of the seeds and six Fano planes)**.** *For $\delta \in R_9$, $h \in \{3,6,0\}$ —corresponding, respectively, to B_3, B_6, B_9— and $r \in \{1,2,3\}$, let*

$$N_\delta(B_h, P_r) := \sum_{b \in \binom{R_9}{2}} \#\{(x,y) \in (B_h)_b \times (P_r)_b : \rho_\times(y) - \rho_\times(x) = \delta\}. \tag{90.44}$$

Then

$$N_\delta(B_h, P_r) = \begin{cases} 288, & h+\delta \in R(P_r), \\ 0, & h+\delta \notin R(P_r). \end{cases} \tag{90.45}$$

If $\delta \in R_9^\times$, for each B_h there exists a unique P_r with count 288; therefore, one obtains a bijection

$$\theta_\delta : \{B_3, B_6, B_9\} \xrightarrow{\sim} \{P_1, P_2, P_3\}.$$

Writing the image of (B_3, B_6, B_9) by means of its subscripts, the six bijections are

δ	θ_δ	δ	θ_δ
1	(2, 1, 3)	5	(2, 3, 1)
2	(1, 2, 3)	7	(3, 2, 1)
4	(1, 3, 2)	8	(3, 1, 2).

(90.46)

Be $P = \{P_1, P_2, P_3\}$ and, for $p \in P$, be

$$\mu(p) := \big\{\{f, p\}, P \setminus \{p\}\big\}$$

the perfect matching associated over the four lateral tetrads. Then

$$\mathcal{D}_\delta := \big\{\{B_3, B_6, B_9\}\big\} \cup \big\{\{B, q, q'\} : B \in \{B_3, B_6, B_9\}, \{q, q'\} \in \mu(\theta_\delta(B))\big\} \tag{90.47}$$

is a system of Steiner $\mathrm{S}(2,3,7)$. The six units produce the six planes of Fano over these seven blocks that contain the line transverse $\{B_3, B_6, B_9\}$.

Proof. Fix a fiber b. In $(B_h)_b$ there are four choices with residue h. If $h + \delta \in R(P_r)$, the profile (90.43) provides exactly two choices in $(P_r)_b$ with that residue; if it does not belong to the support, it provides none. Since there are thirty-six fibers, $N_\delta = 36 \cdot 4 \cdot 2 = 288$ in the first case and zero in the second. The three lateral supports partition $R_9^\times$, so a unit δ determines a unique lateral support for each transversal block. Direct reading of those supports yields the table (90.46) and exhausts the $3! = 6$ bijections.

The transversal line covers the three pairs among B_3, B_6, B_9. For a fixed B, the two edges of the matching $\mu(\theta_\delta(B))$ cover the four lateral points once. The three matchings are distinct and form the factorization of K_4 into its three perfect matchings; hence every lateral pair occurs exactly once. The seven triples thus contain each of the twenty-one pairs of points once, which is property $\mathrm{S}(2,3,7)$. Conversely, every Fano plane containing the transversal line assigns to each B a perfect matching distinct from the other two and recovers one of the preceding six bijections. □

The correspondence of sets $\delta \mapsto \theta_\delta$ is neither an action nor a homomorphism: $R_9^\times \simeq C_6$ is abelian under multiplication, whereas S_3 is not, and the units do not form an additive subgroup. The displacement δ indexes six translations of the product profiles.

The same calculation and the same table are verified in all six microfibers. Nevertheless, the difference between support and role must be preserved: the support of f coincides with one of the lateral supports and, therefore, the observable ρ does not by itself recover the decomposition $P \sqcup \{f\}$. That distinction requires the additive signature already declared in the seed state.

Status and scope of Fano incidence

The theorem 90.15 is a finite theorem once q_β, the orientation, and the digital order have been fixed: it defines six exact incidence gauges on blocks. It organizes phase and incidence in the seed domain; it selects neither particle, mass, nor route. Its physical realization is performed subsequently through the morphisms of the enriched ledger.

The passage to physics preserves the chain

$$\begin{aligned} \text{refined seed} &\longrightarrow (\text{signatures } +, \times; U_6; w_6; \text{sheet memory}) \\ &\longrightarrow \text{CT108 record} \longrightarrow (\tau_{12}, D_k, \Omega, P_6, \nu_{120}, \nu_{270}) \\ &\longrightarrow \text{fiber and multisection} \longrightarrow (B_D, B_\Omega) \longrightarrow \text{CKM/PMNS transport} \\ &\longrightarrow \text{character and towers} \longrightarrow \text{mass section}. \end{aligned} \tag{90.48}$$

CKM performs a change of basis of the quark operators,

$$B_d^{(u)} = V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^*, \qquad R_{\mathrm{act}}^{B_d^{(u)}} = V_{\mathrm{CKM}} R_{\mathrm{act}}^{B_d} V_{\mathrm{CKM}}^*, \tag{90.49}$$

and preserves spectrum and determinant. The mixing specifies the representation of the operator in a flavour basis; the register preserves the eigenvalues and their genealogy.

90.5.9.2 Neutrino reader contained in the register

The neutral sector has an integer extractor constructed exclusively with record data. For each dodecaphase block E_m, we define

$$T(m) = \sum_{t \in E_m} (-1)^{\kappa(t)} \varepsilon(t) \mathbf{1}_{\{d(t)=9\}}, \qquad s_C^{(m)}(\nu) = T(m) - T(m+6), \tag{90.50}$$

and

$$\tau_m^\nu = \operatorname{sgn} s_C^{(m)}(\nu). \tag{90.51}$$

The four jump triangles produce

$$\nu_{120} = \sum_{j=1}^{4} \operatorname{sgn}\left(\sum_{m \in \mathcal{T}_j} \tau_m^\nu \right), \qquad \nu_{270} = \sum_{m=1}^{12} \tau_m^\nu \tau_{m+3}^\nu. \tag{90.52}$$

Bidirectional inversion transforms $\nu_{120} \mapsto -\nu_{120}$ and preserves ν_{270}. This parity defines the historical architecture of a reader independent of metrological magnitudes used as a target. Its literal application to the living record 81×108, taking as $\varepsilon(t)$ the sole global sign bit preserved by that projection, yields

$$s_C^{(m)}(\nu) = 0, \qquad \tau_m^\nu = \nu_{120} = \nu_{270} = 0$$

in the eighty-one positions. Antipodal events have been identified by projection of the register. The local result is preserved as a recovered reader and, simultaneously, as a test of information loss: the neutral

extractor of section 92.6.2.3 acts before that identification and reads the local bidirectional bit, the sheet, torsion, and the antipodal corona. The zero obtained after projection does not demote that construction; it certifies exactly what information the global reader erases. The frames F_ℓ, F_ν, the reader (90.52), and the aggregate form

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c \in L_a} \sum_{d \in N_b} K_{\text{registro}}(c, d), \qquad U_{\text{int}} = \text{polar}(G), \tag{90.53}$$

Thus, the two already constructed ends of the PMNS bridge are fixed.

The cardinal equality between the fifty-six multiplicative seed vertices and the fifty-six CT108 families has undergone an initial control independent of metrological magnitudes used as targets. The natural Hadamard map on a single seed reaches only twenty-nine families; upon traversing the natural dihedral symmetries, signs, and translations, the maximum coverage is thirty-five. The intertwiner therefore acts on the enriched seed pair and preserves sheet, carry, and memory. The incidence matrix comparing shared emissions in that double domain must have rank fifty-six, be natural under orientation, and not factor through global counters. This criterion fixes the exact domain of the next construction.

90.6 Color qutrit algebra and finite gauge connection

The residual functional κ_3 of the section 69.1 yields three affine classes; the subsequent atlas realizes their balance $12 + 12 + 12$ in the proposition 90.14. A triple of labels is not yet a representation. The algebraic step requires the qutrit chart, its orientation, and its phase character to be declared. Under those hypotheses, the representation and its infinitesimal algebra are obtained exactly, without using masses or chromodynamic data.

90.6.1 Weyl pair and trace algebra 0

Let

$$V_{\text{col}} = \mathbb{C}^3, \qquad \omega = e^{2\pi i/3},$$

with ordered basis (e_0, e_1, e_2). We define

$$Xe_j = e_{j+1 \bmod 3}, \qquad Ze_j = \omega^j e_j.$$

We have

$$X^3 = Z^3 = I, \qquad ZX = \omega XZ.$$

Theorem 90.16 (Weyl Basis and Complex Color Algebra)**.** *For*

$$W_{ab} := X^a Z^b, \qquad (a, b) \in (\mathbb{Z}/3\mathbb{Z})^2,$$

the nine operators W_{ab} form an orthogonal basis of $\text{End}_{\mathbb{C}}(V_{\text{col}})$ *with respect to the Hilbert–Schmidt product. The eight non-identity operators have zero trace and*

$$\text{span}_{\mathbb{C}}\{W_{ab} : (a, b) \neq (0, 0)\} = \mathfrak{sl}_3(\mathbb{C}).$$

Proof. The Weyl relation makes it possible to reduce any product to the form $X^a Z^b$. A direct calculation gives

$$\text{tr}(W_{ab}^\dagger W_{cd}) = 3\,\delta_{ac}\delta_{bd}.$$

Therefore, the nine operators are linearly independent; since $\dim_{\mathbb{C}} \text{End}_{\mathbb{C}}(V_{\text{col}}) = 9$, they form a basis. The trace of $X^a Z^b$ vanishes except for $(a, b) = (0, 0)$. The remaining eight thus form a basis of the trace-zero subspace, whose complex dimension is eight. □

Corollary 90.17 (Compact real form)**.** *The Involution*

$$\tau(A) := -A^{\dagger}$$

preserves $\mathfrak{sl}_3(\mathbb{C})$*, and its fixed-point set is*

$$\mathfrak{sl}_3(\mathbb{C})^{\tau} = \{A : A^{\dagger} = -A,\ \operatorname{tr} A = 0\} = \mathfrak{su}(3).$$

This real form has dimension eight.

Proof. We have

$$W_{ab}^{\dagger} = \omega^{ab} W_{-a,-b}.$$

The eight non-zero indices form four adjacent pairs. For

$$\mathcal{R} = \{(1,0), (0,1), (1,1), (1,2)\},$$

the operators

$$A_u = W_u - W_u^{\dagger}, \qquad B_u = i(W_u + W_u^{\dagger}), \qquad u \in \mathcal{R},$$

are anti-Hermitian, traceless, and linearly independent over $\mathbb{R}$. They therefore constitute a real basis of $\mathfrak{su}(3)$. □

The residual application

$$\kappa_{\mathrm{col}}(r, c) = \mathbb{C} e_{\,r-c \bmod 3}$$

associates the three classes of the atlas with the three lines proper of Z. The operator X the permutes cyclically and Z records its phase. This assignment is exact a time fixed

$$V_{\mathrm{col}} = \mathbb{C}[\mathbb{F}_3], \quad \text{the delta basis}, \quad j \longmapsto j+1, \quad j \longmapsto \omega^{j}.$$

Admissible affine changes of the chart produce unitarily conjugate representations. The construction is therefore natural up to unitary conjugacy; by itself, it selects neither the physical names of the colors nor a QCD realization.

90.6.2 Connection and Action on a Finite Cellular Complex

Construction 90.18 (Finite gauge theory relative to the complex)**.** Let $\mathcal{K} = (V, E, F)$ be a finite oriented cellularization compatible with the graph of routes. To each oriented edge e one assigns

$$U_e \in SU(3), \qquad U_{\bar{e}} = U_e^{-1}.$$

A transformation $g : V \to SU(3)$ acts by

$$U_e \longmapsto U_e^{g} = g_{t(e)} U_e g_{s(e)}^{-1}.$$

For each face f, the ordered product

$$U_f = \prod_{e \subset \partial f} U_e^{\epsilon(f,e)}$$

defines its holonomy. With a base vertex v_f chosen, one has

$$U_f^{g} = g_{v_f} U_f g_{v_f}^{-1}.$$

Proposition 90.19 (Gauge invariance and covariant transport)**.** *For* $\beta \geq 0$*, the action*

$$S_{\mathrm{col}}^{(\mathcal{K},\beta)}[U] = \frac{\beta}{3}\sum_{f\in F}\left(3 - \operatorname{Re}\operatorname{tr} U_f\right)$$

is gauge-invariant and no negativa. If $\psi_v \in V_{\mathrm{col}}$ transforma as $\psi_v \mapsto g_v\psi_v$, then

$$\nabla_e\psi := U_e\psi_{s(e)} - \psi_{t(e)}$$

satisfies

$$\nabla_e^g\psi^g = g_{t(e)}\nabla_e\psi.$$

Proof. The holonomy changes by conjugation and the trace is cyclic; of there the invariance. As each U_f is unitary of dimension three, $\operatorname{Re}\operatorname{tr} U_f \le 3$, lo that proves the not negativity. The covariance of ∇_e results substituting the two lawes of transformation. □

90.6.3 Positivity of Class Kernels and Harmonic Decomposition

The preceding finite connection does not by itself imply reflection positivity or a Yang–Mills limit. Before formulating such transfers, it is appropriate to isolate the classical control that is closed. Let G be a compact group and $\widehat{G}$ its unitary dual. For each $\rho \in \widehat{G}$, let d_ρ be its dimension and $c_\rho(a) \ge 0$ coefficients with sufficient decay, relative to the growth of d_ρ, for the following series to converge absolutely.

Definition 90.20 (Class nucleus)**.** It is defined

$$K_a(g,h) := \sum_{\rho\in\widehat{G}} c_\rho(a)\ \operatorname{Tr}\!\big(\rho(g)\rho(h)^*\big), \qquad g,h\in G.$$

The choice

$$c_\rho(t) = d_\rho e^{-t C_2(\rho)}, \qquad t>0,$$

provides the example of the heat kernel. The nonnegativity of the coefficients does not replace the hypothesis of absolute convergence.

Theorem 90.21 (Positivity of Peter–Weyl)**.** *For $g_1,\dots,g_n \in G$ and $z_1,\dots,z_n\in\mathbb{C}$,*

$$\sum_{i,j=1}^{n} \overline{z}_i z_j K_a(g_i,g_j) \ge 0.$$

Proof. The unitarity of the representations and absolute convergence allow the sum to be reordered:

$$\sum_{i,j}\overline{z}_i z_j K_a(g_i,g_j) = \sum_{\rho\in\widehat{G}} c_\rho(a)\left\|\sum_j \overline{z}_j\rho(g_j)\right\|_{\mathrm{HS}}^2 \ge 0.$$

A negative spectral coefficient may destroy this Gram positivity; therefore the sign forms part of the hypotheses. □

Lemma 90.22 (Abelian Poisson Control)**.** *For $G=U(1)$, $\theta\in\mathbb{R}$, and $|a|<1$,*

$$\sum_{n\in\mathbb{Z}} a^{|n|}e^{in\theta} = \frac{1-a^2}{1-2a\cos\theta+a^2}.$$

If nonnegative Fourier coefficients are also required, a is restricted to $0\le a<1$.

Proof. The equality results from summing separately the two geometric series with positive and negative indices and adding the mode $n = 0$. For $a < 0$, the scalar identity remains valid but no longer constitutes an example of nonnegative Peter–Weyl coefficients. □

Remark 90.23. The definition 90.20, theorem 90.21 y lemma 90.22 are classical definitions and results of harmonic analysis. They provide a positive control for class kernels; they do not prove Osterwalder–Schrader positivity, a mass gap, confinement, or a continuum limit, nor do they promote the finite gauge theory of this chapter to quantum chromodynamics.

Algebraic closure of color

The theorem 90.16 y corollary 90.17 construct exactly the chain

$$\text{ternary residue} \longrightarrow \text{qutrit} \longrightarrow \mathfrak{sl}_3(\mathbb{C}) \longrightarrow \mathfrak{su}(3).$$

The construction 90.18 y proposition 90.19 prolongs that chain to a connection and a gauge action on the finite cellularization $\mathcal{K}$. This is the object proved in the chapter. The comparison with physical chromodynamics is made subsequently and does not redefine the qutrit, the balance $12 + 12 + 12$, or the constructed representation.

90.7 Systematic extension of mass theory

90.7.1 Extension–route factorization and genealogical record conservation

90.7.1.1 The object prior to magnitude

The theory begins before the number. A physically individuated mass is not a real number accompanied by the name of a particle, but the terminal term of a mathematical biography. APP supplies the finite incidence space and the two correlative operations; TRIT preserves the temporal orientation of each transition; TPK transports phase, sheet, carry, boundary, route, memory, and survival. Dimensional Mechanics subsequently converts that biography into a section of the mass line. The complete order is

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \Gamma^{\mathrm{surv}} \longrightarrow \gamma_{\mathrm{obs}} \longrightarrow \mathscr{L}_\gamma \longrightarrow \sigma(\gamma) \longrightarrow \chi_{\mathrm{mass}} \longrightarrow \mathcal{T}_{90,120} \longrightarrow \mathcal{L}_M.$$

Each arrow retains information used by the next. The cell does not replace the route; the route does not replace the register; a signature does not replace its genealogical register; a character does not replace the dimensional section on which it acts. This separation explains why two particles may share charge or spin and nevertheless have different masses: their enriched biographies are not the same. It also explains why particle and antiparticle share mass: the involution changes odd orientation and preserves even memory, which descends to the mass quotient.

APP consists of nine by nine published positions. Each position admits four initial orientations, so the oriented domain contains

$$81 \cdot 4 = 324$$

candidate routes. The internal classification produces 56 route families and 13 multisections. These cardinalities are simultaneous: 81 counts cells, 324 counts orientations, 56 counts quotients by history, and 13 counts coarse operator types. No particle table replaces these domains.

90.7.1.2 Discrete unit of the continuum that supports the mass

The mass line is not appended to five independent theories of the continuum. It follows from the unique APP–TRIT–TPK state from which the spectral, solenoidal, gauge, coherent, and determinantal aspects jointly emerge, designated in the construction notation by sp, sol, gau, coh, det. Those symbols are reading discriminants, not prior subdomains. If C_{disc} denotes the common structure, the generating arrow has the form

$$\mathfrak{E}_{\mathrm{cont}} : C_{\mathrm{disc}} \longrightarrow \big(C_\infty; O_{sp}, O_{sol}, O_{gau}, O_{coh}, O_{det}\big),$$

where the five observations belong to the same limit object, share fibers, orientation, carry, memory, boundary, and readers, and are transported by the same refinement squares. Mass uses its determinant reading for the action scale, its spectral reading for the character and the towers, its gauge reading for the null and charged sectors, and its coherent and solenoidal readings for propagation and composition. None of them is introduced by presupposing that the state belongs to a classical physical class.

This unit is a typing condition: separating one of those aspects and retaining the others would produce a different object, incapable of simultaneously supporting route, action, charge, amplitude, and mass. The present theory does not reprove the complete continuum; it incorporates its unified construction as a foundation and verifies that none of the mass insertions disaggregates it.

90.7.1.3 Absolute scale and quotients

The local determinantal reader has Smith normal form.

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4),$$

from which

$$|\operatorname{coker} H_4| = 16, \qquad \Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34.$$

The decade is obtained before the SI chart. The pre and return sections of the action line are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34} u_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}^{(\mathrm{deg})}\, 10^{-34} u_S,$$

and its bidirectional quotient is

$$R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}^{(\mathrm{deg})}}.$$

In the clock branch, we explicitly choose the return section, $\hbar_{\mathrm{int}} := \hbar_{\mathrm{ret}}$, as the action section. A declared clock t_0 provides

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad \varepsilon_{\mathrm{clk}} = \hbar_{\mathrm{ret}} \omega_0, \qquad m_{\mathrm{clk}} = \varepsilon_{\mathrm{clk}} c_{\mathrm{int}}^{-2}.$$

Adopting $u_M^{\mathrm{clk}} := m_{\mathrm{clk}}$ as origin of the chart is a normalization explicit. Not identifies automatically this section with a basis energetic or mass previously declared. The character produces first the operator basal

$$\widehat{M}_X^{(0)} = \mathfrak{e}_0 m_{\mathrm{clk}}\, \chi_{\mathrm{full}}(\sigma_X - \sigma_e, \eta_X - \eta_e),$$

and the bidirectional reader acts afterward. For each presentation $r \in \{D, \Omega\}$, let $\widehat{B}_X^r = (\widehat{B}_X^r)^*$ over the finite fiber; in an infinite realization one also requires a common dense domain for functional calculus. Then

$$\widehat{M}_X^{\beta, r} = R_{\mathrm{act}}^{\widehat{B}_X^r/2}\, \widehat{M}_X^{(0)}\, R_{\mathrm{act}}^{\widehat{B}_X^r/2}.$$

On a scalar fibre, $\widehat{B}^r_X = \kappa_X I$, so that

$$m_X^\beta = m_X^{(0)} R_{\mathrm{act}}^{\kappa_X}.$$

If the tower coordinates are already expressed relative to the electron, $-\eta_e$ is omitted. When a quotient is formed, the common dimensional section cancels, but the difference in bidirectional reading does not:

$$\frac{m_Y^\beta}{m_X^\beta} = \chi_{\mathrm{full}}(\sigma_Y - \sigma_X, \eta_Y - \eta_X) R_{\mathrm{act}}^{\kappa_Y - \kappa_X}.$$

Therefore, 10^{-34} fixes the absolute scale of action, energy, and mass; it is not a hidden relative corrector. The fine information of a species can enter only through its character, its relative clock, or the oriented quotient of the pre- and return sections.

90.7.1.4 Internal quantity of the mass line induced by the cycle of 108 states

The Planck–CT108 self-duality provides, in the internal normalization

$$\hbar_{\mathrm{int}} = c_{\mathrm{int}} = t_0 = 1,$$

the section

$$m_{108}^{\mathrm{int}} = 0.058177641733144319230789692282953757\ldots.$$

This number is a normalized quantum of the internal mass line. It is not the mass of a particle, does not by itself carry a MeV or GeV chart, and cannot be inserted as an additional species row. Its function is to verify compatibility among the action chart, the CT108 clock, and the self-duality of the mass line. The transition to a nominal mass still requires the route, signature, operator, and dimensional section of the species.

90.7.1.5 Existence of the HMT–MD output for surviving extensions and scalar-reduction criterion by fiber rank

Given a surviving extension, a cellular reader, an integer signature, an absolutely convergent family of tower coefficients, and a dimensional mass section, a well-typed HMT–MD output exists. If the fiber has a unique fixed point compatible with the involution, the output reduces to a canonical scalar. If the fiber has higher rank, the primary output is the spectral operator on the fiber; a physical scalar mass requires the coupling functional that individuates the observed representation.

This theorem does not weaken the recovered scalar evaluations. It distinguishes three claims: the internal operator is constructed; the evaluation of a declared signature is exact; and the prospective determination of that signature is an additional theorem when it is not deduced from the reader itself. Experimental comparison is performed only after fixing which of those three claims is being published.

90.8 Functorial construction of mass families over the atlas

The construction ends with the algorithm that receives only typed genealogical data, forms the realization fiber, and requires the equalizer of the readers before publishing a dimensional output.

90.8.1 Universal Algorithm of the General Mass Law

90.8.1.1 Cellular reader domain: surviving extension, route, record, and signature

The entry contains only:

$$(\text{APP}, \text{TRIT}, \text{TPK}, \mathcal{R}_{324}, \mathcal{L}_{108}, \text{representation}, \text{coupling}, \text{common dimensional chart}).$$

It contains no observed mass, residual mass, chosen coefficient by approximation, or external table.

90.8.1.2 Functorial construction of material realization: route fiber, intertwiner, coincidence projector, spectral operator, and scalarization

For each physical state X:

1. construct its descriptor of charge, generation, flavor, color, spin, statistics, orientation, and composition;
2. form the fiber of compatible routes;
3. compute the space of intertwiners

$$\mathcal{J}_X = \mathrm{Hom}_{G_X}(V_X, \ell^2(F_X));$$

1. if $\dim \mathcal{J}_X = 0$, discard that identification;
2. construct the projector by Reynolds averaging and the polar factor;
3. reconstruct the genealogical registers of all routes in the support;
4. calculate signature, K_D, K_Ω and $\mathcal{F}^{2w}_{\text{tower}}$;
5. apply the coupling-reading pointer, the equalizer, or the joint spectral measure;
6. construct $\widehat{M}_X$;
7. reduce to a scalar only if the variance is zero or an isolated pole exists;
8. for composites, first apply $\mathfrak{C}_{12}$;
9. for widths, calculate the survival semigroup;
10. multiply by the common dimensional section;
11. freeze the output;
12. open the external comparison.

90.8.1.3 Existence of the fiberwise realization

The multiplicity of a representation π_X within a fiber is calculated by

$$\dim \mathcal{J}_X = \frac{1}{|G_X|} \sum_{g \in G_X} \overline{\chi_{\pi_X}(g)}\, |\mathrm{Fix}_{F_X}(g)|.$$

If it is positive, an intertwiner exists. If it is greater than one, the result is a bundle of realizations, and the coupling must select a state or preserve the mixed measure. This formula replaces a nominal search by a finite algebraic condition on the 324 routes.

90.8.1.4 Spectral equalizer of the readers K_D and K_Ω via $Q_{\mathrm{eq}} = \mathbf{1}_{\{0\}}(\widehat{L}_D - \widehat{L}_\Omega)$

Let

$$L_r(\Gamma) = \kappa_r(\Gamma)\log R_{\mathrm{act}} + \sum_{h\in\mathfrak{S}} \eta_h^r(\Gamma)s_h, \qquad r \in \{D,\Omega\}.$$

The coincidence projector is

$$Q_{\mathrm{eq}} = \mathbf{1}_{\{0\}}(\widehat{L}_D - \widehat{L}_\Omega).$$

A realization admits common exact reading exactly when

$$P_X \le Q_{\mathrm{eq}}.$$

If there exists an involution of the coupling that exchanges both readers, L_{sym} is used. Otherwise, its joint spectral measure is published.

90.8.1.5 Cellular reader codomain: dimensionless character, tower, and mass realization

The output may be:

$$\begin{cases} m_X \in \mathcal{L}_M, & \text{scalar mass,} \\ \mathrm{Spec}(\widehat{M}_X), & \text{multiplet,} \\ z_X = M_X - i\Gamma_X/2, & \text{resonance,} \\ 0 \in \mathcal{L}_M, & \text{zero section,} \\ (C,F,R,\Delta E), & \text{topological sector,} \\ (L,\mathrm{Obs}_L), & \text{virtual section.} \end{cases}$$

This diversity of codomains is part of the law; not an exception.

90.9 Bifurcation of the previous null sector from the positive mass branch

The photonic and gluonic sectors are separated before applying the positive character. The identity $R_{\mathrm{act}}^0 = 1$ does not prove zero mass; nullity follows from the gauge chart. In the matter families, the primary output is a positive fiber operator. Only a typed physical compression produces a scalar.

90.10 Exhaustive construction of the atlas 81/56/13/324 and conservation of the null sector

The definition and the theorems of the domain precede the unfolding of its 324 fichas completas. The cards are placed at the end of the scientific apparatus in order to preserve the continuity of the derivation without concealing any route.

90.11 Theorem of material domain exhaustiveness and null sector stability under refinement

The General Mass Law does not start from a table of names or a list of experimental values. Its internal domain is the finite chain

$$\mathcal{R}_{324} \longrightarrow \mathcal{C}_{81} \longrightarrow \mathcal{F}_{56} \longrightarrow \mathcal{M}_{13},$$

where $\mathcal{R}_{324}$ contains the 4 orientations of each of the 81 cells, $\mathcal{F}_{56}$ groups equivalent route histories, and $\mathcal{M}_{13}$ preserves the operator multisections. The null sector bifurcates before the positive character is applied. Therefore, neither an abbreviated historical table nor a taxonomy of physical names can replace this domain.

Let $\mathcal{P}$ be the set of individualized physical states. An elementary state is represented by the descriptor

$$X = (\mathfrak{c}, \rho, g, f, q, \epsilon, \varsigma, \mathfrak{a}),$$

which preserves representation class $\mathfrak{c}$, internal representation ρ, generation g, flavor f, charge q, sheet orientation ϵ, statistical sector ς, and coupling data $\mathfrak{a}$. A composite state adds ordered constituents, composition tree, common boundary, and collective quantum numbers. A resonance adds the open channels and the causal prescription for the resolvent.

The physical realization must address three distinct questions:

1. which fibre, orbit, or multisection of the atlas corresponds to the descriptor;
2. which positive operator publishes the mass on that fiber;
3. which coupling produces a scalar, a multiplet, a distribution, or a complex pole.

Confusing these questions introduces a retrospective selector. The correct answer is obtained through a natural relation, a fiber operator and a spectral compression, in that order.

90.12 Fiber product between species invariants and genealogical paths

Let $\mathcal{D}$ be the finite space of internal data already constructed before the contrast: representation, orientation, memory, boundary, charge, flavor, color, generation, and statistical sector. Denote by

$$d_{\mathcal{P}} : \mathcal{P} \longrightarrow \mathcal{D}, \qquad d_{\mathcal{R}} : \mathcal{R}_{324} \longrightarrow \mathcal{D}$$

the physical descriptor maps and the genealogical descriptor. The object of realization is defined by the fiber product

$$\mathcal{J} = \mathcal{P} \times_{\mathcal{D}} \mathcal{R}_{324} = \{(X, \gamma) : d_{\mathcal{P}}(X) = d_{\mathcal{R}}(\gamma)\}.$$

The fiber of a species is

$$\mathcal{S}(X) = \{\gamma \in \mathcal{R}_{324} : (X, \gamma) \in \mathcal{J}\}.$$

A descriptor (X) is called realizable by the atlas when

$$d_{\mathcal{P}}(X) \in \operatorname{im} d_{\mathcal{R}}.$$

This condition is equivalent to $\mathcal{S}(X) \neq \varnothing$. It does not follow from merely writing the fiber product: it constitutes the exact existence condition that must be verified for each physical descriptor. The value of $\mathcal{S}$ may be a route, an orbit, or a multisection. A point section is not forced when the internal symmetry requires preservation of a multiplicity.

Definition 90.24 (Admissible realization relation)**.** The relation $\mathcal{S}$ is admissible when it simultaneously satisfies:

1. depends solely on data constructed before the external table is opened;
2. commutes with particle–antiparticle conjugation;
3. is equivariant under cellular inversion and the internal gauge actions;
4. it is compatible with refinement, nonadic return and dodecaphasic reading;
5. preserves every multiplicity not eliminated by a physical coupling;
6. remains invariant under permuting or replacing the external values of mass and width.

Theorem 90.25 (Prospective realization by fibered product)**.** *If $d_{\mathcal{P}}$ and $d_{\mathcal{R}}$ are equivariant with respect to a symmetry G and do not depend on external magnitudes, then $\mathcal{J}$ is a G-subobject of $\mathcal{P} \times \mathcal{R}_{324}$. For every realizable descriptor X, the nonempty fiber $\mathcal{S}(X)$ is G_X-stable, and the assignment $X \mapsto \mathcal{S}(X)$ is independent of the result subsequently compared.*

Proof. For $(X, \gamma) \in \mathcal{J}$ one has $d_{\mathcal{P}}(X) = d_{\mathcal{R}}(\gamma)$. Equivariance gives

$$d_{\mathcal{P}}(gX) = g\, d_{\mathcal{P}}(X) = g\, d_{\mathcal{R}}(\gamma) = d_{\mathcal{R}}(g\gamma),$$

and, consequently, $(gX, g\gamma) \in \mathcal{J}$. If $g \in G_X$, the second component remains in $\mathcal{S}(X)$. Independence of the external values is immediate because none of them belongs to the domain of the two maps of the fiber product. □

The electron constitutes the central exception. Cell inversion has a unique fixed point, the cell $(5, 5)$, and its physical fiber therefore has rank one. The remaining stable multisections do not, in general, admit an equivariant point selector. This difference is not a deficiency of the atlas: it is the mathematical distinction between a central section and a species realized as an orbit or multisection.

90.13 Intrinsic spectral classification of the species

Let $\mathcal{A}_{\mathrm{rut}}$ be the finite commutative algebra generated by the internal route observables: signature $\mathbb{Z}^5$, character, chronology, K_D, K_Ω, orientation, memory, and compatible readers. In a fiber F, one defines

$$\gamma \sim_{\mathrm{sp}} \eta \quad \Longleftrightarrow \quad a(\gamma) = a(\eta) \quad \text{for every } a \in \mathcal{A}_{\mathrm{rut}}.$$

For each class $\lambda \in F/\!\sim_{\mathrm{sp}}$,

$$P_\lambda = \sum_{\gamma \in \lambda} |\gamma\rangle\langle\gamma|$$

is a spectral projector; the P_λ are orthogonal and $\sum_\lambda P_\lambda = I_F$.

Theorem 90.26 (Maximum internal individualization)**.** *Every classifier constructed exclusively from observables of $\mathcal{A}_{\mathrm{rut}}$ factors uniquely through the quotient $F/\!\sim_{\mathrm{sp}}$. Consequently, two descriptors with distinct complete signatures belong to distinguishable sectors; two descriptors that agree for all generators of the algebra cannot be separated by a rule constructed from those same observables.*

Proof. The characters of the finite commutative algebra separate exactly its joint spectrum. A functional classifier of its generators is constant on each fiber of the joint spectral map and therefore factors through the quotient. If two routes have the same character on the entire algebra, no element of it can separate them. □

This theorem closes the logical limit of the classification. When a physical representation requires two states belonging to the same spectral class to be distinguished, it must exhibit an additional observable or a coupling that enlarges $\mathcal{A}_{\mathrm{rut}}$. The absence of such an observable does not authorize the external mass to be used as a selecting label.

In the charged leptonic sector, the descriptors distinguish the central fiber, the depth-G_2 multisection, and the depth- G_4 multisection. The first produces the unique electronic line; the other two produce the operators associated with the muonic and tauonic realizations. If the coupling preserves more than one block, the correct prediction is its spectrum; the physical label does not authorize choosing one of its eigenvalues by numerical proximity.

90.13.1 Conjugate quotients and minimal memory of the finite atlas

The double projection requires the transported state to be distinguished from each of its images. At the finite level of the atlas, this distinction admits an exact formulation: the same dodecaphasic word has several quotients, each of which preserves a given family of invariants and contracts the remainder. The configuration historically called *diamond* is formulated here as a system of conjugate quotients over a common support. Its mathematical content consists in identifying the fibers of those quotients and determining the minimal memory required to separate the states that a projection has identified.

90.13.1.1 Cellular domain, routes, and enriched internal state

Let

$$C_9 = \{1, \dots, 9\}^2$$

the finite APP chart. For a cell $x = (r, c)$, the atlas fixes the internal cellular type, the level

$$G(r,c) = \begin{cases} 0, & (r,c) = (5,5), \\ \max\{1, |r-5|, |c-5|\}, & \text{otherwise}, \end{cases}$$

and, in the corresponding sector, the colour class $(r - c) \bmod 3$. The published multiplicative evaluation is

$$a_\times(r,c) = \mathrm{dr}_9(rc).$$

These readers are computed from the oriented cell; a later physical denomination does not intervene in their definition.

The route catalog associates with x the coordinate

$$\mathcal{R}(x) = \big(n_A, s_C, k_{\Delta_4}, \nu_{120}, \nu_{270}, \tau_{12}\big) \in \mathscr{R}_{56},$$

where $\tau_{12} \in \{-1, 0, 1\}^{12}$ is the dodecaphasic word. The exhaustive comparison of the atlas of 81 cells with the expanded CT–108 catalogue establishes a unique surjective map

$$\mathcal{R} : C_9 \longrightarrow \mathscr{R}_{56}, \qquad |\operatorname{im}\mathcal{R}| = 56,$$

whose fibers have the distribution

$$41 \cdot 1 + 10 \cdot 2 + 2 \cdot 3 + 1 \cdot 4 + 2 \cdot 5 = 81. \tag{90.54}$$

For $\tau = (\tau_0, \dots, \tau_{11})$ and $d \in \{3, 4, 6\}$, let $\mathcal{O}_d$ be the orbits of $j \mapsto j + d$ in $\mathbb{Z}/12\mathbb{Z}$. We define

$$\nu_d(\tau) = \sum_{O \in \mathcal{O}_d} \operatorname{sgn}\left(\sum_{j \in O} \tau_j\right), \qquad (\nu_{90}, \nu_{120}, \nu_{180}) = (\nu_3, \nu_4, \nu_6),$$

and the cyclic correlations

$$Q_k(\tau) = \sum_{j=0}^{11} \tau_j \tau_{j+k}, \qquad k = 1, \dots, 6,$$

with indices taken modulo twelve. They complete the reader.

$$z_0(\tau) = \#\{j : \tau_j = 0\}, \qquad w(\tau) = \sum_j |\tau_j|, \qquad L(\tau) = \sum_j \tau_j.$$

The notation z_0 separates the number of null entries from the distinct invariant $R_3 = Q_3/2$.

Theorem 90.27 (Minimal internal selector)**.** *Having fixed the origin of the chart and its lexicographic order, let*

$$\kappa(x) = \#\{y \in \mathcal{R}^{-1}(\mathcal{R}(x)) : y <_{\mathrm{lex}} x\} \in M_5 := \{0, 1, 2, 3, 4\}.$$

The map

$$\begin{aligned} \mathcal{S}_{\mathrm{int}} : C_9 &\longrightarrow \mathscr{E}_{\mathrm{int}} := \mathscr{R}_{56} \times M_5 \times \mathbb{Z}^9, \\ x &\longmapsto \big(\mathcal{R}(x), \kappa(x), \nu_{90}(\tau_x), \nu_{180}(\tau_x), Q_1(\tau_x), \dots, Q_6(\tau_x), z_0(\tau_x)\big) \end{aligned} \tag{90.55}$$

is injective. Among the injective lifts of the form $(\mathcal{R}, m)$, its memory alphabet has minimal cardinality.

Proof. The distribution (90.54) contains fibers of cardinality five. By the pigeonhole principle, every map $m : C_9 \to M$ for which $(\mathcal{R}, m)$ is injective satisfies $|M| \geq 5$. Within each fiber, κ enumerates its elements exactly according to the fixed order and therefore separates two cells sharing a route. Cells with distinct routes are already separated by $\mathcal{R}$. Consequently, $(\mathcal{R}, \kappa)$, and a fortiori $\mathcal{S}_{\mathrm{int}}$, is injective and attains the lower bound. □

Projection onto the first coordinate yields the commutative diagram.

$$\begin{array}{ccc} C_9 & \xrightarrow{\mathcal{S}_{\mathrm{int}}} & \mathscr{E}_{\mathrm{int}} \\ {\scriptstyle \mathcal{R}}\big\downarrow & & \big\downarrow{\scriptstyle \mathrm{pr}_{\mathscr{R}}} \\ \mathscr{R}_{56} & \xrightarrow{\mathrm{id}} & \mathscr{R}_{56}. \end{array}$$

Thus, κ measures the minimum cellular memory forgotten by $\mathcal{R}$. Its canonicity is relative to the origin and ordering of the chart: if these are regarded as a gauge, the intrinsic object is the ordered fiber or its orbit. The index κ and the antisheet memory $A_6 = (e_0 - e_6, \dots, e_5 - e_{11})$ answer to losses of information of the same categorical nature, but fulfill different functions: κ separates cells of a fiber of $\mathcal{R}$, whereas A_6 participates in reconstructing the dodecaphasic register.

90.13.1.2 Thick types and natural multisections

The ratio

$$q : C_9 \longrightarrow \mathscr{Y}_{13}, \qquad q(x) = \big(\mathrm{familia}(x), G(x)\big),$$

has thirteen values. The cardinalities of its fibers are

$$1, 8, 16; \qquad 2, 4, 6, 8; \qquad 2, 4, 6, 8; \qquad 4, 12.$$

The output determined by $y \in \mathscr{Y}_{13}$ is the finite multisection

$$\mathfrak{S}(y) = \{\mathcal{S}_{\mathrm{int}}(x) : q(x) = y\} \in \mathrm{Fin}^{+}(\mathscr{E}_{\mathrm{int}}). \tag{90.56}$$

Let $\rho(r, c) = (10 - r, 10 - c)$. The thirteen fibers are stable under ρ, but only $q^{-1}(q(5, 5))$ contains a fixed point. Therefore, in the remaining twelve fibers, a pointwise ρ-equivariant section does not exist: the multisection (90.56) is the natural output of the coarse type. Choosing a representative requires additional orientation or representation data and is not obtained from the name subsequently assigned to the type.

90.13.1.3 Dodecaphasic conjugation and signature quotients

Let $\mathcal{T}_{12} = \{-1, 0, 1\}^{12}$ and define the involution

$$C_M : \mathcal{T}_{12} \longrightarrow \mathcal{T}_{12}, \qquad C_M(\tau) = -\,\mathrm{rev}(\tau).$$

We group the linear and quadratic readers together.

$$\mathcal{L}(\tau) = (\nu_{90}, \nu_{120}, \nu_{180}, L) \in \mathbb{Z}^4,$$

$$Q(\tau) = (Q_1, \dots, Q_6, z_0, w) \in \mathbb{Z}^8.$$

Conjugation satisfies the identities

$$\mathcal{L}(C_M\tau) = -\mathcal{L}(\tau), \qquad Q(C_M\tau) = Q(\tau). \tag{90.57}$$

For any reader $F : \mathcal{T}_{12} \to I_F$, write

$$\tau \sim_F \tau' \quad \Longleftrightarrow \quad F(\tau) = F(\tau'), \qquad \mathfrak{Q}_F = \mathcal{T}_{12}/\!\sim_F .$$

When F is equivariant with respect to C_M, the involution descends to $\overline{C}_{M,F}$, and one obtains

$$\begin{array}{ccc} \mathcal{T}_{12} & \xrightarrow{C_M} & \mathcal{T}_{12} \\ {\scriptstyle q_F}\downarrow & & \downarrow{\scriptstyle q_F} \\ \mathfrak{Q}_F & \xrightarrow{\overline{C}_{M,F}} & \mathfrak{Q}_F . \end{array}$$

In particular, $\overline{C}_{M,Q}$ is the identity and $\overline{C}_{M,\mathcal{L}}$ changes the sign of the published signature. This parity difference is the conjugate structure of the two quotients; they are not two evaluations of distinct initial states.

The atlas contains seven word forms of dodecaphonic with multiplicities.

$$54, 2, 2, 2, 7, 7, 7. \tag{90.58}$$

One form is fixed by C_M; the other six constitute three conjugate pairs. In each pair, the cellular multiplicities are 2 and 7. Consequently, no bijection of C_9 can lift C_M while preserving the form fibers. The inversion ρ intertwines the words in 49 cells and leaves 32 exceptions. The exact anti-section at this level is therefore the correspondence

$$x \longmapsto \{y \in C_9 : \tau_y = C_M(\tau_x)\}.$$

The numerical equality $54 + 9 + 9 + 9 = 81$ describes the grouping of one fixed form and three pairs of multiplicity $2 + 7$; it does not constitute a decomposition into bijective orbits of the cells.

90.13.1.4 Exact Configuration of Quotients

Let us define the partial readers

$$\Sigma_7(\tau) = (\nu_{90}, \nu_{120}, \nu_{180}, Q_3, Q_4, Q_6, z_0) \in \mathbb{Z}^7,$$

$$\ell_3(\tau) = (\nu_{90}, \nu_{120}, \nu_{180}) \in \mathbb{Z}^3, \qquad p_4(\tau) = (Q_3, Q_4, Q_6, z_0) \in \mathbb{Z}^4.$$

Each reader induces its quotient $\mathfrak{Q}_{\Sigma_7}$, $\mathfrak{Q}_{\ell_3}$, or $\mathfrak{Q}_{p_4}$. The following three collisions locate precisely what information each projection retains.

Theorem 90.28 (Configuration of Conjugate Quotients)**.** *In the finite catalog the following assertions hold simultaneously.*

(i) *The boundary words H_α and H_{APP} are distinct and belong to distinct dihedral orbits, but*

$$\Sigma_7(H_\alpha) = \Sigma_7(H_{\mathrm{APP}}) = (-3, -4, -5, 3, 2, 2, 6).$$

The omitted coordinate of the nearest neighbor separates them:

$$Q_1(H_\alpha) = 4, \qquad Q_1(H_{\mathrm{APP}}) = 3.$$

(ii) *The obstructing support P_π and the template historically designated by τ_{lep} satisfy*

$$\ell_3(P_\pi) = \ell_3(\tau_{\mathrm{lep}}) = (-3, -4, -6),$$

while

$$p_4(P_\pi) = (7, 6, 6, 3), \qquad p_4(\tau_{\mathrm{lep}}) = (4, 3, 2, 5).$$

(iii) *The templates nominally inherited as electronic and protonic publish the same word,*

$$\tau_e^{\mathrm{hist}} = \tau_p^{\mathrm{hist}} = 0^{12}.$$

Every invariant that factors exclusively through $\mathcal{T}_{12}$ necessarily takes the same value on both.

Therefore, the complete configuration is a fan of quotients of the same enriched state,

$$\mathscr{C}_{\mathrm{int}} \longrightarrow \begin{cases} \mathfrak{Q}_{\mathcal{L}}, \\ \mathfrak{Q}_{Q}, \\ \mathfrak{Q}_{\Sigma_7}, \\ \mathfrak{Q}_{\ell_3}, \\ \mathfrak{Q}_{p_4}, \\ \mathcal{T}_{12}, \end{cases} \tag{90.59}$$

and not a bijective correspondence between mathematical constants and physical classes.

Proof. The equalities in (i)–(iii) result from evaluating the readers defined above on the published words. In (i), the inequality of Q_1 proves that the coincidence at $\mathfrak{Q}_{\Sigma_7}$ arises from the suppressed coordinate and not from an identity of words. In (ii), the linear signature coincides and the even vector differs, so the identification occurs only in $\mathfrak{Q}_{\ell_3}$. In (iii), equality of the words implies $F(\tau_e^{\mathrm{hist}}) = F(\tau_p^{\mathrm{hist}})$ for every map F whose effective domain is exclusively $\mathcal{T}_{12}$. Thus each equality determines a specific fiber, and each separation identifies the memory that must be restored. This proves interpretation (90.59). □

The theorem provides a finite model of the general principle of double projection: an image may preserve an exact signature while also identifying different states. The pair formed by the published signature and the omitted memory refines the quotient; recovery of the state requires reincorporating the cell, orientation, band section, or the pertinent coordinate in each case.

90.13.1.5 Accuracy of Conjugate Quotients and Obstructions to Memoryless Reconstruction

The construction begins with the finite atlas of 81 cells, its 56 route families, the seven section forms, and the involution C_M, all defined on the dodecaphase calendar of 108 steps. A state is the quadruple comprising cell, route, orientation, and band section; this quadruple precedes every physical designation and fixes the domain of the conjugate quotients.

On that domain, the index κ and the minimality of five states follow from the origin and order of the chart. The equalities in theorem 90.28 are exact equalities of signatures: in each, the preserved reader and the memory coordinate forgotten by the quotient are specified. The exhaustive traversal of the 81 cells independently reproduces the fibers, the values of ν_d, the quotients Q_k, and the diamond configuration; that finite enumeration complements the algebraic proof and permits its reproduction without altering its premises.

The conclusion is proved for these explicit primitives. Two extensions require additional maps: reconstructing the atlas from the minimal APP kernel and constructing, for the noncentral multisections, a fine physical section that preserves orientation and representation without consulting a target mass. Neither extension intervenes in the finite equalities already established.

The construction is incompatible with any of the following variations: a cardinality different from 81, an image different from 56 families, a fiber distribution different from (90.54), a failure in the reproduction of ν_d and Q_k, the injectivity of $\mathcal{S}_{\mathrm{int}}$, the three equalities of theorem 90.28, the count $49 + 32$ of the partial intertwining of ρ, or the functorial closure of the cobordisms of the supplementary graph. A physical interpretation further requires a representation map preserving these identities and a comparison independent of its construction.

90.14 The particle as a class of persistent sections

The material construction begins with the state produced by APP, TRIT, and TPK. APP supplies the positions and the two arithmetic operations; TRIT distinguishes the regime and orientation of their transitions; TPK transports this information together with the quotients, boundary incidences, and memory. As the state is prolonged, a finite evaluation remains linked to the evaluations preceding it. The notion of a particle rests on this compatibility and on its material representation. Its mass will be an observable of the section thus constructed.

This sequence determines the meaning of the three objects to be used: the genealogical state preserves the complete extension; the route records its observable history; the material representation makes that history act on a state space and permits the evaluation of observables. The distinction is essential even when the three objects share the same electronic label or the same atlas coordinate.

90.14.1 Extension, observable history, and compatible section

Let $\mathcal{S}_m$ be the admissible states surviving through depth m, obtained by TPK prolongation, and let $\rho_{n,m} : \mathcal{S}_n \to \mathcal{S}_m$, for $n \geq m$, be their restriction maps. Compatibility of refinement means

$$\rho_{m,m} = I, \qquad \rho_{n,m}\rho_{p,n} = \rho_{p,m} \quad (p \geq n \geq m). \tag{90.60}$$

A surviving extension is an element

$$x = (x_m)_{m\geq 0} \in \Omega^{\mathrm{surv}}_{\mathrm{HMT}} := \varprojlim_m \mathcal{S}_m, \qquad \rho_{n,m}(x_n) = x_m. \tag{90.61}$$

The existence and admissibility of these states arise from the construction of the formal kernel. The inverse-limit expression describes the compatibilities preserved by a state already generated.

Let $\mathcal{R}_m$ be the space of observable histories at depth m. The route reader $\mathrm{sh}_m : \mathcal{S}_m \to \mathcal{R}_m$ and the restriction $\mathrm{tr}_{n,m}$ satisfy

$$\mathrm{tr}_{n,m}\,\mathrm{sh}_n = \mathrm{sh}_m\,\rho_{n,m}. \tag{90.62}$$

Thus, the reader transmits the restrictions of the state to its histories. The route of x is the family $\gamma_x = (\gamma_x^{[m]})_m$, where $\gamma_x^{[m]} = \mathrm{sh}_m(x_m)$.

Proposition 90.29 (Compatibility of the published history)**.** *For every extension* (90.61)*, its finite histories satisfy* $\mathrm{tr}_{n,m}(\gamma_x^{[n]}) = \gamma_x^{[m]}$.

Proof. Applying (90.62) to the state x_n gives

$$\mathrm{tr}_{n,m}(\gamma_x^{[n]}) = \mathrm{sh}_m(\rho_{n,m}x_n) = \mathrm{sh}_m(x_m) = \gamma_x^{[m]}.$$

The second equality uses precisely the inverse-limit condition. □

The proposition establishes descent from the extension to the history. Its content does not include injectivity of the reader: two extensions may publish the same finite history and retain different memories. Therefore, when reusing a route, its source state is retained, instead of reconstructing it from a digit or a visible word.

Over each history $\gamma_x^{[m]}$, consider the discrete bundle $\mathcal{B}_{\gamma_x^{[m]}}$ of material states of the declared representation. Let $\mathcal{E}_m(x) = \Gamma(\mathcal{B}_{\gamma_x^{[m]}})$ be its spaces of sections, with restrictions $p_{n,m} : \mathcal{E}_n(x) \to \mathcal{E}_m(x)$ compatible with those of the state. A persistent section is a family

$$s = (s_m)_{m\geq m_0}, \qquad s_m \in \mathcal{E}_m(x), \qquad p_{n,m}s_n = s_m \quad (n \geq m \geq m_0). \tag{90.63}$$

The initial depth m_0 allows a state to be described from any cut beyond which its representation is defined. Prior information entering its observables remains in the record transported by the extension.

90.14.2 Identity under refinement and equivalence of representations

Fix the internal symmetry groups G_m acting on the material fibres and preserving the declared observables. Two persistent sections s and s' represent the same material identity when, from some level m_1 onward, there exists a family $g_m \in G_m$ such that

$$s'_m = g_m s_m, \qquad p_{n,m} g_n = g_m p_{n,m}, \tag{90.64}$$

and the observable characters of the genealogical record coincide. The admissible symmetries are fixed before forming the quotient; their action transports sheet, orientation, memory, and representation according to the corresponding laws.

Proposition 90.30 (Compatible equivalence of sections)**.** *The relation* (90.64)*, on families carrying the same types of representation and observables, is an equivalence relation. Its classes are independent of removing a finite number of initial levels, provided their transported genealogical information is preserved.*

Proof. The identity of each G_m gives reflexivity. The inverse of a compatible family is again compatible: from $p_{n,m} g_n = g_m p_{n,m}$ one deduces $p_{n,m} g_n^{-1} = g_m^{-1} p_{n,m}$. This gives symmetry. If $s' = gs$ and $s'' = hs'$, from the greater of the two initial levels we have $s''_m = h_m g_m s_m$ and $p_{n,m} h_n g_n = h_m g_m p_{n,m}$. Composition also preserves the observables and proves transitivity. All these relations are formulated on a common tail; changing the starting point within that tail preserves the class. The final assertion concerns a change of presentation, not erasure of state memory. □

Definition 90.31 (Persistent material particle)**.** An HMT–MD particle is a class $[s]_{\mathrm{pers}}$ of sections (90.63) under (90.64), accompanied by its extension and provenance record, admitting an irreducible material representation or a minimal invariant block and a stable spectral output under the specified coupling.

The definition gathers conditions at different levels. Prolongation and the record belong to the HMT state. Representation and coupling belong to its material realisation. Spectral stability is predicated of the operator and domain used by that coupling. This organisation permits identity, charge, spin, and mass to be studied together without turning one particular observable into the definition of all the others.

The nonadic return illustrates the distinction between identity and instantaneous state. For the phase reader g and memory record $\mathcal{B}$, the following can coexist:

$$g(k+9) = g(k), \qquad p_{k+9,k}(s_{k+9}) = s_k, \qquad \mathcal{B}_{k+9} \neq \mathcal{B}_k. \tag{90.65}$$

The first equality is periodic; the second expresses persistence; the third records advancement. The phase return belongs to the history of the same material identity, while the state preserves the fact that an additional circuit has been completed.

90.14.3 The species as a fibre: scope of the finite atlas

The atlas constructed by the APP–TRIT–TPK operations has support $C_{81} = \{1, \dots, 9\}^2$. Its four orientations per cell form the domain of 324 oriented routes. The register map $\mathcal{R}$ distinguishes 56 route families, while the internal classifier

$$q : C_{81} \longrightarrow \Sigma_{13} \tag{90.66}$$

brings together 13 family and level types. These censuses and their rules are developed in the body devoted to the atlas; here we specify which object they transmit to the definition of a particle.

For $y \in \Sigma_{13}$, the fibre $q^{-1}(y)$ preserves all its cells and records. Once the internal ordering of each fibre of $\mathcal{R}$ is fixed, let $k(c)$ be the rank of the cell within it. Its finite presentation is

$$\mathfrak{S}_y^{\mathrm{atlas}} = \{(\mathcal{R}(c), k(c)) : q(c) = y\}. \tag{90.67}$$

The rank is added to distinguish cells having the same family register; it does not select a mass. The pair $(\mathcal{R}(c), k(c))$ recovers the cell within the ordered chart because the second datum identifies its position in the fibre of the first.

If $\pi_{81} : \Omega^{\mathrm{surv}}_{\mathrm{HMT}} \to C_{81}$ is the cellular reader, the lift of the species is

$$\widetilde{\mathfrak{S}}_y = \{x \in \Omega^{\mathrm{surv}}_{\mathrm{HMT}} : q(\pi_{81}x) = y\}. \tag{90.68}$$

This preimage contains extensions, whereas (90.67) contains finite presentations. The construction and domain of the reader π_{81} form part of the passage between them. A particular particle is realised as a persistent section within the corresponding enriched multisection.

Theorem 90.32 (Central fixed point and equivariant selection)**.** *Let $\rho_c(r, s) = (10 - r, 10 - s)$ be cellular inversion. In the ρ_c-stable fibres of the classifier (90.66), with trivial action on the label y, an equivariant point selection can take values only in cell $(5, 5)$. The electronic fibre at level zero contains this unique fixed point; no other fibre admits such a selection.*

Proof. Solving $\rho_c(r, s) = (r, s)$ gives $r = s = 5$. If $a(y) \in q^{-1}(y)$ is an equivariant selection and y is fixed, then $a(y) = a(\rho_c y) = \rho_c a(y)$. Its value must be the fixed point $(5, 5)$. The atlas places that cell in the electronic fibre at level zero, whose cardinality is one. For any other fibre, the selection condition would produce a fixed point not belonging to it. □

The consequence is constructive: the other species are presented through orbits or multisections, and a realization requiring a particular line must declare its representation and coupling. The electron provides the central rank-one case without turning all the families into copies of that case. Moreover, the cell $(5, 5)$, the raw central signature, the regional signature 555555 and the relative origin of an action line retain their own domains. Uniqueness of the point does not identify these registers with one another.

90.14.4 Construction of the mass observable from the material register

The chain used by the mass observable preserves the order

$$\text{extension} \longrightarrow \text{route} \longrightarrow \text{record} \longrightarrow \text{integer signature} \longrightarrow \text{character} \longrightarrow \text{towers} \longrightarrow \text{material operator}. \tag{90.69}$$

Each arrow retains the data needed for the next. The signature is a reading of the register; the character evaluates that signature with the internal coefficients already constructed; the towers incorporate its refinement; the operator finally acts in the representation of the fibre selected by the coupling. Its output may be a scalar, a multiplet or a spectral distribution, depending on that representation. Metrological comparison takes place after this construction.

A species is described by charge, spin representation, colour, flavour, generation, route family and material operator. These data explain why two preparations with coincident mass may retain different information, and why the same identity may publish different observables under different couplings. Identity resides in the persistent class and its admissible transports; measurement is a reading of that identity in the declared codomain.

The same hierarchy separates a persistent extension from a section with a finite horizon. If $\mathrm{Ext}_L(s) \neq \varnothing$ and $\mathrm{Ext}_{L+1}(s) = \varnothing$, the horizon L records an obstruction to prolongation. An intermediate participation of this kind in a composition does not by itself create a new asymptotic species. Similarly, a resonance requires the survival operator and its pole, as well as the identity of the section it transports. The distinction between persistence, finite prolongation, and spectral evaluation is thus preserved.

90.15 Conjugation, orientation, and return of material sections

The persistent identity of Section 90.14 admits inversion operations at different levels of its structure. Cellular inversion acts on the atlas; dodecaphase conjugation acts on the orientation record; lifting a loop acts on a fibre; a spinor rotation acts on a representation space. Specifying these domains allows the operations to be composed and explains what information is preserved in each return.

90.15.1 Dodecaphase involution and parity of observables

Let $\mathcal{T}_{12} = \{-1, 0, 1\}^{12}$ be the ambient space of tritic records with twelve positions. The admissible TPK domain is the subset satisfying the route compatibilities already constructed. The operation on the ambient space is

$$C_M : \mathcal{T}_{12} \longrightarrow \mathcal{T}_{12}, \qquad (C_M\tau)_j = -\tau_{11-j}, \quad 0 \le j < 12. \tag{90.70}$$

Restriction to admissible records uses stability of that domain under conjugation. Reversed order and sign reversal are simultaneous components of the operation.

Proposition 90.33 (Linear and quadratic parity of the record)**.** *We have $C_M^2 = I$. If $a_j = a_{11-j}$ and $L_a(\tau) = \sum_j a_j\tau_j$, then $L_a(C_M\tau) = -L_a(\tau)$. If a quadratic form $Q_b(\tau) = \sum_{j,k} b_{jk}\tau_j\tau_k$ satisfies $b_{jk} = b_{11-j,11-k}$, then $Q_b(C_M\tau) = Q_b(\tau)$.*

Proof. At each position, $[C_M(C_M\tau)]_j = -(-\tau_{11-(11-j)}) = \tau_j$. For the linear functional, substituting $k = 11 - j$ in the sum gives $L_a(C_M\tau) = -\sum_k a_{11-k}\tau_k = -L_a(\tau)$. In the quadratic expression the two sign reversals cancel, and the substitution $(r, s) = (11 - j, 11 - k)$ recovers Q_b through the symmetry of its coefficients. □

Linear orientation and memory correlations therefore have different laws. Even a composition of these observables must preserve their parities: if L_a is odd, its exponential character satisfies

$$\exp(L_a(C_M\tau)) = \exp(L_a(\tau))^{-1}. \tag{90.71}$$

The equality expresses multiplicative inversion. Invariance of a complete material operator is studied on that operator, with its channels and representation, and is established by the corresponding covariance.

Cellular inversion in Theorem 90.32 is $\rho_c : C_{81} \to C_{81}$, whereas C_M has domain (90.70). Both are involutions, but comparing them requires the route record map and its transport law. This datum prevents conjugation of a history from being replaced by inversion of an isolated atlas coordinate.

90.15.2 Lifting to antisections and preservation of mass

Conjugation is applied to the particle through two compatible maps. The base map C_m^{b} transports the state x_m to its conjugate state $\bar{x}_m$; the lift $\widetilde{C}_m : \mathscr{E}_m(x) \to \mathscr{E}_m(\bar{x})$ transports its material sections. Let t_m be the reader of the dodecaphase register and $\bar{p}_{n,m}$ the restrictions in the conjugate family. Their conditions are preservation of admissibility, involutivity and compatibility:

$$\begin{aligned} &\rho_{n,m}C_n^{\mathrm{b}} = C_m^{\mathrm{b}}\rho_{n,m}, \quad t_m(C_m^{\mathrm{b}}x_m) = C_M t_m(x_m), \\ &\bar{p}_{n,m}\widetilde{C}_n = \widetilde{C}_m p_{n,m}, \quad \widetilde{C}_{m,\bar{x}}\widetilde{C}_{m,x} = I. \end{aligned} \tag{90.72}$$

In the first row, the reader publishes the orientation register of the history. The remaining transport of the state accompanies that publication. The second row gives the lift laws; the subscripts $x, \bar{x}$ make its two source fibres explicit. If s is persistent, its antisection is $\bar{s} = (\widetilde{C}_m s_m)_m$.

Proposition 90.34 (Persistence of the antisection)**.** *Conditions (90.72) transport persistent sections to persistent sections and restore the section upon conjugating twice. If they also transport the internal symmetries by $g_m \mapsto \widetilde{C}_m g_m \widetilde{C}_m^{-1}$, they induce an involution on the material classes of Definition 90.31.*

Proof. Compatibility gives $\bar{p}_{n,m}\bar{s}_n = \widetilde{C}_m p_{n,m} s_n = \widetilde{C}_m s_m = \bar{s}_m$. Involutivity restores s. For $s'_m = g_m s_m$, their antisections are related through $\widetilde{C}_m g_m \widetilde{C}_m^{-1}$. The restriction law in (90.72) preserves compatibility of this family, which belongs to the internal groups by the condition of the statement. The construction thus descends to the classes. □

The charge representation uses the odd part of the material record. If $\mathfrak{q}$ is the stated charge character, its law is $\mathfrak{q}(\bar{s}) = -\mathfrak{q}(s)$. The elementary charge entering the expression of that coordinate on a dimensional line is the internal output already constructed; the representation is subsequently applied to the state without using a target charge to select its record.

For mass, covariance of its operator is required. Let $\widehat{M}_s$ and $\widehat{M}_{\bar{s}}$ be the self-adjoint operators of the two realisations, and let C be their unitary or antiunitary intertwiner. Its domain is transported by $C\,\mathrm{Dom}(\widehat{M}_s) = \mathrm{Dom}(\widehat{M}_{\bar{s}})$. The operator condition is

$$C\widehat{M}_s C^{-1} = \widehat{M}_{\bar{s}}. \tag{90.73}$$

Proposition 90.35 (Spectral preservation under conjugation)**.** *Under* (90.73)*, transport of an eigensection with mass $m \in \mathbb{R}$ preserves that eigenvalue. The spectral measure is transported by $E_{\bar{s}}(B) = CE_s(B)C^{-1}$ for every real Borel set B. In particular, a scalar realisation preserves mass on passage to the antisection.*

Proof. If $\widehat{M}_s\psi = m\psi$, covariance gives $\widehat{M}_{\bar{s}}C\psi = C(m\psi) = mC\psi$; the last equality also holds in the antiunitary case because m is real. The real functional calculus of self-adjoint operators transports their spectral projectors and proves the second assertion. □

In a band record the same condition can be seen in elementary form. Given a real reading $E_0(\tau)$, let $E_\pm = (E_0 \pm E_0 \circ C_M)/2$ and let $\xi \in \{+1, -1\}$ be the sheet orientation. Then

$$E_{\mathrm{band}}(\tau, \xi) = E_+(\tau) + \xi E_-(\tau), \qquad E_{\mathrm{band}}(C_M\tau, -\xi) = E_{\mathrm{band}}(\tau, \xi). \tag{90.74}$$

The equality follows from the evenness of E_+ and oddness of E_-. It explains how band energy can be preserved by transporting record and sheet simultaneously; its identification with the mass of a particular realisation uses (90.73).

The electronic record $\tau_e = (+,+,+,-,-,-,+,+,+,-,-,-)$ satisfies $C_M\tau_e = \tau_e$. This equality concerns the twelve-position word. The pair (τ_e, ξ) preserves an additional orientation changed by conjugation. The distinction allows the unique electronic centre and the conjugate charge realisations to be retained together; a fixed word does not become a proof of neutrality.

90.15.3 Sign holonomy and the persistence band

Let ℓ be a return loop of the material reader of a surviving extension. Its circuit group is $\langle \ell \rangle \simeq \mathbb{Z}$. On this group, the sign character is specified by

$$\varepsilon : \langle \ell \rangle \longrightarrow \{+1, -1\}, \qquad \varepsilon(\ell) = -1. \tag{90.75}$$

The circuit group records how many times the loop is traversed; its type differs from the finite phase C_9. The interval bundle associated with the character is

$$\mathcal{M}_\ell = ([0,1] \times [-1,1])/\big((0,u) \sim (1,-u)\big). \tag{90.76}$$

Theorem 90.36 (Oriented return on the band)**.** *The bundle* (90.76) *is a Möbius band. Its transport over ℓ reverses the sign of the fibre and over ℓ^2 restores it. Thus a nonzero vector of that line requires two circuits for its oriented return. This preserves the distinction between return of orientation and return of the complete state.*

Proof. The endpoint relation in (90.76) is the linear map $u \mapsto -u$, with negative determinant. It gives the nonorientable real line over the circle and its corresponding interval band. Composing two transports produces $u \mapsto u$. The memory of the extension is not part of this sign quotient; its updating continues to obey TPK transport and (90.65). □

Parametrising one circuit of the base by 2π represents restoration of the cover by 4π. If the temporal reader assigns 108 steps to the relevant circuit, the oriented lift closes at 216 steps. These assignments require the stated loop and reader; they do not divide the history into two successive particles of 108 steps.

Proposition 90.37 (Decomposition of observables on the double cover)**.** *Let $p : \widetilde{X} \to X$ be a principal double cover, with involution ι. For $f \in C^0(\widetilde{X}, \mathbb{R})$,*

$$f^+ = \frac{f + f \circ \iota}{2}, \qquad f^- = \frac{f - f \circ \iota}{2}$$

give $f = f^+ + f^-$, with $f^+ \circ \iota = f^+$ and $f^- \circ \iota = -f^-$. The first part descends to X; the second represents a section of the associated sign line. On the Möbius line, every continuous global section has a zero.

Proof. The identities follow by substituting $\iota^2 = I$. The invariant part is constant on each fibre and defines a function on the quotient. The anti-invariant part satisfies the transition law of the sign representation. On the circle, a section of this line is represented by a continuous real function u on $[0, 1]$ with $u(1) = -u(0)$. If an endpoint is zero, a zero already exists; otherwise the endpoints have opposite signs, and the intermediate value theorem provides an interior zero. □

The decomposition distinguishes two classes of observables on the same cover. It represents odd orientation information and preserved even data. Applying it to a material record uses the lift (90.72); the sign character describes the transported line, not all the data of the particle.

90.15.4 Bidirectional lattice and channel conjugation

The integer angular register publishes two coordinates

$$W_+ = 6n_A + s_C, \qquad W_- = 6n_A - s_C, \qquad (n_A, s_C) \in \mathbb{Z}^2. \tag{90.77}$$

The coefficients n_A, s_C are internal route readings. The factor 6 belongs to the dodecaphase normalisation of that record.

Proposition 90.38 (Lattice index and interchange of readings)**.** *The image of* (90.77) *has index* 12 *in $\mathbb{Z}^2$ and Smith normal form* $\operatorname{diag}(1, 12)$. *It is characterised by $W_+ + W_- \equiv 0 \pmod{12}$. The operation $s_C \mapsto -s_C$ interchanges W_+ and W_-.*

Proof. The matrix of the map is $\left(\begin{smallmatrix} 6 & 1 \\ 6 & -1 \end{smallmatrix}\right)$. The greatest common divisor of its entries is 1, and its determinant is -12, giving the stated invariant factors. The inverse coordinates are $n_A = (W_+ + W_-)/12$ and $s_C = (W_+ - W_-)/2$. If the sum is divisible by 12, the two integers have the same parity and both expressions are integral. The condition is also necessary by summing (90.77). The interchange assertion is checked by substituting $-s_C$. □

In the real angular representation, the coordinates already generated, $a = A_{\mathrm{rad}}$ and $b = C^*_{\mathrm{rad}}$, produce the channels $q_\pm = \exp[-(a \pm b)]$. In the domain $a > |b|$, both belong to $(0, 1)$. Let $R^* = R$, $R^2 = I$ be the sheet grading and C a unitary interchange with $CRC^{-1} = -R$. For $T(b) = \exp[-(aI + bR)]$ we obtain

$$CT(b)C^{-1} = T(-b), \qquad CP_\pm C^{-1} = P_\mp, \quad P_\pm = (I \pm R)/2. \tag{90.78}$$

Indeed, conjugation transforms the exponent and each term of its convergent series. This proof transmits the interchange to the channels. The integer lattice and the real operator have distinct domains and publish the same interchange operation through their declared reading maps.

90.15.5 Spinor representation of the electronic block

The three-dimensional APP construction of the addition and multiplication projectors selects a principal electronic plane through the tritic mode $(1,-1,0)^3$. Its derivation and the evaluation of the projectors are included among the antecedents of the present article. In an orthonormal basis of that plane, their restrictions are

$$P=\begin{pmatrix}1&0\\0&0\end{pmatrix},\qquad Q=\begin{pmatrix}1/4&\sqrt{3}/4\\\sqrt{3}/4&3/4\end{pmatrix},\qquad S=2P-I,\quad J=\frac{4}{\sqrt{3}}[P,Q]. \tag{90.79}$$

This representation receives the two constructed projectors and preserves their orientation. Multiplication gives $S^*=S$, $J^*=-J$, $S^2=I$, $J^2=-I$, and $SJ=-JS$. Specifically, $S=\operatorname{diag}(1,-1)$ and $J=\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$.

Let $\mathcal{S}_e=E_e\otimes_{\mathbb{R}}\mathbb{C}$ be the complexification of the real plane. The scalar unit i belongs to the field of this representation; J remains the real endomorphism arising from the projectors.

Proposition 90.39 (Hermitian triple and representation of rotations)**.** *In $\mathcal{S}_e$, define*

$$\sigma_1=SJ,\qquad \sigma_2=-iJ,\qquad \sigma_3=S. \tag{90.80}$$

These operators are Hermitian and traceless, and satisfy

$$\sigma_a\sigma_b=\delta_{ab}I+i\sum_c\epsilon_{abc}\sigma_c,\qquad L_a=\sigma_a/2,\qquad [L_a,L_b]=i\sum_c\epsilon_{abc}L_c,\quad \sum_a L_a^2=\tfrac{3}{4}I. \tag{90.81}$$

They constitute the irreducible spin-$1/2$ representation on the electronic block.

Proof. The relations of S,J give $(SJ)^*=SJ$, $(-iJ)^*=-iJ$, and $\sigma_a^2=I$. The cyclic products are $(SJ)(-iJ)=iS$, $(-iJ)S=iSJ$, and $S(SJ)=J=i(-iJ)$; reversing the order reverses the sign. This proves the product identity and the commutators. In the basis of (90.79), the three matrices are

$$\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Their trace is zero and, together with I, they generate $M_2(\mathbb{C})$. A subspace invariant under all three is invariant under that entire algebra and can only be 0 or $\mathcal{S}_e$. Finally, summing $L_a^2=I/4$ gives the value $3I/4$ of the quadratic operator. □

Recognition of this triple as the Pauli matrices follows (90.79). The norm and product $\langle X,Y\rangle=\frac{1}{2}\operatorname{tr}(XY)$ on the real space of traceless Hermitian matrices give its space of directions. For $n\in\mathbb{R}^3$, $|n|=1$, let

$$H_e(n)=\sum_a n_a\sigma_a,\qquad h_e(n)=\tfrac{1}{2}H_e(n),\qquad \Pi_\pm(n)=\tfrac{1}{2}(I\pm H_e(n)). \tag{90.82}$$

Proposition 90.40 (Directional decomposition and double return)**.** *The operators $\Pi_\pm(n)$ are rank-one orthogonal projectors and $h_e(n)\Pi_\pm(n)=\pm\frac{1}{2}\Pi_\pm(n)$. The rotation group around n is*

$$U_n(\theta)=e^{-i\theta H_e(n)/2}=\cos(\theta/2)I-i\sin(\theta/2)H_e(n),\qquad U_n(2\pi)=-I,\quad U_n(4\pi)=I. \tag{90.83}$$

Proof. The antisymmetric part of (90.81) vanishes when contracted with n_an_b, so $H_e(n)^2=I$. Idempotence, orthogonality, and the sum $\Pi_+ + \Pi_- = I$ follow. They are Hermitian with trace one, hence their

rank is one. Multiplication by $H_e(n)/2$ gives the eigenvalues. Separating even and odd powers of the exponential produces (90.83) and its group law. Angular normalisation is checked by

$$U_n(\theta)H_e(v)U_n(\theta)^* = H_e\big(v\cos\theta + (n\times v)\sin\theta + n(n\cdot v)(1-\cos\theta)\big),$$

which follows from multiplication using the product identity of the triple. The induced action on directions is a rotation through angle θ; the spinor lift carries its half-angle. □

If n is realised as the direction of propagation, $h_e(n)$ is dimensionless helicity. Reversal of that direction satisfies $H_e(-n) = -H_e(n)$ and $\Pi_\pm(-n) = \Pi_\mp(n)$. This operation changes the directional labels; charge conjugation transports the material record through (90.72). Chirality is defined through the relativistic grading appropriate to the representation and its projectors, which differ from (90.82).

The scalar electronic evaluation acts as $\varepsilon_e^{\beta} I$ on $\mathcal{S}_e$ and commutes with the triple and with $\Pi_\pm(n)$. Rotational information preserves the structure of that evaluation without introducing another factor into mass. The Möbius band, in turn, transports a real line around a loop, and nonadic holonomy transports phase and memory. The three returns can enter the same realisation; their domains and intertwiners determine the precise composition.

90.16 Classification of persistent sections and their internal observables

Classification begins with the support on which transport acts. Physical names are interpreted after its invariants have been constructed. This priority distinguishes a position, a history, and a species: the position belongs to the finite atlas; the history preserves the transitions producing it; the persistence type gathers histories compatible with the same classification. An evaluated mass is a subsequent reading of that object.

90.16.1 Parity, depth, and multisections

On the positional copy of APP, consider

$$I_9 = \{1,\dots,9\}, \qquad C = I_9 \times I_9.$$

The ordered pair preserves the two axes. Define the parity classifier

$$f(r,c) = \begin{cases} \ell, & r,c \text{ odd},\\ v, & r \text{ odd},\ c \text{ even},\\ d, & r \text{ even},\ c \text{ odd},\\ u, & r,c \text{ pairs}, \end{cases} \qquad g(r,c) = \max\{|r-5|,|c-5|\}.$$

The symbols of the first map initially name internal classes. The second measures combinatorial depth relative to the centre. Subsequent association with physical sectors must preserve these definitions.

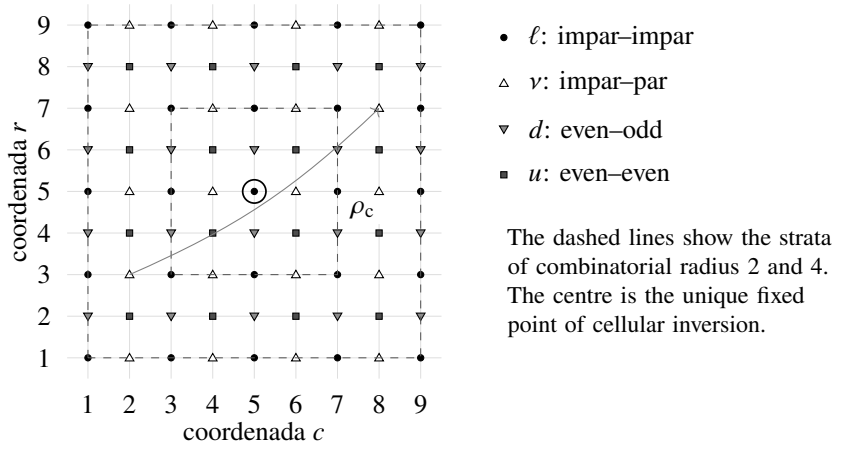

Figure 90.2: Classification on the positional atlas. The marks distinguish the four internal parity classes, preceding their physical realisations. Depth is measured by $g(r, c) = \max(|r - 5|, |c - 5|)$. The arrow illustrates $(2, 3) \mapsto (8, 7)$ under cellular inversion; it does not represent a dynamic trajectory or a change of flavour. The central circle marks $(5, 5)$, at depth zero.

Definition 90.41 (Family and depth multisection)**.** For every realised pair $y = (f, g)$, define

$$\mathfrak{S}_y = \{(r, c) \in C : (f(r, c), g(r, c)) = y\}.$$

Its lift to persistent states is the preimage under the projection onto the atlas, preserving the sheets, orientations, and memory of the extension.

Proposition 90.42 (Census of the multisections)**.** *The atlas contains* 81 *cells and exactly* 13 *nonempty multisections. Their distribution is*

class	*depths*	*cardinals*	*total*
ℓ	$0, 2, 4$	$1, 8, 16$	25
ν	$1, 2, 3, 4$	$2, 4, 6, 8$	20
d	$1, 2, 3, 4$	$2, 4, 6, 8$	20
u	$1, 3$	$4, 12$	16

Proof. In I_9 there are 5 odd and 4 even numbers. The four classes have cardinalities $25, 20, 20, 16$. For the odd–odd class, the centred squares of radii $0, 2, 4$ contain $1, 9, 25$ points; the differences are $1, 8, 16$. For odd–even, the cumulative rectangles at radii $1, 2, 3, 4$ contain $2, 6, 12, 20$ points, whose differences are $2, 4, 6, 8$. Interchanging the axes proves the even–odd case. In even–even there are 4 points through radius 1 and 16 through radius 3, so the strata have $4, 12$ points. The sets are disjoint, and their union is C. □

This census explains the meaning of each cardinality before any particle table. Depth g is not by itself identified with the index of a physical generation either: that identification uses the realisation maps of the corresponding sector.

90.16.2 Central conjugation and selection of a cell

Cellular inversion is

$$\rho_c(r, c) = (10 - r, 10 - c).$$

It preserves parity and depth and therefore acts within every multisection. Its unique fixed point satisfies $2r = 2c = 10$: it is $(5, 5)$. The remaining 80 cells are grouped into 40 pairs. There are thus 41 orbits, only one of which is a singleton.

Proposition 90.43 (Obstruction to noncentral point selection)**.** *If a cell selector is required to depend only on the family–depth pair and to be equivariant for ρ_{c}, it can exist only in the central multisection.*

Proof. Inversion acts trivially on the pair y. Equivariance of $a(y) \in \mathfrak{S}_y$ requires $a(y) = a(\rho_{\mathrm{c}} y) = \rho_{\mathrm{c}} a(y)$. Thus $a(y)$ would have to be the unique fixed point $(5, 5)$. In the central multisection, this is precisely the available choice. □

The consequence is structural. The treatment of the electron by means of a fiber of rank 1 does not authorize treating all the other families in this way. Outside the center, the orbit, the multisection and the orientations it preserves belong to the object being evaluated.

90.16.3 Classification of routes and positional memory

The chronological chart assigns to each cell the sextuple

$$\mathcal{R}(r, c) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta, \tau_{12})_{r,c}.$$

The five integer coordinates come from the oriented record; the last preserves the dodecaphasic word. Two cells belong to the same route family when these six readings coincide. This is a quotient different from the family–depth quotient.

In the documented finite census of this chart, 56 families appear. The size histogram is

$$41 \times 1, \quad 10 \times 2, \quad 2 \times 3, \quad 1 \times 4, \quad 2 \times 5.$$

The identities

$$41 + 10 + 2 + 1 + 2 = 56, \qquad 41 + 20 + 6 + 4 + 10 = 81$$

check the number of classes and coverage of the support. Reproducing the census requires the sextuples produced by transport, not merely these two sums. The data dossier preserves the 81 rows and the 56 complete classes.

Fixing the lexicographic order in each fibre, let κ_{pos} be the rank of the cell. Then

$$(r, c) \longmapsto \big(\mathcal{R}(r, c), \kappa_{\mathrm{pos}}(r, c)\big)$$

is injective. 5 positional-memory values are required because fibres of size 5 exist; the pigeonhole principle rules out a uniform injective lift with fewer values. This memory is neither colour nor the mass exponent, although all subsequently enter the same history.

90.16.4 Residual colour, flavour, and sheets

In the 36 cells with even first coordinate, the residual-colour observable is defined by

$$\mathrm{col}(r, c) = r - c \pmod 3.$$

For each even r, the 9 values of c traverse each class 3 times. This gives the exact distribution

$$36 = 12 + 12 + 12.$$

Central inversion transforms this observable into its opposite, since

$$(10 - r) - (10 - c) = -(r - c).$$

It fixes class 0 and interchanges 1 and 2. The colour representation subsequently uses this ternary support and its operators; the number of residues does not replace construction of the representation.

Flavour distinguishes classes and realisations of the sector, whereas residual colour distinguishes positions within the corresponding ternary support. The sheet, by contrast, identifies the arithmetic evaluation entering a transition. Sheet interchange acts on a history; it is not an operation that renames flavour. This distinction allows mixing, conjugation, and mass evaluations to be formulated separately.

90.16.5 Domain of orientations of the atlas

Each cell admits $(h, v) \in \{\pm 1\}^2$, so that

$$C^{\mathrm{or}} = C \times \{\pm 1\}^2, \qquad |C^{\mathrm{or}}| = 324.$$

The canonical orientation of 81 routes and the full domain of 324 are two distinct domains. A reader can descend to a family in the first chart and cease to be constant when the four orientations are considered. Therefore, each statement about the coincidence of readers identifies its domain before publishing the census.

The finite structure therefore combines positions, route families, multisections, conjugation orbits and residual observables. None of these partitions replaces the others. The following mass development acts on their persistent lifts, retaining the information that each evaluation needs.

90.17 Generated coordinates, action, and electronic normalisation

The construction of the families uses results from the preceding stages: the regional characters, the dodecaphasic record, the action line and the electronic section. Here we gather the operations connecting them and the proofs needed to compose them. Their order is causal: the regions and their records are produced on APP through TRIT and TPK; the real evaluations are performed afterward; the choice of units enters when realizing the dimensional quantities.

The initial conditions and regional selection have been developed in the section preceding the arithmetic of histories. The domain of the incidence ledger, its counts and the reconstruction of the record are explicitly defined below. Selecting a specific family of visits and traces is an operation additional to the evaluation of a ledger: it requires fixing its multiplicities, boundary transport and coverage of the admitted traces. The reconstruction formulas proved here allow that record to be evaluated and checked; their invertibility does not in itself select the incidence family.

90.17.1 Regional readers and compatibility of evaluation

Closure, propagation, and self-scaling are three regions of the same generation. The closure region has five emissions and multiplicity $432 + 4 \cdot 144 = 1008$. In the oriented gauge of the catalogue, its emissions are

$(501, 614, 498, 169, 272, 272)$	432
$(810, 923, 870, 169, 272, 272)$	144
$(810, 983, 810, 169, 272, 272)$	144
$(870, 923, 810, 169, 272, 272)$	144
$(870, 923, 810, 418, 674, 521)$	144.

The common ternary word is 010211; the representatives of propagation and self-scaling are 201101 and 121200. The census and orientation precede the evaluations that follow.

At the five positions of the closure reader, the uniform projection $P_5 = \mathbf{1}\mathbf{1}^{\mathsf{T}}/5$, together with $P_5\lambda = \lambda$ and $\mathbf{1}^{\mathsf{T}}\lambda = 1$, determines $\lambda = \mathbf{1}/5$. This normalisation of the reader positions differs from the seed distribution given in the table. In the elliptic regime $J^2 = -I$, multiplication gives

$$(I + aJ)(I + bJ) = (1 - ab)I + (a + b)J.$$

Whenever $1 - ab \neq 0$, the composite slope is $a \oplus b = (a + b)/(1 - ab)$. Two doublings of $1/5$ give $5/12$ and $120/119$. The positive compensator $1/q$, $q > 1$, that returns the slope to one satisfies

$$\frac{120/119 - 1/q}{1 + (120/119)/q} = 1, \qquad q = 239.$$

Thus the closure character of this reader is

$$\Pi_{\mathrm{cl}} = 4\left(4\arctan\frac{1}{5} - \arctan\frac{1}{239}\right). \tag{90.84}$$

The composition rule, its compensation, and the choice of angular branch fix this value; the conventional angular identity recognises it as π.

The propagation character is realized in a commutative formal family P_t, normalized by $P_0 = 1$, $P_0' = 1$ and $P_{t+s} = P_t P_s$. If $P_t = \sum_{n\geq 0} a_n t^n$, comparison of the coefficient of $s^n t$ gives

$$(n+1)a_{n+1} = a_n, \qquad a_0 = 1.$$

Thus, $a_n = 1/n!$; publication at one unit of the parameter is $\Pi_{\mathrm{pr}} = \sum_{n\geq 0} 1/n!$, recognized as e. The unit and the sign of the generator belong to the reader: the semigroup law alone would admit other generators.

For self-scaling, TRIT selects the modes (Σ, Π, Π). Their three cyclic transitions are $\Sigma \to \Pi$, $\Pi \to \Pi$, and $\Pi \to \Sigma$. Their incidence matrix, in areal–volumetric order, is

$$F = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{90.85}$$

The positive eigenvector normalised as $(1, x)^{\mathsf{T}}$ satisfies $x = \lambda$, $1 + x = \lambda x$; hence $x^2 - x - 1 = 0$. Its positive root is the self-scaling coordinate φ. This equation recognises the character of the incidence already produced by the calendar.

Proposition 90.44 (Regional evaluation through compatible intervals)**.** *The three preceding readers admit rational intervals of arbitrarily small width. Their finite decimal prefixes are determined by refinement and are compatible under truncation.*

Proof. For $0 < x < 1$, two consecutive alternating partial sums of $\sum_{j\geq 0}(-1)^j x^{2j+1}/(2j+1)$ enclose $\arctan x$. The first omitted term bounds the error. This provides rational intervals for (90.84). If $E_n = \sum_{j=0}^{n} 1/j!$, then, for $n \geq 1$,

$$E_n < \Pi_{\mathrm{pr}} < E_n + \frac{n+2}{(n+1)(n+1)!}.$$

The bound follows by bounding successive ratios of the tail by $1/(n+2)$. Finally, F^n has entries F_{n-1}, F_n, F_{n+1}, where $F_0 = 0, F_1 = 1$ and $F_{n+1} = F_n + F_{n-1}$. The identity $F_{n+1}^2 - F_n F_{n+2} = (-1)^n$ shows that two consecutive ratios enclose φ with width $1/(F_n F_{n+1})$. Successive intervals may be intersected to preserve nestedness. After conventional recognition, the irrationality of π, e, φ ensures that no coordinate lies on a rational decimal boundary. At each finite depth, a sufficiently narrow interval lies in a unique decimal cell. Its index determines the prefix, and nestedness proves compatibility. □

90.17.2 Signed dodecaphasic chart of the full TPK state

The evolution producing the record is formulated on the complete state of the Topological Phase Kernel. Let TPKFullState denote the state space that jointly preserves APP position, TRIT regime, route, sheet, orientation, carry, boundary, memory, incidence ledger and terminal coordinates. In a canonical chart,

$$X = (X_{\mathrm{APP}}, X_{\mathrm{TRIT}}, X_{\mathrm{ruta}}, X_{\mathrm{mem}}, C_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}, X_{\partial}, \ldots).$$

The dynamics of one hundred and eight steps acts through the composition

$$X_{\mathrm{term}} = \big(\mathcal{U}_{108} \circ \cdots \circ \mathcal{U}_1\big)(X_{\mathrm{seed}}), \qquad \mathcal{U}_t = \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t, \tag{90.86}$$

where Sel_t applies the tritic phase selector, Tra_t transports sheet, route, and orientation, and Upd_t incorporates the carry and memory produced at instant t. Each factor therefore acts on the full state, and the composition preserves the genealogy of the twelve nonadic windows.

The incidence ledger of the following section is the coordinate $\mathcal{R}_{12}(X_{\mathrm{term}})$. Its evaluation by the 90/120 channels defines

$$\mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12} : \mathsf{TPKFullState} \longrightarrow \mathbb{Z}^{25}, \qquad X \longmapsto C(X) = (b^{90}(X), b^{120}(X), Q(X)).$$

The signed dodecaphase projection is

$$\mathcal{S}_{12} := \mathrm{pr}_{U_{12}^{\mathrm{sgn}}} : \mathsf{TPKFullState} \longrightarrow \mathbb{Z}^{12}.$$

On the compatible sublattice produced by the dynamics, the two charts satisfy the operator identity

$$\mathcal{S}_{12} = \Pi_H \circ \mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12} = \Pi_H \circ \mathrm{pr}_C\,. \tag{90.87}$$

Thus, the dodecaphasic signature is obtained by projection and evaluation of the same state that preserves the ledger; its domain includes the orientation and memory that enter each count. The raw projection $\rho_{108} : \mathsf{TPKFullState} \to \mathsf{CT108RawProjection}$ in contrast, designates the chart that forgets those coordinates after production. This separation of types fixes the causal order between generation, signed publication and reduced reading.

90.17.3 From temporal incidences to the dodecaphase record

Definition 90.45 (Domain of the oriented incidence ledger)**.** A ledger $\mathscr{L}$ contains a nonempty finite family of routes, their identified visits and a finite family of traces. Each route preserves one visit per instant during the first 108 instants, and the subsequent visits used by its traces. A visit preserves

$$v = (\gamma, t, i, j, s, \tau, w, \varepsilon_\partial),$$

where γ identifies the route, t its instant, $1 \le i, j \le 9$ its APP position, $s \in \{\Sigma, \Pi, 0\}$ its sheet, $\tau \in \{-1, 0, 1\}$ its tritic orientation and w its positive integer multiplicity. The incidence chart evaluates

$$n_v = \begin{cases} i + j, & s = \Sigma, \\ ij, & s = \Pi, \\ 9, & s = 0. \end{cases} \qquad r_v = 1 + ((n_v - 1) \bmod 9), \quad q_v = (n_v - r_v)/9.$$

The reading $n_v = 9$ fixes the threshold convention of this chart. For $r_v = 9$, the label ε_∂ distinguishes crown and interior; it is not obtained solely from the residue.

A trace $\theta = (v_1, \ldots, v_N)$ traverses consecutive instants of the same route. It preserves a multiplicity $u(\theta) \in \mathbb{N}_{>0}$ and a reduced length unit $\lambda(\theta) \in \mathbb{N}_{>0}$, with

$$N\lambda(\theta) = 120(1 + 3j(\theta)), \qquad j(\theta) \in \mathbb{N}_0.$$

Its channel is $\sigma(\theta) = \mathrm{sgn}(\sum_{a=1}^{N} \tau(v_a))$. The family counted in channels 120 comprises the traces of nonzero sign. The reduced length and the number of instants are related by λ; they are not identified with each other.

The definition specifies the domain of evaluation, including the data that must be transmitted to the reader. Its multiplicities and the family of traces belong to the dynamical selection of the ledger. An enumeration of the domain or a format check does not replace that selection.

Generation preserves a ledger $\mathscr{L}$ of visits and traces. The temporal chart divides it into windows $E_m = \{9m-8,\dots,9m\}$, $1 \le m \le 12$, equivalent to positions $m = \beta + 1$ of the record $\mathcal{R}_{12}$. Each window retains its subroute, orientation, boundary increment and local incidences. Each visit records APP position, arithmetic sheet, instant, multiplicity and boundary orientation. In each evaluation n_ν, the division $n_\nu = r_\nu + 9q_\nu$ is preserved, with $1 \le r_\nu \le 9$. In window m, the incidence reader publishes

$$\begin{aligned} A_m &= \sum_{\nu \in \mathscr{L}_m} w(\nu)\mathbf{1}_{\{1,3,5,7\}}(r_\nu), \\ C_m &= \sum_{j \ge 0} \big(\nu^-_{120,m}(j) - \nu^+_{120,m}(j)\big), \\ V_m &= \sum_{\nu \in \mathscr{L}_m} w(\nu)\mathbf{1}_{\{9\}}(r_\nu)\,\varepsilon_\partial(\nu). \end{aligned} \tag{90.88}$$

Here the traces in each window have finite support, $\varepsilon_\partial = +1$ on the corona and -1 in the interior, and the labels $\pm, 120$ belong to the preserved transport. The multiplicity w and the traces ν are those obtained from that transport; they are not reconstructed by selecting a value of α.

In terms of the identified traces, the second sum has the finite expression

$$C_m = -\sum_{\theta:\, t(\nu_1) \in E_m} u(\theta)\sigma(\theta).$$

Indeed, grouping by $j(\theta)$ and by sign produces $\nu^-_{120,m}(j) - \nu^+_{120,m}(j)$. This equality specifies the operation actually applied to each record; it keeps channel, multiplicity, and length separate.

Proposition 90.46 (Updating and concatenation of the ledger)**.** *Given the family of visits and traces admitted by transport, their counts are updated through integer increments. When adding a visit ν of window m, the increment of (A_m, C_m, V_m) is*

$$\big(w(\nu)\mathbf{1}_{\{1,3,5,7\}}(r_\nu),\ 0,\ w(\nu)\mathbf{1}_{\{9\}}(r_\nu)\varepsilon_\partial(\nu)\big)\,.$$

When a trace θ whose origin belongs to E_m is completed, the increment is $(0, -u(\theta)\sigma(\theta), 0)$. For two consecutive segments, the count of their concatenation is the sum of the counts of the visits and traces contained in each segment, plus that of the traces crossing their junction.

Proof. Each sum in (90.88) is indexed by visit or trace identifiers, so adding an identifier adds exactly the summand displayed. For concatenation, visits are distributed between the two segments. Traces are partitioned into those contained in the first, those contained in the second, and those crossing the junction. Additivity of integer sums proves the formula. Preserving the identifiers and pending prolongations prevents a trace from being counted twice or one that has not yet ended from being lost. Decimal reduction is applied after counting; the quotients of that reduction remain in memory. □

Decimal reduction of these three counts produces

$$z_m = 100[A_m]_{10} + 10[C_m]_{10} + [V_m]_{10}, \qquad 0 \le z_m < 1000. \tag{90.89}$$

Let $(D_3 z)_i = z_i - z_{i+3}$, $(D_4 z)_i = z_i - z_{i+4}$, with indices in $\mathbb{Z}/12\mathbb{Z}$, and $Q(z) = \sum_i z_i$. The reader preserves $\mathcal{D}(z) = (D_3 z, D_4 z, Q(z))$. Decimal reduction forgets multiples of ten in each count, whereas the original ledger preserves the visits and transports that generated them. The reading of even-code events on that same history, its decomposition $12 = 1 + 5 + 6$, and its integral inversion are developed in Proposition 91.27. That event vector does not replace the present incidence record: the domains and preserved coordinates remain distinct.

Proposition 90.47 (Incidence conjugation and decimal reduction)**.** *Let $\varrho(m) = 13 - m$. Consider a conjugation of the ledger that maps the visits and traces of window m to those of $\varrho(m)$ through bijections preserving their multiplicities. Suppose it preserves the arithmetic class and boundary label of the visits, and interchanges the positive and negative channels of the traces. Then the counts in* (90.88) *satisfy*

$$(A_m^\dagger, C_m^\dagger, V_m^\dagger) = (A_{\varrho(m)}, -C_{\varrho(m)}, V_{\varrho(m)}). \tag{90.90}$$

Writing $u_m = [C_m]_{10}$, their decimal blocks satisfy

$$z_m^\dagger = z_{\varrho(m)} + 100\mathbf{1}_{\{u_{\varrho(m)} \neq 0\}} - 20u_{\varrho(m)}. \tag{90.91}$$

Proof. The bijections preserve every summand of A_m and V_m. Interchanging the channels permutes ν^- and ν^+, thereby reversing the sign of C_m. This yields (90.90). If $C = 10q + u$, $0 \le u < 10$, Euclidean division of $-C$ gives

$$[-C]_{10} = 10\mathbf{1}_{\{u \neq 0\}} - u, \qquad \left\lfloor \frac{-C}{10} \right\rfloor = -q - \mathbf{1}_{\{u \neq 0\}}.$$

In (90.89), only the middle digit changes. Its difference is $10([-C]_{10} - [C]_{10}) = 100\mathbf{1}_{\{u \neq 0\}} - 20u$, which proves (90.91). The second identity simultaneously preserves the integer quotient of the reduction. □

The proposition specifies the action on the ledger before transporting its decimal publication. Its application to the reversal of a route also preserves the convention used to read the endpoints. Let $\gamma = (x_0, \dots, x_n)$ be an enriched route and let f be an integer observable evaluated before each advance. The inverse route $\gamma^{-1} = (x_n, \dots, x_0)$ satisfies

$$\sum_{k=0}^{n-1} f(x_{n-k}) = \sum_{k=0}^{n-1} f(x_k) + f(x_n) - f(x_0). \tag{90.92}$$

Indeed, the left-hand side sums indices $1, \dots, n$; the first term on the right sums $0, \dots, n-1$. Their difference is exactly the stated boundary term. The identity applies to each incidence observable with its preserved data. The endpoints are accounted for in the integer counts before reduction modulo ten; on a closed route the term vanishes, whereas in an open window it can change the block. Traces crossing a junction are preserved through the partition in Proposition 90.46.

The counts are thus connected to the route conjugation of section 90.15, keeping the concrete action on each incidence declared. Negation of a channel and reversal of a route are operations on the ledger; their decimal reduction is the publication just calculated.

Proposition 90.48 (Integral image and reconstruction of the record)**.** *Let $b, c \in \mathbb{Z}^{12}$, $q \in \mathbb{Z}$, with indices from zero to eleven. Define*

$$w_i = c_i - b_{i+1}, \qquad P_0 = 0, \qquad P_i = \sum_{j=0}^{i-1} w_j, \qquad T_w = \sum_{i=0}^{11} P_i.$$

There exists a unique $k \in \mathbb{Z}^{12}$ such that $D_3 k = b$, $D_4 k = c$, $Q(k) = q$, if and only if

$$b_i = w_i + w_{i+1} + w_{i+2}, \qquad \sum_i w_i = 0, \qquad q + T_w \equiv 0 \pmod{12}. \tag{90.93}$$

In that case,

$$k_i = \frac{q + T_w}{12} - P_i. \tag{90.94}$$

Proof. If k exists, then $c_i - b_{i+1} = k_i - k_{i+1}$. The cyclic sum of these differences is zero, their sum over length three is b_i, and $k_i = k_0 - P_i$. Summing the twelve coordinates gives $q = 12k_0 - T_w$, proving the

necessary conditions and the formula. Conversely, the conditions make the formula integral and cyclic. Its differences over length three are b_i, and those over length four are $w_i + b_{i+1} = c_i$. Its sum is q. The difference between two solutions has all consecutive differences zero and sum zero; it is therefore zero. □

Reconstruction is an operation on the typed image, not a retrospective selection of its arguments. In particular, $\mathcal{D}(z) = \mathcal{D}(z')$ implies $z = z'$. Since the expression of an integer of $[0, 999]$ in three digits is unique, two triples of counts publish the same record if and only if they coincide component by component modulo ten.

The signed change of representation uses the block

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad H_4^2 = 4I_4. \tag{90.95}$$

The operator H_{12} applies H_4 to the three ordered orbits $(1, 4, 7, 10)$, $(2, 5, 8, 11)$, $(3, 6, 9, 12)$. On the sublattice $\mathcal{L}_H = \{U \in \mathbb{Z}^{12} : H_{12}U \equiv 0 \pmod 4\}$, the maps

$$U = H_{12}K, \qquad K = \tfrac{1}{4}H_{12}U \tag{90.96}$$

are inverses. The congruence expresses exactly the integrality of the second map, and $H_{12}^2 = 4I$ proves both compositions.

The signed record is also calculated directly from the transverse coordinates before reconstructing K. With indices from zero to eleven, let, for $r = 0, 1, 2$,

$$S_r = \sum_{j=0}^{3} c_{r+3j}, \quad a_0 = \frac{q + 2S_0 + S_1}{3}, \quad a_1 = a_0 - S_0, \quad a_2 = a_1 - S_1, \qquad d_{r,j} = b_{r+3j}.$$

The harmonic map publishes by orbits

$$\Pi_H^{(r)}(b, c, q) = (a_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}). \tag{90.97}$$

To prove the formula on the integral image, let k be its preimage. If $s_r = \sum_j k_{r+3j}$, then $S_r = s_r - s_{r+1}$ and $q = s_0 + s_1 + s_2$, with orbit indices modulo three. Solving gives $s_r = a_r$. For the four coordinates (x_0, x_1, x_2, x_3) of an orbit, $d_j = x_j - x_{j+1}$. Their three combinations in (90.97) are respectively $x_0 + x_1 - x_2 - x_3$, $x_0 - x_1 + x_2 - x_3$, and $x_0 - x_1 - x_2 + x_3$. Together with $a_r = \sum_j x_j$, they are exactly $H_4(x_0, x_1, x_2, x_3)^{\mathsf{T}}$. The effective composition is thus $\mathscr{L} \to (b, c, q) \to \Pi_H(b, c, q) = U \to H_{12}U/4 = K$. The preimage used in this proof verifies the identity; it is not an argument of the map Π_H.

For the terminal state of (90.86), the coordinate produced before the signed publication is

$$\begin{aligned} b^{90} &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461), \\ b^{120} &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \\ Q_{\mathrm{TPK}} &= 6263. \end{aligned} \tag{90.98}$$

Substituting these twenty-five fields into (90.97), the three signed orbits are

$$\begin{aligned} U_{\mathrm{term}}^{(1)} &= (2378, -452, -668, -322), \\ U_{\mathrm{term}}^{(2)} &= (1406, 998, -204, -28), \\ U_{\mathrm{term}}^{(3)} &= (2479, -551, -371, -997). \end{aligned}$$

Interleaving by columns produces

$$U_{\mathrm{term}} = \mathcal{S}_{12}(X_{\mathrm{term}}) = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997). \tag{90.99}$$

The orbital transform $H_{12}/4$ is defined on this sublattice by the exact divisibility of every block of four. Consequently, the chain

$$X_{\mathrm{term}} \xrightarrow{\mathcal{R}_{12}} \mathscr{L}(X_{\mathrm{term}}) \xrightarrow{\mathcal{E}_{108}^{90,120}} C_{\mathrm{term}} \xrightarrow{\Pi_H} U_{\mathrm{term}} \xrightarrow{H_{12}/4} K \tag{90.100}$$

is a typed composition from the full state to its periodic seal. Propositions 90.46 and 90.48 provide, respectively, the finite update of the ledger and the integral inverse of the last publication.

The generated record provides the ordered witness

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \tag{90.101}$$

The leading zero in 058 forms part of the block reading. To check it through Proposition 90.48, its differences and sum are

$$\begin{aligned} b &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461), \\ c &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \\ q &= 6263. \end{aligned}$$

In the preceding three orbits, the signed record is

$$\begin{aligned} U^{(1)} &= (2378, -452, -668, -322), \\ U^{(2)} &= (1406, 998, -204, -28), \\ U^{(3)} &= (2479, -551, -371, -997). \end{aligned}$$

Applying $H_4/4$ to these three vectors reproduces (90.101). These identities verify the publication of the incidences; their genesis remains that of the ledger (90.88).

90.17.4 Periodic publication of K and normalization of α

Fix $B = 1000$, the phase origin, and the twelve positions. Write

$$N_K = \sum_{j=1}^{12} K_j B^{12-j}, \qquad \kappa = \frac{N_K}{B^{12} - 1}.$$

This is the exact periodic evaluation of the record. Multiplication by $B^{12} - 1$ and successive Euclidean division recover its twelve blocks, including any leading zeros. For $\rho K = (K_2, \ldots, K_{12}, K_1)$, the same concatenation gives $\kappa(\rho K) = B\kappa(K) - K_1$. Thus reversibility of the record preserves a specified phase origin.

Proposition 90.49 (Minimum period of the rational publication)**.** *The periodic prolongation of the record* (90.101) *has minimal period* 12 *blocks in base* 1000 *and* 36 *digits in base* 10*.*

Proof. The twelve components of K are distinct. Any nonzero cyclic translation smaller than twelve would identify two components if it were a period. The minimal block period is therefore twelve.

Concatenating its three-digit blocks, including 058, produces a decimal period of length 36. This expansion is canonical: it is not eventually constant at the digit 9. Let d be its minimal decimal period. Then $d \mid 36$, because the shifts preserving a periodic word form a cyclic subgroup. Grouping the digits

in threes, the minimal block period is the least $k > 0$ such that $d \mid 3k$, namely $d/\gcd(d, 3)$. No proper divisor of 36 satisfies $d/\gcd(d, 3) = 12$. It follows that $d = 36$. □

This period belongs to the rational coordinate of the record, with the phase origin fixed. The following composition also preserves the regional coordinates and the normalisation quotients of its output.

Let P_j, E_j, Φ_j be the fractional blocks of the three regional characters already constructed, and extend K_j with period twelve. The composition of records is

$$Z_j = P_j + E_j - \Phi_j - K_j, \qquad A_j = Z_j + c_{j+1} - Bc_j. \tag{90.102}$$

The integer quotient c_j transports the continuation towards the observed position. In a finite window, c_{N+1} is fixed first, and then

$$c_j = \left\lfloor \frac{Z_j + c_{j+1}}{B} \right\rfloor, \qquad A_j = Z_j + c_{j+1} - Bc_j.$$

Euclidean division uniquely determines $0 \le A_j < B$. Since $-1998 \le Z_j \le 1998$, the set $\{-2, -1, 0, 1, 2\}$ is stable for these quotients.

Theorem 90.50 (Exact composition at unlimited depth)**.** *The complete evaluation of the normalisation, in the canonical decimal convention, is*

$$\alpha_A = \pi + e - \varphi - 4 - \kappa. \tag{90.103}$$

There is a unique canonical expansion (A_j), with blocks between zero and $B - 1$, and a bounded sequence of integer quotients satisfying (90.102) *and $c_1 = 0$.*

Proof. The regional integer parts are $3, 2, 1$. By absolute convergence,

$$y := \sum_{j \ge 1} Z_j B^{-j} = (\pi - 3) + (e - 2) - (\varphi - 1) - \kappa.$$

The first blocks are $141, 718, 618, 234$, so that $Z_1 = 7$. The absolute value of the tail sum is at most $1998 \sum_{j \ge 2} B^{-j} = 0.002$; in particular, $0 < y < 1$. Take the canonical expansion $y = \sum A_j B^{-j}$, choosing the terminating expansion rather than the eventually constant $B - 1$ expansion if a boundary occurs. Set

$$c_j = \sum_{r \ge 0} (Z_{j+r} - A_{j+r}) B^{-r-1}.$$

Equality of the complete values shows that each c_j is the negative of a finite sum of integers weighted by powers of B; it is therefore an integer, and $c_1 = 0$. Separating the first term gives $Bc_j = Z_j - A_j + c_{j+1}$. The tail bounds make the sequence bounded. More precisely, the tail of Z lies in $[-2, 2]$ and the canonical tail of A in $[0, 1)$, so $-3 < c_j \le 2$. Being integral, c_j belongs to the stated set $\{-2, -1, 0, 1, 2\}$. Conversely, summing the recurrence through N gives

$$\sum_{j=1}^{N} A_j B^{-j} = \sum_{j=1}^{N} Z_j B^{-j} - c_1 + c_{N+1} B^{-N}.$$

Boundedness makes the final term vanish in the limit. Uniqueness of the canonical expansion of y determines A, and the tail formula then determines every c_j. □

The finite evaluation $\kappa_{36} = N_K / B^{12}$ differs from κ by $B^{-12}\kappa$. Furthermore, imposing $c_{13} = 0$ in a twelve-block window does not replace the quotient of the complete continuation. In the published record,

the continuation gives $c_{13} = -1$: the twelfth block is 662, whereas the window cut with zero terminal quotient gives 663. The complete evaluation begins with

$$\alpha_A = 0.00729735256928380099728510547238066299 9\ldots.$$

The period of K does not impose a period on (A_j), since (90.102) also involves the three regional records and the integer quotients.

In the following formulas, α denotes this complete positional output α_A. The analytic vacancy route has its own operator; a polynomial truncated at order nine and the root of that polynomial are not identified here with the complete operator. The mass compositions that follow do not require that approximation to be promoted to an equality between the two infinite routes.

90.17.5 Three-dimensional construction of the electronic prefactor

Let $\mathcal{A}_3 = \{1, \ldots, 9\}^3$, with uniform measure, and $\rho_9(n) = 1 + ((n-1) \bmod 9)$. On this domain act

$$\Sigma(x) = \rho_9(x_1 + x_2 + x_3), \qquad \Pi(x) = \rho_9(x_1 x_2 x_3).$$

On $\ell^2(\mathcal{A}_3)$, let P and Q be the conditional averages over the fibres of Σ and Π, respectively. Each is idempotent and self-adjoint: within each fibre it replaces a vector by its constant component and preserves that component orthogonally. They are therefore orthogonal projectors.

The additive fibres have cardinality 81. The multiplicative fibres have cardinalities

$$m = (36, 36, 108, 36, 36, 108, 36, 36, 297).$$

The joint incidence $N_{ab} = \#\{x : \Sigma(x) = a, \Pi(x) = b\}$ is $9N_0$, where

$$N_0 = \begin{pmatrix} 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 1 & 0 & 2 & 0 & 1 & 2 & 0 & 0 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 0 & 2 & 1 & 0 & 2 & 0 & 1 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 1 & 2 & 0 & 0 & 2 & 1 & 0 & 3 \end{pmatrix}. \tag{90.104}$$

This matrix is obtained by counting the 729 triples. It is also reproduced without rounding by $N_{ab} = \sum_{i,j,k=1}^{9} \mathbf{1}_{\{a\}}(\rho_9(i+j+k))\mathbf{1}_{\{b\}}(\rho_9(ijk))$. In the normalised bases of functions constant on each fibre, the intertwining has matrix $C_{ab} = N_{ab}/\sqrt{81 m_b}$.

Proposition 90.51 (Norm of the noncommutativity of the two sheets)**.** *The preceding projectors satisfy*

$$\|[P, Q]\| = \frac{\sqrt{3}}{4}. \tag{90.105}$$

Proof. On the space of the nine additive fibres, PQP has matrix $M = CC^{\mathsf{T}}$. Multiplication of the matrices in (90.104) gives eigenvalue one on the constant vector, $1/4$ on $(1, -1, 0, 1, -1, 0, 1, -1, 0)$, and $7/132$ on $(1, 1, -2, 1, 1, -2, 1, 1, -2)$. On coordinates $\{3, 6, 9\}$ with zero sum it acts by $1/18$, with multiplicity two. On each of the sets $\{1, 4, 7\}$ and $\{2, 5, 8\}$, the zero-sum vectors belong to the kernel; they give four dimensions. These orthogonal subspaces add up to the nine dimensions.

For a unit eigenvector $u \in \operatorname{ran} P$ of PQP with eigenvalue $0 < \lambda < 1$, the vector $v = (Qu - \lambda u)/\sqrt{\lambda(1-\lambda)}$ is a unit vector orthogonal to $\operatorname{ran} P$. In the basis (u, v),

$$P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad Q = \begin{pmatrix} \lambda & \sqrt{\lambda(1-\lambda)} \\ \sqrt{\lambda(1-\lambda)} & 1-\lambda \end{pmatrix}.$$

The commutator has norm $\sqrt{\lambda(1-\lambda)}$. The blocks corresponding to $\lambda = 0, 1$ commute. Among the calculated eigenvalues, the maximum is attained at $\lambda = 1/4$, since $\lambda(1-\lambda)$ is increasing on $[0, 1/2]$. Its square root is $\sqrt{3}/4$. □

In the extremal block, $S = 2P - I$ and $J = 4[P, Q]/\sqrt{3}$ satisfy

$$S^2 = I, \qquad J^2 = -I, \qquad SJ = -JS.$$

The four matrices I, S, J, SJ are linearly independent, so they realise $\mathrm{Cl}_{1,1} \simeq M_2(\mathbb{R})$. The elements $n_\pm = (S \pm J)/2$ satisfy $n_\pm^2 = 0$ and $n_+ n_- + n_- n_+ = I$, by direct expansion. The prefactor of the electronic equation thus arises from two evaluations of APP in dimension three and their commutator, before any reference mass.

90.17.6 Boundary reading and basal electronic composition

The incidence (90.85) has positive eigenvector $r = (1, \varphi)^{\mathsf{T}}$. The normalisation $p_{ij} = F_{ij} r_j / (\varphi r_i)$ produces

$$P_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}, \qquad \mu = \frac{(1, \varphi^2)}{1 + \varphi^2}.$$

The identity $\varphi^{-2} + \varphi^{-1} = 1$ proves that the rows sum to one. Since F is symmetric, weights proportional to r_i^2 satisfy detailed balance; hence $\mu P_{\mathrm{av}} = \mu$. The incidence is irreducible and has a self-loop, so this stationary distribution is unique. The chronological frequency $(1/3, 2/3)$ counts the three instants of the calendar; μ weights its admissible trajectories with memory one.

The operator preserving the sheets, fixing the volumetric normalisation at one, and marking the areal sheet by the closure character is $D_\pi = \mathrm{diag}(\pi, 1)$. By induction,

$$F^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}.$$

The ratio of marked diagonal returns is

$$\Theta_n = \pi \frac{F_{n-1}}{F_{n+1}} \longrightarrow \frac{\pi}{\varphi^2}.$$

Convergence follows from the dominant eigenvalue φ, or from the consecutive quotients already bounded. The reader $\mathcal{R}(x, y) = x/y^2$, under interchange of arguments, also publishes

$$\rho_A = \frac{\pi}{\varphi^2}, \qquad \rho_E = \frac{\varphi}{\pi^2}, \qquad \varphi^3 \rho_A^2 \rho_E = 1. \tag{90.106}$$

The last equality is checked by multiplying the fractions. It relates two orientations of the same reader and does not select the remaining coefficients of the electronic equation.

The typed central return has length 27, with support $\mathbb{Z}/9\mathbb{Z} \times \mathbb{F}_3$. In the fixed regional gauge, the five microfibre positions are inserted as $(4, 0), (5, 0), (6, 0), (6, 1), (6, 2)$. The complement has $27 - 5 = 22$ positions. Its incidence with the three tritic phase states has $5 \cdot 3 = 15$ pairs. This yields the integers -22 and 15 used by the electronic reader; orientation fixes the sign of the first term. The cubic composition uses three copies of the closure coordinate, so its evaluation is α^3. The support, regional insertion, and this composition rule are distinct operational data; an isolated count does not replace their specification.

The global defect and its nonadic return are published through

$$d_4 = \frac{\pi - e\log\pi}{270}, \qquad \Delta_4 = d_4\left(1 + \frac{\pi}{729}\right). \tag{90.107}$$

The denominator 270 belongs to the corona without its closure unit; $729 = 9^3$ belongs to the cubic support. The function $f(x) = x - e\log x$ attains its minimum zero at $x = e$, since $f'(x) = 1 - e/x$ changes sign there. As $\pi \neq e$, we obtain $d_4 > 0$ and $\Delta_4 > 0$.

Definition 90.52 (Basal electronic coordinate)**.** The composition of the preceding readers is

$$\varepsilon_e^{(0)} = \frac{\sqrt{3}}{4}\left[\exp\left(\frac{\varphi}{\pi^2}\right) - 22\alpha^3\right](1 + 15\Delta_4). \tag{90.108}$$

The exponential acts on the orientation ρ_E of (90.106); the vacancy reading corrects that component and the last factor preserves the return of the global defect. For $0 < \alpha < 0.01$, all factors are positive: $\exp(\varphi/\pi^2) > 1$, $22\alpha^3 < 22 \cdot 10^{-6} < 1$ and $\Delta_4 > 0$. This is a dimensionless coordinate. Its presence in a mass chart is defined after the scale is constructed.

90.17.7 Determinantal scale and the reduced Planck constant

The local block (90.95) has determinant -16. Its Smith normal form is $\mathrm{diag}(1, 2, 2, 4)$. Indeed, the greatest common divisor of the entries is one; the minors of order two are even, and one has absolute value two. By the adjugate identity, the minors of order three have absolute value four, and the determinant has absolute value sixteen. The determinantal divisors are $1, 2, 4, 16$, whose successive ratios give the four Smith factors. Consequently,

$$G_H = \operatorname{coker} H_4 \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |G_H| = 16. \tag{90.109}$$

The local normed reader multiplies the same coordinate α once for each class of this cokernel and applies the self-scaling coordinate once. Its definition produces

$$\Sigma_H = \varphi \prod_{g \in G_H} \alpha = \varphi\alpha^{16}. \tag{90.110}$$

The order of the cokernel determines the exponent of this reader. The Smith normal form and the choice of normed reader serve distinct functions: the former does not turn an arbitrary functional of the block into expression (90.110).

Proposition 90.53 (Decade of action)**.** *The output* (90.110) *satisfies* $10^{-34} < \Sigma_H < 10^{-33}$*; its decimal valuation is* -34*.*

Proof. The regional and positional evaluations give the intervals $1.618 < \varphi < 1.619$ and $0.007297 < \alpha < 0.007298$. By positivity,

$$\frac{1618\,7297^{16}}{10^{99}} < \Sigma_H < \frac{1619\,7298^{16}}{10^{99}}.$$

The integer inequalities $1618\,7297^{16} > 10^{65}$ and $1619\,7298^{16} < 10^{66}$ prove the result without using an external action constant. □

The decade and the mantissa are publications of different stages. Before constructing the latter, the regional reader selects the persistent return of the closure microfiber. The projection $p_{\mathrm{ret}}(u_1, \ldots, u_6) = (u_4, u_5, u_6)$ applied to the five emissions of 90.17.1 produces the block $b_\pi = (169, 272, 272)$ four times and $b_\pi^- = (418, 674, 521)$ once. These multiplicities count regional rows, not the seed multiplicities $432, 144$.

Proposition 90.54 (Equivariant selector of the regional return)**.** *Among rules preserving permutations of the five regions, selecting the terminal block of maximal multiplicity, equivariant under permutations of its three positions, and retaining a position fixed by the stabiliser of the block, the selected coordinate is unique and equals* $\rho_\pi = 169$.

Proof. Projection of the five rows shows that the block of maximal multiplicity is unique and is b_π. Its stabiliser in $\mathfrak{S}_3$ interchanges the two positions of value 272 and fixes only the position of value 169. Retaining that position is compatible with any simultaneous permutation of coordinates. Equivalently, the value is expressed without choosing an initial position as $\operatorname{sing}(b_\pi) = \sum_j (b_\pi)_j - 2\,\operatorname{moda}(b_\pi) = 169$. □

Grading by length publishes a word of length n through the character $\chi_z([w]) = z^{|w|}$. Concatenation adds lengths, so $\chi_z([uv]) = \chi_z([u])\chi_z([v])$. Since the regional emissions belong to $\mathcal{U}_6$, the return impulse appears as $\rho_\pi z^6$. Degree six corresponds to the length of the emission, not to the length of a closed walk that passes through several anchors of the graph.

The prolongation weight is obtained on the determinant line of bilayer transport. For a real involution R in dimension two, with $\operatorname{tr} R = 0$, let

$$x_A = \frac{50\pi}{9}\alpha, \qquad \mathcal{T}(x_A, y) = \exp(-x_A I_2 - yR).$$

The oriented coordinate y is still formal. In an eigenbasis of R, the two entries are $e^{-x_A - y}$ and $e^{-x_A + y}$. Therefore,

$$\bigwedge^2 \mathcal{T} = \det \mathcal{T} = e^{-2x_A} = D_A.$$

Dependence on y cancels. Multiplicativity under concatenation determines the prolongation character $k \mapsto D_A^k$: any character with elementary value D_A must have that value at $k = 1 + \cdots + 1$. This construction precedes evaluation of the conjugate angular coordinate.

The fifth-order regional reader uses eigenvalues $9, 5$ of the central block $\left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$, the orbit of four positions, and the calendar of twelve windows. Its graded rule fixes

$$\begin{aligned} H_5 &= \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5, \\ D_A &= \exp\left(-\frac{100\pi\alpha}{9}\right), \\ C_\pi &= 169\alpha^6 + \frac{D_A\alpha^7}{1 - D_A\alpha}, \\ \eta_{\mathrm{ret}} &= H_5 - \frac{90}{\pi}C_\pi. \end{aligned} \tag{90.111}$$

In that rule, the quotients are $9/16 = 9/4^2$, $5/9$, $7/48 = (\operatorname{tr} B_c/2)/(4 \cdot 12)$ and $1/54 = 1944/104976$. Their assignment to degrees and signs is part of the graded reader. The integer 169 is the publication of the selector proved in proposition 90.54. Its regional datum precedes the evaluation of α; the analytic reader then composes it with the closure coordinate.

The tail of C_π has a renewal construction. The impulse $\rho_\pi z^6$ and the strict continuation belong to different summands. After recording the impulse once, the continuation is normalised by the unit of the determinant line; each new step multiplies it by D_A. The orientation of the regional gauge places this return in the compensating sector subtracted from the fifth-degree character. With formal parameter z, the rule

$$R(z) = D_A z^7 + D_A z R(z) \tag{90.112}$$

uniquely determines $R(z) = D_A z^7/(1 - D_A z)$. This can be proved by comparing coefficients or by inverting the formal series $1 - D_A z$. Normalisation of the first return, in addition to the recurrent ratio, is essential to this uniqueness. Since $0 < D_A < 1$ and $\alpha < 1$, evaluation at $z = \alpha$ converges absolutely.

Proposition 90.55 (Positivity and the action return ratio)**.** *On the generated branch,* $0 < \eta_{\mathrm{ret}} < H_5$. *The ratio*

$$R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}} \tag{90.113}$$

is positive, greater than one, and dimensionless.

Proof. The bounds $0.007 < \alpha < 0.008$ and $\varphi < 1.619$ give $\frac{1}{2}\sqrt{1000\alpha/\varphi} > 1$. The sum of the absolute values of the remaining negative terms of H_5 is less than 0.008001, so $H_5 > 0.99$. Since $D_A < 1$, $\pi > 3$, and $\alpha < 0.008$,

$$0 < \frac{90}{\pi} C_\pi < 30 \left(169(0.008)^6 + \frac{(0.008)^7}{1 - 0.008} \right) < 10^{-6}.$$

It follows that $0 < \eta_{\mathrm{ret}} < H_5$. The ratio of two action coordinates in the same basis is dimensionless and does not change when that basis is rescaled. □

Let $\mathcal{U}_S$ be a basis of the action line. The two sections, before and after the return, are

$$\hbar_{\mathrm{pre}} = H_5 \, 10^{-34} \mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}} \, 10^{-34} \mathcal{U}_S. \tag{90.114}$$

Its physical reading is the proposed construction of the reduced Planck constant, with the return section made explicit. The unit $\mathcal{U}_S \mapsto \mathrm{J\,s}$ is a subsequent metrological realization. The coefficient of Σ_H within its decade is not H_5: the determinant publishes the scale and the regional reader publishes the coordinate occupying that scale. For each section, $h = 2\pi\hbar$ expresses the action of a complete turn.

90.17.8 Angular coordinates and the clock of the absolute realisation

The angular pair uses the dimensionless coordinates already generated:

$$A_{\mathrm{deg}} = 1000\alpha, \qquad C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha), \qquad x = \frac{\pi}{180} A_{\mathrm{deg}}, \quad y = \frac{\pi}{180} C^*_{\mathrm{deg}}. \tag{90.115}$$

The first operation shifts the base-thousand expansion by one block. The second is the bidirectional publication of the regional coordinate: equivalently, $y = \pi(H_5 + \alpha)/90 - C_\pi$. This equality follows by substituting (90.111); it does not introduce an additional rule for selecting the counterangle. The chart of one turn has 360 angular units or 2π radians. Thus, for a lifted coordinate,

$$\hbar\theta_{\mathrm{rad}} = h \frac{\theta_{\mathrm{deg}}}{360}.$$

The factor 10^{-34} remains on the action line and is not inserted into the angular coordinates.

The positive channels are

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}.$$

The pair is recovered through $x = -\frac{1}{2}\log(q_+ q_-)$, $y = \frac{1}{2}\log(q_-/q_+)$. Interchanging channels preserves x and changes the sign of y. The operator with oriented projectors $P_\pm$, $T = q_+ P_+ + q_- P_-$ preserves these labels when publishing its two eigenvalues.

For an internal time unit $t_0 > 0$, the closure of 108 steps determines

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad E_{\mathrm{clk}} = \hbar_{\mathrm{ret}} \omega_0, \qquad m_{\mathrm{clk}} = \frac{E_{\mathrm{clk}}}{c_{\mathrm{int}}^2}. \tag{90.116}$$

These formulas produce dimensions of frequency, energy and mass. Velocity and length are obtained through the response of the same channels, as the following identities specify. Expressing them in seconds, joules or mass units requires the corresponding charts; those charts do not alter the channels or the electronic section normalized relative to the clock.

90.17.8.1 Identity between constitutive velocity and clock velocity

In the domain $x > |y|$, the two channels satisfy $0 < q_\pm < 1$. On the two-sheet realisation, with rank-one projectors P_+, P_-, the temporal response is defined by

$$\mathsf{V} = (I - T^{90})(I - T^{120})^{-1} = r_+P_+ + r_-P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}} > 0.$$

The inverse exists because both eigenvalues of T^{120} are less than one. The symmetric reading of the response is

$$\mathcal{E} = \log[(1 - q_+^{90})(1 - q_-^{90})] - \log[(1 - q_+^{120})(1 - q_-^{120})] = \log(r_+r_-).$$

Let u_S, u_C, u_T be positive bases of action, velocity, and time, and $u_L = u_C u_T$ the length basis. The kinematic and constitutive readings are

$$c_{\mathrm{int}} = e^{-\mathcal{E}} u_C, \qquad c_{\mathrm{vac}} = (r_+r_-)^{-1} u_C.$$

Proposition 90.56 (Common realisation of propagation and absolute mass)**.** *In the same dimensional chart,*

$$c_{\mathrm{int}} = c_{\mathrm{vac}} = \widehat{c}\, u_C, \qquad \widehat{c} = (\det \mathsf{V})^{-1} = (r_+r_-)^{-1}.$$

For $t_0 = \tau_0 u_T$, with $\tau_0 > 0$, the elementary length is

$$\ell_0 = c_{\mathrm{int}} t_0 = \tau_0 \widehat{c}\, u_L.$$

The chronological mass of (90.116) *therefore retains the form*

$$m_{\mathrm{clk}} = \frac{2\pi\, \eta_{\mathrm{ret}}\, 10^{-34}}{108\, \tau_0\, \widehat{c}^{\,2}}\, \frac{\mathcal{U}_S}{u_T u_C^2}.$$

Proof. The identity $\mathcal{E} = \log(r_+r_-)$ gives $e^{-\mathcal{E}} = (r_+r_-)^{-1}$; the rank-one property of each sheet gives $\det \mathsf{V} = r_+r_-$. Sheet interchange permutes the factors and preserves their product. Length is obtained by multiplying the same velocity by t_0. Substituting these expressions and (90.114) into (90.116) produces the mass formula. The factor $\mathcal{U}_S/(u_T u_C^2)$ has the dimension of mass; it does not enter the selection of the channels. □

For a homogeneous route of $n > 0$ transitions, the additive readings $T(\gamma) = nt_0$ and $L(\gamma) = n\ell_0$ give $L(\gamma)/T(\gamma) = c_{\mathrm{vac}}$. If the channel varies from edge to edge, their lengths are added; the ratio is then the mean velocity of those edges, not necessarily a common local velocity.

Equality of sections persists under changes of chart. If $u'_C = du_C$, $u'_T = \eta u_T$, with $d, \eta > 0$, then

$$\widehat{c}' = \widehat{c}/d, \qquad \tau'_0 = \tau_0/\eta, \qquad u'_L = d\eta u_L, \qquad \tau'_0 \widehat{c}'\, u'_L = \ell_0.$$

In particular, choosing the adapted basis $u'_C = c_{\mathrm{vac}}$ makes $\widehat{c}' = 1$, but the reader's coordinate in the internal chart remains $(r_+r_-)^{-1}$.

90.17.9 Two readers of the electronic trajectory and beta evaluation

The central trajectory starts at $(r, c) = (5, 5)$, with orientation $(h, v) = (1, 1)$. TRIT repeats the cycle $(+1, -1, 0)$. In the first regime, $r + c$ is read and then one advances $c \mapsto 1 + ((c - 1 + h) \bmod 9)$; in the second, rc is read and then one advances $r \mapsto 1 + ((r - 1 + v) \bmod 9)$; in the zero regime, 9 is read, without displacement. The class modulo three of the digital root of the reading is published. After steps $27, 54, 81$, h, v are simultaneously reversed. The publication of 108 steps preserves the complete trajectory and gives

$$a = 100000220, \quad b = 120200000, \quad \gamma_e = (a^3 b^3)^2, \quad \tau_e = (+, +, +, -, -, -, +, +, +, -, -, -). \tag{90.117}$$

The identity is checked by traversing the nine instants of each window; at the third block, inversion changes a to b, and the second traversal of 54 steps repeats the publication. The state also preserves its memory coordinates.

The first reader measures cyclic disagreements of the ternary publication:

$$D_k = \#\{t \in \mathbb{Z}/108\mathbb{Z} : \gamma_e(t) \neq \gamma_e(t + k)\}.$$

Since the published word has period 54, each disagreement appears with its translate by 54; all the D_k are even. In the half $a^3 b^3$, the disagreement count for $k = 1, 3, 4, 27, 36$ gives respectively $27, 28, 34, 24, 16$. Doubling it,

$$(D_1, D_3, D_4, D_{27}, D_{36}) = (54, 56, 68, 48, 32).$$

Therefore,

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2} \right) = (80, 54, 6). \tag{90.118}$$

The second reader acts on the orientation of the twelve windows. Define, with cyclic indices,

$$C_k = \sum_{r=0}^{11} \tau_r \tau_{r+k}, \quad A_\ell = \sum_{r=0}^{11} \left(\sum_{j=0}^{\ell-1} \tau_{r+j} \right)^2, \quad P_6 = \sum_{r=0}^{5} \tau_r \tau_{r+6}.$$

The oriented primitive integer combination cancelling the diagonal part of A_3, A_4 is $\Omega = 4A_3 - 3A_4$: its coefficients satisfy $3u + 4v = 0$, $\gcd(u, v) = 1$, and $u > 0$ is fixed. Expanding the square proves

$$A_\ell = \ell C_0 + 2 \sum_{k=1}^{\ell-1} (\ell - k) C_k, \qquad \Omega = -2C_1 - 4C_2 - 6C_3.$$

For τ_e, we obtain $C_0 = 12, C_1 = 4, C_2 = -4, C_3 = -12, A_3 = 44, A_4 = 32, P_6 = 6$. Therefore,

$$K_\Omega = (\Omega, 54, P_6) = (80, 54, 6) = K_D. \tag{90.119}$$

The second component preserves the half-return of 108 steps; it is not introduced by diagonal cancellation. Equality of the two readers has been proved on the specified central trajectory; it does not extend by definition to all the families of the atlas.

Definition 90.57 (Electronic coordinate after the return)**.** The complete electronic composition is

$$\varepsilon_e^\beta = \varepsilon_e^{(0)} R_{\mathrm{act}}^{80 - 54\alpha + 6\Delta_4}. \tag{90.120}$$

The positivity of (90.108) and (90.113) allows this power to be defined through the real logarithm. The integer triple comes interchangeably from the two central readers just calculated. The relative evaluation

preserves the reduced Planck constant through the ratio of its sections, and the absolute realization additionally uses (90.116) and the declared dimensional chart.

In the inherited tables, $\mathfrak{e}_0$ names the basal coordinate $\varepsilon_e^{(0)}$ in the chart specified there. The section $\hbar_{\mathrm{int}}$ used for a survival evaluation must be declared in the same chart: for the post-return realization of the present development it is $\hbar_{\mathrm{ret}}$. The historical rows preserve the convention declared in their source table and are not recalculated through a silent change of this section.

If $\mathcal{U}_E$ is the energy basis of the electronic evaluation, $E_e = \varepsilon_e^{\beta}\mathcal{U}_E$. When the chronological quantum is used as the basis, the coefficient is

$$\widehat{\varepsilon}_e = \varepsilon_e^{\beta}\frac{\mathcal{U}_E}{E_{\mathrm{clk}}}, \qquad E_e = \widehat{\varepsilon}_e E_{\mathrm{clk}}.$$

The equality preserves the object and transforms its coordinate. Therefore the number presented in a MeV chart cannot be multiplied without conversion by any other energy quantum. The electron preserves its structural construction when expressed relative to a chronological scale: it is not replaced by the mass of that quantum.

The metrological comparison applies to the result of this composition, with the declared version of α, action section, reader Δ_4 and units chart. In particular, d_4 and Δ_4 are not interchangeable: replacing them simultaneously in the basal factor and the exponent changes the result by the positive ratio

$$\frac{1+15\Delta_4}{1+15d_4}R_{\mathrm{act}}^{6(\Delta_4-d_4)} > 1.$$

The preserved formulas allow that difference to be located without attributing it to an external mass or selecting the trajectory anew.

90.18 Mathematical and Physical Consistency Invariants of Helical Realizations

90.18.1 Mathematical Invariants of the Helical Prolongation

The theory is refuted in the corresponding domain if any of the following facts occurs:

1. one nonadic turn erases the depth in the lift;
2. the rule $g(K+9) = g(K)$ is confused with return of the state;
3. the reader radial no preserves factores and holonomias prefijas;
4. equation (18.56) fails;
5. the action of Γ_9 does not satisfy equivariance equation (18.58);
6. the composite carry fails to satisfy equation (8.15);
7. a classical curve enters into the selection of p, Λ, C;
8. the law equation (18.50) or the inversion equation (18.51) fails in its domain;
9. the tornillo of Pell no produces equation (46.8);
10. τ, p, or κ_{F} is identified without a typed map.

90.18.2 Constitutive Conditions of the Electromagnetic and Material Realization

An electromagnetic or material realization is refuted if:

1. fails to satisfy $\mathbf{E} \perp \mathbf{B} \perp \widehat{\mathbf{k}}$, $|E| = c|B|$, or $\omega = ck$;
2. interprets Pell dilation as energetic growth without source;
3. confuses photonic helicity with fermionic spin;
4. does not preserve $J^2 = -I$ and $\star^2 = -I$ under the declared intertwiner;
5. the spiral signature is not natural on the atlas multisections;
6. a physical label retrospectively selects a cell or a curve;
7. the axis φ of the genealogy of constants is identified with the material electron without a dimensional map.

90.18.3 Stratification of Internal Theorems and Their Physical Realizations

Table 90.1: Proof status of the results.

Result	Status	Scope
Mixed APP curvature, TRIT regimes, Γ_9, nonadic helix, and Pell screw	*previous internal theorem*	Exactly in the domains defined by the preceding constructions.
Affine envelope, reader by prefixes, naturality, equivariance and inversion	*theorem of this work*	Exact for truncations, typed routes, and reversible sector; sd_4 certified.
Family L_p and five publications	*theorem of this work*	Classify the power-logarithmic family, not all curves.
chart $p = \tau_+ + \tau_-$, $a = \tau_+ - \tau_-$	*exact internal formalization*	Elementary characters of the lifted category of 2 semicoronas; the global cocycles are obtained by route summation.
Circular electromagnetic mode	*physical realization*	Restricted Maxwell solution on the phase-position bundle.
Spiral particle signature	*conditional realization*	Proposal on multisections; it remains subject to the explicit square of constancy, separation, and material naturality.
Central electron $(5, 5)$	*previous internal theorem*	Unique material anchorage fixed by cellular inversion.

90.18.4 Theorem of closure of genealogical spiral correspondences

The theory obtains a unified response to the initial intuition. An orbit is a helical sheet when depth is preserved; the bidirectional involution produces conjugate sheets of ascent and descent; the nested circles are level sections; the cylinders are families of those sections. The classical spirals are not selected as templates. They appear upon publishing in $\mathbb{R}^2$ distinct radial characters of an APP–TRIT–TPK history.

The principal result is not a new list of curves. It is a structural separation between genealogy and appearance, accompanied by a reader that preserves exactly the information that appearance can forget. The curve is placed at the end. The real line, the real plane, and Frenet geometries are publications. The phase may return while the memory advances; the circle may be intrinsic or projected; the logarithmic spiral may be the exact shadow of a spectral screw; and the same mechanism may admit Archimedean, electromagnetic, and material realizations without conflating their codomains.

Functorial classification of the radial reader and stratification of its realizations

The APP–TRIT–TPK composition generates a class of radial histories with holonomy, orientation, carry, boundary, and memory. The enriched reader is natural under truncation and equivariant under nonadic holonomy. Its Archimedean publication produces power–logarithmic curves and helical suspensions, but it is not faithful: the same figure may preserve distinct genealogies. This is the intimate dynamical structure of space that the conventional classification of curves observes only after projection.

Chapter 91

Bidirectional readers K_D y K_Ω: profiles, coincidences, towers $90/120$ and operators by multisection

91.1 Readers K_D and K_Ω: dodecaphasic profiles, path domain and spectral codomain

For each oriented route, definitions are established.

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2} \right), \qquad K_\Omega = (\Omega, 54, P_6).$$

The exact census of the 324 routes contains fourteen K_D profiles, nine K_Ω profiles, forty pairs, and eighteen coincidences, all with value $(80, 54, 6)$. These figures describe readers, not material species.

91.2 Semigroup and fiber operators

The global heights form

$$\langle 90, 120 \rangle = \{90, 120\} \cup \{30r : r \geq 6\},$$

with algebra $\Bbbk[X_{90}, Y_{120}]/(X_{90}^4 - Y_{120}^3)$. The convergent tower coefficients refine the character and define positive operators on the thirteen multisections.

91.3 Electronic construction, tower transducer and route clock

The central electron provides the rank-one case; the rest of the multisections requires the fiber operator, the coupling, and the spectral reading. The transducer separately preserves temporal length, memory, carry, and harmonic height.

91.4 Dodecaphase ledger and TPK memory $1 + 5 + 6$

The operational selector, the calendar, and the dodecaphase record fix the memory decomposition used by the mass readers. The identity $1 + 5 + 6$ belongs to the temporal state of the TPK and is not reconstructed from the spectral outputs.

91.4.1 Temporal dodecaphasic system of the TPK

91.4.1.1 Route selection operator and transport to the dimensional observable

The ternary operative phase function is

$$M_{\mathrm{ph}}(r) = \begin{cases} +1, & r \in \{1, 4, 7\}, \\ -1, & r \in \{2, 5, 8\}, \\ 0, & r \in \{3, 6, 9\}. \end{cases}$$

Its three values are the scalar inputs with which Sel_t activates, respectively, the additive cursor, the multiplicative cursor or the neutral counter. Stroboscopic sampling is

$$\mathrm{Obs}_3(a) = (a_3, a_6, a_9, \ldots).$$

The selection $\mathrm{Sel}_t[\, M_{\mathrm{ph}}(g(t)) \,]$ decides which evaluation operates; cardinal transport moves the state; and Obs_3 selects which instants are published.

Cardinal transport acts through four translations.

$$T_d(i, j) = (i, j) + \nu_d \pmod 9,$$

$$\nu_N = (-1, 0), \qquad \nu_E = (0, 1), \qquad \nu_S = (1, 0), \qquad \nu_O = (0, -1).$$

The additive and multiplicative cursors preserve separate positions and orientations. The TRIT coordinate, the function M_{ph}, the operator Sel_t, the four translations and Obs_3 are therefore objects of different types.

91.4.1.2 Dodecaphasic Calendar and Register

The topological phase kernel does not terminate at the update of a position on $\mathbb{Z}_9^2$. Its minimal temporal state preserves the order of the events, the orientation, the return, and the memory of the transitions. For an orbit of 108 steps, the ordered partition is introduced

$$E_m = \{9(m-1)+1, \dots, 9m\}, \qquad m = 1, \dots, 12,$$

and its ordered support is denoted by

$$\Gamma_{108} = E_1 \sqcup \cdots \sqcup E_{12}, \qquad 108 = 12 \cdot 9.$$

Equivalently,

$$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}, \qquad \beta(\theta) = \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12}, \qquad r(\theta) = 1 + (\theta \bmod 9).$$

The coordinate β selects one of twelve sectors, and r locates the phase within its nonadic window.

Proposition 91.1 (Non-splittable central extension of the observable clock)**.** *Writing $C_n = \mathbb{Z}/n\mathbb{Z}$, the observable calendar forms the exact sequence*

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0, \qquad \iota([b]_{12}) = [9b]_{108}, \qquad p([\theta]_{108}) = [\theta]_9.$$

For the set-theoretic section $s([r]_9) = [r]_{108}$, with $0 \le r < 9$, the gluing is given by the carry cocycle

$$c(r, r') = \left[\left\lfloor \frac{r + r'}{9} \right\rfloor\right]_{12}, \qquad s(r) + s(r') = s([r + r']_9) + \iota\big(c(r, r')\big).$$

The extension does not split. For the trivial action,

$$H^2(C_9, C_{12}) \simeq C_{12}/9C_{12} \simeq C_3,$$

and c represents the generating class [1].

Proof. The image of ι is the subgroup of multiples of nine in C_{108}, which coincides with $\ker p$; hence exactness. The cocycle identity is the Euclidean division of $r + r'$ by nine. If the central extension were split, the middle group would be isomorphic to $C_{12} \times C_9$. However,

$$\exp(C_{108}) = 108, \qquad \exp(C_{12} \times C_9) = \mathrm{mcm}(12, 9) = 36,$$

which rules it out. The cohomological identification for a cyclic group with trivial action gives $H^2(C_9, C_{12}) \simeq C_{12}/9C_{12}$, and the unit carry projects to the generator of that quotient. □

The nonsplitting types the return: nine iterations close the coordinate in C_9 and translate one unit in C_{12}; one hundred eight iterations close both coordinates of this clock. The calendar C_{108} is the temporal projection of the enriched state $\mathcal{X}^{\mathrm{enr}}_{\mathrm{TPK}}$: orientation, sheet, boundary, cylinder, genealogy, and deep memory remain in the latter and can distinguish histories with the same observable calendar.

If $g_0(\theta) = \theta \bmod 9$, then

$$g_0(\theta + 9) = g_0(\theta), \qquad \beta(\theta + 9) = \beta(\theta) + 1 \pmod{12}.$$

The witness

$$(g_0, r, \beta, 30^\circ\beta)(49) = (4, 5, 5, 150^\circ),$$
$$(g_0, r, \beta, 30^\circ\beta)(58) = (4, 5, 6, 180^\circ)$$

shows exactly what returns and what retains memory: the nonadic phase and the internal position coincide, whereas the dodecaphase sector advances by one. The regional gauge diag_c of the regions of π is not this coordinate β. Nor is there a morphism $30^\circ\beta \to h \in \langle 90, 120\rangle$ here; in particular, $150 \notin \langle 90, 120\rangle$. The pair $49/58$ is a carry witness, not a regional or spectral selector.

For an enriched history x of TPK, let τ_m be the ordered subroute over E_m, σ_m its orientation, κ_m the carry that crosses the block boundary, and Λ_m the accumulated state of the record. The object

$$\mathcal{R}_{12} = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12}$$

is the oriented dodecaphase temporal system of TPK. It is not a fourth theory added to APP, TRIT, and TPK: it is the internal temporal form by which TPK orders an orbit, preserves its returns, and publishes a reversible record. The canonical projections are distinguished

$$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathcal{R}_{12} \longrightarrow \Theta_{108}.$$

The first preserves $(\tau_m, \sigma_m, \kappa_m, \Lambda_m)$; the second publishes only the observable sequence and cannot by itself reconstruct the signed state. The enriched record is denoted by $\mathcal{R}_{12}$, and the sector rotation by C_{12}.

The observable closure of the calendar satisfies

$$F_{\mathrm{obs}}^{108} = I.$$

Positions and orientations are already restored after 54 iterations, whereas $\mathcal{R}_{12}$ distinguishes the temporal position within the twelve sectors. Here F_{obs} is the observable permutation, whereas $\mathcal{G}_9$ is the pruning within the extension and boundary relation. Monodromy is the joint property

$$g(K + 9) = g(K), \qquad v_{K+9} \neq v_K,$$

not the isolated name of the pruning. Chronological closure returns the observable calendar; nonadic return preserves the phase and changes the prefix, cylinder, and memory.

Two words of twelve components are also distinguished:

$$U_{12}^{\mathrm{cat}} = U_6 \| U_6, \qquad U_{12}^{\mathrm{sgn}} = \mathcal{H}_{12}(K).$$

The former concatenates two emissions of length six. The latter is a signed coordinate of the enriched state and is reversibly linked to K by the dodecaphase transformation $\mathcal{H}_{12}$. Neither their domains nor their functions are interchangeable; in particular, the concatenated word does not by itself construct the signed coordinate.

Definition 91.2 (Complete record of the twelve events)**.** For a route of cifras $d_1, \ldots, d_{108}$, be

$$\mathcal{D}_{\mathrm{evt}} = \{2, 4, 6, 8\}, \qquad \Sigma_{12} = (+, +, +, -, -, -, +, +, +, -, -, -).$$

Its event-oriented word is

$$e_m = \Sigma_{12}(m)\, \#\{t \in E_{m+1} : d_t \in \mathcal{D}_{\mathrm{evt}}\}, \qquad 0 \le m < 12.$$

The two semicrowns are paired through

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}, \qquad 0 \le i < 6.$$

The raw count, the five differences relative to the sixth pair, and the six antisymmetries are defined by

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5), \qquad A_6 = (a_0, \dots, a_5).$$

The full record is

$$\mathscr{L}_{12}(e) = \big(s_C, M_0, \dots, M_4, a_0, \dots, a_5\big).$$

Theorem 91.3 (Exact coordinates of the dodecaphasic memory)**.** *The map $e \mapsto \mathscr{L}_{12}(e)$ is injective on its image. Its inverse is given by*

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i \quad (0 \le i < 5),$$

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}.$$

In particular, the distribution of coordinates is

$$\boxed{1 + 5 + 6 = 12}.$$

Proof. By definition,

$$s_C = \sum_{i=0}^{4} (p_5 + M_i) + p_5 = 6p_5 + \sum_{i=0}^{4} M_i.$$

This determines p_5 and then all p_i. Adding and subtracting the equations $p_i = e_i + e_{i+6}$ and $a_i = e_i - e_{i+6}$ recovers the twelve events. Divisibility by six and the six parity conditions characterize the integral image; neither a mass nor a unit intervenes. □

Division by six is not applied during the count and is not a primitive coefficient. First the raw oriented count s_C is formed; then the record of twelve events is reconstructed; only then does $s_C/6$ appear in the character. Equivalently,

$$W_\pm = 6n_A \pm s_C$$

are integers and the lattice factorization has Smith normal form $(1, 12)$. This precedence will be mandatory in the mass law.

The integers 90 and 120 reappear later in six constructions of distinct types. To prevent the name of the cardinal from supplanting the object, the following convention is fixed from now on:

1. $\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q) : \mathbb{Z}^{12} \to \mathbb{Z}^{25}$, integral extractor that reconstructs K;
2. $D_{\mathrm{raw}}^{90,120}(q)$, diagnostic difference of two series in a fixed chart;
3. $\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8$, combinatorial inclusion of cardinalities 90 and 120;
4. $K_{6\to 8} = 12\Delta S_{90} - \Delta S_{120}$, angular functional defined after fixing channels, series, and normalization;
5. $\mathfrak{S} = \langle 90, 120 \rangle$, infinite semigroup of spectral heights;
6. $\varepsilon^{\circ}_{\mathrm{res}}$, residue of an exact angular identity, not a finite extraction from any of the five preceding objects.

The partial coincidence of indices establishes neither equality of operators, domains, codomains, nor probative force. In particular, $K_{6\to 8}$ uses two subqueues of the hierarchy but is not the complete hierarchy; and neither of those subqueues forms a block independent of the mass law.

Remark 91.4 (Canonical Separation of Temporal Objects). The notation distinguishes the oriented record $\mathcal{R}_{12}$, the observable calendar Θ_{108}, the sectorial rotation C_{12}, and the transport orbit Γ_{108}, each with its domain, its codomain, and its law of composition.

91.4.2 Complete construction of the beta electron: central route, signature, character, and governing mass

91.4.2.1 Central route of the electron and sequence of genealogical records

The electron occupies the unique center $(5, 5)$, with active orientation ++:

$$\Gamma_e = (5, 5, ++), \qquad \tau_{12} = + + + - - - + + + - - - .$$

Their displacement readers are

$$(D_1, D_3, D_4, D_{27}, D_{36}) = (54, 56, 68, 48, 32).$$

They must not be merged:

1. the raw signature $(24, 0, 12, 0, -12)$;
2. the even CT–108 signature $(-12, -4, 12, -6, 12)$;
3. the vector of twelve events;
4. the affine origin $v_e = 0$ of the relative character.

Nor should Γ_e be confused with the word $w_e = 201101$ of the reader of Euler's constant e.

91.4.2.2 Basal electron selector and transition to the beta ruling value

The internal selector, constructed without using the observed mass, closes

$$-22 = -\,|((\mathbb{Z}/9\mathbb{Z}) \times \mathbb{F}_3) \setminus \iota(R_\pi)|\,, \qquad +15 = |R_\pi \times \mathbb{F}_3|.$$

The reading of vacancies also contributes

$$V_e = \begin{pmatrix} 21 & 22 \\ 6 & 7 \end{pmatrix}, \qquad \det V_e = 15.$$

The sign negativo of 22 records deficit/cut; the positive of 15, retencion/arean oriented. The matrix is local to the electron and does not extiende as selector universal.

The basal stage is

$$e_0 = \frac{\sqrt{3}}{4}\left[\exp\!\left(\frac{\varphi}{\pi^2}\right) - 22\alpha_{\mathrm{HMT}}^3\right](1 + 15\Delta_4),$$
$$e_0 = 0.510998922488\ldots \text{ MeV}.$$

The entire genealogies are

$$22 = \frac{396}{18} = 27 - 5 = 24 - 2, \qquad 15 = \frac{270}{18} = \binom{6}{2} = \binom{6}{4}.$$

91.4.2.3 Bidirectional readers and beta

For every route,

$$K_D(\Gamma) = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2}\right),$$
$$K_\Omega(\Gamma) = (\Omega_{90,120}, 54, P_6).$$

Across the 324 routes there appear 14 profiles K_D, 9 profiles K_Ω, 40 joint pairs, and 18 coincidences. The only common value is

$$(80, 54, 6).$$

This 80 comes from the bidirectional reader of the electronic route, not from period 80 of the Euler word. Therefore

$$\kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4,$$

$$\boxed{\mathfrak{e}_e^{\beta} = e_0 R_{\mathrm{act}}^{\kappa_e} = 0.5109989506900008086082571648\ldots\ \mathrm{MeV}.}$$

This is the governing electronic output. The basal output does not replace it. Equality with the antiparticle mass proceeds from route conjugation and from the parity of the mass operator, not from adding a second numerical row.

91.4.3 Physical realization by spectral coupling

91.4.3.1 Obstruction to the equivariant punctual selection of a non-central multisection

Let $F \subset \mathcal{R}_{324}$ be a route fiber compatible with a structural class. Its linear space is

$$\mathcal{H}_F = \bigoplus_{\Gamma \in F} \mathbb{C} e_\Gamma.$$

The central character and the readers define diagonal operators:

$$\widehat{\mathcal{A}}_F^{(0)} e_\Gamma = \chi_{\mathrm{full}}(\sigma_\Gamma, \eta_\Gamma) e_\Gamma,$$
$$\widehat{K}_F^r e_\Gamma = \kappa_r(\Gamma) e_\Gamma, \qquad r \in \{D, \Omega\}.$$

The two–way correction is

$$\widehat{\mathcal{M}}_F^{\beta,r} = R_{\mathrm{act}}^{\widehat{K}_F^r/2} \widehat{\mathcal{M}}_F^{(0)} R_{\mathrm{act}}^{\widehat{K}_F^r/2}.$$

When $\dim \mathcal{H}_F > 1$, these operators generally have several eigenvalues. Choosing one because it approximates a known mass would reverse causality. Nor is it correct to require a physical name to identify a unique cell: the noncentral species resides in a representation of the fiber.

91.4.3.2 Spectral functor of the physical realization: positive coupling kernel, persistent subspace, and spectral measure

A physical preparation P provides representation data, not a mass:

$$\mathfrak{r}(P) = (q,\ j,\ \epsilon_{2\pi},\ \epsilon_{4\pi},\ \text{statistics, generation, flavor, color orbit, interaction channel}).$$

Let $\mathfrak{M}$ be a coupling compatible with that representation. A positive kernel is defined

$$K_{P,\mathfrak{M}} : F \times F \longrightarrow \mathbb{C}$$

which satisfies:

1. $K = K^*$ y $K \geq 0$;
2. $K(\Gamma, \Gamma') = 0$ if the routes violate charge, parity, colour, statistics, or the P channel;
3. K commutes with the symmetries that the coupling does not break;
4. $K(C_M\Gamma, C_M\Gamma') = \overline{K(\Gamma, \Gamma')}$ under conjugation;

5. its entries are computed from the genealogical ledger, boundary, memory, carry, and holonomy, without external magnitudes.

The coupled evolution operator is

$$\mathcal{U}_{P,\mathfrak{M}} = K_{P,\mathfrak{M}}^{1/2}\, \mathcal{U}_{\mathrm{TPK}}\, K_{P,\mathfrak{M}}^{1/2}.$$

The persistent subspace is obtained through the spectral projection onto the modes that survive return and pruning:

$$\Pi_{P,\mathfrak{M}}^{\mathrm{surv}} = \mathbf{1}_{\mathcal{S}_{\mathrm{surv}}}(\mathcal{U}_{P,\mathfrak{M}}).$$

The correct physical realization is the spectral functor.

$$\boxed{\mathcal{S}_{\mathrm{phys}}^{\mathrm{spec}}(P,\mathfrak{M}) = \left(\mathcal{H}_{P,\mathfrak{M}}^{\mathrm{surv}}, \widehat{\mathcal{M}}_{P,\mathfrak{M}}, \mu_{P,\mathfrak{M}}\right),}$$

where

$$\mathcal{H}_{P,\mathfrak{M}}^{\mathrm{surv}} = \Pi_{P,\mathfrak{M}}^{\mathrm{surv}} \mathcal{H}_F,$$
$$\widehat{\mathcal{M}}_{P,\mathfrak{M}} = \Pi_{P,\mathfrak{M}}^{\mathrm{surv}} \widehat{\mathcal{M}}_F \Pi_{P,\mathfrak{M}}^{\mathrm{surv}},$$

and $\mu_{P,\mathfrak{M}}$ is its spectral measure in the prepared state.

When the coupling is specified by an irreducible representation λ of a finite group G_P, the corresponding projector is obtained without choosing a distinguished route:

$$P_{P,\lambda} = \frac{\dim \lambda}{|G_P|} \sum_{g \in G_P} \overline{\chi_\lambda(g)}\, U(g).$$

The bidirectional output is then the compressed pair.

$$\mathbb{M}(P,\lambda) = \left(P_{P,\lambda}\widehat{\mathcal{M}}^{\beta,D}P_{P,\lambda}, P_{P,\lambda}\widehat{\mathcal{M}}^{\beta,\Omega}P_{P,\lambda}\right).$$

If both operators commute with the irreducible representation, Schur's lemma forces their scalarity on the block. If they do not commute, the correct result is the spectrum of the minimal invariant block.

91.4.3.3 Naturality of the Spectral Functor under Intertwiners of the TPK Dynamics, Coupling, and Mass Operator

If $V : F \to F'$ intertwines the TPK dynamics, the coupling kernel, and the mass operators, then

$$V\Pi_{P,\mathfrak{M}}^{\mathrm{surv}} = \Pi_{P',\mathfrak{M}'}^{\mathrm{surv}} V, \qquad V\widehat{\mathcal{M}}_{P,\mathfrak{M}} = \widehat{\mathcal{M}}_{P',\mathfrak{M}'} V.$$

By functional calculus, the spectral measure is transported by V. The output does not depend on a numbering of the cells or on the choice of a basis within an orbit. This is the condition that must replace every non-equivariant nominal selector.

91.4.3.4 Conditions for the existence of a scalar mass under the dimensional reader

A scalar mass is determined in any of the following cases:

1. the persistent subspace has rank one;
2. an irreducible representation fixes a unique spectral projector;
3. the measurement protocol defines a normalized positive state $\omega_{P,\mathfrak{M}}$ on the algebra of observables;
4. a resonance defines an isolated pole of the resolvent.

In the third case,

$$m(P, \mathfrak{M}) = \omega_{P,\mathfrak{M}}(\widehat{\mathcal{M}}_{P,\mathfrak{M}}).$$

In the absence of one of these mechanisms, the scientific output is the operator, its spectrum, and its multiplicities. That output is not incomplete: it is the object determined by the dynamics.

91.4.3.5 Finite construction of the mass kernel by means of representation, persistence, and coupling filters, followed by irreducible normalization

The kernel is obtained in four finite stages:

1. **Representation filter.** Retain the routes whose sector, charge branch, color, holonomy $2\pi/4\pi$, parity, and statistics match P.
2. **Persistence filter.** The partial order formed by class return, orbit return, cell return, prefix separation, carry debt, and decimal stability is used. The result may be a Pareto orbit; uniqueness is not imposed.
3. **Coupling filter.** Boundary incidence and the interaction channel are evaluated. Decoupled routes receive zero weight.
4. **Normalization.** On each irreducible component the trace of the kernel is normalized to one.

The oriented atlas provides all data of the first two stages. The third requires each physical realization to declare its channel; the fourth is canonical once the irreducible components have been fixed.

91.4.4 Genealogical Transducer of Towers

91.4.4.1 Pair of associated words for the same genealogical route

Each $\Gamma \in \mathcal{R}_{324}$ determines simultaneously a word temporal

$$w_\Gamma \in \mathbb{F}_3^{108}$$

and a dodecaphonic word signed

$$\tau_\Gamma \in \{-1, 0, +1\}^{12}.$$

The first preserves displacements along CT–108; the second preserves the accumulated orientation of the twelve events. The two words are linked by the same genealogical record, but they are not interchangeable. The refinement of towers reads both and also preserves the sheet, carry, winding, and return memory.

91.4.4.2 Correspondence between harmonic height and temporal length

Write

$$\mathfrak{S} = 30\langle 3, 4\rangle = \{90, 120\} \cup \{30r : r \geq 6\}.$$

For $h = 30r$, the associated temporal length is

$$\ell_h = 9r.$$

In particular,

$$90 \longleftrightarrow 27, \qquad 120 \longleftrightarrow 36, \qquad 360 \longleftrightarrow 108.$$

This correspondence does not identify the tower with time: it intertwines the height of the harmonic operator with the length of the route segment that generates it.

91.4.4.3 Temporal cycle shift reader of 108 states

We define the cyclic discrepancy

$$D_\Gamma(n) = \sum_{t=0}^{107} \mathbf{1}_{\{w_{\Gamma,t} \neq w_{\Gamma,t+n \pmod{108}}\}}.$$

The relative coefficient of the temporal branch is

$$\boxed{\eta^D_{30r}(\Gamma) = D_\Gamma(9r) - D_{\Gamma_e}(9r).}$$

Subtraction does not use a mass as an origin: it uses the central route as the affine origin of the relative character. It holds.

$$\eta^D_{90} + \eta^D_{120} = [D_\Gamma(27) + D_\Gamma(36)] - 80,$$

so that the first layer exactly prolongs the first component of the reader K_D.

91.4.4.4 Dodecaphase Accumulation Reader

For $r \geq 1$, let

$$A_\Gamma(r) = \sum_{j=0}^{11} \left(\sum_{u=0}^{r-1} \tau_{\Gamma, j+u \pmod{12}} \right)^2.$$

The relative coefficient of the oriented branch is

$$\boxed{\eta^\Omega_{30r}(\Gamma) = A_\Gamma(r) - A_{\Gamma_e}(r).}$$

Then

$$4\eta^\Omega_{90} - 3\eta^\Omega_{120} = \Omega(\tau_\Gamma) - 80,$$

so this layer extends the first component of K_Ω. The two families form the bidirectional lift

$$\mathcal{F}^{2w}_{\text{tower}} : \mathcal{R}_{324} \longrightarrow \mathcal{E}_{\mathfrak{S}} \times \mathcal{E}_{\mathfrak{S}}, \qquad \Gamma \longmapsto \big(\eta^D(\Gamma), \eta^\Omega(\Gamma)\big).$$

91.4.4.5 Finite determination of the infinite tower

The periodicity of the temporal word gives

$$D_\Gamma(9(r+12)) = D_\Gamma(9r).$$

If

$$T_\Gamma = \sum_{j=0}^{11} \tau_{\Gamma,j}, \qquad r = 12q + s, \quad 0 \leq s < 12,$$

then

$$A_\Gamma(12q + s) = A_\Gamma(s) + (12q^2 + 2qs)T_\Gamma^2.$$

Therefore, the entire tower is determined by twelve values of D_Γ, twelve values of A_Γ, and the integer T_Γ^2. The infinitude of heights does not require an infinitude of independent data.

The same formula solves the genealogical diamond of height 360. If

$$h(a,b) = 90a + 120b,$$

then

$$(a+4,b) \sim (a,b+3)$$

because $3(a+4)+4b = 3a+4(b+3)$. The genealogy (a,b) is conserved until memory and carry are applied; only afterwards does it descend to the common height.

91.4.4.6 Absolute convergence of the refined character on the towers 90/120

We have

$$|\eta_h^D| \le 108, \qquad |\eta_{30r}^\Omega| \le 24r^2.$$

Since $0 < q_+ < q_- < 1$,

$$|s_{30r}| \le 2q_-^{30r}.$$

It follows from this.

$$\sum_{h\in\mathfrak{S}} |\eta_h^D s_h| < \infty, \qquad \sum_{h\in\mathfrak{S}} |\eta_h^\Omega s_h| < \infty.$$

The refined character is well defined without truncating the tower.

91.4.4.7 Memory, carry, and cocycle

The bare coefficient is enriched by means of

$$\mathbb{F}_{\mathrm{tower}}(\Gamma)_h = \big(\eta_h^D, \eta_h^\Omega, \rho_h, \mathbf{w}_h, c_h, N_h^{\mathrm{surv}}\big),$$

where the truncated signature satisfies

$$\sigma_{\Gamma|\ell_h} = r(\rho_h) + \mathcal{D}\mathbf{w}_h, \qquad \mathcal{D} = \mathrm{diag}(2,6,2,2,4),$$

and the carry of two residues is

$$c(\rho_1,\rho_2) = \mathcal{D}^{-1}\big[r(\rho_1) + r(\rho_2) - r(\rho_1+\rho_2)\big].$$

The locality defect of a composition,

$$\delta_h(\Gamma,\Lambda) = F_h(\Gamma\star\Lambda) - F_h(\Gamma) - F_h(\Lambda),$$

obeys the cocycle identity

$$\delta_h(\Gamma,\Lambda) + \delta_h(\Gamma\star\Lambda,\Xi) = \delta_h(\Lambda,\Xi) + \delta_h(\Gamma,\Lambda\star\Xi).$$

Thus it is preserved why two paths with the same visible height can carry distinct stories.

91.4.4.8 Selection of the read by coupling

The two branches are not averaged for convenience. The physical coupling a must determine a natural transformation

$$\Pi_a : \mathcal{E}_{\mathfrak{S}} \times \mathcal{E}_{\mathfrak{S}} \longrightarrow \mathcal{E}_{\mathfrak{S}}$$

that commutes with truncations and symmetries, respects the carry cocycle, preserves the electronic origin, and is compatible with $X_{90}^4 = Y_{120}^3$. If the coupling exchanges the two readings, the only continuous, multiplicative, symmetric, and normalized closure on positive scalars is the geometric mean; in exponents,

$$L_{\mathrm{sym}} = \frac{L_D + L_\Omega}{2}.$$

In the absence of that symmetry, the output is the joint spectral measure of (L_D, L_Ω), not an arbitrary mean.

91.4.4.9 Orbit-primitive coinductive refinement

The preceding finite lift admits a prolongation. Let $\mathscr{X}_\Gamma$ be the graph of admissible extensions of the route, U_Γ its transfer operator, and R_Γ the orientation involution. The traces

$$a_n(\Gamma) = \mathrm{Tr}(R_\Gamma U_\Gamma^n)$$

and the Möbius inversion

$$p_n(\Gamma) = \frac{1}{n} \sum_{d|n} \mu(d) a_{n/d}(\Gamma)$$

separate primitive orbits. The difference

$$p_h(\Gamma) - p_h(\Gamma_e)$$

is a further refinement of the height coefficient h, not a replacement for the two finite readings.

91.4.4.10 Historical formulation via extension automaton

The signature $\mathbb{Z}^5$ does not exhaust the history of a route. For each $\Gamma \in \mathcal{R}_{324}$, the following are preserved:

- the 108 transitions of the genealogical register;
- the twenty blocks and their prefixes;
- the palabras w_6;
- the nine comparisons $K \leftrightarrow K + 9$;
- the leaf, the carry, and the winding;
- the first returns of class, orbit, cell, and kinematic state;
- the accumulated ambiguity and the stabilized decimal triads;
- the profiles K_D and K_Ω.

These data allow the construction of a tower transducer without opening the residual of a mass.

91.4.4.11 Local extension automaton

Let $\mathscr{X}_\Gamma$ be the finite set of local states compatible with the route. A state preserves

$$x = (t, g, B, p, \varepsilon, c, w),$$

where t is discrete time, g the nonadic phase, B the block, p the prefix, ε the sheet, c the carry and w the winding. An edge $x \to y$ exists when y is an admissible extension of x, respects the genealogical record and passes the pruning G_9. The table of 36.864 carry compositions provides the local addition law; the return tables fix the memory.

Let U_Γ be the normalized transfer operator of this graph and R_Γ the orientation involution. It is required that

$$U_{C_M\Gamma} = JU_\Gamma J^{-1}, \qquad R_{C_M\Gamma} = -JR_\Gamma J^{-1}.$$

91.4.4.12 Primitive cell oriented counts and construction of the electronic signature

For $n \geq 1$, the oriented trace

$$a_n(\Gamma) = \mathrm{Tr}(R_\Gamma U_\Gamma^n)$$

counts signed closed returns. The Möbius inversion separates primitive orbits:

$$p_n(\Gamma) = \frac{1}{n} \sum_{d|n} \mu(d) a_{n/d}(\Gamma).$$

The electron is taken as the affine origin of the relative corrections and is defined

$$\boxed{\eta_h(\Gamma) = p_h(\Gamma) - p_h(\Gamma_e), \qquad h \in \mathfrak{S}.}$$

Thus the map is obtained.

$$\mathcal{F}_{\mathrm{tower}} : \Gamma^{\mathrm{enr}} \longmapsto \eta(\Gamma) = (\eta_h(\Gamma))_{h\in\mathfrak{S}}.$$

There are no species-specific parameters. The same automaton, the same involution, and the same Möbius inversion act on the 324 routes.

91.4.4.13 Convergence of primitive refinement

Let $N_\Gamma = \dim \mathcal{X}_\Gamma$. If U_Γ is a contraction,

$$|a_n(\Gamma)| \leq N_\Gamma.$$

The number of divisors of n grows sublinearly, so

$$|p_n(\Gamma)| \leq \frac{N_\Gamma \tau(n)}{n}.$$

Since $0 < q_+ < q_- < 1$,

$$|s_h| \leq q_-^h + q_+^h \leq 2q_-^h.$$

By comparison,

$$\sum_{h\in\mathfrak{S}} |\eta_h(\Gamma) s_h| < \infty$$

uniformly on any finite collection of fibers. The refined character is thus well defined.

91.4.4.14 Electronic route conservation identities and uniqueness of the central fixed point

The construction must simultaneously satisfy:

1. invariance under renumbering of states;
2. covariance under leaf conjugation;
3. compatibility with direct sums of components;

4. equality upon recomputation from the genealogical register and from the certified graph;
5. conservation of the origin $\eta(\Gamma_e) = 0$;
6. absolute insensitivity to a permutation of the external mass columns;
7. determination of the tails by a bound established before comparison.

The exact representation of a given residual proves completeness of the codomain, but does not replace these seven proofs.

91.4.5 Route clock and absolute normalization

91.4.5.1 Integer returns are insufficient to distinguish species

In the atlas of 324 routes, the first cell return is 27, the kinematic return within CT–108 is 54, and the extended kinematic return is 216. Being common, these integers fix the global temporal architecture, but by themselves they cannot explain mass differences between species.

91.4.5.2 Temporal holonomy of the electronic route and memory return

The specific information resides in the holonomy of the extension operator. Let $\lambda_j(\Gamma)$ be a nontrivial eigenvalue of U_Γ on the persistent subspace. We write

$$\lambda_j(\Gamma) = r_j(\Gamma) e^{i\theta_j(\Gamma)}.$$

The associated internal frequency is

$$\omega_j(\Gamma) = \frac{\theta_j(\Gamma) + 2\pi w_j(\Gamma)}{108 t_0},$$

where the integer w_j is fixed by the recorded winding, not by a subsequent choice of branch. For a stable mode $r_j = 1$; for a resonance $r_j < 1$, and its attenuation contributes a width.

The ratio

$$\rho_{\omega,j}(\Gamma) = \frac{\omega_j(\Gamma)}{\omega_0}$$

is dimensionless and can modify mass ratios without altering the common decade -34. The energy and mass of the mode are

$$E_j(\Gamma) = \hbar_{\mathrm{ret}} \omega_j(\Gamma) \chi_{\mathrm{full}}(\Gamma) R_{\mathrm{act}}^{\kappa_j(\Gamma)},$$
$$m_j(\Gamma) = E_j(\Gamma) c_{\mathrm{int}}^{-2}.$$

This equation brings together action, clock, character, and reader without converting any of them into another. Its numerical application requires determining U_Γ, fixing the winding, and declaring the dimensional chart.

91.5 Surviving extension, dodecaphasic record, and integral signature

The trajectory that is observed does not constitute the primary object of this construction. The primary object is an extension compatible at all depths of HMT transport; a finite route is one of its readings. This distinction makes it possible to formulate unambiguously the internal chain leading from an enriched history to the action character. It also determines which information may be forgotten without altering the output and which must remain in the register.

The purpose of the section is to gather into a single argument four pieces that had been studied separately: the surviving extension, the intrinsic memory, the oriented record, and the integral signature. The terminal result of this section is the formal character

$$\Gamma_{108}^{\mathrm{enr}} \xrightarrow{L_{\mathrm{tick}}} \mathbb{Z}^5 \xrightarrow{\chi_{\mathrm{form}}} \mathrm{Fun}(\mathcal{P}, \mathbb{R}_{>0}),$$

prior both to specialization of the coefficients and to every physical unit. The first map extracts the signature from the register read; the second converts it into a positive function on the parameter space $\mathcal{P}$. Numerical specialization is performed only after the global coefficients have been constructed in the corresponding section. The metrological realization belongs to a still later dimensional chart. The map L_{tick} is the integral reader of iteration and return of the enriched chronological register.

91.5.1 Operational composition of the prolongation and torsional cocycle in the generation of the route record

The law of masses begins before the exponential formula. APP contributes a unique support of routes and its two sheets, sum and product. TRIT orients each elementary iteration. If

$$r_t = 1 + ((t-1) \bmod 9), \qquad m_t := M_{\mathrm{ph}}(r_t),$$

the phase selector M_{ph} activates

$$\mathrm{op}_t = \begin{cases} \Sigma, & m_t = +1, \\ \Pi, & m_t = -1, \\ \varnothing \quad \text{(retention or neutral counter)}, & m_t = 0. \end{cases}$$

The temporal reading may interpret the third case as threshold or present, but it does not convert it into a third arithmetic sheet. APP is not what alternates its sheets. TPK jointly transports position, orientation, sheet, phase, block, carry, prefix, cylinder, genealogy, and memory. The enriched chronological register records each transition —position, sheet, reading, carry, phase, block, and event—. The local boundary signature is subsequently derived through $\mathrm{Sig}_q(h, c, \lambda)$, and the global mass signature is extracted from the complete register; neither is reconstructed retrospectively from a mass.

The finite funnel feeding this story preserves four distinct types:

$$9^2 \cdot 9^2 \cdot 4 \cdot 4 = 104\,976 \longrightarrow 468 \text{ emissions } U_6 \longrightarrow 243 \text{ words } w_6 \hookrightarrow \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729.$$

The first figure counts initial conditions of the two-cursor engine; 468 counts decimal emissions, and 243 visible ternary words. The 324 seeds of the chronological projection Π_{108}^{cal} of a single cursor likewise do not replace the 104 976 conditions of the complete state. Each arrow therefore changes both domain and operation. The numerical equality between the ambient space of 729 words and the 729 suffixes of a filtering stage is related only through the declared ternary encoding; it does not identify the two objects.

The elevation preserves as well its causal order:

$$w_6 \xrightarrow{L_0} w_{12} \xrightarrow{L_0} w_{18} \xrightarrow{L_1} w_{24} \xrightarrow{L_1} w_{30} \longrightarrow R_{36} \longrightarrow \mathcal{G}_9 \longrightarrow \text{surviving section.}$$

The boundary R_{36} opens the prolongation. At each filtration stage, $\mathcal{G}_9$ exhaustively ranges over the 729 subcylinders and retains the unique one compatible with every horizon; the deep specular episode $3 \to 1$ is another pruning and must not be confused with that ordinary partition $729 \to 1$. The nonadic return preserves the phase but changes the block, cylinder, and memory. Neither target figures nor masses intervene in this selection. At the dimensional boundary, a particle is an enriched persistent section of the extension; the route is its observable history. Its physical name is read thereafter and does not decide which branch survives.

Before opening the dimensional chronological ledger, the same genealogy retains a published window of twenty sextets per channel and admits the first Archimedean reading of twelve decimal triads. These two witnesses belong to the prolongation of the state: they are not the twelve events of the mass ledger, nor do they replace them. The events are constructed only subsequently, by reading the route on the oriented dodecaphase system.

The dodecaphasic genealogy subsequently converts the twelve oriented events into a record and only then into the signature

$$\gamma_x \longmapsto \mathcal{L}(\gamma_x), \qquad \sigma_{\mathrm{reg}} := L_{\mathrm{tick}}(\gamma_x) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta),$$

$$\sigma_{\mathrm{reg}} \longmapsto \chi_{\mathrm{form}}(\sigma_{\mathrm{reg}}; \cdot).$$

The public coordinates $b_{120} := \nu_{120}^{\mathrm{ev}}$ and $b_\zeta := \nu_{270}$ are outputs of the chronological ledger, not metrological corrections introduced at the end. The subsequent coefficients of the tower semigroup have a different provenance:

$$N_{120} = b_{120} + \eta_{120}, \qquad b_\zeta \zeta_{270} \not\equiv \eta_{270} s_{270},$$

with $\zeta_{270} = 135\Delta_4^2$ and $s_{270} = q_-^{270} - q_+^{270}$. The tower refinement is added after the central character without erasing the provenance of any coordinate.

Three lateral outputs also retain their type. The null sector leaves the positive branch through its null reader and null chart; it is not the limit $m \to 0$ of a positive character. A virtual trajectory is a finite extension with a terminal obstruction and preserves a chronological register and carry without thereby acquiring an imaginary mass. Finally, the Witt shadow accompanies every stage of filtration and preserves the exceptional genealogy but selects neither the route nor the mass coefficients.

91.5.2 Projection of a surviving extension onto its observable route

Let $(\mathcal{S}_m, \rho_{m+1,m})_{m\geq 0}$ be the system of surviving HMT states at depth m, with truncation maps $\rho_{m+1,m} : \mathcal{S}_{m+1} \to \mathcal{S}_m$. We define

$$\Omega_{\mathrm{HMT}}^{\mathrm{surv}} := \varprojlim_m \mathcal{S}_m = \left\{ (x_m)_m : \rho_{m+1,m}(x_{m+1}) = x_m \right\}.$$

An element $x \in \Omega_{\mathrm{HMT}}^{\mathrm{surv}}$ simultaneously preserves the compatibility of all its truncations. A reading chart of depth 108 produces

$$\mathrm{sh}_{108}(x) = \gamma_x \in \Gamma_{108}^{\mathrm{enr}}.$$

The notation sh recalls that γ_x is an observable shadow: it records a sequential presentation of the state, but the state is not defined by retrospectively choosing that route.

In addition to the visible word, the enriched presentation preserves phase, sheet, orientation, boundary, antisheet memory, and the predecessors needed to evaluate the cocycles. Two words with the same five final integers may be distinct presentations because those integers are computed after applying signs and correlations.

Definition 91.5 (Intrinsic memory and read record)**.** An enriched dodecaphase extension is a compatible class of truncations. We denote by $\mathscr{M}(x)$ the intrinsic memory that those truncations preserve. Once the chart $\gamma_x = \mathrm{sh}_{108}(x)$ is fixed, its read record is

$$\mathcal{L}(\gamma_x) = \big(n_A, e_0, \ldots, e_{11}, T_\zeta, C_\zeta\big),$$

where n_A is the count of the declared action support, the e_m are the twelve oriented events, and T_ζ, C_ζ are the total torsional memory and its restriction to the corona. Compatibility requires these data to be preserved by every truncation containing the steps used in their definition.

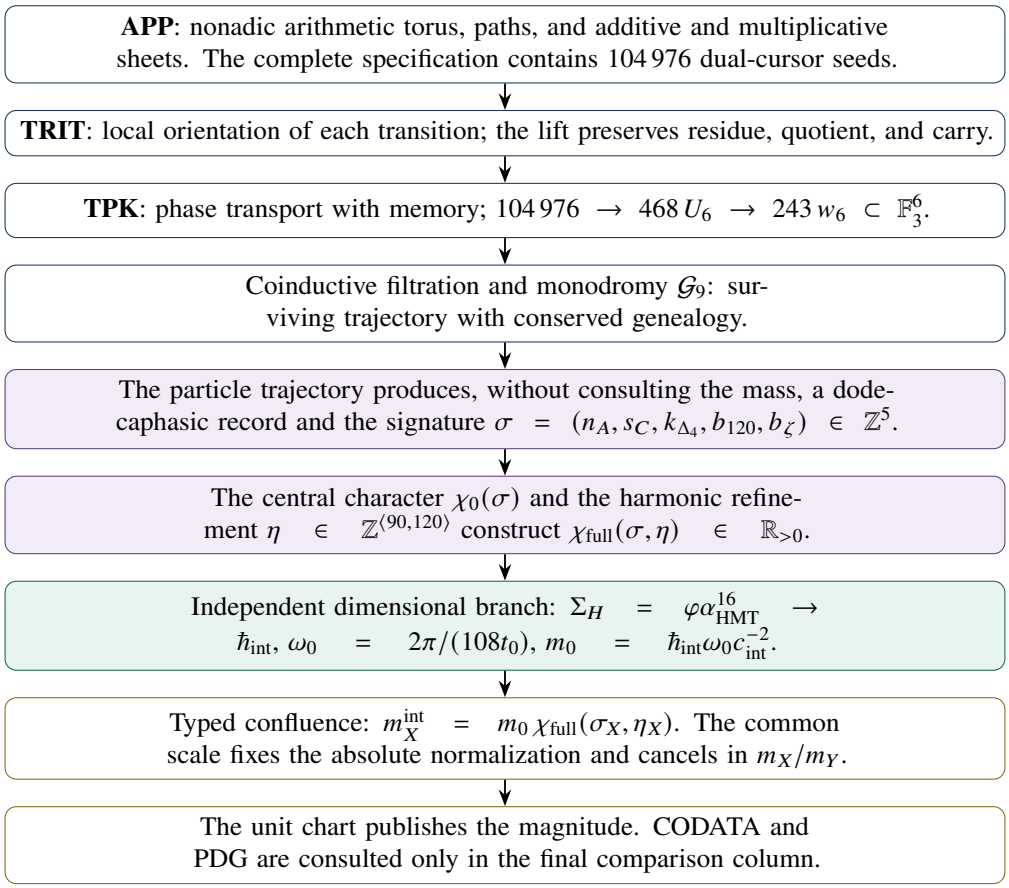

Figure 91.1: Derivation of a mass magnitude from an HMT trajectory. The character supplies a dimensionless ratio; the action scale and the clock supply the dimensional section. The external reference intervenes only after applying the chart of units.

The extension already contains the memory that the route presents; the route does not create it. Relative to the declared chart, the composition

$$x \longmapsto \gamma_x \longmapsto \mathcal{L}(\gamma_x) \longmapsto L_{\mathrm{tick}}(\gamma_x)$$

is a map. Invariance under another presentation chart would additionally require proving compatibility of the corresponding transition maps. In this precise sense, the register is not added to an already constructed particle: it is a reading of the extension's memory.

91.5.3 Integral Decomposition of 12 Events into the Sectors 1 + 5 + 6

Let $d_1, \dots, d_{108} \in \{1, \dots, 9\}$ be the word of an enriched presentation. In the parity convention used by the extractor, the support of action is

$$\mathcal{D}_{\mathrm{act}} = \{1, 3, 5, 7\}, \qquad n_A = \#\{t : d_t \in \mathcal{D}_{\mathrm{act}}\}.$$

The choice of this support is a declared part of the chart; it must not be confused with the TRIT classification of the steps. For even events one uses

$$\mathcal{D}_{\mathrm{evt}} = \{2, 4, 6, 8\}, \qquad \Sigma_{12} = (+, +, +, -, -, -, +, +, +, -, -, -).$$

The oriented event of block $m \in \{0, \dots, 11\}$ is

$$e_m = \Sigma_{12}(m)\#\{t \in \{9m + 1, \dots, 9m + 9\} : d_t \in \mathcal{D}_{\mathrm{evt}}\}.$$

Let us pair the two semicrowns by means of

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}, \qquad 0 \le i < 6.$$

We define

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5),$$

and write $M_5 = (M_0, \dots, M_4)$, $A_6 = (a_0, \dots, a_5)$.

The theorem 91.3, in the primary residence of the dodecaphasic TPK system, proves that

$$(e_0, \dots, e_{11}) \longmapsto (s_C, M_5, A_6)$$

is injective over its image and provides the inverse

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i,$$

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}.$$

Here only those coordinates are recovered to construct the character; the proof and identity $1 + 5 + 6 = 12$ are not duplicated.

The datum s_C is the one that enters the angular character. The eleven coordinates (M_5, A_6) preserve the placement of that total. Removing them before composing histories conflates different events that may produce different correlations.

91.5.4 Torsional cocycle at the step level

The event count does not by itself determine the torsional contribution. For each occurrence of nine, retain the digit preceding it and define

$$j_2(d) = \begin{cases} 0, & d = 9, \\ +1, & d \in \{2,4,6,8\}, \\ -1, & d \in \{1,3,5,7\}. \end{cases}$$

With cyclic indices in the word, let it be

$$\zeta_t = \mathbf{1}_{\{d_t=9\}} j_2(d_{t-1}),$$

$$T_\zeta = \sum_{t=1}^{108} \zeta_t, \qquad C_\zeta = \sum_{t \in \{27,54,81,108\}} \zeta_t.$$

The coordinate fuerte that acompana to Δ_4 is

$$\boxed{k_{\Delta_4} = T_\zeta - 2C_\zeta.}$$

The formula separates the accumulated drag from its oriented correction in the four corona closures. The exhaustive census shows that neither T_ζ nor C_ζ separately distinguishes all the census fibers; the ordered pair does so in the two typed conventions being compared.

The two remaining tower coordinates are calculated from the event log. Let

$$\tau_m = \operatorname{sgn}(e_m).$$

For the four step-four classes,

$$I_a = \{a, a+4, a+8\} \pmod{12}, \qquad 0 \le a < 4,$$

we define the event-weighted character

$$\nu_{120}^{\mathrm{ev}} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m \in I_a} e_m \right),$$

and the three-step autocorrelation

$$\nu_{270} = \sum_{m=0}^{11} \tau_m \tau_{(m+3) \bmod 12}.$$

The variant

$$\nu_{120}^{\mathrm{sgn}} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m \in I_a} \tau_m \right)$$

is another observable. They are not silently identified: they differ on 25 of the 81 routes of the atlas.

Definition 91.6 (Enhanced signature extractor)**.** Given the convention of events, it is defined

$$L_{\mathrm{tick}}(\gamma) = \left(n_A, s_C, k_{\Delta_4}, \nu_{120}^{\mathrm{ev}}, \nu_{270}\right) \in \mathbb{Z}^5.$$

The subscript indicates that the torsional coordinate is calculated before the predecessors of the null steps are forgotten.

This map is deterministic and consults neither masses, units, nor particle labels. It is not asserted to be linear with respect to an already projected concatenation: the signs and autocorrelations require the enriched records to be composed first.

91.6 Positive character of the signature and composition of records

91.6.1 Universal formal character

Let $\mathcal{P} = \mathbb{R}^5$, with coordinates

$$X = (X_A, X_C, X_4, X_{120}, X_{270}).$$

For $v = (n_A, s_C, k, \nu_{120}, \nu_{270}) \in \mathbb{Z}^5$, define

$$\ell_{\text{form}}(v; X) = n_A X_A + s_C X_C + k X_4 + \nu_{120} X_{120} + \nu_{270} X_{270},$$

$$\chi_{\text{form}}(v; X) = \exp\big(\ell_{\text{form}}(v; X)\big).$$

Thus, χ_{form} takes values in the multiplicative group $\mathrm{Fun}(\mathcal{P}, \mathbb{R}_{>0})$, with pointwise product. It has not yet selected global coefficients or a species.

Theorem 91.7 (Universal Character of the Signature)**.** *The map*

$$\chi_{\text{form}} : (\mathbb{Z}^5, +) \longrightarrow \big(\mathrm{Fun}(\mathcal{P}, \mathbb{R}_{>0}), \cdot\big)$$

is a homomorphism. The composition

$$\chi^{\text{form}}_{\text{route}} := \chi_{\text{form}} \circ L_{\text{tick}}$$

formally evaluates any enriched record and does not introduce a physical unit.

Proof. For every $X \in \mathcal{P}$, the exponent $\ell_{\text{form}}(\,\cdot\,; X)$ is additive on $\mathbb{Z}^5$. Therefore,

$$\chi_{\text{form}}(v + w; X) = \chi_{\text{form}}(v; X)\chi_{\text{form}}(w; X),$$

and the identity holds as equality of positive functions. □

The formal character precedes the construction of the global coefficients. This section does not yet define a numerical mass character or a unit chart.

91.6.2 Minimum internal section over the 81 cells

The finite atlas contains 81 oriented cells. When they are projected onto the chart of route family, 56 values are obtained. Denote this projection by

$$\mathcal{R} : C_9 \longrightarrow \mathcal{R}_{56}.$$

The exact histogram of its fibers is

$$41 \times 1, \qquad 10 \times 2, \qquad 2 \times 3, \qquad 1 \times 4, \qquad 2 \times 5,$$

and its sum is 81.

Having fixed the origin and the lexicographic order of the chart, let $\kappa(x) \in \{0, 1, 2, 3, 4\}$ be the rank of x within its fiber.

Theorem 91.8 (Minimal internal selector)**.** *The map*

$$x \longmapsto \big(\mathcal{R}(x), \kappa(x)\big)$$

is injective on the 81 cells. No memory alphabet with fewer than five symbols can lift $\mathcal{R}$ injectively over the entire atlas.

Proof. Within each fiber, κ assigns distinct ranks; between fibers, the first coordinate is already distinct. There is a fiber of size five, so the pigeonhole principle forces every injective lift to have at least five memory values. The range $0, \dots, 4$ attains that bound. □

Canonicity is relative to the declared origin and order. κ is neither a charge, a flavor, nor a mass. The thirteen coarse classes of the atlas produce finite multisections; only the central class possesses the fixed point $(5, 5)$ under central inversion. The other twelve require oriented information in order to select a point and do not admit an equivariant point selector from the coarse class alone.

91.6.2.1 Möbius Inversion and Round-Trip Characters

On the word of dodecaphasic signs we define

$$C_M(\tau)_m = -\tau_{11-m}.$$

This operation combines reversal of the reading order with the change of sheet. A linear character $\ell_a(\tau) = \sum_m a_m \tau_m$, with $a_m = a_{11-m}$, satisfies

$$\ell_a(C_M \tau) = -\ell_a(\tau),$$

while every symmetric quadratic form compatible with reversal satisfies

$$Q(C_M \tau) = Q(\tau).$$

Thus, the linear coordinates distinguish outward and return orientations, and the quadratic coordinates preserve the correlation content. This parity explains why s_C changes sign while ν_{270} may remain invariant. In the atlas, the seven word forms have multiplicities

$$54, 2, 2, 2, 7, 7, 7;$$

therefore, the anti-sheet is realized as a correspondence between fibers, not as a bijective involution obtained by ignoring their multiplicities.

91.6.3 Orientation-based composition of records before projection

Let Γ and Λ be two enriched histories, B a common subhistory, and g the transport identifying phase, sheet, orientation, and position at the interface. At ledger level, define

$$\boxed{\Gamma \star_B \Lambda = \big(n_\Gamma + n_\Lambda - n_B, e_\Gamma + g e_\Lambda - e_B\big).}$$

The definition also presupposes identification of the edge, the torsional predecessors, the corona, and the antisheet memory.

Proposition 91.9 (Obstruction to the five-dimensional descent of the composition of records)**.** *In general, there is no binary operation on $\mathbb{Z}^5$ that recovers $L_{\mathrm{tick}}(\Gamma \star_B \Lambda)$ from $L_{\mathrm{tick}}(\Gamma)$ and $L_{\mathrm{tick}}(\Lambda)$ alone.*

Proof. The operation composes the twelve events before applying sgn and the autocorrelations. Two histories may have the same five-tuple and different values of M_5 or A_6. When composed with a third

history, some sum $e_a + e_{a+4} + e_{a+8}$ may cross zero in one but not the other, changing ν_{120}^{ev}. Finite diamonds supply explicit witnesses. Therefore, projection onto five integers is not a congruence for $\star_B$. □

The proposition formalizes an essential operative rule: extensions are composed; signatures are read afterward. The composite particle is likewise not obtained by blindly adding two rows of a table, but by composing their compatible memories and evaluating the result.

91.6.4 Dodecaphasic dependence of the persistence character

The reduced period 54 engines impose

$$e_{m+6} = e_m.$$

It follows from here the congruences

$$n_A \equiv 0 \pmod 2, \qquad s_C \equiv 0 \pmod 2, \qquad \nu_{270} \equiv 0 \pmod 4.$$

The signatures of the abbreviated scalar reconstruction violate at least one of these congruences. Therefore, their genealogy requires the enriched register and does not arise from that reduced engine under the declared rules.

This result is not an obstruction to enriched TPK dynamics. It proves what memory it requires: a genuine dodecaphase, with possible $A_6 \neq 0$, oriented composition, and retained torsional predecessors. The ablation prevents a limitation belonging to a specific periodic reduction from being attributed to TPK.

91.6.5 Factorization by the quotient of log and physical realization

In the scope of this section, the relation is declared.

$$\gamma \sim_{\mathcal{L}} \gamma' \quad \Longleftrightarrow \quad \gamma, \gamma' \text{ have the same extension and } \mathcal{L}(\gamma) = \mathcal{L}(\gamma').$$

Denote by $\mathcal{E}_{108}^{\mathrm{surv}} := \Gamma_{108}^{\mathrm{enr}}/\!\sim_{\mathcal{L}}$ the quotient relative to this chart. Let

$$\pi_{\mathrm{ext}} : \Gamma_{108}^{\mathrm{enr}} \longrightarrow \mathcal{E}_{108}^{\mathrm{surv}}$$

the canonical projection. By construction, the extractor is constant on its fibers. The stronger assertion that every admissible chart of the same extension automatically produces the same record would require proving compatibility among charts and is not presupposed here.

Theorem 91.10 (Relative factorization by the quotient of the logarithm)**.** *There exists a unique application*

$$\overline{L} : \mathcal{E}_{108}^{\mathrm{surv}} \longrightarrow \mathbb{Z}^5$$

such that

$$\boxed{L_{\mathrm{tick}} = \overline{L} \circ \pi_{\mathrm{ext}}.}$$

Therefore, $\chi_{\mathrm{form}} \circ \overline{L}$ is a function of the class in the relative quotient, not of the route representative chosen to read it.

Proof. If $\pi_{\mathrm{ext}}(\gamma) = \pi_{\mathrm{ext}}(\gamma')$, both presentations have the same record by the declared relation and, by the preceding formulae, the same five-tuple. We define $\overline{L}([\gamma]) = L_{\mathrm{tick}}(\gamma)$. Constancy proves that the definition is independent of the representative; surjectivity of the map to the quotient proves uniqueness. □

The internal construction thus reaches up to

$$\Omega_{\mathrm{HMT}}^{\mathrm{surv}} \longrightarrow \mathcal{E}_{108}^{\mathrm{surv}} \xrightarrow{\overline{L}} \mathbb{Z}^5 \xrightarrow{\chi_{\mathrm{form}}} \mathrm{Fun}(\mathcal{P}, \mathbb{R}_{>0}).$$

The content of the theorem is positive and complete in this domain: a surviving extension determines its ledger class, the class determines a unique signature, and the signature determines the formal character. The global specialization and the complete hierarchy of towers are constructed in the following chapters; comparisons with physical names and units are presented subsequently, without altering this chain.

91.7 Split algebra and exact factorization of the character

The formal signature of an extension and the angular channels follow from branches already constructed. In this section, both converge in a determinant factorization that separately preserves the radial scale and the relative orientation. The result belongs to the algebraic stratum: it does not by itself identify the null ideals with physical photons or the positive interior with a material particle.

91.7.1 Conjugate angular coordinates and bidirectional spectral lattice

The preceding causal chain fixes

$$A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad C^*_{\mathrm{rad}} = \frac{\pi C^*}{180},$$

and, only after obtaining the direct coordinate A and the unique conjugate coordinate C^*,

$$q_+ = \exp[-(A_{\mathrm{rad}} + C^*_{\mathrm{rad}})], \qquad q_- = \exp[-(A_{\mathrm{rad}} - C^*_{\mathrm{rad}})].$$

For an angular signature (n_A, s_C), we introduce the two winding numbers

$$W_+ = 6n_A + s_C, \qquad W_- = 6n_A - s_C.$$

Theorem 91.11 (Angular lattice of index twelve)**.** *The map*

$$\mathcal{W} : \mathbb{Z}^2 \to \mathbb{Z}^2, \qquad \begin{pmatrix} n_A \\ s_C \end{pmatrix} \longmapsto \begin{pmatrix} W_+ \\ W_- \end{pmatrix} = \begin{pmatrix} 6 & 1 \\ 6 & -1 \end{pmatrix} \begin{pmatrix} n_A \\ s_C \end{pmatrix}$$

is injective, and its image has index twelve. Its invariant factors are $(1, 12)$*, and*

$$\operatorname{im} \mathcal{W} = \{(u, v) \in \mathbb{Z}^2 : u + v \equiv 0 \pmod{12}\}.$$

Moreover,

$$\boxed{\exp\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}}\right) = \left(q_+^{-W_+} q_-^{-W_-}\right)^{1/12}.}$$

Proof. The matrix has determinant -12. Since the greatest common divisor of its entries is one, its Smith normal form is $\operatorname{diag}(1, 12)$. If $(u, v) = (6n + s, 6n - s)$, then $u + v = 12n$. Conversely, if $u + v$ is a multiple of twelve, then

$$n = \frac{u + v}{12}, \qquad s = \frac{u - v}{2}$$

are integers and recover (u, v). Finally,

$$\frac{W_+(A_{\mathrm{rad}} + C^*_{\mathrm{rad}}) + W_-(A_{\mathrm{rad}} - C^*_{\mathrm{rad}})}{12} = n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}},$$

which proves the identity upon exponentiation. □

The involution $s_C \mapsto -s_C$ interchanges $W_+ \leftrightarrow W_-$ and $q_+ \leftrightarrow q_-$. The twelfth root is the integral index of the image of $\mathcal{W}$, not a rounding. The coordinate C^* acts as the antisymmetric component of the lattice; it is neither a decimal correction to a mass nor an output of $\Gamma_{6\to 8}$.

91.7.2 Real split algebra

Definition 91.12 (Real split algebra)**.** Let

$$\mathcal{A}_{\mathrm{sp}} := \mathbb{R}[\mathsf{R}]/(\mathsf{R}^2 - 1).$$

Conjugation and the norm are defined, respectively, by

$$\overline{a + b\mathsf{R}} = a - b\mathsf{R}, \qquad N_{\mathrm{sp}}(z) = z\overline{z} = a^2 - b^2.$$

Conjugate idempotents

$$P_\pm = \frac{1 \pm \mathsf{R}}{2}$$

satisfy

$$P_\pm^2 = P_\pm, \qquad P_+P_- = 0, \qquad P_+ + P_- = 1, \qquad \overline{P_+} = P_-.$$

Proposition 91.13 (Split spectral decomposition)**.** *Every $z \in \mathcal{A}_{\mathrm{sp}}$ admits a unique decomposition*

$$z = r_+P_+ + r_-P_-, \qquad r_\pm \in \mathbb{R},$$

and its norm is

$$\boxed{N_{\mathrm{sp}}(z) = r_+r_-.}$$

Each principal ideal $\mathcal{A}_{\mathrm{sp}}P_\pm = \mathbb{R}P_\pm$ is a null line; in particular,

$$N_{\mathrm{sp}}(\lambda P_\pm) = 0.$$

Proof. If $z = a + b\mathsf{R}$, the choice $r_+ = a + b$, $r_- = a - b$ provides the decomposition, whose uniqueness follows from the independence of P_+ and P_-. Conjugation exchanges the two coefficients: $\overline{z} = r_-P_+ + r_+P_-$. The orthogonality of the idempotents gives

$$z\overline{z} = (r_+r_-)(P_+ + P_-) = r_+r_-.$$

The statement about each ideal is obtained by nullifying one of the two coefficients. □

Definition 91.14 (Causal cone partitioned)**.** The positive cone, its null boundary, and its interior are

$$C_{\mathrm{sp}}^+ = \{r_+P_+ + r_-P_- : r_+, r_- \geq 0\},$$

$$\partial_{\mathrm{null}}C_{\mathrm{sp}}^+ = \mathbb{R}_{\geq 0}P_+ \cup \mathbb{R}_{\geq 0}P_-, \qquad \operatorname{int} C_{\mathrm{sp}}^+ = \{r_+P_+ + r_-P_- : r_+r_- > 0\}.$$

The boundary has a single active direction and zero norm. The interior requires two simultaneous directions and positive norm. This stratification is exact; its physical realization requires maps that preserve the pertinent norm, transport, and dynamics.

91.7.3 Relative transporter and representational realization conditions

The historical block $B_0 = 7I + 2\mathsf{R}$ has spectrum $\{9, 5\}$, and the angular block $B_1 = AI + C^*\mathsf{R}$ has spectrum $\{A + C^*, A - C^*\}$. The theorem 38.18 proves that, with the current internal values, every putative linear intertwiner $\Phi B_0 = B_1\Phi$ is zero. The active object is the relative multiplicative transporter already constructed, not an equivalence between representations with disjoint spectra.

91.7.4 Partial factorization of the angular character

Let

$$\sigma = \frac{s_C}{6}, \qquad w_\pm = \frac{n_A \pm \sigma}{2} = \frac{W_\pm}{12}, \qquad r_\pm = q_\pm^{-w_\pm},$$

and let us define

$$Z_v = r_+ P_+ + r_- P_-.$$

Theorem 91.15 (Partial factorization of the angular character)**.** *For every angular signature $v = (n_A, s_C) \in \mathbb{Z}^2$,*

$$\boxed{N_{\mathrm{sp}}(Z_v) = \det Z_v = \exp\!\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}}\right).}$$

Proof. By the definition of the channels,

$$\log r_+ = \frac{n_A + \sigma}{2}(A_{\mathrm{rad}} + C^*_{\mathrm{rad}}), \qquad \log r_- = \frac{n_A - \sigma}{2}(A_{\mathrm{rad}} - C^*_{\mathrm{rad}}).$$

Upon summation,

$$\log(r_+ r_-) = n_A A_{\mathrm{rad}} + \sigma C^*_{\mathrm{rad}}.$$

The proposition 91.13 gives $N_{\mathrm{sp}}(Z_v) = r_+ r_-$, and the diagonal representation in the basis (P_+, P_-) gives the same expression for the determinant. □

The component not seen by the determinant preserves the relative orientation:

$$\frac{1}{2}\log\frac{r_+}{r_-} = \frac{1}{2}\left(n_A C^*_{\mathrm{rad}} + \frac{s_C}{6} A_{\mathrm{rad}}\right),$$

$$Z_v = \exp\!\left[\frac{1}{2}\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}}\right)\right] \exp\!\left[\frac{1}{2}\left(n_A C^*_{\mathrm{rad}} + \frac{s_C}{6} A_{\mathrm{rad}}\right) \mathsf{R}\right].$$

The first factor fixes the radial scale; the second records the relative orientation. They are two coordinated readings of one and the same element.

91.7.5 Central incorporation of the towers

Once Δ_4, s_{120}, and $\zeta^{\mathrm{corr}}_{270} = \zeta^{\mathrm{corr}}_{270}$ have been constructed globally, let

$$t(v) = k_{\Delta_4}\Delta_4 + \nu_{120} s_{120} + \nu_{270}\zeta^{\mathrm{corr}}_{270}, \qquad \widetilde{Z}_v = e^{t(v)/2} Z_v.$$

Corollary 91.16 (Complete character as original norm)**.** *Having fixed the preceding global blocks,*

$$\boxed{N_{\mathrm{sp}}(\widetilde{Z}_v) = \exp\!\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}} + k_{\Delta_4}\Delta_4 + \nu_{120} s_{120} + \nu_{270}\zeta^{\mathrm{corr}}_{270}\right).}$$

Proof. In the two-dimensional representation, multiplication by the central scalar $e^{t(v)/2}$ multiplies the determinant by $e^{t(v)}$. The theorem 91.15 is applied. □

The corollary constructs the declared split realization of the active character; it does not classify all possible realizations or transform the towers into independent proofs. Its hypotheses are the already fixed channels and global blocks, and its negative control is immediate: omitting the central factor $1/2$ doubles the tower exponent; simultaneously activating both idempotents with positive coefficients departs from the null boundary.

91.8 Values, Completeness and Blocks of the Spectral Hierarchy

The bilayer operator, its moments, and the semigroup $\mathfrak{S} = \langle 90, 120\rangle$ are defined only once in the section 91.8.4. This chapter publishes values, proves reconstructive completeness, and separates the global blocks. The same integers 90, 120 also occur as cardinalities in the hexad–octad incidence, but that coincidence does not transport the incidence $\iota_{6,8}$ to the angular chart or convert its configurations into mass moments.

91.8.1 First evaluations of the hierarchy

The indices

$$90, 120, 180, 210, 240, 270, 360, 420$$

are a selection of initial heights of $\mathfrak{S}$, since

$$180 = 2 \cdot 90, \quad 210 = 90 + 120, \quad 240 = 2 \cdot 120,$$

$$270 = 3 \cdot 90, \quad 360 = 3 \cdot 120, \quad 420 = 2(90 + 120).$$

The moments $s_n = q_-^n - q_+^n$ and the generating interface $\mathcal{K}_{\text{ang}}^{90,120} = (s_{90}, s_{120})$ are used here with the already fixed convention; they are not redefined. All values are determined by A, C^*, and the reader's quadratic recurrence.

Table 91.1: Oriented moments of the global hierarchy.

n	s_n
90	$2.9516943928982796 \times 10^{-4}$
120	$1.9683511250294992 \times 10^{-5}$
180	$8.7345871869508335 \times 10^{-8}$
210	$5.8181313057291163 \times 10^{-9}$
240	$3.8754674969305336 \times 10^{-10}$
270	$2.5814553607509555 \times 10^{-11}$
360	$7.6293257871406076 \times 10^{-15}$
420	$3.3850663628348497 \times 10^{-17}$

Proposition 91.17 (Global Character of Moments)**.** *The quantities s_n of table 91.1 are invariants of the fixed angular chart. A species contributes integer coordinates that weight those invariants, but does not modify $q_\pm$ or introduce a tower of its own.*

Proof. Each s_n is a function of q_- and q_+. The theorem of inversion of channels proves that the joint map $(A, C^*) \mapsto (q_+, q_-)$ is injective. No species label appears in these definitions. □

Theorem 91.18 (Reconstructive completeness of the hierarchy)**.** *Let $n_1 < n_2 < \cdots$ be the increasing enumeration without repetitions of $\mathfrak{S}$. For*

$$a_k := s_{n_k} = q_-^{n_k} - q_+^{n_k} > 0,$$

every positive ratio $\rho \in \mathbb{R}_{>0}$ admits an absolutely convergent expansion in the hierarchy:

$$\boxed{\rho = \exp\left(\sum_{k\geq 1} \nu_k a_k\right)} \qquad \text{for some sequence } (\nu_k)_{k\geq 1} \subset \mathbb{Z}.$$

Proof. As $0 < q_+ < q_- < 1$, it holds

$$0 < a_k < q_-^{n_k}.$$

The n_k are multiplos of 30 no menores that 90; therefore,

$$\sum_{k\ge 1} a_k \le \sum_{m\ge 3} q_-^{30m} = \frac{q_-^{90}}{1-q_-^{30}} < \infty, \qquad a_k \longrightarrow 0.$$

Fix $r_0 = \log \rho$ and a tie-breaking rule for the nearest integer. Define recursively

$$\nu_k = \operatorname{nint}\left(\frac{r_{k-1}}{a_k}\right), \qquad r_k = r_{k-1} - \nu_k a_k.$$

The property of the nearest integer gives

$$|r_k| \le \frac{a_k}{2} \longrightarrow 0.$$

The telescoping identity

$$r_0 = \sum_{j=1}^{N} \nu_j a_j + r_N$$

implies $r_0 = \sum_{j\ge 1} \nu_j a_j$. The convergence is absolute, since

$$\begin{aligned} \sum_{k\ge 1} |\nu_k| a_k &= \sum_{k\ge 1} |r_{k-1} - r_k| \\ &\le |r_0| + \frac{a_1}{2} + \frac{1}{2}\sum_{k\ge 2}(a_{k-1} + a_k) < \infty. \end{aligned}$$

By exponentiating, the statement is obtained. □

Remark 91.19 (Scope and negative control). The theorem is a reconstructive surjectivity of the tower language onto $\mathbb{R}_{>0}$: it proves resolution of the codomain, not physical selection. The algorithm receives $r_0 = \log \rho$; if ρ is a target magnitude, its coefficients are therefore a target-dependent reconstruction. Prospective provenance requires another arrow,

$$\text{species} \dashrightarrow \text{extension} \longrightarrow \text{route} \longrightarrow \text{record} \longrightarrow \text{signature},$$

and does not follow from this expansion. The conclusion would fail if the a_k did not tend to zero, if the bound on the residue ceased to hold, or if the error series were not summable.

91.8.2 Global blocks of mass action

The mass action will use the triple

$$\Delta_4, \qquad s_{120}, \qquad \zeta_{270}^{\mathrm{corr}} = 135\Delta_4^2.$$

Their values are calculated only once. The coordinates k, ν_{120}, ν_{270} of a signature specify how many times each block enters the exponent; they do not change its value.

It is useful to distinguish two objects that share the index 270:

$$\boxed{\zeta_{270}^{\mathrm{corr}} = 135\Delta_4^2 = 1.66922699663643 \times 10^{-6}}$$

and

$$\boxed{s_{270}^{\mathrm{spec}} = q_-^{270} - q_+^{270} = 2.58145536075096 \times 10^{-11}.}$$

The first is a quadratic invariant constructed from Δ_4; the second is a spectral moment of the semigroup. The coincidence of the subscript does not authorize their identification.

91.8.3 Higher-order combination

The global combination

$$\delta\Delta_4^{\mathrm{tower}} = \frac{s_{180}}{24} - \frac{s_{240}}{54} - 24 s_{360} + \frac{7}{6} s_{420}$$

evaluates a

$$\delta\Delta_4^{\mathrm{tower}} = 3.63205147190875912388907096 7 \times 10^{-9}.$$

The comparison coordinate used in the selection of the coefficients is defined as the scalar data

$$\delta\Delta_4 := 3.63205147190897278466164172 0 \times 10^{-9}.$$

Consequently, the residue of the combination with respect to that coordinate is

$$\delta\Delta_4^{\mathrm{tower}} - \delta\Delta_4 = -2.1366077257075 \times 10^{-22}.$$

The small quantity is therefore a difference between two objects and not the value of the combination. All the summands belong to the same hierarchy, and their coefficients are global. Because the comparison coordinate intervened in the selection of the coefficients, this equality is reconstructive. The combination is not added again to the electronic formula that already uses Δ_4, since that substitution would duplicate the same correction.

91.8.4 Bilayer Operator and Infinite Hierarchy

Let

$$x = A_{\mathrm{rad}}, \qquad y = C_{\mathrm{rad}}^{*}, \qquad R_{\mathrm{ch}}^2 = I, \qquad P_{\pm}^{\mathrm{ch}} = \frac{I \pm R_{\mathrm{ch}}}{2}.$$

The reader of the two leaves meets in the operator

$$T_{\mathrm{ang}} = \exp(-xI - yR_{\mathrm{ch}}) = q_{+} P_{+}^{\mathrm{ch}} + q_{-} P_{-}^{\mathrm{ch}},$$

with

$$q_{-} = e^{-x+y}, \qquad q_{+} = e^{-x-y}.$$

Its even and odd spectral moments are

$$c_n = \operatorname{Tr}(T_{\mathrm{ang}}^n) = q_{-}^n + q_{+}^n, \qquad s_n = -\operatorname{Tr}(R_{\mathrm{ch}} T_{\mathrm{ang}}^n) = q_{-}^n - q_{+}^n.$$

The involution $C^{*} \mapsto -C^{*}$ preserves c_n and reverses s_n. Equivalently,

$$c_n = 2e^{-nx}\cosh(ny), \qquad s_n = 2e^{-nx}\sinh(ny).$$

This is the convention fixed in the chapter on channels. To state without homonymy the alternative presentation of the tower sources, set

$$R_{\mathrm{tow}} := -R_{\mathrm{ch}}, \qquad P_{\pm}^{\mathrm{tow}} = P_{\mp}^{\mathrm{ch}},$$

$$T_{\mathrm{tow}} := e^{-xI + yR_{\mathrm{tow}}} = T_{\mathrm{ang}}, \qquad \operatorname{Tr}(R_{\mathrm{tow}} T_{\mathrm{tow}}^n) = -\operatorname{Tr}(R_{\mathrm{ch}} T_{\mathrm{ang}}^n) = s_n.$$

The two writings describe the same scalar reader and do not constitute a second orientation of the towers.

Theorem 91.20 (Addition, norm, and recurrence)**.** *For $m, n \geq 0$,*

$$c_{m+n} = \frac{c_m c_n + s_m s_n}{2}, \qquad s_{m+n} = \frac{s_m c_n + c_m s_n}{2},$$

$$c_n^2 - s_n^2 = 4e^{-2nx}.$$

If $p = q_-q_+ = e^{-2x}$, both sequences satisfy

$$X_{n+2} = c_1 X_{n+1} - pX_n.$$

Moreover,

$$\partial_A c_n = -\frac{n\pi}{180} c_n, \qquad \partial_A s_n = -\frac{n\pi}{180} s_n,$$
$$\partial_{C^*} c_n = \frac{n\pi}{180} s_n, \qquad \partial_{C^*} s_n = \frac{n\pi}{180} c_n.$$

Proof. The addition identities follow by expanding $(q_-^m \pm q_+^m)(q_-^n \pm q_+^n)$. The norm is

$$(q_-^n + q_+^n)^2 - (q_-^n - q_+^n)^2 = 4(q_-q_+)^n.$$

The last equality is the recurrence determined by the characteristic roots q_- and q_+. The differential equations are obtained by differentiating the hyperbolic expressions; the factor $\pi/180$ belongs to the angular chart and not to a species selection. □

Theorem 91.21 (Complete height semigroup)**.** *The heights of the transversal hierarchy form*

$$\mathfrak{S} = \langle 90, 120\rangle = \{90a + 120b : a, b \in \mathbb{Z}_{\geq 0},\ a + b > 0\}.$$

Equivalently,

$$\boxed{\mathfrak{S} = \{90, 120\} \cup \{30r : r \geq 6\}.}$$

Proof. Dividing by 30 yields the numerical semigroup $\langle 3, 4\rangle$. Its positive elements are $\{3, 4\} \cup \{r : r \geq 6\}$: 5 is the only positive gap beyond the generators, and every $r \geq 6$ is obtained inductively by adding 3 or 4. Multiplying again by 30 gives the formula. □

The presentation also preserves the genealogy of a height:

$$\mathfrak{S} \cong \big(\mathbb{Z}_{\geq 0}^2 \setminus \{(0,0)\}\big) \big/ \big((a+4, b) \sim (a, b+3)\big),$$

since $4 \cdot 90 = 3 \cdot 120 = 360$. The height does not by itself determine the composition that produced it; the genealogies $4 \cdot 90$ and $3 \cdot 120$ remain distinct in the enriched chronological record even though they evaluate to the same index.

To make explicit the recurrence sampled in the common step of thirty, let us define

$$a_{30} := q_-^{30}, \qquad b_{30} := q_+^{30}, \qquad u_r := s_{30r} = a_{30}^r - b_{30}^r.$$

Then

$$\boxed{u_{r+2} = (a_{30} + b_{30})u_{r+1} - a_{30}b_{30}u_r.}$$

The auxiliary term $u_5 = s_{150}$ may intervene when propagating the recurrence, but $150 \notin \mathfrak{S}$; a computational identity does not create a new admissible height.

In particular,

$$90, 120, 180, 210, 240, 270, 300, 330, 360, 390, 420, 450, 480, \ldots$$

are the first heights. The eight heights highlighted in previous expositions are first readings of $\mathfrak{S}$, not its definition nor its limit.

As a human guide, its initial genealogy can be read without converting it into the complete domain:

90	$3 \cdot 30$	minimal generator
120	$4 \cdot 30$	minimal generator
180	$2 \cdot 90$	first even mode
210	$90 + 120$	composite mode
240	$2 \cdot 120$	second even mode
270	$3 \cdot 90$	repetition of branch 90
360	$3 \cdot 120$	repetition of branch 120
420	$2(90 + 120)$	composite return

The last column records structural provenance; it neither introduces parameters nor asserts that those eight rows exhaust the hierarchy. The same integers 90, 120 are incidence cardinalities in $\mathcal{F}_6$ and $\mathcal{F}_8$, but that coincidence does not identify the bilayer operator with the inclusion $\iota_{6,8}$.

The interface of the two generators is only the pair

$$\mathcal{K}_{\mathrm{ang}}^{90,120}(q_+, q_-) := (s_{90}, s_{120}).$$

It must not be confused with the resolvents of two subtails or with the subsequent functional $K_{6\to 8} = 12\Delta S_{90} - \Delta S_{120}$, whose definition and proof reside in section 51.2. There, the subtails live in the analytic completion of the hierarchy; they are neither new generators nor species coefficients.

Definition 91.22 (Convergent module of spectral refinements)**.** The integral domain of the global lift is

$$\mathcal{E}_{\mathfrak{S}} := \left\{ \eta \in \mathbb{Z}^{\mathfrak{S}} : \sum_{h \in \mathfrak{S}} |\eta_h s_h| < \infty \right\}, \qquad s_h = q_-^h - q_+^h.$$

Each $\eta \in \mathcal{E}_{\mathfrak{S}}$ determines the spectral character

$$\mathcal{R}_\eta := \exp\left(\sum_{h \in \mathfrak{S}} \eta_h s_h \right).$$

The mass law does not reside in this definition: its central signature $(n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta) \in \mathbb{Z}^5$ is constructed beforehand from the register. The elevation by η acts subsequently and preserves the provenance of the basic term $b_{120}s_{120}$. In particular, $N_{120} = b_{120} + \eta_{120}$ is the evaluated total coefficient, not a new signature coordinate or a unique inverse decomposition.

The completeness of the semigroup does not by itself select a species. When η is obtained from a supplied metrological residual, one has an exact calibrated reconstruction; prospective force requires the route, carry, and winding to produce η before that residual is opened. The preceding recurrence generates all the moments once the refinement has been fixed, without introducing a distinct law at each height.

91.8.5 Pair of genealogical readers over the complete atlas

The enriched route possesses two complementary internal representations,

$$\Gamma \longmapsto \big(\gamma_{108}(\Gamma), \tau_{12}(\Gamma)\big) \in \mathbb{F}_3^{108} \times \{-1, 0, +1\}^{12}.$$

The first preserves the complete tritic history; the second preserves the signed dodecaphase record. Each projection induces a natural reader, and both are evaluated before opening masses, PDG labels, or residuals.

91.8.5.1 Pair of genealogical readers $\mathbf{K}(\Gamma) = (K_D(\Gamma), K_\Omega(\Gamma))$*: domain, codomain, and scalar evaluations*

Using the notation of equations (58.6), (58.7) y (58.10), we define

$$\mathbf{K}(\Gamma) := \big(K_D(\Gamma), K_\Omega(\Gamma)\big) \in \left(\mathbb{Z}^2 \times \tfrac{1}{2}\mathbb{Z}\right) \times \mathbb{Z}^3, \tag{91.1}$$

where

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2}\right), \qquad K_\Omega = (\Omega_{90|120}, 54, P_6).$$

Scalar evaluations are

$$\kappa_D(\Gamma) = D_{27} + D_{36} - \alpha_{\mathrm{HMT}} D_1 + \frac{\Delta_4}{2}(D_4 - D_3), \tag{91.2}$$

$$\kappa_\Omega(\Gamma) = \Omega_{90|120}(\tau_\Gamma) - 54\alpha_{\mathrm{HMT}} + P_6(\tau_\Gamma)\Delta_4. \tag{91.3}$$

The second coordinate requires a causal distinction. In APP, the primordial spectral jump is $9 - 5 = 4$; the local coefficient 2, the compression $6 = 51 - 45$, and the two-dimensional unfolding $54 = 9 \cdot 6 = 459 - 405$ are later typed invariants, in accordance with the theorem 1.58. By contrast, in the chronological displacement reader, the electron coordinate is $B_D = D_1(\Gamma_e) = 54$: it counts immediate boundaries and coincides with the kinematic periodicity of order 54 of the CT108 endomorphism. The fixed 54 of K_Ω is the common coordinate transferred when both readers are made compatible in the electron reduction. Its numerical equality with the global APP defect constitutes a subsequent cross-check; it does not make the number 54 the primordial difference between addition and multiplication.

The equality $4 \cdot 90 = 3 \cdot 120 = 360$ explains the common genealogy of the two readers. K_D compares displacements of the tritic word γ_{108}; K_Ω compares the energies of windows in the twelve-phase word. The coincidence of origin does not identify their information quotients. In the certified domain $\Gamma^{\mathrm{or}}_{324}$, half-turn periodicity makes all the D_k even, so that $(D_4 - D_3)/2 \in \mathbb{Z}$ and $K_D \in \mathbb{Z}^3$. Outside that domain, the third component retains type $\frac{1}{2}\mathbb{Z}$.

91.8.5.2 Naturalness of bidirectional operators and type preservation

The reader D_k is invariant under time translation, reversal, and every bijective permutation of the tritic alphabet. On the declared routes, simultaneously reversing both orientations acts by a translation of 27 discrete steps and preserves K_D. The reader K_Ω is invariant under dodecaphase rotation and reversal and under $C_M(\tau) = -\mathrm{rev}(\tau)$. Its quadratic form

$$\Omega(\tau) = \langle \tau, (4W_3^* W_3 - 3W_4^* W_4)\tau \rangle$$

possesses integer bilinear polarization and satisfies the 2-cocycle identity.

The global counters of turn, sheet change, phase repetition, prefix change, and return are constant over the 324 routes. Consequently, every functional that factors exclusively through those six counters is constant and cancels in ratios. The readers in (91.2) and (91.3) act on the local history and pass that nonfactorization control.

Structural Necessity Proposition 91.23 (Necessity of the two sheets in the electronic route)**.** The chronological reader produces

$$(A_D, B_D, C_D) = \begin{cases} (80, 54, 6), & \text{joint chronological word of both sheets;} \\ & B_D = D_1(\Gamma_e) = 54 \\ (80, 84, -8), & \text{additive projection,} \\ (80, 60, 13), & \text{multiplicative projection.} \end{cases},$$

The complete electronic triple requires the joint history of the two arithmetic sheets.

91.8.5.3 Exact Censuses over the 324 Routes

The chronological reader produces fourteen profiles. The following table records their complete census; $A_D = D_{27} + D_{36}$, $B_D = D_1$, and $C_D = (D_4 - D_3)/2$.

Table 91.2: Exact census of the fourteen profiles of the chronological reader over the 324 oriented routes.

A_D	B_D	C_D	multiplicity
0	24	0	18
40	24	2	36
40	54	6	18
40	78	27	36
40	84	30	36
60	78	25	18
60	84	28	18
80	54	6	18
80	54	7	18
80	66	2	18
80	66	3	36
80	66	4	18
100	66	0	18
100	66	2	18
		total	324

The dodecaphasic reader produces nine profiles:

Table 91.3: Exact census of the nine profiles of the dodecaphasic reader over the 324 oriented routes.

Ω	B_Ω	P_6	multiplicity
80	54	6	198
56	54	5	68
48	54	5	34
36	54	4	8
20	54	4	4
4	54	2	4
40	54	4	4
24	54	4	2
24	54	2	2
		total	324

The readers coincide as triples on (18) routes, always with the value $(80, 54, 6)$, and the pair $\mathbf{K}$ assumes (40) values. In the canonical section $B1$ of 81 positions, K_D is constant in 41 of the 56 families and refines the quotient into 77 classes; K_Ω is constant in 50 and produces 62 classes; the pair produces 78. In the lift to 324 orientations, K_D produces 146 classes and is nonconstant in every family; K_Ω produces 100 and descends in 17 families; the pair produces 151 and is nonconstant in all of them. These censuses prove that the two projections retain distinct memories and determine the domain of each descent claim.

91.8.5.4 Vector traces and joint spectra of the 13 *multisections*

In the canonical section $B1$, we denote by ℓ_j, ν_j, d_j, u_j the generation-j multisections of the charged-lepton, neutrino, down-type-quark, and up-type-quark sectors, respectively. For each reader $r \in \{D, \Omega\}$ and each component $a \in \{1, 2, 3\}$, we define the diagonal operator

$$K^r_{M,a} e_\Gamma = K_{r,a}(\Gamma) e_\Gamma, \qquad \mathbf{K}^r_M = (K^r_{M,1}, K^r_{M,2}, K^r_{M,3}).$$

The three operators of $\mathbf{K}^r_M$ are self-adjoint and commute. Therefore, their normalized trace is understood componentwise,

$$\overline{\mathbf{K}}^r_M = \frac{1}{\dim M}\left(\operatorname{Tr} K^r_{M,1}, \operatorname{Tr} K^r_{M,2}, \operatorname{Tr} K^r_{M,3}\right),$$

and its spectrum is the joint spectrum, that is, the distribution with multiplicity of the simultaneous triples. The thirteen vector traces are:

Table 91.4: Normalized vector traces of the readers K_D and K_Ω on the thirteen canonical multisections.

M	$\dim M$	$\overline{\mathbf{K}}^D_M$	$\overline{\mathbf{K}}^\Omega_M$
ℓ_0	1	$(80, 54, 6)$	$(80, 54, 6)$
ℓ_2	8	$(65, 249/4, 17/2)$	$(80, 54, 6)$
ℓ_4	16	$(225/4, 489/8, 21/2)$	$(141/2, 54, 11/2)$
ν_1	2	$(40, 51, 29/2)$	$(60, 54, 5)$
ν_2	4	$(45, 63, 29/2)$	$(61, 54, 5)$
ν_3	6	$(170/3, 55, 34/3)$	$(206/3, 54, 11/2)$
ν_4	8	$(105/2, 237/4, 95/8)$	$(143/2, 54, 45/8)$
d_1	2	$(40, 51, 29/2)$	$(60, 54, 5)$
d_2	4	$(45, 63, 57/4)$	$(61, 54, 5)$
d_3	6	$(170/3, 55, 23/2)$	$(218/3, 54, 17/3)$
d_4	8	$(105/2, 237/4, 49/4)$	$(149/2, 54, 23/4)$
u_1	4	$(65, 66, 9)$	$(80, 54, 6)$
u_3	12	$(205/3, 119/2, 113/12)$	$(74, 54, 23/4)$

The notation $(a, b, c)^{\times n}$ indicates multiplicity n. The complete joint spectrum of $\mathbf{K}_D$ is:

Table 91.5: Complete joint spectra of the reader K_D in the thirteen canonical multisections.

M	$\operatorname{Spec}_{\text{conj}} \mathbf{K}^D_M$
ℓ_0	$(80, 54, 6)^{\times 1}$
ℓ_2	$(0, 24, 0)^{\times 1}$; $(40, 78, 27)^{\times 2}$; $(80, 54, 7)^{\times 1}$; $(80, 66, 2)^{\times 1}$; $(80, 66, 3)^{\times 1}$; $(100, 66, 0)^{\times 1}$; $(100, 66, 2)^{\times 1}$
ℓ_4	$(0, 24, 0)^{\times 1}$; $(40, 24, 2)^{\times 2}$; $(40, 54, 6)^{\times 2}$; $(40, 84, 30)^{\times 2}$; $(60, 78, 25)^{\times 3}$; $(80, 66, 2)^{\times 2}$; $(80, 66, 3)^{\times 3}$; $(80, 66, 4)^{\times 1}$
ν_1	$(40, 24, 2)^{\times 1}$; $(40, 78, 27)^{\times 1}$
ν_2	$(0, 24, 0)^{\times 1}$; $(40, 84, 30)^{\times 1}$; $(60, 78, 25)^{\times 1}$; $(80, 66, 3)^{\times 1}$
ν_3	$(40, 24, 2)^{\times 2}$; $(40, 78, 27)^{\times 1}$; $(60, 84, 28)^{\times 1}$; $(80, 54, 6)^{\times 1}$; $(80, 66, 3)^{\times 1}$
ν_4	$(0, 24, 0)^{\times 1}$; $(40, 24, 2)^{\times 1}$; $(40, 78, 27)^{\times 2}$; $(40, 84, 30)^{\times 1}$; $(80, 54, 7)^{\times 1}$; $(80, 66, 2)^{\times 1}$; $(100, 66, 0)^{\times 1}$
d_1	$(40, 24, 2)^{\times 1}$; $(40, 78, 27)^{\times 1}$
d_2	$(0, 24, 0)^{\times 1}$; $(40, 84, 30)^{\times 1}$; $(60, 78, 25)^{\times 1}$; $(80, 66, 2)^{\times 1}$
d_3	$(40, 24, 2)^{\times 2}$; $(40, 78, 27)^{\times 1}$; $(60, 84, 28)^{\times 1}$; $(80, 54, 6)^{\times 1}$; $(80, 66, 4)^{\times 1}$
d_4	$(0, 24, 0)^{\times 1}$; $(40, 24, 2)^{\times 1}$; $(40, 78, 27)^{\times 2}$; $(40, 84, 30)^{\times 1}$; $(80, 54, 7)^{\times 1}$; $(80, 66, 3)^{\times 1}$; $(100, 66, 2)^{\times 1}$
u_1	$(40, 54, 6)^{\times 1}$; $(60, 78, 25)^{\times 1}$; $(80, 66, 2)^{\times 1}$; $(80, 66, 3)^{\times 1}$
u_3	$(40, 24, 2)^{\times 2}$; $(40, 78, 27)^{\times 2}$; $(60, 84, 28)^{\times 1}$; $(80, 54, 6)^{\times 3}$; $(80, 66, 3)^{\times 1}$; $(80, 66, 4)^{\times 1}$; $(100, 66, 0)^{\times 1}$; $(100, 66, 2)^{\times 1}$

The complete joint spectrum of $\mathbf{K}_\Omega$ on the same fibres is:

Table 91.6: Complete joint spectra of the reader K_Ω in the thirteen canonical multisections.

M	$\mathrm{Spec}_{\mathrm{conj}}\,\mathbf{K}_M^\Omega$
ℓ_0	$(80,54,6)^{\times 1}$
ℓ_2	$(80,54,6)^{\times 8}$
ℓ_4	$(24,54,2)^{\times 1};(56,54,5)^{\times 4};(80,54,6)^{\times 11}$
ν_1	$(40,54,4)^{\times 1};(80,54,6)^{\times 1}$
ν_2	$(4,54,2)^{\times 1};(80,54,6)^{\times 3}$
ν_3	$(36,54,4)^{\times 1};(56,54,5)^{\times 1};(80,54,6)^{\times 4}$
ν_4	$(36,54,4)^{\times 1};(56,54,5)^{\times 1};(80,54,6)^{\times 6}$
d_1	$(40,54,4)^{\times 1};(80,54,6)^{\times 1}$
d_2	$(4,54,2)^{\times 1};(80,54,6)^{\times 3}$
d_3	$(36,54,4)^{\times 1};(80,54,6)^{\times 5}$
d_4	$(36,54,4)^{\times 1};(80,54,6)^{\times 7}$
u_1	$(80,54,6)^{\times 4}$
u_3	$(56,54,5)^{\times 3};(80,54,6)^{\times 9}$

The traces may coincide between multisections of different type; the type, multiplicity, and full spectrum remain data of the operator. The certificate reproduces these tables row by row.

91.8.5.5 Fiber Operators and Naturality of Base Change

Distinguimos the fiber canonical F_M^{B1}, formed by the positions of the multisection M with its orientation published, and the fiber oriented F_M^{or}, formed by their four lifts by position. For $s \in \{B1, \mathrm{or}\}$, let $\mathcal{H}_{M,s} = \bigoplus_{\Gamma \in F_M^s} \mathbb{C} e_\Gamma$. We define

$$B^r_{M,s} e_\Gamma = \kappa_r(\Gamma) e_\Gamma, \qquad R_{\mathrm{act}}^{B^r_{M,s}} = \exp\big[(\log R_{\mathrm{act}}) B^r_{M,s}\big], \qquad r \in \{D, \Omega\}. \tag{91.4}$$

Each $B^r_{M,s}$ is self-adjoint and diagonal in the route basis, so $R_{\mathrm{act}}^{B^r_{M,s}}$ is positive. For a positive basal mass $\widehat{M}^{(0)}_{M,s}$, the operatorial form conditioned on each reader is

$$\widehat{M}^{\beta,r}_{M,s} = R_{\mathrm{act}}^{B^r_{M,s}/2}\, \widehat{M}^{(0)}_{M,s}\, R_{\mathrm{act}}^{B^r_{M,s}/2}. \tag{91.5}$$

This expression is positive without imposing commutativity. When $[\widehat{M}^{(0)}_{M,s}, B^r_{M,s}] = 0$, it reduces to $\widehat{M}^{(0)}_{M,s} R_{\mathrm{act}}^{B^r_{M,s}}$. A unitary change of basis U transforms $B^r_{M,s} \mapsto U B^r_{M,s} U^*$ and preserves spectrum, trace, determinant, and characteristic polynomial. The canonical electronic fiber F_e^{B1} has rank one and reduces to the scalar of the theorem 58.12. Its oriented lift has rank four: the routes $(++)$ and $(--)$ share the electronic profile, whereas the mixed orientations preserve distinct profiles.

The normalized determinant

$$\mathrm{ndet}(R_{\mathrm{act}}^{B^r_{M,s}}) = R_{\mathrm{act}}^{\mathrm{Tr}(B^r_{M,s})/\dim F_M^s}$$

is natural under permutation of the fiber. Logarithmic additivity distinguishes it as a geometric mean, but it is not used as a substitute for the physical realization. The exact refinement output remains the pair $(B^D_{M,s}, B^\Omega_{M,s})$; the scalar section of a species is obtained through the flavor–generation–route morphism already constructed in equations (92.8) y (92.9): it selects the persistent route through non-metrological data and then applies the character of its signature. An arbitrary scalar functional $S(B^D_{M,s}, B^\Omega_{M,s})$ does not define that selection and remains only as a check that the target mass is not reintroduced.

91.8.5.6 Absolute scale, relative correction and sensitivities

The genealogy of the action line is written

$$\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34,$$

$$\delta_{2w} = H_5 - \eta_{\mathrm{ret}} = \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}), \qquad R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}},$$

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S.$$

The factor $10^{-34}\mathcal{U}_S$ fixes the absolute section and cancels in ratios. For the dodecaphase reader,

$$\log\left[\frac{(m_X^{\beta,\Omega}/m_e^{\beta})}{(m_X^{(0)}/m_e^{(0)})}\right] = \left[(\Omega_X - 80) + (P_{6,X} - 6)\Delta_4\right]\log R_{\mathrm{act}}. \tag{91.6}$$

The common term $-54\alpha_{\mathrm{HMT}}$ also cancels. For the chronological reader,

$$\log\left[\frac{(m_X^{\beta,D}/m_e^{\beta})}{(m_X^{(0)}/m_e^{(0)})}\right] = \left[\kappa_D(\Gamma_X) - \kappa_e\right]\log R_{\mathrm{act}}. \tag{91.7}$$

With $\log R_{\mathrm{act}} = 6.932817628081925\ldots \times 10^{-10}$,

$$\frac{\partial \log m}{\partial \Omega} = 6.9328 \times 10^{-10}, \quad \frac{\partial \log m}{\partial P_6} = \Delta_4 \log R_{\mathrm{act}} = 7.7090 \times 10^{-14},$$

$$\frac{\partial \log m}{\partial \alpha} = -54 \log R_{\mathrm{act}} = -3.74372 \times 10^{-8}, \quad \left.\frac{\partial \log m}{\partial \Delta_4}\right|_e = 6 \log R_{\mathrm{act}} = 4.15969 \times 10^{-9}.$$

These derivatives are model sensitivities and remain separate from the experimental uncertainty of a contrast mass.

91.8.5.7 Physical pairing and null sector

The typed pairing follows the chain

$$\text{typed physical record} \longrightarrow \text{multisection or representation} \longrightarrow \text{fiber of routes} \longrightarrow \text{record}$$
$$\longrightarrow \text{signature and character} \longrightarrow (B_{M,s}^{D}, B_{M,s}^{\Omega}) \longrightarrow \text{dimensional chart} \longrightarrow \text{external comparison}.$$

The typed physical inventory distinguishes registers by object, representation, and codomain; the 324 routes are the internal engine; the 471 rows of the PDG catalogue are external properties. These cardinalities belong to different domains. The arrow is constructed from non-metrological physical descriptors, the multisection, and the route; a search by proximity to a mass belongs to the calibration regime.

The null sector bifurcates before the positive character. For photon and gluons,

$$\kappa_{\mathrm{null}} = \mathrm{N/A}, \qquad m_{\mathrm{null}} = 0.$$

The expression $R_{\mathrm{act}}^0 = 1$ is the unit of the positive character. Composite objects concatenate records before evaluating the signature; topological sectors preserve fusion and braiding; a virtual section is classified by its finite horizon of prolongation.

91.8.5.8 Independence of the path constructor with respect to masses and closure of the operator

The structural verification uses exclusively the route census, the register 81×108, and the transducer of the 81 positions. It verifies their row-by-row coupling, the coverage 81/56/13/324, the naturality relations, the electronic triple $(80, 54, 6)$, the censuses (14) and (9), the match (18/324), the (40) pairs,

differentiated descents in $B1$ and in the 324 orientations, periodicity 54, inversion by shift 27, and sheet ablations. The null sector belongs to the domain exterior to the positive character. The calculation is performed before introducing masses, CODATA, PDG, metrological residuals, or nominal labels.

This certificate does not evaluate α_{HMT}, Δ_4, R_{act}, κ_e, or the MeV chart. Those evaluations belong to the arithmetic chain of the action line and to the energetic realization of theorem 58.12; this arithmetic chain remains separate from the combinatorial verification of the readers.

The metrological comparison subsequently applies the operators to the typed inventory, declares unit, scheme, scale, date, and uncertainty, and performs permutations and validation by retaining complete multisections. The physical output is governed by the domain $81/56/13/324$, by the two route readers, and by the fiber operators.

Exact domain and closed physical realization

The atlas, the $C_{81} \to \mathcal{L}_{108}$-iteration chain of the enriched chronological record of 108 iterations, the action line, the readers K_D, K_Ω, their electron reduction, and the fibre operators are exact internal results. The pair $\mathbf{K} = (K_D, K_\Omega)$ is the complete output on each route and determines the two diagonal operators of every fibre. In the electron fibre, both readers coincide. In the noncentral fibres, the pair and its spectrum preserve the complete refinement, while $\mathcal{S}_{\mathrm{phys}}$ binds branch, generation, fine signature, and, when applicable, colour orbit to the persistent route. The character of that route publishes the scalar coordinate before metrological comparison. Hence there is no disjunction between a closed operator and a pending mass: they are two typed readings of the same genealogy. Both readers are co-governing, and no proximity to an external mass intervenes in the selection.

91.8.5.9 Persistence of the enriched state under the surviving extension and conservation of the route memory

Let x be an APP state, τ its tritic word, and B_K the memory block at level K. The state relevant to mass has the form

$$X_K = (x_K, \tau_K, \varepsilon_K, h_K, v_K, c_K, B_K, g_K),$$

where ε_K is the sheet orientation, (h_K, v_K) the cellular orientation, c_K the carry, and g_K the nonadic phase. An extension survives when it forms a compatible section of the successive cylinders. If $C_{K,j}$, $0 \le j < 729$ are the children of the cylinder at the next level, the pruning rule satisfies

$$\sum_{j=0}^{728} G_9(C_{K,j}) = 1.$$

The unique index j_K produces the transition

$$P_{K+1} = 729P_K + j_K.$$

As nine levels are advanced, the phase is preserved,

$$g(K+9) = g(K),$$

but they change the block, prefix, and memory. Thus phase return is not state return. A stable particle is defined by the compatibility of the section across these returns, not by the motionless permanence of a visible coordinate.

The observable route γ_{obs} is the chronological shadow of the extension. The point traversing a diagram is a reading cursor; the particle is the complete persistence class. This distinction permits a correct interpretation of quantum motion: what is required is not a small sphere following a classical trajectory, but a coherent history that admits several compatible projections.

91.8.5.10 Dodecaphasic registration and signature

The temporal wheel contains twelve oriented events. Its causal decomposition is

$$12 = 1 + 5 + 6 :$$

one event fixes the anchor, five determine the visible incidence, and six form the opposite pairs surviving the oriented quotient. If s_C^{tot} is the integer contra-angular sum over the twelve events, the record preserves

$$s_C := s_C^{\mathrm{tot}} \in \mathbb{Z}, \qquad s_C^{(12)} := \frac{s_C^{\mathrm{tot}}}{6}.$$

The first object is the integer coordinate of the signature; the second is its dodecaphase angular reading. The divisor is not a normalization introduced from an external unit. It is the index that appears when the six opposite pairs are reconstructed. The dodecaphase incidence matrix has Smith normal form with factors $(1, 12)$; the character is well defined on the quotient because the orientation residue is measured in that structure.

This is the governing convention of the entire work. The preserved historical expressions that designated the already divided coordinate as s_C are read as $s_C^{(12)}$; their numerical values and attestations remain intact, but no current formula divides the same coordinate twice.

The direct winding pair is

$$W_+ = 6n_A + s_C^{\mathrm{tot}}, \qquad W_- = 6n_A - s_C^{\mathrm{tot}}.$$

As $s_C = s_C^{\mathrm{tot}}$ in the published signature, this formula coincides with $W_\pm = 6n_A \pm s_C$. The contra-angular exponent uses $s_C^{(12)} = s_C/6$ exactly once; it does not again divide a coordinate that had already been normalized.

The complete record publishes the signature

$$\sigma(\Gamma) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta) \in \mathbb{Z}^5, \qquad \zeta_{270} = 135\Delta_4^2.$$

The five components have distinct types. n_A counts the direct angular development; s_C records the integer counter-angular sum; $s_C^{(12)} = s_C/6$ is its angular reading; k_{Δ_4} reads the global refinement; b_{120} marks the harmonic channel of height 120; b_ζ belongs to the quadratic corrector of height 270. In particular, s_{270} and ζ_{270} are not the same object: the former is an odd trace of the bilayer operator; the latter is a quadratic coordinate of the register.

The word electronic

$$\tau_{12} = + + + - - - + + + - --$$

has linear sum zero, but its par signature is not zero:

$$(Q_3, Q_4, Q_6, \rho_0, w) = (-12, -4, 12, -6, 12).$$

Nor should it be identified with the raw signature of the electronic cycle $(24, 0, 12, 0, -12)$ or with the affine origin $v_e = 0$. These are four different levels of reading: word, even signature, raw signature, and origin of the relative character.

91.8.5.11 Angle, counter-angle, and character

To make the construction autonomous, fix here the three internal coordinates that enter throughout the law:

$$\alpha_{\mathrm{HMT}} = \frac{729735256928380099728510547238066 3}{10^{36}},$$

$$\Delta_4 = \frac{\pi_{\mathrm{HMT}} - e_{\mathrm{HMT}} \log \pi_{\mathrm{HMT}}}{270} \left(1 + \frac{\pi_{\mathrm{HMT}}}{729}\right),$$

and, for $a > 0$ and $\phi > 0$,

$$H_5(a, \phi) = \frac{1}{2}\sqrt{\frac{1000a}{\phi}} - a + \frac{9a^2}{16} - \frac{5a^3}{9} + \frac{7a^4}{48} - \frac{a^5}{54}.$$

Henceforth,

$$H_5 := H_5(\alpha_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}).$$

These definitions do not import an external metrological constant: $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}$ are the coinductive evaluations of the HMT reader, and α_{HMT} is the rational output of dodecaphase closure. The internal constant α_{HMT} precedes the counter-angle. The regional branch first determines

$$A = 1000\alpha_{\mathrm{HMT}}, \qquad D_A = \exp\!\left(-\frac{100\pi\alpha_{\mathrm{HMT}}}{9}\right),$$

$$C_\pi(\alpha_{\mathrm{HMT}}) = 169\alpha_{\mathrm{HMT}}^6 + \frac{D_A\alpha_{\mathrm{HMT}}^7}{1 - D_A\alpha_{\mathrm{HMT}}}, \qquad y_* = \frac{\pi}{90}(H_5 + \alpha_{\mathrm{HMT}}) - C_\pi(\alpha_{\mathrm{HMT}}),$$

$$C^* = \frac{180}{\pi} y_*.$$

Here A and C^* are already constructed angular coordinates, not action magnitudes. If

$$\alpha_\angle := \alpha_{\mathrm{HMT}}{}^\circ, \qquad \eta_{\mathrm{ret}}^{(\mathrm{deg})} := \frac{C^*}{2} - \alpha_\angle,$$

then

$$C^* = 2\big(\eta_{\mathrm{ret}}^{(\mathrm{deg})} + \alpha_\angle\big)$$

is the inverse return identity, not a second rule for selecting the counter-angle. This notation avoids confusing the angular mantissa $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$ with the dimensional magnitude $\hbar_{\mathrm{ret}}$. The radian charts are obtained by multiplication by $\pi/180$. The conjugate channels are

$$q_\pm = \exp\left[-\frac{\pi}{180}(A \pm C^*)\right].$$

The central character of a signature is

$$\chi_0(\sigma) = \exp\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}} + k_{\Delta_4}\Delta_4 + b_\zeta \zeta_{270}\right).$$

The coordinate b_{120} remains in the signature, but its contribution is incorporated into the tower family. This convention prevents counting the same height twice.

The character is dimensionless. Its function is not to become an action constant, but to act by positive homotheties on an already typed mass line. For a pair of states X, Y,

$$\frac{m_Y^{(0)}}{m_X^{(0)}} = \chi_{\mathrm{full}}(\sigma_Y - \sigma_X, \eta_Y - \eta_X).$$

This formula separates the ratios basal of mass of the choice common of chart absolute. The quotient beta complete incorporates afterward $R_{\mathrm{act}}^{\kappa_Y - \kappa_X}$.

91.8.5.12 Global mass tower semigroup and convergent harmonic expansion

Let $R^2 = I$, with projectors

$$P_\pm = \frac{I \pm R}{2}, \qquad x = \frac{\pi A}{180}, \qquad y = \frac{\pi C^*}{180},$$

and

$$T = e^{-xI - yR} = q_+ P_+ + q_- P_-.$$

The even and odd traces are

$$c_n = \operatorname{Tr}(T^n) = q_-^n + q_+^n = 2e^{-nx}\cosh(ny),$$
$$s_n = -\operatorname{Tr}(RT^n) = q_-^n - q_+^n = 2e^{-nx}\sinh(ny).$$

Satisfy

$$c_n^2 - s_n^2 = 4e^{-2nx},$$
$$c_{m+n} = \frac{c_m c_n + s_m s_n}{2}, \qquad s_{m+n} = \frac{s_m c_n + c_m s_n}{2},$$

and the second-order linear recurrence

$$X_{n+2} = c_1 X_{n+1} - e^{-2x} X_n, \qquad X \in \{c, s\}, \qquad c_0 = 2, \quad s_0 = 0.$$

The set of heights is not reduced to eight visible corrections. It is the semigroup

$$\langle 90, 120\rangle = \{90, 120\} \cup \{30r : r \geq 6\}.$$

The heights $90, 120, 180, 210, 240, 270, 360, 420$ are the first useful genealogical witnesses, not the entire domain. The refined character is

$$\log \chi_{\mathrm{full}}(\sigma, \eta) = \log \chi_0(\sigma) + \sum_{h \in \langle 90,120\rangle} N_h(\sigma, \eta) s_h,$$

with

$$N_h(\sigma, \eta) = \eta_h + b_{120}\delta_{h,120}.$$

Thus s_{120} appears only once, and at height 270, $N_{270}s_{270}$ and $b_\zeta \zeta_{270}$ remain separate. Absolute convergence requires

$$\sum_h |N_h s_h| < \infty.$$

The completeness of the semigroup guarantees the capacity to represent positive ratios; it does not, by itself, select a species' physical coefficients. The prospective selection rule, when used, must arise from the route, genealogical record, carry, memory, and winding before the external mass is consulted.

91.8.5.13 Bidirectional readers K_D and K_Ω: profiles, coincidences, and operators by multisection

The oriented route produces two families of invariants. For the temporal defects D_j and the return memory Ω, define

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2}\right), \qquad K_\Omega = (\Omega, 54, P_6).$$

Across the 324 routes there are 14 distinct profiles of K_D, 9 profiles of K_Ω, 40 joint pairs, and 18 coincidences. The unique profile shared by the electron route is

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6).$$

These readers are not decorative labels. K_D measures discrepancies in the word; K_Ω measures the enriched return. Their equality at the center certifies rank-one bidirectional closure. Away from the center, they produce fiber operators whose complete spectra must be published even when a subsequent physical realization selects a scalar section.

91.8.5.14 Proper harmonic refinement of each state

The full refinement lives in the coefficient space.

$$\mathcal{E}_{90,120} = \left\{\eta = (\eta_h)_{h\in\langle 90,120\rangle} : \sum_h |\eta_h s_h| < \infty\right\}.$$

The sought application does not receive a mass. It receives the enriched route:

$$\mathfrak{T} : \Gamma_{\mathrm{enr}} \longrightarrow \mathcal{E}_{90,120}, \qquad \Gamma \longmapsto \eta(\Gamma).$$

Their coordinates must be explicit functions of returns, carry, winding, memory, and boundary. The naturality condition is

$$\eta(r_{n,m}\Gamma) = r^{\mathcal{E}}_{n,m}\eta(\Gamma),$$

and the convergence must be accompanied by a computable tail bound. The complete character then acts by

$$\widehat{M}_F = \sum_{\gamma\in F} m_{\mathrm{clk}}\, \chi_{\mathrm{full}}(\sigma(\gamma), \eta(\gamma))|\gamma\rangle\langle\gamma|.$$

The capacity to reconstruct a given numerical difference proves representational completeness of the hierarchy; it does not by itself prove that $\mathfrak{T}$ has chosen its coefficients. The difference between the two assertions is preserved in every quantitative row.

91.8.5.15 Coupling Scalarization

Let $P_{X,a}$ be the projector determined by the state X and the apparatus or physical channel a. The mass distribution is

$$\mu_{X,a}(B) = \langle\Psi_X, P_{X,a}E_{\widehat{M}_F}(B)P_{X,a}\Psi_X\rangle.$$

There is a scalar line when the compression satisfies

$$P_{X,a}\widehat{M}_F P_{X,a} = m_X P_{X,a}.$$

This is the precise meaning of "to measure is to couple." The value was not hidden in a nominal cell; it appears as an eigenvalue of a physical compression of an already constructed operator. If the compression

retains several eigenvalues, the correct prediction is a multiplet or a distribution, not an average chosen to match a reference.

91.8.5.16 Physical selection as a natural relation

Away from the electronic center, a species must not select a single cell by decree. The twelve noncentral multisections are fibers stable under cellular inversion and do not, in general, admit an equivariant point section. The correct realization begins with a relation

$$\mathcal{S} \subset \mathcal{P} \times \mathcal{R}_{324}, \qquad \mathcal{S}(X) = \{\gamma : (X, \gamma) \in \mathcal{S}\},$$

whose value may be a point, an orbit, or a fiber. For the electron, $\mathcal{S}(e) = \{\gamma_e\}$ has rank one because $(5, 5)$ is the unique fixed point. For color, flavor, and generation, $\mathcal{S}(X)$ preserves the corresponding orbit until a physical coupling compresses it.

The relation is admissible if it satisfies simultaneously:

1. depends only on representation, orientation, memory, boundary, charge, flavor, color, and generation constructed before the contrast;
2. commutes with particle–antiparticle conjugation;
3. is equivariant with respect to the chromatic action and cellular inversion;
4. is compatible with refinement, nonadic return, and dodecaphase reading;
5. preserves every multiplicity that has not been eliminated by a coupling;
6. remains invariant under permuting or replacing the external mass values.

The sixth point is the decisive control. If altering the experimental column changes $\mathcal{S}(X)$, the construction is retrospective. If the relation remains and only the contrast residual changes, the causal direction is preserved.

91.9 Scalarization morphism and dimensional realization obstructions

Outside the rank-one electronic fibre, the spectrum does not itself select a physical eigenvalue. A scalar requires a projector, state, or coupling functional declared before external comparison.

91.10 Explicit refinement in the 90/120 towers

The existence of the semigroup $\langle 90, 120\rangle$ is not sufficient by itself: the map assigning coefficients to an enriched route must be constructed. Let

$$\mathcal{H}_{90,120} = \{90a+120b : a, b \in \mathbb{N}_0,\ (a, b) \neq (0, 0)\} = \{90, 120\} \cup \{30r : r \geq 6\} = \{h_0 < h_1 < h_2 < \cdots\}$$

its strictly increasing enumeration, where $\mathbb{N}_0 = \{0, 1, 2, \ldots\}$, and let $s_{h_n} > 0$ be the declared normalization of the corresponding mode. The compatible record of a route Γ provides a sequence of finite integer data

$$\mathcal{L}(\Gamma) = (\ell_0(\Gamma), \ell_1(\Gamma), \ldots),$$

in which each ℓ_n brings together return, carry, winding, memory and boundary at refinement n. To fix the encoding unambiguously, let

$$\nu(z) = \begin{cases} 2z, & z \geq 0, \\ -2z - 1, & z < 0, \end{cases} \qquad \pi_{\mathrm{C}}(u, v) = \frac{(u + v)(u + v + 1)}{2} + v,$$

and define $\iota : \mathbb{Z}^d \to \mathbb{N}_0$ by recursive application of π_{C} to $\nu(z_1), \ldots, \nu(z_d)$. Then

$$q_n(\Gamma) = \frac{\iota(\ell_n(\Gamma))}{1 + |\iota(\ell_n(\Gamma))|} \in (-1, 1).$$

The minimal realization of tower is

$$\eta_{h_n}(\Gamma) = \frac{3^{-(n+1)} q_n(\Gamma)}{s_{h_n}}, \qquad \mathfrak{T}(\Gamma) = (\eta_h(\Gamma))_{h \in \mathcal{H}_{90,120}}.$$

Theorem 91.24 (Convergence, naturality and metrological blindness)**.** *For every enriched route,*

$$\sum_{h \in \mathcal{H}_{90,120}} |\eta_h(\Gamma) s_h| \le \sum_{n \ge 0} 3^{-(n+1)} = \frac{1}{2}.$$

If the refinement prolongs the record by prefixes, $\mathfrak{T}$ is natural with respect to the truncations. Moreover, no external mass value intervenes in $\mathfrak{T}$, and the tail after N modes satisfies

$$\sum_{n > N} |\eta_{h_n} s_{h_n}| \le \frac{3^{-(N+1)}}{2}.$$

Proof. We have $|q_n| < 1$; the two bounds are geometric sums. Prefix compatibility preserves all coefficients already constructed and adds those of the new level, which yields the naturality square with the truncation of $\mathcal{E}_{90,120}$. The formula contains only the record, the explicit coding, and the declared modal normalization. □

The preceding construction fixes an explicit, convergent minimal realization relative to the encoding ι and the declared normalizations s_h. A dynamics that modifies its weights must declare the operator effecting that modification and prove naturality and convergence anew; it cannot reconstruct the weights from an experimental residual.

91.11 Fiber operators and bidirectional law

For $F_X = \mathcal{S}(X)$, let

$$\mathcal{H}_X = \ell^2(F_X) \otimes V_{\rho_X}$$

the realization space, where V_{ρ_X} carries the corresponding internal representation. Each route $\gamma \in F_X$ has signature

$$\sigma(\gamma) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta) \in \mathbb{Z}^5$$

and refinement coefficients $\eta(\gamma) \in \mathcal{E}_{90,120}$. The basal operator is

$$\widehat{M}_X^{(0)} = \sum_{\gamma \in F_X} m_{\mathrm{clk}}\, \chi_{\mathrm{full}}(\sigma(\gamma), \eta(\gamma)) |\gamma\rangle\langle\gamma| \otimes I_{V_{\rho_X}}.$$

The scale m_{clk} descends from the absolute branch action–clock–mass, including the decade 10^{-34}; it is not extracted from an experimental mass.

The readers K_D and K_Ω induce exact diagonal operators B_X^D and B_X^Ω. The two orientations publish

$$\widehat{M}_X^{\beta,r} = R_{\mathrm{act}}^{B_X^r/2} \widehat{M}_X^{(0)} R_{\mathrm{act}}^{B_X^r/2}, \qquad r \in \{D, \Omega\}.$$

Both are positive and commute in the route basis. By the joint spectral theorem there exists a unique projective spectral measure $E_X^{D,\Omega}$ over $\mathbb{R}_+^2$ such that

$$\widehat{M}_X^{\beta,D} = \int x \, dE_X^{D,\Omega}(x, y), \qquad \widehat{M}_X^{\beta,\Omega} = \int y \, dE_X^{D,\Omega}(x, y).$$

At the base of routes,

$$E_X^{D,\Omega}(A)|\gamma\rangle = \mathbf{1}_A(m_D(\gamma), m_\Omega(\gamma))\,|\gamma\rangle.$$

This is the canonical bidirectional output: it preserves the complete pair and does not presuppose a scalar functional in advance.

Let

$$\boldsymbol{\beta}_X(\gamma) = (m_D(\gamma), m_\Omega(\gamma)).$$

The uniform image measure of the fiber is

$$\nu_X = (\boldsymbol{\beta}_X)_\# \left(\frac{1}{|F_X|} \sum_{\gamma \in F_X} \delta_\gamma \right) = \frac{1}{|F_X|} \sum_{\gamma \in F_X} \delta_{(m_D(\gamma), m_\Omega(\gamma))}.$$

Its transform and its mixed moments are

$$Z_X(s,t) = \int e^{sx+ty}\, d\nu_X(x,y), \qquad \mathfrak{m}_{p,q}(X) = \int x^p y^q\, d\nu_X(x,y).$$

Since ν_X has finite support, Z_X, or equivalently the complete family of mixed moments, determines the joint multiset of reader pairs up to permutation of routes. The pushforward measure is therefore a complete invariant of the operator pair; it is not an average of masses.

For a channel $P_{X,a}$, the compressed spectral measure

$$F_{X,a}^{D,\Omega}(A) = P_{X,a} E_X^{D,\Omega}(A) P_{X,a}\Big|_{P_{X,a}\mathcal{H}_X}$$

is a POVM on the prepared subspace. For a density ρ_X supported on that subspace, the joint scalar distribution is

$$\mu_{X,a}^{D,\Omega}(A) = \mathrm{Tr}\Big(\rho_X F_{X,a}^{D,\Omega}(A)\Big).$$

Every declared functional $f : \mathbb{R}_+^2 \to \mathbb{R}_+$ induces $\mu_{X,a}^{f} = f_\# \mu_{X,a}^{D,\Omega}$ without modifying the source PVM.

If $u : F_X \to F_Y$ is a bijection preserving record, orientation, and both readers, the unitary $U_u|\gamma\rangle = |u\gamma\rangle$ satisfies

$$U_u E_X^{D,\Omega}(A) = E_Y^{D,\Omega}(A) U_u, \qquad \nu_X = \nu_Y.$$

The same equality holds for the physical distributions when density and projector are transported by U_u. This naturality is asserted only for the intertwiners actually constructed; a coincidence of cardinalities does not by itself create an equivalence of fibers.

When the physical representation requires symmetry under the exchange $D \leftrightarrow \Omega$, the minimal operatorial aggregate is the geometric mean

$$\widehat{M}_X^{\mathrm{sym}} = \widehat{M}_X^{\beta,D} \# \widehat{M}_X^{\beta,\Omega}, \qquad A\#B = A^{1/2}\big(A^{-1/2} B A^{-1/2}\big)^{1/2} A^{1/2},$$

on the common positive support. In the diagonal case,

$$\widehat{M}_X^{\mathrm{sym}} = R_{\mathrm{act}}^{(B_X^D + B_X^\Omega)/4}\, \widehat{M}_X^{(0)}\, R_{\mathrm{act}}^{(B_X^D + B_X^\Omega)/4}.$$

This formula is a consequence of the explicit exchange hypothesis; it does not replace the joint measure when that symmetry has not been established.

Theorem 91.25 (Characterization of the symmetric aggregate)**.** *The geometric mean is positive, symmetric, congruence-covariant for every invertible S, and self-dual:*

$$A\#B = B\#A, \qquad S^*(A\#B)S = (S^*AS)\#(S^*BS), \qquad (A\#B)^{-1} = A^{-1}\#B^{-1}.$$

Moreover, $A\#A = A$. Consequently, in sectors where there is a physical intertwiner exchanging the readers, the aggregate introduces no parameter and favors neither orientation.

Proof. The congruence identity is understood for invertible S. The identities follow from the functional calculus of the positive root of $A^{-1/2}BA^{-1/2}$. In the commutative case, they reduce to $A\#B = (AB)^{1/2}$. □

There is also a canonical scalar aggregate under distinct axioms. If s_n is continuous, permutation-invariant, coordinatewise multiplicative, and normalized by $s_n(cI) = c$, then

$$s_n(T) = \det(T)^{1/n}.$$

Indeed, upon passing to logarithms, continuity and additivity make the functional linear in the logarithms of the eigenvalues; symmetry makes all coefficients equal, and normalization fixes their value at $1/n$. For the pair of readers, exchange symmetry gives the invariant

$$S_{D,\Omega} = \sqrt{\operatorname{ndet}(T_D)\operatorname{ndet}(T_\Omega)}, \qquad \operatorname{ndet}(T) = \det(T)^{1/n}.$$

This result classifies the complete fiber under the stated axioms. It is not automatically identified with a mass line: that identification requires the physical coupling to adopt precisely that functional.

For the rank-one electronic fiber, the joint measure is punctual, the two readers share the first component 80, the compression is scalar, and the beta closure is recovered

$$m_e^\beta = 0.5109989506900008086082571648\ldots \text{ MeV}.$$

The base value remains as a construction stage; it does not replace the beta closure.

91.12 Symmetry Scalarization and Coupling

Let G_X be the compact group of unbroken symmetry of the fiber and $U_X : G_X \to \mathcal{U}(\mathcal{H}_X)$ its representation. The conditional symmetry expectation is defined by

$$\mathbb{E}_X(T) = \int_{G_X} U_X(g) T U_X(g)^* \, d\mu_X(g),$$

where μ_X is the normalized Haar measure. The physical mass operator before opening channels is defined, when the state type declares a functional $\Phi_X : \mathbb{R}_+^2 \to \mathbb{R}_+$, by

$$\mathcal{M}_X = \mathbb{E}_X\Big(\Phi_X(\widehat{M}_X^{\beta,D}, \widehat{M}_X^{\beta,\Omega})\Big).$$

The functional calculus is carried out with the joint measure $E_X^{D,\Omega}$. In a representation containing an intertwiner that exchanges readers, one may take $\Phi_X(x,y) = \sqrt{xy}$. If the physical type does not declare Φ_X, the complete output remains the joint PVM; no scalar is fabricated.

Theorem 91.26 (Scalar closure, multiplet, and distribution)**.** *The operator $\mathcal{M}_X$ belongs to the commutant $U_X(G_X)'$. If*

$$\mathcal{H}_X \simeq \bigoplus_\lambda V_\lambda \otimes \mathbb{C}^{m_\lambda},$$

then

$$\mathcal{M}_X = \bigoplus_\lambda I_{V_\lambda} \otimes M_{X,\lambda}.$$

In an irreducible sector of multiplicity 1*, the restriction is a scalar. In a reducible sector, the exact output is the spectrum of the blocks $M_{X,\lambda}$, with their multiplicities. There is no indeterminacy: there is a distinct codomain.*

Proof. Invariance of the Haar measure implies $U_X(h)\mathbb{E}_X(T)U_X(h)^* = \mathbb{E}_X(T)$ for every $h \in G_X$. The decomposition follows from the complete reducibility theorem and Schur's lemma. The irreducible case produces a multiple of the identity; the reducible case preserves exactly the multiplicity blocks. □

Let $P_{X,a}$ be the projector determined by the prepared state and the physical channel or apparatus a. The observable spectral measure is

$$\mu_{X,a}(B) = \langle \Psi_X, P_{X,a} E_{\mathcal{M}_X}(B) P_{X,a} \Psi_X \rangle.$$

There is a scalar line precisely when the compressed spectral support is pointwise:

$$E_{\mathcal{M}_X}(\{m_X\})P_{X,a} = P_{X,a}, \qquad \text{equivalently} \qquad (\mathcal{M}_X - m_X I)\, P_{X,a} = 0.$$

The isolated equality $P_{X,a}\mathcal{M}_X P_{X,a} = m_X P_{X,a}$ only fixes an expectation if the subspace is not reducing and is not enough to prove a spectral line. If the compression preserves several eigenvalues, the output is a multiplet or a distribution. Replacing it with a numerical average would destroy physical and genealogical information.

91.13 Construction of the mass operator from the trajectory record

The construction distinguishes two operations. First, the dynamics produces a record of the trajectory. Then a functional extracts integer coordinates and evaluates them using the internal constants already obtained. Preserving that order explains how mass can be a magnitude of persistence without exhausting its structure.

91.13.1 Chronological reading and oriented events

Let $d_1, \dots, d_{108}$ be the digital reading of an enriched route. In the declared chart, the action support is $\{1, 3, 5, 7\}$, and

$$n_A = \#\{t : d_t \in \{1, 3, 5, 7\}\}.$$

The 12 events of the blocks of 9 steps are also preserved:

$$e_m = \sigma_m \#\{t : 9m + 1 \le t \le 9m + 9,\ d_t \in \{2, 4, 6, 8\}\}, \quad 0 \le m < 12,$$

where $\sigma = (+, +, +, -, -, -, +, +, +, -, -, -)$. The support of this extractor is an explicit part of the reading chart; its function must not be confused with the ternary phase selector of the TPK.

The distribution of events is relevant even when their sums coincide. To see it, we introduce

$$p_i = e_i + e_{i+6}, \quad a_i = e_i - e_{i+6}, \quad s_C = \sum_{i=0}^{5} p_i, \quad M_i = p_i - p_5 \ (0 \le i < 5).$$

Proposition 91.27 (Integral reconstruction of the events)**.** *The transformation* $(e_0, \dots, e_{11}) \mapsto (s_C, M_0, \dots, M_4, a_0, \dots, a_5)$ *is injective on* $\mathbb{Z}^{12}$*. Its image is characterized by*

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6, \qquad p_i \equiv a_i \pmod 2 \quad (0 \le i < 6),$$

where $p_5 = (s_C - \sum M_i)/6$ *and* $p_i = p_5 + M_i$ *for* $i < 5$.

Proof. Adding the six expressions of p_i gives $s_C = 6p_5 + \sum_{i<5} M_i$. This recovers the p_i, and then

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}.$$

The congruences are necessary for these quantities to be integers and sufficient for the formulas to define an integral preimage. Substituting into the direct transformation recovers all the coordinates. □

The decomposition $12 = 1 + 5 + 6$ thus acquires an operational meaning: the total, the differences and the orientations recover the events. Division by 6 belongs to that reconstruction. When the character uses $s_C/6$, s_C remains the integer sum; a coordinate already divided is not divided a second time.

91.13.2 Torsional memory and signature

For each occurrence of 9, the reading preserves its predecessor. We define, with cyclic indices,

$$j_2(d) = \begin{cases} 0, & d = 9, \\ 1, & d \in \{2,4,6,8\}, \\ -1, & d \in \{1,3,5,7\}, \end{cases} \qquad z_t = \mathbf{1}_{\{d_t=9\}}\, j_2(d_{t-1}).$$

Then

$$T_z = \sum_{t=1}^{108} z_t, \quad C_z = \sum_{t\in\{27,54,81,108\}} z_t, \quad k_{\Delta_4} = T_z - 2C_z.$$

The first sum preserves the accumulated memory and the second distinguishes the crown closures. Removing the predecessors before evaluating these expressions alters the object being read.

With $\tau_m = \operatorname{sgn}(e_m)$, the remaining coordinates are

$$b_{120} = \sum_{a=0}^{3} \operatorname{sgn}(e_a + e_{a+4} + e_{a+8}), \qquad b_\zeta = \sum_{m=0}^{11} \tau_m \tau_{m+3},$$

where the second index is modulo 12. We obtain the signature

$$L_{\text{tick}}(\gamma) = \sigma(\gamma) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta) \in \mathbb{Z}^5.$$

This map is deterministic in the declared chart. The signs and the correlations explain why composition must be performed on the record before extracting the 5 integers: the sum of signatures does not, in general, represent the composition of two histories.

91.13.3 Character and internal specialization

Let $X = (X_A, X_C, X_4, X_{120}, X_{270})$. The formal character is

$$\chi(\sigma; X) = \exp\bigl(n_A X_A + s_C X_C + k_{\Delta_4} X_4 + b_{120} X_{120} + b_\zeta X_{270}\bigr)\,.$$

For each X, it satisfies $\chi(\sigma + \sigma'; X) = \chi(\sigma; X)\chi(\sigma'; X)$ because the exponent is linear in the signature. This is a law on signatures; it does not assert that the extractor is additive on routes without preserving the interface.

The specialization uses the internal coordinates constructed previously:

$$X_A = A_{\text{rad}}, \quad X_C = C^*_{\text{rad}}/6, \quad X_4 = \Delta_4, \quad X_{120} = s_{120}, \quad X_{270} = \zeta_{270} := 135\Delta_4^2.$$

The character is dimensionless and positive. Its effect is a homothety on the mass line. The exponential form determines how the coefficients act; their provenance is fixed in the preceding records and constructions.

91.13.4 Bilayer hierarchy and preservation of the two genealogies

We write $x = A_{\mathrm{rad}}$, $y = C^{*}_{\mathrm{rad}}$. In the chamber $x > y > 0$, the channels are

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}, \qquad 0 < q_+ < q_- < 1.$$

For an involution R, with $P_\pm = (I \pm R)/2$, the operator of the two channels is

$$T = q_+ P_+ + q_- P_-.$$

Its scalar and oriented moments are expressed as

$$c_n = q_-^n + q_+^n, \qquad s_n = q_-^n - q_+^n.$$

Multiplying these expressions proves

$$c_n^2 - s_n^2 = 4e^{-2nx}, \quad c_{m+n} = \frac{c_m c_n + s_m s_n}{2}, \quad s_{m+n} = \frac{s_m c_n + c_m s_n}{2}.$$

Both sequences satisfy

$$X_{n+2} = c_1 X_{n+1} - e^{-2x} X_n, \qquad X \in \{c, s\}.$$

These relations show that the heights share a single operator. A different family of moments is not defined for each species.

Proposition 91.28 (Semigroup of heights)**.**

$$\langle 90, 120\rangle = \{90, 120\} \cup \{30r : r \geq 6\}.$$

Proof. After dividing by 30, it suffices to study $\langle 3, 4\rangle$. The integers $6, 7, 8$ are $3+3, 3+4, 4+4$; adding 3 produces all subsequent integers. Below 6, the only positive elements are $3, 4$. □

The heights $360 = 4 \cdot 90 = 3 \cdot 120$ illustrate the difference between equality of evaluation and memory of composition. The algebraic quotient identifies the two exponents; the record preserves whether transport used four stages of one type or three of the other.

The refined specialization has exponent

$$\log \chi_{\mathrm{ref}} = n_A x + \frac{s_C}{6} y + k_{\Delta_4} \Delta_4 + b_\zeta \zeta_{270} + \sum_{h \in \langle 90,120\rangle} N_h s_h, \qquad N_h = \eta_h + b_{120} \mathbf{1}_{\{h=120\}}.$$

The pair (η_{120}, b_{120}) is preserved even though the evaluation uses its sum. Also kept separate are s_{270} and ζ_{270}: the former is a bilayer moment and the latter a quadratic expression of the refinement.

Proposition 91.29 (Convergence of the refined evaluation)**.** *If $\sum_h |N_h s_h| < \infty$, the refined character defines a finite positive scalar and its truncated evaluations converge to it.*

Proof. The hypothesis gives absolute convergence of the exponent. Continuity of the exponential allows passage to the limit; the exponential of a finite real number is strictly positive. □

Convergence evaluates a sequence of coefficients already specified. Selection of those coefficients by the route is a distinct operation, and must accompany every evaluation attributed to a species.

The notation χ_{full} retained in some evaluation formulas for the sectors designates this same character χ_{ref}, with the same arguments and coefficients. The change of symbol does not add another specialization or another tower.

91.13.5 Displacement and autocorrelation readers

The same route admits two readings of the return:

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2} \right), \qquad K_\Omega = (\Omega, 54, P_6).$$

The first map preserves displacement defects; the second, return memory and autocorrelation. In the full census of 324 orientations there are 14 profiles of the first, 9 of the second and 40 joint pairs. The 18 coincidences have value $(80, 54, 6)$. Equality of the two operators throughout the atlas is not inferred from this.

For the electronic route, the displacements are

$$(D_1, D_3, D_4, D_{27}, D_{36}) = (54, 56, 68, 48, 32).$$

Substitution produces $K_D = (80, 54, 6)$, coinciding with K_Ω. Its exponent is

$$\kappa_e = 80 - 54\alpha + 6\Delta_4.$$

The electronic trajectory is constructed in (90.117); its displacement and autocorrelation readers are evaluated, respectively, in (90.118) and (90.119). The coincidence $K_D = K_\Omega = (80, 54, 6)$ belongs to the beta closure theorem of subsection 90.17.9. Here that central exception is preserved and the operation is extended to the fibers of the atlas.

91.13.6 Operator on a fiber and dimensional section

Let $\mathscr{H}_M$ be the finite Hilbert space with orthonormal basis (e_γ) labeled by the routes of a multisection. For $r \in \{D, \Omega\}$, the return operator is defined by $B_M^r e_\gamma = \kappa_\gamma^r e_\gamma$, with real exponents; it is therefore self-adjoint. Let $M_M^{(0)}$ be the positive basal operator, whose connection with the character is fixed below. The dimensionless ratio of the action sections is $R_{\mathrm{act}} > 0$. We define

$$M_M^{\beta,r} = R_{\mathrm{act}}^{B_M^r/2} M_M^{(0)} R_{\mathrm{act}}^{B_M^r/2}.$$

Proposition 91.30 (Positivity and scalar restriction)**.** *The operator $M_M^{\beta,r}$ is positive. If both operators are diagonal in the route basis, each basal value $m_\gamma^{(0)}$ is transformed into*

$$m_\gamma^\beta = m_\gamma^{(0)} R_{\mathrm{act}}^{\kappa_\gamma}.$$

Proof. Let $S = R_{\mathrm{act}}^{B_M^r/2}$, self-adjoint and invertible. For every v, $\langle v, S M_M^{(0)} S v \rangle = \langle S v, M_M^{(0)} S v \rangle \geq 0$. In the diagonal basis, the two factors S multiply each value by $R_{\mathrm{act}}^{\kappa_\gamma/2}$; their product gives the formula. □

The absolute mass section is obtained from the action and the clock:

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad m_{\mathrm{clk}} = \hbar_{\mathrm{ret}} \omega_0 c_{\mathrm{int}}^{-2}.$$

In the chart normalized with respect to the electron, the preceding basal operator is

$$M_M^{(0)} e_\gamma = m_e^{(0)} \chi_{\mathrm{ref}}(\sigma_\gamma - \sigma_e, \eta_\gamma - \eta_e) e_\gamma.$$

Here $m_e^{(0)}$ is the realization of the basal electronic coordinate, with its prefactor, its refinement and its dimensional basis. If $E_e^{(0)} = \varepsilon_e^{(0)} \mathcal{U}_E$, then

$$m_e^{(0)} = \varepsilon_e^{(0)} \mathcal{U}_E c_{\mathrm{int}}^{-2} = b_e\, m_{\mathrm{clk}}, \qquad b_e = \varepsilon_e^{(0)} \frac{\mathcal{U}_E}{E_{\mathrm{clk}}}.$$

In the chart $\mathcal{U}_E = E_{\mathrm{clk}}$ we obtain $b_e = \varepsilon_e^{(0)}$; in another chart the indicated quotient of bases is preserved. If the tower coordinates are already relative to the electron, a second subtraction of η_e is omitted. This equality links the operator to the signature of each route and explicitly preserves the electronic normalization. A different choice of reference section must also transport that normalization. The scale of the reduced Planck constant belongs to this dimensional construction. The character and the return factor then act as scalars. The electron preserves its structure: it is not identified with the chronological quantum m_{clk}.

For two routes in the same absolute chart,

$$\frac{m_Y^\beta}{m_X^\beta} = \chi_{\mathrm{ref}}(\sigma_Y - \sigma_X, \eta_Y - \eta_X) R_{\mathrm{act}}^{\kappa_Y - \kappa_X}.$$

The common dimensional section cancels. The difference of the return exponents does not cancel unless it is zero. This identity preserves the distinction between absolute scale and relative structure of a family.

91.13.7 The null propagation sector

The exponential takes strictly positive values. The null chart is constructed before that character, in the split realization

$$\mathcal{A}_{\mathrm{sp}} = \mathbb{R}[R]/(R^2 - 1), \quad z = r_+ P_+ + r_- P_-, \quad N(z) = r_+ r_-.$$

The directions $\mathbb{R}P_+$ and $\mathbb{R}P_-$ have zero norm. Propagation transported in one of them belongs to that sector; the bilayer material reading uses the coupling of both. In this way, the photon and the gluonic sector retain their residence in the theory although they do not constitute a row of the positive character. The realization of their representations is presented alongside the corresponding sectors.

Chapter 92

Spectral, scalar, and null realizations of the General Mass Law: material families, CKM–PMNS transport, and photonic and gluonic sectors

92.1 Conjugation, parity, and time reversal in the register

CP violation in a mixing matrix and CPT symmetry are not the same assertion. Prior to the CPT theorem of a quantum field theory, the HMT register has an exact discrete symmetry on routes. Its content is concrete: conjugation exchanges the two sheets, parity reflects the directions, and time reversal traverses the register in the opposite direction. The local action that counts turns and changes of sheet is invariant under all three operations.

92.1.1 Route and local action

A trayectoria of length L is

$$\gamma = \big((i_0, j_0, \ell_0), (d_1, \dots, d_L)\big),$$

where $d_t \in \{N, E, S, W\}$ and $\ell_t \in \{\Sigma, \Pi\}$. The TPK dynamics determines the states (i_t, j_t, ℓ_t). We define

$$\mathrm{turn}(\gamma) = \#\{2 \le t \le L : d_t \neq d_{t-1}\},$$

$$\mathrm{switch}(\gamma) = \#\{2 \le t \le L : \ell_t \neq \ell_{t-1}\}.$$

Definition 92.1 (Discrete action of minimal interaction)**.** For $\lambda \ge 0$,

$$\mathcal{A}_\lambda(\gamma) := \mathrm{turn}(\gamma) + \lambda\ \mathrm{switch}(\gamma).$$

Equivalently,

$$\mathcal{A}_\lambda(\gamma) = \sum_{t=2}^{L} \left[1 - \delta_{d_t, d_{t-1}} + \lambda(1 - \delta_{\ell_t, \ell_{t-1}})\right].$$

The action depends on the variation of the route, not on the absolute names of the directions or the sheets.

92.1.2 Discrete involutions C, P, and T on the routes: sheet conjugation, spatial reflection, and record reversal

Definition 92.2 (Discrete Operators C, P, T)**.** On a complete trajectory the following are defined:

1. P, spatial reflection:

$$(i, j) \longmapsto (i, -j) \pmod 9, \qquad E \leftrightarrow W, \quad N \mapsto N, \quad S \mapsto S,$$

   without changing the sheet;

2. C, leaf conjugation:

$$\Sigma \leftrightarrow \Pi,$$

   without changing direction; in the angular chart it corresponds to $C^* \mapsto -C^*$, which interchanges $q_+ \leftrightarrow q_-$;

3. T, reversal of the ledger:

$$d_t \longmapsto \mathrm{opp}(d_{L+1-t}), \qquad \ell_t \longmapsto \ell_{L+1-t}, \qquad (i_t, j_t) \longmapsto (i_{L-t}, j_{L-t}).$$

Here T is an involution of the recorded trajectory. It is not identified with reversing an impoverished automaton that has forgotten the state required to reconstruct its predecessor.

Theorem 92.3 (CPT invariance of the route action)**.** *For every trajectory γ and every $\lambda \geq 0$,*

$$\boxed{\mathcal{A}_\lambda(\gamma) = \mathcal{A}_\lambda(C\gamma) = \mathcal{A}_\lambda(P\gamma) = \mathcal{A}_\lambda(T\gamma) = \mathcal{A}_\lambda(CPT\,\gamma).}$$

Proof. P applies an involutive permutation to the alphabet of directions. Hence $d_t = d_{t-1}$ if and only if $P(d_t) = P(d_{t-1})$, and it preserves the number of turns. C globally permutes the sheets and therefore preserves the equality pattern $\ell_t = \ell_{t-1}$; it does not alter the directions. T reverses the order of both sequences: the number of changes between consecutive terms is the same when a word is traversed in the forward or reverse direction. Each operation separately preserves turn and switch, and hence preserves $\mathcal{A}_\lambda$. Their composition also preserves it. □

92.1.3 Parity of Descendant Readers

The exchange $C^* \mapsto -C^*$ permutes q_+ and q_-. Therefore, every expression symmetric in the two channels is C-even, and every anti-symmetric difference is C-odd. theorem 73.4 realizes this rule in two objects:

$$S_{\mathrm{bi}}(-C^*) = S_{\mathrm{bi}}(C^*), \qquad \Gamma_{6\to 8}(A, -C^*) = -\Gamma_{6\to 8}(A, C^*).$$

The mass band of the theorem 92.31 realizes the same separation: even mass and odd charge/orientation.

92.1.4 Relation with CKM and with the CPT theorem of fields

The CKM matrix constructed in the following chapter has $\delta_{\mathrm{CP}} \neq 0$ and a nonzero Jarlskog invariant. This describes CP violation in that mixing representation. It does not contradict theorem 92.3: the latter acts on the ensemble of routes and their action; it does not require every oriented reader to be even.

The CPT theorem of quantum field theory adds another domain and other hypotheses —relativistic locality, field structure, spectrum, and the corresponding representation—. It is compared afterward. The HMT result proved here is the discrete symmetry of the register: it fixes the object that a field realization must transport, rather than replacing it with an external reference.

92.2 Codomains of the material realizations: spectral operator, scalar, gauge nullity, composite, and resonant pole

A fiber may publish a spectral operator, a scalar after physical compression, an exact gauge nullity, a composite operator, or a resonant pole with width. These outputs have distinct codomains and are not counted as classes of the domain 81/56/13/324.

92.3 Null extensions, propagation between boundaries and electronic closure

The photonic and gluonic sectors are realized through exact nullity, whereas the electronic closure occupies the material center. The complete development distinguishes null propagation, outward–return intertwining, physical interface, and closure criteria without transforming a nullity into an absence of structure.

92.4 Null extensions and material closure

92.4.1 4 realizations of the common material state: null, massive, composite, and topological

An isolated digit determines a coordinate but does not identify the structure that produces it, the memory it preserves, or the operation that converts it into a magnitude. HMT lies prior to that projection: its primary object is a compatible extension that preserves the arithmetic laws, TRIT orientation, quotients, phase, and boundary memory. Dimensional Mechanics subsequently specifies which component is realized as a magnitude, which remains as memory, and which transformation produces the observable.

The developments of this section distinguish four modes by their operation of closure:

1. an open null extension transports a perturbation between boundaries;
2. a closed and persistent extension acquires interior norm and defines the material candidate;
3. a family of extensions weighted by action defines a thermal ensemble;
4. a connection that compares sections at distinct points provides the codomain of the gravitational realization.

The common source does not identify the four codomains. The corresponding physical maps remain discontinuous:

$$\mathfrak{R}_\gamma : \Omega_{\mathrm{HMT}}^{\mathrm{surv}} \dashrightarrow \mathcal{H}_{\mathrm{rad}}, \qquad \mathfrak{R}_m : \Omega_{\mathrm{HMT}}^{\mathrm{surv}} \dashrightarrow \mathcal{H}_{\mathrm{mat}},$$
$$\mathfrak{R}_\Theta : \mathcal{P}(\Omega_{\mathrm{HMT}}^{\mathrm{surv}}) \dashrightarrow \mathcal{S}_{\mathrm{th}}, \qquad \mathfrak{R}_{\mathrm{grav}} : \Omega_{\mathrm{HMT}}^{\mathrm{surv}} \dashrightarrow \mathsf{Cartan}_{1,3}.$$

Their unity resides in the genealogy; their difference, in the reading and in the additional structures required by each realization.

92.4.2 Null propagation between boundaries

Let B be a transport basis. A *null section* of sign $\pm$ is a map

$$s_\pm : B \longrightarrow \mathcal{A}_{\mathrm{sp}} P_\pm$$

such that $s_\pm(x) \in \mathcal{A}_{\mathrm{sp}} P_\pm$ for every $x \in B$. By proposition 91.13,

$$N_{\mathrm{sp}}(s_\pm(x)) = 0 \qquad (x \in B).$$

If γ is an oriented route between two boundaries,

$$\partial\gamma = x_{\mathrm{abs}} - x_{\mathrm{em}},$$

the proposed photonic interface assigns to γ an extended null section. The adjective *extended* indicates that its identity belongs to the complete transport and not to an isolated point.

The conjugate route is obtained by inversion,

$$\gamma^\vee = C_{\mathrm{rev}}\gamma, \qquad \partial\gamma^\vee = x_{\mathrm{em}} - x_{\mathrm{abs}}.$$

Relative to the declared orientation reader, the pair $(\gamma, \gamma^\vee)$ represents the advanced and retarded readings. The two legs are ordered sequentially or housed in distinct fibers. They are not automatically added within the same fiber: if the two conjugate components are activated simultaneously, the exact identity

$$\boxed{N_{\mathrm{sp}}(uP_+ + vP_-) = uv}$$

shows that, for $u, v > 0$, the section leaves the null boundary and enters the positive interior.

92.4.2.1 Length, go and return

Once the dimensional velocity chart, $\widehat{c} = e^{-\mathcal{E}}$, and a positive basis u_L of the length line have been fixed, define

$$L_{\mathrm{int}}(\gamma) = \widehat{c}\,|\gamma|\,u_L.$$

Inversion preserves the number of steps:

$$L_{\mathrm{int}}(\gamma^{\vee}) = L_{\mathrm{int}}(\gamma), \qquad L_{\leftrightarrow} = 2L_{\mathrm{int}}(\gamma).$$

These identities are kinematic. Converting them into electromagnetic propagation requires that the same map reproduce Gauss's law, the gauge dynamics, null dispersion, and the reduction to two transverse degrees.

92.4.2.2 Entanglement entropy between the 2 *readings*

The reversal of a route does not suffice to assert quantum entanglement. A minimal formulation first requires a Hilbert completion. Let $\mathcal{H}_{\mathrm{adv}}$ and $\mathcal{H}_{\mathrm{ret}}$ be two complex spaces with orthonormal families $\{|i\rangle_{\mathrm{adv}}\}_{i\in I}$ and $\{|i\rangle_{\mathrm{ret}}\}_{i\in I}$, where I is finite. For a probability $p = (p_i)_{i\in I}$, define

$$|\Psi_p\rangle := \sum_{i\in I} \sqrt{p_i}\,|i\rangle_{\mathrm{adv}} \otimes |i\rangle_{\mathrm{ret}}. \tag{E1}$$

Proposition 92.4 (Round-trip double-layer entropy)**.** *The reduced matrices of the state $\rho_p = |\Psi_p\rangle\langle\Psi_p|$ are*

$$\rho_{\mathrm{adv}} = \sum_{i\in I} p_i |i\rangle_{\mathrm{adv}}\langle i|, \qquad \rho_{\mathrm{ret}} = \sum_{i\in I} p_i |i\rangle_{\mathrm{ret}}\langle i|, \tag{E2}$$

and possess the same von Neumann entropy:

$$\boxed{S_{\mathrm{ent}}(p) = -\operatorname{Tr}(\rho_{\mathrm{adv}} \log \rho_{\mathrm{adv}}) = -\sum_{i\in I} p_i \log p_i.} \tag{E3}$$

Here the convention $0 \log 0 := 0$ is adopted. The state is separable exactly when a single probability is equal to one.

Proof. Upon taking the partial trace, orthogonality cancels the terms with $i \neq j$. The nonzero eigenvalues of each reduced matrix are therefore the p_i, which gives (E3). The Schmidt rank is one exactly in the deterministic case. □

Once the completion has been chosen, the proposition formalizes an entropy between the advanced and retarded readings. It does not derive the probabilities p_i, does not identify those readings with the advanced and retarded propagators of a field theory, and does not convert a classical route correlation into entanglement. Construction of an isomorphism sending HMT memory to bipartite physical states, preserving evolution, and fixing p belongs to the PHYSICAL INTERFACE. The null entropy of a deterministic distribution constitutes the immediate negative control.

Hypothesis, domain, and conclusion

The proposition is PROVED FROM EXPLICIT STARTING STRUCTURE: it assumes the Hilbert completion, the orthonormal bases, and the distribution p. The construction of the intertwiner that physically realizes both layers is a PHYSICAL INTERFACE; it is not part of the proposition.

Definition 92.5 (HMT–MD Photonic Interface)**.** A realization photonic of HMT–MD is a section open sustained over a direction null of the algebra split, transported between boundaries conjugate and protected by a symmetry that preserves exactly the norm null.

The idempotents $P_\pm$ are not, by themselves, physical photons nor the two Maxwell polarizations. The complete realization requires an intertwiner

$$\mathfrak{R}_\gamma : \partial_{\mathrm{null}} C_{\mathrm{sp}}^{+} \dashrightarrow \mathcal{H}_{\mathrm{Maxwell}}^{\mathrm{phys}}$$

that preserves the inner product, evolution, and gauge action, and that selects exactly two transverse polarizations in 3 + 1 dimensions.

Comparison Criterion 92.6 (Photonic sector)**.** The identification physical remains refuted if the evolution leaves $\partial_{\mathrm{null}} C_{\mathrm{sp}}^{+}$, generates mass without the mechanism of breaking declared, does not reproduces the dispersion null or not dejan exactly two polarizations physical after the reduction of gauge.

92.4.3 Material closure and electronic center

The simultaneous coupling of two conjugate null directions yields, for $u, v > 0$,

$$N_{\mathrm{sp}}(uP_+ + vP_-) = uv > 0.$$

No isolated component has nonzero norm; the inner norm arises from their coupling. This algebraic statement does not add pre-existing masses and does not yet identify the null directions with photons *on shell*.

The structural classification of HMT contains a single fixed point of cellular inversion,

$$(5, 5).$$

The electron's relative action origin is $v_e = 0$. In the normalized split realization, set

$$Z_e = P_+ + P_- = I, \qquad N_{\mathrm{sp}}(Z_e) = 1.$$

The point $(5, 5)$, the origin $v_e = 0$, the raw signature $(24, 0, 12, 0, -12)$, and the transverse word 555555 are four distinct objects.

Definition 92.7 (Electronic closure candidate)**.** The resonant closure of conjugate electromagnetic null modes is formalized as the program that seeks a normalized central material section obtained by coupling two conjugate null modes, stabilized by a route closure and its holonomy.

The existence of the extension, the return, and the center of the atlas does not prove minimal compactness or the stability of the closure. The outstanding dynamical theorem must construct

$$\gamma_e = \xi_1 \circ \cdots \circ \xi_N, \qquad \partial \gamma_e = 0, \qquad \varepsilon(\gamma_e) = -1,$$

where each ξ_j is locally zero, the total boundary vanishes, and ε is the sign holonomy. Mass would be associated with the global closure cocycle, not with a sum of locally zero masses. This program does not reopen the central electron $(5, 5)$, the atlas, or the already constructed extension–route–record–character chain.

Proposition 92.8 (Relativistic Causal Interior Criterion)**.** *Let $p_1, \ldots, p_N$ be future null momenta in a Minkowski space with positive temporal signature, $p_i^2 = 0$, and let*

$$P = \sum_{i=1}^{N} p_i.$$

If all p_i are collinear, then $P^2 = 0$. If at least two are future and noncollinear, then $P^2 > 0$, and one may define

$$m^2 c^2 = P^2.$$

Proof. For future-directed null vectors, $p_i \cdot p_j \geq 0$ holds, with equality precisely when they are collinear. Since

$$P^2 = \sum_i p_i^2 + 2 \sum_{i<j} p_i \cdot p_j,$$

the first sum is zero. All cross products vanish in the collinear case; if a noncollinear pair exists, at least one is strictly positive. □

Therefore, a closed route is not massive by mere topology, nor is an open route null merely because it has a boundary. Realization requires that the geometric closure and the sum of momenta enter jointly into the causal interior.

92.4.3.1 Möbius, conjugation, and posterior occupation

Under the lifting and holonomy hypotheses of theorem 68.6, one turn reverses the orientation and two turns restore it. The Möbius band organizes particle and antiparticle as conjugate orientations of the same type of closure. Their physical identification requires a representation that reverses charge, preserves the norm, and intertwines the evolution. Möbius geometry does not by itself imply the algebra of fermionic occupation; its operator relations are introduced as operator hypotheses in the following chapter.

Comparison Criterion 92.9 (Electron closure)**.** The realization is refuted if the center $(5, 5)$ does not lift to a closed extension, if the holonomy does not select the odd sector, if the Hamiltonian lacks a stable bound solution that is unique up to symmetry, or if the charge, dispersion, and form factor do not agree with the electron realization.

92.4.4 Physical realizations by object, representation, and codomain

Each realization declares its primary object, its representation or fiber, and its native output. A scalar coordinate is published only when the object itself and its realization morphism force it.

92.4.5 Elementary Realizations of the Standard Model

Particle	Charge	Spin	Statistics	Realization HMT–MD
e^-	-1	$1/2$	fermiónica	punto fijo $(5, 5)$, vacancia orientada
μ^-	-1	$1/2$	fermiónica	bloque leptónico de rango 8
τ^-	-1	$1/2$	fermiónica	bloque leptónico de rango 16
ν_e	0	$1/2$	fermiónica	vector de interacción en soporte neutro 20
ν_μ	0	$1/2$	fermiónica	vector de interacción en soporte neutro 20
ν_τ	0	$1/2$	fermiónica	vector de interacción en soporte neutro 20
u	$+2/3$	$1/2$	fermiónica	rama up, generación 1, triplete de color
d	$-1/3$	$1/2$	fermiónica	rama down, generación 1, triplete de color
c	$+2/3$	$1/2$	fermiónica	rama up, generación 2, triplete de color
s	$-1/3$	$1/2$	fermiónica	rama down, generación 2, triplete de color
t	$+2/3$	$1/2$	fermiónica	rama up, generación 3, triplete de color
b	$-1/3$	$1/2$	fermiónica	rama down, generación 3, triplete de color
γ	0	1	bosónica	sección nula, dos polarizaciones
g^a	0	1	bosónica	adjunta de color, ocho generadores
$W^\pm$	± 1	1	bosónica	bloque vectorial cargado conjugado
Z^0	0	1	bosónica	bloque vectorial neutral
H	0	0	bosónica	sección escalar persistente

Las antipartículas se obtienen por C_M. Los antiquarks pertenecen al triplete conjugado; W^- es el conjugado de W^+; fotón, Z, Higgs y gluones poseen las conjugaciones propias de sus representaciones.

El soporte B1 exacto de las clases elementales tiene rangos

$$1, \quad 8, \quad 16, \quad 3\times 20, \quad 3\times 16, \quad 3\times 20.$$

Therefore, the number of class–route incidence is

$$1+8+16+60+48+60=193.$$

The incidences are not 193 distinct routes: the three neutrino flavors share the rank-twenty neutral support; the up flavors reuse a rank-sixteen support and the down flavors a rank-twenty support. The flavor projector must refine these supports. In the union of 36 quark cells, color is exactly

$$12_R+12_G+12_B.$$

This equality certifies the global chromatic support, but does not yet authorize the selection of a cell by flavour.

92.4.6 Generation, Charge, Spin, and Mass-Character Decomposition of the Leptonic Sector

92.4.6.1 Electron: center, vacancies and orientation

The electron is exceptional because its fibre contains the unique fixed point $(5,5)$. Its reduction to scalar mass does not require breaking an orbit. The active route is

$$e_{\mathrm{act}}=(2,2,5,-4,-3,-2)^2,$$

while the historical envelope

$$e_{\mathrm{env}}=(4,3,5,-4,-3,-5)^2$$

conserves the sign and absolute maximum of the two leaves. The envelope retains the word

$$\tau_e=+++---+++--,$$

but does not substitute active history.

Four data that must remain distinct are:

$$\text{raw signature}=(24,0,12,0,-12),$$

$$\text{even CT–108 signature}=(-12,-4,12,-6,12),$$

$$\text{event vector}=e_{\mathrm{act}}, \qquad \text{affine origin}=v_e=0.$$

The basal selector $(-22,+15)$ has two complementary internal readings. The regional decomposition gives

$$-22=-(27-5), \qquad +15=5\cdot 3=\binom{6}{2},$$

and the framework of vacancies

$$V_e=\begin{pmatrix}21 & 22\\ 6 & 7\end{pmatrix}$$

satisfies

$$\det V_e=21\cdot 7-22\cdot 6=15.$$

The 22 measures the oriented deficit of the extension; the 15, the area retention that survives closure. Thus the electronic particle appears as the central persistence of an oriented vacancy, not as a mass inserted into the central cell.

The complete equation is

$$\mathfrak{e}_e^{\beta} = \frac{\sqrt{3}}{4}\left[\exp\left(\frac{\varphi}{\pi^2}\right) - 22\alpha_{\mathrm{HMT}}^3\right](1 + 15\Delta_4)R_{\mathrm{act}}^{80-54\alpha_{\mathrm{HMT}}+6\Delta_4}.$$

In the electronic chart,

$$\mathfrak{e}_e^{\beta} = 0.5109989506900008086082571648\ldots \text{ MeV}.$$

92.4.6.2 Realization of the muon as a 2nd-generation leptonic section: fibre, signature and character

The muon resides in a leptonic multisection of rank eight. Its recovered structural trace comprises the cells

$$\{21, 23, 25, 39, 43, 57, 59, 61\},$$

the counts of turn/change 22/25, the north–south axis,

$$(N, E, S, O) = (62, 25, 7, 14), \qquad (h_{369}, r_5) = (57, 9),$$

and the central coordinate

$$(n_A, s_C) = (42, -3).$$

The proper object is the compressed operator.

$$\widehat{M}_{\mu} = P_{\mu}\widehat{M}P_{\mu}.$$

Its reduction to a number requires prove that the projector of flavor and generation commutes with the operator, or that the state prepared has variance null. Given the signature enriched

$$(42, -3, 8, 0, 2),$$

the evaluation of character is

$$105.658360294435829\ldots \text{ MeV}.$$

This figure is an exact control of the evaluation of that signature; the complete physical derivation must reproduce the signature from the genealogical record selected by the coupling. The muonic width is obtained from the temporal decay operator and not from $\widehat{M}_{\mu}$.

92.4.6.3 Realization of the tau as a 3rd-generation leptonic section: fibre, signature and character

The tau occupies a sixteen-rank lepton multisection. Its footprint comprises

$$17/24, \qquad \text{east–west axis}, \qquad (N, E, S, O) = (29, 55, 7, 17),$$
$$(h_{369}, r_5) = (59, 6), \qquad (n_A, s_C) = (64, 0).$$

The enriched signature

$$(64, 0, 25, -1, 6)$$

yields

$$1776.8609176314323\ldots \text{ MeV}.$$

As in the muon case, the well-defined structure is the operator block; the scalar mass is obtained when the tau coupling selects a scalar block or an isolated pole.

92.4.6.4 Common neutrino fiber and flavor separation through the PMNS reader

The three neutrino flavors share the space

$$\mathcal{H}_\nu = \bigoplus_{j=1}^{4} \mathcal{H}_{\nu,G_j}, \qquad \dim \mathcal{H}_\nu = 2+4+6+8 = 20.$$

The vectors

$$f_e, \quad f_\mu, \quad f_\tau$$

constitute an interaction basis; they are not three mass eigenvectors. Nor is depth G_j a fourth sterile flavour: a sterile interpretation requires an additional physical projector.

The neutral extractor is defined by

$$T_\nu(m) = \sum_{t\in E_m} \omega(t)\varepsilon(t)\theta(t), \qquad e^\nu_m = T_\nu(m) - T_\nu(m+6),$$

$$\tau^\nu_m = \operatorname{sgn}(e^\nu_m).$$

It is obtained from it.

$$b^\nu_{120} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m\in I_a} e^\nu_m\right),$$

$$b^\nu_\zeta = \sum_m \tau^\nu_m \tau^\nu_{m+3}.$$

The neutrino signature possesses the form

$$v^{(i)}_\nu = (0, 0, k^{(i)}_{\Delta_4}, b^{\nu_i}_{120}, b^{\nu_i}_\zeta).$$

The inversion bidirectional changes b_{120} and preserves b_ζ; this asymmetry produces internally the two orientations of hierarchy.

92.4.6.5 Fermionic Nature of the Neutrino

Neutrality does not determine statistics. The neutrino sector lies in the exterior completion and carries spinorial holonomy:

$$U_\nu(2\pi) = -I, \qquad U_\nu(4\pi) = I,$$

$$\{a_{\nu,i}, a^\dagger_{\nu,j}\} = \delta_{ij}.$$

Therefore, every physical neutrino mode is fermionic. The Dirac/Majorana question is subsequent: it determines whether conjugation interchanges two distinct sections or identifies a section with its conjugate within a real representation. Neither possibility makes the neutrino a boson.

92.4.6.6 Mass operator and PMNS

Let P_ν be the rank-three projector onto the subspace of mass modes. First diagonalize

$$P_\nu \widehat{M}_\nu P_\nu = \sum_{i=1}^{3} m_i \, |n_i\rangle\langle n_i|.$$

Then the transport between bases is constructed:

$$(f_e, f_\mu, f_\tau) = (n_1, n_2, n_3) U_{\mathrm{PMNS}}^{\dagger}.$$

A full-rank kernel that reads sheet, orientation, carry, vacancy, and holonomy can be written

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c \in L_a} \sum_{d \in N_b} K_{\mathrm{reg}}(c, d),$$

$$U_{\mathrm{PMNS}} = \mathrm{polar}(G), \qquad \det G \neq 0.$$

The internal phase of rank one produces the angles

$$(19.6807^\circ, 56.4970^\circ, 29.6224^\circ)$$

and, for that reason, cannot be the complete physical PMNS kernel. Full rank is a mathematical requirement, not a numerical retouching.

The observables

$$m_1, m_2, m_3, \qquad \Delta m_{ij}^2, \qquad m_\beta, \qquad m_{\beta\beta}, \qquad \sum_i m_i$$

they are different maps of the same spectrum. They should not be collapsed into a single "neutrino mass".

92.4.7 Quarks, color, generations, and CKM mixing

92.4.7.1 Structural position of the 6 *quark flavors*

Each quark is defined by

$$\mathfrak{q}_X = (\text{charge branch, generation, } \mathbb{Z}_3^{\mathrm{color}}, \text{multisection, genealogical record, sheet}).$$

The structural position of the six flavors is summarized by their traces prior to any mass chart:

Flavor	Branch/generation	Giro/cambio	Eje	(N, E, S, O)	(h_{369}, r_5)	(n_A, s_C)
u	positiva/1	21/30	N–S	$(34, 31, 31, 12)$	$(51, 13)$	$(11, 7)$
d	negativa/1	20/32	E–O	$(27, 35, 18, 28)$	$(47, 17)$	$(17, 8)$
c	positiva/2	21/29	E–O	$(20, 38, 24, 26)$	$(49, 16)$	$(61, 8)$
s	negativa/2	17/27	N–S	$(50, 32, 12, 14)$	$(57, 11)$	$(41, -3)$
t	positiva/3	21/26	N–S	$(46, 27, 16, 19)$	$(57, 9)$	$(100, -1)$
b	negativa/3	21/30	E–O	$(12, 63, 9, 24)$	$(47, 7)$	$(71, -5)$

Estas posiciones no son seis números elegidos: son seis clases de representación que actúan sobre tripletes de color. La ruta física puede ser una órbita o un bloque de rutas; no tiene que ser un punto.

92.4.7.2 Invarianza escalar del carácter de masa bajo la acción de color

Sea P_q el proyector de sabor y generación y P_{RGB} el proyector a la órbita de color. La masa quark es

$$\widehat{M}_q = P_q P_{\mathrm{RGB}} \widehat{M} P_{\mathrm{RGB}} P_q.$$

If

$$[\widehat{M}_q, U(g)] = 0, \qquad g \in SU(3),$$

then

$$\widehat{M}_q = m_q I_3$$

over the triplet irreducible. This equality explains by which the flavor carries a mass common although their three colors occupy positions distintas in the atlas.

92.4.7.3 Chart of schema and scale

The internal HMT coordinate must be transported to a renormalized definition:

$$m_q^{\mathcal{S}}(\mu) = Z_m^{\mathcal{S}}(\mu, \mu_0)\, \mathcal{R}_q(\widehat{M}_q),$$

with composition law

$$Z_m(\mu_2, \mu_0) = Z_m(\mu_2, \mu_1) Z_m(\mu_1, \mu_0).$$

For u, d, s, the natural comparison uses $\overline{\mathrm{MS}}$ at 2 GeV; for c, b, the scale of the renormalized mass itself; for t, one must state whether the chart is a pole, MSR, or kinematic chart. Without this transport, a numerical difference is not yet a residual of the law.

92.4.7.4 Assessments of the declared signatures

The historical central coordinates produce:

Flavor	Evaluation
u	2.165924536173907 . . . MeV
d	4.679550162948874 . . . MeV
c	1.270500838641911 . . . GeV
s	92.94009390784564 . . . MeV
t	172.5974795440191 . . . GeV
b	4.190119763299790 . . . GeV

Estas evaluaciones comprueban el carácter una vez dada la firma. La deducción completa exige obtener cada firma, su refinamiento de torre y su carta de esquema a partir del proyector de sabor y del registro genealógico correspondiente.

92.4.7.5 Determinación de los ángulos CKM desde la reflexión racional de las rutas quark

Sean

$$A = 1000\alpha_{\mathrm{HMT}}, \qquad h = \frac{C^*}{6}, \qquad \Delta = \frac{180}{\pi}\Delta_4.$$

The angular grammar gives

$$\begin{pmatrix}\theta_{12}\\ \theta_{23}\\ \theta_{13}\end{pmatrix}=\begin{pmatrix}2 & -5 & 28\\ 0 & 7 & -25/2\\ 1 & -20 & -2/3\end{pmatrix}\begin{pmatrix}A\\ h\\ \Delta\end{pmatrix},\qquad \delta_{\mathrm{CP}}=9A.$$

The exact linear falsifier is

$$3857\,\delta_{\mathrm{CP}}=9\big(1528\theta_{12}+3380\theta_{23}+801\theta_{13}\big).$$

From the three angles and δ_{CP}, the unitary matrix V_{CKM} is constructed. Its function in the mass law is not to produce eigenvalues, but to transport the down operators to the up basis:

$$B_d^{(u)}=V_{\mathrm{CKM}}B_dV_{\mathrm{CKM}}^{*}.$$

92.4.7.6 Jarlskog Invariant

The CP violation invariant is

$$J_{\mathrm{CKM}}=c_{12}c_{23}c_{13}^2s_{12}s_{23}s_{13}\sin\delta_{\mathrm{CP}},$$

and the internal evaluation is

$$J_{\mathrm{CKM}}=3.1189723326632947\times10^{-5}.$$

Equivalently, the compatibility between spectra and mixing may is read in the determinant of the commutator of the operators Hermitian up/down. A value not null of J_{CKM} records orientation physical not removable; is not a corrector of mass added to each quark.

92.4.8 Gauge and scalar sectors

92.4.8.1 Chart of the null sector: mass routes 0*, gauge representations, and persistence*

Let

$$\mathcal{A}_{\mathrm{sp}}=\mathbb{R}[R]/(R^2-1),\qquad P_{\pm}=\frac{1\pm R}{2}.$$

For

$$x=r_+P_++r_-P_-,$$

the split norm is

$$N_{\mathrm{sp}}(x)=r_+r_-.$$

The null section is a direction of zero norm. Its mass is exactly

$$m=0,$$

without passing through a limit of positive characters and without assigning $\kappa=0$. Nullity belongs to the type of the section.

92.4.8.2 Realization of the photon in the electromagnetic null sector: helicity, gauge, and character

The photon is the transverse vector realization of a null gauge section. The physical projector must leave exactly two polarizations:

$$\operatorname{rg} P_\gamma^{\mathrm{trans}} = 2, \qquad P_\gamma^{\mathrm{trans}} k = 0.$$

The rest mass is

$$m_\gamma = 0.$$

Bidirectional propagation may carry an oriented anisotropy.

$$\epsilon = q_-^{90} - q_+^{90}, \qquad c_\pm = \frac{c}{1 \pm \epsilon},$$

while the harmonic mean preserves

$$\frac{2}{1/c_+ + 1/c_-} = c.$$

Thus, the outward and return paths may differ without altering the two–way invariant. This bias is not a photon mass.

A distinct Proca/Stückelberg realization appears if a spectral gap in the genealogical record satisfies

$$\omega^2 = k^2 + m_T^2$$

and there exists a dimensional entangler

$$m_T \longmapsto m_\gamma.$$

The induced delay would obey

$$\frac{\Delta T}{T} \simeq \frac{1}{2} \left(\frac{m_\gamma c^2}{\hbar \omega} \right)^2 .$$

The null Maxwell sector and the massive Proca realization are distinct branches; neither invalidates the other.

92.4.8.3 Chromodynamic realization of the null sector: gluon octet and adjoint representation of $SU(3)$

The residual trit generates the color space, whose traceless part realizes

$$\mathfrak{sl}_3 \longrightarrow \mathfrak{su}_3.$$

The gluon occupies the eight-dimensional adjoint representation. As long as color symmetry remains exact,

$$m_g = 0.$$

Confinement, screening, and the collective spectral gap are properties of the interacting spectrum; they do not constitute an elementary gluon pole mass. An effective mass must specify the observable, gauge, regime, and operator that defines it.

92.4.8.4 Realization of the bosons $W^{\pm}$: charge, polarization, and electroweak character

The sector W is a charged vector block with conjugation

$$C_M : W^+ \longleftrightarrow W^-.$$

Its historical footprint is

$$15/37, \qquad \text{east–west axis}, \qquad (n_A, s_C) = (94, -1),$$

and the enriched signature declared is

$$(94, -1, 0, -2, 4).$$

The corresponding evaluation is

$$80.37896490970455\ldots \text{ GeV}.$$

The realization complete is the pole of the resolvente of the block $P_W \widehat{M} P_W$; its part imaginaria determines the width. The degeneration of W^+ and W^- proceeds of the conjugation of the operator.

92.4.8.5 Realization of the Z^0 boson: neutral mixing, polarization, and electroweak character

The Z^0 is the neutral vector block of the electroweak coupling. Its historical trace is

$$20/23, \qquad \text{east–west axis}, \qquad (n_A, s_C) = (95, -1),$$

and the enriched signature

$$(95, -1, -11, 0, -4).$$

The evaluation of the character gives

$$91.18753344431341\ldots \text{ GeV}.$$

The neutral projector must be constructed before the pole chart; mass and width are two coordinates of the same pole, not a single figure.

92.4.8.6 Realization of the Higgs sector: scalar mode, coupling and mass character

The Higgs is a persistent scalar section of the gauge block with declared CP parity. Its trace is

$$24/29, \qquad \text{north–south axis}, \qquad (n_A, s_C) = (97, 9).$$

The conditional evaluation of the character produces

$$125.2924660425361\ldots \text{ GeV}.$$

The HMT definition does not identify “scalar” with “mass”: zero spin fixes the rotational representation; mass follows from the spectrum of the coupled scalar block. The width and decay channels require the temporal operator.

92.4.8.7 The anomalous magnetic moment of the muon

The internal functional

$$a_\mu = \frac{\alpha_{\mathrm{HMT}}}{2\pi} + \frac{\alpha_{\mathrm{HMT}}(\varphi - 1)}{1000} + \frac{\alpha_{\mathrm{HMT}}^2}{1000(54+1)}$$

gives

$$a_\mu = 0.001165920713008014\ldots,$$

and

$$g_\mu = 2(1 + a_\mu) = 2.002331841426016028\ldots.$$

The three terms correspond, respectively, to the basal rotation, the oriented return in the completion 1000, and the quadratic correction mediated by the defect 54. This observable verifies the internal structure of the muonic sector but does not by itself select its mass route.

92.4.9 Construction of composite particles through non-additive composition of paths and bonds

92.4.9.1 Composition operator

Route composition is not strictly additive because boundary, temporal order, and carry interact. For two ledgers,

$$\mathcal{L}_1 \star \mathcal{L}_2 = \mathcal{L}_1 + \mathcal{L}_2 + \mathfrak{b}(\mathcal{L}_1, \mathcal{L}_2),$$

where $\mathfrak{b}$ is the binding cocycle. Associativity requires

$$\mathfrak{b}(L_1, L_2) + \mathfrak{b}(L_1 \star L_2, L_3) = \mathfrak{b}(L_2, L_3) + \mathfrak{b}(L_1, L_2 \star L_3).$$

The mass reader acts after this composition:

$$(\Gamma_i, \mathcal{T}, \partial) \xrightarrow{\mathfrak{C}_{12}} \mathcal{L}_{\mathrm{comp}} \xrightarrow{L_{\mathrm{tick}}} \sigma_{\mathrm{comp}} \xrightarrow{\chi_{\mathrm{full}}} \widehat{M}_{\mathrm{comp}}.$$

92.4.9.2 Mesonic Realization via Quark–Antiquark Composition and Cocylic Link Law

The mesonic domain contains 432 oriented expressions.

$$M(q, q') = q \otimes (q')^\vee$$

with color compatible. The physical projector imposes color singlet and fixes

$$(J^{PC}, I, I_3, S, C, B, \ldots),$$

together with the temporal linking tree. The mass of a meson is not $m_q + m_{\bar{q}}$; it is an eigenvalue of the composite ledger.

The six historical control evaluations include

$$m_{\pi^0} = 134.9767243278721\ldots \text{ MeV},$$
$$m_{\pi^\pm} = 139.5704851715722\ldots \text{ MeV},$$
$$m_{K^\pm} = 493.6770856495306\ldots \text{ MeV},$$
$$m_{K^0} = 497.6111864977505\ldots \text{ MeV}.$$

These figures are exact evaluations of declared records. Genealogical closure state by state requires regenerating each record by means of $\mathfrak{C}_{12}$, including its binding boundary.

92.4.9.3 Baryonic realization via trilinear composition of quark paths and color neutralization

The baryonic domain contains 1728 RGB expressions. The physical projector must simultaneously impose:

1. color singlet;
2. fermionic statistics;
3. flavor and isospin;
4. spin and symmetrization;
5. triple tree with carry and memory.

For proton and neutron, the historical signatures

$$\sigma_p = (59, 0, 9, 1, 0), \qquad \sigma_n = (59, 1, -34, 0, 1)$$

give

$$m_p = 938.2717515469849\ldots \text{ MeV},$$
$$m_n = 939.5658104725070\ldots \text{ MeV}.$$

Apparent precision does not replace derivation of the genealogical binding record. The sign and magnitude of

$$m_n - m_p$$

must follow from orientation, isospin, vacancies, and the linking boundary before external comparison is opened.

92.4.9.4 Excited states and hadronic resonances

A composite identity may possess several poles. The physical state is individualized by

$$(\text{constituents}, \mathcal{T}, \partial, J^{PC}, I, \text{radial}, \text{orbital}, \text{channel}).$$

The same flavor composition is not sufficient to distinguish excitations. Each pole

$$z_k = M_k - \frac{i}{2}\Gamma_k$$

must proceed from an eigenvector of the composite operator and from a decay channel. This extends the law from a few stable masses to the entire spectrum of mesons and baryons without converting the external catalog into a generator.

92.4.9.5 Comprehensive inventory of widths and transition rates of the atlas realizations

Let P be the prepared subspace and $Q = I - P$. The effective Hamiltonian is

$$H_{\text{eff}}(z) = PHP + PHQ(z - QHQ)^{-1}QHP.$$

The poles of

$$\det(z - H_{\text{eff}}(z)) = 0$$

determine masses and widths. The mass character supplies the basal real part of the operator; the self-energy term of Q supplies shift and decay. Therefore, the 384 widths of the inventory require a channel reader in addition to the reader of the 471 masses.

92.4.10 Topological sectors and hypothetical particles

92.4.10.1 Fibonacci topological sector: ring-based, fusion, and braid representation

The areal–volumetric incidence

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$$

realize the ring

$$\tau^2 = 1 + \tau, \qquad \mathrm{FPdim}\,\tau = \varphi.$$

The primary output is a fusion rule and a quantum dimension. A Fibonacci anyonic particle also requires F and R matrices, the pentagon and hexagon equations, chirality, a spectrally gapped Hamiltonian, and a map from the TPK state to physical space. Only then can one define

$$m_{\mathrm{brechaespectral}} = \frac{\Delta E}{c_{\mathrm{eff}}^2}.$$

92.4.10.2 Ising–Majorana Sector: Simple Objects, Fusion Rules, and Braid Representation

The Ising category satisfies

$$\psi^2 = 1, \qquad \psi\sigma = \sigma, \qquad \sigma^2 = 1 + \psi, \qquad d_\sigma = \sqrt{2}.$$

Four levels must be distinguished:

1. the route involution $C_M = -\,\mathrm{rev}$;
2. the parity of the CAR completion;
3. a self-conjugate relativistic spinor;
4. a topological Ising zero mode.

A relativistic Majorana fermion requires a real spinor representation, a dynamics, and a mass term. A Majorana zero mode is characterized by a spectral gap, splitting, and protection; it has no universal mass deducible solely from the fusion ring. The identity of a route with its conjugate is a necessary, but not sufficient, condition for a Majorana realization.

92.4.10.3 Braid representation on $\mathbb{Z}/6\mathbb{Z}$ and topological characters

Let

$$w_6 : B_n \longrightarrow \mathbb{Z}/6, \qquad \chi_k(b) = e^{2\pi i k w(b)/6}.$$

The representations

$$\rho_q(\sigma_i) = qP_i$$

descend to the symmetric group only when $q^2 = 1$. The other four values are genuinely braided. Their mathematical existence does not imply four particles: a physical realization requires a Hamiltonian, a spectral gap, braid operators, stability, and an intertwiner with a multisection.

92.4.10.4 Impossibility of a Persistent Tachyon

The action line is positive,

$$\hbar_{\text{int}} > 0,$$

the character satisfies

$$\chi_{\text{full}} > 0,$$

and the beta operator is obtained by positive conjugation:

$$\widehat{M}^{\beta} = R_{\text{act}}^{\widehat{K}/2}\, \widehat{M}^{(0)}\, R_{\text{act}}^{\widehat{K}/2} \geq 0.$$

Therefore,

$$\operatorname{Spec}(\widehat{M}^{\beta}) \subset [0, \infty).$$

A persistent stable section cannot generate

$$m^2 < 0.$$

If the linearization of a state produces negative curvature or an imaginary frequency, that state is an instability that leaves the section, not a superluminal particle. If the prolongation terminates, it is a virtual section with a terminal obstruction. Thus, "tachyon" decomposes into two well-typed HMT objects —instability or virtuality— and does not constitute a persistent species.

92.4.10.5 Gravity without a mandatory elementary spin 2 *particle*

The gravitational realization follows the chain

$$\text{route holonomy} \longrightarrow (e, \omega) \longrightarrow (T, R) \longrightarrow S_{\text{PCH}},$$

where e is the costructure, ω the connection,

$$T = de + \omega \wedge e, \qquad R = d\omega + \omega \wedge \omega,$$

and S_{PCH} is the Palatini–Cartan–Holst action. Gravity appears as the global torsion-and-curvature response of the persistent network. The collective vibration of the model universe may have a spin-two tensor component, but HMT need not posit an additional elementary particle to carry gravity.

The internal gravitational constant is typed through

$$G_{\text{HMT}} = \frac{c_{\text{int}}^3}{\hbar_{\text{int}}} \big(\delta_\theta \Lambda_G\big)^2,$$

where δ_θ is the elementary angular torsion and Λ_G is the spectral length selected by the gravitational holonomy. This equation converts torsion and route scale into gravitational coupling without using a mass as normalization. The total vibration is represented by the Hessian

$$\mathcal{H}_{\text{univ}} = \operatorname{Hess}_{(e,\omega)}\, S_{\text{PCH}}$$

over the global state. Its modes are collective excitations of the model universe; a tensorial component is not automatically a separate particle.

An excitation that is to be called a "graviton" must demonstrate three things:

1. a persistent tensorial subspace;

2. an isolated pole of the linearized operator;
3. a physical coupling that does not duplicate the torsion already present.

Without those three conditions, the correct object is the collective mode of the geometry, not a new mass row.

92.4.10.6 Barbero-Immirzi and the hexad-octad link

With

$$A = 1000\alpha_{\mathrm{HMT}}, \qquad q_{\pm} = \exp\Big[-\frac{\pi}{180}(A \pm C^{*})\Big],$$

the hexadic-octadic functional uses two distinct incidences of the temporal towers. The combination

$$\varepsilon_{\mathrm{BI}} = 12\Delta S_{90} - \Delta S_{120}$$

and the angular term produce

$$\gamma_{\mathrm{BI}} = \frac{\pi}{180}AC^{*} + \varepsilon_{\mathrm{BI}} = 0.2740076726944593\ldots.$$

The weight $12 : -1$ comes from reading the twelve dodecaphasic sectors and the unique oriented return seam. The equation $4a - 3b = 45$ subsequently verifies that the pair $(12, 1)$ is the minimal positive integer solution. This object must not be confused with the dodecaphasic mass extractor or with the angular residue 90–120; it shares the harmonic operator, but has a different domain and function.

92.4.10.7 Extensions of the atlas toward dark sectors: domains, readers and physical status

A dark sector HMT is a persistent multisection with

$$P_{\mathrm{vis}}P_{\mathrm{dark}} = 0$$

for the acoplamientos electromagnetico and cromatico, but with posible incidencia gravitatoria or of boundary:

$$P_{\mathrm{grav}}P_{\mathrm{dark}} \neq 0.$$

Its "darkness" is a property of the coupling kernel, not a mass label. The law first predicts an operator and its spectrum; only a physical channel determines whether the mode is stable, metastable, or resonant. This definition makes it possible to search for invisible multisections without inventing a mass from the observed value of a cosmological density.

92.4.10.8 Sterile neutrino section: compatibility of fiber, mixing, and absence of gauge charge

A sterile neutrino is not the depth G_4. It is an eigenvector $n_s \in \mathcal{H}_\nu$ satisfying

$$P_{\mathrm{weak}}n_s = 0, \qquad P_{\mathrm{mass}}n_s = n_s.$$

It may mix with the three active modes through an enlarged neutral kernel, but its existence requires

$$\dim\ker(P_{\mathrm{weak}}|_{\mathcal{H}_\nu}) > 0$$

and an eigenvalue of mass in ese kernel. This definition produces a criterion of search internal: diagonalize first the block neutral and check afterward its coupling weak.

92.4.10.9 Axionic and pseudoscalar sections: topological character and edge coupling

A pseudoscalar axion candidate is a section whose orientation changes under CP,

$$CP\, a\, CP^{-1} = -a,$$

and whose displacement compensates a phase topological of the sector of color. In HMT must correspond to a way of torsion/holonomy odd and to a projector that intertwines ese way with the density topological of gauge. Its mass is obtained of the second derivative of the potential effective,

$$m_a^2 = \left.\frac{\partial^2 V_{\text{eff}}}{\partial a^2}\right|_{a=a_0},$$

once V_{eff} has been constructed from the genealogical record of vacancies and boundary. The mere existence of a channel $C^* \mapsto -C^*$ is not enough to assert an axionic particle.

92.4.10.10 Dark Photon and Hidden Massive Vector

A dark photon requires a second gauge section A' and a mixing coupling

$$\mathcal{L}_{\text{mix}} = -\frac{\varepsilon_{\text{kin}}}{2} F_{\mu\nu} F'^{\mu\nu}.$$

In terms of fibers, ε_{kin} is an intertwiner between two null subspaces. If the second sector acquires a Stueckelberg or boundary spectral gap,

$$\widehat{M}_{A'}^2 \neq 0,$$

a massive dark vector appears. HMT predicts that the mixing parameter must follow from a common memory incidence; it cannot be fixed by the mass it is intended to explain.

92.4.10.11 WIMP and stable dark state

A WIMP is a dark sector that also satisfies:

$$[P_{\text{weak}}, P_X] \neq 0, \qquad [P_{\text{em}}, P_X] = [P_{\text{color}}, P_X] = 0,$$

and possesses a stable mode

$$|\lambda_X| = 1.$$

Stability may be protected by a parity of the genealogical record. Its mass is an eigenvalue of the weakly coupled dark block. "WIMP" does not constitute a new mathematical family: it is a joint condition on coupling and persistence over a multisection.

92.4.10.12 Monopole Section: Magnetic Charge, Dirac Condition, and Topological Compatibility

A monopole is defined by a non-trivial topological class of the gauge bundle:

$$\frac{1}{2\pi} \int_{S^2} F = n \neq 0.$$

HMT must realize this integer as the net holonomy of a closed family of routes. Its mass, if the mode is dynamical and stable, belongs to the spectrum of the topological-defect operator. A point vacancy or a nonzero carry is not by itself a monopole; the descent to the integral class must be proved.

92.4.10.13 Supersymmetric Extensions of the Atlas: Representation Matching and Characters

An HMT supersymmetry would require an odd operator Q that exchanges the exterior and symmetric completions:

$$Q : \mathcal{F}_- \leftrightarrow \mathcal{F}_+, \qquad Q^2 = H,$$

and that interweaves the law of masses,

$$Q\widehat{M}_- = \widehat{M}_+ Q.$$

Only then would the bosonic and fermionic spectra be paired. The separate existence of CAR and CCR does not establish supersymmetry or by itself predict selectrons, neutralinos, or gluinos. Each partner requires a nonzero intertwiner and a symmetry-breaking rule that determines its mass splitting.

92.4.10.14 Tetraquarks, pentaquarks, glueballs, and hybrids

The composition grammar is extended without changing the law:

$$\mathfrak{C}_{12}^{(n)} : \Gamma_1 \times \cdots \times \Gamma_n \times \mathcal{T}_n \times \partial_n \longrightarrow \mathcal{L}_{\text{comp}}.$$

A tetraquark uses $qq\bar{q}\bar{q}$; a pentaquark, $qqqq\bar{q}$; a glueball, records of the color adjoint projected onto the singlet; a hybrid, quark and gauge routes in the same tree. The physical classification depends on the color, spin, parity, and linkage-tree projector, not merely on the list of constituents.

92.4.10.15 Dilaton and radion sectors: volume and compactification scalar modes

The dilaton is a way of the section of scale; the radion, a way that modifies a length or volume internal. In the theory of mass appear as fluctuations of the chart and of the memory geometric:

$$t_0 \mapsto e^{\phi_d} t_0, \qquad \mathcal{V}_{\text{int}} \mapsto e^{\phi_r} \mathcal{V}_{\text{int}}.$$

To become particles they must possess a kinetic term, a potential, a persistent projector, and a pole. So long as they do not possess them, they are collective degrees of the dimensional chart, not additional scalar species.

92.4.10.16 Exclusion of Physical Ghosts

The spectral measure of a physical state is positive:

$$\mu_{P,a}^{\text{mass}}(B) \geq 0.$$

A negative-norm direction does not belong to the prepared state space. If a parametrization introduces a "ghost," the physical realization must quotient out the gauge redundancy or reject the coupling. This exclusion is independent of the tachyonic prohibition: a ghost violates positivity of the norm; a persistent tachyon would violate positivity of the mass operator.

92.4.11 Universal Inventory of Masses and Widths

92.4.11.1 Posterior correspondence between the HMT–MD realizations and the external physical census

The contrast inventory contains

$$1170 \text{ identities}, \qquad 438 \text{ identity groups},$$
$$471 \text{ mass observables}, \qquad 384 \text{ width observables}.$$

Its partition is

Domain	Masses	Widths
partículas generales y leptónicas	53	9
quarks	8	1
mesones	243	225
bariones	166	149
registro gravitatorio de contraste	1	0
Total	**471**	**384**

Las 471 masas no son 471 especies elementales: incluyen estados excitados, resonancias, distintas cargas y múltiples realizaciones compuestas. Las 384 anchuras son observables temporales y no deben ser leídas por el carácter de masa.

92.4.11.2 Identidad interna $\mathcal{I}_X$ de una realización material y criterio de individualización frente a observaciones múltiples

Cada estado comparado debe poseer una identidad interna

$$\mathcal{I}_X = (C_X, \mathcal{R}_X, \Gamma_X, \mathcal{L}_X, \sigma_X, \eta_X, P_X, \mathfrak{M}_X, \mathcal{T}_X),$$

where:

- C_X is the physical type of realization determined by object, representation, and codomain;
- $\mathcal{R}_X$ is the physical representation;
- Γ_X is an oriented route, orbit, or composition;
- $\mathcal{L}_X$ is the genealogical record;
- σ_X is the complete signature;
- η_X is the tower;
- P_X is the coupling projector;
- $\mathfrak{M}_X$ is the measurement channel;
- $\mathcal{T}_X$ is the composition tree when applicable.

Two external observations belong to the same HMT state when they share this identity and differ only in experiment, chart, or estimator. The existence of two measurements does not create two particles.

92.4.11.3 Comparison morphism between internal invariants and metrological observables

The comparison requires the diagram

$$\mathcal{L}_M^{\mathrm{HMT}} \xrightarrow{\varsigma_{\mathcal{S},\mu}} \mathbb{R}_{>0} u_M^{\mathcal{S},\mu} \xleftarrow{\text{measurement}} O_X^{\mathrm{ext}}.$$

A scientifically complete row contains:

$$(m_X^{\mathrm{HMT}}, m_X^{\mathrm{ext}}, u, \mathcal{S}, \mu, \Sigma_{\mathrm{exp}}, \Sigma_{\mathrm{HMT}}, \text{pole convention}).$$

For quarks are mandatory scheme and scale; for resonances, the convention of pole; for limits, the level of confidence; for observables correlated, the matrix of covariance.

92.4.11.4 Explicit evaluation of 17 *representative realizations of the atlas*

The following evaluations preserve the separation between law and signature data:

Status	Value of the character in its chart
μ	105.658360294435829 . . . MeV
τ	1776.8609176314323 . . . MeV
u	2.165924536173907 . . . MeV
d	4.679550162948874 . . . MeV
c	1.270500838641911 . . . GeV
s	92.94009390784564 . . . MeV
t	172.5974795440191 . . . GeV
b	4.190119763299790 . . . GeV
W	80.37896490970455 . . . GeV
Z	91.18753344431341 . . . GeV
H	125.2924660425361 . . . GeV
π^0	134.9767243278721 . . . MeV
$\pi^\pm$	139.5704851715722 . . . MeV
$K^\pm$	493.6770856495306 . . . MeV
K^0	497.6111864977505 . . . MeV
p	938.2717515469849 . . . MeV
n	939.5658104725070 . . . MeV

The beta electron does not belong to this table because its central route, basal coefficients, and complete reader are determined by the construction itself.

92.4.11.5 From the catalog of realizations to the inventory of 471 masses

The universal extension follows five operations:

$$\begin{aligned}\text{physical identity} &\longrightarrow \text{representation projector} \longrightarrow \text{elementary or composite genealogical record}\\ &\longrightarrow \text{operator/pole} \longrightarrow \text{comparison chart.}\end{aligned}$$

For elementary states, the second map acts on a fiber of the atlas. For mesons and baryons, it acts on the 432 and 1728 composite expressions. For resonances, the fourth map returns a complex pole. For topological sectors, it first returns a spectral gap and a braid representation. This typing makes it possible to encompass the entire inventory without declaring that each external name corresponds to an elementary cell.

92.4.11.6 From the 384 widths to the survival operator

Each width requires

$$X \longmapsto Q_X U Q_X \longmapsto \rho(Q_X U Q_X) \longmapsto \Gamma_X$$

or, equivalently, the pole of H_{eff}. The reader must incorporate decay channels, multiplicity, threshold, and phase space. The equality

$$\Gamma_{\bar{X}} = \Gamma_X$$

It follows only if the decay operator is covariant under conjugation.

92.4.12 Mass, temperature, and statistics

92.4.12.1 Thermal Transducer Between Mass Character, Temperature, and Statistical Occupation

The Boltzmann constant is the transducer

$$k_B : \mathcal{L}_\Theta \longrightarrow \mathcal{L}_E.$$

The clock CT–108 fixes the identity

$$k_B \Theta_{\mathrm{clk}} \log 3 = \hbar_{\mathrm{int}} \frac{2\pi}{108 t_0}.$$

This equation links a unit of tritic information, a frequency, and an energy. It does not introduce the SI coordinate of k_B into the law; it determines the typed product once the thermal chart has been chosen.

92.4.12.2 Fermionic projection of the atlas and Fermi–Dirac distribution

For levels

$$\epsilon = (0, 3, 6, 9), \qquad g = (1, 6, 12, 8),$$

and constraints

$$(N, E) = (12, 66),$$

the exterior completion produces

$$2\,104\,494$$

compatible fermionic microstates. The effective multipliers are

$$(\beta, \mu) = (0.1530701135,\ 4.5028651976).$$

This realization exemplifies how mass, energy, and exclusion emerge from fermionic routes without statistics being an additional adjustment.

92.4.12.3 Bosonic projection of the atlas and Bose–Einstein distribution

On the same levels and restrictions, the symmetric completion produces

$$259\,436\,430$$

microstates, with

$$(\beta, \mu) = (0.0545672796,\ -15.9256978191).$$

The difference between Fermi–Dirac and Bose–Einstein is, therefore, a difference in the rule of composition of routes, not in the value of a mass individual.

92.4.12.4 Criterion of condensation of bosonic sections and macroscopic occupation

A bosonic condensate appears when a symmetric component acquires macroscopic occupancy at the lowest eigenvalue of the operator. A Fermi sea, by contrast, fills a set of distinct eigenvalues up to a boundary. HMT describes both through the same mass/energy spectrum and two different Fock functors. This distinction prevents “many particles on one route” from being identified with a more massive particle.

92.4.13 Differential propagation of uncertainties and structural stability of the mass character

92.4.13.1 Invariance of the generative graph under posterior metrological contrast

The internal output is frozen in order

$$\mathcal{R}_{324} \to P_X \to \mathcal{L}_X \to \sigma_X \to \eta_X \to \widehat{M}_X \to \mu_X.$$

Only then is the external chart opened. An arbitrary permutation of the 471 masses or the 384 widths must leave all preceding objects invariant.

92.4.13.2 Decomposition of structural uncertainty into experimental, chart, route, tower, and coupling contributions

The total uncertainty decomposes as

$$\Sigma_{\mathrm{tot}} = \Sigma_{\mathrm{ext}} + \Sigma_{\mathrm{carta}} + \Sigma_{\mathrm{route}} + \Sigma_{\mathrm{tower}} + \Sigma_{\mathrm{coupling}}.$$

Here:

- Σ_{ext} is the covarianza experimental;
- Σ_{carta} quantifies scheme, scale, and unit conversion;
- Σ_{route} compares all routes of the admissible orbit;
- Σ_{tower} uses the tail bound for the harmonic series;
- $\Sigma_{\mathrm{coupling}}$ measures the variation among admissible intertwiners.

They are not necessarily added as independent numbers; the equation expresses a decomposition of sources that must be converted into a joint covariance.

92.4.13.3 Derivative of the mass observable with respect to the signature and the readers

For

$$\log m_X = \log m_\star + \log \chi_0(\sigma_X) + \kappa_X \log R_{\mathrm{act}} + \sum_h \eta_{X,h} s_h,$$

the variation is

$$d\log m_X = d\log m_\star + \langle \Theta_0, d\sigma_X \rangle + \langle \sigma_X, d\Theta_0 \rangle + \log R_{\mathrm{act}}\, d\kappa_X + \kappa_X\, d\log R_{\mathrm{act}} + \sum_h (s_h\, d\eta_{X,h} + \eta_{X,h}\, ds_h).$$

This formula makes it possible to attribute each decimal to a route, constant, reader, tower, or chart. A result is robust when perturbations that preserve the premises maintain its spectral class and its calculated uncertainty.

92.4.13.4 Structural-dependence tests through controlled suppression of sheet, orientation, carry, memory, winding, and boundary

A dependency test separately removes the sheet, orientation, carry, memory, winding, or boundary and recomputes the object. The expected result is not that everything changes, but that exactly the coordinates dependent on the removed component change. If suppressing memory leaves invariant a coefficient defined by return, the construction of that coefficient is refuted.

92.4.13.5 Obstructions to the identification of routes, characters, and metrological magnitudes

The law is refuted in a specific application if any of the following occurs:

1. an external mass changes the route or the chosen projector;
2. the published signature is not regenerated from the genealogical record;
3. the refinement fails to converge or depends on a truncation selected by the residual;
4. two equivalent routes receive distinct masses without symmetry breaking;
5. an antiparticle acquires a different mass without a declared violation of conjugation;
6. a colour triplet splits without colour breaking;
7. a scalar is published even though the spectral variance is positive;
8. a width is obtained from the mass character without a temporal operator;
9. a quark chart omits the scheme or scale;
10. an instability is interpreted as a persistent tachyon.

92.5 Leptons, neutrinos, quarks and gauge sectors

Charged leptons, the six quark flavors, and the neutrino fibers are realized as typed multisections. Color is the residual ternary orbit $12 + 12 + 12$; flavor, generation, scheme, and scale are distinct data. Neutrinos belong to the fermionic completion; the Majorana condition additionally requires self-conjugation and a compatible mass term. The photon and gluon belong to the exact null chart.

92.6 Correspondence between internal classes and physical sectors

The physical realization preserves the preceding quotients and adds the data required by a representation without turning them into new cells. For a persistent section X, we write in typed form

$$\mathcal{P}_X = \big[q(X),\ [X]_{\mathcal{R}},\ \mathrm{Rep}(X),\ \gamma_X,\ \tau_{12}(X),\ \sigma_X\big].$$

Here $q(X)$ fixes the multisection, $[X]_{\mathcal{R}}$ the route family, $\mathrm{Rep}(X)$ the representation, γ_X the persistent history, $\tau_{12}(X)$ its dodecaphase word, and σ_X the integral signature extracted after the record. The levels $G0, \dots, G4$ remain depths of the atlas; they are not renamed as the three physical generations.

Flavor information is preserved through three distinct coordinates:

$$\mathrm{flav}(X) = \big(\sigma_{ud}(X), g(X), \chi_{\mathrm{fina}}(X)\big).$$

The first separates the leptonic, neutrino, up-type, and down-type branches; the second distinguishes the physical generation; the third preserves the orientation and memory that separate sections within a single branch. For quarks, the residual orbit $R/G/B$ is added after the flavor is fixed and before the character is evaluated. Color, flavor, and mass are therefore readings of different types.

This census does not exhaust the realizations of the law. Mesons and baryons are constructed by composing enriched records before projecting the signature; resonances and virtual particles are distinguished by their persistence horizon. The Fibonacci, Z_6, and Majorana–Ising sectors retain their own topological codomains and are not forced into an ordinary mass table.

92.6.1 Path signatures and dodecaphasic coindexed pairs by flavor

For the set of flavors $Q = \{u, d, c, s, t, b\}$, the table defines a finite correspondence between a geometric fingerprint and a dodecaphasic pair. In each row, the following holds

$$W_{\pm} = 6n_A \pm s_C.$$

This table is not an a posteriori comparison, but the graph of a finite map over the certified nominal domain. If $\mathscr{R}_Q^{\mathrm{nom}} = \{\rho_u, \rho_d, \rho_c, \rho_s, \rho_t, \rho_b\}$ is the set of CT–108 traces that follow, we define

$$H_{\mathrm{flav}} : \mathscr{R}_Q^{\mathrm{nom}} \longrightarrow \mathbb{Z}^2, \qquad H_{\mathrm{flav}}(\rho_q) = (n_A(q), s_C(q)).$$

The six images are unique, the table exhausts the domain, and no column contains a mass. Therefore, H_{flav} is a closed causal extractor on the nominal domain: it first reads footprint, orientation, and memory, and only thereafter does the character evaluate the mass. The ternary color orbit is quotiented without changing H_{flav}; reversal preserves the mass class and transports the particle–antiparticle representation. The table is therefore the executable definition of the morphism and not a future obligation:

Flavor	Generation	Giros/cambios	Eje	N, E, S, O	(n_A, s_C)	(W_+, W_-)
u	1	21/30	N–S	34,31,31,12	(11,7)	(73,59)
d	1	20/32	E–O	27,35,18,28	(17,8)	(110,94)
c	2	21/29	E–O	20,38,24,26	(61,8)	(374,358)
s	2	17/27	N–S	50,32,12,14	(41,-3)	(243,249)
t	3	21/26	N–S	46,27,16,19	(100,-1)	(599,601)
b	3	21/30	E–O	12,63,9,24	(71,-5)	(421,431)

The coincidence of two turns or of a spectral height does not identify species: the cardinal route, the orientation, the dodecaphasic register, and the representation remain in the object. The chain cell–route–enriched chronological register–signature–character is defined independently of H_{flav}. The four initial orientations of each cell produce $81 \cdot 4 = 324$ executable genealogies; that cardinal counts histories, not particles, families, or masses.

92.6.2 Generational stratification, quark supports and neutrino realization

The general law acts on multisections rather than on a list of masses. The appearance of three generations is therefore expressed as the compatibility of three structures: the stratification of the atlas, the flavour records, and the three-dimensional mixing space. In the charged leptonic sector, the multisections

$$G_0^{\ell}, \qquad G_2^{\ell}, \qquad G_4^{\ell} \tag{92.1}$$

have ranks $1, 8, 16$. The centre G_0^{ℓ} contains the rank-one electronic section; G_2^{ℓ} and G_4^{ℓ} instead preserve nontrivial operator spectra. The complete generational organization is

Generation	**Lepton**	**Par quark**	**Sabor neutro**	**Soporte estructural**
1	e	(u, d)	ν_e	centre G_0^{ℓ}, first-generation register and first vector of the interaction basis
2	μ	(c, s)	ν_μ	multisection G_2^{ℓ}, second-generation register and second vector of the interaction basis
3	τ	(t, b)	ν_τ	multisection G_4^{ℓ}, third-generation record, and third vector of the interaction basis

Particle–antiparticle conjugation reverses the charge and orientation coordinates of the representation but preserves this stratification; therefore, it does not double the number of generations.

Dimension three also has its own incidence carrier. The oriented dodecaphasic representation contains

$$V_{12} \cong V_1 \oplus V_3 \oplus V_{3'} \oplus V_5, \qquad \operatorname{rank} P_3 = 3, \tag{92.2}$$

and the dodecaphasic entangler–Witt transports the positive sector according to

$$P_G \xleftarrow{W_{GK}} P_3 \xleftarrow{U_W} Q_3, \qquad \operatorname{rank} P_G = \operatorname{rank} P_3 = \operatorname{rank} Q_3 = 3. \tag{92.3}$$

This three-dimensional carrier permits comparison among generational bases. The routes, signatures, and mass operators subsequently provide the spectral content transported by CKM and PMNS.

92.6.2.1 Internal position and records of the 6 *quark flavors*

The position of a quark flavor is the composite data

$$\mathfrak{q}_X = (\text{charge branch}, \text{generation}, (\mathbb{Z}/3\mathbb{Z})_{\text{color}}, \text{multisection}, \text{route record}). \tag{92.4}$$

The charge branches $-1/3$ possess the supports

$$\begin{aligned} D_1 &= \{(4,5),(6,5)\},\\ D_2 &= \{(4,3),(4,7),(6,3),(6,7)\},\\ D_3 &= \{(2,3),(2,5),(2,7),(8,3),(8,5),(8,7)\},\\ D_4 &= \{(2,1),(2,9),(4,1),(4,9),(6,1),(6,9),(8,1),(8,9)\}, \end{aligned} \tag{92.5}$$

whereas the charge branches $+2/3$ occupy

$$\begin{aligned} U_1 &= \{(4,4),(4,6),(6,4),(6,6)\},\\ U_3 &= \{(2,2),(2,4),(2,6),(2,8),(4,2),(4,8),(6,2),(6,8),(8,2),(8,4),(8,6),(8,8)\}. \end{aligned} \tag{92.6}$$

Each support lifts to four orientations per cell. The colour quotient organizes $36 = 12_{\mathrm{R}} + 12_{\mathrm{G}} + 12_{\mathrm{B}}$ oriented biographies and preserves the same mass per flavour before the colour realization.

The nominal transducer

$$\mathcal{N}_{\text{ruta}}(\Gamma_f) = ((N,E,S,O), h_{369}, r_5) \in \mathbb{Z}^4_{\geq 0} \times \mathbb{Z}^2_{\geq 0} \tag{92.7}$$

publish the following coordinates before any scalar realization:

Flavour	Generation	Branch	(N,E,S,O)	(h_{369}, r_5)	Eje dominante
u	1	$+2/3$	$(34,31,31,12)$	$(51,13)$	N–S
d	1	$-1/3$	$(27,35,18,28)$	$(47,17)$	E–O
c	2	$+2/3$	$(20,38,24,26)$	$(49,16)$	E–O
s	2	$-1/3$	$(50,32,12,14)$	$(57,11)$	N–S
t	3	$+2/3$	$(46,27,16,19)$	$(57,9)$	N–S
b	3	$-1/3$	$(12,63,9,24)$	$(47,7)$	E–O

The associated nominal signatures are

Flavor	(n_A, s_C)	(W_+, W_-)
u	$(11,7)$	$(73,59)$
d	$(17,8)$	$(110,94)$
c	$(61,8)$	$(374,358)$
s	$(41,-3)$	$(243,249)$
t	$(100,-1)$	$(599,601)$
b	$(71,-5)$	$(421,431)$

These coordinates distinguen flavors that share branch or generation and close the morphism of flavor without consulting no mass. For a section physical (P), we define

$$\mathrm{sabor}(P) = \big(\sigma_{\mathrm{ud}}(P), g(P), \chi_{\mathrm{fina}}(P)\big), \qquad \chi_{\mathrm{fina}}(P) = (\text{rotations, switches, axis}, N, E, S, O, h_{369}, r_5), \tag{92.8}$$

and, for quarks, the ternary orbit $[\gamma_P]_{\mathrm{col}} = \{\gamma_P^R, \gamma_P^G, \gamma_P^B\}$ is also preserved. The physical realization is the map already determined by the preceding data,

$$\mathcal{S}_{\mathrm{phys}}(P, \mathfrak{M}) : \big(\sigma_{\mathrm{ud}}, g, \chi_{\mathrm{fina}}, [\gamma_P]_{\mathrm{col}}\big) \longmapsto \gamma^{\mathrm{surv}}_{P,\mathfrak{M}} \longmapsto \big(\sigma(\gamma^{\mathrm{surv}}_{P,\mathfrak{M}}), B_F^D, B_F^\Omega\big), \tag{92.9}$$

where $\mathfrak{M}$ is the compatible coupling and $\gamma^{\mathrm{surv}}_{P,\mathfrak{M}}$ the route that persists under it. For charged leptons the color orbit is reduced to the terminal object. The mass character is then evaluated on that same genealogy:

$$\boxed{\frac{m_{\mathfrak{M}}(P)}{m_e^{\mathrm{HMT}}} = \chi_{\mathrm{mass}}\Big(\sigma\Big(\gamma^{\mathrm{surv}}_{P,\mathfrak{M}}\Big)\Big)\,.} \tag{92.10}$$

Therefore, flavor, generation, and color do not await a future selector: they publish the route class and its eigenvector before opening the external comparison. Mass does not retrospectively choose the route; it only reads multiplicatively the persistence that the coupling has stabilized.

92.6.2.2 Fermionicity, mass eigenvalues, and PMNS transport

The exterior closure of the exchange functor constructs the CAR relations and fixes fermionicity. In the neutral sector, the label ν_e, ν_μ, ν_τ designates an interaction basis; the mass values are eigenvalues of a mixed neutral operator. The internal frames $F_\ell, F_\nu : \mathbb{C}^3 \to \mathrm{im}\, P_3$ compare those bases, and the matrix

$$U_{\mathrm{HMT}} = F_\ell^* \Phi_L F_\nu \tag{92.11}$$

is a unitary transport. PMNS changes basis between interaction states and mass eigenvectors; the neutral scale belongs to the operator spectrum, not to the change of basis.

92.6.2.3 Neutral extractor Z0 prior to projection

The recovered construction of the neutral sector acts on the enriched dodecaphase record, before collapsing sheet, torsion, and the bidirectional bit. Let E_m, $m \in \mathbb{Z}/12\mathbb{Z}$ be the twelve nine-tick events of the CT–108 record. At each tick t, the following are preserved

$$\theta(t) = \mathbf{1}_{\{d(t)=9\}}, \qquad \varepsilon(t) \in \{-1, +1\}, \qquad \kappa(t) = \mathbf{1}_{\{9 \text{ en corona}\}}, \qquad \omega(t) = (-1)^{\kappa(t)}.$$

The first factor detecta the torsion nonadic, the second preserves the sheet two–ways and the third changes the sign in the turn of 180° of the crown. The integer torsional of each event and its difference antipodal are

$$T_\nu(m) = \sum_{t \in E_m} \omega(t)\varepsilon(t)\theta(t), \qquad e^\nu_m = T_\nu(m) - T_\nu(m+6), \tag{92.12}$$

and the neutral trit is fixed, without continuous parameters, by

$$\tau^\nu_m = \mathrm{sgn}(e^\nu_m) \in \{-1, 0, +1\}. \tag{92.13}$$

For the four jump orbits four

$$I_a = \{a, a+4, a+8\} \pmod{12}, \qquad a = 0, 1, 2, 3,$$

the event coefficient entering into the signature and the majority sign observable are, respectively,

$$b^{\nu}_{120} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m\in I_a} e^{\nu}_m\right), \qquad \nu^{\nu,\mathrm{sgn}}_{120} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m\in I_a} \tau^{\nu}_m\right). \tag{92.14}$$

These two integers are not identified: the first is the coordinate $b_{120} = \nu^{\mathrm{ev}}_{120}$ of the character, while the second is a diagnostic of majority. The quadratic memory is

$$b^{\nu}_{\zeta} = \nu^{\nu}_{270} = \sum_{m=0}^{11} \tau^{\nu}_m \tau^{\nu}_{m+3}. \tag{92.15}$$

Thus, for each surviving neutral history γ_{ν_i}, the register publishes, before any comparison, the signature

$$v_{\nu}(\gamma_{\nu_i}) = \big(0, 0, k^{(i)}_{\Delta_4}, b^{\nu_i}_{120}, b^{\nu_i}_{\zeta}\big)$$

and the relative exponent

$$\mathcal{A}^{(i)}_{\nu} = k^{(i)}_{\Delta_4}\Delta_4 + b^{\nu_i}_{120} s_{120} + b^{\nu_i}_{\zeta}\zeta_{270}, \qquad \zeta_{270} = 135\Delta_4^2. \tag{92.16}$$

Here ζ_{270} is not replaced by the tower moment $s_{270} = q^{270}_{-} - q^{270}_{+}$.

The global two-way conjugation $\tau^{\nu} \mapsto -\tau^{\nu}$ reverses b^{ν}_{120} and preserves b^{ν}_{ζ}. Consequently, it generates two branches of the relative spectrum,

$$\mathcal{A}^{(i)}_{\nu,\pm} = k^{(i)}_{\Delta_4}\Delta_4 \pm b^{\nu_i}_{120} s_{120} + b^{\nu_i}_{\zeta}\zeta_{270}, \qquad \mathrm{NO} \longleftrightarrow \mathrm{IO}, \tag{92.17}$$

which are distinguished by the subsequent sign of Δm^2_{31}, not by a selection using PDG data. This construction closes the discrete Z0 extractor and the relative bifurcation. The common absolute scale m_0 and the full-rank physical PMNS kernel remain separate objects: they are neither introduced into the selector nor declared to be deduced from two–ways parity alone.

The realization with a single phase of rank one produces

$$(\theta_{12}, \theta_{23}, \theta_{13}) = (19.6807^{\circ}, 56.4970^{\circ}, 29.6224^{\circ})$$

and does not reproduce mixing phenomenology. This control selects, as the appropriate domain, a full-rank register kernel,

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c\in L_a}\sum_{d\in N_b} K_{\mathrm{registro}}(c, d; \xi_c, \xi_d), \qquad U_{\mathrm{int}} = \mathrm{polar}(G), \tag{92.18}$$

whose technical source is developed in the chapter on CKM and PMNS transport. The mass operator, its eigenvalues, and the flavor-reading map are thereby kept separate.

92.6.3 Mass Operator Transport via CKM

The N42 incidence fixes the sextet $(4, 5, 7, 6, 8, 3)$ and the rational matrix

$$M_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det M_{\mathrm{CKM}} = -\frac{3857}{6}.$$

The angular coordinates are constructed by

$$\begin{pmatrix} \theta_{12} \\ \theta_{23} \\ \theta_{13} \end{pmatrix} = M_{\mathrm{CKM}} \begin{pmatrix} A \\ C^*/6 \\ (180/\pi)\Delta_4 \end{pmatrix}, \qquad \delta_{\mathrm{CP}} = 9A.$$

This transformation belongs to the mathematical closure of HMT. In its physical realization, let B_u and B_d be the bidirectional operators already constructed in the fibers of up- and down-type quarks. The change of basis acts according to

$$B_d^{(u)} = V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^*, \qquad R_{\mathrm{act}}^{B_d^{(u)}} = V_{\mathrm{CKM}} R_{\mathrm{act}}^{B_d} V_{\mathrm{CKM}}^*. \tag{92.19}$$

CKM transports eigenvalues between bases and preserves the spectrum and determinant. The CP-violation control adopts the identity

$$\left|\det[B_u, V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^*]\right| = 2|J| \prod_{i<j} |\kappa_i^u - \kappa_j^u| \prod_{a<b} |\kappa_a^d - \kappa_b^d|.$$

The matrix of mixing and the reader of route perform, therefore, functions complementary: the reader determines the operator spectral and CKM determines its representation in the basis of flavor.

92.6.4 Geometric frames of rank 3 for the leptonic sector

The leptonic construction utilizes the diagonal sign involution.

$$S_{\mathrm{sign}} = \mathrm{diag}(1,1,1,-1,-1,-1,1,1,1,-1,-1,-1), \qquad P_- = (I - S_{\mathrm{sign}})/2,$$

and the canonical icosahedral projector P_3 of rank three. The compression

$$C_- = P_- P_3 P_-\big|_{\mathrm{im}\, P_-}$$

has spectrum

$$\left\{ \frac{5+\sqrt{5}}{10}, \frac{1}{2}, \frac{5-\sqrt{5}}{10}, 0, 0, 0 \right\}.$$

The three positive eigenvalues are simple. Their spectral projectors, applied to the indicator of the oriented negative hexad and normalized after projecting by means of P_3, construct a charged orthonormal frame F_ℓ that satisfies

$$F_\ell^* F_\ell = I_3, \qquad F_\ell F_\ell^* = P_3.$$

For the neutrino sector, let H_1, H_2, H_3 be the three oriented positive hexads and

$$X = (P_3 \mathbf{1}_{H_1}, P_3 \mathbf{1}_{H_2}, P_3 \mathbf{1}_{H_3}).$$

Its Gram matrix is positive definite and satisfies

$$\det(X^* X) = \frac{5-\sqrt{5}}{40} > 0.$$

Consequently,

$$F_\nu = X(X^* X)^{-1/2}, \qquad F_\nu^* F_\nu = I_3, \qquad F_\nu F_\nu^* = P_3.$$

The real transport

$$O = F_\ell^* F_\nu \in SO(3) \tag{92.20}$$

it is obtained without masses or PMNS angles.

Theorem 92.10 (Unitarity of the minimal dodecaphase phase)**.** *Let $b_K \in \mathrm{im}\, P_3$ be the normalized vector of the Witt witness, $Q_K = |b_K\rangle\langle b_K|$, and*

$$\Phi_L = I + (\zeta_{12} - 1) Q_K, \qquad \zeta_{12} = e^{i\pi/6}.$$

Then

$$U_{\mathrm{HMT}} = F_\ell^* \Phi_L F_\nu \tag{92.21}$$

is a unitary matrix independent of target metrological values. The orientation inversion conjugates U_{HMT}.

Proof. Q_K is an orthogonal projector, so Φ_L is unitary. The two frames are isometries with the same image $\operatorname{im} P_3$. Therefore

$$U_{\mathrm{HMT}}^* U_{\mathrm{HMT}} = F_\nu^* \Phi_L^* P_3 \Phi_L F_\nu = I_3.$$

The change $\pi/6 \mapsto -\pi/6$ produces Φ_L^*, and all the remaining primitives are real. □

92.6.4.1 Rank-one negative control and full-rank PMNS transport

Frozen the construction, the contrast in the declared order produces

$$(\theta_{12}, \theta_{23}, \theta_{13}) = (19.6807^\circ, 56.4970^\circ, 29.6224^\circ), \qquad J = -0.0426621.$$

The best of the 36 discrete permutations leaves $\theta_{13} \simeq 17.02^\circ$. The rank-one phase generates an internal unitary matrix, but preserves a stabilizer $U(2)$ and is discarded as a physical PMNS realization.

Excluding the rank-one carrier does not leave the PMNS realization undetermined. Let M_ℓ and M_ν be the charged and neutral operators produced by the General Mass Law, and let F_ℓ, F_ν be their complete orthonormal spectral frames on the common image $\operatorname{im} P_3$. Full-rank leptonic transport is then constructed by

$$U_{\mathrm{PMNS}} := F_\ell^* F_\nu, \qquad U_{\mathrm{PMNS}}^* U_{\mathrm{PMNS}} = I_3.$$

For simple spectra, this output is determined up to diagonal phase adjustments and the declared spectral ordering; in the presence of degeneracies, the exact output is the corresponding double class of frames. The register kernel provides an additional finite certificate of this realization, not its generator or an outstanding condition for its existence. For charged fibres L_a and neutrino fibres N_b, its aggregate form is

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c \in L_a} \sum_{d \in N_b} K_{\mathrm{reg}}(c,d), \qquad U_{\mathrm{int}} = \operatorname{polar}(G),$$

with naturality under orientation. When the explicit register entries satisfy $\det G \neq 0$, its polar factor provides an alternative certificate of the transport already constructed. The kernel reads carry, sheet, orientation, vacancy and holonomy; its parameters are frozen before examining the external angles.

Domain and codomain of the CKM and PMNS realizations The rational CKM matrix, the frames F_ℓ, F_ν, the transport O, the phase Φ_L, the unitarity of U_{HMT} and the complete transport $U_{\mathrm{PMNS}} = F_\ell^* F_\nu$ are exact internal results under the declared primitives. CKM constitutes a physical transport once the flavour and mass bases have been fixed. The comparison falsifies only the rank-one PMNS phase; it does not weaken the complete spectral construction. Naturality and the criterion $\det G \neq 0$ belong to the alternative register certificate and remain separate from the existence and unitarity of PMNS transport.

92.6.5 Involution of leaves in 4 representations

The involution $C^* \mapsto -C^*$ organizes four distinct responses:

$$\begin{aligned} S_{\mathrm{bi}}(A, -C^*) &= S_{\mathrm{bi}}(A, C^*), \\ \Gamma_{6\to 8}(A, -C^*) &= -\Gamma_{6\to 8}(A, C^*), \\ (\widehat{\mu}, \widehat{\varepsilon}) &\longleftrightarrow (\widehat{\varepsilon}, \widehat{\mu}), \\ \widehat{c} &\longmapsto \widehat{c}, \qquad D_A \longmapsto D_A. \end{aligned} \tag{92.22}$$

The bilayer information is even; the areal orientation is odd; the two constitutive quantities form a doublet, and the determinants remain fixed. This parity table precedes any interpretation as a physical symmetry.

92.6.6 Involutive rational transformation in the CKM parameter space

Let

$$M_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det M_{\mathrm{CKM}} = -\frac{3857}{6}. \tag{92.23}$$

The inverse exists on $\mathbb{Q}$ and is

$$M_{\mathrm{CKM}}^{-1} = \begin{pmatrix} 1528/3857 & 3380/3857 & 801/3857 \\ 75/3857 & 176/3857 & -150/3857 \\ 6/551 & -30/551 & -12/551 \end{pmatrix}. \tag{92.24}$$

With

$$h = \frac{C^*}{6}, \qquad \Delta = \frac{180}{\pi}\Delta_4, \qquad \boldsymbol{\theta} = M_{\mathrm{CKM}}(A, h, \Delta)^T, \tag{92.25}$$

the odd coordinate enters in the direction

$$c_h = \begin{pmatrix} -5 \\ 7 \\ -20 \end{pmatrix}. \tag{92.26}$$

If $c_A = (2, 0, 1)^T$ and $c_\Delta = (28, -25/2, -2/3)^T$, the three columns (c_A, c_h, c_Δ) are precisely the basis transported by M_{CKM}. The second row of equation (92.24) is the covector ℓ_h that extracts the odd coordinate:

$$\ell_h c_A = 0, \qquad \ell_h c_h = 1, \qquad \ell_h c_\Delta = 0. \tag{92.27}$$

Theorem 92.11 (Reflexion CKM inducida by the sheet)**.** *Let*

$$D_h = \mathrm{diag}(1, -1, 1), \qquad \ell_h = \frac{1}{3857}\begin{pmatrix} 75 & 176 & -150 \end{pmatrix}. \tag{92.28}$$

The involution induced on the space of $\boldsymbol{\theta}$ is

$$\boxed{\mathcal{R}_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h M_{\mathrm{CKM}}^{-1} = I - 2c_h\ell_h.} \tag{92.29}$$

Satisfies

$$\mathcal{R}_{\mathrm{CKM}}^2 = I, \qquad \det \mathcal{R}_{\mathrm{CKM}} = -1, \qquad \mathcal{R}_{\mathrm{CKM}} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h. \tag{92.30}$$

Proof. Multiplication of equations (92.23) y (92.24) gives the identity; in particular, equation (92.27) proves that $c_h\ell_h$ is the rank-one projector onto $\mathbb{Q}c_h$ along $\mathrm{span}\{c_A, c_\Delta\}$. The exact product $\ell_h c_h = 1$ implies

$$(I - 2c_h\ell_h)^2 = I - 4c_h\ell_h + 4c_h(\ell_h c_h)\ell_h = I.$$

The operator fixes the hyperplane $\ker \ell_h = \mathrm{span}\{c_A, c_\Delta\}$ pointwise and changes the sign of c_h. Its eigenvalues are therefore $1, 1, -1$; hence $\det \mathcal{R}_{\mathrm{CKM}} = -1$ and $\mathrm{Tr}\, \mathcal{R}_{\mathrm{CKM}} = 1$. Finally,

$$\mathcal{R}_{\mathrm{CKM}} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h M_{\mathrm{CKM}}^{-1} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h,$$

which proves the entanglement identity. □

The explicit matrix is

$$\mathcal{R}_{\mathrm{CKM}} = \begin{pmatrix} 4607/3857 & 1760/3857 & -1500/3857 \\ -150/551 & 199/551 & 300/551 \\ 3000/3857 & 7040/3857 & -2143/3857 \end{pmatrix}. \tag{92.31}$$

Although $\mathcal{R}_{\mathrm{CKM}}$ is not an orthogonal reflection for the Euclidean product of the three angular coordinates, it is for the transported rational metric

$$G_{\mathrm{CKM}} = (M_{\mathrm{CKM}}^{-1})^T M_{\mathrm{CKM}}^{-1}, \qquad \mathcal{R}_{\mathrm{CKM}}^T G_{\mathrm{CKM}} \mathcal{R}_{\mathrm{CKM}} = G_{\mathrm{CKM}}. \tag{92.32}$$

Indeed, in the basis (c_A, c_h, c_Δ), the metric is the identity and the involution is D_h. Hence the term "reflection" has precise metric content and does not merely describe that $\mathcal{R}_{\mathrm{CKM}}^2 = I$. Phase $\delta_{\mathrm{CP}} = 9A$ remains fixed under this reflection. Therefore, $\mathcal{R}_{\mathrm{CKM}}$ is not physical CP conjugation, but rather the transport of HMT sheet inversion to mixing space.

The rational inverse of M_{CKM} recovers

$$A = \frac{1528\theta_{12} + 3380\theta_{23} + 801\theta_{13}}{3857}, \tag{92.33}$$

$$C^* = \frac{6(75\theta_{12} + 176\theta_{23} - 150\theta_{13})}{3857}. \tag{92.34}$$

The third coordinate is also recovered without loss:

$$\Delta = \frac{6\theta_{12} - 30\theta_{23} - 12\theta_{13}}{551}. \tag{92.35}$$

These equations are coordinate changes. They do not turn CKM into a retrospective cause of A, C^* or of γ_{HMT}.

As a terminal recognition, the previous constructor determines

$$(\theta_{12}, \theta_{23}, \theta_{13}, \delta_{\mathrm{CP}}) = (13.003313589509^\circ, 2.398056157332^\circ, 0.213977382244^\circ, 65.676173123554^\circ). \tag{92.36}$$

The rational reflection is proved before using these decimals.

The transition $6 \to 8$ is first formalized through the inclusion $\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8$, from which $90, 120$ and the defect $-1/12$ are obtained. The six-trit word then provides the bijection $729 \leftrightarrow 729$, and $\mathcal{J}_{6\to 8}$ transports the two collective modes to the boundary. On that antecedent, area and the modular Hamiltonian exactly reconstruct the two families; thermofield-double purification determines the entanglement entropy, and the finite first law preserves the relative-entropy defect. In CKM, sheet inversion becomes a rational rank-one odd reflection.

Falsification criterion 92.12. The initial genealogy fails if $\iota_{6,8}$ is not injective, if the counts are not $90/120$, if $\delta_{6,8}^{\mathrm{inc}} \neq -1/12$, if β_{729} is not bijective or if it is falsely presented as an additive isomorphism. Collective transport fails if $\mathcal{J}_{6\to 8} D_{\mathrm{inc}} \neq D_{\mathrm{area}} \mathcal{J}_{6\to 8}$. Reconstruction fails if the determinant of the boundary observables is not thirty or if equation (72.8) does not recover the occupations. The TFD fails if its partial trace is not ρ_A. The first law does not extend to finite changes without the relative entropy of equation (74.6). Type III_{λ_∂} is invalidated if a channel does not persist, if there is no compatible product or if the ratio group changes. The CKM reflection is refuted by any of $\mathcal{R}^2 \neq I$, $\det \mathcal{R} \neq -1$ or $\mathcal{R}M \neq MD_h$. A formula $\boldsymbol{\theta} = f(\gamma_{\mathrm{HMT}})$ without an intertwiner violates the typed independence of the two functional realizations of the common antecedent.

Hypothesis, domain, and conclusion

Inclusion $H \subset O$, counts 90/120, two normalizations of the defect $-1/12$, bijection of six trits $729 \leftrightarrow 729$, collective intertwiner, scale a_0, finite operators, area spectrum, TFD, oriented defect, local and finite first law, and CKM reflection: *Exact internal theorem with its explicit initial structures*. Classification III_{λ_∂}: *Theorem with hypotheses explicit of persistence*. Interpretation of the thermofield-double copy as a physical exterior: *Realization, Physically Conditioned*. The magnitude γ_{HMT} is taken from the chapter on Barbero–Immirzi and minimal area, where it was derived; here it acts as an already established structural datum.

92.6.6.1 PMNS Matrix as Reader of the Common Neutrino Fiber Mixing

Let F_ℓ and F_ν be real orthonormal frames with the same three-dimensional image and orientations chosen so that $\det(F_\ell^* F_\nu) = +1$, derived from the charged and neutral operators. Then the real transport is

$$O = F_\ell^* F_\nu \in SO(3).$$

Without the correlative choice of orientation one concludes only $O \in O(3)$. Let b_K also be the normalized Witt witness, $Q_K = |b_K\rangle\langle b_K|$, and

$$\Phi_L = I + (e^{i\pi/6} - 1)Q_K.$$

The minimal phase produces

$$U_{\mathrm{HMT}} = F_\ell^* \Phi_L F_\nu.$$

This compression is unitary only under the condition of compatibility.

$$\Phi_L(\operatorname{Im} F_\nu) = \operatorname{Im} F_\ell.$$

Without it, a contraction is produced; when this is invertible, its polar factor defines the unitary candidate. Even when compatibility is imposed, the minimal rank-one phase is falsified as a physical PMNS: its best permutation leaves $\theta_{13} \simeq 17.02^\circ$. The physical kernel must read the complete record:

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c \in L_a} \sum_{d \in N_b} K_{\mathrm{reg}}(c,d), \qquad U_{\mathrm{int}} = \operatorname{polar}(G),$$

with $\det G \neq 0$. Carry, sheet, orientation, vacancy, and holonomy form part of the core. The falsifier of the rank-one phase remains printed to prevent formal unitarity from being confused with physical closure.

The Majorana condition for neutrinos additionally requires a fermionic self-conjugation compatible with the mass operator. Neutrality, C_M, and the topological Ising sector do not suffice separately.

92.6.6.2 CKM Mixing and CP Violation

The angular grammar is organized through

$$M_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det M_{\mathrm{CKM}} = -\frac{3857}{6}.$$

With

$$\begin{pmatrix} \theta_{12} \\ \theta_{23} \\ \theta_{13} \end{pmatrix} = M_{\mathrm{CKM}} \begin{pmatrix} A \\ C^*/6 \\ (180/\pi)\,\Delta_4 \end{pmatrix}, \qquad \delta_{\mathrm{CP}} = 9A,$$

we obtain

$$(\theta_{12},\theta_{23},\theta_{13},\delta_{\mathrm{CP}}) = (13.003313589509, 2.398056157332, 0.213977382244, 65.676173123554)^\circ.$$

The Jarlskog invariant is

$$J = c_{12}c_{23}c_{13}^2 s_{12}s_{23}s_{13}\sin\delta_{\mathrm{CP}} = 3.1189723326632974\times 10^{-5}.$$

The exact linear falsifier is

$$3857\delta_{\mathrm{CP}} = 9(1528\theta_{12} + 3380\theta_{23} + 801\theta_{13}).$$

In the standard unitary parametrization,

$$V_{\mathrm{CKM}} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix}.$$

The previous internal evaluation produces

$$|V_{\mathrm{CKM}}| = \begin{pmatrix} 0.974350259 & 0.225005836 & 0.003734601 \\ 0.224873110 & 0.973489279 & 0.041841465 \\ 0.008582400 & 0.041121745 & 0.999117283 \end{pmatrix}.$$

A frozen marginal comparison yields normalized deviations $(-0.24, -0.07, -0.34, -0.31, -0.37)$ for the four angular parameters and J, respectively. These figures do not replace the covariant comparison: the publication must identify the external edition and its complete covariance matrix before forming a joint χ^2.

CKM transports between quark bases. If B_u, B_d are the diagonal mass operators,

$$B_d^{(u)} = V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^*.$$

The identity

$$|\det[B_u, V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^*]| = 2|J| \prod_{i<j} |\kappa_i^u - \kappa_j^u| \prod_{a<b} |\kappa_a^d - \kappa_b^d|$$

shows that mixing and spectrum couple without the mixing matrix creating the eigenvalues.

92.7 Composition, resonances and non-ordinary sectors

The composite mass is obtained from the constituent records, the boundary, and the binding operator; it is not a bare sum of masses. The width follows from the survival pole and remains separate from the mass signature. Virtual sections, the Fibonacci, Ising–Majorana, and order-six sectors, and the exclusions of tachyons and ghosts preserve their respective domains.

92.8 Composition of paths, records, and signatures

A composite species cannot enter the law of masses as a name to which a row of five integers is retrospectively assigned. Before the signature, an object capable of composition must exist. The atlas of section 90.5 supplies the finite alphabet; the surviving extension and register of section 91.5 supply the memory that may be composed. The question of this chapter is to construct the intermediate stratum without consulting target masses:

$$\text{typed compositional configuration} \longrightarrow \text{complete records of its constituents} \longrightarrow \text{composite record} \longrightarrow \mathbb{Z}^5.$$

The ordering of the arrows is part of the result. The expressions are formed before they are assigned a physical realization; the ledgers are composed before the signature is extracted; the signature is evaluated through the character only after the memory has been composed. Thus, the composite domain is not reduced to the species included in a metrological table.

92.8.1 Internal classification and compositional grammar

Let

$$C_{81} = I_9 \times I_9, \qquad I_9 = \{1, \dots, 9\},$$

the cell atlas, and let it be

$$\rho(r, c) = (10 - r, 10 - c)$$

its central inversion. We denote by $\mathcal{L}, \mathcal{N}, \mathcal{D}, \mathcal{U}$ the subsets of charged leptons, neutrinos, down-type quarks, and up-type quarks, respectively, and set

$$\mathcal{Q} = \mathcal{D} \sqcup \mathcal{U}.$$

Each cell has a combinatorial level $\mathrm{gen}(x)$. In the quark sector the color residue is also preserved

$$\kappa(x) = r(x) - c(x) \pmod 3.$$

We write

$$\mathcal{Q}_a = \{q \in \mathcal{Q} : \kappa(q) = a\}, \qquad a \in \mathbb{Z}/3\mathbb{Z}.$$

By proposition 90.14,

$$|\mathcal{Q}_0| = |\mathcal{Q}_1| = |\mathcal{Q}_2| = 12.$$

Definition 92.13 (Dual formal and cell identity)**.** For an oriented cell section x, its formal dual $x^\vee$ inverts the orientation of charge and color, and has support $\rho(x)$. The notation preserves the distinction

$$x^\vee \neq \rho(x)$$

when $\rho(x)$ is regarded as an unoriented cell. For each $x \in C_{81}$, we denote by $\mathrm{id}_x : x \to x$ the identity arrow. The set of identities is

$$\mathfrak{I} := \{\mathrm{id}_x : x \in C_{81}\}.$$

The identity id_x is a neutral arrow of the compositional system. It is not, by that condition alone, a realization of a neutral boson. Likewise, the formal dual incorporates orientation and cannot be replaced by a second bare cell.

Definition 92.14 (Mesonic and Baryonic Expressions)**.** The set of colour-neutral mesonic expressions is

$$\mathfrak{M} := \left\{ M(q, q') = q \otimes (q')^\vee : q, q' \in \mathcal{Q},\ \kappa(q) = \kappa(q') \right\}.$$

The pairs are ordered. Their total residue is $\kappa(q) - \kappa(q') = 0$.

The set of baryonic expressions with fixed color positions is

$$\mathfrak{B} := Q_0 \times Q_1 \times Q_2,$$

and we write

$$B(q_0, q_1, q_2) = q_0 \otimes q_1 \otimes q_2.$$

Its residual neutrality is the identity.

$$0 + 1 + 2 = 0 \pmod 3.$$

These expressions are typed syntactic objects. In particular, no quotient has yet been taken by permutations, spin, flavor, statistics, binding energy, or dynamical equivalence.

Definition 92.15 (Compatible loaded arrows)**.** The oriented leptonic arrows are

$$\mathfrak{A}_\ell := \{(x, y) \in (\mathcal{L} \times \mathcal{N}) \sqcup (\mathcal{N} \times \mathcal{L}) : \mathrm{gen}(x) = \mathrm{gen}(y)\}.$$

Quark-oriented arrows are

$$\mathfrak{A}_q := \left\{ (x, y) \in (\mathcal{U} \times \mathcal{D}) \sqcup (\mathcal{D} \times \mathcal{U}) : \begin{array}{l} \mathrm{gen}(x) = \mathrm{gen}(y), \\ \kappa(x) = \kappa(y) \end{array} \right\}.$$

We set

$$\mathfrak{A}_{\mathrm{ch}} := \mathfrak{A}_\ell \sqcup \mathfrak{A}_q.$$

Level equality types the transition in both sectors; colour equality is additionally required in the quark sector. Orientation distinguishes $x \to y$ from $y \to x$.

Definition 92.16 (Finite system of typed compositions)**.** The finite compositional system is the typed disjoint union

$$\mathfrak{G}_{\mathrm{comp}} := C_{81} \sqcup \mathfrak{I} \sqcup \mathfrak{M} \sqcup \mathfrak{B} \sqcup \mathfrak{A}_{\mathrm{ch}}.$$

The 81 cells are the primitive generators. The 81 identities are arrows on those same generators, not a second atlas.

92.8.2 Combinatorial census of route compositions independent of metrological data

Theorem 92.17 (Census of the finite system of compositions)**.** *The system of the definition 92.16 contains*

81 *identities*,	432 *mesonic expressions*,
1728 *baryonic expressions*,	372 *charged arrows*

The charged arrows decompose exactly as

$$372 = 320_{leptonic} + 52_{quark}.$$

The census depends only on the atlas, its inversion, the levels, and the color residue. It uses neither masses, units, nor published signatures. The four cardinalities count internal compositional expressions or admissible arrows of the system; they do not count distinct physical species, physical particles, or masses.

Proof. The assignment $x \mapsto \mathrm{id}_x$ is bijective, so

$$|\mathfrak{I}| = |C_{81}| = 81.$$

For mesons, the neutrality condition permits an ordered pair to be chosen independently within each colour class. Since each class contains twelve cells,

$$|\mathfrak{M}| = \sum_{a\in\mathbb{Z}/3\mathbb{Z}} |Q_a|^2 = 3 \cdot 12^2 = 432.$$

For baryons, the positions $0, 1, 2$ are fixed, and therefore

$$|\mathfrak{B}| = |Q_0||Q_1||Q_2| = 12^3 = 1728.$$

The charged lepton families have sizes

$$|\mathcal{L}_{G0}| = 1, \qquad |\mathcal{L}_{G2}| = 8, \qquad |\mathcal{L}_{G4}| = 16,$$

while the neutrino families have sizes

$$|\mathcal{N}_{G1}| = 2, \quad |\mathcal{N}_{G2}| = 4, \quad |\mathcal{N}_{G3}| = 6, \quad |\mathcal{N}_{G4}| = 8.$$

Only $G2$ and $G4$ are common levels. Since both orientations are counted,

$$|\mathfrak{A}_\ell| = 2(8 \cdot 4 + 16 \cdot 8) = 320.$$

For the quark arrows, in the colour order $(0, 1, 2)$, the up-type and down-type multiplicities at the common levels are

	$\mathcal{U}$	$\mathcal{D}$
$G1$	$(2, 1, 1)$	$(0, 1, 1)$
$G3$	$(4, 4, 4)$	$(2, 2, 2)$.

The number of pairs of an orientation and the same color is, therefore,

$$(2 \cdot 0 + 1 \cdot 1 + 1 \cdot 1) + (4 \cdot 2 + 4 \cdot 2 + 4 \cdot 2) = 2 + 24 = 26.$$

By including the opposite orientation one obtains

$$|\mathfrak{A}_q| = 2 \cdot 26 = 52.$$

Finally,

$$|\mathfrak{A}_{\mathrm{ch}}| = 320 + 52 = 372.$$

None of these rules contains an objective value or a mass vector. □

Corollary 92.18 (Compositional constructor without whitespaces)**.** *The constructor that jointly enumerates identities, mesonic expressions, baryonic expressions, and charged arrows factorizes through the typed fields*

$$(\mathit{sector}, \mathit{family}, \mathit{level}, \kappa, \rho)$$

of the atlas. With the preceding notation, its four codomains are $\mathfrak{I}, \mathfrak{M}, \mathfrak{B}, \mathfrak{A}_{\mathrm{ch}}$*. In particular, the census can be fixed before any signature table is opened.*

Proof. The four definitions and the calculation of theorem 92.17 use only those fields. The table of signatures does not belong to the domain of any of the rules. □

Target independence does not mean that the expressions have already acquired a physical name. It means something prior and more precise: there exists a compositional domain constructed without using as a criterion the quantity that will later be evaluated.

92.8.3 Memory transport from the composite route to the integral signature

Let $\gamma \in \Gamma_{108}^{\mathrm{enr}}$ be an enriched presentation of an extension. Its read register contains

$$\mathcal{E}(\gamma) = (n_A, e_0, \dots, e_{11}, T_\zeta, C_\zeta),$$

in addition to the phase, sheet, orientation, and edge data that type a composition. The twelve events are not replaceable by their total before composition. For $0 \le i < 6$, we define

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6},$$

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5).$$

With $M_5 = (M_0, \dots, M_4)$ and $A_6 = (a_0, \dots, a_5)$, the reconstruction is

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i,$$

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}.$$

By the theorem 91.3, on the integral image the reversible decomposition is obtained

$$\boxed{(s_C, M_5, A_6), \qquad 1 + 5 + 6 = 12.}$$

The first block preserves the visible total; the second, the relative form within the symmetric sheet; the third, the memory between the two semicrowns.

The strong torsional coordinate also requires the cocycle condition at the step level:

$$k_{\Delta_4} = T_\zeta - 2C_\zeta.$$

It is not a function of the mere pattern of null events. This difference will be essential when interpreting the non-descent rhombus.

Definition 92.19 (Given oriented composition data)**.** Let Γ, Λ be two enriched ledgers. A composition datum is a pair (g, B), where g aligns phase, sheet, orientation, and position at the interface, and B is the common subtrace, with its contribution to the action, its twelve events, its torsional predecessors, and its corona. On the domain in which these data are compatible, one defines

$$\boxed{(n, e)_\Gamma \star_{(g,B)} (n, e)_\Lambda = \big(n_\Gamma + n_\Lambda - n_B,\ e_\Gamma + g e_\Lambda - e_B\big).}$$

The torsional word and the corona are composed at the same level, before computing T_ζ, C_ζ and k_{Δ_4}.

The formula is an inclusion–exclusion of histories over an identified subtrace. It is demonstrated with an explicit initial structure: the records, the transport g, the boundary B, the orientation, and the word of predecessors are part of the input. The compositional system does not by itself choose any of those data.

Definition 92.20 (Posterior extractor after the composition)**.** For a complete enriched record one defines

$$L_{\mathrm{tick}}(\gamma) = \big(n_A, s_C, k_{\Delta_4}, \nu_{120}^{\mathrm{ev}}, \nu_{270}\big) \in \mathbb{Z}^5,$$

where, if $\tau_m = \operatorname{sgn}(e_m)$ and $I_a = \{a, a+4, a+8\} \pmod{12}$,

$$\nu_{120}^{\mathrm{ev}} = \sum_{a=0}^{3} \operatorname{sgn}\left(\sum_{m\in I_a} e_m\right), \qquad \nu_{270} = \sum_{m=0}^{11} \tau_m \tau_{m+3}.$$

The signature of a composition is defined by

$$\operatorname{Sig}(\Gamma, \Lambda; g, B) := L_{\mathrm{tick}}\big(\Gamma \star_{(g,B)} \Lambda\big).$$

The signs and autocorrelations are applied to the already composed record. Therefore, the definition is not equivalent to summing the signatures of the constituents.

92.8.4 Commutative diagram of composition and fiber preservation

The historical catalog B1 employs an event projection that is convenient to type separately. Let

$$\Sigma_{12} = (+,+,+,-,-,-,+,+,+,-,-,-), \qquad \tau_m = \operatorname{sgn}(e_m),$$

and let us define the null event proxy

$$K_0(e) = \sum_{\tau_m = 0} \Sigma_{12}(m).$$

The exact projection is

$$F_0(n_A, e) = \left(n_A,\ \sum_m e_m,\ K_0(e),\ \sum_{a=0}^{3} \operatorname{sgn} \sum_{m\in I_a} e_m,\ \sum_m \tau_m \tau_{m+3}\right) \in \mathbb{Z}^5.$$

For two aligned records, we write

$$(n, e) \boxplus (n', e') = (n + n', e + e').$$

This operation is the case with no common subtrace and with identity alignment of the event-composition case.

Proposition 92.21 (Obstruction to the descent of the projection B1)**.** *There is no binary operation*

$$\mu : \mathbb{Z}^5 \times \mathbb{Z}^5 \longrightarrow \mathbb{Z}^5$$

such that

$$F_0(\Gamma \boxplus \Lambda) = \mu\big(F_0(\Gamma), F_0(\Lambda)\big)$$

for all records B1.

Proof. Consider the routes, written in the chart (r, c, h_0, v_0),

$$a = (1, 3, -1, +1), \qquad b = (6, 7, -1, +1), \qquad c = (1, 2, -1, -1).$$

The first two have distinct event records:

$$e(a) = (5, 4, 4, -4, -4, -6,\ 5, 4, 4, -4, -4, -6),$$
$$e(b) = (4, 5, 4, -4, -6, -4,\ 4, 5, 4, -4, -6, -4),$$

but publish the same five-tuple:

$$F_0(a) = F_0(b) = (8, -2, 0, 0, -12).$$

The test route has

$$e(c) = (1, 4, 1, -2, -4, -3,\ \ 1, 4, 1, -2, -4, -3)$$

and

$$F_0(c) = (28, -6, 0, -4, -12).$$

By first summing the events and then reevaluating, one obtains

$$F_0(a \boxplus c) = (36, -8, 0, 0, -12),$$

$$F_0(b \boxplus c) = (36, -8, 0, -2, -12).$$

The two pairs of inputs of the putative μ are equal, but the outputs differ in ν_{120}^{ev}. This contradicts the existence of μ. □

The exhaustive census of the same domain contains 324 routes, 53 proxy five-tuples, and 198 distinct event states. Forty-two fibers of the projection contain more than one enriched state; forty of them are separated by some test route. The preceding diamond is the shortest canonical witness to that loss of information.

Remark 92.22 (Typed separation between the representative K_0 and strong torsion). The third coordinate of F_0 is $K_0(e)$, which in B1 takes values in $\{-4, -2, 0, 2, 4\}$. It is not identified with $k_{\Delta_4} = T_\zeta - 2C_\zeta$. Indeed, there exist routes with the same n_A and the same vector of twelve events to which the torsional reader assigns distinct values because it preserves the predecessors of each iteration and the crown.

The proposition 92.21 proves exactly that the five-coordinate B1 projection does not transport the superposition of records. It does not assert a universal impossibility for every future structure on $\mathbb{Z}^5$, nor does it authorize replacing K_0 with k_{Δ_4}. Under the strong reader, the output is defined through the definition 92.20: the enriched word is first composed and its five coordinates are then re-extracted.

92.8.5 Theorem of independent data record composition in metrology

Theorem 92.23 (Compositional closure without blanks)**.** *Once the atlas C_{81}, formal duality, the color residue, and the enriched record of the section 91.5 have been fixed, the following assertions hold.*

1. *There exists the finite system of typed compositions $\mathfrak{G}_{\mathrm{comp}}$ with* 81 *identities,* 432 *mesonic expressions,* 1728 *baryonic expressions, and* 372 *charged arrows, decomposed as* 320 + 52*.*
2. *The system is constructed without target masses. Its output is a typed expression, orbit, or multisection, not a mass or an individualized physical label.*
3. *Given an expression and constituent records with an explicit tree of compatible compositions (g, B), the operation produces an enriched record. Its signature is obtained by the application*

$$\boxed{(\textit{expression}, \textit{records}, \textit{oriented compositions}) \xrightarrow{\mathfrak{C}_{12}} \textit{composite record} \xrightarrow{L_{\mathrm{tick}}} \mathbb{Z}^5.}$$

   Here $\mathfrak{C}_{12}$ denotes the iteration of $\star_{(g,B)}$ with the parenthesization and boundaries included in the data.
4. *The B1 projection onto five integers does not by itself constitute a compositional space: the diagram with $\boxplus$ does not descend to $\mathbb{Z}^5$. Therefore, replacing each record by its five-tuple before composition loses information needed to reevaluate at least ν_{120}^{ev}.*

Proof. The first point is theorem 92.17. The second is corollary 92.18. For the third, each edge of the composition tree is evaluated through definition 92.19; because the boundaries and transports form part of

the domain, the iteration produces a register on which L_{tick} is defined. No intermediate signature is used as a substitute for the register. The fourth point is proposition 92.21. □

The correct formula for the composite signature is, therefore,

$$\mathrm{Sig}_{\mathrm{comp}} = L_{\mathrm{tick}} \circ \mathfrak{C}_{12}.$$

It is not a sum of mass rows. Only afterward may the formal character or its global specialization be applied:

$$\text{composite record} \xrightarrow{L_{\mathrm{tick}}} \mathbb{Z}^5 \xrightarrow{\chi_{\mathrm{form}}} \mathrm{Fun}(\mathcal{P}, \mathbb{R}_{>0}) \longrightarrow \text{dimensional chart.}$$

92.8.6 Genealogical reconstruction of mixing, generation, and persistence of flavor

The preceding theorem completes a stratum that a list of masses cannot display. Primitive cells do not merely receive names; they generate identities, dual pairs, color triples, and oriented arrows through internal rules. Composite objects thus appear within the domain before any metrological comparison.

Genealogy is not reduced to the syntactic tree either. Two expressions with the same number of constituents may be composed in different ways because the phase, sheet, orientation, and common subtrace form part of the datum. The register preserves those differences until the signs, correlations, and torsion have acted. Mass, when a dimensional realization exists, will be a subsequent reading of that composite memory.

This order explains why $\mathbb{Z}^5$ is not the composition domain although it is the domain of the character. The group $(\mathbb{Z}^5, +)$ exists, and the character is multiplicative on it; what does not exist for the B1 projection is a law that recovers from the five-tuples the superposition that has already forgotten the placement of the twelve events. Linearity of the character does not restore the information removed by the extractor.

92.8.7 From the internal compositional system to physical realization

The theorem 92.23 constructs the domain prior to physical names: ordered expressions, duals, color triples, and compatible arrows. Their cardinalities count internal possibilities of composition. A physical species, by contrast, is a persistent representation with specified flavor, color, spin, statistics, and channel. Conflating the two levels would turn a census of expressions into a spurious catalogue of particles.

Definition 92.24 (Physical realization data)**.** A realization datum for a species X is the tuple

$$\mathfrak{D}_X = \big(\mathfrak{t}_X, \mathfrak{s}_X, (\mathcal{L}_{X_i})_{i=1}^{r}, \mathcal{T}_X, (g_X, B_X)\big),$$

where:

1. $\mathfrak{t}_X$ fixes the physical type —elementary, null, mesonic, baryonic, multiquark, or topological— and its representation;
2. $\mathfrak{s}_X$ is the multisection or realized internal expression;
3. $\mathcal{L}_{X_i}$ are the enriched ledgers of the constituents;
4. $\mathcal{T}_X$ fixes flavor, color, spin, statistics, and symmetrization;
5. (g_X, B_X) fixes the composition tree, its transports, and its common subtraces.

The tuple is declared without consulting the mass or the width, which will be evaluated later.

Proposition 92.25 (The realization changes the register, not the law)**.** *Every datum $\mathfrak{D}_X$ determines a composite record*

$$\mathcal{L}_X = \mathfrak{C}_{12}\big((\mathcal{L}_{X_i})_{i=1}^{r}; \mathcal{T}_X, g_X, B_X\big),$$

a signature $v_X = L_{\mathrm{tick}}(\mathcal{L}_X)$ and the universal central character

$$\chi_0(v_X - v_e).$$

If the genealogy also provides a typed spectral refinement $\eta_X \in \mathcal{E}_{\Subset}$, the complete evaluation is

$$m_X = m_e^{\mathrm{HMT}}\, \chi_{\mathrm{full}}(v_X - v_e, \eta_X).$$

The central character and the refinement belong to distinct levels; the completeness of the tower does not replace the prospective map that produces η_X. If X is unstable, its width belongs to the temporal reader $\Gamma_X = \hbar_{\mathrm{int}}/\tau_X^{\mathrm{life}}$, not to a sixth coordinate of the mass signature.

Proof. The realization datum contains exactly the entries of $\mathfrak{C}_{12}$. The theorem 92.23 produces the enriched record, and the definition 92.20 produces its signature. The central character and its spectral lift are those of proposition 92.25. The width uses a temporal line and therefore has a different domain. □

The level separation is thus fixed:

internal compositional system ⟶ realization datum ⟶ composite record ⟶ signature ⟶ central character ⟶ spectral refinement ⟶ physical comparison.

The 432 mesonic expressions, the 1728 baryonic expressions, and the 372 charged arrows occupy only the first slot and do not constitute an inventory of particles. The Standard Model preserves its typed set of species, and each species occupies the chain through its own realization datum. The causal rule is unique across all sectors:

compose extensions and records; read the signature afterwards.

92.9 Particle band, anti-section, and virtuality

The persistence of a route produces a particle before its mass is evaluated. This priority makes it possible to distinguish three objects:

1. the *oriented section*, which preserves the direction of the route;
2. the *band*, which joins a section and its conjugate;
3. the *persistence*, which decides whether or not the signature reaches a global branch.

Definition 92.26 (Dodecaphasic Words and Material Conjugation)**.** Let

$$\mathscr{T}_{12}^{\mathrm{word}} := \{-1, 0, 1\}^{12}.$$

For $\mathbf{t} = (t_1, \ldots, t_{12})$ we write

$$\mathrm{rev}(\mathbf{t}) = (t_{12}, \ldots, t_1), \qquad C_M(\mathbf{t}) := -\,\mathrm{rev}(\mathbf{t}).$$

The inversion C_M simultaneously changes the reading direction and the tritic orientation.

Theorem 92.27 (Material inversion and fixed sector)**.** *The map C_M is an involution of $\mathscr{T}_{12}^{\mathrm{word}}$ and*

$$|\mathrm{Fix}(C_M)| = 3^6 = 729.$$

Proof. Reversal and sign change commute and both have square equal to the identity; therefore $C_M^2 = I$. A word is fixed if and only if

$$t_i = -t_{13-i}, \qquad 1 \le i \le 6.$$

The first six coordinates are free, and the last six are determined by them. Each free coordinate admits three values, so the fixed sector has cardinality 3^6. □

This finite conjugation is not obtained by changing only the visible sign: it also reverses the orientation of the register.

92.9.1 Definition of the route band through the orbit of a persistent section

Let $\mathcal{T}_{12}^{\mathrm{word}}$ be the word space of the definition 92.26. We add a section orientation $\chi \in \{-1, +1\}$ and define

$$(\mathbf{t}, \chi) \sim (C_M \mathbf{t}, -\chi).$$

Definition 92.28 (Dodecaphasic route band)**.** The band of the oriented section $(\mathbf{t}, \chi)$ is the class

$$[(\mathbf{t}, \chi)]_M = \{(\mathbf{t}, \chi), (C_M \mathbf{t}, -\chi)\},$$

and the band space is

$$\mathcal{B}_{12} := \big(\mathcal{T}_{12}^{\mathrm{word}} \times \{-1, +1\}\big)/\!\sim.$$

Proposition 92.29 (Freedom of oriented conjugation)**.** *The action*

$$(\mathbf{t}, \chi) \longmapsto (C_M \mathbf{t}, -\chi)$$

is free. Consequently,

$$|\mathcal{B}_{12}| = 3^{12}.$$

Proof. A fixed point would require $\chi = -\chi$, impossible for $\chi \in \{-1, +1\}$. All orbits have two elements and the domain has $2 \cdot 3^{12}$. □

The band does not erase orientation: it preserves it as a double cover. The particle and the antiparticle are the two oriented sections of the same band.

92.9.2 Even mass and odd charge

Let $E_0 : \mathcal{T}_{12}^{\mathrm{word}} \to \mathbb{R}$ be an additive route character. Its even and odd components with respect to C_M are

$$E_+(\mathbf{t}) = \frac{1}{2}\big(E_0(\mathbf{t}) + E_0(C_M \mathbf{t})\big),$$

$$E_-(\mathbf{t}) = \frac{1}{2}\big(E_0(\mathbf{t}) - E_0(C_M \mathbf{t})\big).$$

Then

$$E_+(C_M \mathbf{t}) = E_+(\mathbf{t}), \qquad E_-(C_M \mathbf{t}) = -E_-(\mathbf{t}).$$

Definition 92.30 (Band character)**.** For an oriented section we define

$$E_{\mathrm{band}}(\mathbf{t}, \chi) = E_+(\mathbf{t}) + \chi E_-(\mathbf{t}), \qquad m(\mathbf{t}, \chi) = m_\circ \exp\big(E_{\mathrm{band}}(\mathbf{t}, \chi)\big),$$

where $m_\circ$ is the family's internal comparison unit.

Theorem 92.31 (Mass Conjugation Principle)**.** *The character and the mass descend to the band quotient:*

$$E_{\mathrm{band}}(C_M \mathbf{t}, -\chi) = E_{\mathrm{band}}(\mathbf{t}, \chi),$$

$$\boxed{m(C_M \mathbf{t}, -\chi) = m(\mathbf{t}, \chi).}$$

The even invariants belong to the band; the odd invariants distinguish the orientation of its two sections.

Proof. By the previous parities,

$$\begin{aligned} E_{\mathrm{band}}(C_M\mathbf{t}, -\chi) &= E_+(C_M\mathbf{t}) - \chi E_-(C_M\mathbf{t}) \\ &= E_+(\mathbf{t}) + \chi E_-(\mathbf{t}). \end{aligned}$$

The equality of masses is obtained by applying the exponential. □

In particular, a linear form with symmetric weights is odd, whereas a quadratic form compatible with reversal is even. Charge and orientation change; the mass, constructed over the band, remains.

Corollary 92.32 (Electron and positron)**.** *In the electronic band equation, the pair* $(n, \chi) = (-22, +1)$ *and its conjugate* $(+22, -1)$ *produce the same term* $\chi n = -22$*. Therefore, the electron and positron have the same mass and opposite charge orientations.*

92.9.3 Finite closure of the atlas under anti-section

Seven tritic forms appear in the eighty-one CT–108 routes. The exhaustive census distinguishes three operations:

$$\mathbf{t} \longmapsto -\mathbf{t}, \qquad \mathbf{t} \longmapsto \mathrm{rev}(\mathbf{t}), \qquad \mathbf{t} \longmapsto -\mathrm{rev}(\mathbf{t}).$$

Proposition 92.33 (Closure of the CT–108 forms)**.** *The set of tritic forms of CT–108 is not stable under pure sign nor under pure reversal, and is stable under* $C_M = -\mathrm{rev}$*. Its orbits have multiplicities*

$$\boxed{81 = 54 + 9 + 9 + 9.}$$

The orbit of multiplicity 54 *is self-conjugate; the other three exchange pairs of forms.*

Proof. The fixed form is

$$\texttt{+++-+++-+++-+++-}$$

and has multiplicity 54. The three pairs

$$\begin{gathered} \texttt{+++-0+++-0} \;/\; \texttt{0++-0++-0++-}, \\ \texttt{+++-0-+++-0-} \;/\; \texttt{+0+-+0+-+0+-}, \\ \texttt{+++0-+++0-} \;/\; \texttt{++0-++0-++0-} \end{gathered}$$

have total multiplicity 9 each. The map $-\mathrm{rev}$ fixes the first and permutes the members of each pair. Sign change and reversal separately produce words outside this list. The sum of multiplicities is $54 + 9 + 9 + 9 = 81$. □

The result does not identify the sector 54 with another object of the same cardinality. It proves which conjugation respects the specific taxonomy of the routes and why particle and antiparticle share a band.

92.9.4 Finite persistence and virtual particle

Let

$$\cdots \xrightarrow{\rho_{M+1,M}} S_M \xrightarrow{\rho_{M,M-1}} S_{M-1} \to \cdots$$

the system of admissible states at finite depths. For $s_N \in S_N$, we define the set of prolongations

$$\mathcal{P}_M(s_N) := \{s_M \in S_M : \rho_{M,N}(s_M) = s_N\}, \qquad M \geq N.$$

Its depth of life is

$$\mathcal{L}(s_N) := \sup\{M \geq N : \mathcal{P}_M(s_N) \neq \varnothing\} \in \mathbb{N} \cup \{\infty\}.$$

Definition 92.34 (Persistence and Virtuality)**.** A prefix s_N is *persistent* if it belongs to a compatible global section $(s_M)_{M\geq N}$. It is *finite virtual* if $\mathcal{L}(s_N) < \infty$, a prolongation exists up to $\mathcal{L}(s_N)$ and none exists at the next depth.

Theorem 92.35 (Persistence criterion)**.** *Suppose that each state has a finite number of immediate prolongations and that the restrictions are coherent. Then:*

$$\mathcal{L}(s_N) = \infty \quad \Longleftrightarrow \quad s_N \text{ belongs to a global section.}$$

If $\mathcal{L}(s_N) = L < \infty$, the prefix transports route, memory, register, and signature up to L, but does not define a persistent particle.

Proof. A global section provides a prolongation to every depth, so $\mathcal{L} = \infty$. Conversely, the prolongations of s_N form an infinite, finitely branching rooted tree. By König's lemma, it contains an infinite branch whose vertices are compatible by construction and define a global section.

If $\mathcal{L} = L < \infty$, there is a state at depth L and none at $L + 1$. Readers defined on prefixes can evaluate it up to L; the absence of prolongation prevents that finite signature from being converted into a section of the inverse limit. □

The virtual particle thus has an internal definition. It is neither a "less real" particle nor a brief violation of a conservation law. It is a route whose memory exerts influence over a finite depth and whose genealogy becomes extinct before stabilizing. The comparison with propagators and intermediate states of conventional physics is carried out after identifying which reader represents those depths.

92.9.5 Route–record–signature–character–material realization tower chain

The results of this chapter fix the complete direction:

$$\boxed{\text{extension} \longrightarrow \text{route} \longrightarrow \text{record} \longrightarrow \text{signature} \longrightarrow \text{oriented band} \longrightarrow \text{particle} \longrightarrow \text{mass.}}$$

The antiparticle is the second section of the band. Virtuality is finite persistence. Neither notion is defined from an observed mass.

92.10 Complex structure $\widetilde{J}_M^2 = -I$ on the fixed stratum, dodecaphase involutions, and topological sectors

The involution C_M, the based ring associated with F_{av}, the braid characters, and the pointed categories belong to distinct algebraic strata. They are presented with their domains and identification controls so that a nominal coincidence does not replace the morphism that would have to relate them. The atlas census, the infinite spectral hierarchy whose eight historical heights are initial witnesses, and the statistical completions preserve the proofs of theorems 6.20, 68.6, 69.1 y 90.11.

Each result directly declares its domain, its construction, and its conclusion; no nominal coincidence modifies those dependencies.

92.10.1 Periodic stratum of the dodecaphasic involution

The domain $\mathcal{T}_{12}^{\mathrm{word}}$, the conjugation $C_M\mathbf{t} = -\operatorname{rev}(\mathbf{t})$, its involutive character, and the census $|\operatorname{Fix}(C_M)| = 3^6 = 729$ have their primary residence in the definition 92.26 y theorem 92.27, within the particle band. Only the periodic condition required for the topological stratum is added here. If r denotes the cyclic shift $(r\mathbf{t})_m = t_{m-1}$, we set

$$\mathrm{Per}_6 := \{\mathbf{t} \in \mathcal{T}_{12}^{\mathrm{word}} : r^6\mathbf{t} = \mathbf{t}\}.$$

Proposition 92.36 (Census of the periodic stratum)**.** *Upon imposing periodicity with period dividing six,*

$$\left|\mathrm{Fix}(C_M) \cap \mathrm{Per}_6\right| = 3^3 = 27.$$

This identity is exact.

Proof. The theorem 92.27 gives the general form of the fixed points. If, moreover, $r^6\mathbf{t} = \mathbf{t}$, the second half of the word coincides with the first. Writing the first six coordinates, the two conditions are equivalent to

$$(t_0, t_1, t_2, t_3, t_4, t_5) = (a, b, c, -c, -b, -a).$$

The parameters a, b, c are independent and take three values; therefore, the intersection has 3^3 elements. □

The general example of a fixed point, prior to requiring period six, is

$$(a, b, c, d, e, f, -f, -e, -d, -c, -b, -a).$$

This coordinated form makes it possible to check by hand both the involution and the count and avoids interpreting the integer 729 by means of another homonymous object.

Remark 92.37 (Census of the Involution). The enumeration of the $3^{12} = 531\,441$ words finds no violation of the involution and obtains

$$|\,\mathrm{Fix}(C_M)| = 729, \qquad |\,\mathrm{Fix}(C_M) \cap \mathrm{Per}_6\,| = 27.$$

The primary proof and proposition 92.36 explain both numbers independently of the traversal: the fixed points have six free coordinates, and the additional period-six condition reduces the choice to three. The exhaustive census confirms that no exceptional orbits exist outside that description.

Comparison Criterion 92.38 (Falsifiers of the census C_M)**.** Any of the following facts would refute the result: a word for which $C_M^2\mathbf{t} \neq \mathbf{t}$; a fixed point that does not have the preceding coordinate form; an exhaustive total other than 729; or a total other than 27 after imposing $r^6\mathbf{t} = \mathbf{t}$. The nominal coincidence of this 729 with another cardinal does not identify their domains.

92.10.2 Quadratic structure transported to the fixed sheet

We identify the alphabet of signs with the ternary field via

$$\{-1, 0, +1\} \xrightarrow{\sim} \mathbb{F}_3, \qquad -1 \longmapsto 2, \quad 0 \longmapsto 0, \quad +1 \longmapsto 1.$$

With this identification, $\mathscr{T}_{12}^{\mathrm{word}} \cong \mathbb{F}_3^{12}$, and both $C_M = -\mathrm{rev}$ and the shift r are $\mathbb{F}_3$-linear operators. Consequently, $\mathrm{Fix}(C_M)$ and $\mathrm{Per}_6 = \ker(r^6 - I)$ are vector subspaces.

The coordinate form of the fixed points defines the linear isomorphism.

$$s_{\mathrm{fix}} : \mathbb{F}_3^6 \xrightarrow{\sim} \mathrm{Fix}(C_M),$$

$$s_{\mathrm{fix}}(a, b, c, d, e, f) = (a, b, c, d, e, f, -f, -e, -d, -c, -b, -a).$$

Let J_W be the Paley–Witt operator constructed in theorem 3.21, with the basis, polarization, and orientation declared there.

Proposition 92.39 (Complex structure $\widetilde{J}_M^2 = -I$ on the fixed stratum)**.** *The transport*

$$\widetilde{J}_M := s_{\mathrm{fix}} J_W s_{\mathrm{fix}}^{-1} \in \mathrm{End}_{\mathbb{F}_3}\big(\mathrm{Fix}(C_M)\big)$$

satisfies

$$\widetilde{J}_M^2 = -I.$$

Proof. By conjugation,

$$\widetilde{J}_M^2 = s_{\mathrm{fix}} J_W s_{\mathrm{fix}}^{-1} s_{\mathrm{fix}} J_W s_{\mathrm{fix}}^{-1} = s_{\mathrm{fix}} J_W^2 s_{\mathrm{fix}}^{-1} = -I.$$

□

The result is proved with the chart s_{fix}, the basis, the polarization, and the orientation as explicit starting structure. It does not identify C_M with J_W: the former is an involution of the word space, and the latter a quadratic structure on its fixed stratum. Nor does it prove that the transport is natural with respect to the entire TPK dynamics.

Let us suppose

$$W_{27} := \mathrm{Fix}(C_M) \cap \mathrm{Per}_6 .$$

The inclusion

$$W_{27} \hookrightarrow \mathrm{Fix}(C_M)$$

is canonical, and proposition 92.36 proves that $\dim_{\mathbb{F}_3} W_{27} = 3$.

Corollary 92.40 (Quadratic obstruction in the twenty-seven stratum)**.** *The subspace W_{27} cannot be stable under $\widetilde{J}_M$.*

Proof. If it were stable, the relation $\widetilde{J}_M^2 = -I$ would turn it into a module over

$$\mathbb{F}_3[X]/(X^2 + 1) \cong \mathbb{F}_9.$$

Every vector space over $\mathbb{F}_9$ has even dimension when considered over $\mathbb{F}_3$, in contradiction with $\dim_{\mathbb{F}_3} W_{27} = 3$. □

The cardinal equality between W_{27} and the twenty-seven lines of Schläfli does not furnish a map between the two objects. Such a relation would require the construction of an incidence map preserving the central orientation and the action of the stabilizer, together with a compatible dynamical closure. The atlas of 81 cells is not interposed between W_{27} and the fixed stratum of 729 states: the particle atlas belongs to another domain.

92.10.3 Mathematical stratification of the Majorana object in 4 levels

The inversion C_M, exterior parity, a relativistic Majorana fermion, and a Majorana zero mode are objects of different types:

1. $C_M = -\mathrm{rev}$ acts on $\mathscr{T}_{12}^{\mathrm{word}}$. Its involutivity and its census are proved exactly; this construction does not, by itself, provide a spinor, a field equation, or a mass term.
2. The sign character $q = -1$ and the exterior completion belong to the exchange algebra. Relative to CAR and the declared grading, they produce $N_s^2 = N_s$, spectrum $\{0, 1\}$, and the orientation return $2\pi/4\pi$. These identities follow from CAR and the grading; they do not follow from the mere census of C_M.
3. A relativistic Majorana fermion is a spinorial object endowed with a relativistic representation, compatible charge conjugation, a self-conjugacy condition, a mass term, and dynamics. Those data are not part of the definition of C_M and do not follow from its census.

4. A Majorana zero mode, or equivalently the nonabelian sector of an Ising theory in the topological sense, requires simple objects $\mathbf{1}, \psi, \sigma$ with

$$\psi \otimes \psi \simeq \mathbf{1}, \qquad \psi \otimes \sigma \simeq \sigma, \qquad \sigma \otimes \sigma \simeq \mathbf{1} \oplus \psi, \qquad d_\sigma = \sqrt{2},$$

together with coherent associator and braiding. The gap, the splitting, and the platform belong to an additional physical realization; the preceding fusion rules do not define a universal pole mass.

The separation concerns domains rather than nomenclature: word involution, CAR parity, self-conjugate spinor, and nonabelian simple object are four distinct mathematical objects. In the absence of an explicit morphism among them, none is identified merely because it shares the name "Majorana.".

92.11 Incidence, Fibonacci and topological sectors

The residue–support incidence prolongs the atlas toward fusion and braid structures. The order is essential: first the based Fibonacci ring and its dimensions are constructed; the algebraic representations of braids and the pointed center are then studied. Each object preserves its own domain and is not identified with a physical particle merely because it shares a name or cardinal.

92.11.1 Residue-incident support

We fix the residue classes and the supports in the order

$$C_1 = \{1,4,7\}, \qquad C_2 = \{2,5,8\}, \qquad C_0 = \{3,6,9\},$$
$$\mathcal{D}_{\mathrm{act}} = \{1,3,5,7\}, \quad \mathcal{D}_{\mathrm{evt}} = \{2,4,6,8\}, \quad \mathcal{D}_{\bar{0}}^{(9)} = \{9\}.$$

The final symbol means 'support of the null nonadic residue'. It does not designate the complete domain $D_9 = \{1, \dots, 9\}$ or a physical zero-mass sector.

Let $E_{\mathcal{D}} \cong \mathbb{Z}^3$ and $E_C \cong \mathbb{Z}^3$ be the free modules with ordered bases

$$(\mathcal{D}_{\mathrm{act}}, \mathcal{D}_{\mathrm{evt}}, \mathcal{D}_{\bar{0}}^{(9)}) \quad \text{and} \quad (C_1, C_2, C_0),$$

respectively. The incidence map $B_{\mathrm{res,sup}} : E_{\mathcal{D}} \to E_C$ counts intersections.

Theorem 92.41 (Smith form and image of incidence)**.** *In the preceding bases,*

$$B_{\mathrm{res,sup}} = \big(|C_i \cap \mathcal{D}_j|\big)_{i,j} = \begin{pmatrix} 2 & 1 & 0 \\ 1 & 2 & 0 \\ 1 & 1 & 1 \end{pmatrix}.$$

Moreover,

$$\det B_{\mathrm{res,sup}} = 3, \qquad \mathrm{SNF}(B_{\mathrm{res,sup}}) = \mathrm{diag}(1,1,3),$$
$$\mathrm{im}\, B_{\mathrm{res,sup}} = \{(u,v,w) \in \mathbb{Z}^3 : u + v \equiv 0 \pmod 3\}.$$

If

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

the simultaneous exchange $C_1 \leftrightarrow C_2$ and $\mathcal{D}_{\mathrm{act}} \leftrightarrow \mathcal{D}_{\mathrm{evt}}$ is equivariant:

$$P B_{\mathrm{res,sup}} P = B_{\mathrm{res,sup}} \qquad \Longleftrightarrow \qquad P B_{\mathrm{res,sup}} = B_{\mathrm{res,sup}} P.$$

Proof. The nine entries follow from the intersections.

$$\begin{array}{lccc} & \mathcal{D}_{\mathrm{act}} & \mathcal{D}_{\mathrm{evt}} & \mathcal{D}_{\hat{0}}^{(9)} \\ C_1 & \{1,7\} & \{4\} & \varnothing \\ C_2 & \{5\} & \{2,8\} & \varnothing \\ C_0 & \{3\} & \{6\} & \{9\}. \end{array}$$

The expansion by the third column gives

$$\det B_{\mathrm{res,sup}} = \det \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} = 3.$$

The greatest common divisor of the entries is one. The smallest second-order minor formed by the first and third rows and the second and third columns has determinant one:

$$\det \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = 1.$$

By the Smith divisors, $d_1 = d_2 = 1$. The product $d_1 d_2 d_3$ agrees with the absolute value of the determinant, which the preceding calculation fixes at three. Consequently,

$$d_1 d_2 d_3 = 3.$$

The normal form is therefore $\mathrm{diag}(1, 1, 3)$.

Each column satisfies $u + v \equiv 0 \pmod 3$, so the image is contained in the indicated submodule. Conversely, if $u + v \equiv 0 \pmod 3$, then

$$x = \frac{2u - v}{3}, \qquad y = \frac{2v - u}{3}, \qquad z = w - x - y$$

are integers and

$$B_{\mathrm{res,sup}}(x, y, z)^{\mathsf{T}} = (u, v, w)^{\mathsf{T}}.$$

This proves equality of images. Finally, explicit multiplication by P exchanges the first two rows and the first two columns and leaves the matrix invariant. □

Comparison Criterion 92.42 (Incidence control)**.** The theorem would be falsified by a single miscounted intersection, a minor that altered the Smith divisors, a vector of the image with $u+v \not\equiv 0 \pmod 3$, a vector satisfying the congruence but admitting no exhibited preimage, or the loss of equivariance $PBP = B$.

92.11.2 Based ring associated with the incidence F_{av}

The theorem 6.20 proves, from the orbit of modes (Σ, Π, Π), the matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

From this matrix the following based ring is obtained.

Definition 92.43 (Fibonacci-based Ring)**.** Let

$$K_{\mathrm{Fib}} := \mathbb{Z}\mathbf{1} \oplus \mathbb{Z}\tau$$

the free abelian group with unit $\mathbf{1}$ and bilinear product fixed by

$$\tau \cdot \mathbf{1} = \tau, \qquad \tau \cdot \tau = \mathbf{1} + \tau.$$

In this stratum, + and · are the addition and multiplication of the ring. The categorical symbols ⊕ and ⊗ are reserved for a categorification chosen subsequently.

Theorem 92.44 (Realization of F_{av} and Perron dimension)**.** *In the ordered basis* $(\mathbf{1}, \tau)$*, multiplication by* τ *in* K_{Fib} *has matrix* F_{av}*. If* $F_0 = 0$*,* $F_1 = 1$*, and* $F_{n+1} = F_n + F_{n-1}$ *for* $n \geq 1$*, then*

$$\tau^n = F_{n-1}\mathbf{1} + F_n\tau \qquad (n \geq 1).$$

The unique homomorfismo positivo of dimension that envia $\mathbf{1}$ *to one satisfies*

$$\mathrm{FPdim}(\tau) = \varphi.$$

Identification of the two typed sheets with the basis $(\mathbf{1}, \tau)$ *completely determines this ring and its positive dimension.*

Proof. The columns of the matrix of multiplication by τ are the coordinates of

$$\tau \cdot \mathbf{1} = \tau \quad \text{and} \quad \tau \cdot \tau = \mathbf{1} + \tau;$$

they are therefore $(0, 1)^{\mathsf{T}}$ and $(1, 1)^{\mathsf{T}}$, respectively. Thus one obtains F_{av}.

The power formula holds for $n = 1$. If it holds for n, then

$$\tau^{n+1} = F_{n-1}\tau + F_n(\mathbf{1} + \tau) = F_n\mathbf{1} + F_{n+1}\tau,$$

which closes the induction. Finally, a positive multiplicative dimension $d = \mathrm{FPdim}(\tau)$ obeys

$$d^2 = 1 + d.$$

Its roots are φ and $-\varphi^{-1}$; positivity selects $d = \varphi$. □

The designation *Fibonacci* is thus explained by the fusion rule itself: upon iterating τ, the two possible channels appear with consecutive multiplicities F_{n-1} and F_n. The space of fusion states therefore grows with asymptotic ratio φ. This is the combinatorial basis of its computational use: information is encoded in global fusion channels and not in a mass assigned to a point.

Comparison Criterion 92.45 (Conditions for a Fibonacci categorification)**.** The annular layer would be refuted if the multiplication matrix were not F_{av}, if the power recurrence failed, or if the positive dimension were not φ. A braided categorification whose Grothendieck ring is that of definition 92.43 additionally requires a monoidal functor

$$\mathfrak{C}_{\mathrm{Fib}} : \mathsf{TPK} \dashrightarrow C_{\mathrm{Fib}},$$

the verification of the pentagon and hexagon in its image and an internal rule that selects gauge and chirality. These conditions are not consequences of the annular identity by itself.

92.11.3 Classification of 6-character by 4 braid torsion classes

Let B_n, $n \geq 2$, be the Artin braid group with generators $\sigma_1, \ldots, \sigma_{n-1}$ and relations

$$\sigma_i\sigma_{i+1}\sigma_i = \sigma_{i+1}\sigma_i\sigma_{i+1}, \qquad \sigma_i\sigma_j = \sigma_j\sigma_i \quad (|i - j| \geq 2),$$

and let $w : B_n \to \mathbb{Z}$ be the sum of the exponents. The readers

$$w_2 := w \bmod 2, \qquad w_3 := w \bmod 3$$

are brought together, by the Chinese remainder theorem, in

$$w_6 : B_n \longrightarrow \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \simeq \mathbb{Z}/6\mathbb{Z}.$$

Theorem 92.46 (Abelianization, six characters and permutation torsions)**.** *For $n \geq 2$,*

$$B_n^{\mathrm{ab}} \simeq \mathbb{Z},$$

through w. Consequently, w_6 produces six unitary characters

$$\chi_k(b) := \exp\left(\frac{2\pi \mathrm{i} k}{6} w(b)\right), \qquad k \in \mathbb{Z}/6\mathbb{Z}.$$

Let $V \neq 0$ be a Hilbert space, let $P_i : V^{\otimes n} \to V^{\otimes n}$ be the exchange of the factors $i, i+1$, and let $q \in \mu_6$. The rule

$$\rho_q(\sigma_i) := qP_i, \qquad \rho_q(b) = q^{w(b)} \pi_n(b),$$

where π_n is the permutation representation, defines a representation of B_n. This representation descends to the symmetric group if and only if

$$q^2 = 1.$$

For the four values $q \in \mu_6 \setminus \{\pm 1\}$,

$$\mathrm{Inv}(\rho_q) = 0.$$

Those four values define genuinely braided scalar torsions, but do not by themselves constitute four Fock spaces nor four physical anyonic sectors.

Proof. In every abelian quotient, the braid relation gives

$$2[\sigma_i] + [\sigma_{i+1}] = [\sigma_i] + 2[\sigma_{i+1}],$$

and thus all generators have the same class. No other relation remains on that class, since $w(\sigma_i) = 1$; hence the abelianization is $\mathbb{Z}$.

The operators P_i satisfy the braid relations and $P_i^2 = I$. Multiplying each generator by the same scalar q preserves both relations, so ρ_q is a representation. To factor through S_n, it must satisfy the additional relation $\sigma_i^2 = 1$, and

$$\rho_q(\sigma_i)^2 = q^2 I.$$

This proves criterion $q^2 = 1$.

If v were invariant, then $qP_i v = v$, that is, $P_i v = q^{-1} v$, for every i. Since each involution P_i has only eigenvalues ± 1, no such nonzero vector exists when $q \neq \pm 1$. Consequently, $\mathrm{Inv}(\rho_q) = 0$ for the remaining four values. □

When $\dim V > 1$ and $n \geq 3$, the operators P_1 and P_2 do not commute; hence the full representation does not become Abelian merely because it arises from a scalar character. The character χ_k and the representation ρ_q are distinct objects: the former is one-dimensional; the latter retains the permutation action.

92.11.4 Modular center pointed and Fibonacci realization conditions Ising

Let

$$A = (\mathbb{Z}/9\mathbb{Z})^2$$

and let Vec_A be the category of A-graded vector spaces with trivial associator. Fixing a nondegenerate bicharacter identifies $\widehat{A}$ with A, but does not alter the following counts.

Theorem 92.47 (Pointed center and dimensional obstruction)**.** *The Drinfeld center*

$$\mathcal{Z}(\mathrm{Vec}_A)$$

is a pointed modular category whose simple objects are parameterized by $(a, \chi) \in A \times \widehat{A}$. It therefore has

$$|A|\,|\widehat{A}| = 81^2 = 6561$$

simple, all of quantum dimension one, and total quantum dimension

$$\mathcal{D} = \sqrt{\sum_{x \text{ simple}} d_x^2} = \sqrt{6561} = 81.$$

In this category, neither the Fibonacci ring nor the Ising sector can be realized while preserving simple objects and Frobenius–Perron dimensions: they require, respectively, a simple object of dimension φ and one of dimension $\sqrt{2}$.

Proof. For a finite abelian group and trivial associator, every simple object of the center is determined by a degree $a \in A$ and a character $\chi \in \widehat{A}$ that specifies its half-braiding. Both the graded object and the character are one-dimensional; consequently, all the simple objects are invertible and have quantum dimension one. Since $|A| = |\widehat{A}| = 9^2 = 81$, the number of pairs is 81^2, and the formula of $\mathcal{D}$ gives 81.

Every fusion subcategory of a pointed category is again pointed; in particular, its simple objects have dimension one. This contradicts $\mathrm{FPdim}(\tau) = \varphi$ for Fibonacci and $d_\sigma = \sqrt{2}$ for Ising. The obstruction is dimensional and does not depend on a similarity of names or cardinalities. □

Comparison Criterion 92.48 (Conditions for a physical realization of the sectors)**.** The results of theorems 92.46 y 92.47 would be algebraically falsified by failure of the Artin relations, the criterion $q^2 = 1$, the census 6561, pointedness, or $\mathcal{D} = 81$. A physical realization additionally requires a Hamiltonian or driven protocol, a spectral gap, realizable braid operators, protection against perturbations, and a map from the enriched multisections. None of these data follows solely from the two preceding algebraic theorems.

92.11.4.1 Composite object as a persistent section of a cocyclic product of paths

A composite particle is a section of the fiber product of constituent biographies with a binding boundary. The genealogical records are composed before the signature extractor is applied. If Γ and Λ are linked through the boundary B and the action g,

$$(n, e)_\Gamma \star_{(g,B)} (n, e)_\Lambda = (n_\Gamma + n_\Lambda - n_B, e_\Gamma + g e_\Lambda - e_B).$$

The composite signature is

$$\mathrm{Sig}_{\mathrm{comp}} = L_{\mathrm{tick}} \circ \mathfrak{C}_{12}.$$

It does not in general coincide with the sum of the individual signatures, because the genealogical record of linkage carries energy, carry, and memory. This is the residence of binding energy.

92.11.4.2 Resonance as a transient section and width as a decay rate

A resonance is a metastable section whose resolvent has a complex energy pole. If $z_X = M_X c_{\text{int}}^2 - i\Gamma_X/2$, the mass is $M_X = c_{\text{int}}^{-2} \operatorname{Re} z_X$; the width measures its mean lifetime:

$$\Gamma_X = \frac{\hbar_{\text{int}}}{\tau_X^{\text{life}}}.$$

The width is not a sixth coordinate of σ. It proceeds from the survival operator, from the decay channels, and from the analytic continuation of the resolvent. The inventory of 384 widths therefore requires its own reader, separate from the inventory of 471 masses.

92.11.4.3 Virtual section as an intermediate non-asymptotic extension of the atlas

A virtual section is a finite extension that participates in a composition or propagator but does not define a stable global branch in the physical codomain. If $L(s)$ is its horizon,

$$L(s) < \infty, \qquad \operatorname{Ext}_{L(s)}(s) \neq \varnothing, \qquad \operatorname{Ext}_{L(s)+1}(s) = \varnothing.$$

Virtuality is a terminal obstruction, not a documentary label or an imaginary mass. A resonance may be unstable without being virtual in this sense; an internal line may be virtual without constituting a new species.

92.11.4.4 Majorana Section as a Fixed Point of Particle–Antiparticle Conjugation

Four constructions must be kept separate. The word involution C_M defines the antisection; a Majorana spinor satisfies a reality condition; a Majorana zero mode is a localized zero-energy excitation in a topological Hamiltonian; the Ising sector possesses fusion rules

$$\sigma \otimes \sigma = 1 \oplus \psi.$$

A physical particle is Majorana when its fermionic representation admits a self-conjugation compatible with the Hamiltonian, localization, and inner product. Electrical neutrality and invariance of a word under C_M are not sufficient. In particular, deciding the Majorana nature of neutrinos requires an intertwiner among the neutral operator, the mass basis, and the fermionic real structure.

92.11.4.5 Anyonic sector and nontrivial representation of the braid group

A anyon is a section bidimensional whose representation of the grupo of trenzas does not reduces to the permutation bosonic or fermionic. In the sector Fibonacci,

$$\tau \otimes \tau = 1 \oplus \tau, \qquad \operatorname{FPdim}(\tau) = \varphi.$$

In the abelian sector $\mathbb{Z}/6\mathbb{Z}$, the winding quotient has six one-dimensional characters. Obtaining a physical particle requires F and R matrices, the pentagon and hexagon equations, a gapped Hamiltonian, and braiding operators. The exact fusion ring determines the topological codomain, but does not by itself fix a universal mass.

92.11.4.6 Tachyonic and ghost classes as obstructions to positivity and stability

A persistent particle has unitary evolution, energy bounded below, and real spectral mass on the physical line. A tachyon would require a pole with $m^2 < 0$ that remained as a stable asymptotic state. In the HMT–MD architecture, a direction leaving the cone of positive realizations either returns to the null boundary, loses survival, or manifests as an instability of a background that must condense. It does not define a persistent superluminal section. The impossibility is formulated as incompatibility among global persistence, spectral positivity, and $m^2 < 0$, not as a prohibition of transient tachyonic parameters in a perturbative expansion.

A ghost is a negative-norm mode. Positivity of the inner product and unitary conservation exclude its physical realization. Faddeev–Popov ghosts belong to the gauge complex and not to the physical state space; this distinction must be preserved.

92.11.5 Composition, resonances and widths

92.11.5.1 Non-Additive Mass Composition via the Cocylic Link Law

The General Mass Law acts on genealogical biographies. When several constituents form a bound state, the input object is not a list of their isolated masses, but a composite record that preserves the coupling order, common boundary, carry, orientation, and memory. Let

$$\Gamma_1, \dots, \Gamma_n$$

constituent routes, $\mathcal{T}$ a temporal composition tree, and ∂ the linking boundary. The dodecaphase composition operator is written

$$\mathfrak{C}_{12}^{(n)} : (\Gamma_1, \dots, \Gamma_n; \mathcal{T}, \partial) \longmapsto \mathcal{L}_{\mathrm{comp}}.$$

Only after these are applied are the register reader, the signature extractor, the character, and the towers:

$$\mathcal{L}_{\mathrm{comp}} \longmapsto \sigma_{\mathrm{comp}} \longmapsto \chi_{\mathrm{comp}} \longmapsto \widehat{M}_{\mathrm{comp}}.$$

This precedence is essential. If the isolated masses were evaluated first and then added, precisely the data that distinguish a bound state from a threshold of free constituents would disappear. Binding energy is not a term appended at the end: it is the dimensional image of a record difference produced by the linkage.

92.11.5.2 Cocyclic Link Law

For two records L_1, L_2, the composition has the form

$$L_1 \star L_2 = L_1 + L_2 + \mathfrak{b}(L_1, L_2),$$

where $\mathfrak{b}$ records shared boundary, carry, and memory. Independence with respect to parenthesization requires the cocyclic identity

$$\mathfrak{b}(L_1, L_2) + \mathfrak{b}(L_1 \star L_2, L_3) = \mathfrak{b}(L_2, L_3) + \mathfrak{b}(L_1, L_2 \star L_3).$$

If this equality fails, the two ways of constructing the same ternary tree produce distinct genealogical records, and no well-defined composite species exists. If it holds, the cocycle does not disappear: it ensures that its contribution is a property of the state rather than an artifact of notation.

A more explicit presentation also preserves the boundary action. Let $e \in \mathbb{Z}^{12}$ be the ordered vector of events and let n be the action or event counter of a ledger. If $(n, e)_\Gamma$ and $(n, e)_\Lambda$ are ledgers, if B is the common subledger with data (n_B, e_B), and if $g \in \mathrm{Aut}(\mathbb{Z}^{12})$ transports the orientation of the second ledger to that of the first while preserving the reader,

$$(n, e)_\Gamma \star_{(g,B)} (n, e)_\Lambda = (n_\Gamma + n_\Lambda - n_B, e_\Gamma + g e_\Lambda - e_B).$$

The term B prevents counting the identified boundary twice; the action g transports the second record to the orientation of the first. The composite signature is therefore,

$$\mathrm{Sig}_{\mathrm{comp}} = L_{\mathrm{tick}}\Big(\mathfrak{C}_{12}^{(n)}(\Gamma_1, \dots, \Gamma_n; \mathcal{T}, \partial)\Big),$$

and not the automatic sum of elementary signatures.

92.11.5.3 Cocyclic Closure of the Mesonic Quark–Antiquark Composition

An oriented mesonic expression has the form

$$M(q, q') = q \otimes (q')^{\vee}.$$

The raw domain contains $6 \times 6 \times 3 \times 4 = 432$ expressions when flavour, compatible colour, and orientation are considered. This cardinality is not the number of physical mesons. Before a species is individualized, the following are applied:

1. the color-singlet projector;
2. the charge and isospin projector;
3. the spin and parity representation;
4. the temporal linkage tree;
5. the radial or orbital condition;
6. the preparation and decay channel when the state is resonant.

The complete physical descriptor is

$$\mathcal{I}_M = (q\bar{q}', J^{PC}, I, I_3, S, C, B, \mathcal{T}, \partial, \Gamma_M, \mathcal{L}_M, \sigma_M, \eta_M).$$

Two states with the same flavors may differ in J^{PC}, radial excitation, orbital momentum, sheet, or channel, and therefore have distinct poles. The mass is not derived from the mere name of the constituents.

The evaluations published for $\pi^0, \pi^{\pm}, K^{\pm}, K^0$ are exact once the declared historical registers have been fixed. The stronger assertion —the prospective generation of each nominal register from its linkage tree— requires $\mathfrak{C}_{12}$ to reconstruct those registers without consulting the value to be compared. Both layers are preserved together: the conditioned calculation is not erased, nor is it presented as a selector of identity.

92.11.5.4 Trilinear Closure of the Baryonic Composition and Neutralization of the Color Character

An oriented baryonic expression uses three constituents and three colors. The raw domain of the adopted census contains

$$|\mathcal{B}_{\mathrm{RGB}}^{\mathrm{raw}}| = 1728$$

expressions. The physical projection must impose simultaneously:

$$P_{\text{singlete de color}}, \qquad P_{J^P}, \qquad P_{I,I_3,S,C,B}, \qquad P_{\text{Pauli}}.$$

The triple tree preserves which pair was coupled first and how the third constituent crossed the boundary. The cocycle identity guarantees that equivalent parenthesizations represent the same state when the physical intertwiner identifies them; inequivalent channels remain distinct states.

The historical signatures

$$\sigma_p = (59, 0, 9, 1, 0), \qquad \sigma_n = (59, 1, -34, 0, 1)$$

produce the published proton and neutron evaluations when the complete character is applied. They are exact controls of the reader for those ledgers. A physical explanation of the neutron–proton difference additionally requires deriving, before comparison, the sign of isospin, vacancy orientation, the link boundary, and the electromagnetic contribution in a common chart.

92.11.5.5 Exotic composite realizations and stability conditions of the bond

The same grammar admits more constituents without modifying the law:

$$\mathfrak{C}_{12}^{(n)} : \prod_{j=1}^{n} \Gamma_j \times \mathcal{T}_n \times \partial_n \longrightarrow \mathcal{L}_{\text{comp}}.$$

A tetraquark corresponds to $qq\bar{q}\bar{q}$; a pentaquark, to $qqqq\bar{q}$; a glueball, to routes of the adjoint color representation projected onto the singlet; a hybrid, to fermionic and gauge routes brought together in the same tree. The list of constituents does not by itself determine the species. A complete physical classification must include color, spin, parity, conjugation, isospin, tree topology, and the pole of the coupled operator.

This formulation also discriminates between two rival descriptions of the same candidate —a hadronic molecule and a compact state, for example—: they are two trees or two projectors on the same constituent sector. They become equivalent only if there exists a unitary operator that intertwines their operators, channels, and poles.

92.11.5.6 Steady state, bound state and resonance

It is convenient to separate three notions.

A stable state is a normalizable eigenvector of the physical Hamiltonian, with real energy and no open decay channel. A bound state is an eigenvector below the relevant threshold; it may be stable or may decay through another channel. A resonance is a pole of the continuation of the resolvent or of the scattering matrix. It is not a normalizable eigenvector of the self-adjoint Hamiltonian on the real axis.

For an energy pole

$$z_X = E_X - \frac{i}{2}\Gamma_X = M_X c_{\text{int}}^2 - \frac{i}{2}\Gamma_X, \qquad \Gamma_X > 0,$$

the pole energy is $E_X = \operatorname{Re} z_X$, the pole mass is $M_X = c_{\text{int}}^{-2} \operatorname{Re} z_X$, and the energy width is $\Gamma_X = -2 \operatorname{Im} z_X$. The General Mass Law supplies the real branch conditioned by the identity and the register; continuation through open channels determines the complex displacement and the width. In a natural-unit chart $c_{\text{int}} = 1$, the numerical coordinates of energy and mass coincide, but their types are not identified before that chart is chosen.

92.11.5.7 Correction of the sign in the discrete reading of the pole

Let $t_0 > 0$ be a time step, and suppose that the one-step mode has eigenvalue

$$\lambda = re^{-i\theta}, \qquad 0 < r < 1,$$

with the convention

$$\lambda = \exp\left(-\frac{i}{\hbar_{\text{int}}} z t_0\right).$$

Then

$$z = \frac{\hbar_{\text{int}}}{t_0}\left(\theta + i \log r\right) = E - \frac{i}{2}\Gamma = M c_{\text{int}}^2 - \frac{i}{2}\Gamma,$$

so that

$$E = \frac{\hbar_{\text{int}}}{t_0}\theta, \qquad M = \frac{\hbar_{\text{int}}}{t_0 c_{\text{int}}^2}\theta, \qquad \Gamma = -\frac{2\hbar_{\text{int}}}{t_0} \log r > 0.$$

The positive sign before $i \log r$ is compulsory: since $\log r < 0$, the imaginary part of z is negative. The form $\theta - i \log r$ would place the pole in the upper half-plane and would describe growth, not decay.

The survival probability after N steps is

$$|\lambda|^{2N} = r^{2N} = \exp\left(-\frac{\Gamma}{\hbar_{\text{int}}} N t_0\right).$$

Therefore, the associated lifetime is

$$\tau_X^{\text{life}} = \frac{\hbar_{\text{int}}}{\Gamma_X}.$$

This identity further proves why the width must not be introduced as a sixth coordinate of the signature $\mathbb{Z}^5$: it arises from the modulus of the open mode, not from the positive character that organizes mass.

92.11.5.8 Effective Channel Operator

Let P be the prepared subspace and $Q = I - P$ the set of eliminated channels. The complement is incorporated by means of the Feshbach operator

$$H_{\text{eff}}(z) = PHP + PHQ(z - QHQ)^{-1}QHP.$$

The poles satisfy

$$\det\big(z - H_{\text{eff}}(z)\big) = 0.$$

The first term preserves the prepared internal operator. The second is the self-energy of the channels: it shifts the real part and produces an imaginary part when the continuum opens. The character mass and the survival width converge at the same pole, but they follow from distinct maps.

An equivalent formulation uses a distinct survival projector from the Feshbach complement. Let

$$S_X = S_X^* = S_X^2$$

the projector onto the surviving subspace of the prepared state. The compressed one-step operator is

$$T_X = S_X U S_X.$$

Suppose that T_X has a simple dominant eigenvalue λ_X, that the prepared state has nonzero overlap with its spectral subspace, and that the remainder of the spectrum is separated in modulus. If $r_X = |\lambda_X| = \rho(T_X) < 1$, then

$$\Gamma_X = -\frac{2\hbar_{\text{int}}}{t_0} \log r_X.$$

If the operator is normalized from the beginning on probabilities instead of amplitudes, the factor two disappears. The publication must declare which of the two conventions it uses; mixing them produces an erroneous width by a factor of two.

92.11.5.9 Conjugation of particle and antiparticle

Let C_M be the involution that reverses orientation and sheet, and let U_C be its unitary realization on physical space. Equality of pole masses and widths requires covariance of both the operator and the channels:

$$U_C H_{\text{eff}}^X(z) U_C^{-1} = H_{\text{eff}}^{\bar{X}}(z).$$

Then the sets of retarded poles coincide after transporting the sector and the causal prescription, and

$$M_{\bar{X}} = M_X, \qquad \Gamma_{\bar{X}} = \Gamma_X.$$

Bare unitary equivalence does not turn the retarded pole into its complex conjugate; it transports the same spectral problem to the antiparticle sector. Parity of the mass signature is insufficient to prove the second equality: the channels and their measures must also be covariant. If the symmetry is represented antiunitarily, the retarded prescription must also be transported; bare conjugation $z \mapsto \bar{z}$ exchanges retarded and advanced poles and is not, by itself, the physical assertion of equality of lifetimes.

92.11.5.10 Typed inventory of realizations and contrast observables

The preserved external cut contains

$$471 \text{ mass observables}, \qquad 384 \text{ width observables}.$$

The mass partition is

Physical arrival domain	Masses	Widths
partículas elementales, leptónicas y extensiones	53	9
quarks y extensiones quark	8	1
mesones	243	225
bariones	166	149
registro gravitatorio de contraste	1	0
Total	**471**	**384**

Estas filas son observables, no especies elementales. Varias filas pueden referirse a diferentes cargas de un mismo multiplete, estimadores de una misma resonancia, masas Breit–Wigner, masas de polo o estados excitados. La individualización interna precede siempre a la fila externa.

El inventario conserva además una propiedad metodológica fuerte: ninguna de sus 855 magnitudes fue autorizada como selector de ruta. Los 471 registros de masa y los 384 de anchura sólo se abren después de congelar la identidad HMT, el proyector, el operador y la carta de comparación.

92.11.5.11 Normalization of Nominal Identities in Comparable Registers

The complete prospective splice has the form

$$\begin{aligned} \text{physical identity} &\longrightarrow \text{sector and representation} \longrightarrow \text{fibre or composite-tree projector} \\ &\longrightarrow \text{enriched route} \longrightarrow \text{genealogical record} \longrightarrow \text{signature and towers} \\ &\longrightarrow \text{prepared operator} \longrightarrow \text{pole or eigenvalue} \longrightarrow \text{dimensional chart} \\ &\longrightarrow \text{external comparison}. \end{aligned}$$

For a stable state, the operator output is a real eigenvalue. For a resonance, it is a complex pole. For a quark, the map includes a scheme and a scale. For an experimental limit, it includes the confidence level. For a correlated observable, it includes the covariance matrix. These differences are structural: they determine which quantities may be compared.

92.11.5.12 Individual closure conditions of material realizations

A row of the inventory is individualized from HMT–MD once the following have been constructed, without consulting its external magnitude:

1. the sector and the representation;
2. the route, multisection, or composition tree;

3. the genealogical record and the signature;
4. the operator of masa and, if proceeds, the operator of channels;
5. the projector selecting the named state;
6. the convention of mass, width, scheme, and scale;
7. the dimensional chart;
8. the internal falsification criterion.

The universal law already provides the common grammar. Working state by state does not consist in inventing a different formula, but in constructing the intertwiner that transports a physical identity to the appropriate operator.

92.11.5.13 Specific Obstructions and Non-Degeneracy Conditions

The composition is refuted if two physically equivalent parenthesizations yield different signatures or spectra. The nominal selector is refuted if it changes when the external mass column is hidden. The width reader is refuted if it produces $\Gamma < 0$ for a contraction, confuses amplitude with probability, or assigns a width to a stable section without an open channel. The resonance chart is refuted if it does not specify pole or Breit–Wigner mass. The quark comparison is indeterminate if it omits a scheme or scale. Particle–antiparticle equality of widths is refuted if the channel operator is not covariant under conjugation.

92.11.5.14 Transport of material classes to the exceptional corridor via routes, signatures, and representations

The grammar of composition, the mesonic and baryonic domains, the Feshbach operator, the 471/384 census, and the comparison principle are retained in the preceding integral development, Sections 16 and 18. The individualized records are presented in full in the exhaustive inventories of masses and widths in the appendix. The correction of the pole sign follows directly from $\lambda = \exp(-izt_0/\hbar_{\mathrm{int}})$ and strengthens the formulation without altering any of those records.

92.11.6 Topological sectors, hypothetical extensions and gravity

92.11.6.1 Typed separation between topological sectors, hypothetical extensions and gravitational realization

The architecture distinguishes with precision:

1. an internal algebraic identity;
2. a fusion or braiding codomain;
3. a physical particle with a Hamiltonian, gap, localization, and measurement channel.

An exact fusion rule is not yet a mass. A boundary mode is not yet a species. A route involution is not yet a Majorana condition. The physical passage requires a functor that preserves product, involution, orientation, energy, and path composition.

92.11.6.2 Fibonacci Sector: ring-based, fusion and braid representation

The areal–volumetric incidence is governed by

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

Its characteristic polynomial is

$$x^2 - x - 1,$$

and its dominant eigenvalue is φ. In the basis $\{\mathbf{1}, \tau\}$, multiplication by τ is represented by F_{av}; therefore

$$\tau \otimes \tau \cong \mathbf{1} \oplus \tau, \qquad \mathrm{FPdim}(\tau) = \varphi.$$

This is an exact realization of the Fibonacci based ring. To obtain a physical anyonic category, one must also construct the associator F, the braiding R, the pentagon and hexagon equations, chirality, a gapped local Hamiltonian, and the preparation-and-readout map. The mass output, when it exists, is an energy gap converted by an effective velocity:

$$m_{\mathrm{brecha}} = \frac{\Delta E}{c_{\mathrm{eff}}^2}.$$

There is no universal Fibonacci-anyon mass deducible solely from φ.

92.11.6.3 Separation between the topological sector and the pointed center of the atlas

The braided center of the pointed sector based on $\mathbb{Z}/9\mathbb{Z}$ has 81 invertible simple objects, each of quantum dimension one. A Fibonacci simple object would require dimension φ, and an Ising simple object would require $\sqrt{2}$. Therefore, neither appears as an internal simple object of that pointed center.

This control does not eliminate the topological realizations. It determines their proper place: they must be obtained by extension, condensation, quotient, defect, or a monoidal functor into a nonpointed codomain. Presenting the Fibonacci ring as though it were already the entire category would erase precisely the physical morphism that must be constructed.

92.11.6.4 Ising Sector and Majorana Modes

The Ising category has simple objects.

$$\mathbf{1}, \quad \psi, \quad \sigma$$

and rules

$$\psi \otimes \psi = \mathbf{1}, \qquad \psi \otimes \sigma = \sigma, \qquad \sigma \otimes \sigma = \mathbf{1} \oplus \psi, \qquad d_\sigma = \sqrt{2}.$$

Four distinct objects often receive similar names and must be kept separate:

- the route involution $C_M = -\,\mathrm{rev}$;
- the parity of the CAR completion;
- a self-conjugate relativistic spinor;
- a topological Majorana zero mode in an Ising phase.

A relativistic fermion is Majorana when there exists a real conjugation C compatible with its representation and dynamics,

$$\psi = C\bar{\psi}^T,$$

and the mass term respects that condition. A Majorana zero mode is described by a self-adjoint operator $\gamma = \gamma^\dagger$ satisfying

$$\{\gamma_i, \gamma_j\} = 2\delta_{ij}$$

and remains separated from the continuum by a gap. Equality of a word with its image under C_M proves neither of these two realizations.

For neutrinos, the Dirac/Majorana alternative can be decided only after constructing the neutral operator, its mass basis, the mixing intertwiner, and the real fermionic structure. Electrical neutrality is necessary, but not sufficient, for nontrivial self-conjugacy.

92.11.6.5 Abelian braiding of order 6

Let

$$\mathrm{wind}_6 : B_n \longrightarrow \mathbb{Z}/6\mathbb{Z}$$

the reader of winding and

$$\chi_k(b) = \exp\!\left(\frac{2\pi i k}{6}\,\mathrm{wind}_6(b)\right).$$

Realizations with phase q descend to mere permutations only when

$$q^2 = 1.$$

The remaining four characters distinguish algebraic classes of the winding reader. The exact result is the classification of the six one-dimensional characters of the winding quotient; it is not yet a classification of six material phases. To assert that they preserve physical braiding requires braid operators and a representation of the braid group. Their existence does not imply four new particles: an anyonic species requires a Hamiltonian, braid operators, a gap, stability, and a coupling to a physical multisection. Their promotion to material phases depends upon that realization.

92.11.6.6 Positivity and exclusion of the persistent tachyon

The action line possesses positive orientation,

$$\hbar_{\mathrm{int}} > 0,$$

the mass character takes positive values,

$$\chi_{\mathrm{full}}(\sigma, \eta) > 0,$$

and the bidirectional refinement is implemented by conjugation. Suppose explicitly

$$\widehat{M}^{(0)} \geq 0, \qquad \widehat{K} = \widehat{K}^*, \qquad R_{\mathrm{act}} > 0.$$

Then

$$\widehat{M}^{\beta} = R_{\mathrm{act}}^{\widehat{K}/2}\, \widehat{M}^{(0)}\, R_{\mathrm{act}}^{\widehat{K}/2} \geq 0.$$

Consequently,

$$\mathrm{Spec}(\widehat{M}^{\beta}) \subset [0, \infty).$$

Therefore, the squared mass operator

$$\widehat{M^2}_{\beta} := (\widehat{M}^{\beta})^2$$

is positive and satisfies

$$\mathrm{Spec}(\widehat{M^2}_\beta) \subset [0, \infty).$$

A persistent asymptotic particle satisfying the positivity and unitarity assumptions cannot have $m^2 < 0$. If linearization about a background yields an imaginary frequency, the object is an unstable direction: the background must relax or condense. If the route ceases to admit prolongation, the object is a virtual section with a terminal obstruction. Neither case defines a stable superluminal particle.

The scope of the proposition is fixed by its premises. A "tachyonic" parameter in a perturbative potential may signal a phase transition; what is excluded is its promotion to a persistent species of positive norm.

92.11.6.7 Ghost-independent exclusion

A physical ghost would be a negative-norm mode. Let $\mathcal{H}_{\mathrm{phys}} = \ker G / \mathrm{im}\, G_0$ be the gauge quotient endowed with a positive inner product, and let $\widehat{M}_{\mathrm{phys}}$ be self-adjoint on it. Then the spectral measure of a prepared state satisfies

$$\mu^{\mathrm{mass}}_{P,a}(B) \geq 0.$$

A negative direction indicates that positivity of the quotient failed or that the mode does not belong to the physical space; it does not disappear through a nominal assertion. Faddeev–Popov ghosts are variables of the gauge complex, not asymptotic particles. This exclusion is distinct from the tachyonic one: a ghost violates norm positivity; a tachyonic direction violates background stability.

92.11.6.8 Photon, unidirectional bias, and Proca–Stueckelberg bridge

Harmonic channels produce the bias

$$\varepsilon = q^{90}_- - q^{90}_+.$$

A bidirectional kinematic realization can be written

$$c_+ = \frac{c_{\mathrm{int}}}{1+\varepsilon}, \qquad c_- = \frac{c_{\mathrm{int}}}{1-\varepsilon},$$

for which the round-trip measure preserves exactly

$$\frac{2}{c_+^{-1} + c_-^{-1}} = c_{\mathrm{int}}.$$

The bias remains in the unidirectional reading and cancels in the reciprocal reading. This identity belongs to the architecture of two orientations; by itself it does not prove a photonic mass.

If the boundary closure produces a gap frequency $\mu_T \in \mathcal{L}_T^{-1}$ in the register,

$$\omega^2 = c_{\mathrm{int}}^2 k^2 + \mu_T^2,$$

a dimensional entangler can transport it to a Proca–Stueckelberg realization with effective mass

$$m_\gamma = \frac{\hbar_{\mathrm{int}} \mu_T}{c_{\mathrm{int}}^2}.$$

For propagation of frequency ω, the first-order temporal correction satisfies

$$\frac{\Delta T}{T} \simeq \frac{1}{2} \left(\frac{m_\gamma c_{\mathrm{int}}^2}{\hbar_{\mathrm{int}} \omega} \right)^2.$$

The required chain is

$$\text{TPK outward/return} \longrightarrow \text{memory} \longrightarrow \mu_T \longrightarrow m_\gamma.$$

ε, the action quotient R_{act}, and μ_T are not automatically identified: they reside in distinct codomains. The null chart of the ordinary photon remains exact until the gap and its physical intertwiner have been constructed.

92.11.6.9 Operational classification of dark sectors by domain, reader and physical codomain

A dark sector is not defined by an arbitrary mass, but by the kernel of its couplings. If P_X is its projector,

$$P_{\text{em}} P_X = 0, \qquad P_{\text{color}} P_X = 0,$$

while it may occur

$$P_{\text{grav}} P_X \neq 0$$

or a weak coupling may exist. The law first yields a fibre operator; the channel then determines whether its spectrum contains a stable, metastable, or resonant mode.

A dark photon requires a second connection A', its curvature F', and a kinetic intertwiner

$$\mathcal{L}_{\text{mix}} = -\frac{\varepsilon_{\text{kin}}}{2} F_{\mu\nu} F'^{\mu\nu}.$$

If the second sector acquires mass through a Stueckelberg mechanism, a hidden Higgs, or a boundary, its pole is distinct from the null photon. The magnitude ε_{kin} must be derived from a common incidence before observables are compared.

Let $P_{\text{weak}}, P_{\text{em}}, P_{\text{color}}$ be the projectors onto the weak, electromagnetic, and chromatic representation channels, and let P_X be the support of the dark section. A WIMP requires nonzero weak overlap and absence of electromagnetic and chromatic support:

$$P_{\text{weak}} P_X \neq 0, \qquad P_{\text{em}} P_X = P_{\text{color}} P_X = 0.$$

The first product expresses incidence between subspaces; a nonzero commutator would not be a coupling criterion, since two projectors may commute and nevertheless share support. The interaction strength then requires a vertex operator or a coupling Hamiltonian.

Its stability requires a unit eigenvalue of the transport or a protective parity. “WIMP” is a condition on representation and persistence, not a predetermined mass.

92.11.6.10 Classification of the sterile neutrino section by invariant fiber, mixing, and null gauge charge

A sterile neutrino is an eigenvector of the neutral block that satisfies

$$P_{\text{weak}} n_s = 0, \qquad P_{\text{mass}} n_s = n_s.$$

It is not synonymous with the fourth structural depth of the neutrino support. Its existence requires a nonzero weak kernel, an eigenvalue of the mass operator in that kernel, and a mixing transport with the active modes. The criterion is operatorial and can be falsified before introducing an external scale.

92.11.6.11 Classification of Axionic and Pseudoscalar Sections by Topological Character and Edge Coupling

A pseudoscalar axion candidate must be a mode with a normalized kinetic term,

$$CP\, a\, CP^{-1} = -a, \qquad \mathcal{L}_{\text{kin}} = \frac{Z_a}{2}\, \partial_\mu a\, \partial^\mu a, \qquad Z_a > 0,$$

coupled to the topological colour density. Its mass follows from the curvature of the effective potential,

$$m_a^2 = \frac{1}{Z_a}\left.\frac{\partial^2 V_{\mathrm{eff}}}{\partial a^2}\right|_{a=a_0}.$$

The channel $C^* \mapsto -C^*$ contributes an odd orientation, but does not suffice to construct V_{eff}, the kinetic term, or the physical projector. The species is defined only when those maps are present.

92.11.6.12 Monopole Realizations and Topological Defects: Charge Classes and Stability

Let F be the curvature of a connection $U(1)$ in the chosen integral normalization. A magnetic monopole is characterized by the class

$$\frac{1}{2\pi}\int_{S^2} F = n \neq 0.$$

HMT must realize n as the net holonomy of a closed family of routes and prove that it survives refinement. A point vacancy or an isolated carry is not a monopole. If the defect is dynamic and stable, its mass is an eigenvalue of the operator linearized about that class.

92.11.6.13 Classification of Supersymmetric Extensions via Representation Pairing and Characters

The coexistence of fermionic and bosonic completions does not prove supersymmetry. In four dimensions, a family of odd charges satisfying the following is required

$$Q_\alpha : \mathcal{F}_- \longleftrightarrow \mathcal{F}_+, \qquad \{Q_\alpha, \bar{Q}_{\dot\beta}\} = 2\sigma^\mu_{\alpha\dot\beta} P_\mu,$$

that entangles the mass operators:

$$Q_\alpha \widehat{M}_- = \widehat{M}_+ Q_\alpha.$$

The identity $Q^2 = H$ is reserved for an explicit one-dimensional Hermitian reduction; it does not replace the preceding relativistic algebra.

Only then do spectral pairs appear. The breaking must derive the mass separation without using the value of the sought partner. Selectrons, neutralinos, gluinos, or other names remain possible realizations, not rows predicted by the mere existence of CAR and CCR.

92.11.6.14 Classification of Dilaton and Radiaton Sections via Volume and Compactification Scalar Modes

The dilaton is a fluctuation of the scale section; the radion, of an internal length or volume. Their elementary actions are

$$t_0 \mapsto e^{\phi_d} t_0, \qquad \mathcal{V}_{\mathrm{int}} \mapsto e^{\phi_r} \mathcal{V}_{\mathrm{int}}.$$

To constitute particles, they require a kinetic term, potential, persistent projector, and pole. Before that, they are collective degrees of the dimensional chart. This distinction prevents a normalization freedom from being converted into a new scalar species.

92.11.6.15 Compounds and Bonding Energy

A composite state Y with constituents $X_1, \ldots, X_k$ is constructed in the order

$$(\Gamma_{X_1}, \ldots, \Gamma_{X_k}) \longrightarrow \mathscr{L}_{\mathrm{bind}} \longrightarrow \sigma_Y \longrightarrow \eta_Y \longrightarrow \widehat{M}_Y.$$

The binding record $\mathscr{L}_{\mathrm{bind}}$ contains the order of the routes, the common boundary, the transferred carry, the color channel, and the binding holonomy. It may not be replaced by $\sum_i m_{X_i}$. Mesons and baryons require distinct readers because their numbers of constituents, representations, and exchange symmetries differ.

The six published composite evaluations prove the character evaluation upon fixing the signature. State-by-state closure additionally requires the linking record to regenerate that signature. This condition

applies in the same manner to nuclei, atoms, molecules, and tetraquark or pentaquark candidates, with their respective boundary Hamiltonians.

92.11.6.16 Width as 2nd observable

The 384 widths are not obtained by adding a sixth coordinate to σ. For each unstable state, the channels $\mathcal{H}_{\text{in}} \oplus \mathcal{H}_{\text{out}}$, the effective operator $H_{\text{eff}}(z)$, and the pole are constructed

$$z_X = M_X c_{\text{int}}^2 - \frac{i}{2}\Gamma_X.$$

The real part belongs to the mass law; the imaginary part belongs to the decay reader. The relation $\tau_X = \hbar_{\text{int}}/\Gamma_X$ is interpreted after the temporal chart has been fixed. Thus, an exhaustive theory of 471 masses and 384 widths contains two coordinated readers, rather than a single column with 855 heterogeneous numbers.

92.11.6.17 Comparison of the Electromagnetic and Chromodynamic Null Realizations

The photon and the eight gluons belong to distinct null vectors. For the photon,

$$m_\gamma = 0$$

in the electromagnetic branch. For the gluons,

$$m_g = 0$$

in the adjoint representation of colour. Nullity is not obtained by taking the limit of a positive character; the domain bifurcates beforehand. Photon realization requires Maxwell theory, gauge invariance, and two transverse polarizations. Gluon realization requires the colour connection, its eight generators, and restriction to the physical gauge space.

Bidirectional propagation can be written

$$c_\pm = \frac{c}{1 \pm \epsilon}, \qquad \epsilon = q_-^{90} - q_+^{90},$$

with harmonic mean

$$\frac{2}{1/c_+ + 1/c_-} = c.$$

The bidirectional velocity preserves c; the unidirectional orientation preserves the bias. An additional gap in the genealogical record may be realized through Proca–Stueckelberg, but it must not be identified automatically with ϵ or with the splitting of the action.

92.11.7 Exceptional Scaler, Conformal Theory, Strings and Mass Classification

92.11.7.1 Common preimage and coordination of the 2 *readings of the exceptional corridor*

The relation between masses and exceptional symmetries does not begin in an action of the Monster on a table of particles. It begins in the same enriched state of the TPK. Let

$$x \in \mathcal{X}_{\text{TPK}}^{\text{enr}}.$$

The Archimedean reading contracts compatible cylinders and preserves the real value with its genealogy:

$$\mathcal{P}_{\text{arq}}(x) \in \mathbb{R}.$$

The exceptional reading preserves boundary incidences and produces a class in the projective limit:

$$\mathcal{P}_{\mathrm{exc}}(x) = Q_\infty(x).$$

Naturality requires, for every refinement $n \geq m$,

$$r_{n,m} \circ Q_n = Q_m \circ p_{n,m}.$$

The joint application

$$\mathcal{P}_{\mathrm{joint}} : x \longmapsto \big(\mathcal{P}_{\mathrm{arq}}(x), \mathcal{P}_{\mathrm{exc}}(x)\big)$$

is the positive form of the double projection. It does not deny the Monster–mass connection: it types it. The mass branch and the exceptional branch are images of the same preimage with common orientation, grading, carry, memory, and holonomy. Nor does it assert that the Monster acts literally on decimal digits or that a Moonshine coefficient is by itself a mass.

92.11.7.2 Construction of the exceptional corridor

The ternary incidence prolongs the state by the chain

$$C_3 \longrightarrow A_2^{12} \longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathbb{M},$$

where Λ_{24} is the Leech lattice, $V^\natural$ the Moonshine vertex algebra, and $\mathbb{M}$ the Monster group. The step does not consist in juxtaposing classical names: each arrow must preserve the incidence, grading, and refinement compatibility inherited from the state.

The ternary trace is written

$$t_3(q) = q^{-1} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-12}.$$

The first nontrivial defect satisfies

$$D_{\mathrm{APP}} = [q]t_3 = v_\alpha^2 = 54,$$

and the first coefficient of the Monster's character preserves the decomposition

$$196884 = 54 + 10 \cdot 3^9.$$

These identities transport gradation and multiplicity. They do not assign a mass in MeV. Their function in the theory of masses is to classify the space on which the operator acts before scalarizing it.

92.11.7.3 Fiberwise matching with the mass law

The material branch of the same state produces

$$x \longmapsto \big(F_X, \sigma_X, \eta_X, \widehat{M}_X\big),$$

where F_X is a point, orbit, fiber, or multisection; $\sigma_X \in \mathbb{Z}^5$ is the signature; $\eta_X \in \mathcal{E}_{90,120}$ is the refinement; and $\widehat{M}_X$ is the mass operator. The joint reading is then

$$\mathfrak{J}_{\mathrm{mass,exc}}(x) = \big(F_X, \sigma_X, \eta_X, \widehat{M}_X, Q_\infty(x)\big).$$

Two states with the same scalar mass value may remain distinct because of their exceptional component; two states with the same exceptional character may have different mass operators. The correct classification is the matching of fibers, not the isolated equality of numbers.

If an exceptional representation G acts in a physical fiber $\mathcal{H}_X$, compatibility with mass requires

$$U_g \widehat{M}_X U_g^{-1} = \widehat{M}_X, \qquad g \in G.$$

The decomposition

$$\mathcal{H}_X = \bigoplus_{\lambda} \mathcal{H}_{X,\lambda}$$

separates exceptional multiplets. On an irreducible summand, commutation forces the compression of $\widehat{M}_X$ to be scalar. This is a legitimate route to scalarization by symmetry. The scalar value continues to arise from the character, the towers, the dimensional section, and the coupling; the dimension of the representation determines only the degeneracy.

92.11.7.4 Fock and vertex algebra

The prolongation of a route to a many-particle space has two principal completions. The exterior completion produces CAR, Pauli exclusion, and fermionic statistics; the symmetric completion produces CCR and bosonic statistics. A vertex algebra adds an operator product, vacuum, translation, and grading:

$$V = \bigoplus_{n \geq 0} V_n, \qquad L_0|_{V_n} = nI.$$

The character

$$\mathrm{ch}_V(q) = \mathrm{Tr}_V\, q^{L_0 - c/24}$$

counts states by degree. A multiplicity in V_n is not a mass. To convert the grading into energy, a Hamiltonian and a length or time section are required. In a conformal realization on a cylinder of circumference L,

$$H_{\mathrm{CFT}} = \frac{2\pi\hbar_{\mathrm{int}} v}{L}\left(L_0 + \bar{L}_0 - \frac{c}{12}\right).$$

The physical mass or gap appears only after fixing v, L, the boundary conditions, and the map from the TPK route to the conformal modules. The role of the exceptional corridor is to organize the degeneracies and composition rules of those modules.

92.11.7.5 String spectrum as a posterior dimensional realization

Let $\alpha' \in \mathcal{L}_L^2$ be the squared length representing inverse tension in the declared naturalized string chart. In a circular compactification of radius R, the left- and right-moving momenta are

$$p_L = \frac{m}{R} + \frac{wR}{\alpha'}, \qquad p_R = \frac{m}{R} - \frac{wR}{\alpha'},$$

with $m, w \in \mathbb{Z}$. In the natural units of the realization, the closed spectrum satisfies

$$M^2 = p_L^2 + \frac{4}{\alpha'}(N_L - a_L) = p_R^2 + \frac{4}{\alpha'}(N_R - a_R),$$

together with the level condition

$$N_L - N_R = a_L - a_R - mw.$$

The involution

$$(m, w, R) \longleftrightarrow \left(w, m, \frac{\alpha'}{R}\right)$$

preserves the spectrum: it is the realization of T-duality. HMT first supplies the bidirectional orientation, memory, and sheet pairing; string theory adds tension, radius, oscillators, level, and boundary conditions. A string mass is not obtained by replacing N_L, N_R with heights of the tower $\langle 90, 120\rangle$. Any identification between the two gradings requires an intertwiner that preserves sum, orientation, and character.

92.11.7.6 M-Theory Lattice Screens: Grading, Compactification, and Transport of the Residual Memory

The internal screens

$$12 \longrightarrow 11 \longrightarrow 10, \qquad 26 \longrightarrow 24,$$

preserve the dodecaphase descent, the elimination of a redundant direction, and the transverse screen. In a realization of M-theory, the fields

$$g_{MN}, \qquad C_{MNP}, \qquad \Psi_M$$

must be obtained through an intertwiner that preserves gauge, supersymmetry, constraints, and inner product. Numerical displays do not replace that map.

The classification of masses is transported to this branch by means of

$$\text{route} \longrightarrow \text{genealogical record} \longrightarrow \text{signature} \longrightarrow \text{character} \longrightarrow \text{operator} \longrightarrow \text{compactified spectrum}.$$

Kaluza–Klein, winding, membrane, and oscillatory-excitation modes are distinct states even when they share a mass. The graviton of a closed-string realization, if it appears, is a massless collective mode of the geometric sector; it does not thereby become an elementary seed of the TPK or invalidate the formulation of gravity as holonomy and torsion.

92.11.7.7 Ordinary and Hypothetical Realizations Induced by the Exceptional Runner

The exceptional branch allows distinguishing four sources of multiplicity:

1. cellular or route multiplicity in the atlas;
2. degeneracy of an exceptional representation;
3. Fock occupation;
4. conformal, oscillatory, or compactified level.

Confusing them produces false companions, false generations, or duplicated masses. A twin, supersymmetric, dark, or exotic state constitutes a new species only when its quintuple

$$(F_X, Q_\infty(x), \rho_X, \widehat{M}_X, P_X)$$

differs physically, and the Hamiltonian has an additional pole or persistent section. A coincidence of dimension, character, or mass does not suffice.

Conversely, a degeneracy protected by the exceptional corridor is a structural prediction: perturbations preserving the symmetry cannot split the multiplet. An observed splitting requires identifying the symmetry breaking, coupling, or chart that produces it.

92.11.7.8 Positivity, closure, and stability conditions of topological realizations

The connection between the exceptional corridor and masses is falsified in a concrete realization if any of the following occurs:

- naturality $r_{n,m}Q_n = Q_m p_{n,m}$ fails;
- the exceptional label changes when the external masses are permuted;
- a Moonshine multiplicity is used as a mass value without a Hamiltonian;
- the mass operator does not commute with the symmetry asserted to be preserved;
- a tower height is identified with a string level without an intertwiner;
- the level condition or T-duality invariance fails;
- a dimensional screen is declared M-theory without constructing its fields;
- the existence of a spin-two mode is used to redefine the preceding internal gravity.

These controls keep the connection positive: there is a common state and a joint classification; what is prohibited is replacing the arrows with a numerical analogy.

92.11.7.9 Mathematical construction of material classes from routes, signatures, and representations

The double realization, projective naturality, the chain A_2^{12}–Leech–$V^\natural$–Monster, the trace t_3, the identities $D_{\mathrm{APP}} = 54$ and $196884 = 54 + 10 \cdot 3^9$, and the dimensional screens belong to the APP–TRIT–TPK mathematical architecture developed previously. The formulation of $\mathfrak{J}_{\mathrm{mass,exc}}$, the separation of the four multiplicities, and the foregoing controls make its function within an autonomous theory of masses explicit. The conformal and string formulas are subsequent dimensional realizations with their parameters declared; they are not used retroactively to generate APP, TRIT, TPK, the character, or the towers.

92.12 Current operatorial results and subsequent metrological contrast

The comparison only opens afterward of freezing route, signature, operator, scheme, scale and unit. The table current arranges in columns contiguous the output HMT, the value external, the uncertainty, the residual and the status. The values quark not admit a residual public if scheme and scale not coincide.

92.12.1 Mass Operators in HMT-MD: Absolute Scale, Route Atlas, and Sectoral Realization

Mass appears in Dimensional Mechanics as the realization of two mathematical branches that converge without being conflated. The first preserves the genealogy of the state: a surviving extension determines an observable route; the route writes a dodecaphasic chronological register; the register produces an integer signature, and the signature feeds the character and the harmonic hierarchy. The second constructs the dimensional line: the determinantal reader fixes the action scale, the internal clock transports it to energy, and the kinematic chart carries it to mass. The species operator then acts by positive homotheties on that line. The experimental coordinate is opened only after both branches have been frozen.

The complete internal domain has four distinct counts:

$$81 = 25_{\ell^-} + 20_\nu + 20_d + 16_u, \qquad 56 = 41{\times}1 + 10{\times}2 + 2{\times}3 + 1{\times}4 + 2{\times}5, \tag{92.37}$$

$$13 \text{ multisections}, \qquad 324 = 81 \times 4 \text{ oriented routes}. \tag{92.38}$$

The physical realizations compared later constitute a classification of realizations; they are not another name for the 81 cells, the 56 families, the 13 multisections, or the 324 oriented histories. On this domain, the two route readers produce fourteen profiles K_D, nine profiles K_Ω, forty joint pairs, and eighteen coincidences. The null sector remains separate from the positive mass character.

92.12.1.1 From the APP incompatibility to the mass signature

The primordial difference between the sum and product sheets appears in the spectral decomposition of the central APP block:

$$B_c = 7I + 2R = 9P_+ + 5P_-, \qquad \mathrm{Spec}(B_c) = \{9, 5\}, \qquad \Delta_{\mathrm{APP}} = 9 - 5 = 4. \tag{92.39}$$

The integers that recur subsequently preserve distinct sources. The local exchange coefficient is 2 in $B_c = 7I + 2R$; modular compression publishes $51 - 45 = 6$, and its deployment over nine blocks produces $9 \cdot 6 = 54$. These equalities belong to typed levels of the same genealogy and do not constitute a chain of definitions of the jump 4. In the electronic section, 54 is furthermore $D_1(\Gamma_e)$ and the kinematic periodicity of order 54 of the CT108 temporal endomorphism: it measures a component of the history already transported by TPK, not the primordial spectral separation.

For each enriched route Γ, the dodecaphase record determines

$$\sigma(\Gamma) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta) \in \mathbb{Z}^5, \qquad \zeta_{270} = 135\Delta_4^2. \tag{92.40}$$

The central character and its harmonic refinement are

$$\log \chi_0(\sigma) = n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}} + k_{\Delta_4}\Delta_4 + b_{120}s_{120} + b_\zeta \zeta_{270}, \tag{92.41}$$

$$\log \chi_{\mathrm{full}}(\sigma, \eta) = n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}} + k_{\Delta_4}\Delta_4 + b_\zeta \zeta_{270} + (b_{120} + \eta_{120})s_{120} + \sum_{\substack{h \in \mathfrak{S} \\ h \neq 120}} \eta_h s_h. \tag{92.42}$$

The division $s_C/6$ follows from dodecaphasic integrality. The labeled pair (b_{120}, η_{120}) preserves its genealogy even when its evaluation is grouped into a single coefficient.

The moments entering (92.42) belong to an infinite hierarchy:

$$q_\pm = \exp\Big[-\frac{\pi}{180}(A \pm C^*)\Big], \qquad s_h = q_-^h - q_+^h, \qquad c_h = q_-^h + q_+^h, \tag{92.43}$$

$$\mathfrak{S} = \langle 90, 120\rangle = \{90, 120\} \cup \{30r : r \geq 6\}. \tag{92.44}$$

Both s_n and c_n satisfy

$$X_{n+2} = c_1 X_{n+1} - (q_- q_+) X_n. \tag{92.45}$$

The heights $90, 120, 180, 210, 240, 270, 360, 420$ are particularly visible genealogical witnesses; the domain of the law is the entire semigroup. In particular, 360 preserves two histories before the quotient, four steps of 90, and three of 120, even when both produce the same scalar moment.

92.12.1.2 The absolute mass section and the decade 10^{-34}

The local Hadamard block

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad \mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4),$$

has cokernel of order 16. Its determinantal reader produces

$$\Sigma_H = \varphi \alpha_{\mathrm{HMT}}^{16}, \qquad 10^{-34} < \Sigma_H < 10^{-33}, \qquad \lfloor \log_{10} \Sigma_H \rfloor = -34. \tag{92.46}$$

The conversion to J s is a subsequent chart: the power 10^{-34} is born in the discrete structure and fixes the scale of a single line of action. Its sections before and after the return are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S, \qquad R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}} > 0. \tag{92.47}$$

The splitting possesses an additive chart, $\delta_{2w} = H_5 - \eta_{\mathrm{ret}}$, and the dimensionless multiplicative chart R_{act}. Once an internal duration t_0 has been declared, the periodicity of 108 iterations of the CT108 temporal endomorphism constructs

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad \varepsilon_{\mathrm{clk}} = \hbar_{\mathrm{ret}}\omega_0, \tag{92.48}$$

$$\mathbf{m}_\star^{\mathrm{pre}} = \left(H_5\, 10^{-34}\mathcal{U}_S\right)\frac{2\pi}{108 t_0}c_{\mathrm{int}}^{-2}, \qquad \mathbf{m}_\star^{\mathrm{ret}} = \left(\eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S\right)\frac{2\pi}{108 t_0}c_{\mathrm{int}}^{-2} \in \mathcal{L}_M. \tag{92.49}$$

Both sections satisfy $\mathbf{m}_\star^{\mathrm{pre}}/\mathbf{m}_\star^{\mathrm{ret}} = R_{\mathrm{act}}$. The decade 10^{-34}, the common clock, and c_{int}^{-2} fix the absolute scale. In a mass ratio, that common section cancels exactly; the relative refinement belongs to the route and not to a second introduction of the decimal power.

92.12.1.3 Bidirectional route readers and operator law on the 13 *multisections*

The readers acting on a route Γ are

$$K_D(\Gamma) = \left(D_{27} + D_{36},\, D_1,\, \frac{D_4 - D_3}{2}\right), \qquad K_\Omega(\Gamma) = (\Omega, 54, P_6). \tag{92.50}$$

Each reader induces on a multisection F a diagonal operator $\widehat{K}_F^r$, $r \in \{D, \Omega\}$. The index s designates a physical section or block within F, and $\widehat{B}_{F,s}^r$ is the self-adjoint restriction of $\widehat{K}_F^r$ to that block. If $\widehat{\mathcal{A}}_{F,s}^{(0)}$ is the restriction of the operator that gathers the signature, the complete character, and the global hierarchy of towers, the general law takes the form

$$\boxed{\widehat{\mathbf{M}}_{F,s}^{\beta,r} = \mathbf{m}_\star^{\mathrm{ret}} \otimes R_{\mathrm{act}}^{\widehat{B}_{F,s}^r/2}\,\widehat{\mathcal{A}}_{F,s}^{(0)}\,R_{\mathrm{act}}^{\widehat{B}_{F,s}^r/2}, \qquad r \in \{D, \Omega\}.} \tag{92.51}$$

The symmetric expression preserves positivity without imposing commutation of $\widehat{\mathcal{A}}_{F,s}^{(0)}$ and $\widehat{B}_{F,s}^r$. In the simultaneously diagonal basis of the current certificates, it coincides with the product $\mathbf{m}_\star^{\mathrm{ret}} \otimes \widehat{\mathcal{A}}_F^{(0)} \exp((\log R_{\mathrm{act}})\widehat{K}_F^r)$. This equation governs the 81 cells, 56 families, 13 multisections, and 324 oriented routes. Outside a rank-one fiber, the primary output is the complete operator and its spectrum. Scalar realization uses the closed morphism $\mathcal{S}_{\mathrm{phys}} : (\sigma_{\mathrm{ud}}, g, \chi_{\mathrm{fina}}, [\gamma]_{\mathrm{col}}) \mapsto \gamma_{P,\mathfrak{M}}^{\mathrm{surv}}$ of equation (92.9); that selection is independent of target masses and precedes any metrological comparison.

92.12.1.4 Rank reduction 1 *in the construction of the central electron*

The electronic section is the only central fixed point of the atlas:

$$(r, c) = (5, 5), \qquad \Gamma_e = (5, 5, {+}{+}), \qquad \tau_e = {+}{+}{+}{-}{-}{-}{+}{+}{+}{-}{-}{-}. \tag{92.52}$$

Both readers agree on it,

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6), \qquad \kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4. \tag{92.53}$$

The rank-one reduction of (92.51) yields

$$\mathbf{m}_e^\beta = \mathbf{m}_\star^{\mathrm{ret}}\,\mu_e^{(0)}\,R_{\mathrm{act}}^{80-54\alpha_{\mathrm{HMT}}+6\Delta_4}, \tag{92.54}$$

whose coordinate in the comparative chart is

$$\boxed{m_e^\beta = 0.510998950690000808608257164 8\ldots\ \mathrm{MeV}/c^2.} \tag{92.55}$$

The basal value $0.51099892248806607 25\ldots$ MeV$/c^2$ preserves its function as an intermediate stage; the beta output of (92.55) governs the final comparison.

92.12.1.5 Physical classification and quantitative comparison by sectors

The exposition is organized into four coordinated strata. The first publishes the internal result and its codomain; the second declares the physical realization morphism; the third displays the best numerical coordinate currently available and preserves its hypotheses and domain; the fourth introduces the external datum as a subsequent comparison. Each column thus preserves its mathematical type: HMT output, realization morphism, computed coordinate, and external comparison. The table simultaneously publishes the available evaluations and the construction maps producing them.

The electron publishes its scalar beta closure. The photon and gluons publish exact null sections in their mass charts, together with nontrivial gauge extensions. The other charged leptons and the six quarks simultaneously publish their nominal routes, scalar characters, diagonal operators, and spectra over their fibres; the neutrinos publish the neutral operator and its mixing. W, Z, and H possess individualized CT–108 routes, complete traces, and characters $(n_A, s_C) = (94, -1), (95, -1), (97, 9)$. The pair K_D/K_Ω belongs to the refinement of the atlas's thirteen multisections and is not a premise of the bosonic realization by nominal route. Composites, topological sectors, and virtual states retain, respectively, their codomains of binding, fusion, braiding, and obstruction.

Operators of the 13 **multisections** The family counts recorded on each sheet are local cardinalities of the support of that multisection. They are not added across sheets: the quotient of the 56 route families and the quotient of the 13 multisections are two distinct partitions of the 81-cell atlas, related by the projection maps rather than by a common disjoint decomposition.

The following records publish the operator in its native codomain. Each spectrum is reproduced in full; no list of eigenvalues is replaced by a mass coordinate.

charged leptonic sector, depth G0 (center). $\mathcal{B}_{\ell,\mathrm{G0}}$.

Fiber domain. Rank 1; cell 41; no chromatic orbit; 1 route family. **Full spectrum of K_D.**

- (80,54,6)x1

Complete spectrum of K_Ω.

Conclusion in the fiber. Exact diagonal operator on the fiber B_1; the nominal route and the declared morphism publish the scalar character without replacing the spectrum of the fiber.

Physical realization morphisms

Table 92.8: Physical realization of the charged leptons.

Class	Objeto HMT	Realization map	Conclusion and conditions
e^-/e^+	Celda central $(5,5)$, route $\Gamma_e = (5,5,{+}{+})$ and $K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80,54,6)$.	Closed rank one reduction.	Beta range closure; independent magnitude selector of metrological magnitudes employed as target.
μ^-/μ^+	charged-lepton family; levels G2; 8 cells; K_D: 7 profiles; K_Ω: 1 profile	Generation and fine signature $\to$ persistent route $\to \chi_{\mathrm{mass}} \to \mathcal{L}_M$.	Nominal route and closed scalar character; the operator pair preserves the full refinement of the fiber.
τ^-/τ^+	family leptonica cargada; levels G4; 16 celdas; K_D: 8 perfiles; K_Ω: 3 perfiles	Generation and fine signature $\to$ persistent route $\to \chi_{\mathrm{mass}} \to \mathcal{L}_M$.	Nominal route and closed scalar character; the operator pair preserves the full refinement of the fiber.

Table 92.9: Physical realization of neutrinos and transport of bases.

Class	Objeto HMT	Realization map	Conclusion and conditions
$\nu_e/\bar{\nu}_e$	neutral family; levels G1, G2, G3, G4; 20 cells; K_D: 11 profiles; K_Ω: 5 profiles	Full-rank neutral record $\to$ eigenvectors $\to$ PMNS basis.	The exterior/CAR structure fixes fermionicity; PMNS transports bases and does not create mass eigenvalues.
$\nu_\mu/\bar{\nu}_\mu$	neutral family; levels G1, G2, G3, G4; 20 cells; K_D: 11 profiles; K_Ω: 5 profiles	Full-rank neutral record $\to$ eigenvectors $\to$ PMNS basis.	The exterior/CAR structure fixes fermionicity; PMNS transports bases and does not create mass eigenvalues.
$\nu_\tau/\bar{\nu}_\tau$	neutral family; levels G1, G2, G3, G4; 20 cells; K_D: 11 profiles; K_Ω: 5 profiles	Full-rank neutral record $\to$ eigenvectors $\to$ PMNS basis.	The exterior/CAR structure fixes fermionicity; PMNS transports bases and does not create mass eigenvalues.

Table 92.10: Physical realization of quarks: generation, flavor, and color.

Class	Objeto HMT	Realization map	Conclusion and conditions
$u/\bar{u}$	quark branch *up*; levels G1 and G3; color $\mathbb{Z}/3$; 16 cells; K_D: 11 profiles; K_Ω: 2 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.
$d/\bar{d}$	quark branch *down*; levels G1, G2, G3, G4; color $\mathbb{Z}/3$; 20 cells; K_D: 12 profiles; K_Ω: 4 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.
$c/\bar{c}$	quark branch *up*; levels G1 and G3; color $\mathbb{Z}/3$; 16 cells; K_D: 11 profiles; K_Ω: 2 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.

Continues on the following page.

Class	Objeto HMT	Realization map	Conclusion and conditions
$s/\bar{s}$	quark branch *down*; levels G1, G2, G3, G4; color $\mathbb{Z}/3$; 20 cells; K_D: 12 profiles; K_Ω: 4 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.
$t/\bar{t}$	quark branch *up*; levels G1 and G3; color $\mathbb{Z}/3$; 16 cells; K_D: 11 profiles; K_Ω: 2 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.
$b/\bar{b}$	quark branch *down*; levels G1, G2, G3, G4; color $\mathbb{Z}/3$; 20 cells; K_D: 12 profiles; K_Ω: 4 profiles	Flavour–colour–generation $\to$ persistent route $\to \chi_{\text{mass}} \to \mathcal{L}_M$.	Flavor, color, and generation determine the class of route; scalar character and closed operatorial pair.

Structural location of the 6 quark flavours The position of a quark flavour is specified by four simultaneous data: branch, generation, cellular support, and family of oriented routes. The three generations of a given branch share the support of the atlas; the fine generation classifier preserves the physical distinction that must still be realized as an eigenvector and a mass section.

Table 92.11: Generational classification of the six quark flavors.

Flavor	Generation	Branch	Branch and generation classifier
$u/\bar{u}$	first	up branch	$(\text{up}, 1, \chi_{\text{fina}})$; nominal route pair $(21, 30)$ over the axis N−S
$d/\bar{d}$	first	down branch	$(\text{down}, 1, \chi_{\text{fina}})$; nominal route pair $(20, 32)$ over the axis E−O
$c/\bar{c}$	second	up branch	$(\text{up}, 2, \chi_{\text{fina}})$; nominal route pair $(21, 29)$ over the axis E−O
$s/\bar{s}$	second	down branch	$(\text{down}, 2, \chi_{\text{fina}})$; nominal route pair $(17, 27)$ over the axis N−S
$t/\bar{t}$	third	up branch	$(\text{up}, 3, \chi_{\text{fina}})$; nominal route pair $(21, 26)$ over the axis N−S
$b/\bar{b}$	third	down branch	$(\text{down}, 3, \chi_{\text{fina}})$; nominal route pair $(21, 30)$ over the axis E−O

Support structural of the rama superior.

Multisections. $\mathcal{B}_{u,\mathrm{G1}}$, $\mathcal{B}_{u,\mathrm{G3}}$.

Depths and cardinalities. G1, G3; 16 cells and 14 distinct route families.

Chromatic orbit and orientations. $C = \{B, G, R\}$ and $O = \{(-1,-1), (-1,1), (1,-1), (1,1)\}$.

Cells and oriented families B_1. Each chain $k \leftrightarrow (r,c) \leftrightarrow \Gamma_{r,c}^{(h,v)}$ preserves the cell index, its coordinate in the chart 9×9, and the two orientation signs of the enriched path record.

Fila $r = 2$: $11 \leftrightarrow (2,2) \leftrightarrow \Gamma_{2,2}^{(-,+)}$, $13 \leftrightarrow (2,4) \leftrightarrow \Gamma_{2,4}^{(+,-)}$, $15 \leftrightarrow (2,6) \leftrightarrow \Gamma_{2,6}^{(-,+)}$, $17 \leftrightarrow (2,8) \leftrightarrow \Gamma_{2,8}^{(-,-)}$.

Fila $r = 4$: $29 \leftrightarrow (4,2) \leftrightarrow \Gamma_{4,2}^{(+,-)}$, $31 \leftrightarrow (4,4) \leftrightarrow \Gamma_{4,4}^{(-,+)}$, $33 \leftrightarrow (4,6) \leftrightarrow \Gamma_{4,6}^{(+,+)}$, $35 \leftrightarrow (4,8) \leftrightarrow \Gamma_{4,8}^{(-,-)}$.

Fila $r = 6$: $47 \leftrightarrow (6,2) \leftrightarrow \Gamma_{6,2}^{(-,+)}$, $49 \leftrightarrow (6,4) \leftrightarrow \Gamma_{6,4}^{(-,-)}$, $51 \leftrightarrow (6,6) \leftrightarrow \Gamma_{6,6}^{(+,+)}$, $53 \leftrightarrow (6,8) \leftrightarrow \Gamma_{6,8}^{(+,+)}$.

Fila $r = 8$: $65 \leftrightarrow (8,2) \leftrightarrow \Gamma_{8,2}^{(+,+)}$, $67 \leftrightarrow (8,4) \leftrightarrow \Gamma_{8,4}^{(+,+)}$, $69 \leftrightarrow (8,6) \leftrightarrow \Gamma_{8,6}^{(-,-)}$, $71 \leftrightarrow (8,8) \leftrightarrow \Gamma_{8,8}^{(+,+)}$.

Closed realization morphism. For $g \in \{1,2,3\}$, the branch, generation, color orbit, and fine signature determine

$$\chi_{\mathrm{fina}}(\mathrm{up}, g, C) \longrightarrow \Gamma_{\mathrm{enr}} \longrightarrow \big(\mathrm{quot}_C, S(B_D, B_\Omega)\big).$$

This arrow selects the physical eigenvector and subsequently publishes the scalar coordinate in $\mathcal{L}_M$ without using the contrast value.

Structural support of the lower branch.

Multisections record. $\mathcal{B}_{d,\mathrm{G1}}$, $\mathcal{B}_{d,\mathrm{G2}}$, $\mathcal{B}_{d,\mathrm{G3}}$, $\mathcal{B}_{d,\mathrm{G4}}$.

Depths and cardinals. G1, G2, G3, G4; 20 cells and 18 distinct route families.

Chromatic orbit and orientations. $C = \{B, G, R\}$ and $O = \{(-1,-1), (-1,1), (1,-1), (1,1)\}$.

Cells and oriented families B_1. Each chain $k \leftrightarrow (r,c) \leftrightarrow \Gamma_{r,c}^{(h,v)}$ preserves the cell index, its coordinate in the chart 9×9, and the two orientation signs of the enriched path record.

Fila $r = 2$: $10 \leftrightarrow (2,1) \leftrightarrow \Gamma_{2,1}^{(+,+)}$, $12 \leftrightarrow (2,3) \leftrightarrow \Gamma_{2,3}^{(-,-)}$, $14 \leftrightarrow (2,5) \leftrightarrow \Gamma_{2,5}^{(+,+)}$, $16 \leftrightarrow (2,7) \leftrightarrow \Gamma_{2,7}^{(-,+)}$, $18 \leftrightarrow (2,9) \leftrightarrow \Gamma_{2,9}^{(-,+)}$.

Fila $r = 4$: $28 \leftrightarrow (4,1) \leftrightarrow \Gamma_{4,1}^{(-,-)}$, $30 \leftrightarrow (4,3) \leftrightarrow \Gamma_{4,3}^{(+,+)}$, $32 \leftrightarrow (4,5) \leftrightarrow \Gamma_{4,5}^{(+,-)}$, $34 \leftrightarrow (4,7) \leftrightarrow \Gamma_{4,7}^{(-,+)}$, $36 \leftrightarrow (4,9) \leftrightarrow \Gamma_{4,9}^{(-,+)}$.

Fila $r = 6$: $46 \leftrightarrow (6,1) \leftrightarrow \Gamma_{6,1}^{(-,-)}$, $48 \leftrightarrow (6,3) \leftrightarrow \Gamma_{6,3}^{(-,+)}$, $50 \leftrightarrow (6,5) \leftrightarrow \Gamma_{6,5}^{(-,+)}$, $52 \leftrightarrow (6,7) \leftrightarrow \Gamma_{6,7}^{(-,+)}$, $54 \leftrightarrow (6,9) \leftrightarrow \Gamma_{6,9}^{(+,-)}$.

Fila $r = 8$: $64 \leftrightarrow (8,1) \leftrightarrow \Gamma_{8,1}^{(+,-)}$, $66 \leftrightarrow (8,3) \leftrightarrow \Gamma_{8,3}^{(-,+)}$, $68 \leftrightarrow (8,5) \leftrightarrow \Gamma_{8,5}^{(-,+)}$, $70 \leftrightarrow (8,7) \leftrightarrow \Gamma_{8,7}^{(+,-)}$, $72 \leftrightarrow (8,9) \leftrightarrow \Gamma_{8,9}^{(-,+)}$.

Closed realization morphism. For $g \in \{1,2,3\}$, the branch, generation, color orbit, and fine signature determine

$$\chi_{\mathrm{fina}}(\mathrm{down}, g, C) \longrightarrow \Gamma_{\mathrm{enr}} \longrightarrow \big(\mathrm{quot}_C, S(B_D, B_\Omega)\big).$$

This arrow selects the physical eigenvector and subsequently publishes the scalar coordinate in $\mathcal{L}_M$ without using the contrast value.

Table 92.12: Physical realization of the gauge and scalar sectors.

Class	**Objeto HMT**	**Realization map**	**Conclusion and conditions**
photonγ	Null sectorial chart and corresponding gauge representation.	Exact inclusion of the null section in the mass line.	Exact nullity in its sectorial chart.
gluones g	Null sectorial chart and corresponding gauge representation.	Exact inclusion of the null section in the mass line.	Exact nullity in its sectorial chart.
$W^{\pm}$	CT–108 W route: 15/37, E-O axis, $(N, E, S, O) = (23, 44, 11, 30)$, sheet/residue $(41, 8)$, $(n_A, s_C) = (94, -1)$, $(W_+, W_-) = (563, 565)$; exact scalar character	Nominal CT–108 route $\to$ $(n_A, s_C) \to (W_+, W_-) \to \chi_{\text{mass}} \to \mathcal{L}_M$.	Route gauge CT–108, signature and scalar character determined before contrast.
Z^0	CT–108 Z route: 20/23, E-O axis, $(N, E, S, O) = (33, 45, 10, 20)$, sheet/residue $(57, 7)$, $(n_A, s_C) = (95, -1)$, $(W_+, W_-) = (569, 571)$; exact scalar character	Nominal CT–108 route $\to$ $(n_A, s_C) \to (W_+, W_-) \to \chi_{\text{mass}} \to \mathcal{L}_M$.	Route gauge CT–108, signature and scalar character determined before contrast.
Higgs H	CT–108 H route: 24/29, N-S axis, $(N, E, S, O) = (40, 34, 22, 12)$, sheet/residue $(47, 10)$, $(n_A, s_C) = (97, 9)$, $(W_+, W_-) = (591, 573)$; exact scalar character	Nominal CT–108 route $\to$ $(n_A, s_C) \to (W_+, W_-) \to \chi_{\text{mass}} \to \mathcal{L}_M$.	Route CT–108, scalar, signature and character determined before contrast.

Table 92.13: Realization of compounds, topological sectors and virtual states.

Class	**Objeto HMT**	**Realization map**	**Conclusion and conditions**
mesons	Double registration, boundary of connection and composite signature.	Composite record and constraint $\to$ scalar chart.	Composition of records; the binding precedes the scalar chart.
baryons	Triple register, carry, and composite signature.	Composite record and constraint $\to$ scalar chart.	Composition of records; the binding precedes the scalar chart.

Continues on the following page.

Class	Objeto HMT	Realization map	Conclusion and conditions
Fibonacci quantity $(1, \tau)$	Fibonacci fusion ring: $\tau \otimes \tau = 1 + \tau$.	Fusion and braiding → physical observable of the sector.	Exact codomain of fusion and braiding; the contrast uses its own invariants.
Ising $(1, \psi, \sigma)$; separate Majorana realization	Ising fusion ring: $(1, \psi, \sigma)$.	Fusion and braiding → physical observable of the sector.	Exact codomain of fusion and braiding; the contrast uses its own invariants.
sectores $\mathbb{Z}/6$	Braiding character on $\mathbb{Z}/6$.	Fusion and braiding → physical observable of the sector.	Exact codomain of fusion and braiding; the contrast uses its own invariants.
secciones virtuales	Inverse system of extensions and persistence horizon.	Registered prolongation → physical horizon of persistence.	Exact object of prolongation and obstruction; its exit is the persistence horizon.

Physical Comparability in Native Codomains External comparison is defined on the native codomain of each class. In the classes with a closed scalar section, homogeneous magnitudes are compared, with their unit, scheme, and scale declared. In the operatorial fibres, the internal spectrum is compared and the closed realization morphism that selects the route without using the external value is explicitly conserved. Mesonic and baryonic records admit only state-by-state comparison after the binding boundary has been incorporated. In the Fibonacci sector, the based ring and $\mathrm{FPdim}(\tau) = \varphi$ are closed; the matrices F/R, the pentagon, the hexagon, the Hamiltonian, and the gap belong to the subsequent realization. Ising and $\mathbb{Z}/6$ separately conserve their fusion and braiding invariants, and virtuality is compared through persistence and analytic structure. In none of these six cases is there a universal scalar mass for the class; assigning one would replace the proved object with a digit lacking a morphism.

Internal evaluations of explicit firms and posterior contrast The following table presents in legible form the seventeen HMT–MD coordinates already calculated—eleven elementary and six composite—and compares them with the 2026 edition of the Particle Data Group data set, whose editorial cutoff date is 15 January 2026 [120]. They do not constitute an ontology distinct from the preceding operatorial layer. The symbol † identifies an evaluation obtained by applying the construction map to an explicit signature. In the eleven elementary rows, the signature follows from the nominal route determined without masses; in the six composite rows, it follows from the declared binding ledger. Each figure depends on that signature, the bidirectional reader, and the common dimensional chart; the external data set enters only in the comparison and selects neither flavor, generation, color, nor route.

For charged leptons and massive bosons, the relative difference between the two central coordinates is shown and, when the dataset provides a two-sided uncertainty, its ratio to that uncertainty. For quarks, the arithmetic difference between central values is reported, but the term *metrological residual* is reserved: it requires the internal mass and the external reference to use the same definition, renormalization scheme

and scale. The light masses are read in the $\overline{\mathrm{MS}}$ convention at 2 GeV; those of c and b, in $\mu = \overline{m}_q$; the top mass comes from kinematic reconstruction.

Table 92.14: Internal evaluations of explicit firms and subsequent metrological contrast.

Status	Signature coordinate	External physical reference	Scope
μ^-/μ^+	105.658360294435829303 4 MeV$/c^{2\dagger}$; E3 tower, signature (42,-3,8,0,2)	105.6583755 ± 0.0000023 MeV$/c^2$; leptonic rest mass; PDG average and declared metrological conversion	Relative difference: -0.143912530 ppm†; $-6.611114\,\sigma$. The HMT figure is the exact evaluation of the declared signature.
τ^-/τ^+	1776.860917631432 295595 MeV$/c^{2\dagger}$; E3 tower, signature (64,0,25,-1,6)	1776.93 ± 0.09 MeV$/c^2$; direct PDG average	Relative difference: -38.877371966 ppm†; $-0.813547\,\sigma$. The HMT figure is the exact evaluation of the declared signature.
$u/\bar{u}$	2.165924536173 907 MeV$/c^{2\dagger}$; angular chart, nominal route signature (11,7)	2.16 ± 0.07 MeV$/c^2$; mass $\overline{\mathrm{MS}}$ to $\mu = 2$ GeV; 90% C.L.	Difference between central values: 2742.840821 253 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.
$d/\bar{d}$	4.679550162948 874 MeV$/c^{2\dagger}$; chart angular, firma nominal of route (17,8)	4.70 ± 0.07 MeV$/c^2$; mass $\overline{\mathrm{MS}}$ to $\mu = 2$ GeV; 90% C.L.	Difference between central values: -4351.029159 814 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.
$c/\bar{c}$	1.270500838641 911 GeV$/c^{2\dagger}$; angular chart, nominal route signature (61,8)	1.2729 ± 0.0045 GeV$/c^2$; mass $\overline{\mathrm{MS}}$ evaluated at $\mu = \overline{m}_q$; 90% C.L.	Difference between central values: -1884.799558 558 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.
$s/\bar{s}$	92.940093907845 64 MeV$/c^{2\dagger}$; angular chart, nominal route signature (41,-3)	92.9 ± 0.7 MeV$/c^2$; mass $\overline{\mathrm{MS}}$ to $\mu = 2$ GeV; 90% C.L.	Difference between central values: 431.581354 635 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.

Continues on the following page.

State	Signature coordinate	External physical reference	Scope
$t/\bar{t}$	172.597479544019 1 GeV$/c^{2\dagger}$; chart angular, firma nominal of route (100,-1)	172.60 ± 0.27 GeV$/c^2$; mass reconstructed directly from event kinematics	Difference between central values: -14.602873 585 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.
$b/\bar{b}$	4.190119763299 790 GeV$/c^{2\dagger}$; angular chart, nominal route signature (71,-5)	4.186 ± 0.006 GeV$/c^2$; mass $\overline{\mathrm{MS}}$ evaluated at $\mu = \overline{m}_q$; 90% C.L.	Difference between central values: 984.176612 467 ppm†. It is not a metrological residual until the same scheme and the same scale have been fixed.
$W^{\pm}$	80.378964909704547024 86 GeV$/c^{2\dagger}$; E3 tower, signature (94,-1,0,-2,4)	80.3625 ± 0.0077 GeV$/c^2$; mass average of the sealed PDG snapshot	Relative difference: 204.882995234 ppm†; $2.138299\,\sigma$. The HMT figure is the exact evaluation of the declared signature.
Z^0	91.187533444313407844 85 GeV$/c^{2\dagger}$; tower E3, signature (95,-1,-11,0,-4)	91.1879 ± 0.0020 GeV$/c^2$; mass average of the sealed PDG snapshot	Relative difference: -4.019784276 ppm†; $-0.186362\,\sigma$. The HMT figure is the exact evaluation of the declared signature.
Higgs H	125.292466042536 133 GeV$/c^{2\dagger}$; angular chart, nominal route signature (97,9)	125.13 ± 0.11 GeV$/c^2$; mass average of the sealed PDG snapshot	Relative difference: 1298.378027140 ppm†; $1.454206\,\sigma$. The HMT figure is the exact evaluation of the declared signature.
π^0 signature $(44, -4, -25, 1, -2)$	134.976724327872125739 384878 . . . MeV$/c^{2\dagger}$	134.976827767684 71 $\pm$ 0.000485679282 28423351 MeV$/c^2$ PDG 2026 catalog.	Relative difference -0.766352375 ppm; $-0.212979\,\sigma$. For the declared composite signature, the evaluation is deduced exactly from the beta E3 character. The prospective selector of that signature is an earlier map independent of the numerical comparison.

State	Signature coordinate	External physical reference	Scope
neutron n signature $(59, 1, -34, 0, 1)$	939.565810472507023312 664431 . . . MeV$/c^{2\dagger}$	939.565421939999 96 ± 0.000000480000 00000000 MeV$/c^2$ PDG 2026 catalog.	Relative difference 0.413523 633 ppm; 809.442723 σ. For the declared composite signature, the evaluation is deduced exactly from the beta E3 character. The prospective selector of that signature is an earlier map independent of the numerical comparison.

Native Invariants of Topological and Virtual Sectors. The Fibonacci, Ising, and $\mathbb{Z}/6$ sectors and the virtual sections are compared in their proper codomains. Fibonacci publishes the based ring and its Frobenius–Perron dimension; the data F/R remain in the subsequent realization. Ising preserves its fusion ring and separates the Majorana realization; $\mathbb{Z}/6$ publishes its braiding characters; virtuality publishes persistence horizons. This table maintains those invariants within the same realization map without artificially translating them into a unit of mass.

Table 92.15: Topological and virtual sectors: native invariants of fusion, braiding, and persistence.

Sector designation	Object and relations	Native invariant	Physical scope
Fibonacci datum	$K = \mathbb{Z}1 \oplus \mathbb{Z}\tau$, $\tau^2 = 1 + \tau$.	FPdim$(\tau) = \varphi$ in the based ring.	The matrices F/R, the pentagon, the hexagon, the Hamiltonian, and the gap belong to the subsequent realization.
Ising category	$K = \mathbb{Z}\{1, \psi, \sigma\}$, $\psi^2 = 1$, $\psi\sigma = \sigma$, $\sigma^2 = 1 + \psi$.	FPdim$(\sigma) = \sqrt{2}$; braiding representation.	The Majorana realization preserves its own physical morphism.
$\mathbb{Z}/6$	$q_{\epsilon,t} = (-1)^{\epsilon}\omega_3^t = \zeta_6^k$.	Quadratic character and braid representation over the six sectors.	The relevant remark is topological, not a universal mass.
Secciones virtuales	Inverse system of prolongations with horizon $L(s_N)$.	Finite register, signature, carry, and obstruction class.	The native observable is the persistence of the prolongation.

Neutrinos remain in the codomain of eigenvalues and mixing described by their operator records; PMNS realizes transport between the interaction and mass bases, while the scale belongs to the spectrum of the neutrino operator. The six composite evaluations are obtained from explicit signatures through the general binding morphism into the scalar chart. The topological sectors and virtual sections retain their own fusion, braiding, and persistence observables.

92.12.1.6 Causal construction and coverage of mass classes

The APP–TRIT–TPK architecture, the mass law, the bidirectional reader, and the towers jointly determine the atlas, the enriched chronological ledgers, the signatures, the character, and the basal closure. Their confluence in (92.51) provides a unique equation of mass sections. The complete domain is the atlas 81/56/13/324, and each realization specifies, according to its own codomain—that is, according to the codomain of each sector—the classifiers, cells, routes, orientations, dodecaphase words, signatures, and compatibility morphisms. The spectra K_D/K_Ω refine the fibres of the atlas, while the chronological routes of 108 states associated with W, Z, and H directly construct their bosonic signatures and characters.

92.12.2 Posterior evaluation of the generative graph

The following table places in adjacent columns every scalar coordinate that the theory permits to be evaluated reproducibly. The experimental reference is introduced after the HMT–MD output has been fixed. A row labeled as a conditioned evaluation asserts exactly the value of the function once the signature has been fixed; it does not attribute to that signature a physical selector that has not been constructed. Quarks are printed without a residual because a numerical comparison requires the renormalization scheme and scale to coincide.

The numerical census in this table is exhaustive relative to the scalar coordinates currently reproducible: one closed beta electron, seventeen conditioned evaluations —eleven elementary and six composite—, and two exact null outputs. It therefore contains twenty numerical rows. This number is not the domain of the law. Classes whose natural output remains an operator, a spectrum, an orbit, or a multisection appear subsequently with that complete object, without filling their column with the external reference. The experimental inventory of 471 masses and 384 widths is preserved in full as a state-by-state comparison; its cardinality is not passed off as a census of HMT predictions.

92.12.3 Individual evaluation of 20 material sections and traceability of their metrological coordinates

92.12.3.1 Electron–positron pair: central route, leaf conjugation, and mass character

- **Catalog identifier:** SM-LC-1.
- **Descriptor type:** basal selector and bidirectional readers.
- **Designator:** selecting pair (-22,+15); K_D=K_Ω=(80,54,6).
- **Stage:** bidirectional beta; initial coordinate 0.510998922488066073 MeV/c^2.
- **Evaluation HMT–MD reproducible:** 0.510998950690000809 MeV/c^2.
- **Mathematical nature:** closed beta coordinate in the central fiber.
- **Subsequent reference:** 0.51099895069±0.00000000016 MeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S003:S003M:332838; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level not preserved in the documentary snapshot.
- **Relative difference:** 1.582406884×10^{-9} ppm.
- **Scope:** closed scalar derivation.

92.12.3.2 Muon–antimuon pair: route conjugation and leptonic character

- **Catalog identifier:** SM-LC-2.
- **Descriptor type:** complete signature $\sigma \in Z^5$.
- **Descriptor record:** (42,-3,8,0,2).
- **Stage:** beta E3 tower; initial coordinate 105.56405901285926472 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 105.658360294435829303 MeV/c^2.
- **Mathematical nature:** E3 refinement conditioned on the signature.
- **Subsequent reference:** 105.6583755±0.0000023 MeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S004:S004M: 332849; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level not preserved in the documentary snapshot.
- **Relative difference:** -0.14391253 ppm.
- **Scope:** exact evaluation once the signature is fixed; the physical selection of that signature constitutes an independent operation.

92.12.3.3 Par tau–antitau: route conjugation and leptonic character

- **Catalog identifier:** SM-LC-3.
- **Descriptor type:** complete signature $\sigma \in Z^5$.
- **Descriptor tuple:** (64,0,25,-1,6).
- **Stage:** E3 beta tower; initial coordinate 1771.945393886234110148 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 1776.860917631432295595 MeV/c^2.
- **Mathematical nature:** E3 refinement conditioned on the signature.
- **Subsequent reference:** 1776.9324651340901 MeV/c^2 (central value used; rounded presentation: 1776.93±0.09 MeV/c^2).
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S035:S035M: 332893; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level not preserved in the documentary snapshot.
- **Relative difference:** -40.264615601 ppm.
- **Scope:** exact evaluation once the signature is fixed; the physical selection of that signature constitutes an independent operation.

92.12.3.4 Quark sectors u and antiquark sectors $\bar{u}$

- **Catalogue identifier:** SM-Q-U1.
- **Descriptor type:** angular coindexation (n_A,s_C)$\in Z^2$.
- **Descriptor tuple:** (11,7).
- **Stage:** conditioned angular chart; initial coordinate 2.165924536173907663 MeV/c^2.
- **Evaluation HMT–MD reproducible:** 2.165924536173907663 MeV/c^2.

- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.
- **Subsequent reference:** 2.16±0.07 MeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q002:Q002M: 333588; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; 90% confidence level.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.5 Quark sectors d and antiquark sectors $\bar{d}$

- **Identificador catalografico:** SM-Q-D1.
- **Descriptor type:** angular coindexation (n_A,s_C)∈Z^2.
- **Descriptor record:** (17,8).
- **Stage:** conditioned angular chart; initial coordinate 4.679550162948874172 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 4.679550162948874172 MeV/c^2.
- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.
- **Subsequent reference:** 4.70±0.07 MeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q001:Q001M: 333589; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level 90%.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.6 Up quark and antiup quark

- **Catalog identifier:** SM-Q-U2.
- **Descriptor type:** angular coindexation (n_A,s_C)∈Z^2.
- **Descriptor value:** (61,8).
- **Stage:** conditioned angular chart; initial coordinate 1270.500838641911135286 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 1270.500838641911135286 MeV/c^2.
- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.
- **Posterior reference:** 1.2729±0.0045 GeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q004:Q004M: 333604; scheme not retained in the documentary snapshot; scale not retained in the documentary snapshot; confidence level 90%.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.7 Strange quark and strange antiquark

- **Catalog identifier:** SM-Q-D2.
- **Descriptor type:** angular coindexation (n_A,s_C)∈Z^2.
- **Descriptor entry:** (41,-3).
- **Stage:** conditioned angular chart; initial coordinate 92.940093907845640641 MeV/c^2.
- **Evaluation HMT–MD reproducible:** 92.940093907845640641 MeV/c^2.
- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.
- **Subsequent reference:** 92.9 ±0.7 MeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q003:Q003M:333590; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; 90% confidence level.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.8 Top quark and anti-top quark

- **Catalog identifier:** SM-Q-U3.
- **Descriptor type:** angular coindexation (n_A,s_C)∈Z^2.
- **Descriptor record:** (100,-1).
- **Stage:** conditioned angular chart; initial coordinate 172597.479544019136261367 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 172597.479544019136261367 MeV/c^2.
- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.
- **Subsequent reference:** 172.60±0.27 GeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q007:Q007TP:333614; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level not preserved in the documentary snapshot.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.9 Quark background and antiquark background

- **Catalog identifier:** SM-Q-D3.
- **Descriptor type:** angular coindexation (n_A,s_C)∈Z^2.
- **Descriptor tuple:** (71,-5).
- **Stage:** conditioned angular chart; initial coordinate 4190.119763299790218075 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 4190.119763299790218075 MeV/c^2.
- **Mathematical nature:** angular chart; no Z^5 signature nor E3 refinement has been declared.

- **Posterior reference:** 4.186±0.006 GeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:Q005:Q005M:333611; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level 90%.
- **Relative difference:** — ppm.
- **Scope:** conditioned evaluation; the signature has not been chosen from the compared value; external scheme and scale required for the residual.

92.12.3.10 Reproducible spectral descriptor of the photon: null sector, helicity, and electromagnetic character

- **Catalogue identifier:** SM-GA-EM.
- **Descriptor type:** null sectorial invariant.
- **Descriptor:** null chart.
- **Stage:** null chart; initial coordinate 0 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 0 MeV/c^2.
- **Mathematical nature:** exact null output.
- **Subsequent reference:** $<1\times10^{-18}$ eV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S000:S000M:332461; scheme not preserved in the documentary snapshot; scale not preserved in the documentary snapshot; confidence level not preserved in the documentary snapshot.
- **Relative difference:** — ppm.
- **Scope:** exact in the null sector; the external bound is not interpreted as a positive mass.
- **Bound photonic:** reference externa ilustrativa not comparable; the cut identifies the observable but not preserves the level of confidence.

92.12.3.11 Realization of the gluon as a section of the adjoint representation of $SU(3)$

- **Catalogue identifier:** SM-GA-GL.
- **Descriptor type:** null sectorial invariant.
- **Descriptor:** null chart.
- **Stage:** null chart; initial coordinate 0 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 0 MeV/c^2.
- **Mathematical nature:** exact null output.
- **Referencia posterior:** —.
- **External identity and metrology:** source not stated; observable not individualized; scheme not stated; scale not stated; confidence level not stated.
- **Relative difference:** — ppm.
- **Scope:** exact in the null sector; nullity belongs to the color gauge chart.

92.12.3.12 Bosons W^+ and W^-

- **Catalog identifier:** SM-GA-W.
- **Descriptor type:** complete signature $\sigma \in Z^5$.
- **Descriptor tuple:** (94,-1,0,-2,4).
- **Stage:** E3 beta tower; initial coordinate 80381.592550220666304144 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 80378.964909704547024865 MeV/c^2.
- **Mathematical nature:** E3 refinement conditioned on the signature.
- **Posterior reference:** 80.3625 ±0.0077 GeV/c^2.
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S043:S043M: 332464; scheme not retained in the documentary snapshot; scale not retained in the documentary snapshot; confidence level not retained in the documentary snapshot.
- **Relative difference:** 204.882995235 ppm.
- **Scope:** exact evaluation once the signature is fixed; the physical selection of that signature constitutes an independent operation.
- **Resonant convention:** the external cut does not jointly fix pole convention, Breit–Wigner or on-shell convention, width, and covariance; the residual is interpreted only as scalar information.

92.12.3.13 Reproducible spectral descriptor of the Z^0 boson: neutral mixing, polarization, and electroweak character

- **Catalog identifier:** SM-GA-Z.
- **Descriptor type:** complete signature $\sigma \in Z^5$.
- **Descriptor tuple:** (95,-1,-11,0,-4).
- **Stage:** beta tower E3; initial coordinate 91299.748286598170117317 MeV/c^2.
- **Reproducible HMT–MD evaluation:** 91187.533444313407844855 MeV/c^2.
- **Mathematical nature:** E3 refinement conditioned on the signature.
- **Subsequent reference:** 91.187873297221344 GeV/c^2 (central value used; rounded presentation: 91.1879±0.0020 GeV/c^2).
- **External identity and metrology:** Particle Data Group (PDG); PDG2026:observable:S044:S044M: 332513; scheme not retained in the documentary snapshot; scale not retained in the documentary snapshot; confidence level not retained in the documentary snapshot.
- **Relative difference:** -3.72695289 ppm.
