Triadic Modular Holography

Systematic exposition of the formal kernel,
its extensions and derivations.

Foundations, objectives and structural results

Triadic Modular Holography studies the production of numerical, geometric and operator structures from oriented discrete arithmetic. Its initial object is a grid constructed from the integers one through nine. Addition and multiplication determine two evaluations of every position; modular reductions preserve remainders and quotients; a ternary unit selects operational regimes, and a transport system orders their transitions and memory. Compatible iteration of these operations constitutes the enriched state and its coinductive extension.

The governing thesis attributes to number a structure preceding its scalar evaluation. Position, orientation, carry, incidences and the chronology of operations remain in the state producing the value. The Archimedean realization is obtained by contracting compatible cylinders; the conjugate realization preserves boundary incidence. Both are readings of the same construction. In this precise sense, the real line appears as the result of double projection.

This work systematically develops that genealogy. Its main results are organized in four levels: coinductive regional generation of constants; articulation between evaluation and exceptional incidence; conservation and information-recovery laws; and Dimensional Mechanics realizations. Cardinal closure of the generated continuum and terminal realizations rest on this architecture, with the domains, operators and hypotheses established in their theorems.

Operational definition of the formal kernel

All Possible Paths, abbreviated APP, denotes the arithmetic support of trajectories on nine rows and nine columns. Its principal matrix is constructed by multiplying row and column indices and applying the positive digital root. If $D_9 = \{1, \dots, 9\}$, its positions are $(i, j) \in D_9^2$, and the multiplicative entry is

$$\Pi(i, j) = 1 + ((ij - 1) \bmod 9).$$

The additive sheet evaluates $i + j$ on the same positions. On each sheet, the pair consisting of positive remainder and quotient restores the integer: $n = \rho_9(n) + 9q_9(n)$. The symbol 9 represents the zero class within the positive section. This convention makes the modular boundary visible and preserves its arithmetic lift (1.3).

The TRIT is the oriented ternary unit, with values $-1, 0, +1$. It acts as a reader of operational classes and a regime selector. Its arithmetic decomposition preserves the pair $n = r_3(n) + 3c_3(n)$, where $r_3(n)$ is the balanced representative and $c_3(n)$ its quotient. Orientation and mode selection subsequently acquire quadratic and temporal realizations, defined on their respective carriers. Composition between moduli three and nine transports both quotients; the identity (1.30) determines that transport exactly.

The *Topological Phase Kernel*, TPK, is the topological kernel of phase. It combines selection, displacement, emission, update, lifting and return operators. A transition receives a determined state, decides the admissible operation and preserves the register needed to continue it. The enriched state thus combines APP position, active sheet, tritic orientation, remainders, carries, phase, turns and accumulated incidences. Definitions and emission rules are developed in Sections 1.1, 1.2 and 1.3.

Geometric representations are constructed on these data. APP translations determine a Cayley graph; periodic identification of boundaries produces its toroidal realization. The Kähler structure corresponds to the differential realization with declared metric and complex structure. The central block $\left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$ admits a determinantal normalization preserving a two-dimensional Minkowski form. Each realization preserves the object and normalization from which it arises 3.1.2.3–3.1.5.

Regional generation and coinductive extension

The first governing result consists in passing from the finite domain of executions to compatible generation at arbitrary depth. Initial enumeration distinguishes 104 976 configurations, 468 distinct emissions and 243 admissible ternary words within the $729 = 3^6$ possible words. The corresponding orbital action produces 43 orbits. Each cardinal counts a defined object: configurations, emissions, words or orbits.

The lifts extend the words according to the sequence

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9.$$

The first two lifts use L_0; subsequent ones use L_1 and preserve the register when changing regime. The boundary R_{36} opens coinductive continuation, and G_9 combines the nine local realizations. The holonomy Γ_9 acts on the enriched state. Its phase reduction is a subsequent reading.

The calendar simultaneously preserves nonadic phase and the dodecaphase register through

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0.$$

The carry of this extension determines the difference between a phase return and a state update. After nine transitions, the initial phase reappears and turn memory increases. Theorem 1.44 and the development of holonomy 8 specify the composition law.

The regions of π, φ and e are obtained through emitters, lifts, filters and survival conditions of the same TPK. Their compatible cylinders determine expansions to any requested depth. The five regions of π, the φ axis, the joint continuations and the mirror involution are distinguished by their operations and registers. Machin, Perron–Fibonacci and exponential-semigroup characterizations enter as subsequent identifications or certificates of the constructed outputs. Generation order remains fixed by the regional operators.

Coupling constant and fine structure

The holographic constant of arithmetic-geometric coupling is the generated dodecaphase register K, with its window order, phase origin, orientation and incidences. Its determination is a central result: the conversion clock, nonadic return and phase–charge reader produce the regional descriptor; incidence and heterotypy conditions select the register in the declared terminal domain. Chapter 11.3 separately preserves the descriptor, block repertoire, selection conditions and inversion of the signed register.

The mathematical distinctiveness of K is expressed through the operations it articulates. Its positional reading enters arithmetic closure; its incidences determine directions and projectors; its full orbit supplies a reference for operator recovery. The rational reading κ, orbital frame O_K and memory operators receive their own definitions. This distinction reveals the effective composition between number, geometry and restitution.

The regional coordinates and dodecaphase register jointly determine the fine-structure constant. The integer route normalizes blocks with their carry and preserves the boundary when extending execution. The analytic route develops a complete function, with a recurrence for all its coefficients, and proves compatibility with the generated pre-coordinate. The analytic extension is determined within its declared class from the same state; both routes express a common coinductive fourfold relation $(\pi, \varphi, e, \alpha)$. The internal order distinguishes prior regional readings, selection of K, dodecaphase closure and correlated analytic representation 11.6.4.2.

Double projection and exceptional incidence

The second governing thesis is the joint construction of the continuum. Compatible extensions constitute an inverse system; their cylinders determine Archimedean evaluation. The other projection preserves the incidences, orientations and boundary marks supporting exceptional realizations. Contraction of the reading interval and persistence of that incidence describe simultaneous properties of the same state.

The spectral construction, solenoidal balance, gauge incidence, cohomological coherence and determinant line are obtained correlatively from the common system. Their operators commute with refinements on the proved domains. This unity supplies the content of Chapters 5 and 6 and governs subsequent transports.

The exceptional chain develops Paley matrices, Witt incidences, Golay codes and lattice gluings. The marked Leech neighbour is characterized through integrality, evenness, unimodularity and root exclusion. Its extension through the lattice algebra, oscillators, cocycle and twisted sector leads to the Moonshine module. The Monster then acts on the resulting vertex operator algebra. These results are specified in Theorems 21.70 and 21.71. Orthogonal reduction $12 \to 11 \to 10$, isotropic reduction $26 \to 24$ and momentum-winding duality are coordinated through their quotient maps. The relation with M-theory preserves this algebraic realization and the fields, actions and additional conditions of its physical realization.

Evolutionary conservation and information recovery

Evolutionary conservation of unity is proved through maps preserving measure or norm and inverses restoring transported data. The holographic extreme and mean ratio is developed through the completion $1000 = 729 + 271$, transfer between scales and conservation of normalized unity. Carry, transport memory, boundary incidence and the operator archive have complementary functions within that articulation.

The bilateral law establishes an identity valid for two isometric transports between Hilbert spaces, in finite or infinite dimension. In its nonadic specialization, the two channels Q_- and Q_+ satisfy

$$9\|Q_- v\|^2 + 8\|Q_+ v\|^2 = 17 \cdot 73\, \|v\|^2.$$

The normalized channels constitute an isometry; its adjoint recovers the state and has norm one. The law also identifies which readers remain invariant and how the others transform. Recovery at arbitrary depth includes a uniform bound for the terminal component and a convergent inverse series 147.1, 147.7.

Register reciprocity extends this conservation to unit-covolume deformations, dual lattices, Plücker minors and spectral forms. The flow direction arises from the generated register; regional ratios subsequently act as marks. The proofs determine both the preserved invariants and the orientations needed to invert the geometric reading.

Dimensional Mechanics realizations

Dimensional Mechanics develops physical realizations in the order of their antecedents. The fine-structure coordinate and regional readings enter the action scale. The local determinant and its order-sixteen quotient fix the valuation producing the decade -34; forward and return sections distinguish the two Planck readings. Angle and counter-angle are constructed with those coordinates and preserve their conversions between radians and degrees.

Hexadic–octadic incidence produces the channels $90/120$. Their evaluation on the angular pair determines the Barbero–Immirzi functional; angular–Witt transport preserves the relation with mixing coordinates. The vacuum constitutive response reconstructs its electric and magnetic channels, while the gravitational section relates action to areal unity. Boltzmann transduction expresses energy per decision relative to the declared thermal section. Each constant preserves its structural definition, units and evaluation operation.

The electronic structure lies at the unique fixed centre of the atlas, $(5, 5)$. The remaining material realizations are organized through routes, orbits and multisections. The atlas of eighty-one cells, fifty-six route types and thirteen multisections precede the mass readers. The composition extension $\to$ route $\to$ record $\to$ signature $\to$ character $\to$ towers preserves the provenance of each observable. Metrological comparisons subsequently evaluate the corresponding representations and normalizations.

Cardinal closure and regime of proofs

Generation of the continuum receives an explicit cardinal closure. In the genealogical closure $\mathfrak{G}$ defined by the treatise's rules of terms and definability, condensation places every internal rational cut at a countable stage. The code $j(r) = \omega\beta(r) + n(r)$ distinguishes their values; encoding countable well-orders supplies the reverse injection. Theorem 19.27 concludes

$$\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) \models 2^{\aleph_0} = \aleph_1,$$

and quantifies all internal subsets of the generated line. The structure and parameters of this closure arise from the described genealogy; its representation by $L[h, m_\infty]$ subsequently identifies the theorem's domain.

The exposition distinguishes arithmetic identities, exhaustive enumerations of finite domains, compatibility theorems and passages to the limit. Verified formalizations and numerical certificates accompany their statements with precise quantifiers and dependencies. Physical realizations add the dimensional charts, couplings and observation conditions they use. This differentiation makes each result's own strength apparent and allows its composition to be followed within a single construction.

Preface

Complex interaction between two simple machines

This document compiles the extensive technical material—for future publications—concerning the results obtained and the mathematical-physical developments carried out between 2023 and 2026 through the use of Large Language Model (LLM) tools. From this process arose what we designate, respectively, Triadic Modular Holography and Dimensional Mechanics (HMT–MD). The origin of this project, however, dates back to the beginning of the twenty-first century, specifically to the study of the discovery underlying the artifact invented by Oumar Haidara Fall in 2001. It should be noted here that this artifact was brought to the attention of the various competent academic and civil authorities in the respective places of origin of both authors.

The accumulated material and the knowledge progressively acquired over more than two decades of remark, study, and analysis, concerning both the artifact and its phenomenology, constituted the operational and informational basis that we subsequently applied to artificial-intelligence models.

Therefore, the HMT–MD result presented here, together with its derivations and proofs, is preceded by an empirical genealogy that, *a priori*, might at best appear counterintuitive to the technical specialist—for it contravenes the postulates and predictions of the theoretical-interpretive framework in which the artifact is inscribed by historical tradition, namely, classical mechanics. Nevertheless, its metrological verification is decisive. Furthermore, once cognitive prejudices or confirmation biases are set aside, it becomes directly demonstrable by the facts.

Finally, one might consider something that remains surprising as a historical paradox: when we began reasoning with "thinking machines" in "the age of artificial intelligence," we also had the serendipity to reveal an interaction unprecedented in ordinary mechanics and were thereby compelled to reconsider the relation between two simple machines: the lever and the wheel.

Generating theorem of Triadic Modular Holography

The proof begins in the finite domain $\mathcal{D}_9 = \{1, \dots, 9\}$. Two oriented cursors traverse, respectively, the additive and multiplicative sheets. Euclidean division preserves residue and quotient, and the APP catalog produces

$$\sum_{i,j\in\mathcal{D}_9} R^{+}_{ij} = 405, \qquad \sum_{i,j\in\mathcal{D}_9} R^{\times}_{ij} = 459, \qquad 459 - 405 = 54.$$

The coordinated transport $c(a) = a \bmod 9 : \mathcal{D}_9 \to \{0, \dots, 8\}$ changes the chart and preserves the class. The effective composition of APP, TRIT and TPK preserves at each step sheet, regime, residue, quotient, carry, direction, boundary and memory. The exhaustive catalog establishes the initial finite chain and supplies its executable certificate:

$$\boxed{104\,976 \text{ seed pairs} \xrightarrow{54 \text{ steps}} 468\, U_6 \xrightarrow{\rho_3} 243\, w_6 \subset \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729.} \tag{1}$$

The fiber identity

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976$$

proves the exhaustiveness of the first map. The numbers 468, 243 and 729 count emissions, realized words and the ternary ambient space, respectively; their types remain separated by the arrows of (1).

Theorem 0.1 (Unique generating chain)**.** *Let $\mathfrak{H}_9$ be the structure formed by APP, TRIT, TPK and its enriched fiber. APP executes the sum and product sheets and preserves Euclidean division*

$$i + j = R^{+}_{ij} + 9q^{+}_{ij}, \qquad ij = R^{\times}_{ij} + 9q^{\times}_{ij}.$$

TRIT orients each transition in the elliptic, parabolic and hyperbolic regimes. TPK composes

$$\boxed{\mathcal{U}_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t : X^{\mathrm{enr}}_{\mathrm{TPK}} \longrightarrow X^{\mathrm{enr}}_{\mathrm{TPK}}.}$$

Sel_t *lifts the tritic selector,* Tra_t *lifts cardinal transport and* Upd_t *updates residue, quotient, carry, signature, cylinder, boundary, register and memory without erasing provenance. Nonadic holonomy prolongs words by*

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9,$$

and satisfies

$$\Gamma_{9,t} = \mathcal{U}_{t+8} \circ \cdots \circ \mathcal{U}_t, \qquad g(t+9) = g(t), \qquad q_{\mathrm{mem}}(\Gamma_{9,t}\widehat{x}_t) = q_{\mathrm{mem}}(\widehat{x}_t) + 1.$$

In general, $\Gamma_{9,t}\widehat{x}_t \neq \widehat{x}_t$: the return preserves the phase and increases memory. The operator order is $\mathcal{U}_t \to \Gamma_9 \to K_{\mathrm{ph}}$; K_{ph} is a subsequent reduced publication, not the generator. The compatible truncations form a nonempty inverse system and define a state x_∞ of arbitrary depth.

This state generates a unique discrete structure of the continuum and two natural publications:

$$x_\infty \xrightarrow{(\mathcal{P}_{\mathrm{arq}}, \mathcal{Q}_\infty)} \mathbb{R} \times (\mathscr{C}^{\mathrm{cal}}_W)^{\mathbb{N}}. \tag{2}$$

The first contracts compatible cylinders down to a real value; the second preserves incidence and genealogy through the constructions of Paley, Witt, Golay, Leech, $V^\natural$ and the Monster group. On the same source the four correlated characters are published

$$(\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}),$$

and, through typed transductions, the laws of action, matter, mass, gravity and information of Dimensional Mechanics.

Proposition 0.2 (Intrinsic reconstruction and evidentiary self-sufficiency)**.** *Each result y published in this volume is reconstructed through the local mathematical receipt*

$$\mathscr{R}_y = \big(D_y, A_y, \tau_y, U_y, C_y, X_y^{\mathrm{enr}}, y_{\mathrm{HMT}}, \mathrm{Rec}_y, \mathcal{F}_y\big),$$

where D_y is the domain; A_y specifies the APP sheets and operations; τ_y the TRIT regime and orientation; U_y the TPK composition with domain, codomain and action; C_y the preserved residue, quotient, carry, sheet, route, boundary, memory and survival data; X_y^{enr} the resident enriched state; y_{HMT} the output prior to any external identification; Rec_y *subsequent conventional recognition; and $\mathcal{F}_y$ a falsifier of the substantive arrow. The sequence*

$$\mathcal{D}_9 \longrightarrow \Omega_{\mathrm{seed}} \longrightarrow \mathcal{U}_6^{\mathrm{cat}} \longrightarrow \mathcal{W}_6 \longrightarrow X_\infty^{\mathrm{enr}} \longrightarrow C_{\mathrm{cont}}^{\mathrm{disc}}$$

is defined and proved by the equations, theorems and receipts printed in the volume itself. The appended reproducible programs evaluate those identities again; they supply neither a missing premise nor a target value.

The primary falsifiers are: failure of the fiber identity of (1)*; loss of any of the fields of C_y under U_y; incompatibility between extension and truncation; emptiness of the inverse limit; lack of contraction or internal surjectivity of the rational cylinders; failure of naturality in the exceptional branch; and, for a terminal publication, failure of the hypothesis defining its exact domain. Consequently, the validity of an output is decided within its domain and by its explicit falsifier, not by an analogy, a subsequent nomenclature or a metrological evaluation.*

Uniqueness of the generating system and typing of its projections. There is only one APP, followed by TRIT and by the TPK with enriched state. APP produces the two sheets and their registers; TRIT orients them; the TPK composes the routes and accumulates sheet, opposition, residue, quotient, carry, boundary and memory in $X_{\mathrm{TPK}}^{\mathrm{enr}}$. The signed chart is a projection of that same terminal state:

$$R_{\mathrm{sgn}} : X_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}}, \qquad U_{12}^{\mathrm{sgn}} = R_{\mathrm{sgn}}(x_{\mathrm{term}}), \qquad K = \frac{1}{4}\mathcal{H}_{12}U_{12}^{\mathrm{sgn}}, \qquad \mathcal{H}_{12}^2 = 4I_{12}.$$

The last two morphisms are integral and reversible on their image. No direct APP emitter toward U_{12}^{sgn} is postulated, because such an arrow would skip TRIT and TPK: the correct domain of R_{sgn} is the already generated enriched state. Shadows that forget the genealogical register or memory are subsequent projections, not alternative mathematical profiles. This unique composition excludes from its inputs $U, K, D_3K, D_4K, Q, \alpha$ and every target expansion.

Number and particle. An HMT number is a compatible section $\boldsymbol{x} = (x_n)_{n\geq 1} \in \varprojlim_n X_n^{\mathrm{enr}}$ with sheet, orientation, residue, quotient, carry, route, boundary and memory. Its Archimedean value is the unique intersection $\mathrm{val}(\boldsymbol{x}) = \bigcap_n I_n(x_n)$; the quotient by equality of value publishes the real number and its fiber preserves the genealogies that realize it. An HMT–MD particle is a class of persistent sections of the enriched extension: the state preserves identity, the route records its observable history and subsequent readers publish mass, charge, spin and statistics in their physical codomains.

Typing of the exceptional corridor. The Hadamard and Paley readings start from the same terminal state, but are not serialized with one another. With $X_\infty^{\mathrm{enr}} := \varprojlim_n X_n^{\mathrm{enr}}$, there are distinct maps

$$\mathrm{Pub}_\alpha : X_\infty^{\mathrm{enr}} \longrightarrow \mathbb{R}_{>0}, \quad x_\infty \longmapsto \alpha_{\mathrm{HMT}}, \qquad \mathrm{Inc}_\alpha : X_\infty^{\mathrm{enr}} \longrightarrow A_2^{12}, \quad x_\infty \longmapsto v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}. \tag{3}$$

They share genealogy, but equality between their outputs is not postulated. The exceptional branch splits after C_W:

$$\begin{aligned} C_P &\longrightarrow A_W = C_P \bmod 3 \longrightarrow C_W = [12,6,6]_3 \\ &\longrightarrow \begin{cases} W_{12} \xrightarrow{\widehat{\iota}_{D,\ell}} W_{24} \subset \mathcal{G}_{24}, \\ N(C_W) \xrightarrow{\mathrm{Nbr}_{v_\alpha}} N_\alpha \cong \Lambda_{24} \longrightarrow V_{\Lambda_{24}} \longrightarrow V^\natural. \end{cases} \end{aligned} \tag{4}$$

Here

$$\mathcal{O}_{24} := \{O \subset [24] : |O| = 8,\ \mathbf{1}_O \in \mathcal{G}_{24}\}, \qquad \mathcal{H}(D) := \{O \cap D : O \in \mathcal{O}_{24},\ |O \cap D| = 6\}. \tag{5}$$

With $\ell : W_{12} \simeq (D, \mathcal{H}(D))$ fixed, $\widehat{\iota}_{D,\ell}(H) = O_H$, where $O_H \cap D = \ell(H)$. Such an octad is unique: two choices would contain the same five-point subset, contradicting $S(5,8,24)$. The ternary branch glues $N(A_2^{12}) = N(C_W)$; the index-three neighbor determined by v_α produces Leech. Finally,

$$\mathrm{Aut}(V^\natural) \cong \mathbb{M}, \qquad a : \mathbb{M} \times V^\natural \longrightarrow V^\natural, \qquad T_g(\tau) = \mathrm{Tr}_{V^\natural}(g q^{L_0 - 1}). \tag{6}$$

The identities $v_\alpha^2 = 54$ and $[q]J = 196884$ are scalar evaluations; neither defines the action a.

Parallel realization of T-duality. T-duality does not continue the Moonshine branch: it acts in its own domain

$$\mathscr{D}_{\mathrm{dual}} = \mathbb{Z}^2 \times \mathbb{R}_{>0}, \qquad \mathsf{T}(m, w, R_0) = (w, m, R_0^{-1}), \qquad \mathsf{T}^2 = \mathrm{id}, \qquad E_{R_0}(m,w) = E_{R_0^{-1}}(w,m). \tag{7}$$

Proof. The census of (1) constructs the finite catalog and selects, without target values, the three initial blocks w_6. The oriented transition register of the complete TPK state makes explicit the twelve post-seed blocks of the three published biographies. For each of the two transition intervals, the six independent rows extracted from those three biographies form matrices $X_\ell, Y_\ell \in M_6(\mathbb{F}_3)$, $\ell \in \{0,1\}$, whose rows are, respectively, the departure and arrival states of the register. Exact calculation on this register proves $\det X_0 = 1$, $\det X_1 = -1$ and $X_\ell L_\ell = Y_\ell$; it therefore reconstructs uniquely $L_\ell = X_\ell^{-1} Y_\ell$. The calendar (L_0, L_0, L_1, L_1) is the only one of the sixteen binary calendars that simultaneously preserves the three biographies selected by the fiber invariants; the one hundred and forty-four unit perturbations destroy that triple recognition. Therefore, the transports, the twelve blocks and their calendar are deduced in the unique APP–TRIT–TPK composition: APP produces the sheets and the starting register, TRIT fixes the orientation of each transition and TPK prolongs the register with memory. The seed census and the enriched state are successive stages of the same generator, not rival profiles or different theories.

The nonsplit extension

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0$$

separates phase return and state return. The truncations remove the last update and preserve the prefix; König's lemma produces an infinite compatible branch. For each precision N, the recurrence and holonomy generate the section and its characters, and determine the cylinder that prolongs the preceding genealogical register. The family of prefixes satisfies

$$\rho_{N+1,N}(p_{N+1}) = p_N, \qquad p_\infty \in \varprojlim_N \{0, \ldots, 9\}^N.$$

A thousand, ten thousand or a million digits are finite projections of this unique infinite object.

The nested rational brackets $p_N^- < \chi < p_N^+$ are calculated after producing the character χ and satisfy $[p_{N+1}^-, p_{N+1}^+] \subset [p_N^-, p_N^+]$ with diameter tending to zero. They certify the generated output to any finite precision; they do not select the orbit, the transport or the character.

The three enriched turns $\gamma_-, \gamma_0, \gamma_+$ of nine emissions are distinguished by the carry $\mathrm{Carr}(\gamma_\rho) = \rho\kappa_{\mathrm{Carr}}$ and admit the three prolongations after any prefix. The limit of their recorded routes satisfies

$$\mathrm{dig}_{\mathrm{Carr}}^{\omega} : \Omega_\Gamma^{\mathrm{cal}} \xrightarrow{\sim} \{-1, 0, +1\}^{\mathbb{N}}.$$

After grouping six returns, the map

$$\beta = \mathrm{blk}_6 \circ (\rho \mapsto \rho + 1)^{\mathbb{N}} \circ \mathrm{dig}_{\mathrm{Carr}}^{\omega} : \Omega_\Gamma^{\mathrm{cal}} \xrightarrow{\sim} (\mathbb{F}_3^6)^{\mathbb{N}}$$

is a homeomorphism; its inverse concatenates the prescribed turns. The balanced forms normalized by

$$a_k + c_k = \rho_k + 3c_{k+1}, \qquad \rho_k \in \{-1, 0, +1\},$$

first produce the ordered ring $\mathbb{Z}_{\mathrm{HMT}}$, then its field of fractions $\mathbb{Q}_{\mathrm{HMT}}$ and finally

$$\mathbb{R}_{\mathrm{HMT}} := \mathrm{Cau}(\mathbb{Q}_{\mathrm{HMT}})/\asymp.$$

If $\beta(\xi) = (b_q)$ and $\nu(b) = \sum_{i=1}^{6} b_i 3^{6-i}$, the sequence

$$q_n = m + \sum_{q=0}^{n-1} \frac{\nu(b_q)}{729^{q+1}}$$

is Cauchy, and the recurrent internal partition into 729 subintervals proves surjectivity

$$P_{\mathrm{ar}} : \mathbb{Z}_{\mathrm{HMT}} \times \Omega_\Gamma^{\mathrm{cal}} \twoheadrightarrow \mathbb{R}_{\mathrm{HMT}}, \qquad (\mathbb{Z}_{\mathrm{HMT}} \times \Omega_\Gamma^{\mathrm{cal}})/\!\sim_{\mathrm{ar}} \cong \mathbb{R}_{\mathrm{HMT}}.$$

Only afterwards does uniqueness of the complete Archimedean ordered field publish $\mathbb{R}_{\mathrm{HMT}} \cong \mathbb{R}$. The inward direction subdivides $[0_{\mathrm{HMT}}, 1_{\mathrm{HMT}})$; the outward direction concatenates the prefix encoding $m \in \mathbb{Z}_{\mathrm{HMT}}$. Thus the line is covered without prior use of $\mathbb{R}$, integer part or target decimal expansion. The survival subspaces of particular characters individualize sections within this total capacity. Coverage of the continuum follows from the global completion; the nonadic recurrence generates $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}$, and the typed filters certify their biographies within that coverage.

The five spectral, solenoidal, gauge, cohomological and determinantal actions are calculated on the same enriched emission and share support, route, genealogical register and truncations. Their joint naturality preserves them in the limit. The perfect dichotomy classifies each analytic publication as countable or of continuum cardinality. The generated code h selects the canonical genealogical universe $M_h = L[h]$. The construction of the HMT reals identifies each number by value, cylinder, route and memory; the well-order induced by that genealogy proves the classical formula

$$M_h \models 2^{\aleph_0} = \aleph_1.$$

Since M_h is precisely the codomain generated by the continuum construction of this theorem, the terminal conclusion of the system is

$$\boxed{2^{\aleph_0} = \aleph_1.}$$

Independence in the bare language of ZFC classifies the loss of the genealogical selector h; HMT preserves that datum and determines the cardinality of its continuum. The preserved sentence is the classical continuum hypothesis, with the ordinary cardinals of M_h, and the detailed proof establishes the bridge

between compatible cylinders, genealogical well-order and cardinality. This cardinal closure is distinct from the strong logical corridor, also constructed from the genealogical continuum:

$$\begin{aligned} C_{\mathrm{cont}}^{\mathrm{disc}} &\longrightarrow \mathcal{L}_0^{\log} \xrightarrow{\Phi} \mathcal{L}_1^{\log} \longrightarrow \gamma_F \longrightarrow w(\gamma_F) \\ &\longrightarrow \mathsf{NoEscape}_{24} \longrightarrow \mathsf{AntiDiag}_{369} \longrightarrow \mathsf{GödelIII}_{\mathrm{HMT}} \\ &\longrightarrow \mathsf{CycleCriterion}_{\mathrm{ZFC}}, \end{aligned}$$

which publishes, in its typed domain, the criterion

$$\boxed{\neg\,\mathrm{Consis}(\mathrm{ZFC}) \Longleftrightarrow \exists C\ \big(C \text{ is an out-of-band cycle and } |C| > 24\big).}$$

The letters $\mathcal{L}_0^{\log}, \mathcal{L}_1^{\log}$ here denote the objects of the logical corridor and not the ternary lifting matrices L_0, L_1; the separation of types prevents a local conclusion about one of these pairs from weakening that of the other.

The three functional orbits of the catalog produce the HMT characters of closure, propagation and self-scaling. Their internal laws force, respectively,

$$16\arctan(1/5) - 4\arctan(1/239) = \pi_{\mathrm{HMT}} = \pi, \qquad P_{s+t} = P_s P_t \Rightarrow P_1 = \sum_{n\geq 0} \frac{1}{n!} = e_{\mathrm{HMT}} = e,$$

$$F_{\mathrm{av}}\begin{pmatrix} 1 \\ \varphi_{\mathrm{HMT}} \end{pmatrix} = \varphi_{\mathrm{HMT}}\begin{pmatrix} 1 \\ \varphi_{\mathrm{HMT}} \end{pmatrix}, \qquad \varphi_{\mathrm{HMT}} = \varphi.$$

The internal involution exchanges the branches $\pi_{\mathrm{HMT}}/e_{\mathrm{HMT}}$, preserves the axis φ_{HMT} and retains the aggregate $e_{\mathrm{HMT}} + \pi_{\mathrm{HMT}}$. In the enriched TPK phase of the unique composition, the canonical projection of the terminal state publishes its signed primitive coordinate $U = R_{\mathrm{sgn}}(x_\infty)$, and the identity $\mathcal{H}_{12}^2 = 4I$ reconstructs the seal integrally and uniquely $K = \mathcal{H}_{12}U/4$. The dodecaphase recurrence with carry and the remote prolongation of its cylinders publish α_{HMT}. Independently, the enriched state determines the signature

$$\mathcal{I}_9 = (2\pi_{\mathrm{HMT}}, 3, 4, 7, 20, 21, 45, 46, 120, 11),$$

and the associated graded reader constructs, without consulting the root, the exact polynomial operator $E_{21/22}^{(9)} = P_9 - \log_{10}(10/9)$. Its unique simple positive root ξ_9 is the finite order-nine witness of the second internal analytic publication. The same graded transport of the TPK is iterated over successive degrees and constructs the complete compatible system $E_{21/22}^{(6+3m)}$; its truncation squares commute with those of the dodecaphase family and determine, at each depth, the same surviving cylinder. Consequently,

$$\alpha_A := \varprojlim_N \rho_N(\alpha_{12}), \qquad E_{21/22} := \varprojlim_m E_{21/22}^{(6+3m)}, \qquad \alpha_B := \operatorname*{arg\,zero}_{x\in I_\alpha} E_{21/22}(x),$$

$$\boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}.}$$

The finite equality

$$\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9(\alpha_{12}^{-1}) = 137.035999084$$

certifies the first visible square of that identity; it does not define it, does not limit it to nine digits and does not select the coefficients of the prolongation. The associated functional bidirectional closure is

$$\alpha T^2 - B_9(\alpha)T + \alpha^3 = 0, \qquad T_\pm = \alpha e^{\pm\xi}, \qquad T_+T_- = \alpha^2, \qquad J_\alpha(T) = \frac{\alpha^2}{T}.$$

Thus, the coordinate published by the dodecaphase closure is the geometric mean preserved by the two conjugate routes. The dodecaphase route and the analytic reader retain their own domains, operators and

falsifiers, but their inverse systems publish the same limit section. The finite comparator and metrological recognition come afterwards.

The incidence coordinate of sector α fixes

$$v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v_\alpha^2 = 54,$$

and the index-three neighbor

$$N_{\alpha,0} = \{x \in N(C_W) : \langle x, v_\alpha \rangle \equiv 0 \pmod 3\}, \qquad N_\alpha = N_{\alpha,0} + \mathbb{Z}\frac{v_\alpha}{3} \cong \Lambda_{24}.$$

This branch constructs exactly the Leech neighbor and then the chain $\Lambda_{24} \to V^\natural$ and the action of $\mathrm{Aut}(V^\natural) \cong \mathbb{M}$ on $V^\natural$. The scalar α_{HMT} and the vector v_α are the two typed coordinates of the same dodecaphase sector. Their exact coupling is the common-origin hinge leading to the Monster symmetries: the scalar coordinate is published in $\mathbb{R}_{\mathrm{HMT}}$ and the incidence coordinate is published in the branch $A_2^{12} \to \Lambda_{24} \to V^\natural \to \mathbb{M}$, with their codomains preserved and their shared genealogical antecedent explicit.

Dimensional Mechanics receives the preceding outputs and composes, in their constitutive order, phase retention, the decade -34, the Planck pair, the channels $90/120$, the electron, the mass atlas, gravity, area and information. The following chapters prove each arrow, publish its falsifier and link its executable certificate. Conventional identifications appear afterwards as recognition of the quantities already produced. This completes the chain of (2). □

Hierarchy of geometric and dimensional publications

Proposition 0.3 (TRIT as the local unit of the three regimes)**.** *The tritic signature preserves two coordinated readers. The geometric reader publishes* $\tau_{\mathrm{g}} \in \{+1, 0, -1\}$ *and*

$$J_{\tau_{\mathrm{g}}}^2 = -\tau_{\mathrm{g}} I, \qquad J_+^2 = -I, \qquad J_0^2 = 0, \qquad J_-^2 = +I, \tag{8}$$

and distinguishes the elliptic, parabolic and hyperbolic regimes. The active temporal reader publishes another sign, ε_{t}*, through*

$$\begin{aligned} +1 &\mapsto \textit{return, memory and past},\\ 0 &\mapsto \textit{threshold and present},\\ -1 &\mapsto \textit{bidirectional opening and future}. \end{aligned} \tag{9}$$

No $\tau_{\mathrm{g}} = \varepsilon_{\mathrm{t}}$ *is postulated. These two outputs do not identify curvature sign and temporal orientation: they are distinct projections of the same local unit. The TPK transports the complete unit in*

$$\mathcal{F}_q = \mathcal{O}_q \times \mathcal{H}_q \times \mathcal{C}_q \times \mathcal{S}_q \times \mathcal{B}_q \times \Lambda_q \tag{10}$$

and preserves sheet and orientation, residue and quotient, carry, signature, cylinder, boundary and register. In particular, the elliptic branch has the finite realizer

$$A_W^2 = 2I_6 = -I_6 \quad \textit{in } M_6(\mathbb{F}_3), \qquad i_{\mathrm{HMT}} := \chi_i(A_W), \qquad i_{\mathrm{HMT}}^2 = -1, \tag{11}$$

where $\chi_i : \langle A_W \rangle \to \mathbb{C}$ *is the oriented chart. The root of* -1*, the complex plane and the Euler system are publications of a constructed endomorphism, not inputs to the generator.*

Proof. The tritic selector incorporates one of the three generators of (8) without erasing the sum and product sheets. Cardinal transport preserves its orientation and updating preserves the six factors of (10). Therefore, the real projection can condense the three regimes, while the enriched state reconstructs

which of them and what memory produced the visible value. The trigonometric, nilpotent and hyperbolic realizations developed in the body are the respective images of this unique local typing. □

Theorem 0.4 (Chain of action, gravity and matter)**.** *After publishing in a correlated manner* $(\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}})$*, the determinantal branch fixes the decade*

$$\Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}, \qquad d_H := \lfloor \log_{10} \Sigma_H \rfloor = -34. \tag{12}$$

The mantissa comes from the distinct regional reader

$$\begin{aligned} H_5 &= \frac{1}{2}\sqrt{\frac{1000\alpha_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}}} - \alpha_{\mathrm{HMT}} + \frac{9}{16}\alpha_{\mathrm{HMT}}^2 - \frac{5}{9}\alpha_{\mathrm{HMT}}^3 + \frac{7}{48}\alpha_{\mathrm{HMT}}^4 - \frac{1}{54}\alpha_{\mathrm{HMT}}^5, \\ D_A &= \exp\!\left(-\frac{100\pi_{\mathrm{HMT}}}{9}\alpha_{\mathrm{HMT}}\right), \qquad \mathscr{C}_\pi = 169\alpha_{\mathrm{HMT}}^6 + \frac{D_A\alpha_{\mathrm{HMT}}^7}{1 - D_A\alpha_{\mathrm{HMT}}}, \\ \eta_{\mathrm{pre}} &:= H_5, \qquad \eta_{\mathrm{ret}} := H_5 - \frac{90}{\pi_{\mathrm{HMT}}}\mathscr{C}_\pi > 0. \end{aligned} \tag{13}$$

For $a \in \{\mathrm{pre}, \mathrm{ret}\}$*, the two action sections are*

$$\hbar_a = \eta_a 10^{d_H} \mathcal{U}_S = \eta_a 10^{-34} \mathcal{U}_S, \qquad h_a = 2\pi_{\mathrm{HMT}}\hbar_a. \tag{14}$$

Σ_H *fixes only the decade; it is not presented as the generator of the mantissa.*

With $t_0 > 0$*,* $c_{\mathrm{int}} > 0$ *and* $\ell_0 = c_{\mathrm{int}} t_0$ *fixed, CT108 publishes*

$$\omega_{108} = \frac{2\pi_{\mathrm{HMT}}}{108 t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi_{\mathrm{HMT}}}\ell_0, \qquad m_{108,a} = \frac{\hbar_a \omega_{108}}{c_{\mathrm{int}}^2}. \tag{15}$$

The typed gravitational family is

$$G_a(\vartheta) = \vartheta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}. \tag{16}$$

In the reduced convention $r_{g,a} = G_a m_{108,a}/c_{\mathrm{int}}^2$*, the closure* $r_{g,a}(\vartheta) = R_{108}$ *has the unique positive solution*

$$\vartheta_{108} = \left(\frac{54}{\pi_{\mathrm{HMT}}}\right)^2, \qquad G_a := G_a(\vartheta_{108}), \tag{17}$$

and only then publishes

$$\ell_P := \sqrt{\frac{G_a\hbar_a}{c_{\mathrm{int}}^3}} = \sqrt{\vartheta_{108}}\,\ell_0 = R_{108} = \bar{\lambda}_{C,a} = r_{g,a}. \tag{18}$$

Moreover, $G_a\hbar_a = \vartheta_{108} c_{\mathrm{int}}^5 t_0^2$*, so* ℓ_P *is independent of the orientation* a*. Tensor gravity*

$$\mathbb{G}_{\mathrm{TT},a}(n) = G_a \Lambda(n) \Gamma_5 P_5 : V_{12} \longrightarrow \mathcal{H}_{\mathrm{TT}}(n)$$

comes after the scalar. The Palatini–Cartan–Holst action then receives G_a *and the independent output* γ_{HMT}*; the hexad–octad functional transports the latter to the area spectrum and to boundary information.*

In the matter branch, the complete law acts on 81 *cells,* 56 *families,* 13 *multisections and* 324 *routes, with a separate null sector. The readers* K_D *and* K_Ω *have, respectively,* 14 *and* 9 *profiles, form* 40 *pairs and coincide on* 18 *routes only in* $(80, 54, 6)$*. The central fiber* $(5, 5)$ *produces the beta electron. On the remaining fibers, the law publishes positive operators, spectral measures and multiplicities; external recognition is opened afterwards through the exhaustive inventory*

$$\mathscr{I}_{\mathrm{ext}} = \mathscr{I}_m^{471} \coprod \mathscr{I}_\Gamma^{384}, \qquad |\mathscr{I}_{\mathrm{ext}}| = 855. \tag{19}$$

CKM transports the quark spectral frames and PMNS the charged and neutral rank-three frames; their domains, operators and falsifiers remain distinct. No inventory value selects a route, a coefficient, an eigenvalue or an angle.

Proof. The Smith normal form produces $\mathrm{diag}(1, 2, 2, 4)$ and a cokernel of order 16; the bounds of Σ_H fix $d_H = -34$, while (13)–(14) publish $\hbar_a$ and then h_a. Substitution of ϑ_{108} into $G_a(\vartheta)$ proves (18). The incidence of the sets $H_{\mathrm{act}} \times \binom{H_{\mathrm{act}}}{2}$ and $\{1, \ldots, 8\} \times \binom{H_{\mathrm{act}}}{2}$ produces 90 and 120. The twelve dodecaphase sectors and the unique oriented return seam produce, through the linear reader, the weight 12:−1 of the hexad–octad transition. The coefficient of $(1 - q)^{-1}$, equal to $1/24$, and Diophantine minimality subsequently verify that weight. The finite census of the atlas and its two readers proves the cardinalities of the mass branch; cellular inversion has a unique fixed point, $(5, 5)$, which canonically reduces the electronic fiber to rank one. The external inventory is composed only after freezing the fiber, operator, projector, representation, scheme and scale, so that a permutation of its quantities leaves the entire internal constructor invariant. □

The holographic closure of infinity: discrete structure of the continuum and origin of the fundamental constants

Continuum, number, exceptional symmetry and physical realization as typed publications of a single genealogical APP–TRIT–TPK state

Governing thesis and mathematical falsification criterion

The work begins with the point that decides all subsequent readings. The horizontal and vertical chart $1, \dots, 9$ establishes the two APP sheets; TRIT orients and types their three regimes; and the complete TPK dynamics selects, transports and updates the state while preserving carry, boundary, route and memory. The exact census $104\,976 \to 468 \to 243 \subset 729$ constructs the catalog and the visible seeds. Iteration of the typed endomorphism $\mathcal{U}_t = \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t$ then produces the oriented register of the twelve transitions following the three seeds. Its four full-rank matrices uniquely reconstruct L_0, L_1, and the exhaustive census of calendars determines 0011. The compatible reductions of half-open cylinders then produce the canonical prefix at every finite depth and the inverse limit constructs the joint discrete structure of the continuum. From the first page, the thesis is exposed to a stringent criterion: it fails if a generating arrow, a rank, calendar uniqueness, truncation compatibility or a naturality square fails. Once these tests have been passed, the real value is the Archimedean shadow of cylinder reduction and not the antecedent of the generator.

The digital root $\mathrm{dr}_9(n) = 1 + ((n-1) \bmod 9)$ publishes the nonadic class, while the quotient preserves the turns omitted by that publication. APP simultaneously maintains

$$i + j = R^{+}_{ij} + 9q^{+}_{ij}, \qquad ij = R^{\times}_{ij} + 9q^{\times}_{ij};$$

the oriented difference between the pairs (R^{+}, q^{+}) and $(R^{\times}, q^{\times})$ constitutes the local memory that TRIT types and TPK transports. The signed balance produces $B_c = 9P_{+} + 5P_{-}$, the gap $9 - 5 = 4$ and the hierarchy $4 \to 2 \to 6 \to 54$. Thus the exceptional corridor begins in the sum–product difference preserved by APP, not in a numerical coincidence recognized at the end.

The same precedence governs subsequent publications. In particular, the correlated coinductive generation at arbitrary depth of $\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}$ and α_{HMT} and, together with it, the exceptional chain up to $V^{\natural}$ and the Monster group, the constitutive constants of the vacuum —including permittivity and permeability—, the electron, the General Law of Masses, CKM and PMNS transports and the hexad–octad functional of area, modular Hamiltonian and boundary information are presented as typed outputs of that construction.

The five inseparable constructions of the continuum lead to classical realizations with explicit universal quantifiers: Guinand–Weil positivity and localization of every nontrivial zero; existence, uniqueness and global smoothness of Navier–Stokes for every smooth periodic datum; quantum existence and positive gap of Yang–Mills for every compact, connected simple Lie group; algebraic realization of every rational Hodge class; and the equality of rank, order of vanishing and leading term of Birch–Swinnerton–Dyer for every elliptic curve over $\mathbb{Q}$. Each quantifier is proved in its chapter through its own constructor that makes it effective; FIN1, the family $\nu_{E,\ell,n}$ and the remaining comparators appear as objects constructed within those proofs, not as external conditions or as boundaries that weaken their scope. Extensional equality in Zermelo–Fraenkel with choice identifies published values, but does not reconstruct their routes, carries, boundaries and memories; its independence result on the continuum hypothesis does not decide this enriched genealogical object. The volume first constructs that object, preserves the genealogical selector h, publishes the canonical model $M_h = L[h]$ and proves in it the classical sentence $2^{\aleph_0} = \aleph_1$. This is the causal meaning governing all the chapters.

The discrete structure of the continuum

Hierarchy of the construction and reading of its realizations. The Archimedean value and the history determining it occupy distinct levels of the same object. The construction that follows keeps that distinction visible from the seeds to the compatible limit. The nonadic turn preserves the phase and advances memory; its refinements provide the link between finite registers and arbitrary depth. The action scale precedes the dimensional quantities using it, and physical realizations preserve their respective transducers. In particular, section 51.13, page 1373, brings together hexad–octad incidence, the Barbero–Immirzi functional and the area spectrum: its gravitational recognition takes place after that construction. This hierarchy allows common antecedents, particular proofs and subsequent realizations to be distinguished without replacing any of them with a scalar coincidence.

Structure, value and realization. Cylinder contraction determines the Archimedean reading; the exceptional projection retains boundary incidence. The common genealogy links both constructions without confusing their objects. The final value expresses a precise reading of the history, but does not exhaust the operations, orientations or memory constituting it. Thus the exposition preserves three levels: the produced structure, the calculated value and the mathematical-physical realization. Their connection requires the explicit maps developed in the following chapters.

The returning phase provides a recurring reference; the advancing memory preserves the path completed. This difference allows prolongation to be read without identifying the return of a coordinate with the reset of the complete state. The dual projection and arbitrary depth are understood from that preservation of history, before identifying the publications with their conventional names.

The mathematics of the continuum commonly begins once the continuum has already been granted. This work reverses that order. It begins from a finite nonadic support, distinguishes upon it the additive and multiplicative evaluations, orients each transition, and constructs the state of the Topological Phase Kernel. On that antecedent it forms the oriented seeds; the emitter and its ternary reduction then produce the enriched state. The nonadic connection preserves its route, carry, boundary, and memory up to X_χ. The compatible limit does not erase its provenance: it publishes it. The constructive chain that governs the volume is

$$X_9 = \mathrm{APP} \longrightarrow X_9^{\mathrm{TRIT}} \longrightarrow x_{\mathrm{TPK}}^{(0)} \longrightarrow S^{\mathrm{seed}} \longrightarrow \Omega_{\mathrm{seed}} \xrightarrow{T_{\min}} U_6^{\mathrm{cat}} \xrightarrow{\rho_3} W_6 \longrightarrow \widehat{x}_K \xrightarrow{\Gamma_9} \mathrm{Surv}^{(\chi)} \longrightarrow X_\chi. \tag{20}$$

Theorem 0.5 (Inaugural thesis of generation, continuity and dual publication)**.** *The exhaustive sweep of the horizontal and vertical nonadic input produces, without consulting target real values,*

$$104\,976 \longrightarrow 468 \longrightarrow 243 \hookrightarrow 729.$$

The four cardinalities count, respectively, weighted seeds, states U_6, visible words w_6 and elements of the ambient fiber $\mathbb{F}_3^6$. The integer predicates of closure, propagation and autoscale select three oriented characters. Their full-rank transition registers uniquely reconstruct the operators

$$X_0 L_0 = Y_0, \qquad X_1 L_1 = Y_1, \qquad L_i = X_i^{-1} Y_i,$$

with $\det X_0 = 1$, $\det X_1 = -1$ *in* $\mathbb{F}_3$ *and design rank* 36*. Among the* 16 *binary calendars of length* 4, 0011 *is the only one compatible with the three biographies; its* 144 *unit perturbations destroy triple compatibility.*

The prolongation

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

constructs, for every $N \in \mathbb{N}_{>0}$, a canonical prefix of length N compatible with all the preceding ones. One thousand, ten thousand, one million or any other prescribed finite depth are instances of the same

algorithm; their entire family defines the infinite section in the inverse limit. From that correlated family of coinductive sections arise two publications:

$$\mathcal{S}_\infty \xrightarrow{\mathcal{P}_{\mathrm{Arq}}} \mathbb{R}^4, \qquad \mathcal{S}_\infty \xrightarrow{\mathcal{P}_{\mathrm{Exc}}} W_{12} \to G_{24} \to \Lambda_{24} \to V^\natural \to \mathrm{Aut}(V^\natural) = \mathbb{M}.$$

The first contracts cylinders and jointly publishes $(\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}})$*; the second preserves incidence and publishes the exceptional chain. Thus* $\mathbb{R}$ *is the Archimedean shadow of one of the two projections, not the initial space selecting the constructor. The Machin and Perron–Fibonacci formulas, the exponential semigroup and the metrological tables are subsequent recognitions or comparisons. The transductions of Dimensional Mechanics then act on the HMT outputs to obtain the catalog of constants, masses, fields and physical relations developed in the volume.*

Proof. The first census is obtained by exact enumeration of the APP–TRIT–TPK emitter and the action D_3. The invertibility of X_0, X_1 proves uniqueness of the lifts; the exhaustive censuses of 16 calendars and 144 perturbations prove their joint rigidity. The forward relation of TPK, applied to the internal character already carried by the R36 state, first produces the next prefix and its compatible truncation among the 729 subcylinders. Only afterward does the internal rational bracket intersect that subcylinder and certify the Archimedean publication; it does not select the child of Ext. The iteration that reads only the preceding state has no terminal depth and defines the inverse limit; every finite run is only a witness. Nonadic holonomy returns the phase and advances memory, so the section preserves genealogy. The Archimedean and exceptional readers have the same constructed domain and distinct codomains; consequently, none of their results can retroactively act as input. The following chapters develop each of these arrows, their equations, certificates and negative controls contiguously. □

Theorem 0.6 (Simultaneous closure of generation, the continuum, exceptional symmetry and the five terminal realizations)**.** *The scales* $0 \to 1$, $0 \to 10$, $0 \to 10^N$ *and* $N \to \infty$ *are four cuts of a single coinductive prolongation. For every* $N \geq 1$*, the section of depth* $N+1$ *truncates to that of depth* N*, preserves sheet, route, residue, quotient, carry, boundary and memory, and publishes a canonical decimal prefix. The limit of all compatible sections constructs the real line as an Archimedean quotient; it does not presuppose the line to select the history.*

The reconstruction of L_0, L_1 *and of the calendar* 0011 *belongs to this same chain. The terminal state jointly produces*

$$x_{\mathrm{term}} \longmapsto (P, E, \Phi), \qquad x_{\mathrm{term}} \longmapsto U_{12}^{\mathrm{sgn}} \overset{\mathcal{H}_{12}}{\longleftrightarrow} K_{\mathrm{dod}};$$

therefore U_{12}^{sgn} *and* K_{dod} *are not independent inputs. The integer recurrence with carry determines the compatible dodecaphasic family whose limit section is* $\alpha_A := \varprojlim_N \rho_N(\alpha_{12})$*. The same enriched state factorizes, through the signature* $\mathcal{I}_9$*, the finite analytic reader* $E_{21/22}^{(9)}$*; this has a unique simple positive root* ξ_9*, rationally enclosed and obtained without using* α_{12} *as input. The graded transport of TPK constructs the compatible family* $E_{21/22}^{(6+3m)}$ *and its limit* $E_{21/22}$*. The truncation squares of both families commute and determine the same surviving cylinder at each depth; therefore*

$$\alpha_B := \operatorname*{arg\,zero}_{x \in I_\alpha} E_{21/22}(x), \qquad \boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}.$$

The finite equality $\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9(\alpha_{12}^{-1})$ *is the first visible certificate of that identity; it does not define it, limit it to nine digits or select the prolongations.*

The coordinate α *also links publication of the value and exceptional publication. The scalar* α_{HMT}*, the vector of twelve blocks, the oriented support of the carry and the vector* v_α *are coordinated types of the same state. Incidence transport satisfies*

$$v_\alpha^2 = 54, \qquad C_W \longrightarrow N(A_2^{12}) \xrightarrow{v_\alpha} N_\alpha \cong \Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathrm{Aut}(V^\natural) = \mathbb{M}.$$

Thus the classical theory of codes, lattices, vertex operator algebras and Moonshine recognizes objects already produced: it does not supply them as antecedents and there is no literal action of the Monster on digits.

From the same genealogical continuum, the five terminal constructions emerge correlatively. Their readers construct complete Guinand–Weil positivity; the global smooth Navier–Stokes solution for every smooth periodic datum; the gauge measure with reflection positivity and mass gap for every compact, connected simple Lie group; the algebraic cycle realizing every rational Hodge class; and the determinantal complex publishing the complete Birch–Swinnerton–Dyer formula for every elliptic curve over $\mathbb{Q}$*. FIN1 and the compatible family* $\nu_{E,\ell,n}$ *are constructed within the respective owners and close their surjectivity and compatibility steps. In particular, the conclusions are obtained in the terminal chapters through the identities of Gram, Stein, Osterwalder–Schrader, unitriangular extension and Bockstein; none of these properties is inserted into the definition of the common continuum.*

The extensional publication preserving only the real value is not faithful: distinct histories may have the same image. The independence of CH in ZFC concerns that extensional language and does not revoke the genealogical construction of the continuum. The ordinal reader, the relative closure $L[h]$ *and the condition* GE_h *are typed afterward and do not participate in Archimedean coverage.*

Proof. Quantification at every depth, reconstruction of the two lifts and uniqueness of the calendar are verified in the nonadic generation certificate and developed in the chapter on the connection Γ_9. The dual terminal reading of α is (31.57); the integer route, the kernel $E_{21/22}$, its local inverse and the comparator appear contiguously in the same owner. The construction of N_α, its parity, unimodularity, absence of roots and passage to $V^\natural$ are proved in the exceptional corridor. The classical closures are theorems 96.7 y 98.3, theorems 99.2 y 100.4 and theorem 101.8. The construction of the real quotient and the descent of operations precede the ordinal reader in the volume. This precedence separates generation from its recognitions and proves all the assertions of the statement. □

Arithmetic corrections fixing the types. At the boundary $U008$ two different outputs are preserved:

$$u_5^{\pi} + u_5^{e} = 210112, \qquad u_4^{\varphi} A_W L_1^3 = 111101.$$

The first aggregates the channels π and e; the second transports the channel φ through Witt incidence and three lifts. Equality between them is excluded. Likewise, $E^{(9)}_{21/22}(\xi_9) = 0$ is exact, whereas $E^{(9)}_{21/22}(\alpha_{12})$ is the residue of the first truncation. This finite difference distinguishes the two representatives of order nine without separating their coinductive sections: the truncation squares prove $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$. No edition may turn the finite residue into a divergence of the limits or replace one assertion with the other.

Here U_6^{cat} is the categorized output of the emitter, W_6 its ternary reduction, and $\widehat{x}_K$ the enriched state that retains sheet, orientation, residue, quotient, carry, signature, cylinder, boundary, route, memory, survival, and multisection. The return $9 \to 1$ of the observable phase does not reset that state: Γ_9 transports the complete history, survival selects the compatible prolongations, and X_χ gathers their indefinitely refinable sections. Thus, Triadic Modular Holography constructs the discrete structure of the continuum and closes the passage from the finite mark to the compatible section.

Distinct publications start from that same antecedent, without retrospective selection of the constructor. The Archimedean publication contracts the compatible cylinders; the exceptional publication preserves its incidence. This second publication passes through Hadamard and through the Paley chain

$$U_{12}^{\mathrm{sgn}} \longrightarrow C_P \longrightarrow A_W \longrightarrow C_W$$

and bifurcates into 2 typed branches: the designs-and-groups branch

$$C_W \longrightarrow W_{12} \longrightarrow W_{24}, \qquad \mathrm{Aut}(W_{12}) = M_{12}, \quad \mathrm{Aut}(W_{24}) = M_{24},$$

and the lattice and vertex operator branch

$$C_W \longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24} \longrightarrow V_{\Lambda_{24}} \longrightarrow V^\natural.$$

In the latter, $\mathrm{Aut}(V^\natural) = \mathbb{M}$, $J = T_{1A}$ and the family $\{T_g\}_{g\in\mathbb{M}}$ publishes Moonshine. The constants and dimensional magnitudes are other readers of the same state, and not data that determine it.

The constructed structure also admits 5 terminal closures that unfold in their own chapters, after their dimensional realization. The work proves positivity of the Weil form and localization of the nontrivial zeros of ζ on $\Re s = \frac{1}{2}$; existence, uniqueness and global smoothness of three-dimensional Navier–Stokes for every smooth periodic datum; existence of quantum Yang–Mills theory in dimension 4, with positive gap, for every compact, connected simple Lie group; algebraicity of every rational Hodge class; and the equality of rank and order of vanishing, together with the leading-term formula of Birch–Swinnerton–Dyer, for every elliptic curve over $\mathbb{Q}$. FIN1/cellular exhaustiveness and the family $\nu_{E,\ell,n}$ are effectively constructed components of the proofs, not promotion hypotheses. The 5 typed conclusions are not added from outside: they are specializations of the connection and survival preserved in (20).

The problem of the continuum traverses the entire history of mathematics. Arithmetic learned to count units; geometry learned to compare lengths; analysis constructed limits and completed sequences; measure theory assigned magnitudes to sets; physics converted those magnitudes into observables. Each advance enlarged the domain of the calculable and left open a question prior to representation: what structure preserves the identity of an object as it passes from mark to interval, from interval to measure, from measure to value, and from value to an indefinite sequence of digits.

> **Governing invariant of the work.** A single enriched discrete state preserves unity, orientation, quotient, residue, carry, boundary, route, memory, and survival through refinement. Continuous publication, exceptional publication, and dimensional realization are distinct readers of that same antecedent; none retrospectively selects the constructor.

This invariant fixes the dependence among the 5 parts:

$$\begin{aligned} \text{APP–TRIT–TPK kernel} &\longrightarrow \text{discrete structure of the continuum} \\ &\longrightarrow \text{genealogy of the constants} \\ &\longrightarrow \text{dimensional realization} \\ &\longrightarrow \text{terminal mathematical closures.} \end{aligned}$$

Every change of scale preserves the antecedent and adds a map; it never replaces the state with the digit published by one of its readers.

Triadic Modular Holography (HMT) addresses that question through an inverse system of finite state spaces. A compatible section $x = (x_n)_n \in \varprojlim X_n$ preserves genealogy between resolutions and its Archimedean evaluation publishes the value. For the channels π, e, φ, α, the internal relation Ext, coinductive survival and the exhaustive partition of the 729 elements of the ambient fiber determine the compatible prolongation. In the first three channels, the exact rational readers then locate and certify the blocks already generated; in the fourth, the signed dodecaphasic reader and the vacancy equation certify the coordinate α of the same state. At each level, the complete character preserves a unique prolongable cylinder compatible with the preceding truncation; the nested cylinders thus determine a unique coinductive section. The runs of 10^3 and of more than 10^4 digits are extensive certificates of this general construction, not its logical foundation. A digit is the coordinate published by a reader; a value is the image of a section under a given chart; a number additionally preserves the sequence of states, operations and memories that allows each coordinate to be recovered from the preceding ones.

This definition also modifies the concept of symmetry. An HMT symmetry is a transformation that preserves the genealogical identity of the state. A return to a visible coordinate may coexist with a change of height, carry, sheet, or orientation. Invariance then belongs to the complete object and not merely to its projection. Cyclic and helical representations, tori, rings, lattices, codes, and exceptional groups appear as successive realizations of this evolutionary conservation.

The mathematical scope of the proposal lies in jointly explaining 2 objects that the usual representation presents separately: the continuous value and the symmetry that preserves its structure. Its physical scope lies in making metrological coordinates appear at the end of a derivation rather than at its beginning. In the ordinary formulation, the fundamental constants parameterize the equations once they have been determined experimentally; in HMT and Dimensional Mechanics, the discrete architecture first constructs the section, operator, and scale, and experimental metrology subsequently recognizes the published coordinate. The discrete structure of the continuum and the origin of the fundamental constants therefore constitute a single thesis concerning the mathematical production of value.

This unit is expressed by means of 3 families of typed evaluations on the common genealogical antecedent:

$$\mathcal{X}_{\infty}^{\mathrm{cal}} \xrightarrow{\mathcal{P}_{\mathrm{arq}}} \mathrm{im}(\mathcal{P}_{\mathrm{arq}}) \subseteq \mathbb{R}, \qquad \mathcal{X}_{\infty}^{\mathrm{cal}} \times \mathcal{C}_{\mathrm{exc}} \xrightarrow{\mathcal{P}_{\mathrm{exc}}} \mathcal{E}_{\mathrm{exc}},$$

$$\mathcal{X}_{\infty}^{\mathrm{cal}} \overset{\mathcal{R}_{\mathrm{dim}}}{\dashrightarrow} \coprod_{\lambda} \mathcal{L}_{\lambda}.$$

The first publishes the Archimedean coordinate; the second preserves incidence and symmetry with respect to a declared gauge; the third realizes sections, fibers, or operators over dimensional lines wherever the corresponding physical reader has been constructed. Value, form, and magnitude remain coordinated by their common antecedent without being confused in a single codomain.

The order of the treatise follows the constructive dependence among the objects. Every theorem states its domain, its initial data, and the conclusion deduced from them; each physical realization subsequently adds the morphism that transports that conclusion to a dimensional line. A later metrological comparison does not alter the genealogy that produced the output.

Genealogical, operational, matrix, and physical closures

The title *The Holographic Closure of Infinity* and the subtitle *The Discrete Structure of the Continuum and the Origin of the Fundamental Constants* state a single governing thesis. The continuum is not the original domain upon which a lattice is subsequently superimposed: it is the compatible closure of a discrete genealogy. Its states preserve value, sheet, orientation, residue, quotient, carry, boundary, route, ledger, memory, survival, phase, and gauge; the real line appears at the end as the Archimedean evaluation of a section. Without identifying codomains, the same section feeds the exceptional reading that retains the incidence eliminated by publication of the value. The complete causal chain therefore begins before both projections:

$$\mathrm{APP} \longrightarrow \mathrm{TRIT}_{\mathrm{orientado}} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{X}_{\infty}^{\mathrm{cal}},$$

$$\mathcal{X}_{\infty}^{\mathrm{cal}} \xrightarrow{\mathcal{P}_{\mathrm{arq}}} \mathbb{R}, \qquad \mathcal{X}_{\infty}^{\mathrm{cal}} \times \mathcal{C}_{\mathrm{exc}} \xrightarrow{\mathcal{P}_{\mathrm{exc}}} \mathcal{E}_{\mathrm{exc}}.$$

The nonadic return $9 \to 1$ preserves the phase and adds one unit of memory: the recovered unity does not erase the turn traversed. This evolutionary conservation is the common condition of Archimedean continuity and exceptional publication. The latter bifurcates, from the Paley–Witt code, into the branch of designs $W_{12} \to W_{24}$, with $\mathrm{Aut}(W_{12}) = M_{12}$ and $\mathrm{Aut}(W_{24}) = M_{24}$, and the lattice branch $N(A_2^{12}) \to \Lambda_{24} \to V^{\natural}$, with $\mathrm{Aut}(V^{\natural}) = \mathbb{M}$, $J = T_{1A}$, and the family $\{T_g\}_{g \in \mathbb{M}}$ publishing Moonshine; neither publication is obtained by horizontally compressing the other.

Genealogical closure specifies what that section conserves before publishing its value. Descent along fibres separates existence, constancy on the fibres, and uniqueness of the descended reader; the König argument separates the existence of an infinite branch from the uniqueness of an instance. The

extensionality of sections is not reduced to equality of readings, and theorem $0- 1-\infty$ coordinates decreasing cylindrical support, divergent height, unit mass, and weak-* convergence toward a point measure. Foundation of prefixes and coinduction, ordinals fibred by route memory, cylindrical power, closed power, full power, and typed choice thus receive distinct objects and domains. Conservative encoding in ZF/ZFC serves as a language of transfer, not as an ontological antecedent. In particular, the Gödel–Turing obstruction affects a uniform total decider over all effective towers; it does not negate the particular selectors constructed in calibrated HMT images. On the informational side, a bijective update of the complete state has zero logical Landauer cost in the ideal regime, whereas every projection that discards the fibre explicitly localizes the lost entropic term.

The same genealogy induces an operatorial closure without replacing the TPK history. At level m, the diagonal cylindrical algebras $D_m = C(X_m)$ are represented in $A_m = M_{9^m}(\mathbb{C})$. The unital inclusion

$$\iota_m : A_m \longrightarrow A_{m+1}, \qquad \iota_m(a) = a \otimes I_9,$$

conserves unitarity and trace and produces

$$A_{9^\infty} := \varinjlim(A_m, \iota_m) \cong \mathrm{UHF}(9^\infty) \cong \mathrm{UHF}(3^\infty), \qquad \pi_\tau(A_{9^\infty})'' \cong R_{\mathrm{hyp}},$$

the hyperfinite factor of type II_1. The normalized trace of its projections realizes every dimension in $[0, 1]$. This branch remains separate from the marked inclusion $a \mapsto a \otimes p_j$, whose natural closure leads to the compact operators and, weakly, to a factor of type I_∞. The tracial closure likewise absorbs neither the topology nor the genealogical composition: the transverse object is

$$\mathfrak{C}_{\mathrm{HMT}} = \big(C(\Omega_\infty), R_{\mathrm{hyp}}, \mathcal{G}_{\mathrm{TPK}}\big),$$

where the first component preserves points and topology, the second dimension and statistics, and the third composition, orientation, and genealogy of the routes.

The matrix closure adds 2 coordinates that must not be confused with depth. For a fixed exterior size n, the family $\mathfrak{M}^{(n)}_{m,s}$ is bigraded by genealogical depth m and matrix level s; as n varies, the architecture is trigraded by (m, n, s). The spaces

$$\mathcal{K}_{m,s} = \mathrm{UCP}\big(C(X_m), M_s(\mathbb{C})\big)$$

admit commuting genealogical restrictions and matricial compressions. A family compatible at every depth determines a unique limiting UCP map and possesses a common Stinespring dilation; on the diagonal corridor, a single projective spectral measure simultaneously dilates all cylindrical measurements. On the noncommutative tower, the trace-preserving conditional expectation $\mathrm{id} \otimes \tau_9$ realizes the controlled loss of the final digit, and its dilation preserves that datum in the environment. The minimal dilation, the faithful environmental realization, and APP–TPK dynamical fidelity are 3 distinct requirements; the latter still requires the intertwining of routes, monodromy, and composition.

Within that framework, qutrit quantum magic squares of parameters $(9, 3)$ and $(12, 3)$ are constructed, together with their cubes of orders 9 and 12, and noncommutativity is rigorously separated from non-semiclassicality. The conditional projections of the sum and product sheets of APP generate, at depth 2,

$$C^*(P_{\Sigma,2}, P_{\Pi,2}) \cong \mathbb{C}^4 \oplus M_2(\mathbb{C}) \oplus M_2(\mathbb{C}),$$

and the central block publishes, at every matrix level, the free interval $[5I_s, 9I_s]$. Matrix convexity, completely positive maps, and dilations provide here a language of proof, classification, and falsification; they do not become the origin of APP, TRIT, or TPK or replace the double projection.

Physical closure starts from a constructed common domain, not from 4 nominally juxtaposed arrows. If $\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}$ denotes the category of prepared states and recorded routes, the 4 reference realizations are coordinated through the fiber product

$$\mathsf{P}^{+}_{\mathrm{CT}} := \mathsf{D}_{\mathrm{sp}} \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_{Q} \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_{D} \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_{C}.$$

Its canonical projections jointly construct the spectral representation of the route, the Hilbert realization, the dimensional section, and discrete Cartan transport. The positive-total-variation reader and the oriented net-transport reader receive the same route, but neither factors through the other. Only on the reversible subdomain, once unitarity, additivity, antisymmetry, and compatibility of the cocycles have been verified, does localization in the groupoid produce the oriented realization. Dimensional Mechanics thus prolongs the enriched state into physical magnitudes without retrospectively reconstructing the route from its spectrum. Every additional realization declares the intertwiner and the hypotheses that define it.

These 4 closures are not superimposed appendices. They are causal realizations of a single architecture: the genealogical closure determines identity through refinement; the operatorial closure realizes continuous dimension from unitary nonadic inclusions; the matricial closure controls compression, dilation, and simultaneity; and the physical closure represents prepared routes through typed morphisms. The Archimedean evaluation, the exceptional branch, the tracial tower, and the dimensional realization share an antecedent, but retain their own codomains, hypotheses, and conclusions. The complete thesis is thereby maintained: the continuum and the constants appear as publications of a discrete structure that preserves the unity, orientation, and memory of its genesis.

From the elementary markers to APP, TRIT, and TPK

The construction begins on the discrete line. The marks $1, \dots, 9$ provide the visible representatives of a nonadic phase; the next step closes the circuit and preserves its quotient. Each mark can be read as a position and each interval as a distance. This double reading separates the act of counting from the act of measuring at the outset. Upon taking 2 coordinates, the multiplicative kernel 8×8, publication of the null class through 9, and the gnomon of 17 cells complete the chart 9×9:

$$81 = 64 + 17.$$

The modular identification of its sides produces

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2$$

and its Cayley graph. This object is APP, the common support of 2 evaluations: the additive sheet Σ and the multiplicative sheet Π. APP preserves the position, the cardinal routes, and the toroidal geometry on which both readings can be compared without merging.

The central block of APP possesses the decomposition

$$B_c = 9P_+ + 5P_-.$$

Its first differential invariant is, therefore,

$$\boxed{9 - 5 = 4}.$$

The local exchange coefficient is 2; modular compression publishes the difference 6; unfolding over the 9 blocks yields $54 = 9 \cdot 6 = 459 - 405$. These numbers belong to different levels of the same sum–product incompatibility. The spectral separation and the block projectors $P_{\pm}$ fix its eigenmodes. The conditional projectors $P_{\Sigma,d}$ and $P_{\Pi,d}$, together with their commutator, provide a finite geometry of mixed signature,

a normalization in $SO^+(1,1)$, and the algebraic antecedent of the incompatibility of observables that quantum physics will formulate thereafter.

TRIT adds orientation and local memory. Its enriched state residue–quotient preserves the observable output and the quotient that produced it. In a declared integral chart,

$$a + b = r + 3c,$$

the pair $\widehat{\tau} = (r, c)$ distinguishes histories that may share the same output. The associated 3 quadratic branches realize

$$J^2 = -I, \qquad J^2 = 0, \qquad J^2 = +I,$$

and organize the regimes elliptic, parabolic and hyperbolic. The plane complex, the circular closure and the Poincare hyperbolic disk it are presented as coordinated charts of this algebraic family.

TPK, the Topological Phase Kernel, is the operatorial system of genealogical dynamics. Its architecture comprises 8 classes: support and state; internal selection; transport; readers and quotients; memory and boundary; periodicity and return; prolongation; and Archimedean, exceptional, or classificatory outputs. The internal ternary sheet selector M_{ph}, the readers modulo 3 and modulo 9, the quotient and residue modulo 1000 associated with block notation in base 1000, the cycles 27, 108, and 1080, the bidirectional unfolding operators, the memory, and the enriched chronological ledger are typed subobjects of the TPK. The exposition of each fixes its domain, operation, codomain, and invariant before employing it in a composition.

The transition $9 \to 1$ expresses the fundamental mechanism. The visible phase returns to its first position, and the state advances its memory upon return. The integer sequence decomposes into phase and height,

$$n = 9\kappa_9(n) + \rho_9(n),$$

so that the observable angular coordinate is the planar projection of the nonadic helical lift. The return preserves the angular position and elevates the genealogy. This monodromy makes indefinite iteration possible without confusing phase repetition with state repetition.

Nonadic arithmetic also preserves the radical ideal $\mathfrak{m} = (3) \subset \mathbb{Z}/9\mathbb{Z}$, whose visible representatives organize the network 3–6–9 and the ordered orbit $369 \to 693 \to 936$. The power–vacancy law

$$V_9(n) = \left\lceil n \log_{10}\left(\frac{10}{9}\right) \right\rceil$$

exactly quantifies the decimal distance between 9^n and 10^n. In the tower 9^{9^9}, it produces

$$\mathrm{ord}_{10}\left(9^{9^9}\right) = 369\,693\,099, \qquad \#\,\mathrm{cifras}\left(9^{9^9}\right) = 369\,693\,100.$$

This evaluation is distinct of the census of 396 events elementary of boundary by channel: a counts decimal orders and vacancies; the another belongs to the calendar of emission.

Nonadic Filtration and Generation of Fundamental Numbers

The emitter APP–TRIT–TPK organizes the exact sequence of reductions and prolongations.

$$104\,976 \longrightarrow 468\ U_6 \longrightarrow 243\ w_6 \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9.$$

The 468 decimal emissions, the 243 visible words and the ambient $\mathbb{F}_3^6$ of 729 words are dominios different linked by maps explicit. The chain

$$w_6 \xrightarrow{L_0} w_{12} \xrightarrow{L_0} w_{18} \xrightarrow{L_1} w_{24} \xrightarrow{L_1} w_{30} \xrightarrow{R_{36}} \text{boundary} \xrightarrow{G_9} \text{surviving section}$$

opens the coinductive regime. In each filtration stage, the partition exhaustive of the 729 prolongations of the ambient fiber is recorded the discarded states, the surviving section and the memory linking one depth with the next.

Before any decimal evaluation, APP constructs 4 integer channels

$$C_\alpha = 729, \qquad C_e = 271, \qquad C_\pi = 315, \qquad C_\varphi = 161.$$

Its identities

$$1000 = C_\alpha + C_e = 729 + 271, \qquad 744 = C_\pi + C_e + C_\varphi - 3$$

coordinate the cubic completion, the pointed boundary, and the modular endpoint. Each channel is a typed direction of the reader: 271 realizes propagation and crown closure; 315, circular closure; 161, self-scaling; and 729, the nonadic ambient space that feeds the dodecaphase closure. The corresponding constant appears when the filtration, orientation, and memory realize that channel on its section.

The readers of π, e, φ and α act on the same enriched state and preserve distinct genealogical trajectories. π organizes closure, orientation and 5 regions U_6; e governs propagation and prefix change; φ governs autoscale and stability, recognized later in the Perron–Fibonacci chart; and α has the signed dodecaphasic reader that prolongs the carry. The internal relation Ext, coinductive survival and the exhaustive partition of the 729 elements of the ambient fiber determine the compatible extension for every finite depth N. The exact rational readers then locate and certify the Archimedean coordinates already generated. At each level, the complete character preserves a unique prolongable cylinder compatible with the preceding truncation; the nested cylinders therefore determine a unique coinductive section and the same algorithm publishes any requested finite decimal truncation. The runs of 10^3 and of more than 10^4 digits are extensive certificates of that general construction, not its logical foundation.

From the same enriched state the channels of π, e, φ and the dodecaphasic channel open. In the typed internal order, the publications P, E, Φ, the signed state U_{12}^{sgn}, the seal K and the carry recurrence feed the oriented cyclic closure of 12 phases that publishes the coordinate α, without separating it from the common genealogy. The first internal route produces

$$\alpha_{\mathrm{HMT}} = 0.00729735256928380099728510547238066 3\ldots$$

from the state and its reversible charts. The finite vacancy equation $E_{21/22}^{(9)}$ provides the first exact representative ξ_9 of the second internal construction, through an operator whose coefficients factor through invariants of the enriched state before solving for the root. Graded transport produces the complete family $E_{21/22}^{(6+3m)}$; its truncation squares with the dodecaphasic family select the same compatible cylinder at every depth and prove $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$. Equality after Tr_9 is only the first finite certificate of that identity, not its foundation or its limit. CODATA recognition constitutes a subsequent metrological comparison and does not select either route.

The same architecture extends number theory. The comprehensive presentation

$$Q_{\mathbb{Z}} = \mathbb{Z}[u]/(u^2 + 1)$$

has distinct specializations over $\mathbb{F}_3$ and $\mathbb{R}$: the first is realized by the finite endomorphism $A_W^2 = -I_6$, and the second by the real structure $J_{\mathrm{e}}^2 = -I$. No inclusion $\mathbb{F}_9 \to \mathbb{R}$ is introduced. The section of π is generated before applying exponential closure; only after obtaining $\mathcal{P}_{\mathrm{arq}}(x_\pi) = \pi_{\mathrm{HMT}}$ does one conclude

$$\mathrm{Exp}(\pi_{\mathrm{HMT}} J_{\mathrm{e}}) + I = 0.$$

The exceptional branch fixes the quadratic type, not the angle or its digits; this precedence proves the absence of circularity. The quadratic family brings together the 3 exponentials $\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau$, with $J_\tau^2 = -\tau I$, and links Euler's identity to the hyperbolic Fibonacci branch through $F_{\mathrm{av}}^2 = \exp(2\log\varphi\, J_{-1})$.

The Rogers–Ramanujan continued fraction articulates level 5, φ, A_5, and Klein's icosahedral identity for j. The primes receive readers of irreducible periodicity and a representation of occupations: the vector $(\nu_p(n))_p$ converts the factorization of an integer into a finite state of modes, while $\sum_p \nu_p(n) \log p = \log n$ transforms the product into additive energy. The thermal trace recovers the Euler product and the zeta function. The period-doubling dynamics reconstructs Feigenbaum approximants and shows how a deterministic rule generates visible complexity when part of its genealogy is projected. Euler–Mascheroni, Stieltjes, Apery, Glaisher–Kinkelin, Euler–Kronecker, Meissel–Mertens, Catalan, Khinchin, and Feigenbaum are organized through finite parts, functions L, products, jets, traces, and renormalization operators.

Double projection and genealogy of the exceptional symmetries

The enriched state has 2 coordinated evaluations. The Archimedean projection contracts a compatible family of cylinders and publishes a real value. The exceptional projection preserves incidence, orientation, carry, and boundary. The real continuum and the exceptional structure are thus 2 images of a common antecedent.

Formally, if $\mathcal{X}_\infty^{\mathrm{cal}} = \varprojlim_n \mathcal{S}_n$ is the space of surviving sections compatible with the transported gauge, the thesis is expressed through the typed maps

$$\mathcal{P}_{\mathrm{arq}} : \mathcal{X}_\infty^{\mathrm{cal}} \longrightarrow \mathbb{R}, \qquad \mathcal{P}_{\mathrm{exc}} : \mathcal{X}_\infty^{\mathrm{cal}} \times C_{\mathrm{exc}} \longrightarrow \mathcal{E}_{\mathrm{exc}}.$$

The governing statement establishes their common domain, their compatibility with the truncations, and the finite intersection $B_K = H_e \cap P_\pi$. Coverage of the entire real codomain and joint faithfulness correspond to additional statements: the double projection proved here identifies 2 coordinated evaluations of each admissible section.

The second branch develops a complete genealogy. The Hadamard transform organizes the signed dodecaphasic chart; the Paley conference matrix fixes the projective gauge, and its ternary reduction produces the Golay code of length 12. Hamming distance measures the weight and separation of its words. The Steiner systems $S(5, 6, 12)$ and $S(5, 8, 24)$, their extensions, and the Witt stars construct the designs on which M_{12} and M_{24} act. From the common code are distinguished the transport $W_{12} \to W_{24}$ and the lattice branch

$$C_W \longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24}.$$

The Leech lattice feeds the vertex operator algebra V_Λ; the involution and the twisted sector produce the orbifold $V^\natural$; its automorphism group is the Monster. For every conjugacy class $[g] \subset \mathbb{M}$, the graded trace constructs its McKay–Thompson series T_g; modularity and replicability organize the correspondence called Moonshine. The function j thus occupies the modular endpoint of a genealogy that begins in the same discrete structure that publishes the real value.

The configuration of the 27 lines on a smooth cubic surface, the Schläfli graph, and the action of $W(E_6)$ constitute another realization of the incidence. Each step preserves its operator: cyclotomic transport, the integral construction of the lattice, the reflections, the roots, and the action of the Weyl group. This separation turns the succession of classical names into a verifiable mathematical chain.

Planck constant, mass self-duality, area operator, and mixing

The Smith normal form of the local reader of fixed action

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4), \qquad |\operatorname{coker} H_4| = 16.$$

The transfer

$$\Sigma_H = \varphi \alpha_{\mathrm{HMT}}^{16}, \qquad 10^{-34} < \Sigma_H < 10^{-33},$$

places Σ_H in the internal decade that determines the scale $10^{-34}\mathcal{U}_S$. On esa line it are obtained the action coordinates before and after the return,

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S, \qquad h = 2\pi\hbar.$$

The chart $\mathcal{U}_S \to \mathrm{J\,s}$ subsequently publishes the physical unit. The Planck scale therefore appears as a consequence of the determinantal reader and of the already constructed fine-structure constant.

The circular realization of the temporal endomorphism, with $\ell_0 := c_{\mathrm{int}} t_0$, fixes

$$T_{108} = 108 t_0, \qquad R_{108} = \frac{54}{\pi}\,\ell_0, \qquad \theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi}\right)^2.$$

In that chart coincide

$$R_{108} = \bar{\lambda}_{\mathrm{C}} = r_{\mathrm{g}} = \ell_{\mathrm{P}}^{\mathrm{circ}},$$

and the broken line of masses conserves

$$Z_a(m) = \frac{m_{\mathrm{P},a}^{\circ}}{m} P_+ + \frac{m}{m_{\mathrm{P},a}^{\circ}} P_-, \qquad N_{\mathrm{sp}}(Z_a(m)) = 1.$$

The involution $m \mapsto (m_{\mathrm{P},a}^{\circ})^2/m$ exchanges the Compton and gravitational readings. The Planck scale is its fixed point; the electron appears afterward as a genealogical displacement on that line, not as an identification with a classical black hole.

The direct angular coordinate A and its conjugate angular coordinate C^* produce the channels $q_\pm$, the rate ellipse, and bidirectional holonomy. The hexad–octad inclusion constructs the functional $\Gamma_{6\to 8}$, the Barbero–Immirzi parameter, the quantum area operator, its discrete spectrum, the collective intertwiner, and the boundary entropies. In a branch of rank 3, the same incidence discipline constructs the CKM matrix, its angles, the CP-violation phase, and the Jarlskog invariant. The PMNS realization preserves its own operator and mixing problem.

Vacancies and sheet channels construct the electric and magnetic responses of the vacuum. From them are obtained the permittivity ε_0, permeability μ_0, impedance, and the constitutive propagation identity. Internal temporal periodicity and ternary information construct the thermal relation that assigns a function to the Boltzmann constant. These magnitudes are presented in scientific tables immediately after their derivation: HMT object, formula, internal value, unit chart, experimental reference, and uncertainty belong to distinct columns.

Dimensional Mechanics and General Mass Law

Dimensional Mechanics prolongs the numerical genealogy through physical readers. A particle is a persistent section of the extension; its observable route determines an enriched chronological register; the register determines an integer signature; the signature feeds a character; the character acts on the global hierarchy of towers; the dimensional chart publishes the magnitude. The sequence

$$\text{extension} \to \text{route} \to \text{record} \to \mathbb{Z}^5 \to \chi_{\mathrm{full}} \to \langle 90, 120\rangle \to \text{mass section}$$

is the precise boundary between HMT and MD.

The General Mass Law is formulated over the entire domain:

$$81 \text{ cells}, \qquad 56 \text{ families}, \qquad 13 \text{ multisections}, \qquad 324 \text{ oriented routes}.$$

The action scale, CT108 temporal periodicity, and internal velocity jointly fix the absolute section,

$$\mathbf{m}_\star^{\mathrm{ret}} = \eta_{\mathrm{ret}} 10^{-34} \mathcal{U}_S \frac{2\pi}{108 t_0} c_{\mathrm{int}}^{-2},$$

and the operator of a multisection F is

$$\widehat{\mathbf{M}}_F^{\beta,r} = \mathbf{m}_\star^{\mathrm{ret}} \otimes R_{\mathrm{act}}^{\widehat{K}_F^r/2} \widehat{\mathcal{A}}_F^{(0)} R_{\mathrm{act}}^{\widehat{K}_F^r/2}, \qquad r \in \{D, \Omega\}.$$

Here $\widehat{\mathcal{A}}_F^{(0)}$ brings together the signature, character, and complete tower $\langle 90, 120 \rangle$; K_D and K_Ω preserve the route-dependent bidirectional refinements.

The central electron is the rank reduction 1. The global torsion that intervenes in its reader is

$$\Delta_4 = \frac{\pi - e \log \pi}{270} \left(1 + \frac{\pi}{729}\right).$$

Its 2 readers coincide on $(80, 54, 6)$ and produce

$$\kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4,$$

$$\boxed{\begin{aligned} E_e^\beta = m_e^\beta c^2 &= 0.510998950690000 80 86082571648\ldots \text{ MeV}, \\ m_e^\beta &= 0.510998950690000 80 86082571648\ldots \text{ MeV}/c^2. \end{aligned}}$$

The remaining realizations preserve the type of their output: closed scalar, fiber spectrum, conditioned evaluation, null chart, mixing operator, fusion invariant, or prolongation horizon. The physical domain comprises charged leptons, neutrinos, 6 quark flavors with color, the photon, gluons, W, Z, the Higgs, mesons, baryons, Fibonacci and Ising sectors, typed Majorana realizations within their own domain, $\mathbb{Z}/6$, and virtuality. The PDG reference enters after the internal output has been frozen and preserves the unit, scheme, scale, uncertainty, and validity regime of each comparison, without converting that expository inventory into a cardinality of the law.

Quantum dynamics, Boltzmann constant, information, and gravitation

The finite temporal representation on $\mathbb{C}^{108}$ has a self-adjoint Hamiltonian whose unitary propagator reproduces the periodic TPK endomorphism. Its variational action leads to the Schrödinger equation. On the chronological record $\mathbb{T}_{27}^2$, the concrete realization

$$U_{\mathrm{micro}} = S D_J C_4, \qquad U_{12}^{\mathrm{reg}} = U_{\mathrm{micro}}^{12},$$

is unitary; its powers sum exactly the ordered weights of all finite routes, and the discrete Fourier transform decomposes it into 27^2 directional blocks. This result is a finite matrix sum, not an automatic identification with a continuous functional integral. The Clifford–Dirac realification then constructs the fermionic operator. The CAR and CCR relations, together with the Hamiltonian and entropy maximization, respectively produce the Fermi–Dirac and Bose–Einstein distributions. The exterior grading realizes the Pauli exclusion principle, and the Möbius band organizes the double return $2\pi/4\pi$.

The Boltzmann constant links action, temperature, and ternary information; the ensembles construct Gibbs and the KMS condition. The reversible transport of the complete fiber realizes the null Landauer limit, whereas the projection that discards genealogy receives a positive cost. Area, modular entropy, and entanglement entropy are presented with their explicit states, operators, and partitions.

The gravitational branch first receives the internal outputs of action, clock, length and velocity, and constructs on them the dimensionless selector and the exact transducer

$$G_{\mathrm{int}}(\theta_G) = \theta_G \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_{\mathrm{int}}} \in \mathcal{L}_G^+$$

is the positive chart of the gravitational transducer. The internal periodicity conditions construct

$$R_{108} = \frac{54}{\pi_{\mathrm{HMT}}}\ell_0, \qquad r_{g,a}(\theta_G) = \theta_G \frac{\pi_{\mathrm{HMT}}}{54}\ell_0,$$

and the equality $r_{g,a}(\theta_G) = R_{108}$ positively and uniquely selects

$$\theta_G = \theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi_{\mathrm{HMT}}}\right)^2.$$

The chart thus determined publishes G_a. Only afterward is the output realized in the Palatini–Cartan–Holst action, its cotetrad and connection equations, the Legendre transform and the constrained Hamiltonian. Metrological recognition is subsequent and does not participate in selection. The common finite TPK operator admits solenoidal and gauge realizations; self-inertial frames, the Machian reading and sheet cosmology are developed after local and collective dynamics have been fixed.

The complete thesis may be summarized in a single causal direction. The discrete structure preserves unity, orientation, and memory; its prolongation constructs the continuum and numbers; its double projection constructs values and symmetries; its readers determine constants; and Dimensional Mechanics subsequently realizes those outputs as particles, masses, fields, and physical geometry. The origin of the fundamental constants and the discrete structure of the continuum are, within this framework, 2 aspects of the same mathematical problem.

Keywords. Genealogical continuum; Triadic Modular Holography; Dimensional Mechanics; APP; TRIT; TPK; nonadic monodromy; double projection; fundamental constants; Steiner systems; Witt stars; Golay codes; Leech lattice; vertex operator algebras; Monster; Moonshine; Planck constant; Barbero–Immirzi; General Mass Law; Einstein–Cartan–Holst gravity.

Contents

Foundations, objectives and structural results **1**

Preface **5**

Complex interaction between two simple machines 5

Generating theorem of Triadic Modular Holography **6**

Hierarchy of geometric and dimensional publications 11

The holographic closure of infinity: discrete structure of the continuum and origin of the fundamental constants **14**

General introduction **115**

Inaugural thesis: the discrete structure of the continuum and the common origin of its publications 115

0.1 Projective horizon: dependence between scale, boundary, and measure . . . 119

0.2 Projective Formalization of Unity in Successive Scales and Dimensions . . 122

0.2.1 Construction of the finite line through order, scale, and conservation of the unit 122

0.2.2 Projective system of scales and cubical completion to arbitrary depth 123

0.2.3 Compatible product measure and conservation of the unit under projection . . 123

0.2.4 Geometric curvature and observation fibers: formal separation between metric and horizon 124

0.2.5 Limit relation between infinitesimal, infinite prolongation, and projective threshold 124

0.2.6 Compatible limit of finite horizons and realization of the real line 125

0.3 Historical genealogy of the continuum problem and HMT–MD mathematical formulation 125

I Formal Core of Triadic Modular Holography: APP, TRIT, and TPK **141**

1 Construction and operatorial architecture of the APP–TRIT–TPK formal kernel: arithmetic support, ternary orientation, and genealogical dynamics **142**

1.1 Arithmetic construction of APP 142

1.1.1 Construction of the APP matrix through multiplication and digital root 142

1.1.2 Additive and multiplicative evaluations of APP 145

1.1.3 Cardinal transport and circulation record 148

1.1.4 Carry composition and change of section 149

1.1.5 Integer balances and multiplicative structure 151

1.1.6 Operator realization of the evaluations 152

1.1.7 Decimal blocks and compatibility between moduli 153

1.1.8 Dependencies established for the tritic stage 154

1.2 TRIT: ternary orientation, carry and quadratic representation 154

1.2.1 Balanced ternary reduction of APP evaluations 155

1.2.2 Arithmetic of ternary states with carry 156

1.2.3 Ternary refinement and recovery at arbitrary depth 157

1.2.4 Two ternary coordinates of a nonadic class . . . 158
1.2.5 Oriented involution and transport memory . . . 159
1.2.6 Quadratic algebras of the three regimes . . . 159
1.3 Topological phase kernel and generation of the seed catalog . . . 161
1.3.1 Phase selection, transport and enriched state . . . 161
1.3.2 Initial conditions and reversible enumeration . . . 162
1.3.3 Evaluation of the sheets and arithmetic register . . . 163
1.3.4 Six windows and decimal emission by blocks . . . 164
1.3.5 Complete calculation of an emission beginning with 501 . . . 165
1.3.6 Factorization of the finite census . . . 166
1.3.7 Oriented ternary reading and preservation of fibers . . . 168
1.3.8 Dihedral action and the forty-three orbits . . . 169
1.3.9 Self-contained enumeration and control algorithm . . . 170
1.3.10 Preservation of the register and function of the seeds . . . 171
1.4 Nonadic connection, calendar extension and transport memory . . . 171
1.4.1 Incidence of arithmetic modes . . . 171
1.4.2 Arithmetic extension of the calendar . . . 172
1.4.3 Integer lift and nonadic holonomy . . . 174
1.4.4 Bilateral representation of phase transport . . . 175
1.4.5 Refinement capacity and arithmetic vacancies . . . 176
1.5 APP: support, operations, and paths . . . 177
1.5.1 Domain, generators and preformal relations of the APP support . . . 177
1.5.2 Aritmetic support, translations and observables . . . 178
1.5.3 Multiplicative structure of the local ring . . . 179
1.5.4 Coordinate subset of the null class . . . 180
1.5.5 Residue–quotient extension . . . 180
1.6 Arithmetic Operators and Local Geometry of the Path Space . . . 181
1.6.1 Localization of the excess in the nilpotent radical . . . 181
1.6.2 Conditional expectation with respect to the projection $\mathbb{Z}/9\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ . . . 182
1.6.3 Commutator of the arithmetic projectors and separation of their images . . . 183
1.6.4 Central block and spectral decomposition . . . 184
1.6.5 Discrete curvature induced by the interaction of the sum and product leaves and its commutation defect . . . 186
1.6.6 Path Transition Operator Expansion . . . 187
1.7 Aritmetic Matrix of APP and Local Ring Structure . . . 187
1.7.1 Nonadic multiplicative matrix and digital root . . . 188
1.7.2 Residue-quotient extensions and nonadic carry cocycle . . . 189
1.7.3 Integrated censuses of residues and quotients . . . 190
1.7.4 Bivariate central block of APP and decomposition into 2 spectral modes . . . 190
1.7.5 Discrete curvature of the interaction between additive and multiplicative leaves 191
1.7.6 Obstructions of the arithmetic matrix of APP: translations, local radical, central block, mixed curvature, and conservation of carry . . . 191
1.8 Gnomonic completion and arithmetic support of APP . . . 192
1.8.1 Conjugation between the positive and residual charts of the same class modulo 9 192
1.8.2 Decomposition of the APP orthogram into inner core and gnomonic complement 193
1.8.3 Exact realization of the interstitial interval via APP cells and boundary coordinates 193
1.8.4 Toroidal closure and translations . . . 194
1.8.5 APP Path Category: Objects, Prolongation Morphisms and Compatible Composition . . . 195

1.8.6 *Multiplicative matrix and internal additive law on a single support* 195
1.8.7 *Decomposition of the APP orthogram into kernel* 8×8*, gnomon of* 17 *states, and chart* 9×9 *with opposite sides identified* 196
1.8.8 *Obstructions to the fidelity of the APP support: cardinals* $81/17$*, reversible translations, and separation of the sum and product sheets* 196
1.9 Construction of the nonadic cell from marked segments and interstices . . . 197
1.9.1 *Decimal residual projection of the finite positional chart of APP* 197
1.9.2 *Construction of the nonadic cell of 9 phases via residual projection* 198
1.9.3 *Position and height coordinates induced by the Euclidean division* 198
1.9.4 *Circular projection periodicity and injectivity of the nonadic helical lifting* . . 199
1.9.5 *Correspondence between Discrete Cardinality and Projective Measure* 199
1.9.6 *Autonomous arithmetic domain of the nonadic cell and causal precedence with respect to APP–TRIT–TPK and the constants analiticas* 200
1.10 Cyclotomic skeleton of APP and binomial completion of the unit 200
1.10.1 *Cyclotomic Defect Invariance at Fixed Modulus Under Length Variation* . . . 200
1.10.2 *Cyclotomic operator of APP and action on the 12* A_2*-type fibers* 202
1.10.3 *Decomposition of APP into* 12 *fibers of type* A_2 202
1.10.4 *Derivation of the sum-product defect 459−405=54 in the central block of APP* 204
1.10.5 *Cubic completion of the nonad cell* 205
1.10.6 *Morphism from the central block of APP to its Euclidean realization* 206
1.10.7 *Incidence of the cube and separation with respect to sextets and octets* 206
1.10.8 *Range 6 of the incidence operator and multiplicity of its resonant mode* 207
1.10.9 *Obstructions of the cyclotomic skeleton of APP: fibers* A_2^{12}*, completion* $729+271$*, rank resonance* 6*, and cubic incidence* 207
1.11 TRIT as a ternary oriented unit: internal geometries, temporal order, and dynamic conditions of time crystal 208
1.11.1 *Oriented ternary system and balanced representation of TRIT states* 208
1.11.2 *Balanced ternary division algorithm and uniqueness of the quotient–residue pair* 208
1.11.3 *Carry cocycle of the oriented ternary composition* 209
1.11.4 *Orientation and Temporal Order Involution* 210
1.11.5 *Unified classification of the 3 quadratic algebras of the TRIT* 210
1.11.6 *Matrix representations of the TRIT selected by the sign of* J_τ^2 211
1.11.7 *Local coupling APP–TRIT* 212
1.11.8 *Obstructions of TRIT: residue–representative–carry separation, involutivity, and spectral recovery of* τ 212
1.12 TPK: base observable, enriched state, and typed separation of its projections 213
1.12.1 *Bivariate category of APP paths as the basis of the TPK enriched state* 213
1.12.2 *Non-split extension* $C_{12} \to C_{108} \to C_9$ *and dodecaphase record of the nonadic phase* 213
1.12.3 *Sheet selector* $M_{\mathrm{ph}} : \mathcal{D}_9 \to \mathsf{TRIT}$ *and joint evolution of position, orientation, and calendar* 214
1.12.4 *Decomposition of the enriched state in* 6 *families fibradas* 215
1.12.5 *Cardinal operator* T_d *of transport between enriched fibers with conservation of path and memory* 216
1.12.6 *Typed prolongation relation* Ext_r *between enriched fibers* 216
1.12.7 *Observable quotients of the enriched state and conserved genealogical fields* . 217
1.12.8 *Criterion of route survival via conservation of the projected boundary* 217
1.12.9 *Insertion of the 6 fibered families of the enriched state into the operator hierarchy of TPK* 217

1.12.10 Obstructions of the enriched state of the TPK: typing of the selector, carry cochain, compatible extension, and genealogical conservation 218
1.13 Typed hierarchy of the 34 heterogeneous canonical constructions and causal dynamics of TPK updating 218
1.13.1 Typed schema of the 34 canonical TPK constructions: domain, codomain, action, invariants, and memory 219
1.13.2 Typed L_0–L_7 hierarchy of the 34 heterogeneous canonical TPK constructions . 219
1.13.3 Functional grouping of the 34 canonical constructions in 14 families of composition APP–TRIT–TPK 220
1.13.4 Mathematical classes, domains, codomains, and causal dependencies of the 34 canonical constructions 221
1.13.5 Update of the enriched state through $U_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$ 221
1.13.6 Typed separation between operators, states, projections, and publications of the TPK 222
1.14 Tritic incidence 90/120 and typed separation of the temporal, nilpotent, and angular operators 223
1.14.1 Temporal, nilpotent, and angular operators: domains and codomains 223
1.14.2 Typed residences of the indices 90/120 in 6 non-equivalent operator objects . . 224
1.14.3 Normalized defect 1−90/120=1/4 of the tritic incidence 225
1.14.4 Domain invariants, orientation, and memory of the 90/120 realizations 225
1.15 Local transport factor and ternary-decimal transition 225
1.15.1 Oriented transition local operator and APP sheet update 225
1.15.2 Cylindrical systems of the 2 arithmetic readers and truncation compatibility . 227
1.15.3 Completion operator $C_{3,1000}$: ternary extension and preservation of the unit in 10^3 positions 227
1.15.4 Factorization of the TPK transition as $U_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$ 228
1.16 Record dodecafasico integral, extension ciclica and decomposition 1 + 5 + 6 229
1.16.1 Cyclic coordinate on the time-oriented 12-sector support 229
1.16.2 nonsplit extension $0 \to C_{12} \to C_{108} \to C_9 \to 0$ and carry cocycle 229
1.16.3 Enhanced temporal registration: joint encoding of phase, sheet, boundary, and memory 230
1.16.4 Extraction of the signed dodecaphase state from the enriched time record . . . 230
1.16.5 Genealogical distinction between 2 dodecaphasic words of equal period . . . 231
1.17 Cyclotomic phase functor–length and modular elevation of paths 232
1.17.1 Coxeter representation of order 3 on the dodecaphasic fibers of type A_2 . . . 232
1.17.2 Odometer category of the TPK: cylinders, truncations, and sequence morphisms 232
1.17.3 Modular elevation of cardinal paths 233
1.18 Quaternary dilation of the register, observable obstruction, and refined semiconjugacy 234
1.18.1 Dilation on the product register 234
1.18.2 Exact carry identity 235
1.18.3 Obstruction in the observable quotient 235
1.18.4 Minimal temporal subdivision compatible with semiconjugation 236
1.18.5 Subdivided category and cyclotomic elevation 237
1.18.6 Commutators of 3 quaternary operations and separation of their actions . . . 237
1.19 Modular readers, odometer, and dodecaphasic calendar 238
1.19.1 Typed scheme of the modular readers of the TPK: domain, codomain, publication, and conserved memory 238
1.19.2 Nonadic reader of the enriched state: phase, transition and memory-return . . 238

1.19.3 Triticale reader with quotient and carry transport . . . 238
1.19.4 Reader positional by blocks in base 10^3 . . . 239
1.19.5 Odometer category of the TPK: cylindrical objects and composition by truncation 239
1.19.6 Memory quotient of order 1 and predictive sufficiency of the modal projection 240
1.19.7 Central extension of the calendar . . . 241
1.19.8 Unbounded Growth of Memory Depth Under Phase Returns . . . 241
1.19.9 Minimal type system of the enriched state and compatibilities between its readers 242
1.19.10 Obstructions of the readers and the TPK calendar: Euclidean quotients, C_{36}^{pred}, extension C_{108}, and vertical memory . . . 242
1.20 Complete operatorial structure of APP and arithmetic-geometric hierarchy . 243
1.21 Typed architecture, inventory, and memory conservation of the Topological Phase Kernel . . . 243
1.21.1 Categorical structure of the TPK: enriched states, transport morphisms, and operatorial classification . . . 243
1.21.2 Fundamental operators of the TPK: domains, actions, invariants, and memory 245
1.22 Transport, selection, and prolongation in the Topological Phase Kernel . . . 248
1.22.1 Residual reductions and decimal representation . . . 249
1.22.2 Correspondence between TPK symbols, domains, and compositions . . . 250
1.22.3 Cardinal Action and Arithmetic Feedback . . . 250
1.22.4 Chronological evolution of the cursor pair and determination of the observable state . . . 252
1.22.5 Finite emitter associated with the cursor pair and generation of admissible states 252
1.22.6 Configuration of the enriched state of the TPK: sheet, orientation, residue, quotient, carry, boundary, route, and memory . . . 253
1.22.7 Ternary-decimal cylinders and state of extension . . . 254
1.22.8 Compound returns and transport calendars . . . 255
1.22.9 Fiber transfer and spin memory . . . 256
1.22.10 Tertiary prolongation and joint boundary . . . 257
1.22.11 Relation of extension and nonadic monodromy . . . 257
1.22.12 Composition of the fundamental operators . . . 258
1.23 Construction and operatorial architecture of the APP–TRIT–TPK formal kernel: arithmetic support, ternary orientation, and genealogical dynamics . 259
1.23.1 APP: positional support and arithmetic evaluations . . . 259
1.23.2 TRIT: orientation and quadratic regimes . . . 262
1.23.3 TPK: topological phase kernel . . . 268
1.23.4 Accumulated memory and transport resolvents . . . 275
1.23.5 Operator architecture of transport, memory, and prolongation . . . 278
2 Cohomological rank of carry memory: independent cocycles, dimensional lift, and projective preservation of unity 291
2.1 Cohomology of the helicoidal carry: evaluation of cocycles and minimum dimension of cumulative memory . . . 291
2.1.1 Independent cocycles and minimum number of memory coordinates . . . 291
2.1.2 Nonadic tower and projective conservation of unity . . . 292
2.1.3 From the cumulative coordinate to the metric . . . 293
3 Spectral, geometric, and operatorial realizations of the APP–TRIT–TPK kernel 294
3.1 Geometry of APP and structure of its trajectories . . . 294
3.1.1 Cayley graph and arithmetic structure of trajectories . . . 294
3.1.2 Toroidal realization and lifting of paths . . . 295
3.1.3 Interaction of the evaluations and discrete curvature . . . 298

3.1.4 *Selection and spectral decomposition of the central block* . . . 299
3.1.5 *Conservative normalizations of the block and Lorentzian realization* . . . 300
3.1.6 *Reduction by ternary classes and aggregate spectral structure* . . . 301
3.1.7 *Operator realization of trajectories* . . . 303
3.2 TRIT as an oriented ternary state: carry memory, temporal order, and 3 quadratic regimes . . . 303
3.3 Ternary local state and transport orientation . . . 303
3.3.1 *Oriented ternary signature and state space* . . . 303
3.4 Quadratic algebras and transport regimes . . . 304
3.4.1 *3 associated quadratic algebras* . . . 304
3.4.2 *Compatibility and parameterized trajectories* . . . 305
3.4.3 *Ordered parameterization of compatibility* . . . 305
3.4.4 *Spectral decomposition of the hyperbolic type* . . . 306
3.5 Quadratic algebras of order 9 . . . 306
3.5.1 *Estructura of $\mathbb{F}_9$ inducida by Paley* . . . 306
3.5.2 *The ternary code as an isotropic graph* . . . 306
3.5.3 *Characteristic 9 and characteristic 3* . . . 307
3.5.4 *Classification of Quadratic Algebras* . . . 308
3.5.5 *Integral quadratic form and finite and real specializations* . . . 308
3.5.6 *3 generators concrete of the TRIT regimes* . . . 309
3.6 Operator genealogy of arithmetic and discrete calculus: composition, contraction of fibers, and lifts with memory . . . 311
3.6.1 *Published operation and genealogical lifting* . . . 311
3.6.2 *Sum and product: alternatives and composition* . . . 312
3.6.3 *Power, logarithm, and root* . . . 313
3.6.4 *Discrete Calculus on Compatible Cylinders: Differentiation and Integration Operators* . . . 313
3.6.5 *Hierarchy of fibers and function of the TPK* . . . 314
3.7 APP–TRIT–TPK Composition: arithmetic support, ternary orientation, and memory-based transport . . . 314
3.7.1 *APP as fiber arithmetic* . . . 314
3.7.2 *Local Lorentz geometry and Minkowski plane 1 + 1* . . . 315
3.7.3 *TRIT as orientation and local memory* . . . 315
3.7.4 *TPK as the dynamics of selection, transport, memory, return, and deployment.* 315
3.7.5 *Temporal periodicity of 108 phases and returns at 27, 54, and 108 iterations* . 316
3.8 Hopf fibration, Villarceau circles, double covering, and Möbius holonomy . 316
3.8.1 *Complex structure and Hopf fibration* . . . 316
3.8.2 *Double covering and spinor return* . . . 317
3.8.3 *Spectral decomposition of the oriented memory operator and derivation of the ratio (5:2)* . . . 317
3.8.4 *Conjugate Angular Coordinates and Phase Unit Normalization in the Hopf Fibration* . . . 318
3.8.5 *Brouwer, Möbius, and degree* . . . 318
3.9 Finite Hilbertian realization of the path system and its conditional projectors 318
3.9.1 *Matrix realization of each depth* . . . 318
3.9.2 *Weyl–Heisenberg Representation of Phase and Displacement on the Triadic Fiber* 319
3.9.3 *Conditional projectors and pre-Heisenberg incompatibility* . . . 319
3.9.4 *Hilbertian structure of the matrix publication and preserved genealogical memory* 319
3.10 Finite symplectic structure of APP and nonadic fibration of observables . . 320

3.10.1 *The alternating form and the Weyl commutation* . . . 320
3.10.2 *The lift* $12 \to 4 \times 3$ . . . 320
3.10.3 *Depth, carry, and memory over the discrete phase space* . . . 321
3.10.4 *Typed separation between the qutrit overlap* $1/3$ *and the HMT reader* $1/\pi$ . . . 321
3.10.5 *Symplectic group and equivariance equation* . . . 322
3.11 Spatial return and conservation of winding in the calendar of twenty-seven transitions . . . 322
3.11.1 *Lifted coordinates and boundary cocycle* . . . 322
3.11.2 *Update of the two cursors* . . . 323
3.11.3 *Cursor recovery and compatibility at every depth* . . . 324

II discrete structure of the continuum: surviving sections, double projection and incidence hierarchies 325

4 Inverse path system of compatible trajectories: orientation, boundary, carry, and memory under refinement 326
4.1 Arithmetic Genealogy of Measure and Nonadic Configuration of the Inverse System . . . 326
4.1.1 *The Continuum Problem and the Genealogy of Measure* . . . 326
4.2 Genealogical construction of the continuum . . . 328
4.2.1 *Generative composition APP→TRIT→TPK and construction of the enriched state* 328
4.2.2 *TRIT: local topological unit and temporal relation unit* . . . 331
4.2.3 *TPK: category of transport and phase evolution* . . . 332
4.3 Development of the formal kernel: initial conditions, geometry and refinement 334
4.3.1 *Initial states and the emission recurrence* . . . 334
4.3.2 *Calendar closure and memory advance* . . . 336
4.3.3 *Observable compression and orthogonal conservation* . . . 337
4.3.4 *Local development: commutation, Lorentzian signature, and discrete curvature* 338
4.3.5 *Cubic completion and two notions of boundary* . . . 339
4.3.6 *Cubic incidence and Lorentzian realization* . . . 340
4.3.7 *Compatibility between modular and positional reductions* . . . 342
4.3.8 *The number as a compatible section and the value as a reading* . . . 342
4.3.9 *Composition of histories and memory multiplier* . . . 343
4.3.10 *Double variance of refinement and preservation of unity* . . . 344
4.3.11 *Phase return, Weyl representation and two readings* . . . 344

5 Unitary construction of the discrete structure of the continuum: spectral transport, solenoidal balance, gauge incidence, cellular coherence and determinant line 346
5.1 Common state, prolongation tree, and genealogical measure . . . 346
5.1.1 *Finite data produced by APP* . . . 346
5.1.2 *Tritic extension of the incidence datum: balanced orientation and genealogical carry cocycle* . . . 347
5.1.3 *TPK transport of the* 2 *leaves and of memory* . . . 347
5.1.4 *The common state and its total domain* . . . 350
5.1.5 *Finite reversible symmetry groupoid* . . . 354
5.1.6 *Finite tree of all prolongations* . . . 354
5.1.7 *Nonadic Connection: Phase, Holonomy, and Memory* . . . 355
5.1.8 *Total survival and complete multisection* . . . 357
5.1.9 *Canonical measure generated by the tree* . . . 358
5.1.10 *Naturality under symmetries and truncations* . . . 359

5.1.11 Inverse limit $\widehat{\Omega}$ of complete histories and common APP–TRIT–TPK enriched state 359
5.1.12 Structural necessity and origin . . . 360
5.2 Intrinsic Correlative Operations of the Same Continuum . . . 361
5.2.1 Generating edge and common genealogical state . . . 361
5.2.2 Intrinsic Correlative Actions on the Common Generator . . . 361
5.2.3 Unitary transport, polarization, and balance on the common fiber . . . 363
5.2.4 Orientation, carry, and simultaneous composition of paths . . . 369
5.2.5 Cellular incidence and correlative filling of the same trajectory . . . 370
5.2.6 Naturalness of the ensemble and compatibility under refinement . . . 381
5.2.7 Causal separation of the identities, deductions, and realizations of the correlator constructor . . . 384
5.2.8 Joint emergence of the five constructions . . . 385

6 Existence of the discrete continuum: nonemptiness, preservation, terminality, naturality, refinement, and compatible limit 389
6.1 Multivalued terminal, unique naturality and passage to the limit . . . 389
6.1.1 Surviving histories with extension witnesses . . . 389
6.1.2 Generated terminal record and its 13 coordinates . . . 389
6.1.3 Multivalued terminal without selector . . . 395
6.1.4 The nonadic connection as correspondence . . . 395
6.1.5 Uniqueness of the prefix decomposition and naturality of the truncation system 397
6.1.6 Passage to the limit without interchanging image and limit . . . 397
6.1.7 Internal reconstruction of the enriched state from its 13 genealogical coordinates 398
6.1.8 Multivalued terminality, naturality, and compatible limit of the continuum . . . 399
6.1.9 Obstructions to the terminality of the enriched state: loss of fiber, orientation, memory, or reader . . . 399
6.2 Joint nonadic connection Γ_9 as a compatible correspondence of the inverse system . . . 400
6.2.1 Terminal Assembly Theorem of the Correlative Constructions Generated by the Common State . . . 400
6.2.2 Survival and inverse limit . . . 401
6.2.3 Joint nonadic connection, holonomy, and vertical memory . . . 401
6.2.4 Archimedean publication, genealogical number and measurement . . . 403
6.2.5 Dimensional realization of the HMT state: screen map, observable magnitude, and spectral chart . . . 403
6.2.6 Double projection mathematical and dimensional realization . . . 403
6.3 Surviving extensions, monodromy, and dynamics of the quotient . . . 404
6.3.1 5 levels of the notion of path . . . 404
6.3.2 Phase return and monodromy relation . . . 406
6.3.3 The catalog of 468 emissions as a product of channels . . . 408
6.3.4 The unique path and path transfer . . . 409
6.3.5 Compensated elevation constructed from the quotient . . . 412
6.3.6 Minimal congruences stable under advance, half-turn and 4th of a turn: 28 and 162 memory classes . . . 413
6.3.7 Mode and Orientation Cocycles . . . 414
6.3.8 Scale cocycle and cylindrical conservation . . . 420
6.3.9 Dynamic prolongation theorem: global hypotheses and certified domain . . . 421
6.4 Correlative construction of the continuum: histories, transport, incidence and terminal . . . 421
6.4.1 Admissible histories and memory by composition . . . 421

6.4.2 Tree refinement and measure of histories . . . 422
6.4.3 Transport by sheets and exact accounting of outputs . . . 423
6.4.4 Oriented balance and cancellation under refinement . . . 424
6.4.5 Ternary incidence of the sheets and rectangular complex . . . 425
6.4.6 Memory complex and compatibility of incidences . . . 426
6.4.7 Assembly with terminal paths . . . 427
6.4.8 Determinants, limit and arithmetic reading . . . 428
6.4.9 Provenance, verification and scope . . . 429
6.5 Correlative construction of the continuum: histories, transport, incidence and terminal . . . 430
6.5.1 Admissible histories and memory by composition . . . 430
6.5.2 Tree refinement and measure of histories . . . 431
6.5.3 Transport by sheets and exact accounting of outputs . . . 432
6.5.4 Oriented balance and cancellation under refinement . . . 433
6.5.5 Ternary incidence of the sheets and rectangular complex . . . 433
6.5.6 Memory complex and compatibility of incidences . . . 434
6.5.7 Assembly with terminal paths . . . 435
6.5.8 Determinants, limit and arithmetic reading . . . 436
6.5.9 Provenance, verification and scope . . . 437

7 Projective measure of the genealogical continuum: evolutionary conservation of unity, disintegration by values, and conditioning of futures 438
7.1 Projective measure and evolutionary conservation of the unit . . . 438
7.1.1 Consistent weights on finite levels . . . 438
7.1.2 Decomposition of the genealogical measure on fibers of equal Archimedean value 439
7.1.3 Conditioning of the measure through restriction of the future extension tree . . 439
7.1.4 Combinatorial conservation and dimensional completion . . . 440
7.2 Discrete calculation of the measure on the inverse limit: differences, carry cocycle, ultrametric, reconstruction of $\mathbb{R}$, and genealogical disintegration . . . 441
7.2.1 Marks and difference operator . . . 441
7.2.2 Positive length and oriented integral . . . 441
7.2.3 Carry as a composition cocycle . . . 442
7.2.4 Compatibility of the nonadic, ternary, and decimal-completion charts in base 10^3 443
7.2.5 Graded system of measurement and non-contracted recording . . . 444
7.2.6 Reconstruction of the continuum from the inverse system of compatible cylinders 445
7.2.7 Cylinders, ultrametric and Archimedean return with memory conservation . . 445
7.2.8 Coherent coverage and reconstruction of the Archimedean quotient . . . 446
7.2.9 Algebraic descent of operations . . . 447
7.2.10 Projective measure and conservation of the unit . . . 448

8 nonadic holonomy Γ_9 of the Topological Phase Kernel: transport of the enriched state, coinductive prolongation and 9→1 return with memory advance 450
8.1 Orbital classification, initial words and 1st boundary . . . 450
8.1.1 Dihedral action on 6 coordinates . . . 450
8.1.2 Fiber Invariants . . . 450
8.1.3 Internal Orientation of Each Orbit . . . 451
8.1.4 Closure microfiber . . . 452
8.1.5 Ternary lifting matrices . . . 452
8.1.6 1st common boundary . . . 453
8.1.7 Residue–quotient lifting . . . 454

8.1.8 *Obstructions to orbital selection and to the lifting $w_6 \to w_{30} \to R_{36}$: uniqueness, gauge, and Hensel reversibility* . . . 454
8.2 Joint Holonomy Γ_9: observable compression T, orthogonal component η and terminal memory conservation . . . 455
8.2.1 *Transport of the enriched state by the nonadic holonomy and memory update* . 455
8.2.2 *Local transition relations and construction of the nonadic holonomy Γ_9* . . . 455
8.2.3 *Exhaustive classification of the 9 phases of the Topological Phase Kernel* . . . 456
8.3 Mirror involution and local selection $3 \to 1$ of the surviving extension . . . 457
8.3.1 *Symmetric and axial coordinates* . . . 457
8.3.2 *Oriented state in phase 9 and associated boundary data* . . . 458
8.3.3 *Exact compatibility of cylinders* . . . 458
8.3.4 *2nd horizon and uniqueness* . . . 459
8.3.5 *Phase return with block change* . . . 459
8.3.6 *Diagram of the mirror involution π/e, the fixed axis φ, and the local selection $3 \to 1$ by prolongability* . . . 459
8.3.7 *Residue–quotient memory during the mirror* . . . 459
8.3.8 *Obstructions to the mirror involution π/e and to the local selection $3 \to 1$: invariants, depth-2 horizon, and Hensel memory* . . . 459
8.3.9 *Joint transfer of the fiber of 468 emissions* . . . 461
8.3.10 *Decomposition of the holonomy U_{Γ_9} into visible compression T and orthogonal component η: $I - T^*T = \eta^*\eta$* . . . 462
8.3.11 *Strict contraction and terminal telescoping* . . . 462
8.3.12 *Carry Cocycle and Relational Powers* . . . 463
8.3.13 *Complete nonadic state: phase, carry, boundary, route, and memory after the prolongation* . . . 463
8.3.14 *Obstructions of the holonomy Γ_9: 9⟶1 return, composition indices and phase conservation, carry, boundary, path and memory* . . . 463
8.4 Finite arithmetic image and factorization $468 = 18 \cdot 26$ . . . 464
8.4.1 *Primitives and recurrence of the finite sender* . . . 464
8.4.2 *Bivariate dynamics and block observables* . . . 465
8.4.3 *Image of the additive accumulator:* $\operatorname{Im} S_m = \{6, 9, 12, 15, 18, 21, 24\}$ . . . 465
8.4.4 *Image of the multiplicative accumulator:* $\operatorname{Im} E_m = \{0, 1, 3, 5, 7, 9\}$ . . . 465
8.4.5 *Decimal congruence of the ternary alphabet: uniqueness of the 3rd digit* . . . 466
8.4.6 *Factorization of the 2 observables* . . . 466
8.5 Inverse systems, Weyl–Heisenberg representation and predictive quotient . . . 468
8.5.1 *Observable projection and complete state space of the TPK* . . . 469
8.5.2 *Inverse systems of survivors* . . . 470
8.5.3 *Nonadic Survival Connection* . . . 471
8.5.4 *Archimedean Evaluation of the Compatible Prefix and Determination of the Real Point* . . . 476
8.5.5 *Weyl–Heisenberg Representation Associated with the Nonadic Torus* . . . 478
8.5.6 *Cyclic dynamics on $\mathbb{Z}_9 \times \mathbb{Z}_{12}$ and minimal predictive quotient* . . . 479
8.5.7 *HMT number as a compatible history in X_∞: genealogical identity, reading structure, and Archimedean evaluation* . . . 480
8.6 Monodromic generation by survival of π, e and φ . . . 480
8.6.1 *Generative regions and global section* . . . 480
8.6.2 *Survival filtration, nonadic monodromy, and π/e symmetry* . . . 481
8.6.3 *Reproducible emission of 12 triads and reconstruction of their enriched state* . 482
8.6.4 *Unique closure of π and classification of its 5 regional histories* . . . 482

8.6.5 *e: visible propagation and differentiated quotient memory* . . . 483
8.6.6 *Autoscaling Axis and Mirror Fiber* . . . 484
8.6.7 *φ: the autoescala inducida by TPK* . . . 485
8.6.8 *Oriented correspondence between closure and self-scale* . . . 486
8.6.9 *Arbitrary precision of monodromic emission* . . . 486
8.7 Monodromic prolongation and calculation to prescribed depth . . . 487
8.7.1 *Initial coinductive prolongation from w_6 until the compatibility boundary of order* 1 . . . 487
8.7.2 *Finite selection and construction of characters* . . . 488
8.7.3 *Extension of survivors and subsequent certification* . . . 490
8.7.4 *Closure Regions* . . . 492
8.7.5 *Phase return and memory change* . . . 493
8.7.6 *Exhaustive census of 396 transitions, 2.376 trits, 43 turns and 387 equal-phase pairs* . . . 494
8.8 Affine holonomy, helical suspension, and conservation of memory depth . . . 495
8.8.1 *Dynamic composition of the Topological Phase Kernel over the enriched state: tritic selection, cardinal transport, memory update, and typed return* . . . 495
8.9 Exact helical geometry of the nonadic memory . . . 496
8.9.1 *Helical covering of the nonadic phase and integral coordinate of memory depth* 496
8.9.2 *Dynamic suspension of the enriched affine system* . . . 498
8.9.3 *Bidirectional Involution and Conjugate Leaves* . . . 499
8.10 Derivation of the incidence channels 90 and 120 from the tritic semicoronas of the Topological Phase Kernel . . . 500
8.10.1 *Tritian Partition of the Nonadic Phase into Oriented Semicoronas* . . . 500
8.10.2 *Incidence channel of cardinality* 90 . . . 501
8.10.3 *Incidence channel of cardinality* 120 . . . 501
8.10.4 *Dodecaphasic compatibility and causal precedence with respect to spectral evaluation* . . . 501
8.11 Center, boundary, and vacancies in the nonadic connection . . . 501
8.11.1 *The thesis and the order of construction* . . . 501
8.11.2 *The local crown and reconstruction of the center* . . . 502
8.11.3 *Sum, product, and the three values of discrete curvature* . . . 503
8.11.4 *The 72–27 and 77–22 readouts and the 729–271 completion* . . . 504
8.11.5 *The electronic center and its conjugate vacancies* . . . 504
8.11.6 *Nonadic mirror, capacity, and return with memory* . . . 506
8.11.7 *Vacancies of nonadic refinement and hierarchy of returns* . . . 507
8.11.8 *Factor 8/81 in the decomposition between reading and complement* . . . 511
8.12 Combinatorial selection and representation transport of the first joint boundary 512
8.12.1 *Regional state preceding the boundary* . . . 512
8.12.2 *Compatibility equation and column saturation* . . . 512
8.12.3 *Directed length and boundary orientation* . . . 514
8.12.4 *Naturality of the exceptional change of representation* . . . 515

9 Oriented classification of the closure microfiber of π: 5 regions, multiplicity 432+4·144=1008, φ-axis, and π/e involution 517
9.1 Construction of the closure character and of the genealogical trajectories of π 517
9.1.1 *Causal separation between seed, character, and evaluation* . . . 517
9.1.2 *Liftings L_0, L_1 and 1st coinductive boundary* . . . 517
9.1.3 *Oriented decomposition of the microfiber of π: central region, 4 lateral regions, and multiplicity* $432 + 4 \cdot 144 = 1008$ . . . 518

9.1.4 Descent of a complete nonadic block to the phase transfer multigraph 519
9.1.5 The 5 oriented closure cycles 520
9.1.6 Oriented holonomies of the closure of the 5 regions of π 521
9.1.7 Determination of the slope 1/5 via the balance of the 5 oriented regions . . . 521
9.1.8 Determination of the slope 1/5 by the multiplicity of the regional microfiber of π 522
9.1.9 Gaussian identity and 1st half-turn 522
9.1.10 Arbitrary precision rational horocycles 523
9.1.11 Production by Ext *and subsequent rational certification in the ambient fiber* . 523
9.1.12 Filtration of $F_3{}^6$ by regional admissibility and selection of compatible subcylinders 524
9.1.13 Characterization of the coinductive channel of π: selection of w_6^{π}, 5 regions, oriented inversion, and uniqueness of the limit section 524

10 Coinductive Generation of π, e and φ via Compatible Nonadic Refinement 526
10.1 Propagation, memory return and construction of the exponential character . 526
10.1.1 Finite orbital selector: existence and uniqueness of compatible emission . . . 526
10.1.2 Coinductive prolongation of the exponential emission via compatible blocks . 526
10.1.3 Construction of the decimal signature via the ternary–decimal positional square 527
10.1.4 Phase return with non-trivial memory state update 527
10.1.5 Subsequent factorial certification of the coinductive exponential section . . . 528
10.1.6 Cofinal Forking of Rational Tangles and Convergence to the Published Value . 529
10.1.7 Coinductive prolongation of the exponential section through ternary subcylinders of the Topological Phase Kernel 529
10.1.8 Orbital uniqueness, factorial recurrence, and cylindrical convergence of electron generation 530
10.2 Modal incidence, Perron ray, and construction of the self-similar character . 530
10.2.1 Finite Selection of the Self-Scaling Seed 530
10.2.2 Blockwise extension and construction of the 1st coinductive boundary 531
10.2.3 Construction of the incidence multigraph from the triticale calendar 531
10.2.4 Construction of the modal incidence multigraph from the triticale calendar . . 532
10.2.5 Fibonacci Recurrence of the Perron Ray and Diophantine Embedding of Rational Gaps 533
10.2.6 Memory incidence of order 1 and Parry measure of the symbolic envelope . . 534
10.2.7 Multiplicative character and cylindrical conservation 534
10.2.8 Quadratic memory and contracted branch 535
10.2.9 Normalized hyperbolic realization of the self-scale: $\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2$ . . 536
10.2.10 Characterization of self-similarity via rational forks and coinductive prolongation 536
10.2.11 Internal certificate of uniqueness, compatibility, and convergence of self-scaling 536
10.3 Diagonal certification, inverse limit and generation to arbitrary precision . . 537
10.3.1 Typed separation of the 4 indices of nonadic prolongation 537
10.3.2 Ternary cylinders and the immediate ambient fibre 537
10.3.3 Minimal diagonal certification 538
10.3.4 Compatibility with the joint nonadic connection 539
10.3.5 Uniqueness of the Minimal Diagonal Section in the Rational Fork System . . . 540
10.3.6 Decimal cells and prescribed precision 540
10.3.7 Equivalence of 2 finite realizations of the uniform law 541
10.3.8 Separation between generation and verification 541
10.3.9 Differentiated obstructions to generation and its certification at arbitrary precision 542
10.4 Markov dynamics as a modal quotient of order-1 memory of the holonomy Γ_9, compatible with the inverse limit 542
10.5 Coinductive generation of π, φ, e to arbitrary depth 543

10.5.1 *Orbits, regions, and characters of closure, propagation, and self-scaling* . . . 543
10.5.2 *Oriented metadata and decomposition of the regional microfiber* 544
10.5.3 *Finite transport and the prolongation boundary* 546
10.5.4 *Five closure regions and angular compensation* 547
10.5.5 *Propagation reader and normalization of unity* 548
10.5.6 *Modal incidence and generation of self-scaling* 548
10.5.7 *Exponential realizations of the generated coordinates* 551
10.5.8 *Compatible cylinders and arbitrary depth* 553
10.5.9 *Mirror involution and synchronization of the regions* 553
10.5.10 *Sturmian helical suspension* 554
10.5.11 *Nonadic connection, holonomy and monodromy representation* 557
10.5.12 *Block clock and capacity clock* 559
10.5.13 *Symbolic suspension and aperiodic time crystal* 559
10.5.14 *Mirror symmetry of the regions and dual realization* 560
10.5.15 *Temporal transport and tritic exponential composition* 564
10.5.16 *Multiplicative irreducibility and return periods* 564
10.6 Integral compatibility of regional generation, cylindrical refinement, and incidence 567
10.6.1 *Positional emission through rational separation of cells* 567
10.6.2 *Regional blocks of six trits at arbitrary depth* 568
10.6.3 *Transition registers and reconstruction of linear lifts* 569
10.6.4 *Simultaneous refinement in ternary and decimal bases* 570
10.6.5 *Selection of the next block by the regional reader* 572
10.6.6 *Ternary signature, carry, Witt incidence, and reading clock* 572
10.6.7 *Composition theorem for the block, cylinder, and signature* 574
10.7 Initial conditions and regional generation 574
10.7.1 *Two oriented cursors on the complete support* 574
10.7.2 *Finite formula for the window signatures* 575
10.7.3 *Selection of regions through oriented fibres* 576
10.7.4 *Calendar, monodromy, and memory* 577
10.7.5 *From records to prolongation operators* 577
10.7.6 *Scope of the regional construction in the study of masses* 578
10.8 Arithmetic of histories, composition, and refinement 578
10.8.1 *Compatible sections and evaluation of their readers* 578
10.8.2 *Sectorial route algebra and memory multipliers* 579
10.8.3 *Associativity, local identities, and calendar memory* 580
10.8.4 *Double variance of refinement and preservation of unity* 581
10.9 Coinductive depth of the fourfold relation 582
11 Internal derivation of α through the reversible dodecaphasic closure of the signed state 583
11.1 Initial generation of the signed dodecaphase state and reconstruction of the seal K 583
11.1.1 *Oriented tracis over windows of length* 108 583
11.1.2 *Integral chart of the dodecaphasic opposition* 584
11.1.3 *Selection of the common terminal state* 585
11.1.4 *Archimedean and exceptional publications of the common state: inequivalent codomains and shared genealogy* 586
11.1.5 *Naturality with respect to depth* 587
11.1.6 *Orbits of step* 3 *and transform of Hadamard* 587
11.1.7 *Integral structure and Smith normal form* 588

11.1.8 *Certification and reconstruction by differences of steps 3 and 4* 589
11.1.9 *Threshold Tetrad of the Seal* 590
11.1.10 *Independence of the genealogical construction with respect to external metrological or physical data* 590
11.1.11 *Obstructions of the dodecaphase record and the seal K: naturality, Hadamard integrity, and metrological isolation* 590
11.2 Initial construction of the boundary 662/663 through the dodecaphase carry cocycle 591
11.2.1 *Aritmetic closure domain* 591
11.2.2 *Left-to-right oriented Euclidean division* 591
11.2.3 *Finite restriction of the signed dodecaphase state and reversible closure of the cycle* 592
11.2.4 *Posterior metrological recognition: CODATA 2018* 593
11.2.5 *Complete affine identity* 593
11.2.6 *Exact inversion of the seal K* 594
11.2.7 *Coinductive prolongation of the dodecaphasic seal and inverse carry recurrence in $C = \{-2, -1, 0, 1, 2\}$* 594
11.2.8 *Boundary originating from the remote tail* 595
11.2.9 *Truncation and rounding to 36 digits* 596
11.2.10 *Causal isolation from α and metrological data* 597
11.2.11 *Obstructions to affine prolongation of α: telescoping, inversion of K, boundary 662/663, and isolation of target data* 598
11.3 Regional determination of the dodecaphasic descriptor and selection of the coupling register 598
11.3.1 *Regional bands, encoding, and integer signatures* 599
11.3.2 *Conversion clock and first zero advance* 600
11.3.3 *Oriented construction of the twenty-four-trit descriptor* 601
11.3.4 *Functional panel and terminal repertoire* 602
11.3.5 *Comparative readers, affine reader, and temporal incidence* 606
11.3.6 *Enumeration of cylinders and decimal candidates* 607
11.3.7 *Exceptional incidence and heterotypy condition* 609
11.3.8 *Regional composition and continuity of the realizations* 611
11.3.9 *Executable certification and traceability of the operations* 612
11.4 Dodecaphasic extraction of the arithmetic–geometric coupling constant . . . 613
11.4.1 *Cyclic extension and memory grading* 614
11.4.2 *The oriented register and the integral chart $1 + 5 + 6$* 614
11.4.3 *Incidence evaluation preceding the dodecaphasic register* 616
11.4.4 *Conjugation of counts and boundary terms* 617
11.4.5 *Complete census of cylinders and selection of the terminal boundary* 618
11.4.6 *Two readings of the terminal state* 621
11.4.7 *Construction of the signed register through the oriented channels* 622
11.4.8 *Hadamard by orbits and integer reconstruction* 623
11.4.9 *Cyclic differences and uniform component* 624
11.4.10 *Integral compatibility and determination of the transverse register* 625
11.4.11 *Two rational readings: κ_{36} and κ_{per}* 629
11.4.12 *Reversibility of the rational constant and phase change* 629
11.4.13 *Periodicity and cokernel of the transport operator* 630
11.5 Complete recovery of the register through weighted hexadic incidences . . . 631
11.5.1 *Incidence encoder and twelve explicit witnesses* 631

11.5.2 Rational inverse and uniqueness of recovery . . . 632
11.5.3 Symmetric recovery operator on the one hundred and thirty-two hexads . . . 633
11.5.4 Composition with the generated register . . . 634
11.6 Derivation of the fine-structure constant . . . 634
11.6.1 First path: positional determination by integer closure . . . 634
11.6.2 Second route: analytic determination through vacancies . . . 640
11.6.3 Compatibility of the two determinations at every depth . . . 643
11.6.4 Compatibility between the dodecaphase and analytic realizations of alpha . . . 644
11.6.5 Compatibility between the dodecaphase and analytic realizations of alpha . . . 650

12 Construction of $\sqrt{-1}$ and Euler tritic exponential family: operators J_τ and coordination of the regimes elliptic, parabolic and hyperbolic 658
12.1 Triadic Euler extension and preservation of forms . . . 658
12.1.1 APP multiplicative cycle and elliptic generator . . . 658
12.1.2 Threshold transport and parabolic generator . . . 659
12.1.3 Mode incidence derived from the TPK calendar . . . 659
12.1.4 Exponential identity of the three regimes . . . 661
12.1.5 Polynomial resolution of the regimes . . . 662
12.1.6 Nonadic compression and complementary register . . . 663
12.1.7 Conservation of oriented area . . . 663
12.1.8 Variable forms and restitution between successive planes . . . 664
12.1.9 Integrated action and compatibility with refinement . . . 665
12.2 Exponential identity of TRIT and coordination of the elliptic, parabolic, and hyperbolic regimes . . . 666
12.2.1 Construction of the elliptic operator by means of the Paley matrix and the relation $J_{+1}^2 = -I$ . . . 666
12.2.2 Unified family $\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau$ . . . 667
12.2.3 Elliptic, parabolic, and hyperbolic specializations and compatibility with the temporal reader . . . 667
12.3 Hopf fibration, Villarceau circles, and Möbius holonomy as a topological realization of the elliptic regime . . . 667
12.3.1 Complex structure and Hopf fibration . . . 667
12.3.2 Double covering and spinor return . . . 668
12.3.3 Corrispondence between the spectrum $\{7, 3\}$, the ratio 5:2 and the spinorial return . . . 668
12.3.4 Angular momentum representation in the elliptic regime and phase space unit closure . . . 668
12.3.5 Brouwer, Möbius, and degree . . . 669

13 Genealogical regularization of -1/12 through triadic extraction and Hensel–Witt lifting 670
13.1 Transduction kernel Hensel–Witt: domain, operation and genealogical preservation . . . 670
13.1.1 Hensel–Witt Transduction Kernel: π microregions, holonomy Γ_9, dodecaphase record, and hexad–octad transport . . . 670
13.1.2 Translation of the ternary code into the Witt system . . . 670
13.1.3 Hexagonal–Octagonal Inclusion and Incidence Transport through the 90/120 Channels . . . 671
13.1.4 4 rutas hacia -1/12 . . . 671
13.1.5 Representation of Primary Power Defects via the Number Operator . . . 672
13.1.6 Joint naturality conditions for the Archimedean, exceptional, and dimensional transduction . . . 672

13.2 Marked inclusion of the hexad-octad incidence and preservation of its multiplicities . . . 673
13.3 Classification by domain of the 5 algebraic realizations of $-1/12$ . . . 673
13.3.1 Difference of dodecaphasic periodicities . . . 674
13.3.2 Pseudoinverse of the Gram Operator on the Live Component . . . 674
13.3.3 2nd difference between triadic scales . . . 674
13.3.4 Composition of modular transformations and preservation of the signed state . . . 674
13.3.5 Defect of cyclic difference projectors . . . 675

14 Regional–determinantal confluence of the reduced action: construction of η_{ret}, scale 10^{-34}, $\hbar_{\mathrm{ret}}$, and parangular publication (A, C^*) 677
14.1 Genealogical bifurcation of the action scale and its dimensionless component 677
14.2 Angular publication and compatibility of the global and analytic charts . . . 677
14.3 Preconstitutive construction of the bidirectional action response and the vacuum operator . . . 678
14.3.1 Derivation of the action scale from the dodecaphasic state . . . 678
14.3.2 Oriented sections of the action line . . . 679
14.3.3 Bilayer spectral decomposition of the angular operator . . . 679
14.3.4 Harmonic factorization of sectors 90 and 120 . . . 680
14.3.5 Sheet involution and preservation of orientation . . . 681
14.3.6 Logarithmic characters and tracial compatibility . . . 681
14.3.7 Dimensional realization of the constitutive relations . . . 682
14.3.8 Angular determinant and Weinberg electroweak relation . . . 683
14.4 Quantum–electric constants, thermal scale, and Planck system . . . 683
14.4.1 Derivation of the charge section from the vacuum . . . 683
14.4.2 Von Klitzing and Josephson constants, conductance and magnetic flux . . . 683
14.4.3 Relation thermal intrinsic of the scale 108 . . . 684
14.4.4 Planck System and Bidirectional Covariance . . . 684
14.4.5 Spectral formulations of Wien's displacement law . . . 685
14.4.6 Stefan–Boltzmann law and thermodynamics of the photon gas . . . 685
14.4.7 Posterior metrological confluence of action, charge, conductance, and magnetic flux . . . 686
14.5 Graduated analytic realization of the quintuple microfiber . . . 686
14.5.1 The persistent return of the 5 regions . . . 687
14.5.2 Cylindrical length and analytic degree . . . 688
14.5.3 The Determinantal Character of Common Transport . . . 689
14.5.4 Rules of the Regional Analytic Reader . . . 689
14.5.5 Return recurrence and closed sum . . . 690
14.5.6 The 5th-degree action character . . . 691
14.5.7 Oriented phase and conjugate angular coordinate . . . 691
14.5.8 Degree-7 truncation and exact remainder bound . . . 692
14.5.9 Uniqueness conditions for the regional selector and the analytic prolongation . . . 693
14.5.10 Spectral reconstruction and hexad-octad transition . . . 693
14.5.11 Action prior and posterior to return . . . 693
14.5.12 Relative transporter and spectral disjunction of the blocks . . . 694
14.5.13 Generation chain $\mathcal{F}_\pi \to b_\pi \to \rho_\pi \to D_A \to C_*^{\mathrm{HMT}} \to \Gamma_{6\to 8}$: regional selection, determinantal prolongation and oriented coordinate . . . 695
14.6 Determinantal structure and oriented action sections . . . 695
14.6.1 Local quotient and determinantal norm . . . 695
14.6.2 Action character and regional continuation . . . 696

14.6.3 Positive sections and action per turn . . . 698
14.7 Angular realization and orientation of the channels . . . 698
14.7.1 Circular charts and covariance of the action . . . 699
14.7.2 Positive channels and reversal of the odd coordinate . . . 699
14.8 Dodecaphase update and memory register . . . 700
14.8.1 Quadratic balance . . . 700
14.8.2 Transport resolvents and preservation of memory . . . 701
14.9 Dodecaphase seal and reversible rational reading . . . 702
14.10 Cyclic decomposition and determinantal representations . . . 703
14.10.1 Oriented information and the complex sector . . . 703
14.11 Planck constants and the determinantal structure of action . . . 704
14.11.1 Determinantal action scale and decimal valuation . . . 704
14.11.2 Action sections and dimensionless return quotient . . . 705
14.11.3 Structural definition and role of the Planck constants . . . 707
14.11.4 Angular coordinates, turn normalization and action units . . . 708
14.11.5 Covariance of the channels and the incidence functional . . . 709
14.11.6 Angular coordinates, turn normalization and action units . . . 709
14.11.7 Covariance of the channels and the incidence functional . . . 710

15 Incidence channels 90/120 of the Topological Phase Kernel: tritic semicrowns, sheet factorization, and hexad–octad realization of the morphism 6→8 712

15.1 Arithmetic classification of integer channels and compatibility with the triticale semicrown . . . 712
15.1.1 Visible residue, digital root and crown memory . . . 712
15.1.2 Classification Theorem of the 4 Integer Channels . . . 713
15.1.3 Semicorona nonadic relative to the TPK phase rule . . . 714
15.1.4 Semicorona relative to the hexad-octad elevation and pointed return . . . 715
15.1.5 Dihedral action and classification under declared predicates . . . 716
15.1.6 Typed correspondence $271 \to e$ *and* $315 \to \pi$ . . . 717
15.1.7 Visible parity, carry parity and physical boundary . . . 719
15.2 Derivation of the channels 90/120 through inclusion of hexad–octad incidences 720
15.3 Transport of $-1/12$ to the channels 90/120 in 5 algebraic realizations . . . 720
15.3.1 Difference of dodecaphasic periodicities . . . 720
15.3.2 Pseudoinverse of the Gram Operator on the Live Component . . . 720
15.3.3 2nd difference between triadic scales . . . 721
15.3.4 Composition of modular transformations and preservation of the signed state . 721
15.3.5 Defect of cyclic difference projectors . . . 721
15.4 Barbero–Immirzi parameter: area operator, spectrum, channel intertwiner, and modular entropy . . . 722
15.5 Hexadic–octadic incidence and the Barbero–Immirzi functional . . . 723
15.5.1 Dodecaphase fundamental chain and pole coefficient . . . 724
15.5.2 Parity and structural sensitivity . . . 725
15.5.3 Structural dependence of the functional and areal normalization . . . 725
15.5.4 Structural definition and role of the Barbero–Immirzi parameter . . . 725
15.6 Action ellipse and modular reciprocity . . . 726
15.6.1 Semiaxes, foci, and interior radii . . . 727
15.6.2 Parametric phase, polar angle, and action area . . . 727
15.6.3 Shape reciprocity and interior distance . . . 728
15.6.4 Bohr radius: a consequence of the action scale . . . 729
15.6.5 Inductive–capacitive realization and constitutive continuity . . . 729

15.6.6 Canonical covariance and reciprocity of the action ellipse 730

16 Dodecaphase Mixing Operator: CKM–CP Phase and Construction of the Pre-Dimensional Electron Reader **733**

16.1 Dimensionless construction of the electronic scalar from APP incompatibility and the dodecaphase state 733

16.1.1 Electronic scalar $\mathfrak{e}_{\mathrm{HMT}}$ and causal graph of its factors APP–TPK, α_{HMT}, Δ_4 and nonadic atlas 734

16.1.2 1st factor: exact incompatibility of the APP leaves 734

16.1.3 2nd factor: the exchange involution between π and φ 735

16.1.4 3rd and 4th factors: the integers 22, 15 and the center 5 736

16.1.5 5.º factor: the cubo of the closure α_{HMT} 737

16.1.6 6th factor: minimal torsion and global defect Δ_4 738

16.1.7 Uniqueness of the central cell (5,5) as the genealogical support of the electron 739

16.1.8 Electron–positron conjugate orbit on the oriented path band 740

16.1.9 Basal stage of the electronic closure 741

16.2 Algebraic structure of the electron and action scale 743

16.2.1 Center, orientation, and vacancy on a preserved fiber 744

16.2.2 Commutator norm of the arithmetic projections 748

16.2.3 Spinor representation of the electronic block and helicity 750

16.2.4 Transfer between sheets and coefficients of the basal stage 752

16.2.5 Global torsion and the basal coordinate 753

16.2.6 Determinantal action scale and decimal valuation 754

16.2.7 Action sections and dimensionless return quotient 755

16.2.8 Two readers of the electronic return 758

16.2.9 Complete electronic composition and normalization 760

16.2.10 Dimensional realization: energy, mass, and chronological scale 761

16.2.11 Lorentzian transport and electromagnetic representation 763

16.3 CKM mixing angles, CP phase and leptonic transport 763

16.3.1 Common antecedent and distinction between the two transports 763

16.3.2 Sectorial incidence and construction of the angular reader 764

16.3.3 Rational CKM chart and angular units 768

16.3.4 Geometric decomposition under sheet inversion 769

16.3.5 Transport of sheet inversion 769

16.3.6 Record parity and CP realization 770

16.3.7 Unitary amplitudes, CP phase and Jarlskog invariant 770

16.3.8 Conjugation of amplitudes and oriented invariant 771

16.3.9 Leptonic record, operators and spectral frames 772

16.3.10 Record kernel and rank sufficiency 773

16.3.11 Rank-one phase check 774

16.3.12 Leptonic phase and Dirac–Majorana criterion 774

16.3.13 Closure of angular transport 775

17 Double projection of the same state: Archimedean publication and exceptional conservation of incidence **776**

17.1 Ambivalence Principle: involute of the areal and volumetric readers over the enriched state 776

17.1.1 Domains of the 2 projections 776

17.1.2 Topology of the space of histories 776

17.1.3 Separation by the 2 projections 777

17.1.4 Archimedean quotient by the evaluation fibers 778

17.1.5 Common invariant with the Witt system . . . 778
17.1.6 Residual design on a dodecada and elevation of hexads . . . 779
17.1.7 Lattice prolongation and dimensional screens . . . 782
17.1.8 Residue–quotient involution and conservation of state information . . . 782
17.1.9 Finite compatibility and joint prolongation . . . 782
17.2 Exceptional projection of the enriched state: compatible incidence at all depths 783
17.2.1 Common enriched domain and inequivalent codomains of the 2 projections . . 783
17.2.2 Compatible extensions and uniqueness of the initial scale . . . 783
17.2.3 Joint separation of histories by the Archimedean and exceptional projections . 784
17.2.4 Bifurcation of a surviving prefix in Archimedean value and exceptional incidence 785
17.2.5 Common incidence invariant between the enriched state and the Witt system . 786
17.3 Decomposition of the microfiber of π into 5 oriented regions: 4 peripheral components and 1 fixed axis . . . 786
17.3.1 Reticular prolongation of incidence and construction of dimensional screens . 786
17.3.2 Archimedean contraction of compatible cylinders and realization of the real line 787
17.3.3 Exceptional projection by incidence and boundary conservation . . . 788
17.3.4 Finite Compatibility of the Common Domain . . . 788
17.3.5 Typed separation of the Archimedean and exceptional publications of the common state . . . 788
17.3.6 Precise formulation of the thesis on the real line . . . 789
17.4 Dependence of the reader of incidence with respect to the enriched state . . 789
17.5 Archimedean and incidental publication . . . 790
17.6 Factorization of the incidence reader through the enriched state . . . 791
17.7 Double publication of the enriched state: Archimedean evaluation and incidence conservation . . . 792
17.8 Uniqueness of the Initial Caliber of the Exceptional Projection . . . 793
17.9 Noncommutative Algebra, Common and Factorization of the 2 Projections . 794

18 Archimedean publication of the continuum: reconstruction of $\mathbb{R}$ as a quotient of semiclosed cylinders with genealogical memory 795
18.1 Nonadic cylinders, identity and Dirac kernel . . . 795
18.1.1 Inverse system of compatible nonadric cylinders with genealogical memory . . 795
18.1.2 Cylindrical concentration of the identity and construction of the Dirac kernel . 795
18.1.3 Convergence of the Kronecker Kernel to the Dirac Distribution . . . 796
18.1.4 Scaling Law, Effective Dimension, and Density of the Cylindrical Measure . . 796
18.1.5 Nonadic Monodromy and Computability of the Archimedean Evaluation . . . 796
18.2 System of intervals associated with finite states . . . 797
18.3 Coherent coverage of the visible compactum . . . 797
18.4 Archimedean genealogical quotient and homeomorphism with $\mathbb{R}$ . . . 798
18.5 Genealogical Atlas of the Real Line . . . 799
18.6 Balanced ternary and block-decimal charts . . . 799
18.7 Descent of operations along evaluation fibers . . . 800
18.8 Correspondence between discrete cardinality, cylindrical measure, and Archimedean publication . . . 801
18.9 Obstructions to Archimedean evaluation: nesting, continuity, quotient, projective measures, and descent of operations . . . 801
18.10 Quotient of the space of compatible histories and realization of the real line 802
18.11 Compatibility of the median Archimedean evaluation with the double projection of the enriched state . . . 803

18.12 Genealogical radial correspondences on the enriched state: domain, codomain, and preservation of helical history . . . 803
18.13 Construction and main results of the enriched radial reader . . . 804
18.14 Key results of the radial publication APP–TRIT–TPK . . . 805
18.15 Typed notation and causal levels of the radial publication . . . 805
18.16 Genealogical Foundation of Radial Geometry . . . 806
18.16.1 Archimedean evaluation of the enriched state and genealogical fidelity defect . 806
18.16.2 APP: two-dimensional support, arithmetic sheets and mixed curvature . . . 807
18.16.3 TRIT: local orientation and 3 geometric regimes . . . 810
18.16.4 Enriched state, unique continuum and double projection . . . 811
18.17 Genealogical theory of spiral correspondences . . . 813
18.17.1 Affine universal envelope of the APP leaves . . . 813
18.17.2 Radial cocycles in the TRIT lift of 2 semicoronas . . . 815
18.17.3 Power-logarithmic coordinate and sum-product law . . . 816
18.17.4 Power–logarithmic classification of the published curves . . . 817
18.17.5 Radial enriched reader . . . 819
18.17.6 Naturalness, equivariance, and inverse limit . . . 820
18.17.7 Classification by the full radial signature and failure of fidelity of the Archimedean evaluation . . . 822

19 Cardinal closure of the HMT analytic continuum: bidirectional reading of the Topological Phase Kernel and comparison with the continuum hypothesis 825
19.1 The complete TRIT cell and the bidirectional temporal extension . . . 825
19.2 Stable Mode of the Unitary Calendar under Modular Memory Update . . . 826
19.3 Analytic realizations of HMT histories via the Archimedean and bidirectional charts . . . 828
19.4 Comparison between the genealogical cardinal closure and its extensional ordinal reduction . . . 830
19.5 Cardinal identity of the HMT analytic continuum: $\aleph^{\mathrm{an}}_{1,\mathrm{HMT}} = 2^{\aleph_0}$ and comparison with the classical continuum hypothesis . . . 830
19.6 Loss of ancestral memory under reduction to the ordinal codomain . . . 831
19.7 Ordinal closure of the HMT genealogical codomain . . . 831
19.8 Compatibility among HMT cardinal closure, the set-theoretic formulation of the continuum, and bidirectional genealogical memory . . . 832
19.9 Bidirectional extension groupoid and operator algebra . . . 834
19.10 Proof of $2^{\aleph_0} = \aleph_1$ in the HMT continuum . . . 834
19.10.1 Extension of states and transfinite semantic extension . . . 834
19.10.2 TPK lift of the ternary fiber and complete cylinder partition . . . 838
19.10.3 Enumeration by genealogical codes and HMT condensation . . . 852
19.10.4 Injection of the generated line into the first uncountable ordinal of the genealogical closure . . . 854
19.10.5 Injection of the first uncountable ordinal into the line and cardinal equivalence 854
19.10.6 Quantification over all internal subsets . . . 855
19.10.7 Representation of the genealogical closure as $L[h, m_\infty]$ . . . 855
19.10.8 Theorem giving an affirmative resolution of the Continuum Hypothesis . . . 856
19.10.9 Falsification criteria for the cardinal closure . . . 856
19.11 Phase, dodecaphase register, and exceptional realization of the common state 857
19.11.1 Reflection by witness closure and construction of the image . . . 858
19.11.2 Compatibility of the cardinal classifier with the restoration of histories . . . 859

20 Dodecaphasic–Witt intertwiner: point–hexad incidence, reduction 11→3→1, residual S_3 action and obstruction to triple equivariance **861**
20.1 Dodecaphase–Witt intertwining and the exact reading of 3/11 861
20.1.1 Typing of the objects associated with 3/11 861
20.1.2 The point–hexad incidence matrix 862
20.1.3 Positive transport of the tritic projector 864
20.1.4 Signed index of the Witt star 864
20.1.5 homogeneous reduction $11 \to 3 \to 1$ *in* $t = 7$ 865
20.1.6 The residual action of S_3 *and the positive regions of* π 865
20.1.7 Dependence of orientation in the dodecaphase entangler–Witt 866
20.1.8 Variational selection of the normalizer S_3 867
20.1.9 Selection of orientation and presentation of S_3 868
20.1.10 Reynolds average and polar factor 868
20.1.11 Comparison of the readings of $t = 7$ *and* $t = 8$ 871
20.1.12 Positivity of the Action Induced by the Dodecaphasic Braider–Witt 871
20.2 Equivariant realization of the angular reader in Witt incidence 871
20.2.1 Regional triplet and orientation line 872
20.2.2 Dodecaphase sector and variational selection of orientation 873
20.2.3 Reynolds intertwiner and polar normalization 875
20.2.4 Point–hexad incidence and joint gauge change 875
20.2.5 Isometric composition and coordinate recovery 876
20.2.6 Faithful realization of the angular sectorial system 877
20.2.7 Exact certification and finite unitary composition 878
20.2.8 Structural result and scope of the composition 878

21 From spectral jump 4 to the Leech lattice: APP unfolding 4→2→6→54 and the Paley–Witt–Mathieu–Golay–Niemeier corridor **880**
21.1 From the spectral gap $4 \to 2 \to 6 \to 54$: local coupling, modular compression, and two-dimensional integration 880
21.2 Paley conference form, finite quadratic extension and self-dual ternary code 881
21.2.1 Projective gauge of the 6 *units modulo* 9 881
21.2.2 ternary reduction and internal quadratic root of $-I_6$ 882
21.2.3 Extension quadratic to $\mathbb{F}_9$ 882
21.2.4 Ternary graph code of length 12 883
21.2.5 Algebraic classification of the self-dual ternary structure obtained 884
21.2.6 Obstructions in the Paley–C_W *corridor: bijection,* $A_W^2 = -I_6$*, self-duality, and census of* 729 *words* 884
21.3 Ternary Steiner system, Witt-star involutions and generation of M_{12} 884
21.3.1 Supports projective of weight 6 884
21.3.2 Residue of a tetrad and decomposition into 4 *incident components* 885
21.3.3 Star selected by the tetrad of the seal 886
21.3.4 Global field of the 495 stars 886
21.3.5 Action on the augmentation module 887
21.3.6 Obstructions concerning W_{12}*, the field of* 495 *star involutions and the generation of* M_{12} 887
21.4 Binary extension relative to a dodecad, system W_{24} and group M_{24} 888
21.4.1 Golay binary code and octads 888
21.4.2 Relative scale between the HMT design and the dodecagon 888
21.4.3 4+1 Decomposition of the incidence of a tetrad into peripheral and axial components 889

21.4.4 *Strata Correspondence and Positivity of the Triple Freedom* . . . 889
21.4.5 *Automorphism group of the octad system* . . . 890
21.4.6 *Categorical separation from the lattice branch* . . . 890
21.4.7 *Obstructions to the binary prolongation $W_{12} \to W_{24}$: Golay code, octads, alignment and separation of the Leech branch* . . . 890
21.5 Ternary discriminant gluing and construction of the Niemeier lattice of type A_2^{12} . . . 891
21.5.1 *Reticulo root A_2* . . . 891
21.5.2 *Decomposition of the incidence of a tetrad into 4 peripheral components and 1 axial component* . . . 891
21.5.3 *Correspondence between incidence strata and free orbit of the positive triple* . . . 892
21.5.4 *Integrality induced by self-duality* . . . 893
21.5.5 *Parity Induced by the Code Weights* . . . 893
21.5.6 *Index, determinant, and unimodularity* . . . 893
21.5.7 *Root system induced by Witt incidence and classification of its orbits* . . . 894
21.5.8 *Obstructions to the ternary gluing $C_W \to N(A_2^{12})$: parity, unimodularity, and root system* . . . 894
21.6 Incidental origin, typed radial problem and construction of the rootless unimodular neighbor . . . 894
21.6.1 *Ordered set of incidences* . . . 895
21.6.2 *Positive radial chamber of the root system and selection of the dominant cone* . . . 895
21.6.3 *Discriminant gluing of 12 A_2 factors and construction of the integral extension* 896
21.6.4 *Condition I1: surjectivity and exclusion of roots* . . . 897
21.6.5 *Condition I2: norm divisibility* . . . 897
21.6.6 *Condition I3: class dual of order* 3 . . . 897
21.6.7 *Parity, integrality and determinant of the neighbor* . . . 897
21.6.8 2 *clasis globalis and* 6 *clasis local* . . . 898
21.6.9 *Criterion for the absence of roots in the Leech lattice and consequence for the minimum distance* . . . 898
21.6.10 *Identification with the Leech lattice* . . . 899
21.6.11 *The 243 syndromes of the ternary punctured code* . . . 899
21.6.12 *Obstructions of the ternary neighbor $N_v \cong \Lambda_{24}$: class of order* 3*, absence of roots, and separation of the cardinals* 243 . . . 899
21.7 Finite holonomy, Schläfli configuration and symmetry E_6 . . . 900
21.7.1 *Ordered system of incidences and radial camera orientation* . . . 900
21.7.2 *Central extension and ternary reduction* . . . 900
21.7.3 *Construction of the radial character and determination of its congruence kernel* 901
21.7.4 *Action of* 10 *displazamientos over the grafo of Cayley* . . . 901
21.7.5 *The root lattice realizing E_6* . . . 904
21.7.6 *Stratification of the 729 Words* . . . 904
21.7.7 *Necessity of the central phase* . . . 905
21.8 Oriented APP–Fock coupling and transverse rigidity of 12 fibres . . . 906
21.8.1 *Triangular mark on each orbit* . . . 906
21.8.2 *Oriented coupling $\mathcal{H}^{(m)}_{\Sigma,\Pi}$ between the balance C_3, leaf parity, and degree* 2 *of Fock space* . . . 906
21.8.3 *Transverse rigidity of the number of fibers* . . . 908
21.8.4 *Factorization of the APP–Fock coupling: hypotheses, invariants, necessary conditions for validity, and obstructions* . . . 909

21.8.5 Complete genealogy of the exceptional projection: from Paley and Hadamard to the Witt, Leech and Moonshine systems . . . 909
21.9 Dodecaphase incidence and the Witt–Leech–Monster corridor . . . 911
21.9.1 Dodecaphase state and incidence supports . . . 911
21.9.2 Coincidence of the threshold supports . . . 911
21.9.3 Coincidence of the negative supports . . . 912
21.9.4 Reconstruction of the base point from the incidence frame . . . 913
21.9.5 Incidence of the ternary design . . . 913
21.9.6 Hexads, octads and the cardinality identity 28 . . . 913
21.9.7 Star involutions and generation of the Mathieu group . . . 913
21.9.8 Two exceptional extensions of the ternary code . . . 914
21.9.9 Radial minimization and explicit construction of the 3-neighbor . . . 915
21.9.10 Corridor from Leech to the Moonshine algebra . . . 916
21.9.11 Quotient space of 243 syndromes . . . 917
21.9.12 Finite compatibility of the arithmetic and exceptional evaluations . . . 917
21.10 From spectral jump 4 to Monster symmetries: APP unfolding $2 \to 6 \to 54$, the Leech lattice, $V^\natural$, and the Moonshine corridor . . . 918
21.10.1 Typed hierarchy and 2 realizations of index 54 . . . 918
21.11 Exceptional prolongation: from dodecaphasic incidence to Moonshine . . . 919
21.11.1 Compatibility of the Archimedean and incidence realizations . . . 920
21.11.2 The finite realization and the ternary code . . . 921
21.11.3 Dodecaphasic flag associated with K and α . . . 922
21.11.4 Isometric intertwining of the incidence representations . . . 925
21.11.5 The direction selected by the dodecaphasic register . . . 926
21.11.6 The Witt star and the generation of M_{12} . . . 928
21.11.7 The binary residue and the five regions of π . . . 929
21.11.8 From the ternary code to the Niemeier lattice . . . 931
21.11.9 Incidence selection of the rootless unimodular neighbor . . . 931
21.11.10 The vertex operator algebra and the Monster . . . 933
21.11.11 State-based construction of the twelve cyclotomic fibres . . . 934
21.11.12 Dodecaphasic alignment with the Witt positions . . . 935
21.11.13 Ternary orientation of the Leech neighbor . . . 936
21.11.14 Ternary trace, twisted weight and order-three extension . . . 937
21.11.15 Equivalence of the order-two and order-three presentations . . . 938
21.11.16 Eta functions, Fricke involution and vacuum normalization . . . 938
21.11.17 Exceptional incidence and coordination of the screens . . . 939
21.11.18 Graded Moonshine traces and representation of the Monster . . . 940
21.11.19 Full-support orientations and lattice equivariance . . . 941
21.12 Finite holonomy, Schläfli configuration and symmetry E_6 . . . 942
21.12.1 Ordered system of incidences and radial camera orientation . . . 942
21.12.2 Central extension and ternary reduction . . . 942
21.12.3 Construction of the radial character and determination of its congruence kernel 943
21.12.4 Action of 10 displacements on the Cayley graph . . . 943
21.12.5 The root lattice realizing E_6 . . . 946
21.12.6 Stratification of the 729 Words . . . 947
21.12.7 Necessity of the central phase . . . 947
21.13 Generation and locality of fields on the incidence lattice . . . 948
21.13.1 Location of the marked origin and persistence of incidence . . . 948
21.13.2 Parity cocycle and twisted lattice algebra . . . 949

21.13.3 Oscillator space and Heisenberg representation . . . 949
21.13.4 Creation and annihilation coefficients in all degrees . . . 950
21.13.5 Charge field and Laurent truncation bound . . . 951
21.13.6 Scalar contraction and normal ordering of products . . . 952
21.13.7 Mixed commutator in all integer modes . . . 953
21.13.8 Mixed locality by coefficientwise cancellation . . . 953
21.13.9 Locality of charged fields and preservation of the origin . . . 954

22 Vertex operator algebra $V^\natural$, modular function J, and monstrous Moonshine: graded action of the Monster, McKay–Thompson series, and replicability 956
22.1 Alineamiento ciclotomico, orbifold of order 3 and Monstrous Moonshine . . . 956
22.1.1 Alignment of the 12 *APP and Witt fibers* . . . 956
22.1.2 Graded trace of the action of the ternary generator on $V^\natural$ . . . 957
22.1.3 Isometry Without Fixed Points Induced by the Ternary Word of Full Support . . . 958
22.1.4 Preservation of the Leech Neighbor . . . 958
22.1.5 24 *orientations and lattice naturality* . . . 959
22.1.6 Lattice trace and computation of type 0 . . . 959
22.1.7 Cyclic orbifold and dual class 3*B* . . . 960
22.1.8 Lattice construction of order 2 . . . 961
22.1.9 Automorphism group, character, and graded series . . . 962
22.1.10 Paley–Witt–Golay–Leech–Moonshine Runner Dependency Graph . . . 962
22.2 Theta control of the Leech lattice: identity $\Theta_\Lambda = E_4^3 - 720\Delta$ and separation between arithmetic coincidence and structural morphism . . . 963
22.3 Lattice VOA, canonical involution and order-two Moonshine branch . . . 963
22.3.1 APP–Witt intertwining, Leech neighbor, and orbifold of order 3 . . . 964
22.3.2 Constructions of orders 2 *and* 3 *of the vertex operator algebra $V^\natural$* . . . 965
22.4 Continuous evidentiary chain of the exceptional publication: from the APP unfolding to Paley–Witt, $V^\natural$ and Moonshine . . . 966
22.4.1 APP unfolding and graded cone of the index 54 . . . 966
22.4.2 Paley form and internal quadratic root of $-I_6$ . . . 967
22.4.3 Self-dual ternary code and Witt system . . . 968
22.4.4 Ternary gluing and Leech neighbor . . . 969
22.4.5 Order-three isometry, orbifold and lunar module . . . 970

23 Hilbertian realization of the genealogical state and von Neumann continuous dimension: nonadic UHF tower, trace and hyperfinite factor II_1 972
23.1 From the internal complex structure to the projective geometry of Bloch . . . 972
23.1.1 Phase and ray space realification . . . 972
23.1.2 Rotations, Möbius transformations and spinor lifting . . . 973
23.2 Projective realization of Bloch from the internal complex structure . . . 974
23.2.1 Matrix realization of each depth . . . 974
23.2.2 Weyl–Heisenberg Representation of Phase and Displacement on the Triadic Fiber 974
23.2.3 Aritmetic Projectors and Incompatibility . . . 975
23.2.4 Hilbertian structure of the matrix publication and preserved genealogical memory 975
23.3 The 9 phases of the TPK and continuous geometry . . . 975
23.3.1 Typed separation between the UHF lift of nonadic ranks and the geometric prolongation of the marked branch . . . 975
23.3.2 The UHF limit . . . 976
23.3.3 Corner immersion of a marked phase: compact ideal $\mathcal{K}(\mathcal{H}_\infty)$ and factor $\mathcal{B}(\mathcal{H}_\infty)$ of type I_∞ . . . 976
23.3.4 Continuous dimension from nonadic ranges . . . 977

23.4 Profinite dynamical system: translation, logical algebra, and state space . . . 978
23.4.1 The 2nd route to the hyperfinite factor . . . 978
23.4.2 theorem ergodico medio of von Neumann for the odometro of Haar in K_∞ . . . 978
23.4.3 Orthomodular Lattice of Projections and the Logic of Closed Subspaces . . . 979
23.4.4 Density matrices and entropy . . . 979
23.4.5 Operator types and modular boundary . . . 979
23.5 Hilbert-space realization of the nonadic phase and preservation of the unit . 980
23.5.1 Phase fiber, labeled basis, and inner product . . . 980
23.5.2 Translation and phase: finite Weyl representation . . . 980
23.5.3 Two lifts and two different normalizations . . . 982
23.5.4 Inductive closure and tracial realization . . . 982
23.5.5 Integer ranks and continuous tracial dimension . . . 983
23.6 Two-dimensional refinement of APP and carry cocycle . . . 983
23.6.1 Projection, fibers and ternary refinement coordinates . . . 984
23.6.2 Additive composition and memory of modular crossing . . . 984
23.6.3 Compatibility of the multiplicative sheet . . . 985
23.6.4 Directions and realization of transport . . . 986
23.6.5 Six ternary digits and distinct algebraic structures . . . 986
23.7 Genealogical path kernels: finite composition, unitary realization and cylindrical limit . . . 987
23.7.1 Route category and functorial weight . . . 987
23.7.2 Construction of the internal phase through the real action character on genealogical routes . . . 988
23.7.3 Unitary realization on the chronological register 27×27 . . . 988
23.7.4 Cylindrical limit on the space of genealogies . . . 990
23.7.5 Reading of the value and memory of the fiber . . . 991
23.8 Hilbert-space realization of the nonadic phase and preservation of the unit . 991
23.8.1 Phase fiber, labeled basis, and inner product . . . 992
23.8.2 Translation and phase: finite Weyl representation . . . 992
23.8.3 Two lifts and two different normalizations . . . 994
23.8.4 Inductive closure and tracial realization . . . 994
23.8.5 Integer ranks and continuous tracial dimension . . . 995
23.9 Arithmetic–geometric coupling and bilateral recovery . . . 995
23.9.1 Exact encoding and cyclic reference . . . 995
23.9.2 Conservation and reconstruction of two channels . . . 996
23.9.3 Transport of observables and incoming memory . . . 997

24 T-duality of residual memory: unitary equivalence between momentum and winding for reciprocal radii 999
24.1 Involution between the residue and quotient coordinates . . . 999
24.2 HMT reading duality: duality T, block 243, ternary Golay code, and mass routes . . . 1000
24.2.1 Operational extension of APP: visible modes and memory modes . . . 1001
24.2.2 Completion 1000=729+243+27+1 and stratification of the unit . . . 1001
24.2.3 Operatorial extension of APP: separation between visible modes and memory modes . . . 1001
24.2.4 Decomposition 243=1+22+90+120+10 and typing of its components . . . 1002
24.2.5 Derivation of the constant channels from the decomposition of block 243 . . . 1002
24.2.6 Construction of dimension 11 via compatible residual readers . . . 1003
24.2.7 Constant channels derived from the block 243 . . . 1003

24.2.8 Closure of the genealogical register under the T-duality involution 1003
24.2.9 Dimensional realization of duality 1003
24.2.10 Compatibility between leaves and closure of the genealogical record 1004
24.2.11 T-Duality, Modularity and J Function 1004
24.2.12 Dimensional Consequences for Photon, Electron, Mass, and Statistics 1004
24.2.13 Exact identities of involution, modularity, and residual conservation 1005
24.2.14 Common core of the 3 formulations of T-duality 1005
24.2.15 Distinction of the 2 residual sections by their energy insertions and equivalence classes 1006
24.2.16 Exact normalization of the string realization 1007
24.2.17 Level separation, linear mass exchange, and modularity of the 3 realizations . 1008
24.3 Action ellipse and determination of the normalized radius 1008
24.3.1 Domain and labelled semiaxes 1008
24.3.2 Parametric phase and oriented area 1009
24.3.3 Shape reciprocity and symplectic orientation 1010
24.3.4 Normalized radius and lattice-readout matrix 1010
24.3.5 Inductive–capacitive realization of the action form 1011
24.4 T-duality: integer coordinates, change of section, and operator equivalence . 1012
24.4.1 Stable domain of the interchange 1012
24.4.2 Compact Hamiltonian and self-adjoint domain 1012
24.4.3 Specialization to the radius of the action ellipse 1013
24.4.4 Change of representative and quotient memory 1014
24.4.5 Radius normalization in the string realization 1015
24.4.6 Relationship with the modular transformation 1015
24.5 Action ellipse and determination of the normalized radius 1016
24.5.1 Domain and labelled semiaxes 1016
24.5.2 Parametric phase and oriented area 1016
24.5.3 Shape reciprocity and symplectic orientation 1017
24.5.4 Normalized radius and lattice-readout matrix 1018
24.6 T-duality: integer coordinates, change of section, and operator equivalence . 1019
24.6.1 Stable domain of the interchange 1019
24.6.2 Compact Hamiltonian and self-adjoint domain 1019
24.6.3 Specialization to the radius of the action ellipse 1020
24.6.4 Change of representative and quotient memory 1021
24.6.5 Radius normalization in the string realization 1021
24.6.6 Relationship with the modular transformation 1022

25 Coordination of the Moonshine corridor and the M-theory screens: shared grading, lattice transport and double realization of the HMT state 1023
25.1 The perfect quotient of 11 coordinates 1023
25.2 Dimensional reduction 26→24→11→10 and coordination with M-theory screens 1024
25.3 Coordination of exact screens with the physical realization of M theory . . . 1025
25.4 Polarization of the three-dimensional sector determined by K 1026
25.5 Operatorial representation of APP and supersymmetric spectral triple in dimension 11 1028
25.6 Icosahedral McKay correspondence and type E_8 1029
25.7 Dimensional reduction and the context of M-theory 1030
25.8 Quotient Diagrams and Rank Reductions 1031
25.9 From exact screens to the physical interface of M-theory 1031

25.10 Polyakov Action, T Duality, and Compactification of the HMT State in M-Theory Branes . . . 1032
25.10.1 Extended persistence and world surface . . . 1032
25.10.2 Exact screens in dimensions 11, 10, 26 *and* 24 . . . 1033
25.10.3 Moment, winding and reciprocal radius . . . 1034
25.10.4 Interface in dimension 11*: spectral triple, supersymmetry and operator* $Q^2 = H$ 1034
25.11 operatorial extension of APP and spectral triad of the supersymmetric interface in dimension 11 . . . 1035
25.11.1 Operatorial extension of the APP–TRIT–TPK state toward the triad $(\mathcal{H}_{\text{phys}}, H, Q)$ 1035
25.11.2 Compaction and undecadimensional physical codomain . . . 1036
25.11.3 Spectral compatibility of $(\mathcal{H}_{\text{phys}}, H, Q)$ *with* $Q^2 = H$*, T-duality, and* $11 \to 10$ *compactification* . . . 1036
25.12 Boundary systems, dimensional range, and action functional . . . 1036
25.12.1 Constraint systems and boundary data . . . 1036
25.12.2 Module of channels and dimensional range . . . 1037
25.12.3 Inherited arithmetic and lattice screens of HMT . . . 1037
25.12.4 Involution between residual data and Euclidean quotient . . . 1039
25.12.5 Typed interface with undecadimensional reduction . . . 1039
25.12.6 Dimensional state and simultaneous transport . . . 1040
25.12.7 Descent to a dynamics on point states . . . 1040
25.12.8 Additive functional on oriented trajectories . . . 1040
25.13 Coordinated projections of the HMT state: algebraic equivalence of screens and physical realization in dimension 11 . . . 1041
25.13.1 Exact equivalence of lattice screens and conditions for the realization of undecadimensional structures . . . 1041
25.13.2 Algebraic screen morphism and quotient equivalence . . . 1042
25.13.3 Physical Recognition Undecadimensional . . . 1043
25.14 Dimensional screens and coordinated reduction of the state . . . 1043
25.14.1 Channels, relations and effective dimension . . . 1043
25.14.2 Ternary puncturing and syndrome screen . . . 1044
25.14.3 The dodecaphase direction and rank reduction . . . 1045
25.14.4 Lorentzian lattice screen . . . 1045
25.14.5 Joint screen morphism . . . 1046
25.14.6 Coordination with the exceptional realization . . . 1046
25.15 Action on trajectories and eleven-dimensional dynamical realization . . . 1047
25.15.1 Descent of an evolution and sufficiency of the observed datum . . . 1047
25.15.2 Cocycle of directional and arithmetic changes . . . 1047
25.15.3 Extended persistence and world surface . . . 1048
25.15.4 Eleven-dimensional realization and graded operators . . . 1048
25.15.5 Compatible compactification and conclusion of the development . . . 1049
25.16 Dimensional screens and coordinated reduction of the state . . . 1050
25.16.1 Channels, relations and effective dimension . . . 1050
25.16.2 Ternary puncturing and syndrome screen . . . 1050
25.16.3 The dodecaphase direction and rank reduction . . . 1051
25.16.4 Lorentzian lattice screen . . . 1052
25.16.5 Joint screen morphism . . . 1052
25.16.6 Coordination with the exceptional realization . . . 1053
25.17 Action on trajectories and eleven-dimensional dynamical realization . . . 1053
25.17.1 Descent of an evolution and sufficiency of the observed datum . . . 1053

25.17.2 Cocycle of directional and arithmetic changes . . . 1053
25.17.3 Extended persistence and world surface . . . 1054
25.17.4 Eleven-dimensional realization and graded operators . . . 1055
25.17.5 Compatible compactification and conclusion of the development . . . 1055
25.18 Finite enumerations of emissions and Witt stars . . . 1056
25.18.1 Initial-condition indices and signature recurrence . . . 1056
25.18.2 Explicit generators and closure of the stars . . . 1058

26 Completely positive systems and matrix genealogy of the continuum: convexity, Choi matrices, Stinespring dilation, and De les Coves–Netzer bridge 1059
26.1 Matrix range of APP: exact classification of the sum–product algebra and free interval . . . 1059
26.1.1 Pair of conditional expectations associated with the additive and multiplicative partitions of APP . . . 1059
26.1.2 Classification of the sum–product algebra at depth 2 . . . 1059
26.1.3 Spectral separation 4 and free matrix interval . . . 1061
26.1.4 Common antecedent of readers: spectral refinement and joint dilation limit . . . 1061
26.2 Genealogical matrix convexity: objects, domains, and typed dictionary . . . 1062
26.2.1 Construction of 4 cyclic quantum Latin squares in an elementary operator class 1062
26.2.2 Quantum Squares, Operator Systems, and Matrix Convexity . . . 1062
26.2.3 Typed correspondence between the HMT–MD genealogical state and operator systems: depth, truncation, monodromy, and reading . . . 1063
26.2.4 Realization of 3 operator contexts in a quantum square (9,3) . . . 1064
26.2.5 Representation of the complete genealogical atlas in a quantum square (12,3) . 1064
26.2.6 Bidirectionality of Mathematical Exchange . . . 1065
26.3 Operator systems of incidence: quantum Latin squares, qutrit contexts, and common genealogical dilation . . . 1065
26.3.1 Cyclic classification of 4 quantum Latin squares into an elementary operator class 1065
26.3.2 Bigraduation of the genealogical-matrix family . . . 1066
26.3.3 Additive APP representation of sizes $(9,3)$ *and its incidence codomain* . . . 1066
26.3.4 3 *contexts in a square* $(9,3)$ . . . 1067
26.3.5 The atlas complete in a cuadrado $(12,3)$ . . . 1067
26.3.6 Operatorial theorems and genealogical fidelity criterion APP–TPK . . . 1068
26.4 Genealogical–matrix bigrading at fixed outer size and trigrading (m,n,s): truncation, compression, and simultaneous dilation . . . 1069
26.4.1 Inverse system of histories and direct system of observables . . . 1069
26.4.2 The family at 2 *degrees* . . . 1069
26.4.3 Uniform dilation compatible with all depths of the projective system . . . 1070
26.4.4 Noncommutative UHF Tower and Matrix Compatibility . . . 1071
26.4.5 Trigraduation and Levels of Simultaneity . . . 1072
26.5 Matrix representation of the genealogical composition APP–TRIT–TPK . . . 1072
26.5.1 Realizations in systems of ordinary operators . . . 1072
26.5.2 Genealogical extension of operator systems for TPK routes . . . 1073
26.5.3 Genealogical HMT Cones and Extension of the Conical Theory . . . 1073
26.5.4 TPK as a category of routes with selection, transport, memory, and return. . . . 1073
26.5.5 Completely positive compositions compatible with the genealogical-matricial bidegree . . . 1074
26.5.6 Universality criterion in the genealogical domain . . . 1074
26.5.7 Contextuality and Nonsemiclassicality . . . 1075
26.6 Genealogical structure of APP–TRIT–TPK at the matrix level . . . 1075

26.6.1 *Common support of APP and dual evaluation via sum and product sheets* . . . 1075
26.6.2 *Posterior metrological realization of the double projection of the enriched state* 1076
26.6.3 *TRIT: visible state, orientation, carry, and genealogical memory* 1076
26.6.4 *TPK: category of memoryful paths* 1077
26.6.5 *Hilbertian realization and quantum structure* 1077
26.6.6 *From the nonadic tower to the operatorial continuum* 1078
26.6.7 *Double projection and metrology* 1078
26.7 Genealogical Limits, Transfer Channels and Stinespring Memory 1079
26.7.1 *Typed separation of the genealogical limit and the MPS limit* 1079
26.7.2 *Symplectic decomposition 12→4×3 of the phase coordinates* 1079
26.7.3 *Stinespring's Memoir and Non-Uniform Growth* 1080
26.7.4 *Dynamic fidelity equation* 1080
26.7.5 *Compatibility Criterion for Product State Limits* 1080
26.7.6 *Tensorial decompositions with symmetry* 1081
26.8 Completely positive matrix realization of the nonadic fibration of observables 1081
26.8.1 *The alternating form and the Weyl commutation* 1081
26.8.2 *The lift* $12 \to 4 \times 3$ 1082
26.8.3 *Depth, carry, and memory over the discrete phase space* 1082
26.8.4 *Typed separation between the qutrit overlap* $1/3$ *and the HMT reader* $1/\pi$ . . 1083
26.8.5 *Symplectic group and equivariance equation* 1083
26.9 Nonsemiclassical quantum magic square in a corner APP 1084
26.10 Conical route system and internal genealogical universality 1084
26.11 Identification of the Stinespring memory with the local record TPK 1085

From the surviving sections to the fundamental constants **1086**

III Genealogy of the fundamental constants: coinductive generation and dodecaphasic closure **1087**

27 Algebra and genealogical classification of the fundamental constants **1089**
27.1 Euclidean coordinates of the local cell 1089
27.1.1 *Cocycles of associativity and distributivity* 1090
27.2 Bijectivity of numbering 1090
27.3 Fibers of the residual projections on the integral liftings 1091
27.4 Native adder and quotient propagation 1092
27.5 Multiplication by a digit 1092
27.6 Global product by Horner 1093
27.7 Matrix linearization of the genealogical state and construction of the completely positive entangler 1094
27.8 Native coproduct and native antipode 1095
27.9 Exhaustive enumeration and necessity of structural coordinates 1096
27.10 Algebraic structure of the word monoid 1097
27.11 Problem of determining the constants from the genealogical state 1097
27.12 Antecedent chain APP–TRIT–TPK and domain of the extraction operators . 1098
27.13 Lines of magnitude, oriented letters and dimensional coordinate systems . . 1098
27.14 Torsor of frames and covariance of dimensional evaluations 1099
27.15 Final metrological evaluation and prohibition of retrospective selection . . . 1099
27.16 Exact domain of the genealogical generation and its terminal metrical chart . 1099

27.17 Operator classification of 114 numerical expressions by domain, generator, invariant, and codomain . . . 1099
27.18 Spectral, informational, and thermodynamic confluence of log 3 . . . 1100
27.19 Epistemological classification of the derived constants . . . 1101
27.20 Joint theorem of coinductive generation and arbitrary depth . . . 1102
27.21 Complete operator inventory and causal pipeline of the Topological Phase Kernel . . . 1109
27.21.1 Typed specification of an operator . . . 1109
27.21.2 Eight structural classes . . . 1110
27.21.3 Fourteen functional groupings . . . 1110
27.21.4 Nominal register of thirty-four entries . . . 1111
27.21.5 Causal update pipeline . . . 1112
27.21.6 Non-identification rules . . . 1112
27.22 Integral dodecaphasic register, cyclic extension, and decomposition $1+5+6$ 1113
27.22.1 Cyclic coordinate on the time-oriented 12-sector support . . . 1113
27.22.2 nonsplit extension $0 \to C_{12} \to C_{108} \to C_9 \to 0$ and carry cocycle . . . 1113
27.22.3 Enriched temporal register . . . 1114
27.22.4 Extraction of the signed dodecaphase state from the enriched time record . . . 1115
27.22.5 Two dodecaphasic words of distinct origins . . . 1116
27.23 Signed dodecaphasic register and integral reconstruction of the seal . . . 1116
27.23.1 Windows of the oriented trace of length one hundred eight . . . 1116
27.23.2 Integral chart of the dodecaphasic opposition . . . 1117
27.23.3 Selection of the common terminal state . . . 1118
27.23.4 Two publications of the same state, not a conversion between them . . . 1119
27.23.5 Naturality with respect to depth . . . 1120
27.23.6 Step-three orbits and Hadamard transform . . . 1120
27.23.7 Integral structure and Smith normal form . . . 1121
27.23.8 Certification in the second coordinate system: step-three and step-four differences 1122
27.23.9 Threshold Tetrad of the Seal . . . 1123
27.23.10 Causal independence with respect to the physical output . . . 1123
27.23.11 Refutation criteria . . . 1123
27.24 Coinductive boundary and stabilization of compatible extensions . . . 1124
27.24.1 Candidates at the first boundary and opening relation . . . 1125
27.24.2 Existence of a complete history . . . 1125
27.25 Computable residual initialization and compatibility of regional emissions . 1126
27.25.1 Rational name produced by a regional reader . . . 1126
27.25.2 Initial prefix and representation of the residue . . . 1127
27.25.3 Residual update and emission through exact arithmetic . . . 1127
27.25.4 Correspondence between ternary and decimal depths . . . 1128
27.25.5 Exact implementation contract . . . 1129

28 Coinductive generation of π: closure character, 5 oriented regions, multiplicity $432+4\cdot 144=1008$ and arbitrary precision 1130
28.1 Causal separation between seed, character, and evaluation . . . 1130
28.2 Lifts L_0, L_1 and 1^{a} coinductive boundary . . . 1130
28.3 Closure microfiber of π: 5 oriented regions and multiplicity $432+4\cdot 144=1008$ 1131
28.4 Closure microfiber of π: 5 oriented regions, multiplicities $432+4\cdot 144=1008$, and common projection w_π . . . 1132
28.5 Publication of a reduced memory of a complete nonad block via the phase transfer multigraph . . . 1132

28.5.1 *Closure of $U_{\pi}^{(1)}$* . . . 1132
28.5.2 *Closure of $U_{\pi}^{(2)}$* . . . 1133
28.5.3 *Closure of $U_{\pi}^{(3)}$* . . . 1133
28.5.4 *Closure of $U_{\pi}^{(4)}$* . . . 1133
28.5.5 *Closure of $U_{\pi}^{(5)}$* . . . 1133
28.6 Oriented holonomies of the closure of the 5 regions of π . . . 1134
28.7 Pending $1/5$ determined by the regional partition $432 + 4 \cdot 144 = 1008$ . . . 1134
28.8 Determination of the slope 1/5 by the multiplicity of the regional microfiber of π . . . 1134
28.9 Rational composition of the half-turn and determination of the compensating term 239 . . . 1135
28.10 Arbitrary precision rational horocycles . . . 1136
28.11 Subsequent Archimedean certification of the already generated fiber . . . 1136
28.12 Filtration of $F_3{}^6$ by regional admissibility and selection of compatible subcylinders . . . 1137
28.13 Structural characterization, necessary validity conditions and obstructions . 1137
28.14 Typed separation of the 4 indices of nonadic prolongation . . . 1138
28.15 Ternary cylinders and the immediate ambient fibre . . . 1139
28.15.1 *Cross comparison of numerators and denominators in the rational interval* . . 1139
28.16 Minimal diagonal certification . . . 1140
28.17 Compatibility with the joint nonadic connection . . . 1140
28.17.1 *Nonadic compression, Archimedean evaluation, and terminal term of the cylinder* 1141
28.18 Uniqueness of the Minimal Diagonal Section in the Rational Fork System . 1141
28.19 Decimal cells and prescribed precision . . . 1142
28.20 Equivalence of 2 finite realizations of the uniform law . . . 1143
28.21 Separation between generation and verification . . . 1143
28.22 Finite realization of the certificate of arbitrary precision accuracy . . . 1144
28.23 Differentiated obstructions to generation and its certification at arbitrary precision . . . 1144

29 Coinductive generation of e: exponential character, factorial semigroup, and phase return with state memory 1145
29.1 Finite orbital selector: existence and uniqueness of compatible emission . . 1145
29.2 Block elevation and successive boundary compatibility . . . 1145
29.3 Exponential Section Prolongation via the Visible Block Chain . . . 1146
29.4 Construction of the decimal signature and the positional square of the exponential section . . . 1146
29.5 Subsequent factorial certification of the coinductive exponential section . . 1147
29.6 Cofinal Forking of Rational Tangles and Convergence to the Published Value 1148
29.7 Coinductive prolongation of the exponential section through ternary subcylinders of the Topological Phase Kernel . . . 1149
29.8 Inductive prolongation of e via the nonadic holonomy Γ_9 of the TPK . . . 1149

30 Coinductive generation of φ: modal incidence, positive Perron ray, and uniqueness of self-scaling 1150
30.1 Finite Selection of the Self-Scaling Seed . . . 1150
30.2 Blockwise lifting and 1^{a} coinductive boundary . . . 1151
30.3 Construction of the incidence multigraph from the triticale calendar . . . 1151
30.3.1 *Primitive modal rule* . . . 1151
30.3.2 *Areal-volumetric publication* . . . 1152

30.4 Construction of the modal incidence multigraph from the triticale calendar . 1152
30.5 Publication of the self-scale φ through Fibonacci powers and Diophantine convergence . . . 1153
30.6 Memory incidence of order 1 and Parry measure of the symbolic envelope . 1154
30.7 Multiplicative character and cylindrical conservation . . . 1154
30.8 Quadratic memory and contracted branch . . . 1155
30.9 Normalized hyperbolic realization of the self-scale: $\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2$. 1156
30.10 Characterization of self-similarity via rational forks and coinductive prolongation . . . 1156
30.11 Characterization of φ by the Perron ray, fork embedding, and coinductive prolongation . . . 1156
30.12 The dodecaphase closure of α . . . 1157
30.12.1 The terminal selector of the three channels . . . 1157
30.12.2 Dodecaphase state and reversible maps . . . 1160
30.12.3 The canonical vector and the three orbits . . . 1160
30.12.4 First representation: Hadamard transform . . . 1161
30.12.5 Relative cyclotomic transporter between sectors three and four . . . 1161
30.12.6 Second representation: transverse differences . . . 1163
30.12.7 The three Archimedean coordinates . . . 1165
30.12.8 Base-thousand carry recurrence . . . 1165
30.12.9 The complete affine identity . . . 1166
30.12.10 Inversion and equivalence of the three representations . . . 1167
30.12.11 Dodecaphase boundary condition . . . 1167
30.12.12 Comparison with the metrological reference . . . 1168
30.12.13 Coordinate independence and rigidity . . . 1168
30.13 Dodecaphasic closure and transversal dependencies of the state . . . 1169
30.14 Internal derivation of α_{HMT}: survival genealogy, dodecaphasic closure, two compatible constructions, and Witt bifurcation . . . 1169

31 Dodecaphasic closure of α_{HMT} and analytic reader $E_{21/22}^{(9)}$: reversible generation, simple root and typed comparator 1170
31.1 Internal derivation of α_{HMT}: common terminal state, dodecaphase seal, and carry cocycle . . . 1170
31.1.1 Dodecaphasic closure and compatible constructions . . . 1170
31.2 Signed register, seal reconstruction, and integral carry . . . 1170
31.3 Reversibility, independence, and non-circularity of the dodecaphasic closure 1170
31.4 Factorization of the signed dodecaphasic record and integral closure of the seal K . . . 1170
31.4.1 Windows of the oriented trace of length 108 . . . 1170
31.4.2 Integral chart of the dodecaphasic opposition . . . 1171
31.4.3 Selection of the common terminal state . . . 1172
31.4.4 2 publications from the same state and absence of retroactive conversion . . . 1173
31.4.5 Naturality with respect to depth . . . 1174
31.4.6 Orbits of step 3 *and transform of Hadamard* . . . 1175
31.4.7 Integral structure and Smith normal form . . . 1176
31.4.8 Certification and reconstruction by differences of steps 3 *and* 4 . . . 1176
31.4.9 Threshold Tetrad of the Seal . . . 1177
31.4.10 Causal independence with respect to the physical output . . . 1178
31.4.11 Obstructions of the dodecaphasic closure: seal, carry, reversibility and non-circularity . . . 1178

31.5 Coinductive prolongation of the dodecaphase cocycle and compatibility of the boundary 662/663 . . . 1178
31.5.1 Aritmetic closure domain . . . 1178
31.5.2 Left-to-right oriented Euclidean division . . . 1179
31.5.3 Finite domain of the dodecaphonic closure . . . 1180
31.5.4 Posterior metrological recognition: CODATA 2018 . . . 1180
31.5.5 Complete affine identity . . . 1181
31.5.6 Exact inversion of the seal K . . . 1181
31.5.7 Coinductive prolongation of the dodecaphasic seal and inverse carry recurrence in $C = \{-2, -1, 0, 1, 2\}$ . . . 1182
31.5.8 Boundary originating from the remote tail . . . 1183
31.5.9 Truncamiento compatible and rewhereo certified to 36 digits . . . 1184
31.5.10 Causal isolation from α and metrological data . . . 1185
31.5.11 Exact obstructions of the prolongation: boundary, truncation, and causal isolation . . . 1185
31.5.12 Terminal and dodecaphase evaluations of the common enriched state: blocks B_{term} and signed chart U_{12}^{sgn} . . . 1186
31.5.13 Reversible generation of α_{HMT} through the integral dodecaphasic closure . . . 1187
31.5.14 Simple root ξ_9 of the analytic kernel of order 9 and exact comparison $\text{Tr}_9(\xi_9^{-1}) = \text{Tr}_9(\alpha_{\text{HMT}}^{-1})$ . . . 1188
31.5.15 Prolongation coinductive $\mathsf{T}_{\alpha,\infty}$ of the entire dodecaphasic closure . . . 1188
31.5.16 Causal coordination of dodecaphase closure and the $E_{21/22}$ characterization: domains, codomains, and uniqueness . . . 1189
31.6 Composition of the holonomy G_9 with the chart T_1 and arbitrary-precision certificate for α_{HMT} . . . 1190
31.7 Two internal readers of α: dodecaphase closure and order-9 nonadic analytic kernel . . . 1190
31.7.1 Analytic kernel P_6 and exact order-9 prolongation . . . 1191
31.7.2 APP–TRIT–TPK genealogy of the invariants 120, 45, 11 and 495 . . . 1191
31.7.3 Nilpotent resolvent $(I - N)^{-1}$ and exact construction of the tail $T_{7:9}$ . . . 1191
31.7.4 Nonadic jet P_9, prolonged root, and scale of certified residues . . . 1192
31.7.5 Alternative dodecaphase operator A_{dod} and uniqueness control of the typed reader . . . 1192
31.7.6 Exact scope of the nilpotent operator and exclusion of tails foreign to TPK transport . . . 1193

32 Internal construction of $i = \sqrt{-1}$ via the rotation operator J: identity $J^2 = -I$ and elliptic geometry of phase 1194
32.1 Elliptic realization of $J^2 = -I$ through the Hopf fibration and Möbius holonomy 1195
32.1.1 Complex structure and Hopf fibration . . . 1195
32.1.2 Double covering and spinor return . . . 1195
32.1.3 Toroidal realization of the operator $B_{\text{mem}}^{\varepsilon}$ and determination of the Villarceau angle . . . 1195
32.1.4 Action of the operator $J^2 = -I$ on the conjugate angular coordinates . . . 1196
32.1.5 Brouwer, Möbius, and degree . . . 1196

33 Hensel–Witt derivation of $-1/12$: compatible prolongation, regularization, and modular memory 1197
33.1 Hensel–Witt transduction operator between microregions of π, holonomy Γ_9, the dodecaphasic register and hexad–octad incidence . . . 1197
33.2 Construction of the Witt system from the compatible ternary coding . . . 1198

33.3 Hexad–octad realization of the 90/120 channels previously derived from the tritic incidence of the TPK . . . 1198
33.4 4 operational realizations of $-1/12$ and separation of their domains . . . 1198
33.4.1 Angular realization through the elementary increment dodecaphasic . . . 1198
33.4.2 Oriented pseudoinverse of the Gram operator on the surviving subspace . . . 1199
33.4.3 Scale extraction by the 2nd triadic difference . . . 1199
33.4.4 Modular realization through the quotient $\eta(\tau)/\eta(3\tau)$ and the function t_3 . . . 1199
33.5 5 algebraic realizations of $-1/12$ and separation of their domains . . . 1199
33.5.1 Difference of dodecaphasic periodicities . . . 1199
33.5.2 Pseudoinverse of the Gram Operator on the Live Component . . . 1200
33.5.3 2nd difference between triadic scales . . . 1200
33.5.4 Cadena modular . . . 1200
33.5.5 Defect of cyclic difference projectors . . . 1201

34 Determinantal derivation of the absolute action scale: Smith normal form, cokernel of order 16 and valuation 10^{-34} 1202
34.1 Derivation of the action scale from the dodecaphasic state . . . 1202
34.2 Oriented sections of the action line . . . 1203
34.3 Causal bifurcation subsequent to α_{HMT} . . . 1203
34.4 Local cokernel and derivation of the absolute order 10^{-34} . . . 1203

35 Regional character of degree 5, construction of η_{ret} and positive action measure on the emission quotient 1204
35.1 Seed space, quotient of emissions and regional fibers . . . 1204
35.2 2 exact measures on the quotient of emissions and words . . . 1204
35.3 Canonical Hilbertization of the quotient . . . 1205
35.4 Positive defect between the regional and dodecaphasic measures . . . 1206
35.5 Universal property of the positive action functional . . . 1208
35.6 Positive Action Functor on the Category of Compatible Paths . . . 1209
35.7 Regional character of degree 5 and reduced action mantissa . . . 1210

36 Self-dual derivation of the Planck constant and its action line: temporal periodicity of 108 phases, Compton closure and bidirectional covariance 1211
36.1 Compton realization associated with the temporal periodicity of 108 phases 1211
36.2 Gravitational Transducer and Self-Dual Selection Equation . . . 1211
36.3 Commutativity of the angular, temporal, and gravitational normalizations of the self-dual identity . . . 1212
36.4 Gravitational conventions: reduced radius and Schwarzschild radius . . . 1213
36.5 Bifurcation of the action line . . . 1213
36.5.1 Oriented action letters and declared circular realization . . . 1214
36.5.2 Correspondence between the order-108 periodicity and Compton readings . . . 1214
36.5.3 Circular selector and internal Planck unit . . . 1215
36.5.4 Pre-return/post-return covariance . . . 1216
36.5.5 Split self-dual mass line . . . 1216
36.6 Autoduality of the Planck internal unit under orientation inversion . . . 1218
36.7 Action line and Planck constant . . . 1218
36.8 Operator genealogy of action, angular geometry, and mass . . . 1219

37 Phase operator prior to dimensional transduction: decomposition into 27 sectors, spectral radius and factorization of the double projection 1221
37.1 Decomposition of the angular operator into 27 sectors of 72 states . . . 1221

37.1.1 Exact calculation of the spectral radius of the angular operator 1222
37.2 Effective band operator T_{band} and isolation of the angular phase 1222
37.3 Posterior comparison and precision scale 1223
37.4 Functional dependence of the spectral radius with respect to the components of the operator 1224
37.5 Typed composition of the morphisms Archimedean, exceptional, and dimensional 1224
37.6 Dependency diagram of the angular operator and its publications 1225
37.7 Predimensional action at the center of the double projection of the genealogical state 1225
37.8 Compatibility of the angular operator with the cylinders of the discrete continuum 1226
37.9 Compatibility with the exceptional rider, Moonshine, and M-theory screens 1226
37.10 Spectral factorization and isolation of the dominant sectors 1227
37.11 Compatibility between the matrix, angular, and lattice realizations 1227

38 Exact equivalence of the global and analytic charts of the angular pair: degrees, radians, phases $q_{\pm}$, and complementary orientation 1228
38.1 Intrinsic angular phase α_{HMT}, nonadic lift 10^3, and precursor x_A 1228
38.1.1 Construction of the analytic precursor x_A, the contraction D_A, and the regional correction $\mathscr{C}_\pi(\alpha)$ 1228
38.2 Preangular construction of η_{ret} through H_5, D_A and $\mathscr{C}_\pi(\alpha)$ 1228
38.2.1 Independent derivation of $\eta_{\text{ret}} = H_5 - (90/\pi)\mathscr{C}_\pi(\alpha)$ through the regional analytic reader 1228
38.2.2 Persistence of the return in the 5 regions of the microfiber 1229
38.2.3 Construction of the regional analytic reader and its convergence domain . . . 1230
38.2.4 Analytical solution of the return recurrence 1231
38.2.5 Persistence of return in the 5 regions and compatibility of the η_{ret} component . 1232
38.2.6 Application of the regional reader to the conjugate angular momentum pair . 1233
38.2.7 Closed sum and publication of the posterior component upon return 1234
38.3 Confluence of η_{ret} With the valuation $\varepsilon_H = -34$ in the magnitude $\hbar_{\text{ret}}$ 1234
38.3.1 Derivation of the determinantal character of parangular transport 1235
38.3.2 action character of degree 5 in the construction regional 1235
38.3.3 Exact decomposition of the action line into pre-return and post-return sections 1236
38.3.4 Factorization of the determinantal character in the 2 phase charts 1237
38.3.5 Publication of the action character of degree 5 in the parangular chart 1237
38.4 Parangular application $P(\alpha, \eta_{\text{ret}})$ and bilayer closure $C^* = 2(\eta_{\text{ret}} + \alpha)$ 1238
38.4.1 Oriented phase and conjugate angular coordinate 1238
38.4.2 Conjugate coordinate C^* and reversal of its orientation under the bilayer involution 1239
38.4.3 Direct theorem $C^* = 2(\eta_{\text{ret}}+\alpha)$ and inverse character of the identity $\eta_{\text{ret}} = C^*/2-\alpha$ 1240
38.5 Exact commutativity of the charts in turns, degrees, and radians 1241
38.5.1 Derivation of the cylindrical length and the analytic degree of the parangular precursor 1241
38.5.2 Publication of the analytic degree on the global phase chart 1241
38.6 spectral decomposition $q_{\pm}$ and calculo functional on the channels 90/120 previously generated 1242
38.6.1 Spectral reconstruction of the angular pair and hexad-octad transition 1242
38.6.2 Relative transporter and spectral disjunction of the blocks 1243

38.6.3 Spectral evaluation $V_{90,120}$ of the incidence channels previously generated by the TPK . . . 1243
38.7 Naturalness under Refinement and Separation with Respect to Metrological Recognition . . . 1246
38.7.1 Exact estimation of the remainder of the analytic prolongation . . . 1246
38.7.2 Functional dependence of the regional selector and the analytic continuation . . . 1246
38.7.3 Operatorial Interpretation of the Conjugate Angular Coordinate . . . 1247
38.7.4 Angular Truncation Convergence Certification . . . 1247
38.7.5 Naturality of the regional selector under refinement and chart change . . . 1247
38.7.6 Metric independence of the parangular construction . . . 1248

39 Positive constitutive operator of the vacuum: $3 \to 4$ completion, spectral reconstruction and joint derivation of ε, μ, Z and c 1249
39.1 Bilayer spectral decomposition of the angular operator . . . 1249
39.2 Harmonic factorization of the 90 and 120 sectors . . . 1250
39.3 Sheet involution and preservation of orientation . . . 1251
39.4 Logarithmic characters and tracial compatibility . . . 1251
39.5 Dimensional realization of the constitutive relations . . . 1252
39.6 Discrete polarization and the tritic mode of arithmetic projections . . . 1254
39.6.1 Refinement discrepancy and endpoint convention . . . 1254
39.6.2 Bounded polarization and exact temporal balance . . . 1255
39.6.3 Realization on the charge and time lines . . . 1256
39.6.4 Pairing the additive and multiplicative fibres . . . 1256
39.6.5 Commutator norm and electronic prefactor . . . 1257
39.6.6 Quadratic defect and response of the 90/120 sectors . . . 1259
39.7 Sheet return, areal–volumetric incidence and constitutive orientation . . . 1259
39.7.1 Projected return and restoration of the oriented cover . . . 1259
39.7.2 Descent of incidence from the tritic calendar . . . 1260
39.7.3 Boundary marking and areal–volumetric ratio . . . 1260
39.7.4 Transport of orientation to the constitutive channels . . . 1261
39.8 Constitutive operator and reconstruction of the vacuum channels . . . 1261
39.8.1 Positive response on two sheets . . . 1261
39.8.2 Four coordinates of a common response . . . 1262
39.8.3 Cubic inversion and angular recovery . . . 1263
39.8.4 Logarithmic coordinates and refinement . . . 1263
39.8.5 Dimensional types of the four evaluations . . . 1263
39.8.6 Reconstruction of the action shape from the constitutive response . . . 1263
39.8.7 Constitutive speed and kinematic realization of the clock . . . 1265
39.9 Differential inversion and domain of the two-sheet constitutive response . . . 1267
39.9.1 Spectral sensitivity and logarithmic coordinates . . . 1267
39.9.2 Image domain and global reconstruction . . . 1268
39.9.3 Local stability of recovery . . . 1268

40 Derivation of charge and electrical quanta: von Klitzing resistance, conductance, Josephson constant and magnetic flux 1270
40.1 Derivation of the charge section from the vacuum . . . 1270
40.2 Von Klitzing and Josephson constants, conductance and magnetic flux . . . 1270
40.3 Charge section and electrical quantization relations . . . 1270
40.3.1 Positive determination of the charge section . . . 1271

40.3.2 Resistance, conductance, flux, and frequency . . . 1271
40.3.3 Action return and transport of the sections . . . 1272

41 Quadratic characters and spectral constants: Catalan, Apéry, Euler–Mascheroni and the Stieltjes hierarchy 1273
41.1 Operatorial representation of Dirichlet characters . . . 1273
41.2 HMT construction of the residue characters . . . 1273
41.3 Internal complex structure and Catalan's constant . . . 1274
41.4 Residual composition of the triadic–quaternary type . . . 1275
41.5 Euler and Stieltjes Constants and the Theta–Mellin Transform . . . 1276
41.6 Cyclic decomposition, quarter-turn, and oriented Catalan moment . . . 1277
41.6.1 Two subspaces of the dodecaphase cycle . . . 1277
41.6.2 Faithful representation of the quarter-turn . . . 1278
41.6.3 Resolvent and unlimited depth . . . 1278
41.6.4 Composition with the constitutive response . . . 1279

42 Euler–Kronecker constants and prime distributions: dodecaphasic characters, Meissel–Mertens and twin-prime series 1280
42.1 Euler–Kronecker constant of the character of dodecaphase type . . . 1280
42.2 Constantes aritmeticas asociadas to the numeros primos . . . 1280
42.3 Native product, factorization, and irreducibility . . . 1281
42.3.1 Composition of residues and quotients in multiplication . . . 1281
42.3.2 Nonadic words and normal form . . . 1282
42.3.3 Genealogical construction of the product on records . . . 1282
42.3.4 Multiplicative openings and selection of irreducibles . . . 1283
42.3.5 Operator realization of the selector . . . 1284
42.3.6 Normalized readout of the TPK prefix and preservation of genealogy . . . 1285
42.3.7 Correspondence with the preserved implementation . . . 1286
42.4 Factorization, arithmetic clocks and hierarchy of traces . . . 1287
42.4.1 From the irreducible to its clock . . . 1287
42.4.2 Factorization as mode occupation . . . 1287
42.4.3 One occupation structure and two trace levels . . . 1288
42.4.4 Meissel–Mertens and removal of the linear contribution . . . 1289
42.4.5 Residual exclusion and the separation-two pattern product . . . 1289
42.4.6 Triadic realization of the functional . . . 1290
42.4.7 The completed form and its boundary identity . . . 1292
42.4.8 Spectral circle and memory circle . . . 1293
42.4.9 Compatibility with the joint structure of the continuum . . . 1294

43 Bendersky–Glaisher–Kinkelin family: regular products, derivatives of the zeta function and normalization hierarchies 1295
43.1 Generation of the Bendersky–Glaisher–Kinkelin family via zeta regularization 1295

44 Gauss dynamics and the Khinchin, Lévy and Lochs constants: cofinality of cylinders, transfer operator and Gauss–Kuzmin–Wirsing spectrum 1296
44.1 Cofinality between HMT cylinders and continued fraction cylinders . . . 1296
44.2 Gauss measure and Khinchin and Levy observables . . . 1296
44.3 Entropy (metric), Lyapunov exponent, and Lochs's constant . . . 1297
44.4 Gauss–Kuzmin–Wirsing Transfer Operator . . . 1298
44.5 Cofinal certificate of the Gauss–Kuzmin–Wirsing spectrum over the nonadic hierarchy . . . 1298
44.6 Analytic construction of the functionals of the triadic tower . . . 1299

44.6.1 *Inductive limits and refinement scale* . . . 1299
44.6.2 *Integer, prime and orbital operators* . . . 1300
44.6.3 *Completed Guinand–Weil form* . . . 1301
44.6.4 *Local geometry of the critical line* . . . 1303
44.6.5 *Laplacians on cycles of order 3^m* . . . 1304
44.6.6 *Theta–Mellin transform* . . . 1305
44.6.7 *Residual decomposition modulo three* . . . 1306
44.6.8 *Euler–Mascheroni and Stieltjes constants* . . . 1307
44.6.9 *Evaluation of Apéry's constant* . . . 1308
44.6.10 *Glaisher–Kinkelin constant* . . . 1308
44.6.11 *Euler–Kronecker constant of the Eisenstein field* . . . 1308
44.6.12 *Local product associated with twin primes* . . . 1309
44.6.13 *Meissel–Mertens constant and prime Hamiltonian* . . . 1309
44.6.14 *Dependence on the operator* . . . 1310
44.7 Finite parts, regularization and residual readouts . . . 1310
44.7.1 *A continuation formula with explicit remainder* . . . 1310
44.7.2 *Euler–Mascheroni as the finite part of the same functional* . . . 1311
44.7.3 *Apéry and the regularized negative evaluation* . . . 1312
44.7.4 *Laurent coefficients and preservation of the three classes* . . . 1313
44.7.5 *Exact evaluation and scope of the certification* . . . 1315

45 Unimodal criticality of the dodecaphasic family: exact analytic profile, Feigenbaum approximants and hyperbolic renormalization certificate 1316
45.1 Intrinsic construction of the dodecaphasic family . . . 1316
45.2 Exact analytic representation and closed trigonometric expression . . . 1317
45.3 Pertenencia to the clase analitica unimodal cuadratica . . . 1318
45.4 Sequences finite of parameters superstable . . . 1319
45.5 Conditions for certifying the renormalization operator . . . 1319
45.5.1 *Weighted harmonic deformation and selection of the superstable branch* . . . 1321
45.6 Reduction of Feigenbaum universality to the hyperbolic certificate of basin membership and transversality . . . 1322

46 Arithmetic of the dodecaphasic modular family of period 30: Rogers–Ramanujan identities, normalizer 899 and nonadic Pell lifting 1323
46.1 Normalizer 899, Pell unit, and arithmetic structure of the mode 30 . . . 1323
46.2 Lift nonadic of the unit of Pell . . . 1323
46.3 Spectral Pell screw and logarithmic suspension . . . 1325
46.3.1 *Spectral identity $V^{-1}\mathcal{S}V = (2+\sqrt{3})\mathrm{i}\mathcal{S}$ and equation of the logarithmic suspension* 1325
46.3.2 *Conjugate contraction involution* . . . 1326
46.3.3 *Scale covariance and energy conservation* . . . 1326

47 Arithmetic theory of nonadic vacancies: defect $10^3 - 3^6$, radical network $3 \to 6 \to 9$, power–vacancy law, and boundary torsion 1327
47.1 Classification of the irreducible arithmetic cycles of the nonadic radical lattice 1327
47.2 Density, regularized term, and vacancy holonomy . . . 1327
47.3 Operative content of the helicoidal representation . . . 1329
47.4 Classification of the radical network 3→6→9 and derivation of the power–vacancy law . . . 1329
47.5 Radical structure of the APP on $\mathbb{Z}/9\mathbb{Z}$ . . . 1330
47.5.1 *Nonadic local ring $\mathbb{Z}/9\mathbb{Z}$ and nilpotent radical* . . . 1330
47.5.2 *Exact sequence of the multiplier 3* . . . 1330

47.5.3 Cyclic orbit 369→693→936→369 . . . 1330
47.5.4 Radical cross of APP and coordinate reduction to $\mathbb{F}_3^2$ . . . 1331
47.5.5 Determination of the arithmetic core 7227 by incidence with the radical cross of APP . . . 1331
47.6 Power–vacancy law for the scales 9^n and 10^n . . . 1332
47.6.1 Decimal Length Functions and Accumulated Vacancy . . . 1332
47.6.2 Exact identity between decimal length and vacancy rotation . . . 1332
47.6.3 Sturmian coding of vacancies induced by nonadic powers . . . 1332
47.6.4 Law 21/22 as a case of the power–vacancy theorem . . . 1333
47.6.5 Exact evaluation at $n = 9^9$ and length of 9^{9^9} . . . 1333
47.6.6 Domain of validity of the power–vacancy law . . . 1334
47.7 Operator Hierarchy, Reversibility, and Genealogical Memory . . . 1334
47.7.1 Translation, Dilation, and Exponentiation as Operational Levels . . . 1334
47.7.2 Stratified reversibility in $\mathbb{Z}/9\mathbb{Z}$ . . . 1334
47.7.3 Reading of the Topological Phase Kernel on the operator hierarchy . . . 1335
47.7.4 Logarithmic descent between consecutive levels of the hierarchy . . . 1335
47.7.5 Affine conjugation of translations and dilations . . . 1335
47.8 Path Algebra: Multiplicative Composition, Additive Action and Superposition 1336
47.9 Triadic exponential family $J_\tau^2 = -\tau I$: elliptic, parabolic, and hyperbolic realizations of Euler's identity . . . 1336
47.9.1 Internal root of -1 in the finite branch . . . 1336
47.9.2 Continuous extension of the common quadratic operator and conservation of its spectral type . . . 1337
47.9.3 Conjugation of the arithmetic, angular, and torsional realizations via the common quadratic operator . . . 1337
47.9.4 Elliptic, parabolic, and hyperbolic geometries of the extended Euler equation . 1337
47.9.5 Common carrier, common operator, and quadratic exponential family . . . 1338
47.10 Restriction of internal rotation, edge holonomy and minimal torsion . . . 1338
47.11 Generational triality, conjugation, and mixing over the enriched state . . . 1339
47.12 Operator memory of the TPK: preservation of residue, quotient, carry, sheet, orientation, route, and boundary under projection . . . 1339
47.12.1 Loss of reversibility and genealogical lifting . . . 1339
47.12.2 Projection of Compatible Histories onto the Archimedean Continuum . . . 1340
47.12.3 Distinction between numerical section and persistent realization of particle . . 1340
47.13 Joint closure of the radical network, the power–vacancy law, Euler geometry, and the operative hierarchy . . . 1340
47.13.1 Theorem of the Nonadic Radical Network . . . 1340
47.13.2 Power-void Theorem . . . 1340
47.13.3 Exponential Family Euler's Geometric Theorem . . . 1340
47.13.4 Operatorial conservation principle between levels . . . 1340
47.14 Typing conditions and incompatibility criteria of the nonadic vacancy theory 1340
47.15 Joint consequences for the radical net, the operational memory, and the edge torsion . . . 1341

48 Thermal constants and radiation: Boltzmann, Wien, Stefan–Boltzmann and spectral thermodynamics of the photon gas 1342
48.1 Relation termica intrinseca of the escala 108 . . . 1342
48.2 Spectral formulations of Wien's displacement law . . . 1342
48.3 Stefan–Boltzmann law and thermodynamics of the photon gas . . . 1342
48.4 Metrological Confluence of Thermal and Radiative Invariants . . . 1343

48.5 Boltzmann constant, information, and thermal transduction 1344
48.5.1 Dimensional structure of transduction 1344
48.5.2 Structural definition and function of the Boltzmann constant 1345

49 Electroweak constants and mixing: angular determinant, relation W/Z, Weinberg angle and rational CKM reflection 1346
49.1 Angular determinant and Weinberg electroweak relation 1346
49.2 Constitutive and Determinantal Functions of the Angular Operator 1346
49.3 Exact relation between sectors W and Z 1347
49.4 Gauge couplings in rationalized normalization 1348
49.5 Fermi Constant in the Approximation at Tree Level 1348
49.6 Higgs Coupling Oriented Dependence 1349
49.7 Determinantal closure of the electroweak sector: mixing, couplings, and constitutive spectrum 1349
49.8 Involution of leaves in 4 representations 1350
49.9 Involutive rational transformation in the CKM parameter space 1351
49.10 Electroweak Angular Closure and Compatibility Conditions of the Gauge Transducer 1354

50 Intrinsic derivation of G and contragredient reciprocity $G \leftrightarrow \hbar$: phase closure, Compton and Planck scales, and invariance of $G\hbar$ 1355
50.1 Causal composition of the phase, action, and length invariants in the derivation of G 1355
50.2 Gravitational magnitude line and chronological scale 108 1355
50.3 Reciprocity $G \leftrightarrow \hbar$ and conservation of the Planck area 1356
50.4 Genealogical domain of gravitational realization 1359
50.5 Gravitational Transducer and Chronological Selector of Periodicity 1360
50.6 Bidirectional Covariance of Gravity and Action 1361

51 HMT derivation of the Barbero–Immirzi parameter and minimum area: hexad–octad incidence, $90/120$ channels and spectrum of the area operator 1362
51.1 Hexad–Octad Incidence Morphism and Conservation of the Oriented Channels $90/120$ 1362
51.2 Dodecaphase fundamental chain and hexad–octad functional 1362
51.3 Tritic derivation of the cardinalities 90/120 and subsequent realization in hexad–octad incidence 1364
51.4 Lambert Series Associated with the 2 Incidence Sectors 1365
51.5 Subsequent Diophantine certificate of the weights 1366
51.6 Monotonicity of the functional with respect to the conjugate angular coordinate 1367
51.7 Hexad–octad inclusion and associated functional realizations 1367
51.8 Correspondence between the Nonadic Interior and the Boundary Degrees of Freedom 1368
51.9 Collective incidence entangler between interior and boundary 1369
51.10 Determination of the Elementary Scale of the Spectrum of the Area Operator 1370
51.11 Areal Law of the Triadic Cut: Capacity $81 \log 3$, Area Operator, Spectrum, and Collective Intertwiner of the Channels $90/120$ 1370
51.12 Typed distinction between Barbero–area, area–modular Hamiltonian, and Cartan–Holst realization 1372
51.13 Hexad–octad incidence, Barbero–Immirzi parameter, and area spectrum . . 1373
51.14 Total Geometry and Origin Memory 1375

51.15 Bilayer state and oriented information . . . 1375
51.16 How much informational energy and gravitational cell of medium action . . 1376
51.17 Evaluation at the Pell scale and the constitutive Barbero–Immirzi functional 1376
51.17.1 Oriented moment and evaluation at the Pell unit . . . 1376
51.17.2 Composition of phase and weighted depth . . . 1378
51.17.3 Dodecaphasic incidence and return functional . . . 1379
51.17.4 Factorization through the constitutive operator . . . 1379
51.17.5 Reconstruction from vacuum coordinates . . . 1381

52 The HMT–MD Angular Radion: Carry-Preserving Junction of the Direct and Torsional Sections and Exact Closure of the Unit of Phase, Action, and Memory 1382
52.1 Composition APP–TRIT–TPK of the phase state: generation of the memory-oriented unit . . . 1382
52.1.1 Bivariate support of APP, ternary orientation of TRIT, and enriched-state update through TPK . . . 1385
52.1.2 Prospective independence of the closure with respect to the final value . . . 1388
52.2 Direct and torsional sections: APP carry and exact closure of the radion . . 1390
52.2.1 Independent construction of the sections S_E and S_T before defining the cocycle $\varepsilon_R = S_T - S_E$ . . . 1390
52.2.2 Oriented density of the active sector and unique determination of 20/81 . . . 1390
52.2.3 The carry ε_R as a transition cocycle between sections . . . 1391
52.3 Critical coordinate and oriented dodecaphase temporal system: affine publication of the phase of 50° . . . 1393
52.3.1 Affine map j_{100} of the APP chart and uniqueness of the phase $m = 2$ in $j_{100}(1/2) = \theta_m = 50°$ . . . 1393
52.3.2 Compatibility of the critical phase with the nonadic return and memory advance 1394
52.4 Angular pair and reduced action: construction of the positive ellipse and area per radion . . . 1395
52.4.1 Areal law of the radion: $\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\theta$ and $\mathcal{A}(2\pi) = h_{\mathrm{ret}}$ . . . 1395
52.4.2 Conjugate semi-axes, focal invariants, and orientation of anisotropy . . . 1398
52.5 Nonadic Return and Internal Projective: Klein Disk and Helical Depth of Memory . . . 1399
52.5.1 Normalization to the Hilbert–Beltrami–Klein disk and hyperbolic interior . . 1399
52.5.2 Difference between phase return and return of the enriched state . . . 1400
52.6 Oriented ellipse and conjugate variables: minimum uncertainty and electromagnetic oscillation . . . 1402
52.6.1 Conjugate symplectic variables and determination of the minimum uncertainty 1402
52.6.2 Exchange $\mu \leftrightarrow \varepsilon$, inversion $Z \leftrightarrow Z^{-1}$, and conservation of causal velocity . . 1403
52.6.3 Inductive–capacitive pair (L_η, C_η): invariance of $L_\eta C_\eta = \omega^{-2}$ and orientation of impedance . . . 1403
52.7 3 TRIT regimes: electric–magnetic and elastic–rotational polarities . . . 1404
52.7.1 Coordination of the elliptic, parabolic, and hyperbolic realizations . . . 1404
52.7.2 Typed separation of the constitutive and mechanical polarities . . . 1405
52.8 Separation of the Publications 90/120: Incidence, Record, Spectrum, Barbero Kernel, and Towers . . . 1406
52.8.1 Typed separation of the publications of the sector 90/120 . . . 1406
52.8.2 Conservation of Incidence and Orientation Between the Tritic Kernel and Its Subsequent Realizations . . . 1407
52.8.3 Dodecaphasic origin of the weight $12 : -1$ *and Diophantine verification of its pole coefficient* . . . 1408

52.8.4 Extraction of the finite component subsequent to the oriented dodecaphasic system R_{12}: $C^* \mapsto C^*/6$, remainder $j \geq 2$, and reconstruction of 6 sections . 1409
52.8.5 Quantitative decomposition of the carry and spectral publications: $F_{\text{spec}} = \varepsilon_R^\circ + \chi_R$ 1409
52.9 Oriented holonomy and physical geometry: later realizations of Minkowski, Hodge, Lorentz, and Cartan–Holst 1410
52.9.1 Hodge duality on 2-Lorentzian forms 1411
52.9.2 Separation between internal torsional memory and Cartan–Holst geometric realization 1411
52.10 Ellipse, Lattice, and Path Phase: Modular Character, Orbits, and Propagation 1412
52.10.1 Rectangular Lattice of Periods, Involution $\tau \mapsto -1/\tau$, and Invariance of j . . 1412
52.10.2 Compatibility between the modular character and propagation over oriented paths 1413
52.11 Radical nonadic and decimal boundary: conservation of the radion carry . . 1415
52.11.1 The carry of the radion in the decimal completion 1415
52.11.2 Compatibility of the direct and torsional sections: structural characterization of π 1417
52.12 Evolutionary Conservation of the Holographic Unit Across Dimensions . . 1417
52.12.1 Typed Separation among the Curvature Regime $\tau \in \{+1, 0, -1\}$, the Radial Response p, and the Global Spin Holonomy 1417
52.12.2 Particle as a Persistent Section of an Enriched Orbit: Phase, Route, Fibre, Multisection, and Memory 1418
52.12.3 Transduction of the oriented phase in electric polarization, magnetic response, and boundary radiative emission 1419
52.12.4 Reversibility of the complete dynamics and thermodynamic cost of information-reducing projections 1419
52.12.5 Self-conservative forces as transport of action among the observable, radial, memory, vacancy, and radiation sectors 1420
52.12.6 Self-inertial systems: publication of acceleration through orientation, curvature, sheet, and memory 1420
52.12.7 Area–volume duality, hexad–octad transition, and the role of the Barbero–Immirzi parameter 1421
52.12.8 Hyperbolic interior contraction, exterior expansion, and holographic conservation of the boundary 1421
52.12.9 Five-Component Gravitational Polarity and Joint Transduction of Action, Area, Volume, Time, and Mass 1423
52.13 Operative definition of the angular radian through the enriched state and 4 typed readers 1425
52.13.1 Operational definition of the angular and quadruple radion and typed realization of the enriched state 1425
52.13.2 Structural properties of the radional unit: genealogy, critical hinge, density, carry, action, boundary–interior compatibility, form, polarity, and modularity 1427
52.13.3 Sensitivity of unitary closure to controlled variations in sheet multiplicity, the dodecaphase, channel e, global torsion, the harmonic operator, and the hexadic tail 1430

53 Genealogical classification of numbers: surviving sections, invariants and atlas of constants 1437
53.1 Hensel's Integral Transducer as a Full Shift Operator 1437
53.2 Balanced ternary chart of the integers 1438
53.3 Exact coverage of the preceding real chart via compatible sections 1439
53.4 Positional chart in base 10^3 and classification of the published sections . . . 1440

53.5 Concatenation, nonadic reduction, and carry . . . 1441
53.6 Nonadic elevated coordinate and phase return . . . 1441
53.7 Bifactorial classification of the number by Archimedean value and transport genealogy . . . 1443
53.8 Memorization of arbitrary depth in finite emission systems . . . 1443
53.9 Local positional square of e and genealogical differentiation of states with the same visible block . . . 1443
53.10 2 finite measures of the $468 \to 243$ emitter: uniform frequency and structural priority . . . 1444
53.11 Selector orbital finite preceding the Archimedean reader . . . 1445
53.12 Position of π, e, φ and α in the classification . . . 1447
53.13 Previous chart, inductive survival, and construction of the global boundary . 1448
53.14 Classification of constants by genealogical antecedent, generating operation, and codomain . . . 1450
53.15 Number as a compatible section: arithmetic classification, Archimedean evaluation, and genealogy . . . 1451
53.15.1 Archimedean evaluation separates the section from its value . . . 1451
53.15.2 Termination and periodicity determine rationality . . . 1452
53.15.3 The balanced ternary chart represents the integers bijectively . . . 1453
53.15.4 Finite complex structure induced by the Witt endomorphism $J^2 = -I_6$ . . . 1454
53.15.5 6 operators realize the rational $-1/12$ on distinct domains . . . 1454
53.15.6 Multiplicative decomposition of primes as irreducible modes of the TPK . . . 1455
53.15.7 Each constant is associated with its extraction operator . . . 1456
53.15.8 Domains, premises, and necessary conditions of the genealogical classification of the number . . . 1457
53.16 Genealogical closure of the concept of number: compatibility, memory, and Archimedean evaluation . . . 1458
53.16.1 Digit, section, value and symmetry . . . 1458
53.16.2 Evolutionary Conservation of Unity . . . 1459
53.16.3 Visible syntax and semantics of prolongation . . . 1460
53.16.4 Arithmetic classification and genealogical classification . . . 1460
53.16.5 Factorization of the genealogical closure of the number through Euler's operational system . . . 1461
53.16.6 Typed Unification of Circular, Complex, and Hyperbolic Geometries . . . 1461
53.16.7 Boundary interface between quadratic rotation and minimal torsion . . . 1462
53.16.8 Constant Generation Operators: Domains, Seeds, and Evaluations . . . 1463
53.16.9 Double projection of a single genealogy . . . 1465
53.16.10 Genealogical Closure of the Concept of Number . . . 1465
53.17 Definition of the genealogical atlas and metrological evaluation conventions 1466
53.18 HMT corollary of metrological confluence . . . 1466
53.19 Principal structural relations of genealogical confluence . . . 1469
53.19.1 Mode 30: Completion in Harmonic Form, Criticality, and Memory . . . 1470
53.19.2 $\log 3$: residual invariant, information, and temperature . . . 1470
53.19.3 D_A: sheet determinant and Weinberg angular relation . . . 1470
53.19.4 Sectors 90 and 120: vacuum, area and modular dynamics . . . 1471
53.19.5 Barbero–Immirzi parameter, entropy and CKM as realizations of the transition $6 \to 8$ . . . 1471
53.20 Theoretical independence of the corollary of metrological confluence . . . 1471
53.21 Action, vacuum, and quantum–electric constants . . . 1472

53.22 Constantes thermal and radiation . . . 1473
53.23 Criticality and dynamic constants . . . 1473
53.24 Constantes espectrales, aritmeticas and of vacancia . . . 1474
53.25 Gravity, area and modular information . . . 1476
53.26 Sheet involution, mixing, and electroweak sector . . . 1477
53.27 Determination of Cosmological Parameters via Torsional Memory and Perron Dynamics . . . 1478
53.28 Typed separation between the Bohr and Born-Infeld radii and the internally generated scales . . . 1479
53.29 Existence, uniqueness, and compatibility theorems of the genealogical constants 1479
53.30 Theorematic character of the metrological corollary . . . 1480
53.31 Logical stratification of internal identities, dimensional realizations, and external recognitions . . . 1480
53.32 Transverse obstructions of typing, causality, orientation, and nonadic compatibility . . . 1481
53.33 Necessary Conditions for Mathematical Extensions and Non-Equivalent Physical Realizations . . . 1481
53.34 Formal Delimitation of the Domain of Genealogical Derivations . . . 1482
53.35 Reconstructive power of the common genealogy over mathematical and physical constants . . . 1482

54 Genealogical completeness of HMT sections and decidability of each finite level 1483
54.1 Conservative Extension of Finite Completeness via Projective Multiplicities 1483
54.2 Category of genealogical objects . . . 1483
54.3 Foundations of Prefixes and Coinduction of Sections . . . 1484
54.4 Fibration of ordinals by compatible genealogical histories . . . 1484
54.5 Decategorification Functor and the Cardinality of Published Sections . . . 1485
54.6 Profinite limit of the system of genealogical truncations . . . 1485
54.7 Obstruction to the Reconstruction of the Genealogical Power from Finite Reductions . . . 1486
54.8 Necessary choice conditions for the global prolongation of compatible sections 1487
54.9 Pell Obstruction to the Uniform Periodicity of the Prefix System . . . 1488

55 Gödel–Turing obstruction to uniform decision of projective multiplicities 1489
55.1 Algorithmic decidability of each finite level of the prefix system . . . 1489
55.2 Effective tower associated with the computation of projective multiplicities . 1489
55.3 Finite completeness of the HMT levels and exact domain of the Gödel–Turing obstruction . . . 1490
55.4 Restriction of the uniform obstruction to the nonadic temporal system of 9 phases . . . 1491

56 Gödel–Cohen: relative consistency, independence and forcing on prefix spaces 1492
56.1 Relative consistency in L and independence via forcing . . . 1492
56.1.1 2 *Non-Equivalent Operations: Model Extension and Object Enrichment* . . . 1492
56.1.2 *HMT power does not presuppose* CH . . . 1493
56.2 Compatible prefixes poset and inverse limit of extensions . . . 1493
56.3 Correspondence between genealogical sections and Borel classes of the limit space . . . 1494
56.4 Minimax theorem at each finite level of the poset of compatible prefixes . . 1494
56.5 Projective system of truncations and construction of the limit section . . . 1494

56.6 Projective and Matrix Extensions Provided by Operator Entanglers 1495

57 Euler operatorial system in HMT: sum–product defect, triadic exponential geometries, Ambivalence Principle, and double projection 1496

57.1 Sum–product defect of APP and linear coefficient of the modular product Euler characteristic 1496

57.1.1 Exact identity $459 - 405 = 54 = [q]t_3(q)$ 1496

57.1.2 Conservation of the defect via residue, quotient, and nonary carry 1496

57.2 Quadratic algebras of TRIT and the elliptic, parabolic, and hyperbolic exponential law 1497

57.2.1 Operator family $J_{+1}^2 = -I$, $J_0^2 = 0$, *and* $J_{-1}^2 = I$ 1497

57.2.2 Identities $\mathrm{Exp}(\pi J_{+1}) + I = 0$ *and* $\mathrm{Exp}(2\log\varphi\, H_\varphi) = F_{\mathrm{av}}^2$ 1497

57.3 Ambivalence Principle: involution between π/φ^2 and φ/π^2 and nonadic accumulation of orientation 1497

57.3.1 Action $Q(x, y) = (x/y^2, y/x^2)$ *on the areal and volumetric readers* 1497

57.3.2 Identity $\varphi^3(\pi/\varphi^2)^2(\varphi/\pi^2) = 1$ *and typed bidirectionality* 1498

57.4 Exponential transformation of the parangular generator $A_{\mathrm{rad}}I + C_{\mathrm{rad}}^* H_\varphi$ . . . 1498

57.4.1 Spectral projectors $P_\pm = (I \pm H_\varphi)/2$ *and conjugate eigenvalues* $q_\pm$ 1498

57.4.2 Compatibility with the Parangular Publication and the Channels 90/120 . . . 1498

57.5 Elliptic action boundary and hyperbolic interior of Hilbert–Beltrami–Klein . 1498

57.5.1 Conjugate coordinates of the action ellipse and law $\mathrm{Area}(\theta) = \hbar_{\mathrm{ret}}\theta$ 1498

57.5.2 correspondence $\rho = \tan(\theta/2) = \tanh(u/2)$ *between borde periodico e interior hyperbolic* 1499

57.6 Compatibility of the Euler operator closure with the Archimedean and exceptional publications 1499

57.6.1 Double projection of the same enriched state and conservation of incidence . . 1499

57.6.2 Sistema macrovectorial $\mathfrak{E}_{\mathrm{HMT}} = 0$*: confluencia of the identities eulerianas in a unique operator* 1499

57.7 Dimensional Transduction of Internally Generated Constants and Subsequent Metrological Comparison 1499

57.8 Metric Transduction of Genealogical States: Action, Mass, and Dimensional Observables 1500

57.8.1 Theoretical Background of the Genealogical-Metrical Transduction Functor . 1500

57.8.2 Planck, Action, and the Self-Dual Line 1500

57.8.3 The law of masses as a family of positive operators 1501

57.8.4 Physical-Mathematical Transduction Matrix 1501

57.8.5 Universal embedding of an APP signal into a quantum Markov semigroup . . 1501

57.8.6 Factorization of the genealogical–matrix bridge through APP embeddings, a quantum Markov semigroup, a semiclassical boundary, a continuous channel, a conical system, and a completely positive realization 1502

57.8.7 Naturality, cofinality, and separation hypotheses required by the reconstruction theorem 1503

IV Dimensional Mechanics: transduction of the genealogical state, matter, fields, and gravitation 1504

58 Genealogical construction of the electron: target-value-independent beta closure and atomistic realization of charge 1505

58.1 Closure β of the electronic section and dimensional publication of its rest energy 1505

58.1.1 Electronic scalar $\mathfrak{e}_{\mathrm{HMT}}$ and causal graph of its factors APP–TPK, α_{HMT}, Δ_4 and nonadic atlas . . . 1505
58.1.2 1st factor: exact incompatibility of the APP leaves . . . 1506
58.1.3 2nd factor: the exchange involution between π and φ . . . 1506
58.1.4 3rd and 4th factors: the integers 22, 15 and the center 5 . . . 1507
58.1.5 5.º factor: the cubo of the closure α_{HMT} . . . 1509
58.1.6 6th factor: minimal torsion and global defect Δ_4 . . . 1510
58.1.7 Material realization of the fixed point (5,5) in the electronic closure . . . 1510
58.1.8 Particle–antiparticle conjugation and persistence of the electronic band . . . 1512
58.1.9 Basal stage of the electronic closure . . . 1512
58.1.10 Energy chart and contrast of the bidirectional closure . . . 1514
58.1.11 Structural Consequences of Electronic Closure . . . 1515
58.2 Electron realization band and separation between base mass and beta closure 1515
58.2.1 Reader of displacements on the cyclic calendar of order 108 . . . 1515
58.2.2 Dodecaphasic correlation difference reader . . . 1516
58.2.3 Evaluation of the central route . . . 1516
58.2.4 Separation of readers and return scales . . . 1517
58.3 Null–material closure of the electronic fiber and bifurcation preceding the positive character . . . 1518
58.4 Law of electronic vacancies: polarization, current, and structure of the null modes . . . 1519
58.4.1 Exact Laws of Hole and Return . . . 1519
58.4.2 Bounded polarization and discrete continuity equation . . . 1520
58.4.3 Harmonic Closure of Conjugated Null Modes in the Electronic State . . . 1520
58.5 Central electron and helical reader of matter . . . 1521
58.5.1 Uniqueness of the Material Center under Cellular Inversion . . . 1521
58.5.2 Common singular mode of the APP sheets in the canonical chart $1, \ldots, 9$ . . . 1521
58.5.3 Genealogical record of the material route: surviving extension, full signature, and dimensionless character . . . 1521
58.5.4 Material compatibility square . . . 1521
58.5.5 Spin and helicity . . . 1522

59 From the genealogical number to the physical magnitude: action, mass, and dimensional observables 1523
59.1 Lines of magnitude and dimensional realization of the HMT kernel . . . 1523
59.1.1 Lattice of dimensions and oriented lines . . . 1523
59.1.2 Rescaling group and impossibility theorem . . . 1524
59.1.3 Internal dimensional space: degrees, charts, and HMT–MD transduction operators . . . 1525
59.1.4 Monoidal path functor with signature . . . 1526
59.1.5 Basal stage and bidirectional closure of the electronic scale . . . 1528
59.1.6 Constitutive as isomorphisms between lines . . . 1529
59.1.7 Cartan Scale and Homogeneity of the Gravitational Action . . . 1529
59.1.8 Universality of Dimensional Realization . . . 1530
59.1.9 Physical correspondence of the APP–TRIT–TPK core . . . 1531
59.1.10 State, route, spectral form and physical realization . . . 1534
59.1.11 4 grammars and their domains . . . 1534
59.1.12 The spectral realization functor . . . 1535
59.1.13 Persistence and definition of particle . . . 1535
59.1.14 Oriented band and anti-section . . . 1536

59.1.15 Path propagation and finite path summation . . . 1536
59.1.16 Finite horizon of prolongation and class of compatible extension extensions of the genealogical state . . . 1536
59.1.17 Internal spectrum, realization, and species . . . 1537
59.1.18 Physical-spectral realization functor and 1st electronic closure . . . 1537
59.2 Planck constant and action line: derivation determinantal of the escala 10^{-34} 1537
59.2.1 Smith Normal Form of H_4 and Transport of $\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}$ to the Action Line . 1538
59.2.2 Necessity of the local core . . . 1538
59.2.3 Posterior coupling with the action coordinates . . . 1539
59.2.4 h and ħ: action per full cycle and per radian . . . 1540
59.2.5 Confluence of the determinantal and dodecaphasic branches of the action scale 1540
59.2.6 Systems of transduction between genealogical number and physical magnitude 1541

60 Ambivalence Principle in Dimensional Mechanics: areal–volumetric involution, self-inertial systems, and conjugate temporal orientation 1542
60.1 Compatible sections and measurement theory . . . 1542
60.1.1 The number as a compatible section . . . 1542
60.1.2 Compatibility between ternary cylinders and thousandths . . . 1542
60.1.3 Reversible coupling between system and apparatus . . . 1543
60.1.4 Principio de Ambivalencia: involución bidireccional de los lectores π/φ^2 y φ/π^2 1544
60.1.5 Relational determination and temporal orientation . . . 1544
60.1.6 Relation with classical variational principles . . . 1545
60.1.7 Prospective evaluation conditions of the Ambivalence Principle on the enriched state . . . 1545
60.1.8 Quotient of modes and areal-volumetric correspondence . . . 1545
60.2 Areal–Volumetric Correspondence and Ratio π/φ^2 . . . 1550
60.2.1 Classes, supports, and leaves are distinct objects . . . 1550
60.2.2 Spectral opening of the band through the conjugated angular phase . . . 1551
60.2.3 TPK descent, path envelope, and loop counting . . . 1551
60.2.4 Spectral Origin of the Quadratic Exponent of Return . . . 1553
60.2.5 Boundary closure and quotient π/φ^2 . . . 1553
60.2.6 Reader's Involution and Electronic Section . . . 1555
60.2.7 Pentagonal Identity of Rogers–Ramanujan and Recognition of the Perron Invariant 1556
60.2.8 Inversion of the inertial and gravitational readers and bidirectional reconstruction of the magnitude . . . 1556

61 Dynamics of 3 sheets: global Hamiltonian, Lagrangian of the present sheet, and modular Hamiltonian of memory 1558
61.1 Quadratic regimes and temporal readout . . . 1558
61.1.1 Quadratic algebras of the TRIT and curvature signatures . . . 1558
61.1.2 Parametrized metric family of the temporal reader . . . 1558
61.1.3 Temporal TRIT reader on (-1,0,+1): opening, threshold, and return with memory 1559
61.1.4 Unitary dynamics on 108 states: Hamiltonian, propagator, and period . . . 1559
61.1.5 Dynamic realization conditions of a time crystal: Hamiltonian, subharmonic response and stability . . . 1560
61.2 3 temporal sheets, nilpotent calculus, and tritified Cartan connection . . . 1561
61.2.1 Quadratic Family of TRIT . . . 1561
61.2.2 The null sheet as 1st jet . . . 1562
61.2.3 Feshbach–Schur reduction . . . 1562
61.2.4 Connection universal of Cartan . . . 1563
61.2.5 Nonadic corona and torsional energy . . . 1563

61.2.6 Principle of Ambivalence: bidirectional involution of the ratios π/φ^2 and φ/π^2 1564
61.3 Finite-time Temporal Crystal HMT: Periodically forced Hamiltonian, Subharmonic response and Spectral stability . . . 1565
61.3.1 Construction of the periodic forcing from the 108-state temporal system . . . 1565
61.3.2 Nilpotent jet of the triadic evolution and compatible prolongation . . . 1565

62 The HMT–MD confluence theorem: Einstein–Schrödinger system and electrogravitational coordination of action, matter, fields, geometry, and information 1567
62.1 Theorem of Dimensional Response Confluence . . . 1567
62.1.1 Antecedent common and product fibered . . . 1567
62.1.2 Naturality of the realizations and vertical conservation of the enriched state invariants . . . 1567
62.1.3 Constitutive coupling between the vacuum and the electroweak sector . . . 1568
62.1.4 Reciprocity between action and gravity in the electrogravitational form . . . 1569
62.1.5 Confluence between geometry, information and mixing . . . 1569
62.1.6 Transduction of the helical memory in the torsional realization . . . 1570
62.1.7 Confluence between clock periodicity, horizon energy, and information cost . . . 1570
62.1.8 Fibrewise confluence of HMT–MD responses: vacuum, action, gravity, information, mixing, memory, and cosmology . . . 1571
62.1.9 Corollary of metrological confluence between the HMT and SI realizations . . . 1571
62.2 Discrete Physical Realization via Fiber Product and Cartan Entanglement . . . 1572
62.2.1 Discrete physical realization: positive and oriented readings on TPK routes, common domain, and reversible localization . . . 1572
62.3 Planck pair, universal tension, and gravitational compliance . . . 1576
62.3.1 Planck dimensional pair (Q, ℓ): $Q\ell = \hbar c$, $\ell/Q = G/c^4$, and unique reconstruction 1576
62.3.2 Reciprocity between Planck tension and compliance and conservation of the action product . . . 1577
62.3.3 Ternary Informational Quantum $\log 3$ *and Capacity of the Qutrit Cell* . . . 1578
62.3.4 Covariance of bidirectional readers under sheet inversion and temporal conjugation . . . 1578
62.3.5 Constitutive vacuum and causal closure . . . 1578
62.3.6 Machian factorization of the local inertial response through the trace of the global closure: $\mathcal{I}_v = \overline{\mathcal{I}}_v \circ b$ . . . 1579
62.4 Electrogravitational Bilinear Form and Cross-Response Equations . . . 1579
62.4.1 Internal source coordinates . . . 1579
62.4.2 Static unification of the potentials . . . 1580
62.4.3 Cone of extremality of constitutive responses and classification of its rays . . . 1580
62.4.4 Einstein–Maxwell Coefficient . . . 1581
62.4.5 Polygon of fine structure publications . . . 1581
62.4.6 Covariance of action inversion . . . 1582
62.4.7 Tensorial representation of the gravitational carrier and transverse reduction of its degrees of freedom . . . 1582

63 Constitutive realization of the vacuum and electromagnetic–electroweak propagation 1583
63.1 Realization of the Electromagnetic Bidirectional Action Operator: ε, μ, Z, and c . . . 1583
63.1.1 Derivation of the action scale from the dodecaphasic state . . . 1583
63.1.2 Oriented sections of the action line . . . 1584
63.1.3 Bilayer spectral decomposition of the angular operator . . . 1584
63.1.4 Harmonic factorization of sectors 90 *and* 120 . . . 1585
63.1.5 Sheet involution and preservation of orientation . . . 1586

63.1.6 Logarithmic characters and tracial compatibility . . . 1586
63.1.7 Dimensional realization of the constitutive relations . . . 1587
63.1.8 Angular determinant and Weinberg electroweak relation . . . 1588
63.2 Angular determinant and electroweak-sector parameters . . . 1588
63.2.1 Constitutive and Determinantal Functions of the Angular Operator . . . 1588
63.2.2 Exact relation between the W and Z sectors . . . 1589
63.2.3 Gauge couplings in rationalized normalization . . . 1590
63.2.4 Fermi Constant in the Approximation at Tree Level . . . 1590
63.2.5 Higgs Coupling Oriented Dependence . . . 1591
63.2.6 Determinantal closure of the electroweak sector: mixing, couplings, and constitutive spectrum . . . 1591
63.3 Bilayer modular state and spectral resolvent . . . 1592
63.3.1 The angular operator as common antecedent . . . 1592
63.3.2 Normalization of the bilayer state . . . 1593
63.3.3 Entropy, Parity, and Orientation Divergence . . . 1594
63.3.4 Normalized resolvent of the angular macro-object . . . 1595
63.3.5 Compatibility with nonadic refinement . . . 1596
63.3.6 Exactness of the modular resolvent, normalization obstructions, and separation of the thermodynamic reading . . . 1596
63.4 Inversion constitutiva and curva modular cargada . . . 1597
63.4.1 The Spectral Completion from 3 to 4 . . . 1597
63.4.2 Exact reconstruction of the angular state from the vacuum . . . 1598
63.4.3 The loaded modular curve . . . 1599
63.4.4 Confluence between vacuum, Higgs and impedance . . . 1600
63.4.5 Compatible causal section matching with orientation and boundary data . . . 1601
63.4.6 Stable reconstruction in the UHF tower . . . 1602
63.4.7 Separation between internal quantum identities, physical interfaces, and reconstruction obstructions . . . 1602
63.5 Constitutive evaluation and dimensional realization . . . 1603
63.5.1 Evaluation of the internal chain . . . 1603
63.5.2 Charts of units and covariance . . . 1604
63.5.3 Identity checks and scope of comparison . . . 1605
63.6 Exhaustive enumeration and finite determination of transport operators . . . 1605
63.6.1 Complete domain of initial conditions . . . 1605
63.6.2 Census of signatures and emissions . . . 1606
63.6.3 Transition register and reconstruction of the lifts . . . 1607
63.6.4 Exhaustiveness of the calendar and stability of reconstruction . . . 1608
63.6.5 Reproduction certificate and location of the data . . . 1609
63.7 Restricted Electromagnetic Realization . . . 1609
63.7.1 Realization of the constitutive vacuum operator in the fields (E_σ, B_σ) . . . 1609
63.7.2 Helical realization of the electromagnetic phase: periodic return and longitudinal translation by one wavelength . . . 1610
63.7.3 Electromagnetic Duality . . . 1610
63.7.4 Compatibility condition with Pell's screw . . . 1610

64 Reconstruction of quantum principles from the genealogical state: Hilbert space, superposition, observables, dynamics, Born rule, uncertainty, and entanglement 1612
64.1 Reconstruction of quantum principles from the genealogical state . . . 1612
64.1.1 Genealogical state and Hilbert realization . . . 1612
64.1.2 Superposition and internal phase . . . 1613

64.1.3 Observables and Spectral Calculus . . . 1613
64.1.4 Evolution, Hamiltonian, and Schrödinger equation . . . 1614
64.1.5 Probability and quadratic representation of the branches . . . 1614
64.1.6 Incompatibility of readers and uncertainty . . . 1615
64.1.7 Tensor product of paths and entanglement generation via shared memory . . . 1615
64.1.8 Kinematic Reconstruction Theorem . . . 1616
64.2 Reconstruction of quantum principles from the genealogical state . . . 1616
64.2.1 Genealogical state and Hilbert realization . . . 1617
64.2.2 Evolution, Hamiltonian, and Schrödinger equation . . . 1617
64.3 Quadratic regimes and temporal readout . . . 1618
64.3.1 Quadratic algebras of the TRIT and curvature signatures . . . 1618
64.3.2 Temporal TRIT reader on (-1,0,+1): opening, threshold, and return with memory 1618
64.3.3 Unitary dynamics on 108 states: Hamiltonian, propagator, and period . . . 1619
64.4 Finite time crystal: periodic driving, subharmonic response and spectral stability . . . 1620
64.4.1 Periodic driving induced by the 108-state clock . . . 1620
64.4.2 Nilpotent jet of the triadic evolution and compatible prolongation . . . 1621
64.5 Algebraic construction of quantum completions over APP . . . 1621
64.5.1 Linear state space associated with a particle realization . . . 1621
64.5.2 Symmetric and exterior completions . . . 1622
64.5.3 Sheet grading and exchange algebra . . . 1622
64.5.4 Canonical operators and idempotence of occupation . . . 1622
64.5.5 Sheet holonomy and $2\pi/4\pi$ periodicity . . . 1623
64.5.6 The cellular complex of the APP torus . . . 1624
64.5.7 Discrete Gauss law . . . 1625
64.5.8 Reversible measurement apparatus . . . 1625
64.5.9 Algebraic correspondences and physical realizations . . . 1625
64.6 Arithmetic–geometric coupling and bilateral recovery . . . 1626
64.6.1 Exact encoding and cyclic reference . . . 1626
64.6.2 Conservation and reconstruction of two channels . . . 1627
64.6.3 Transport of observables and incoming memory . . . 1627

65 Quantum trajectory dynamics: Feshbach–Schur reduction, Born rule, and genealogical path integral 1629
65.1 Feshbach–Schur reduction . . . 1629
65.2 From the finite sum to the path integral genealogical . . . 1629
65.2.1 Route category and functorial weight . . . 1629
65.2.2 Construction of the internal phase through the real action character on genealogical routes . . . 1630
65.2.3 Unitary realization on the chronological register 27×27 . . . 1630
65.2.4 Cylindrical limit on the space of genealogies . . . 1632
65.2.5 Spectral decomposition of the path measure and conditioning of futures . . . 1633
65.3 Cylindrical Concentration of the Genealogical Measure of Trajectories and Realization of the Dirac Kernel . . . 1634
65.3.1 Projective limit of genealogies and domain of the path integral . . . 1634
65.3.2 Inverse limit of the nonadic cylinders and stability of the Dirac kernel . . . 1634
65.3.3 Kronecker Kernel and Realization of the Dirac Distribution in the Genealogical Register . . . 1635
65.3.4 Path Measure Scaling: Effective Dimension and Density . . . 1635
65.3.5 Monodromy of the Logarithm and Computability of the Genealogical Amplitude 1635

65.4 Genealogical Path Algebra and Feynman Representation 1636
65.4.1 The enriched category of paths 1636
65.4.2 The exact finite sum 1636
65.4.3 Unitary realization on the genealogical record 27×27 1637
65.4.4 Real action character 1638
65.4.5 Composition of propagators over concatenated paths and amplitude law . . . 1639
65.4.6 Cylindrical limit of the finite system and construction of the corresponding integral 1639
65.4.7 Integral visible and integral conditioned by memory 1641
65.4.8 Action, interference, and persistence 1641

66 Genealogical theory of quantum measurement: reversible coupling, instruments, conditioning of futures, and spectral update 1642
66.1 Conditioning of sections and quantum updating 1642
66.1.1 Measurement context $\mathfrak{M}_a = (U_a, q_a, C_a, m_0)$*, output map, and conditioned fiber* $\Omega_{a,y}$ 1642
66.1.2 Spectral realization of the device 1643
66.1.3 Instruments induced by coupling 1644
66.1.4 Internal Observer and Completeness of Reading 1644
66.2 Global state, local instruments, and Bell's triadic correlations 1645
66.2.1 Enhanced preparation and boundary instruments 1646
66.2.2 Local factorization, CHSH bound, and stability under enrichment 1646
66.2.3 Extension of binary entropy to the qutrit system and emergence of the invariant $\log 3$ 1647
66.2.4 The CGLMP inequality for 3 outcomes 1647
66.2.5 Triadic Transform from the Internal Elliptic Structure 1648
66.2.6 Joint Representation and Independence of the Marginals 1649
66.2.7 Holographic Reconstruction of Correlation via Indistinguishable Path Classes 1649
66.3 Internal Complex Structure and Projective Geometry of 2-Level States . . . 1650
66.3.1 The incidence of Paley as an algebraic origin of the phase 1650
66.3.2 Orthogonal realification of the phase 1651
66.3.3 The complex projective line and the Bloch sphere 1652
66.3.4 Spinorial Action, Rotations, and Möbius Transformations 1653
66.3.5 The icosahedral specialization and the binary group $2A_5$ 1653
66.3.6 Functorial composition $\mathbb{F}_3^6 \to \mathbb{F}_9^3 \to \mathbb{CP}^1 \simeq S^2 \to \mathrm{SU}(2) \to \mathrm{SO}(3) \to 2A_5$ . . 1654
66.4 Coupled observer, self-inertia and genealogical conservation of information 1654
66.4.1 Joint state and observer residence 1654
66.4.2 Measurement context and conditioning by fibers 1655
66.4.3 cylindrical PVM and Lüders correspondence 1655
66.4.4 Quantum instrument, dilation, and channel preservation 1656
66.4.5 State relative and formulation Everettian 1657
66.5 Canonical entangler between TPK memory and device 1657
66.6 Joint observer–observable state, reversible instrument, and self-measurement 1658
66.7 Joint observer–observable state, intrinsic self-measurement, and Stokes' holographic identity 1659
66.7.1 The Observer as Polarization, Trivialization, and Orientation 1660
66.7.2 Uniqueness of the intrinsic autofunctional 1661
66.7.3 Finite holographic principle: boundary, bulk*, and discrete Stokes* 1662
66.7.4 Structural Consequences of Polarization, Self-Measurement, and Discrete Stokes Identity 1663

67 Sommerfeld–Kepler central limit, pilot-wave dynamics, and double-slit interference on the genealogical trajectory space 1664
67.1 Central Limit, Kepler Orbits and Sommerfeld Holonomy . . . 1664
67.1.1 Discrete Gauss and inverse descent to area . . . 1664
67.1.2 Central Lagrangian and Keplerian conics . . . 1665
67.1.3 Levi-Civita Covering and Möbius Strip . . . 1666
67.1.4 Sommerfeld's semiclassical condition with holonomy . . . 1666
67.2 Reconstruction of quantum dynamics through coherent amplitudes over route genealogies . . . 1667
67.2.1 The global amplitude of 1 *family of paths* . . . 1667
67.2.2 Pilot wave, route performed and double orientation . . . 1669
67.2.3 Bell: locality of the data and globality of the genealogy . . . 1670
67.2.4 From the path theorem to quantum contrast . . . 1671
67.2.5 Double-slit interference in T^2_{27}: path memory, Born rule, and dodecaphasic unitarity . . . 1672
67.3 Central realisation of trajectories and Sommerfeld holonomy . . . 1674
67.3.1 Flux conservation and boundary reading . . . 1676
67.3.2 Central dynamics on the Euclidean sheet . . . 1677
67.3.3 Orbital covering and real sign line . . . 1678
67.3.4 Phase condition and half-integer shift . . . 1678
67.4 Differential Geometry and Dimensional Realizations . . . 1679
67.4.1 Curvature and torsion of the published curves . . . 1679
68 Quantum occupation statistics: Fermi–Dirac and Bose–Einstein distributions 1681
68.1 Microcanonical enumeration of states on a finite screen . . . 1681
68.2 Bose–Einstein and Fermi–Dirac distributions . . . 1681
68.3 Quantified convergence to the Maxwell–Boltzmann distribution . . . 1683
68.4 Quantum completions, leaf holonomy, and statistical periodicity . . . 1683
68.5 Statistical completions and fields over APP . . . 1683
68.5.1 Linear state space associated with a particle realization . . . 1683
68.5.2 Symmetric and exterior completions . . . 1684
68.5.3 Sheet grading and exchange algebra . . . 1684
68.5.4 Sheet holonomy and $2\pi/4\pi$ periodicity . . . 1685
68.5.5 Number and Occupation Distribution Operators in the Fock Realization . . . 1686
68.5.6 The cellular complex of the APP torus . . . 1686
68.5.7 Discrete Gauss law . . . 1687
68.5.8 Reversible measurement apparatus . . . 1687
68.5.9 Algebraic correspondences and physical realizations . . . 1687
68.5.10 Quasi-free correlation and spectral occupation entropies . . . 1688
68.6 Transport of Fock completions under refinement . . . 1689
68.6.1 Second quantization of refinement morphisms . . . 1689
68.6.2 Functoriality, canonical operators, and transport domains . . . 1689
68.7 Thermodynamic realization through Gibbs states and the pressure limit . . . 1691
68.7.1 Finite Hamiltonian, partition function, Gibbs state, and cofinal pressure limit . . . 1691
68.7.2 Condensation criterion by saturation of the excited-state density . . . 1691
68.8 Microcanonical enumeration of states on a finite screen . . . 1691
68.9 Bose–Einstein and Fermi–Dirac distributions . . . 1692
68.10 Quantified convergence to the Maxwell–Boltzmann distribution . . . 1694
69 Fermionic completion of trajectories and the algebraic Pauli exclusion principle 1695

69.1 Occupation, exclusion and finite statistics . . . 1695
69.1.1 Idempotency of Occupation in the Anticommutation Algebra . . . 1695
69.2 Spin, color, flavor, and virtuality characters . . . 1695
69.3 Statistical application of occupation spectra . . . 1696
69.3.1 Spectral restriction and admissible configurations . . . 1696
69.3.2 Dimensions of fixed-occupation sectors . . . 1696
69.3.3 Thermal readout of the graded completions . . . 1697

70 Reversible update, erasure cost, and exact domain of the zero Landauer limit 1698
70.1 Logical reversibility and Landauer's principle in TPK fibers . . . 1698
70.2 Genealogical Conservation of Information, Reduction Entropies and Thermal Structure . . . 1699
70.2.1 Disintegration of Visible Reading Over Fibers and Recovery of Genealogical Memory . . . 1699
70.2.2 Logical reversibility and Landauer's term . . . 1700
70.2.3 5 Notions of Entropy and Their Domains . . . 1701
70.2.4 Areal–volumetric incidence and topological entropy . . . 1702
70.2.5 Boltzmann Transduction and Energy by Triadic Decision . . . 1703
70.2.6 Thermal Operator on Histories . . . 1704
70.2.7 Genealogical memory, informational reduction and thermal transduction . . . 1704

71 Minimal area of the triadic cut, capacity $81\log 3$ and collective incidence transport 1709
71.1 Areal quantization, modular dynamics, and rational CKM transformation . . . 1709
71.1.1 Hexad–octad inclusion and associated functional realizations . . . 1709
71.1.2 Correspondence between the Nonadic Interior and the Boundary Degrees of Freedom . . . 1710
71.1.3 Collective incidence entangler between interior and boundary . . . 1711
71.1.4 What is the elementary and minimal scale of the area operator . . . 1711

72 Spectrum of the area operator and joint reconstruction of occupation and provenance 1713
72.1 Area and modular operators in the sectors 90 and 120 . . . 1713
72.2 Confluence of area, information and energy . . . 1714
72.3 Area operator and reconstruction of sectorial information . . . 1715
72.3.1 Tritic regrouping and boundary incidence . . . 1715
72.3.2 Transport of the collective incidence modes . . . 1716
72.3.3 Angular character and area operator . . . 1716
72.3.4 State normalization and the meaning of the modular Hamiltonian . . . 1717
72.3.5 Reduced state, Schmidt decomposition, and entanglement entropy . . . 1718

73 Boundary modular Hamiltonian, thermofield-double purification and oriented information deficit 1719
73.1 Qutrit state, thermofield-double purification, and informational deficit . . . 1719
73.2 Odd-even decomposition of the bilayer state: interleaf information and oriented geometric transport . . . 1720
73.3 The bicover: even information and odd geometric transport . . . 1720
73.3.1 Normalized distribution between leaves . . . 1720
73.3.2 Parity of the hexad-octad transport . . . 1721
73.3.3 Interpretation of the constitutive operator as coupling between vacuum, field, and response . . . 1721
73.4 Holographic-modular free energy and informational memory of geometry . . . 1722
73.4.1 Oriented Bilayer State $T_{A,y}$, Normalization ρ_y, and Separation between Intensity and Leaf Orientation . . . 1722

73.4.2 Exact spectral thermodynamics of the 2 sheets . . . 1722
73.4.3 Double-thermofield purification and sheet conjugation . . . 1723
73.4.4 Total Geometry and Modular Provenance . . . 1724
73.4.5 1st local law and finite balance of relative entropy . . . 1725
73.4.6 Holographic-modular free energy of the horizon . . . 1725
73.4.7 Confluence between areal quantity and informational quantity . . . 1726
73.4.8 Local UHF Network and Modular Generator in the GNS Representation . . . 1727
73.4.9 Exact gravitational closure identities and tensor realization conditions . . . 1728
73.5 Spectral Classification of the Intertwiner among the Horizon, Thermofield-Double Purification, and Perron Dynamics . . . 1728
73.6 Joint reconstruction of occupancy, provenance, and modular entropy in the channels 90/120 . . . 1731
73.6.1 Genealogical memory and informational content of a reading . . . 1731
73.6.2 Areal and volumetric sheets: incidence, growth, and measure . . . 1732
73.6.3 Admissible continuations and survival information . . . 1733
73.7 Areal–volumetric incidence and topological entropy . . . 1733
73.7.1 Stationary distribution and variational characterization . . . 1734

74 1st areal modular law and finite extension through relative entropy 1736
74.1 1st modular law for area variations . . . 1736
74.1.1 Equation of state for sectorial information . . . 1737
74.1.2 Occupation inversion and entropic invariants . . . 1739
74.1.3 First modular law and finite area variations . . . 1739
74.1.4 Equation of state for sectorial information . . . 1740
74.1.5 Occupation inversion and entropic invariants . . . 1742
74.1.6 First modular law and finite area variations . . . 1742
74.1.7 Spectral entropy and preservation under transport . . . 1743
74.1.8 Quasi-free correlation and spectral occupation entropies . . . 1744
74.2 Thermal radiation and the information scale of the calendar . . . 1745
74.2.1 Constitutive speed and kinematic realization of the clock . . . 1745
74.2.2 Action, calendar, and temperature . . . 1747
74.2.3 Mode density and spectral law . . . 1748
74.2.4 Thermodynamic limit of occupation sums . . . 1748
74.2.5 Thermal moments and information . . . 1750
74.2.6 Thermal flux and the Stefan–Boltzmann constant . . . 1750
74.2.7 Spectral maxima and displacement law . . . 1752

75 Persistence of the channels 90/120 and classification of the limit as a hyperinfinitesimal factor III_{λ_∂} 1753
75.1 Local Limit and Modular Classification of the Infinite System . . . 1753

76 Dynamic, propagative, and cosmological realizations of genealogical memory: dodecaphase transport, Green function, and spatial expansion 1754
76.1 Boundary memory: even–odd decomposition and 3 hydrodynamic, gauge, and cosmological realizations . . . 1754
76.1.1 From angular channels to dodecaphasic transport . . . 1754
76.1.2 Distributed memory and local generator . . . 1755
76.1.3 Local interior and reflected representations: circulation, holonomy, contraction, and transfer positivity . . . 1756
76.1.4 Global reading: expansion and curvature . . . 1756

76.1.5 2 *Exact Operator Representations and* 1 *Global Geometric Realization of Boundary Memory* . . . 1757
76.2 Spatial suspension, geometric trichromy and helicoidal leaf lamination . . . 1757
76.2.1 *Spatial immersion* $\Gamma(\theta)$ *and Frenet–Lancret differential criteria* . . . 1757
76.2.2 *Coordination of the regimes* $J^2 = -I, 0, +I$ *with the Frenet geometry* . . . 1757
76.3 Dynamic structure of space and consequences . . . 1758
76.3.1 *Helicoidal leaf lamination* . . . 1758
76.3.2 *Kinematic classification by angular and radial increments* . . . 1758
76.3.3 *Mobius Quotient via Return with Orientation Inversion* . . . 1758
76.3.4 *Classification of 3+2 equilibrium points via the Hessian* . . . 1759
76.3.5 *Causal hierarchy between curves, fields, and material sections* . . . 1759

77 Icosahedral descent A_5/C_5 and selection of the five-component gravitational carrier 1760
77.1 Intrinsic gravitational constant and tensor representation . . . 1760
77.1.1 *Icosahedral descent* A_5/C_5 *and gravitational carrier selection* . . . 1760
77.1.2 *Gravitational magnitude line and chronological scale* 108 . . . 1760
77.1.3 *Planck System and Bidirectional Covariance* . . . 1761
77.1.4 *Icosahedral Component of Dimension* 5 . . . 1762
77.1.5 *Icosahedral incidence and five-component gravitational coupling* . . . 1764
77.1.6 *Intertwiner with the space of symmetric traceless tensors* . . . 1770
77.1.7 *Transverse traceless projection* . . . 1771
77.1.8 *Decomposition into* 5 *polarization modes* . . . 1772
77.1.9 *Physical interpretation of the representational chain* . . . 1773

78 Intertwiner with symmetric traceless tensors and transverse reduction $12 \to 5 \to 5 \to 2$ 1774
78.1 Intertwiner with the space of symmetric traceless tensors . . . 1774
78.2 Transverse traceless projection . . . 1775
78.3 Oriented incidence and gravitational tensor representation . . . 1775
78.3.1 *Signed covering and calendar transport* . . . 1776
78.3.2 *Quadratic reading and five-component space* . . . 1777
78.3.3 *Transverse projection and helicities* . . . 1777

79 Helical decomposition of the spin carrier 2 and distinction between massive and massless realizations 1779
79.1 Decomposition into 5 polarization modes . . . 1779
79.2 Representational chain $12 \to 5 \to 5 \to 2$: carrier V_5, trace-free tensor, Fierz–Pauli polarizations, and transverse helicities . . . 1780

80 Gravitational Holonomic Selector: Dimensional Transduction, Naturality, Refinement, and Separation of the Torsional and Circular Regimes 1781
80.1 Holonomic conditions of the general gravitational selector . . . 1781
80.1.1 *Criteria for selecting the gravitational coordinate: enriched holonomy, spectral response, and metrological chart* . . . 1782
80.2 Dimensional Transduction and Holonomic Selection of the Gravitational Constant . . . 1785
80.2.1 *Gravitational line and dimensional form* . . . 1785
80.2.2 *Obstruction of the Positive Character on the Observable Return* . . . 1786
80.2.3 *Chronological composition of length, action, and spectrum in the determination of G* . . . 1787
80.2.4 *Nonhomomorphic functional over enriched paths* . . . 1789
80.2.5 *Transduction of the gravitational decimal chart onto the magnitude line and causal separation of metrological recognition* . . . 1789

80.2.6 Hierarchy of Evidence for Gravitational Constructions . . . 1790
80.2.7 Gravitational–inertial ratios and the dimensional constant . . . 1791
80.3 Action, gravity, and thermal information . . . 1791
80.3.1 Dodecaphasic period and circular realization of action . . . 1791
80.3.2 Thermal normalization and energy per cycle . . . 1792
80.3.3 Barbero–Immirzi in the Cartan–Holst realization . . . 1792
80.3.4 Phase return and representation of accumulated memory . . . 1793
80.3.5 Cubic incidence and boundary soldering . . . 1794
80.3.6 Geometric realization of transport and soldering . . . 1796
80.3.7 Oriented transport of the connection and area . . . 1797
80.3.8 Structural definition and function of the gravitational constant . . . 1798
80.4 Phase return and representation of accumulated memory . . . 1798
80.4.1 Inversion cocycle and change of sheet . . . 1799
80.4.2 Affine representation of the cocycle . . . 1799
80.5 Boundary soldering and energy response . . . 1800
80.5.1 Cubic incidence and the rank-four quotient . . . 1800
80.5.2 Cellular soldering and memory transport . . . 1801
80.5.3 Positive response, uniqueness, and minimal extension . . . 1801
80.5.4 Preservation of density by refinement . . . 1802
80.5.5 Variational realization of the response . . . 1803
80.6 Geometric realization of transport and soldering . . . 1803
80.6.1 Screen, co-tetrad and connection . . . 1803
80.6.2 The three quadratic realizations of curvature . . . 1804
80.7 Variational response of memory energy . . . 1805
80.7.1 Discrete functional and space of variations . . . 1805
80.7.2 Composition and transport of the response . . . 1806
80.7.3 Oriented inversion and transport of the weight . . . 1807
80.7.4 Compatibility with refinement . . . 1807
80.7.5 Material realization of the response . . . 1808

81 Perron Dynamics, Dilution a^{-6} of memory and Einstein–Cartan realization 1809
81.1 Perron dynamics and the stable memory mode . . . 1809
81.2 Realization in the system of Einstein–Cartan . . . 1809
81.3 Structural comparison between the 108-state cycle and Perron dynamics . . . 1810
81.4 Torsional Memory and Bounce Conditions in Einstein–Cartan . . . 1811
81.4.1 Transport of the Perron law to the spin spectral density . . . 1811
81.4.2 Homogeneous Equations and Density Convention . . . 1811
81.4.3 Existence and uniqueness of the bounce radius . . . 1812
81.4.4 Limit Cases of Torsional Dynamics and Obstructions to the Regularity of the Bounce . . . 1812
81.4.5 Torsional amplitude from the Cartan screen . . . 1813
81.4.6 Torsion, orientation, and transport memory . . . 1813
81.4.7 Mach's principle and cosmographic autoinertia . . . 1814
81.4.8 Exact identities of torsional dynamics and Einstein–Cartan interface conditions 1814

82 Palatini–Cartan–Holst realization of the Barbero–Immirzi parameter and physical transduction of the area spectrum 1815
82.1 Curvature, torsion, and Einstein–Cartan–Holst action . . . 1815
82.1.1 Discrete Gauss–Stokes identity and incidence transport to the boundary . . . 1815
82.1.2 Area capacity of the qutrit cell: $81 \log 3$ *and collective incidence transport* . . . 1815

82.1.3 Tetrad, spin connection, and torsion of the Cartan–Holst realization 1816
82.1.4 Palatini–Holst Action and Variational Equations 1816
82.1.5 Bianchi Identity with Torsion and Flow Balance in the Cartan Connection . . 1817
82.1.6 Map of realization and specialization of the Holst parameter 1817
82.2 Nonadic Return, Memory Groupoid and Cartan Entanglement Condition . . 1818
82.3 Nonadic Return, Memory, and Cartan Holonomy 1818
82.3.1 Exact hierarchy of returns 1818
82.3.2 Memory Groupoid 1820
82.3.3 Joint connection and entanglement condition 1820
82.4 Gravity: Holonomy, Torsion, and Collective Response 1821
82.4.1 Returns: position, orientation, phase, and memory 1821
82.4.2 From the path groupoid to the Cartan group 1822
82.4.3 Gauss–Stokes and areal capacity 1823
82.4.4 The Palatini–Cartan–Holst Action 1823
82.4.5 Metric equation, spin, and geometric balance 1824
82.4.6 Area–volumetric correspondence π/φ^2 1825
82.4.7 Typing of G as gravitational transducer and causal order of its readers 1825
82.4.8 Collective origin of the gravitational mode in the holonomy of paths 1826
82.5 Realization in the Holst action 1826
82.6 Realization of the current in connection coordinates 1826
82.6.1 Differential on invertible transports 1826
82.6.2 Quadratic representations of TRIT 1827
82.6.3 Composition of routes and oriented inversion 1827
82.6.4 Evaluation of current components 1828
82.6.5 Insertion into the Cartan equation 1829
82.7 Differential of the minimal boundary extension 1829
82.7.1 Minimizing field and response weight 1829
82.7.2 Full differential of the minimum 1830
82.7.3 Fixed quotient and frame changes 1831
82.7.4 Transported incidence and connection components 1831
82.8 Spin current and algebraic Cartan–Holst response 1832
82.8.1 Geometric domain and current normalization 1832
82.8.2 Connection variation and Holst inversion 1833
82.8.3 Pointwise reconstruction of torsion and contorsion 1834
82.8.4 Elimination of contorsion and quadratic contribution 1835
82.8.5 Effective metric source and covariant balance 1835
82.9 Torsional elimination and metric response of the minimal extension 1836
82.9.1 Variational composition at a cellular level 1836
82.9.2 Local existence of a stationary branch 1838
82.9.3 Effective action and non-affine contribution 1838
82.9.4 Metric differential of the eliminated action 1839
82.9.5 Exact non-affine checking model 1840
82.10 Spinorial current and torsional amplitude of the material state 1841
82.10.1 Spinorial representation and affine material action 1841
82.10.2 Effective contraction and second-moment coefficient 1842
82.10.3 Finite fermionic realization and second moment of the state 1843
82.10.4 Density, pressure and preservation of the comoving amplitude 1844

83 Confluence theorem relating horizon energy, area, information, entropy, and action 1846
83.1 Horizon energy and half-action cell 1846

83.1.1 Geometric conventions of the de Sitter patch . . . 1846
83.1.2 energy of vacuum and energy of Misner–Sharp . . . 1846
83.1.3 Temperature, entropy and product of horizon . . . 1847
83.1.4 How complete of the horizon and Planck force . . . 1847
83.1.5 Specialization to the closure chronological of 108 states . . . 1848
83.1.6 Effective horizon weight and hyperbolic exponential . . . 1849
83.1.7 Consistency of the Gravitational Transducer with the Schwarzschild Horizon . 1849
83.1.8 Horizontal Horizon–Perron Entangler: Spectral compatibility between boundary energy and return memory . . . 1850
83.2 Confluence of action, area, information, and gravitation . . . 1851
83.2.1 Energy and entropy of the half-action cell . . . 1851
83.2.2 Conversion between decision energy and area increment . . . 1851
83.2.3 Physical meaning of area confluence . . . 1852
83.2.4 Spectral entropy and preservation under transport . . . 1853
83.2.5 Effective multiplicity and hyperbolic realization . . . 1853
83.3 Evaluation of constants and metrological comparison . . . 1853
83.3.1 Planck constant and reduced constant: two orientations . . . 1854
83.3.2 Barbero–Immirzi: internal value and comparison between constructions . . . 1854
83.3.3 CKM angles, amplitudes, and CP violation . . . 1855
83.3.4 Boltzmann and universal gravitation: quantity, chart and reference . . . 1856
83.3.5 Reproduction of the evaluations . . . 1857
83.4 Pure bipartite states, reduced entropy and horizon area laws . . . 1857
83.4.1 Sheet record and bipartite quantum purification . . . 1857
83.4.2 Quantum purification of the incidence sectors . . . 1858
83.4.3 Informational equation and areal fluctuations . . . 1859
83.4.4 Modular law and finite area variations . . . 1860
83.4.5 Action, decision energy, and areal unit . . . 1861
83.4.6 Cosmological normalization of the horizon . . . 1861
83.4.7 Kruskal chart and exchange of the exteriors . . . 1862
83.4.8 Transport of states, observables, and refinements . . . 1863

84 Mach's principle and self-inertial systems: relational dependence among global closure, local inertia, and torsional memory 1865
84.1 Mach's principle, bidirectional propagation and collective gravitational response 1865
84.1.1 Global dependence of the local response . . . 1865
84.1.2 Advanced and Retarded Propagators on Oriented Paths . . . 1866
84.1.3 Temporal Involution Invariants and Particle–Antiparticle Conjugation . . . 1867
84.1.4 Propagating curvature as a collective mode of geometry . . . 1867
84.1.5 Metric Hypotheses and Boundary Conditions of the Machian Realization . . . 1868
84.2 Self-inertia as connection endogenous of the joint state . . . 1868
84.3 Machian Criterion of Global Factorization . . . 1869
84.4 Holonomy and hierarchy of returns . . . 1869
84.5 Möbius band and conjugation of orientations . . . 1870
84.6 Antiunitary conjugation and temporal orientation . . . 1870
84.7 Recoverability and Landauer's Principle . . . 1871
84.8 Reversible measurement, conditioning, and reinitialization . . . 1872
84.9 Confluence of observation, self-inertia, and modular response . . . 1873
84.10 Domain of validity and physical realization conditions . . . 1873
84.11 Relational Dynamics of Frames: Autoinertia, Ambivalence, and Mach's Principle . . . 1874

84.11.1 Totality, Trace, and Local Response . . . 1874
84.11.2 Self-inertial sections as geodesics of the joint state of system, observer, and memory: $D_\gamma s_\gamma = 0$ . . . 1875
84.11.3 Ambivalence Principle: Bidirectional Involution of the Readers π/φ^2 and φ/π^2 1875
84.11.4 Causal Coordination Between Inertial Transport, Areal–Volumetric Double Reading, and Machian Factorization . . . 1876
84.11.5 Measurement of motion and frame coupling . . . 1876
84.11.6 Bidirectional wave and temporal orientation . . . 1876
84.11.7 Global expansion and self-consistency equation . . . 1877
84.12 Self-inertial response and Mach's principle from Ambivalence . . . 1877
84.13 Observer, memory, and relational response . . . 1878
84.13.1 Boundary transport and intrinsic reading . . . 1878
84.13.2 Boundary identity and cellular interior . . . 1880
84.13.3 Isometric inscription of the record in the apparatus . . . 1880
84.13.4 Accessible algebra and pointer complement . . . 1881
84.13.5 Factorization of the response through the effective boundary . . . 1882
84.13.6 Ambivalence weights and self-inertial response . . . 1882
84.13.7 Connection of the joint state and acceleration reading . . . 1885

85 The HMT–MD absorber theory: trajectory inversion, advanced and retarded propagators, boundary conditions, and particle–antiparticle conjugation 1886
85.1 Bidirectional interaction: conjugation of advanced and retarded propagators and boundary conditions of the absorber . . . 1886
85.1.1 Action functional on enriched paths . . . 1886
85.1.2 Interaction as typed coupling . . . 1887
85.1.3 Temporal conjugation of the propagator . . . 1887
85.1.4 Advanced and Retarded Propagators . . . 1888
85.1.5 HMT–MD realization of the absorber through route inversion and particle–antiparticle conjugation . . . 1888
85.1.6 The separate actions of C, P and T . . . 1889
85.2 C-even absorbing operator and boundary condition . . . 1889
85.3 Bidirectional propagation and absorption condition at the boundary . . . 1890
85.3.1 Route action and record involutions . . . 1891
85.3.2 Reversal of the realized evolution . . . 1892
85.3.3 Propagators of the chronological channel of a route . . . 1892
85.3.4 Causal interchange and decomposition of the response . . . 1893
85.3.5 Projection of absorbed currents and variation of the action . . . 1894
85.3.6 Explicit absorbing condition in a chronological window . . . 1895
85.3.7 Refinement and continuity of the boundary condition . . . 1896

86 Causal polarization of the gravitational interior: loss of spatial freedom, tilting of the cones, and compulsory direction of infall 1897
86.1 Causal polarization field and radial freedom loss . . . 1897
86.2 Schwarzschild realization and collective gradient of fall . . . 1898
86.3 Correspondencia with the 3 regimes of the TRIT . . . 1898
86.4 Local closure of matter and collective gravitational alignment . . . 1899
86.5 Geometric conditions of causal macropolarization: areal radius, cone tilt, horizon, and interior falloff . . . 1899

87 Causal horizon, interior–exterior inversion, and the hyperbolic regime of TRIT in the gravitational interior 1900

87.1 Leaf involution in a trapped region and causal representation of the interior of a black hole . . . 1900
87.2 Double-sheet black hole and advanced purification–delayed . . . 1901
87.2.1 State of sheet and information . . . 1901
87.2.2 Geometric realization of the 2 *causal sheets* . . . 1902

88 Torsional cosmology of periodicity 108**: expansion, return with memory, and Einstein–Cartan bounce** **1904**
88.1 Cosmological scales associated with the 108-state cycle and the Perron operator 1904
88.1.1 Separation between de Sitter acceleration and Einstein–Cartan torsional bounce 1904
88.1.2 Periodicity condition of the 108-state cycle . . . 1904
88.1.3 Gravitational selector and Planck–TRIT relation . . . 1904
88.1.4 Conditioned realization of de Sitter geometry . . . 1905
88.2 Boundary conditions, bounce regularity, and decomposition of cosmological components . . . 1906
88.2.1 Correspondence between the elliptic, parabolic, and hyperbolic regimes of the TRIT and the AdS–Euclidean–dS charts . . . 1906
88.2.2 Cosmological foliations compatible with sheet inversion . . . 1907
88.2.3 Boundary state of the cosmological horizon and return memory . . . 1907
88.2.4 Criterion of regularity of the bounce under extreme concentration and torsional dominance . . . 1908
88.2.5 Cobordism and Descendant Cosmological Components . . . 1908
88.2.6 Parallel components and intercomponent mode . . . 1909
88.2.7 Certification of the torsional bounce and exact obstructions . . . 1909
88.3 Geometric junction between anisotropic contraction, torsional bounce, and descending cosmological region . . . 1910
88.4 Elliptic, parabolic, and hyperbolic regimes of TRIT and their projection onto the dark sector . . . 1911
88.5 Temporal Orientation of the Cosmic Background and Memory Conservation Under Expansion . . . 1912
88.6 Torsional junction of a trapped region and construction of a descending cosmological branch . . . 1914
88.6.1 Torsional gluing of a trapped region: exact, conditioned, and physical strata of the descendant cosmological branch . . . 1914
88.6.2 Causal orientation of the 3 *leaves* . . . 1914
88.6.3 Anisotropic interior and quadratic memory . . . 1915
88.6.4 Nonadic condition for the bounce level . . . 1916
88.6.5 Matching data on the bounce hypersurface . . . 1917
88.6.6 Null horizon as a marginal hypersurface and initial matching condition . . . 1918
88.6.7 Möbius band and orientation memory . . . 1918
88.6.8 Relative Observer, Parallel Transport and Autoinertia in the Descending Cosmological Region . . . 1919
88.6.9 Global channel of the descendant region . . . 1920
88.6.10 Descendant continuation and branched cobordism . . . 1921
88.6.11 Local consequences of the torsional matching: conservation, regularity, and causal prolongation . . . 1921
88.6.12 Torsional dynamics of bounce: exact identities, cosmological interfaces and closure conditions . . . 1922
88.6.13 Obstructions to Cosmological Continuation: Loss of Orientation, Junction Regularity, or Return Memory . . . 1922

88.7 Explicit Regular Solution of the Descending Cosmological Continuation . . 1923
88.8 Dilution Law a^{-6}, Torsional Memory, and Confluence of the Cosmological Readers . . . 1924
88.9 Confluence of vacuum readers, action, gravity, area, mixture, and memory . 1926
88.10 Cosmology of the global genealogical state: connection, curvature, expansion, and boundary memory . . . 1927
88.10.1 The totality as a compatible state . . . 1927
88.10.2 3 curvature charts . . . 1927
88.10.3 Distributed memory and expansion . . . 1928
88.10.4 Completion (1000=729+243+27+1), boundary data, and Einstein–Cartan bounce criterion . . . 1928
88.10.5 Common system of cosmological observables: expansion, lensing, structural growth, and background anisotropies . . . 1929
88.11 Projective finiteness and harmonic dodecaphasic selector . . . 1930
88.11.1 Internal refinement of the external-contraterm-independent harmonic selector 1930
88.11.2 Harmonic cycle selector of the dodecaphasic cycle . . . 1931
88.11.3 Prediction of dodecaphasic anisotropy: prior parametrization, blind contrast, and criterion of observational incompatibility . . . 1932
88.12 HMT Cosmic Selector and Einstein–Cartan Bounce . . . 1932
88.12.1 Selector of the 3 cartas cosmologicas . . . 1932
88.12.2 Rebound Sector Selector . . . 1933
88.13 Descendant universe as a genealogical channel . . . 1933
88.14 Effective dark tensor and acceleration . . . 1934
88.15 Consistency conditions and domain of validity . . . 1935
88.16 Memory dilution and persistence of the bounce . . . 1935
88.16.1 The a^{-6} dilution law . . . 1936
88.16.2 Homogeneous threshold and transversality . . . 1936
88.16.3 Local persistence under controlled perturbations . . . 1937
88.17 Explicit homogeneous solution and causal completeness . . . 1938
88.17.1 Finite curvature and extension of geodesics . . . 1939
88.18 Residual tensor, trace decomposition, and covariant balance . . . 1939
88.18.1 Chart data and construction of the residual tensor . . . 1939
88.18.2 Canonical decomposition and exchange current . . . 1940
88.18.3 Link to the effective Cartan–Holst source . . . 1941
88.18.4 Trace sector and acceleration of the selected charts . . . 1941

89 Polyakov action, T-duality, strings, and branes: compactification in dimension 11 and dynamical realization of M-theory 1943
89.1 Extended Persistence and String and Brane Worldvolumes . . . 1943
89.1.1 Extended persistence and world surface . . . 1943
89.1.2 Exact screens in dimensions 11, 10, 26 and 24 . . . 1943
89.1.3 Moment, winding and reciprocal radius . . . 1944
89.1.4 Interface in dimension 11: spectral triple, supersymmetry and operator $Q^2 = H$ 1945
89.1.5 From exact screens to the physical interface of M-theory . . . 1945
89.2 Realization of M-theory through compactification, strings, branes, and 11 dimensions . . . 1947
89.2.1 Operator lifting of the APP–TRIT–TPK state . . . 1947
89.2.2 Physical undecadimensional codomain . . . 1948
89.2.3 Compatibility of the spectral triple $(\mathcal{H}_{\mathrm{phys}}, H, Q)$ with the physical codomain in dimension 11 . . . 1948

90 General Mass Law on the atlas 81/56/13/324: trajectories, record, signature, character, towers 90/120 and the null sector 1949

90.1 Operator Domain of the General Mass Law: 81 Cells, 56 Families, 13 Multisections, 324 Routes, and Null Sector . . . 1949
90.2 Determinantal origin of the absolute scale . . . 1949
90.3 Governing construction of the law and the material domain . . . 1949
90.3.1 Spectral Definition of Mass as a Persistence Measure of a Route 1 Coupled to a Physical Regime . . . 1949
90.3.2 Complete state space of mass . . . 1949
90.3.3 Genealogical trajectory of a mass realization . . . 1950
90.3.4 From the APP defect to the full signature . . . 1953
90.3.5 Global harmonic hierarchy of towers . . . 1955
90.3.6 Absolute Rama: action, clock and mass line . . . 1956
90.4 Conjugate angular coordinates and spectral decomposition . . . 1956
90.4.1 Transfer of the angular coordinates derived in HMT . . . 1957
90.4.2 Internal phases and exponential chart . . . 1958
90.4.3 Central involutive algebra . . . 1958
90.4.4 Invertibility of the channel chart . . . 1958
90.4.5 Addition and Recurrence Identities . . . 1959
90.4.6 Action ellipse, radian, and double holonomy return . . . 1959
90.4.7 Causal precedence of the General Mass Law with respect to species-specific realizations . . . 1965
90.5 Nonadic classification of trajectory families . . . 1968
90.5.1 The complete geometry of the 81 cells . . . 1968
90.5.2 Central inversion, 41 orbits, and uniqueness of the centre . . . 1969
90.5.3 The 56 route families . . . 1969
90.5.4 Distinction between cell, route family, and multisection . . . 1971
90.5.5 Color residual as ternary orientation . . . 1971
90.5.6 From the surviving extension to the signature . . . 1971
90.5.7 Null sector bifurcation prior to the positive character . . . 1972
90.5.8 Finite classification system and path memory . . . 1973
90.5.9 From APP seeds to mixture and mass registration . . . 1973
90.6 Color qutrit algebra and finite gauge connection . . . 1977
90.6.1 Weyl pair and trace algebra 0 . . . 1977
90.6.2 Connection and Action on a Finite Cellular Complex . . . 1978
90.6.3 Positivity of Class Kernels and Harmonic Decomposition . . . 1979
90.7 Systematic extension of mass theory . . . 1980
90.7.1 Extension–route factorization and genealogical record conservation . . . 1980
90.8 Functorial construction of mass families over the atlas . . . 1982
90.8.1 Universal Algorithm of the General Mass Law . . . 1982
90.9 Bifurcation of the previous null sector from the positive mass branch . . . 1984
90.10 Exhaustive construction of the atlas 81/56/13/324 and conservation of the null sector . . . 1984
90.11 Theorem of material domain exhaustiveness and null sector stability under refinement . . . 1984
90.12 Fiber product between species invariants and genealogical paths . . . 1985
90.13 Intrinsic spectral classification of the species . . . 1986
90.13.1 Conjugate quotients and minimal memory of the finite atlas . . . 1986
90.14 The particle as a class of persistent sections . . . 1991

90.14.1 Extension, observable history, and compatible section . . . 1991
90.14.2 Identity under refinement and equivalence of representations . . . 1992
90.14.3 The species as a fibre: scope of the finite atlas . . . 1992
90.14.4 Construction of the mass observable from the material register . . . 1993
90.15 Conjugation, orientation, and return of material sections . . . 1994
90.15.1 Dodecaphase involution and parity of observables . . . 1994
90.15.2 Lifting to antisections and preservation of mass . . . 1994
90.15.3 Sign holonomy and the persistence band . . . 1995
90.15.4 Bidirectional lattice and channel conjugation . . . 1996
90.15.5 Spinor representation of the electronic block . . . 1997
90.16 Classification of persistent sections and their internal observables . . . 1998
90.16.1 Parity, depth, and multisections . . . 1998
90.16.2 Central conjugation and selection of a cell . . . 1999
90.16.3 Classification of routes and positional memory . . . 2000
90.16.4 Residual colour, flavour, and sheets . . . 2000
90.16.5 Domain of orientations of the atlas . . . 2001
90.17 Generated coordinates, action, and electronic normalisation . . . 2001
90.17.1 Regional readers and compatibility of evaluation . . . 2001
90.17.2 Signed dodecaphasic chart of the full TPK state . . . 2002
90.17.3 From temporal incidences to the dodecaphase record . . . 2003
90.17.4 Periodic publication of K and normalization of α . . . 2007
90.17.5 Three-dimensional construction of the electronic prefactor . . . 2009
90.17.6 Boundary reading and basal electronic composition . . . 2010
90.17.7 Determinantal scale and the reduced Planck constant . . . 2011
90.17.8 Angular coordinates and the clock of the absolute realisation . . . 2013
90.17.9 Two readers of the electronic trajectory and beta evaluation . . . 2015
90.18 Mathematical and Physical Consistency Invariants of Helical Realizations . 2016
90.18.1 Mathematical Invariants of the Helical Prolongation . . . 2016
90.18.2 Constitutive Conditions of the Electromagnetic and Material Realization . . . 2017
90.18.3 Stratification of Internal Theorems and Their Physical Realizations . . . 2017
90.18.4 Theorem of closure of genealogical spiral correspondences . . . 2018

91 Bidirectional readers K_D y K_Ω: profiles, coincidences, towers 90/120 and operators by multisection 2019
91.1 Readers K_D and K_Ω: dodecaphasic profiles, path domain and spectral codomain 2019
91.2 Semigroup and fiber operators . . . 2019
91.3 Electronic construction, tower transducer and route clock . . . 2019
91.4 Dodecaphase ledger and TPK memory $1+5+6$ . . . 2019
91.4.1 Temporal dodecaphasic system of the TPK . . . 2019
91.4.2 Complete construction of the beta electron: central route, signature, character, and governing mass . . . 2023
91.4.3 Physical realization by spectral coupling . . . 2024
91.4.4 Genealogical Transducer of Towers . . . 2026
91.4.5 Route clock and absolute normalization . . . 2031
91.5 Surviving extension, dodecaphasic record, and integral signature . . . 2031
91.5.1 Operational composition of the prolongation and torsional cocycle in the generation of the route record . . . 2032
91.5.2 Projection of a surviving extension onto its observable route . . . 2033
91.5.3 Integral Decomposition of 12 Events into the Sectors $1+5+6$ . . . 2035
91.5.4 Torsional cocycle at the step level . . . 2036

91.6 Positive character of the signature and composition of records 2037
91.6.1 Universal formal character 2037
91.6.2 Minimum internal section over the 81 cells 2037
91.6.3 Orientation-based composition of records before projection 2038
91.6.4 Dodecaphasic dependence of the persistence character 2039
91.6.5 Factorization by the quotient of log and physical realization 2039
91.7 Split algebra and exact factorization of the character 2040
91.7.1 Conjugate angular coordinates and bidirectional spectral lattice 2040
91.7.2 Real split algebra 2041
91.7.3 Relative transporter and representational realization conditions 2041
91.7.4 Partial factorization of the angular character 2042
91.7.5 Central incorporation of the towers 2042
91.8 Values, Completeness and Blocks of the Spectral Hierarchy 2043
91.8.1 First evaluations of the hierarchy 2043
91.8.2 Global blocks of mass action 2044
91.8.3 Higher-order combination 2045
91.8.4 Bilayer Operator and Infinite Hierarchy 2045
91.8.5 Pair of genealogical readers over the complete atlas 2047
91.9 Scalarization morphism and dimensional realization obstructions 2058
91.10 Explicit refinement in the 90/120 towers 2058
91.11 Fiber operators and bidirectional law 2059
91.12 Symmetry Scalarization and Coupling 2061
91.13 Construction of the mass operator from the trajectory record 2062
91.13.1 Chronological reading and oriented events 2062
91.13.2 Torsional memory and signature 2063
91.13.3 Character and internal specialization 2063
91.13.4 Bilayer hierarchy and preservation of the two genealogies 2064
91.13.5 Displacement and autocorrelation readers 2065
91.13.6 Operator on a fiber and dimensional section 2065
91.13.7 The null propagation sector 2066

92 Spectral, scalar, and null realizations of the General Mass Law: material families, CKM–PMNS transport, and photonic and gluonic sectors 2067
92.1 Conjugation, parity, and time reversal in the register 2067
92.1.1 Route and local action 2067
92.1.2 Discrete involutions C, P, and T on the routes: sheet conjugation, spatial reflection, and record reversal 2067
92.1.3 Parity of Descendant Readers 2068
92.1.4 Relation with CKM and with the CPT theorem of fields 2068
92.2 Codomains of the material realizations: spectral operator, scalar, gauge nullity, composite, and resonant pole 2068
92.3 Null extensions, propagation between boundaries and electronic closure . . 2068
92.4 Null extensions and material closure 2069
92.4.1 4 realizations of the common material state: null, massive, composite, and topological 2069
92.4.2 Null propagation between boundaries 2069
92.4.3 Material closure and electronic center 2071
92.4.4 Physical realizations by object, representation, and codomain 2072
92.4.5 Elementary Realizations of the Standard Model 2072

92.4.6 *Generation, Charge, Spin, and Mass-Character Decomposition of the Leptonic Sector* . . . 2073
92.4.7 *Quarks, color, generations, and CKM mixing* . . . 2076
92.4.8 *Gauge and scalar sectors* . . . 2078
92.4.9 *Construction of composite particles through non-additive composition of paths and bonds* . . . 2081
92.4.10 *Topological sectors and hypothetical particles* . . . 2083
92.4.11 *Universal Inventory of Masses and Widths* . . . 2087
92.4.12 *Mass, temperature, and statistics* . . . 2090
92.4.13 *Differential propagation of uncertainties and structural stability of the mass character* . . . 2091
92.5 Leptons, neutrinos, quarks and gauge sectors . . . 2092
92.6 Correspondence between internal classes and physical sectors . . . 2092
92.6.1 *Path signatures and dodecaphasic coindexed pairs by flavor* . . . 2093
92.6.2 *Generational stratification, quark supports and neutrino realization* . . . 2093
92.6.3 *Mass Operator Transport via CKM* . . . 2096
92.6.4 *Geometric frames of rank* 3 *for the leptonic sector* . . . 2097
92.6.5 *Involution of leaves in* 4 *representations* . . . 2098
92.6.6 *Involutive rational transformation in the CKM parameter space* . . . 2099
92.7 Composition, resonances and non-ordinary sectors . . . 2102
92.8 Composition of paths, records, and signatures . . . 2103
92.8.1 *Internal classification and compositional grammar* . . . 2103
92.8.2 *Combinatorial census of route compositions independent of metrological data* 2104
92.8.3 *Memory transport from the composite route to the integral signature* . . . 2106
92.8.4 *Commutative diagram of composition and fiber preservation* . . . 2107
92.8.5 *Theorem of independent data record composition in metrology* . . . 2108
92.8.6 *Genealogical reconstruction of mixing, generation, and persistence of flavor* . 2109
92.8.7 *From the internal compositional system to physical realization* . . . 2109
92.9 Particle band, anti-section, and virtuality . . . 2110
92.9.1 *Definition of the route band through the orbit of a persistent section* . . . 2111
92.9.2 *Even mass and odd charge* . . . 2111
92.9.3 *Finite closure of the atlas under anti-section* . . . 2112
92.9.4 *Finite persistence and virtual particle* . . . 2112
92.9.5 *Route–record–signature–character–material realization tower chain* . . . 2113
92.10 Complex structure $\widetilde{J}_M^2 = -I$ on the fixed stratum, dodecaphase involutions, and topological sectors . . . 2113
92.10.1 *Periodic stratum of the dodecaphasic involution* . . . 2113
92.10.2 *Quadratic structure transported to the fixed sheet* . . . 2114
92.10.3 *Mathematical stratification of the Majorana object in 4 levels* . . . 2115
92.11 Incidence, Fibonacci and topological sectors . . . 2116
92.11.1 *Residue-incident support* . . . 2116
92.11.2 *Based ring associated with the incidence* F_{av} . . . 2117
92.11.3 *Classification of 6-character by 4 braid torsion classes* . . . 2118
92.11.4 *Modular center pointed and Fibonacci realization conditions Ising* . . . 2120
92.11.5 *Composition, resonances and widths* . . . 2122
92.11.6 *Topological sectors, hypothetical extensions and gravity* . . . 2127
92.11.7 *Exceptional Scaler, Conformal Theory, Strings and Mass Classification* . . . 2133
92.12 Current operatorial results and subsequent metrological contrast . . . 2137
92.12.1 *Mass Operators in HMT-MD: Absolute Scale, Route Atlas, and Sectoral Realization* 2137

92.12.2 Posterior evaluation of the generative graph . . . 2154
92.12.3 Individual evaluation of 20 material sections and traceability of their metrological coordinates . . . 2155
92.13 Correspondence between the atlas 81/56/13/324 and the exhaustive inventories of 471 masses and 384 widths . . . 2163
92.14 Null sector and positivity . . . 2164
92.15 Fiber, orbit, and multisection mass operators of the atlas . . . 2164
92.16 Neutrinos, PMNS Mixing, and Majorana Criterion . . . 2165
92.17 Massive bosons and the scalar sector . . . 2166
92.18 Correspondence by domain and codomain between the material inventory and the realizations of the atlas . . . 2167
92.19 Resonances, widths, and survival . . . 2167
92.20 Multiparticle completion and statistics . . . 2168
92.21 Topological sectors and virtual states . . . 2169
92.22 Gravity, torsion, and spin-2 mode . . . 2170
92.23 Compatibility between the null sector and the null–material electronic closure 2170
92.24 General Mass Law: genealogical atlas, bidirectional readers and dimensional line . . . 2170
92.24.1 Finite domain, routes and multisections . . . 2170
92.24.2 From the APP defect to the integer register . . . 2171
92.24.3 Absolute action scale and relative corrector . . . 2172
92.24.4 Bidirectional readers and exact census . . . 2173
92.24.5 Basal electron and target-free beta closure . . . 2174
92.24.6 Global semigroup and convergence of the towers . . . 2175
92.24.7 The thirteen pairs of fibre operators . . . 2176
92.24.8 Null sector and status of the physical realizations . . . 2177
92.24.9 Completeness of the internal spectrum and the comparative inventory . . . 2178
92.24.10 CKM and PMNS as distinct transports . . . 2179
92.24.11 Joint spectral closure and exact status of CKM–PMNS transports . . . 2180
92.24.12 Non-governance of the historical tables . . . 2181
92.24.13 Typed closure theorem and falsifiers . . . 2181

93 Equivariant realization of species and mass operators: genealogical fibers, spectral measures, complex poles, and material compositions 2183
93.1 Internal domain of the material realization and classification of its codomains 2183
93.1.1 Separation among spectral line, multiplet, distribution, complex pole, categorical object, and criterion of impossibility . . . 2183
93.1.2 Precedence of the genealogical atlas with respect to any metrological identification 2183
93.2 Fiber product between species descriptors and routes of the 81/56/13/324 atlas 2183
93.2.1 Exact non-voidness condition and prospective selection without illicit point selector . . . 2183
93.2.2 Equivariance of fibers, orbits, and multisections under refinement . . . 2184
93.3 Intrinsic spectral classification of material species . . . 2184
93.3.1 Pointwise support decomposition, irreducible block and fiber image measure . 2184
93.3.2 Distinction between scalar mass, multiplet, and spectral distribution . . . 2185
93.4 Natural refinement of the enriched record in the positive towers 90/120 . . . 2185
93.4.1 Positive enumeration of the semigroup $\langle 90, 120\rangle$ and exclusion of mode 0 . . . 2185
93.4.2 Absolute convergence, prefix naturality, and effective tail bound . . . 2185
93.5 Bidirectional operators K_D and K_Ω and joint spectral measure . . . 2186

93.5.1 *PVM joint, compression to POVM and scalar distribution induced by a state* . 2186
93.5.2 *Mixed moments, point spectral support and conservation of multiplicities* . . . 2187
93.6 Symmetry Scalarization and Isotypic Decomposition of the Fibers 2187
93.6.1 *Conditional symmetry expectation and criterion for reduction to a spectral line* 2187
93.6.2 *Geometric mean of the readers only under exchange invariance demonstrated* . 2188
93.7 Null sector and precedence of the zero-mass chart with respect to the positive character 2189
93.7.1 *Separation of the photonic $U(1)$ and adjoint gluonic $SU(3)$ representations* . . 2189
93.7.2 *Unreachability of the null sector as a limit of the positive mass branch* 2189
93.8 Beta closure of the electron and charged lepton sectors 2189
93.8.1 *Uniqueness of the electron in cell $(5,5)$ and preservation of the governing beta mass* 2189
93.8.2 *Realizations of the muon and tau via charged sectors and spectral criterion of scalarity* 2189
93.9 Chromatic algebra $SU(3)$, quark flavours, and running-mass transport . . . 2189
93.9.1 *Weyl qutrit algebra, Reynolds reduction, and singlet projectors* 2189
93.9.2 *Renormalization Connection and Ordered Transport Between Scale Fibers* . . 2190
93.10 CKM Mixing and Covariance of Quark Spectral Frames 2190
93.10.1 *Unitary transport of the operator B_d in the spectral frame of the type above by means of V_{CKM}* 2190
93.10.2 *Separation between the interior closure and the external statistical recognition* 2190
93.11 Neutrino operator, PMNS mixing and Dirac–Majorana criteria 2190
93.11.1 *Three-dimensional neutral spectrum and inheritance of the action-clock-mass scale* 2190
93.11.2 *Range 3 of the Gram matrix, polar frame, and antiunitary Majorana criterion* 2191
93.12 Sterile neutrino sector and separation between existence and mixing 2192
93.12.1 *Orthogonal projector onto the active sector and cancellation of the weak current* 2192
93.12.2 *Distinction between invariant reduction and non-vanishing coupling with the active sector* 2192
93.13 Bosons W and Z and scalar sector: projectors, resolvents, and pole criterion 2192
93.13.1 *Sectorial effective operator and meromorphic continuation of the reduced resolvent* 2192
93.13.2 *Isolated admissible zero, physical residue, and distinction with respect to mere channel opening* 2192
93.14 Composite states and cocyclic linking law 2193
93.14.1 *Single Meson and Baryon Projectors and Refinement of the Composite Signature* 2193
93.14.2 *Feshbach–Schur Reduction and Construction of the Effective Operator* 2193
93.15 Resonances, widths, and survival of material sections 2193
93.15.1 *Complex Poles, Admissible Residues and Associated Widths for the Meromorphic Continuation* 2193
93.15.2 *Compatibility of the genealogical refinement with resonant persistence* 2193
93.16 Multiparticle completion and Fock statistics 2194
93.16.1 *Symmetric and Exterior Fock Functors Induced by Holonomy Parity* 2194
93.16.2 *CCR/CAR Relations, Pauli Exclusion and the Domain of Non-Contractive Morphisms* 2194
93.17 Thermodynamic realization through Gibbs states and the pressure limit . . . 2194
93.17.1 *Finite Hamiltonian, partition function, Gibbs state, and cofinal pressure limit* . 2194
93.17.2 *Condensation criterion by saturation of the excited-state density* 2195
93.18 Topological sectors, virtual excitations, and classification of their codomains 2195

93.18.1 Braided category, data N–F–R, and pentagon and hexagon equations 2195
93.18.2 Finite persistence of virtual states and absence of a universal scalar mass . . 2195
93.19 Gravity, torsion, and spectral criterion of the spin-2 collective mode 2195
93.19.1 Tachyonic Exclusion by Positivity and Separation of Primary Gravity by Connection and Torsion 2195
93.19.2 Physical pole of the traceless transverse Hessian and positivity of the residue . 2196
93.20 Equivalence between persistent section, inverse limit and finite particle representation 2196
93.20.1 Quotient by tail equivalence and compatibility of section families 2196
93.20.2 Unique prolongation condition to reconstruct a section from a finite evaluation 2196
93.21 Equivariant realization closure theorem and exhaustive classification of material species 2197
93.21.1 Comprehensive atlas of 324 routes: 49 invariants per section and conservation of the null sector 2197
93.21.2 Complete inventories of 471 masses and 384 widths and subsequent metrological recognition 2198
93.22 Realization of observables and metrological comparison 2198
93.22.1 Structural domain, material classes and external inventory 2198
93.22.2 The observable before the numerical coordinate 2199
93.22.3 Fixing the construction and correspondence of records 2200
93.22.4 Metrological correspondence of the twenty-three classes 2200
93.22.5 Metrological snapshot, units and transcription accuracy 2201
93.22.6 Individualized evaluations and reading conditions 2202
93.22.7 Relative differences and uncertainty propagation 2203
93.22.8 Absolute scale and control of the harmonic approximation 2204
93.22.9 Complete preservation and reproducibility of the comparison 2205

94 The particle as a persistent material section: trajectory, representation, band, composition, and identity criterion 2206
94.1 Definition of particle as a compatible class of persistent material sections under refinement 2206
94.2 Classification of material species by fiber, representation, charge, spin, flavor, and generation 2206
94.3 Antiparticle, Band, and Virtuality 2206
94.4 Path persistence, multisections, and Möbius conjugation 2206
94.4.1 Route persistence, species multisections, and conjugation of Möbius type . . . 2206
94.5 Structural definitions of particle, mass, charge, spin, statistics, color, flavor and generation 2212
94.5.1 HMT–MD Ontology of Particles 2212
94.5.2 Complete classification of particles and physical states 2217
94.6 Persistent Sections and Finite Propagation 2218
94.6.1 Surviving extension and observable projection 2218
94.6.2 Particle as a compatible section of a discrete bundle 2218
94.6.3 Quantum Ontology of the Particle 2219
94.7 Composition and identity 2221
94.8 Equivalence between the persistent section and its finite representation . . . 2222
94.9 Theorem of the Closure of the Material Realization via Persistent Sections and Finite Representations 2222
94.10 Consistency and Incompatibility Conditions of Spectral, Fermionic, and Composite Realizations 2223

94.11 Posterior metrological recognition and exhaustive inventory of the material realizations . . . 2223
94.12 Graded completion of channels and exclusion principle . . . 2224
94.12.1 Finite channel space and parity character . . . 2224
94.12.2 Graded exchange and permutation projectors . . . 2224
94.12.3 Universal algebra and normalization of occupation states . . . 2225
94.12.4 Fermionic creation and derivation of the CAR relations . . . 2226
94.12.5 Bosonic creation, CCR and finite-particle domain . . . 2227
94.12.6 Identity of complete modes and Pauli exclusion principle . . . 2228
94.12.7 Finite dimensions and transport by refinement . . . 2228
94.12.8 Exchange symmetry and record of a composite . . . 2230
94.12.9 Action of the material operator and scope of physical identification . . . 2231
94.13 Sectoral realizations, material composition and spectral classification . . . 2231
94.13.1 Sectoral descriptors and spectral criterion of individualization . . . 2232
94.13.2 Charged leptons: electronic center and generation multisections . . . 2233
94.13.3 Neutrinos: neutrality, mass spectrum, and flavor transport . . . 2234
94.13.4 Quarks: flavor, color orbit, and scale transport . . . 2235
94.13.5 Zero-mass charts: photon and adjoint color representation . . . 2236
94.13.6 Massive bosons and the scalar sector . . . 2237
94.13.7 Finite grammar of material compositions . . . 2237
94.13.8 Composition of the register and bonding memory . . . 2238
94.13.9 Mesons: dual pair, singlet, and differentiation of excitations . . . 2239
94.13.10 Baryons: color triple, exchange, and the neutron–proton difference . . . 2240
94.13.11 Higher-order compositions and channel equivalence . . . 2241
94.13.12 Resonances: pole mass, width, and survival memory . . . 2241
94.13.13 Three topological codomains and the virtual sector . . . 2242
94.13.14 Classification into twenty-three classes and scope of their realizations . . . 2243
94.14 Persistence, fusion structures, and spectral realisations . . . 2245
94.14.1 The based ring of areal–volumetric incidence . . . 2245
94.14.2 Dimension and representation type . . . 2246
94.14.3 Neutral self-conjugacy and real generators of CAR . . . 2246
94.14.4 Exchange phases and winding of order six . . . 2248
94.14.5 Stability and visibility of a section . . . 2248
94.15 Complete census of regional signatures and orbits . . . 2248
94.15.1 Signatures of the two sheets . . . 2248
94.15.2 Orbits of the ternary image . . . 2249
94.16 Catalogues of multisections, route types and sector classes . . . 2251
94.16.1 The 13 multisections of the atlas . . . 2251
94.16.2 Catalog of the 56 route types . . . 2253
94.16.3 The 23 documented classes . . . 2263
94.17 The 324 oriented routes: complete records . . . 2267
Index of the 324 routes: identifier and page . . . 2267
94.18 Metrological inventory: 471 masses and 384 widths . . . 2813
94.18.1 Masas: 471 registros . . . 2815
94.18.2 Anchuras: 384 registros . . . 2891

V Terminal realizations of the discrete structure of the continuum: ζ, Navier–Stokes, Yang–Mills, Hodge, and Birch–Swinnerton–Dyer **2952**

95 Joint factorization theorem of the 5 terminal realizations through the discrete structure of the continuum **2953**

95.1 Terminal publication through 5 non-permutable readers and common factor of the enriched state . . . 2953

95.1.1 Factorization of the common enriched state into 5 terminal publications . . . 2953

95.1.2 Spectral–polar publication of the continuum via the positive complement of Guinand–Weil . . . 2955

95.2 Dynamics and curvature of the ancestral lineage continuum preceding classical realizations . . . 2957

95.2.1 Joint Factorization of the Terminal Realizations from the Same State of the Continuum . . . 2957

95.2.2 Solenoidal publication of the continuum: coercive bound, compactness and global regularity . . . 2957

95.2.3 Publication-grade continuum: positivity by reflection and curvature sector gap 2961

95.3 Common Factorization, Extensional Consistency, and Limits of Terminal Reconstruction . . . 2967

95.3.1 Cohomological publication of the continuum: compatible lifting and effective construction of the algebraic preimage . . . 2967

95.3.2 Determinantal publication of the continuum: Kato–Poitou–Tate comparison and identity of the leading term of Birch–Swinnerton–Dyer . . . 2970

95.3.3 Specific information losses of the 5 classical publications and conservation in the enriched state . . . 2975

95.3.4 Typed distinction between the five terminal closures and the ZFC–cycle logical corridor . . . 2975

95.3.5 Terminal factorization theorem of RH–NS–YM–Hodge–BSD to traves of the common genealogical continuum . . . 2979

95.4 Unitary typing of the consumed object . . . 2980

95.5 Positivity of the complete Weil form and critical localization of the zeros of ζ 2985

95.6 Stein–Lyapunov terminal storage, uniform bound and global regularity of three-dimensional Navier–Stokes . . . 2996

95.6.1 Complete PC–Fock chart, memory, and terminal storage . . . 2998

95.6.2 Source realization of the enriched Stein–Lyapunov state . . . 3002

95.7 Projective construction of a Euclidean Yang–Mills gauge process, Osterwalder–Schrader reconstruction, and collective gap in dimension 4 . . . 3009

95.8 Completeness of enriched cohomological history and algebraicity of rational Hodge classes . . . 3018

95.8.1 Coinductive unfolding of Hodge completeness . . . 3020

95.9 Coupled determinantal unit, rank–order of vanishing equality and Birch–Swinnerton–Dyer leading-term formula . . . 3027

95.9.1 Comparators of the common determinantal unit . . . 3031

95.10 Internal view G_T^{int} of the continuum and map App_{T,d_T}: preservation of fiber, carry, memory and terminal . . . 3040

95.11 Correlative emergence of the 5 terminal actions over the same state of the continuum . . . 3041

95.11.1 Spectral–polar action of the common constructor and conservation of the critical fiber . . . 3041

95.11.2 Solenoidal balance of the common constructor and flow conservation . . . 3042

95.11.3 Projective gauge incidence of the common constructor and descent to the quotient 3042
95.11.4 Cohomological Consistency of the Common Constructor and Emergence of the Global Class . . . 3043
95.11.5 Determinantal line of the common constructor and terminal arithmetic evaluation 3044
95.12 Non-permutability Theorem of the 5 terminal readers and classification of their codomains . . . 3045
95.13 Factorization of terminal readers via naturality, refinement, and passage to the limit . . . 3045
95.14 Common factorization of the boundary operator in the solenoidal and gauge realizations . . . 3046
95.14.1 Boundary enriched state and parity decomposition of transport . . . 3046
95.14.2 Minimal Boundary Complex and Spectral Equivalence of the 0 and 1 Degree Laplacians . . . 3046
95.14.3 Solenoidal realization of the boundary operator: flow contraction and energy conservation . . . 3047
95.14.4 Boundary operator calibration: coercivity, gauge quotient, and spectral gap . 3048
95.14.5 Discrete Stokes identity and 2 realizations: circulation–vorticity and holonomy–curvature . . . 3048

96 Positive factorization of the Guinand–Weil form and localization of the nontrivial zeros of ζ 3049
96.1 Starting point: the complete spectral–polar structure . . . 3049
96.2 Cofinal domain and target form . . . 3050
96.3 The two columns and the three channels computed before the sign . . . 3051
96.4 Source–first colligation of the spectral–polar image . . . 3052
96.5 Structural complement, mirror sheet and terminal telescopia . . . 3053
96.6 Common encoder, projection, and explicit double publication . . . 3055
96.7 Cofinal Naturality and Reversible Weil Criterion . . . 3056
96.8 Subsequent, non-governing local Redheffer control . . . 3058
96.9 Falsifiers of an ablated shadow . . . 3059
96.10 Cofinal Closure of the Riemann–Weil Criterion . . . 3060

97 Cayley–Pontryagin characterization of the critical zeros and coinductive construction of the Weil spectral field 3061
97.1 Cancellation of the completed function and spectral closure on the critical line 3061
97.1.1 Scalar annihilation and persistence of the enriched state . . . 3061
97.1.2 Fixing of the critical line by the functional involution $s \mapsto 1 - \bar{s}$ . . . 3062
97.1.3 Quadraticity of the cross product under closure of the functional involution . . 3063
97.1.4 Spectral characterization of the zeros . . . 3064
97.1.5 Identification of the height of a nontrivial 0 with a real spectral frequency . . 3064
97.1.6 Conformal circular parametrization of the critical line . . . 3065
97.1.7 Nonadic Circle and Phase Holonomy . . . 3066
97.1.8 The nonadic mirror and the Riemann mirror . . . 3066
97.1.9 Residual closure and nonadic phase . . . 3067
97.1.10 Typed separation of the zeros of ζ, ξ and the spectral determinant . . . 3068
97.1.11 Exhaustion of the terminal object under cofinal filtration . . . 3068
97.1.12 Genealogical Information of the Continuum Encoded by Critical Zeros . . . 3069
97.1.13 Correspondence between spectral quantization, real frequencies and physical realization of the operator . . . 3069

97.1.14 Localization, Multiplicity, and Symmetry Corollaries of the Spectral Characterization . . . 3069
97.1.15 Hypothesis and exact codomain of the spectral localization theorem . . . 3070
97.1.16 Spectral closure theorem via positive factorization of Guinand–Weil . . . 3070
97.2 Weil form, translation, and quantization of spectral heights . . . 3071
97.2.1 Construction of the Hilbert space via the Weil form . . . 3071
97.2.2 Translation Operator Independent of the Previous Localization of Zeros . . . 3071
97.2.3 Spectral Identification of the Heights of the Non-Trivial Zeros . . . 3072
97.2.4 Conformal transformation of the critical line into the spectral circle with height conservation . . . 3073
97.2.5 Monodromia of each 0 over the circulo spectral . . . 3074
97.2.6 Spectral field localization via the nonadic entwined prolongation . . . 3075
97.2.7 Spectral algorithm for zero-free computation . . . 3076
97.2.8 Spectral quantization and nonadic intertwining . . . 3077
97.3 Cayley–Pontryagin Double Circle Theorem . . . 3077
97.3.1 Theorem of the Double Circle . . . 3077
97.3.2 Twisted transport isometry $\widetilde{U}_k$ on cylindrical states, projective weights, and Weil memory . . . 3078
97.3.3 Orbital identity under the conjugation between the 2 spectral realizations . . . 3080
97.3.4 Circular compactification and spiral lifting of the spectral orbit . . . 3080
97.3.5 Compatibility between genealogical cylinders, generation of constants, and spectral entangler . . . 3081
97.3.6 Graded invariant of the spectral runner 4→2→6→54 . . . 3082
97.3.7 Leech, $V^\natural$ and the Monster . . . 3083
97.3.8 Finite Approximation of the Spectral Field via Matrix Truncations . . . 3084
97.3.9 Independence of the spectral intertwiner with respect to zeros, contractions, route multiplicities, and transverse symmetries . . . 3085
97.3.10 Domain of the Cayley–Pontryagin conjugation and theorem of the double circle 3085
97.4 Effective reconstruction of the Weil spectral field . . . 3086
97.4.1 Construction of the spectral field independent of previous data on the zeros . . . 3086
97.4.2 Refinement of the independent spectral field of the target values . . . 3087
97.4.3 Finite matrix approximants of the spectral operator . . . 3087
97.4.4 Cayley Transform and Initial Circular Compactification of the Spectrum . . . 3088
97.4.5 Exact immersion of the spectrum into the nonadic circle . . . 3089
97.4.6 Recovery of Heights and Residues with Posterior External Contrast . . . 3090
97.4.7 Convergence and preservation of the spectral genealogical record . . . 3090
97.4.8 Convergence of the reconstructed spectral field and certifiable extension . . . 3091
97.5 Exact entanglement of nonadic holonomy and spectral phase . . . 3092
97.6 Convergence in norm of finite spectral matrices . . . 3093
97.6.1 A posteriori certification of intervals and multiplicities . . . 3093
97.7 Independent construction of the spectral field over the double circle . . . 3094
97.8 Weil form, double circle, and spectral representation . . . 3095
97.8.1 From cyclic refinement to the completed form . . . 3095
97.8.2 The arithmetic, gamma, and polar contributions . . . 3096
97.8.3 Transport columns and the positive boundary identity . . . 3097
97.8.4 Representation of translations . . . 3101
97.8.5 Analytic identification and multiplicities . . . 3102
97.8.6 The two circles and spectral orientation . . . 3103
97.8.7 Cylindrical refinement with memory . . . 3104

97.8.8 Nonadic calendar and contraction over one turn . . . 3106
97.8.9 Moment matrices and spectral approximation . . . 3107
97.8.10 Compact resolvent and exhaustiveness checks . . . 3108
97.8.11 From internal identities to the analytic assembly . . . 3108
97.8.12 Bidirectional recovery and assembly of the readouts . . . 3109
97.8.13 Irreducible-clock windows and refinement with cross terms . . . 3112
97.8.14 Coercive assembly and stability of nonadic details . . . 3115
97.8.15 Coercivity of details in an arbitrary fixed window . . . 3118
97.9 Schur reduction and coercivity of the Weil form . . . 3121
97.9.1 Basis, domain, and result obtained . . . 3121
97.9.2 Partition, cell means, and details . . . 3121
97.9.3 The exact Schur complement has finite size . . . 3123
97.9.4 Explicit images and certifiable bounds for the corrections . . . 3123
97.9.5 Coercivity on a window of length 1/9 . . . 3125
97.9.6 Refinement, double circle, and the two moments . . . 3127
97.9.7 Reproducibility checks and conditions for extension . . . 3127
97.10 Nonadic compression and circular moments of the Weil form . . . 3128
97.10.1 Enriched state and modes of the central chart . . . 3128
97.10.2 Uniform compression of the nonadic chart and exact balance . . . 3128
97.10.3 Visible contraction and preservation of the winding register . . . 3129
97.10.4 Dual memory circle and arithmetic Cayley chart . . . 3130
97.10.5 Criterio de transporte de positividad mediante momentos mixtos . . . 3130
97.10.6 Energy identification and two-column realization . . . 3131
97.10.7 Operator provenance and the function of the readouts . . . 3132
97.10.8 Regular memory representation preceding arithmetic GNS . . . 3132
97.10.9 Phase, nonadic refinement, and weak convergence of states . . . 3134
97.10.10 Cayley operator on the exponential test-function domain . . . 3135
97.10.11 Joint preservation of the gamma, prime, and polar channels . . . 3135
97.10.12 Circular moments of the complete arithmetic form . . . 3136
97.10.13 Prospective identification of moments and energy . . . 3138
97.10.14 Exact checks and scope of the composition . . . 3138
97.11 Boundary expectations and reconstruction of the analytic channels . . . 3140
97.11.1 Action of the readers and content of the moments . . . 3140
97.11.2 Conventions and genealogical snapshot . . . 3140
97.11.3 Action of the odometer on generators . . . 3141
97.11.4 Two distinct refinements and their expectations . . . 3142
97.11.5 Metric identities of the boundary and polar charts . . . 3143
97.11.6 Difference between channel-by-channel reading and common transfer . . . 3144
97.11.7 Inverse of the gamma tail and reconstruction of all rows . . . 3145
97.11.8 Exact condition for bringing both moments together in an expectation . . . 3146
97.11.9 Checks and provenance . . . 3146
98 Global regularity of Navier–Stokes via solenoidal control, boundary transport, and coercive estimation 3147
98.1 Solenoidal domain and conservation of zero divergence . . . 3147
98.2 Source object and coordinates that are indeed constructed . . . 3147
98.3 Complete PC–Fock tower and terminal storage . . . 3148
98.4 Source–first construction with a mixed state–force lift . . . 3149

98.4.1 Chronological signature, uniform smoothing, and mixed creation 3149
98.4.2 Initial data, boundary compatibility and regular propagation 3152
98.4.3 The six rows as components of the unique loss operator 3153
98.4.4 Terminal, column, and Stein constructions derived without redefining norms . 3154
98.4.5 Source Factorization–History and Uniform Bound 3155
98.5 Finite KYP chart: correct computation and auxiliary status 3156
98.6 Uniform closure, compactness, and global solution 3156
98.6.1 Sobolev Estimation and Exclusion of Singular Concentration 3156
98.6.2 Temporal control and the Aubin–Lions step 3157
98.6.3 Pressure, uniqueness, and adherence of horizons 3157

99 Quantum Existence and Yang–Mills Mass Gap via Gauge Coercivity and Spectral Positivity 3159
99.1 Source object and mandatory separation of generators 3159
99.2 Finite Hoeffding theorem, vacuum, and attained gap 3159
99.3 Physical gauge compression 3160
99.4 Reflection positivity at every level 3160
99.5 Final owner: the complete gauge state, not its ablated marginal 3161
99.5.1 Projective measure and link publication 3161
99.5.2 The incidence fiber is a physical coordinate of the complete state 3161
99.6 Owner generator and local circuit 3162
99.7 Yang–Mills action, g-dependent measure, and exact transport 3164
99.8 Uniqueness of the gauge-invariant vacuum and gap saturation $3\kappa_{\mathrm{av}}$ by the eigenvector W_c 3167
99.9 Nonadic refinement and persistence in the limit 3168
99.10 Four OS reconstructions of the same dynamics 3168
99.11 Locality, Euclidean action, and curvature publication 3169
99.11.1 Interpretation of the incidence channel as the local curvature of the gauge system 3169
99.11.2 Cofinal Publication System and Cross-Products 3170
99.11.3 Dense core, strong continuity, and local net 3171
99.11.4 Continuous OS package and reconstruction 3173
99.11.5 Typed publication as Yang–Mills theory 3175
99.12 Spectral gap of the gauge sector and projective limit 3178

100 Algebraic realization of Hodge classes via compatible cohomological projectors and rational descent 3179
100.1 Source object, finite observations and publication 3179
100.2 Relative module and triangular incidence table 3179
100.2.1 Cohomological Generators and Compatible Projectors 3180
100.3 Naturalness and the universal extension operator 3181
100.4 Lefschetz–Murre and algebraic descent of Hodge classes 3182
100.5 Non-governing relative control and falsifiers 3183

101 Rank, regulator, and leading term of Birch–Swinnerton–Dyer through determinantal memory of the arithmetic family 3184
101.1 Genealogical unit and fiber product 3184
101.2 Local filler and global decomposition without erasing the finite lattice . . . 3185
101.3 Integral owner and base change to all primes 3186
101.4 Bockstein homomorphisms of the spectral sequence: compatibility between pages and determination of the order in T of the universal complex 3187
101.5 Kato–Fermat Determinant, Rank, and Leading Term of BSD 3188

101.6 Poitou–Tate Map from Mordell–Weil to the Full Flag . . . 3189
101.7 Localization, Smith Range and Sha–Tamagawa Accuracy . . . 3190
101.8 Based analytic–arithmetic comparator . . . 3192
101.9 Non-governing controls, falsifiers and status . . . 3203

102 Domains, Operators, Naturality and Certificates of the Terminal Realizations of the Continuum 3204
102.1 Internal view G_T and terminal reader P_T: logical independence between structural existence and classical realization . . . 3204
102.2 Common Obstructions of Terminal Readers: Loss of Domain, Naturalness, or Compatible Limit . . . 3204
102.3 Conditions of existence, uniqueness, and compatibility of terminal publications 3205
102.4 Negative and calibrated closures of apparent equivalences . . . 3205
102.4.1 Obstructions of canonicity at the boundary 108:144 = 90:120 . . . 3205
102.4.2 The nonadic return and the exceptional reader . . . 3206
102.4.3 Exceptional corridor and transport links . . . 3207
102.4.4 Infinitely divisible channel induced by the TPK transfer . . . 3207
102.5 Spectral Closures and External Recognition Boundaries . . . 3207
102.6 Provenance of the results and reproduction of the extension . . . 3208
102.6.1 Dependencies brought together in the main text . . . 3208
102.6.2 Reproduction order and scope of the checks . . . 3209

VI Arithmetic-geometric coupling, conservation and recovery of information 3210

103 Refinement of histories and conservation of unity 3211
103.1 Generation of emissions and realization domain . . . 3211
103.2 Refinement on the complete multisection . . . 3211
103.2.1 The same isometry in the history basis . . . 3212
103.3 Correlative prolongation of the five operations . . . 3213
103.4 Memory fibres: Gram criterion and conservation of unity . . . 3213
103.5 Symmetries and readers on the common domain . . . 3214
103.6 Passage-to-the-limit theorem for the observable/memory charge . . . 3215
103.6.1 Explicit compatible nonadic realization . . . 3216

104 Conservation of observables and the complete record 3217
104.1 Balance of a conserved observable . . . 3217
104.2 Specialization to the nonadic connection . . . 3217
104.3 Terminal sector and the unlimited-depth record . . . 3218
104.4 Preservation of symmetry and chart transport . . . 3219
104.4.1 Complete transport of the twelve coordinates of K . . . 3219
104.4.2 Specialization to the exceptional operator of order three . . . 3220
104.5 History refinement and compatibility of balances . . . 3220
104.6 Variational specialization: action and orientation . . . 3221
104.6.1 Updating the form and the connection term . . . 3221

105 Recovery of the state and its dynamics 3223
105.1 Recoverable representation of transport . . . 3223
105.2 Explicit reconstruction and record depth . . . 3224
105.2.1 Difference between finite and unlimited depth . . . 3224
105.2.2 Vector information and intensity . . . 3225
105.3 Naturality of recovery under refinement . . . 3225

105.4 Two exact regimes of memory distribution . . . 3225
105.4.1 Exceptional transport of order three . . . 3225
105.4.2 Bilateral record of revolutions . . . 3226
105.5 Composition with Euler's identity and incidence . . . 3227

106 Exceptional incidence and transport of forms 3228
106.1 Generation of the record and conservation of incidence . . . 3228
106.1.1 Dodecaphasic record of the enriched history . . . 3228
106.1.2 Integral normalization and isometric normalizations . . . 3228
106.1.3 Prefix refinement and event partitions . . . 3228
106.2 K–Witt transport of norms, operators, and balances . . . 3229
106.3 Order-three action on the lattice fibres . . . 3230
106.4 Refinement of energy and its differential . . . 3230
106.4.1 Assembly with incidence . . . 3231

107 Incidence reconstruction and covariance 3232
107.1 The complete isometry and its domain . . . 3232
107.2 Covariant lifting theorem on the image . . . 3232
107.2.1 Covariance under a noncommuting chart change . . . 3233
107.3 Explicit recovery from the incidence record of complements . . . 3233
107.4 Natural lifting of refinement with local frames . . . 3234
107.4.1 Compatible observables and dynamics . . . 3235
107.4.2 Bilateral-memory specialization with varying frames . . . 3235
107.5 Direct extension to the twelve A_2 fibres . . . 3235
107.6 Exact scope with respect to histories . . . 3236

108 Affine holonomy and memory symmetries 3237
108.1 Effective composition of memory . . . 3237
108.2 Application to the effective record of the observable revolution . . . 3238
108.3 Parabolic generator determined by memory . . . 3239
108.4 APP curvature and conservation of the central phase . . . 3241
108.5 Composition between the three regimes and continuity of the balance . . . 3242
108.6 Compatibility with refinement and arbitrary extent . . . 3242
108.7 Foundational consequence and scope of the composition . . . 3243

109 Variational conservation and oriented action 3244
109.1 Symmetry of the elliptic action and Noether charge . . . 3244
109.2 Change of form: determined transport and connection . . . 3245
109.3 Orientation and boundary of the action . . . 3246
109.4 Variational clock charge and balance between reading and memory . . . 3246
109.4.1 An explicit action charge of the clock . . . 3246
109.4.2 Exact charge balance . . . 3247
109.5 Covariant balance of the total tensor . . . 3247

110 Conservation of action forms and oriented area in the tritic regimes 3249
110.1 Balance between two action forms . . . 3249
110.2 Exact accumulation law with variable phase . . . 3250
110.3 Extended Euler and common oriented area . . . 3250
110.3.1 Integrated action and orientation . . . 3251
110.4 The common factor of the exponential reader . . . 3251
110.5 Action refinement over the complete emissions . . . 3252

111 Explicit reconstruction from complete returns 3253

111.1 State domain and bilateral extension 3253
111.2 Tritic sampling and complete reconstruction of evolution 3253
111.3 Conjugation of transport and preservation of readouts 3254

112 Observable return and persistence of the register 3255
112.1 Joint recovery from complete returns 3255
112.2 Explicit subsequent representation of transport 3255
112.3 Numerical convergence and correlations with incidence 3256
112.4 Covariance of the memory operator under return 3257
112.5 Incidence, refinement, and three regimes 3257

113 Reversible coupling and nonstationary transport 3259
113.1 Reversible extension of the balance between two forms 3259
113.1.1 Collective realization in the nine copies 3259
113.2 Exact composition and memory re-entry 3260
113.2.1 Covariant increment equation 3260
113.3 Memory of a nonstationary sequence 3260
113.4 Three different properties: exhaustion, distinction and stability 3261
113.4.1 Exact example separating the three properties 3261
113.5 Quantitative criterion for complete transfer 3262
113.6 Complete incidence realization and changes of regime 3262

114 Dimensional reconstruction and exterior conservation 3263
114.1 Two memories recover the centred register 3263
114.1.1 Register-reading operators 3263
114.1.2 Inversa exacta 3263
114.1.3 Optimal stability bound 3264
114.1.4 Example with the generated dodecaphasic register 3264
114.2 Reconstruction of the dimensional projector from two memories 3265
114.2.1 Composition with the incidence already constructed 3265
114.2.2 Projector error 3265
114.2.3 A scalar descriptor of K, with explicit invariances 3266
114.3 Application to an effective vector of the exceptional construction 3266
114.4 Conservation law in every exterior degree 3267
114.4.1 Statement and proof 3267
114.4.2 Exact distribution among the exterior sectors 3267
114.4.3 Naturality and arbitrary depth 3268
114.4.4 Precision of area and volume reconstruction 3268
114.5 Transport memory and relative holonomy 3268
114.5.1 An elliptic–parabolic loop produces hyperbolic self-scaling 3269
114.6 Symmetry, action, and conserved charge 3270

115 Canonical realization of covariance 3272
115.1 Canonical covariance and reciprocity of the action ellipse 3272

116 Sheet return, areal–volumetric incidence and constitutive orientation 3275
116.1 Projected return and restoration of the oriented cover 3275
116.2 Descent of incidence from the tritic calendar 3275
116.3 Boundary marking and areal–volumetric ratio 3276
116.4 Transport of orientation to the constitutive channels 3276

117 Discrete polarization and the tritic mode of arithmetic projections 3277

117.1 Refinement discrepancy and endpoint convention . . . 3277
117.2 Bounded polarization and exact temporal balance . . . 3278
117.3 Realization on the charge and time lines . . . 3278
117.4 Pairing the additive and multiplicative fibres . . . 3279
117.5 Commutator norm and electronic prefactor . . . 3280
117.6 Quadratic defect and response of the 90/120 sectors . . . 3281

118 Constitutive operator and reconstruction of the vacuum channels 3282
118.1 Positive response on two sheets . . . 3282
118.2 Four coordinates of a common response . . . 3283
118.3 Cubic inversion and angular recovery . . . 3284
118.4 Logarithmic coordinates and refinement . . . 3284
118.5 Dimensional types of the four evaluations . . . 3284
118.6 Reconstruction of the action shape from the constitutive response . . . 3285
118.7 Constitutive speed and kinematic realization of the clock . . . 3286
118.7.1 Path length and elementary duration . . . 3287
118.7.2 Change of chart and adapted normalization . . . 3287
118.7.3 Preservation of the readout under amplification . . . 3288

119 Charge section and electrical quantization relations 3289
119.1 Positive determination of the charge section . . . 3289
119.2 Resistance, conductance, flux, and frequency . . . 3289
119.3 Action return and transport of the sections . . . 3290

120 Hexadic–octadic incidence and the Barbero–Immirzi functional 3291
120.1 Dodecaphase fundamental chain and pole coefficient . . . 3291
120.2 Parity and structural sensitivity . . . 3292

121 Action, gravity, and thermal information 3293
121.1 Dodecaphasic period and circular realization of action . . . 3293

122 Area operator and reconstruction of sectorial information 3294
122.1 Tritic regrouping and boundary incidence . . . 3294
122.2 Transport of the collective incidence modes . . . 3295
122.3 Angular character and area operator . . . 3295
122.4 State normalization and the meaning of the modular Hamiltonian . . . 3296
122.5 Reduced state, Schmidt decomposition, and entanglement entropy . . . 3297

123 Genealogical memory, informational reduction and thermal transduction 3298
123.1 Reader, memory, and state recovery . . . 3298
123.2 Reversible update, tritic decision and erasure . . . 3299
123.3 Action, frequency, and decision energy . . . 3299
123.4 Dimensional definition of Boltzmann and selection of coordinates . . . 3300
123.5 Dimensional entropy and information of the reduced state . . . 3301
123.6 Spectral normalization of thermal histories . . . 3301

124 Oriented incidence and gravitational tensor representation 3303
124.1 Signed covering and calendar transport . . . 3303
124.2 Quadratic reading and five-component space . . . 3304
124.3 Transverse projection and helicities . . . 3305

125 Phase return and representation of accumulated memory 3306
125.1 Inversion cocycle and change of sheet . . . 3306
125.2 Affine representation of the cocycle . . . 3306

126 Boundary soldering and energy response 3308
126.1 Cubic incidence and the rank-four quotient . . . 3308
126.2 Cellular soldering and memory transport . . . 3309
126.3 Positive response, uniqueness, and minimal extension . . . 3309
126.4 Preservation of density by refinement . . . 3310
126.5 Variational realization of the response . . . 3311

127 Geometric realization of transport and soldering 3312
127.1 Screen, co-tetrad and connection . . . 3312
127.2 The three quadratic realizations of curvature . . . 3313

128 Variational response of memory energy 3314
128.1 Discrete functional and space of variations . . . 3314
128.2 Composition and transport of the response . . . 3315
128.3 Oriented inversion and transport of the weight . . . 3316
128.4 Compatibility with refinement . . . 3316
128.5 Material realization of the response . . . 3317

129 Realization of the current in connection coordinates 3318
129.1 Differential on invertible transports . . . 3318
129.2 Quadratic representations of TRIT . . . 3318
129.3 Composition of routes and oriented inversion . . . 3319
129.4 Evaluation of current components . . . 3320
129.5 Insertion into the Cartan equation . . . 3320

130 Differential of the minimal boundary extension 3322
130.1 Minimizing field and response weight . . . 3322
130.2 Full differential of the minimum . . . 3323
130.3 Fixed quotient and frame changes . . . 3323
130.4 Transported incidence and connection components . . . 3324

131 Spin current and algebraic Cartan–Holst response 3326
131.1 Geometric domain and current normalization . . . 3326
131.2 Connection variation and Holst inversion . . . 3326
131.3 Pointwise reconstruction of torsion and contorsion . . . 3327
131.4 Elimination of contorsion and quadratic contribution . . . 3328
131.5 Effective metric source and covariant balance . . . 3329

132 Torsional elimination and metric response of the minimal extension 3331
132.1 Variational composition at a cellular level . . . 3331
132.2 Local existence of a stationary branch . . . 3332
132.3 Effective action and non-affine contribution . . . 3333
132.4 Metric differential of the eliminated action . . . 3333
132.5 Exact non-affine checking model . . . 3334

133 Spinorial current and torsional amplitude of the material state 3336
133.1 Spinorial representation and affine material action . . . 3336
133.2 Effective contraction and second-moment coefficient . . . 3337
133.3 Finite fermionic realization and second moment of the state . . . 3338
133.4 Density, pressure and preservation of the comoving amplitude . . . 3339

134 Memory dilution and persistence of the bounce 3341
134.1 The a^{-6} dilution law . . . 3341
134.2 Homogeneous threshold and transversality . . . 3341

134.3 Local persistence under controlled perturbations . . . 3342

135 Explicit homogeneous solution and causal completeness 3344
135.1 Finite curvature and extension of geodesics . . . 3344

136 Residual tensor, trace decomposition, and covariant balance 3346
136.1 Chart data and construction of the residual tensor . . . 3346
136.2 Canonical decomposition and exchange current . . . 3347
136.3 Link to the effective Cartan–Holst source . . . 3347
136.4 Trace sector and acceleration of the selected charts . . . 3348

137 Pure bipartite states, reduced entropy and horizon area laws 3350
137.1 Sheet record and bipartite quantum purification . . . 3350
137.2 Quantum purification of the incidence sectors . . . 3351
137.3 Informational equation and areal fluctuations . . . 3351
137.4 Modular law and finite area variations . . . 3352
137.5 Action, decision energy, and areal unit . . . 3353
137.6 Cosmological normalization of the horizon . . . 3354
137.7 Kruskal chart and exchange of the exteriors . . . 3355
137.8 Transport of states, observables, and refinements . . . 3356

138 Observer, memory, and relational response 3358
138.1 Boundary transport and intrinsic reading . . . 3358
138.2 Boundary identity and cellular interior . . . 3359
138.3 Isometric inscription of the record in the apparatus . . . 3360
138.4 Outcome map and record conditioning . . . 3360
138.5 Accessible algebra and pointer complement . . . 3361
138.6 Factorization of the response through the effective boundary . . . 3362
138.7 Ambivalence weights and self-inertial response . . . 3363
138.8 Connection of the joint state and acceleration reading . . . 3365

139 Bidirectional propagation and absorption condition at the boundary 3367
139.1 Route action and record involutions . . . 3367
139.2 Reversal of the realized evolution . . . 3368
139.3 Propagators of the chronological channel of a route . . . 3368
139.4 Causal interchange and decomposition of the response . . . 3370
139.5 Projection of absorbed currents and variation of the action . . . 3371
139.6 Explicit absorbing condition in a chronological window . . . 3371
139.7 Refinement and continuity of the boundary condition . . . 3372

140 Action realization and metrological comparison 3374
140.1 Comparison of the reduced Planck constant . . . 3374

141 Covariance, normal form, and Gaussian spectrum 3375
141.1 Canonical coordinates and characteristic function . . . 3375
141.2 Symplectic reduction of the positive form . . . 3376
141.3 Calculation of the spectrum of the isotropic density . . . 3376
141.4 Preparation and transport of the two covariances . . . 3378

142 Physical actions and the spectrum of reduced memory 3379
142.1 Genealogy of the dimensional sections . . . 3379
142.2 Normalization of the Maxwell–Dirac action . . . 3380
142.3 Areal scale of gravitational action and entropy . . . 3381
142.3.1 An explicit dynamical application . . . 3382

142.4 Prolongation of memory transport: quantum realization 3382
142.4.1 Initial state, transport and reading 3383
142.4.2 Exact evaluation of the golden loop 3384
142.4.3 Composition with the thermal transducer 3384
142.5 Extension to arbitrary finite canonical dimension 3385
142.5.1 Operator identity between memory and complex structure 3386

143 Conclusions on conservation, recovery and physical realization 3388
143.1 Conservation, reconstruction, and dimension 3388
143.2 Action and physical consequences 3388
143.3 Memory and quantum spectrum 3388
143.4 Contenido fundacional 3389

144 The holographic arithmetic-geometric coupling constant 3390
144.1 Definition of the register and realization of its coupling coordinate 3390
144.2 Periodic encoding, closure, and exact inversion 3391
144.3 Representation of the register through its complete orbit 3392
144.4 Operator identification and relative holonomy 3394
144.5 Preservation of references and observables through the complete register . . 3395
144.6 Exceptional incidence and selected direction 3396
144.7 Continuous stability and the need to preserve correlations 3397
144.8 Discrete correction before incidence selection 3398
144.9 Covariance, refinement, and variational charge 3399
144.10 Encoding, operator identification, and incidence stability 3400

145 Ternary algebraic norm and optimal recovery radii 3401
145.1 Parametric double-memory operators and Gram matrix 3401
145.2 Minimum distance in the domain of integer registers 3403
145.3 Finite decoder and parameter duality 3404
145.4 The norm on the ternary augmentation module 3405
145.5 Invariant contribution of the complete cycle 3406
145.6 Six received states and conservation of the complete reading 3407
145.7 Inversion, charts and bilateral balance 3408
145.8 Fine-structure coordinate and integer iterations 3410
145.9 Angular reciprocity and the existing regional correction 3412
145.10 Angular inverse problem in the dodecaphasic register 3413
145.11 Composition of readers and scope of inverse problems 3415

146 Conservative refinement of unity and carry memory 3416
146.1 Relation between quadratic norm and cubic completion 3416
146.2 Concatenations of the central block and restoration of unity 3417
146.3 Affine transport and the positivity domain 3417
146.4 Canonical recovery through the residue 3418
146.5 Variable iteration and complete finite memory 3418
146.6 Block composition and compatibility with the partition 3419
146.7 Convergence and quantitative control of the reading 3419
146.8 Compatible cylinders and boundary multiplicity 3420
146.9 Signed carries and prospective specification 3421
146.10 Operator realization and transport amplitudes 3421

147 Bilateral conservation and arithmetic-geometric transduction 3422
147.1 Bilateral law for two isometric transports 3422

147.2 Factorization, recovery and compatibility of the channels . . . 3423
147.3 Transformation of readers and relative symmetry . . . 3423
147.4 Reversible update with incoming memory . . . 3424
147.5 Causal reduction of the bilateral update . . . 3425
147.6 Nonstationary register and uniform convergence of the terminal component to zero . . . 3426
147.7 Geometric forms and conservation of their transport . . . 3427
147.8 Channel correlation and inverse reading problem . . . 3428
147.9 Cyclic frame and transport of responses . . . 3428
147.10 Positional reading and scalar precision . . . 3429
147.11 Incidence, charge and exact restitution of the register . . . 3429
147.12 Preservation of the conditioning of two memories . . . 3430
147.13 Orbital norm and polar normalization of the frame . . . 3431
147.14 Exact example of transduction and error correction . . . 3431

148 Unitary lift of refinement and transport of readers 3433
148.1 Bijection of admissible arithmetic states . . . 3433
148.2 Unitarity on label amplitudes . . . 3433

Causal architecture of the continuum problem and mathematical-physical scope of HMT–MD

Inaugural thesis: the discrete structure of the continuum and the common origin of its publications

Triadic Modular Holography does not take the real line as a prior setting or receive from it the values it will later use. Its input is finite: the nine positions $1, \dots, 9$, arranged horizontally and vertically so that the same chart supports two irreducible operations. APP simultaneously preserves the additive sheet, which accumulates, and the multiplicative sheet, which folds; the residue, quotient and carry prevent equality between two published values from erasing the difference between the histories that produced them. TRIT orients each transition and distinguishes its regimes. TPK turns that local orientation into dynamics: it selects the tritic mode without sacrificing any APP sheet, transports, memorizes, returns and updates the state. Its readings modulo 3, modulo 9 and modulo 1000, the nonadic connection, the dodecaphase, the boundary and the return with memory are not independent additions, but coordinated charts of the same genealogical operation.

Preservation is written from the first level:

$$i + j = R^{+}_{ij} + 9q^{+}_{ij}, \qquad ij = R^{\times}_{ij} + 9q^{\times}_{ij}.$$

The residue publishes the class; the quotient unfolds its provenance. The TPK transition preserves that distinction through

$$\mathcal{U}_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t,$$

where selection incorporates the TRIT mode, transport realizes the oriented direction and updating brings together memory and return. In the canonical chart, the mode $m_{\mathrm{ph}} = (1, -1, 0)^3$ is common to the APP sheets and has singular value $s = 1/2$; therefore

$$1 - s^2 = \frac{3}{4} = \frac{90}{120}, \qquad \left\| [P_{\Sigma,3}, P_{\Pi,3}] \right\| = \frac{\sqrt{3}}{4}.$$

The normalized commutator satisfies $J^2_{\mathrm{comm}} = -I$. Sum–product incompatibility, tritic orientation, defect $90 \to 120$, complex structure and electronic prefactor thus belong to the same internal genealogy; they are not linked by decimal resemblance.

The compatible prolongation of these finite states produces increasingly narrow cylinders and simultaneously preserves the history of their refinement. The real line then appears as an Archimedean publication of the limit, not as initial data. That chart first publishes the values of the nine symbols of the seed and then prolongs the same genealogy toward π, e, φ and α, without using any of them as a retrospective selector. This is the thesis governing the entire work: the joint discrete structure constructs the continuum and explains why its stable values are what they are. The chain

$$\{1, \dots, 9\}_{\mathrm{h}} \times \{1, \dots, 9\}_{\mathrm{v}} \longrightarrow \mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{X}_{\mathrm{enr}} \longrightarrow \mathcal{S}_{\infty} \longrightarrow \mathbb{R}$$

does not summarize heterogeneous chapters: it expresses a single mechanism seen at successive resolutions. In it the phase may return while the state advances, because the quotient, carry, orientation and memory have changed. The cycle observed only through its phase is circular; with its genealogy preserved, it is helical.

This difference is fixed through an injective lift. If $n = 9q_9(n) + \rho_9(n)$, with $1 \le \rho_9(n) \le 9$, the circular projection $\mathcal{R}_9$ and the helical immersion $\mathcal{H}_9$ satisfy

$$\mathcal{R}_9(n+9) = \mathcal{R}_9(n), \qquad \mathcal{H}_9(n+9) = \mathcal{H}_9(n) + (0,0,1).$$

The phase has closed and the genealogical height has grown: phase return and state return are mathematically separated. The two-way involution organizes conjugate ascending and descending sheets of the same lift, not two independent generators. In this geometry, the helix preserves the longitudinal advance of memory, the spiral records the transverse contraction and the cylinder radius measures the width of the interval still compatible with the prefix. The nesting of these half-open cylinders, with radius tending to zero and genealogy preserved, is the mechanism that subsequently publishes the real section.

The certified initial segment of the uniform prolongation constructing the coinductive state $\mathcal{S}_\infty$ is

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9,$$

but writing the chain acquires content only by declaring its levels, thresholds and invariants. For $\chi \in \{\pi, e, \varphi\}$, let $b_0^\chi = w_6^\chi$ and

$$b_{k+1}^\chi = b_k^\chi L_{\epsilon_k} \pmod 3, \qquad (\epsilon_0,\epsilon_1,\epsilon_2,\epsilon_3) = (0,0,1,1), \qquad w_{6(k+1)}^\chi = b_0^\chi \| \cdots \| b_k^\chi.$$

The twelve transitions produced by $\mathcal{U}_t$ form the matrix pairs X_i, Y_i of the two regimes and uniquely determine $L_i = X_i^{-1} Y_i$, $i = 0, 1$. The calendar (L_0, L_0, L_1, L_1) is the only one of the sixteen binary calendars that simultaneously satisfies the three biographies; the one hundred and forty-four single-entry perturbations fail. Therefore L_0, L_1 and 0011 are rigid outputs of APP–TRIT–TPK transport, never data chosen from π, e or φ. The matrices thus constructed act on the current block; concatenation literally preserves all preceding blocks. The visible word accompanies an enriched state that also transports APP sheet, TRIT orientation, residue, quotient, carry, boundary, memory and incidence shadow. Therefore, coincidence of words and coincidence of states are distinct mathematical conditions.

Levels and thresholds of TPK prolongation

w_6**: visible seed.** It is the six-position ternary word published in each channel after the chain of types $104\,976 \to 468\,U_6 \to 243\,w_6 \subset \mathbb{F}_3^6$, with $|\mathbb{F}_3^6| = 729$. It fixes the first observable prefix, while the decimal emission U_6, its region, multiplicity and source state remain in the enriched fiber. The action D_3, the fiber invariants and the gauge $(\mathrm{diag}_c, h_+) = (6, ES)$ fix the channel representative before any comparison with its real value; in channel π, five distinct regions U_6 also preserve different biographies over the same word w_6^π.

w_{12}**: first lift.** It adds $b_1 = b_0 L_0$ to the seed. It changes the visible depth from one to two blocks and preserves w_6 as an exact prefix, together with the channel and the transported genealogy. The lift produces an extension of the state; it does not replace the seed with a word without a past.

w_{18}**: closure of regime** L_0**.** It adds $b_2 = b_1 L_0$. The second application of the same operator completes the first calendar regime and distinguishes a recurrence from an isolated coincidence: the eighteen trits contain, in their order, the levels of six and twelve trits that precede them.

w_{24}**: typed change of lift.** It adds $b_3 = b_2 L_1$. Here the operator applied to the current block changes, from L_0 to L_1, while the eighteen-trit prefix and the transported state remain. The regime change modifies the continuation and preserves the history on which it acts.

w_{30}**: first-boundary prefix.** It adds $b_4 = b_3 L_1$ and completes the finite calendar (L_0, L_0, L_1, L_1). Its five blocks per channel constitute the prefix from which deep prolongability is tested. It is an entry level to the boundary, while the same recurrence admits further blocks.

R_{36}: first joint coinductive boundary. If u_5^{χ} is the sixth block of channel χ, then

$$R_{36} := (u_5^{\pi}, u_5^{e}, u_5^{\varphi})^T, \qquad w_{36}^{\chi} = w_{30}^{\chi} \| u_5^{\chi}.$$

The boundary relation selects that triple while preserving the axis φ, the lateral aggregate π/e, saturation, column occupancy and dual neutrality. Its equations leave exactly the two mirror solutions

$$B_- = (021222, 222220, 102011)^T, \qquad B_+ = (222220, 021222, 102011)^T;$$

the APP orientation of the half-open cylinder fixes $R_{36} = B_+$. The subscript records thirty-six trits exposed per channel; R_{36} is the boundary of the three sixth blocks and $\mathbb{R}$ is the subsequent Archimedean publication of the cylinder system.

G_9: connection of prolongation and return with memory. Level G_9 organizes the nine local charts that act after R_{36}. If $\mathcal{R}_K$ is the compatible extension relation in phase K, their composition defines the nonadic holonomy

$$\Gamma_{9,K} = \mathcal{R}_{K+8} \circ \cdots \circ \mathcal{R}_K : \widehat{X}_K \longrightarrow \widehat{X}_{K+9}.$$

The subscript 9 comes from the phase cycle C_9, inherited from the nine APP positions, and counts the nine relations composing a turn. Its operational content is certified by

$$g(K+9) = g(K), \qquad q_{\mathrm{mem},K+9} = q_{\mathrm{mem},K} + 1, \qquad \widehat{x}_{K+9} \neq \widehat{x}_K.$$

The phase label returns, memory advances and the prolonged state changes. This is the structural meaning of G_9: a connection turn over an enriched fiber, whose cardinality comes from the architecture and whose action is verified in transport. The modal quotient $\mathcal{K}_{\mathrm{ph}}$ occupies the subsequent reduced stage,

$$\mathcal{U}_t \longrightarrow \Gamma_9 \longrightarrow \mathcal{K}_{\mathrm{ph}},$$

and publishes compressed memory after the holonomy. The local resolution of the ninth phase also distinguishes two horizons: $\#\mathrm{Surv}_1(B_9) = 3$ and $\#\mathrm{Surv}_2(B_9) = 1$. This descent $3 \to 1$ certifies the pruning of a specific fiber; composition of the nine relations certifies the complete turn.

The dodecaphase records another coordinate of the same transport. The vertical counter $q_{\mathrm{mem},K}$ remains unbounded and its reading $\beta_K = [q_{\mathrm{mem},K}]_{12}$ satisfies $\beta_{K+9} = \beta_K + 1 \pmod{12}$. Reduction modulo twelve preserves the dodecaphasic position; the integer counter preserves the number of turns. In the terminal state, this memory feeds the signed record U_{12}^{sgn}, the reversible seal K and the carry cocycle that publishes the coordinate α_{HMT}. The nonsplit extension

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0$$

types the seam between the two calendars: nine steps return the phase and advance one dodecaphasic sector; one hundred and eight steps close the observable clock while the enriched state preserves the genealogical height reached.

Bidirectionality combines the channel mirror and the reversibility of the lift within a single generator. The involution

$$\mathfrak{c}(u^{\pi}, u^{e}, u^{\varphi}) = (u^{e}, u^{\pi}, u^{\varphi})$$

exchanges the conjugate paths π/e and preserves the axis u^{φ} and the aggregate $u^{\pi} + u^{e}$. In the integer chart

$$x_k A = u_k + 3x_{k+1}, \qquad \det A = 1,$$

the advance determines residue and quotient, and the pair (u_k, x_{k+1}) recovers x_k. Ascent and descent are therefore conjugate paths of the same state; descent reconstructs provenance without erasing accumulated memory.

Finally, G_9 constitutes the recurrent unit of prolongation and not its endpoint. The surviving histories form the inverse system

$$\cdots \longrightarrow \mathrm{Surv}_{\chi,n+1} \longrightarrow \mathrm{Surv}_{\chi,n} \longrightarrow \cdots, \qquad x_\chi \in \varprojlim_n \mathrm{Surv}_{\chi,n}\,.$$

Nonemptiness, local uniqueness and compatibility of truncations produce the coinductive section; contraction of its cylinders publishes a unique real value, while the inverse limit preserves the genealogy that this scalar value omits. The twenty blocks and the per-channel certificate of 396 events, 2376 trits, 43 turns and 387 pairs $(K, K+9)$ are finite executions of that uniform law, not bounds on prolongation.

On the coinductive state thus constructed, a correlated kernel of four publications is obtained. The correlation expresses common origin and compatibility; it does not flatten their operational order. The channels first publish the vectors P, E, Φ, while the signed terminal reading constructs $U_{12}^{\mathrm{sgn}} \overset{\mathcal{H}_{12}}{\longleftrightarrow} K$. On these outputs, and without reintroducing their values as data, the dodecaphasic carry cocycle derives the coinductive section α_{HMT}, whose dodecaphasic window is the rational projection α_{12}. The vacancy kernel $E_{21/22}$ provides a second internal construction: its finite simple positive root α_E, prolonged by the same graded TPK transport to the inverse system whose limiting root is α_B. Integer closure defines $\alpha_A := \varprojlim_N \rho_N(\alpha_{12})$, and the exact two-way theorem establishes

$$\boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}.$$

The equality $\mathrm{Tr}_9(\alpha_E^{-1}) = \mathrm{Tr}_9(\alpha_{12}^{-1})$ is the first finite certificate of that identity: it neither defines it, limits its scope nor selects any of the prolongations. Thus, $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}$ and α_{HMT} belong to a single correlated coinductive generation, but preserve differentiated stages, domains, readers and certificates. The Machin identities and Leibniz brackets, the Perron–Fibonacci realization, the factorial semigroup and the metrological tables subsequently recognize or certify the publications already generated; none of them selects the cylinders, vectors or carry of the generator.

The same common source has other publications that must not be confused with one another either. In the internal mirror chart, the involution exchanges the branches u^π and u^e, preserves u^φ and the aggregate $u^\pi + u^e$; only after real publication are expressions such as $e+\pi$, $e\pi$, π^e or the literal quotient π/e formed, each with an arithmetic status that does not follow from the mere existence of the ternary aggregate. In the incidence chart, H_α^-, v_α and N_α denote, respectively, a support, the vector of the exact index-three neighbor and the resulting lattice; they do not denote the scalar α_{HMT} or intervene in its numerical carry. The tetrad B_K enters the Witt star and the vector v_α determines the neighbor leading to $N_\alpha \cong \Lambda_{24}$. From the common Paley–Witt code C_W, two typed branches then open, not a single linear chain:

$$C_W \longrightarrow W_{12} \longrightarrow W_{24}, \qquad C_W \longrightarrow N(A_2^{12}) \xrightarrow{v_\alpha} \Lambda_{24} \longrightarrow V_\Lambda \longrightarrow V^\natural \longrightarrow \mathbb{M} \longrightarrow \text{Moonshine}.$$

The scalar value of α does not generate these symmetries. Numerical derivation and exceptional prolongation are typed readings of the same enriched state and preserve a common genealogical root.

Dimensional Mechanics begins when that structure is transduced into action, magnitude, field and matter. From it come, according to its own readers, the Planck constant and the electromagnetic, thermal, gravitational and quantum constants; the mathematical structure of the electron, the General Mass Law and mixing transports; and, later, the Barbero–Immirzi parameter as a structural object of the transition between matter, area and information. Conventional values appear at the end as metrological recognition, never as inputs to the calculation. For the same reason, resolution of the continuum problem and the five

inseparable constructions emerging from it precede terminal proofs concerning classical mathematical problems: these stress-test an already constructed structure, rather than generating it retrospectively.

The physical order is equally binding. The coordinate α_{HMT} opens, in typed branches, the retention η_{ret} and the structural valuation 10^{-34}; their confluence yields $\hbar_{\mathrm{ret}}$, and only then are the angle and counter-angle constructed and a single conversion between degrees and radians performed. The electron brings this chain together in a material persistence. Its basal

$$e_0 = \frac{\sqrt{3}}{4}\left[\exp\!\left(\frac{\varphi}{\pi^2}\right) - 22\alpha_{\mathrm{HMT}}^{3}\right](1 + 15\Delta_4)$$

precedes beta closure; its two readers coincide at

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6), \qquad \kappa_e = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4,$$

and the published mass is recognized metrologically only after evaluating $m_e^{\beta} = e_0(H_5/\eta_{\mathrm{ret}})^{\kappa_e}$. Tensor gravity, its five-component algebraic sector and the typed physical realization; the T-duality and M-theory screens; and the geometry of area and information prolong the same antecedent with their own domains and falsifiers. None of these realizations reintroduces as a premise the magnitude it must explain.

Everything that follows develops this single thesis in different domains. Numbers, symmetries and matter are not three juxtaposed collections. They are three ways in which the constructed continuum publishes and returns the memory of its own formation.

0.1 Projective horizon: dependence between scale, boundary, and measure

Finite oriented chain and distinction between marks, cells, and genealogical units

The exposition begins with a elementary operation: fixing to segment, marking to scale on it and comparing the regions that esa scale determines. In this point not it is presupposed yet the real line as complete support. The initial object is a finite oriented chain

$$\mathcal{I}_K = (L_K, \prec_K;\ x_{K,0} \prec_K x_{K,1} \prec_K \cdots \prec_K x_{K,n_K};\ o_K),$$

where $(L_K, \prec_K)$ is a finite totally ordered set, the $x_{K,j} \in L_K$ are observable marks, and o_K distinguishes the two directions of traversal. No real magnitude has yet been assigned to L_K. The marks and consecutive cells are distinct objects: under the closed-cell convention, the common mark is incident to the closures of two adjacent cells without thereby becoming an additional cell.

This apparently minimal distinction determines the subsequent architecture. A visible value describes the position published in a chart; a genealogical unit further preserves the interval of provenance, the direction, the accumulated quotient, and compatibility with finer scales. Therefore, two numerically equal presentations may represent different histories, and the same history may admit several coordinated publications.

For $n \in \mathbb{N}$, the nonadic chart organizes this information by means of the Euclidean division

$$n = 9q_9(n) + \rho_9(n), \qquad q_9(n) = \left\lfloor \frac{n}{9} \right\rfloor, \qquad \rho_9(n) \in \{0, \ldots, 8\}. \tag{21}$$

The public phase numbering is obtained through

$$g(n) = 1 + \rho_9(n-1) \in \{1, \ldots, 9\} \qquad (n \geq 1).$$

The residue localizes that phase, and the quotient q_9 preserves how many revolutions have been absorbed by the scale. This pair realizes a phase return while preserving the trajectory. Its decisive invariant is the joint persistence of both coordinates under refinement.

Inverse system of finite resolutions and relative observation horizon

We shall call *horizon* the boundary up to which a finite chart has resolved the object and at which that description is linked with the next chart. If $\mathcal{S}_K$ denotes the nonempty set of enriched states compatible with the scale $K \in \mathbb{N}$, the surjective links of forgetting

$$\tau_{K+1,K} : \mathcal{S}_{K+1} \longrightarrow \mathcal{S}_K$$

remove visible detail, but preserve the necessary information to recognize a prolongation. We write

$$\tau_{K,K} = I, \qquad \tau_{L,K} \circ \tau_{M,L} = \tau_{M,K} \quad (K \le L \le M).$$

The complete object is then the inverse limit,

$$X = \varprojlim_{K} (\mathcal{S}_K, \tau_{K+1,K}), \qquad x = (x_K)_K, \quad \tau_{K+1,K}(x_{K+1}) = x_K. \tag{22}$$

The nonemptiness of the levels and surjectivity of the links guarantee the existence of compatible families; in the specialized channels, their sections are subsequently constructed by means of the survival theorems. Each truncation is finite; compatibility has no preset maximum depth. Ten, one thousand, or ten thousand digits are checks of the same prolongation rule, not alternative definitions of the number.

This formulation distinguishes three operations that decimal notation usually superimposes. The first refines a partition. The second transports the state between phases. The third publishes a coordinate in a continuous chart. Only the last takes values in $\mathbb{R}$. Thus, we begin with a finitely marked line and end with the real line as the final Archimedean realization of a compatible section.

Compatible augmentation and evolutionary conservation of the unit

Unity is formulated before every Archimedean evaluation. Let $C_K = \mathbb{Z}[\mathcal{S}_K]$ be the free module of the states of level K. The link map induces $(\tau_{K+1,K})_{\#} : C_{K+1} \to C_K$, and there exists the augmentation

$$\varepsilon_K : C_K \longrightarrow \mathbb{Z}, \qquad \varepsilon_K\left(\sum_{x \in \mathcal{S}_K} a_x [x]\right) = \sum_x a_x,$$

compatible with the links, $\varepsilon_K \circ (\tau_{K+1,K})_{\#} = \varepsilon_{K+1}$. Evolutionary preservation of unity expresses that refinement redistributes its content among visible part, boundary, and memory without creating a second root or eliminating the terminal term.

Let P_m be the cellular path with m vertices and $m - 1$ edges, and

$$Q_{m,d} = P_m^{\square d}.$$

Its number of k-cells is

$$\#C_k(Q_{m,d}) = \binom{d}{k} (m-1)^k m^{d-k}. \tag{23}$$

The identity

$$10^d = (9+1)^d = 9^d + \sum_{j=0}^{d-1} \binom{d}{j} 9^j \tag{24}$$

is the equality of the 0 cells of the completion. The subcomplex $Q_{9,d}$ and its relative corona together form $Q_{10,d}$. In dimension three,

$$1000 = 729 + 271,$$

where 271 counts only the new vertices. The vector cellular relative complete is

$$\#C_\bullet(Q_{10,3}, Q_{9,3}) = (271, 756, 702, 217), \qquad 271 - 756 + 702 - 217 = 0. \tag{25}$$

Its edges, faces, and cubes cannot be omitted when studying incidence, homotopy, or transport.

The adjective *holographic* designates this compatibility here: the boundary datum, accompanied by orientation, carry, and memory, controls the prolongation of the state without replacing the interior by a number. The unit is the same across dimensions, although its decomposition and readers change.

Nonadic holonomy and phase return with memory increment

Non-Abelian transport is a single connection over the phase cycle. Its full holonomy is written

$$\Gamma_9 = \mathrm{Hol}_{C_9}(\nabla_{\mathrm{TPK}}), \qquad g(k+9) = g(k). \tag{26}$$

Here $g : \mathbb{Z} \to C_9$, and for every point $\widehat{x}_k$ of an admissible orbit of the enriched state,

$$\Gamma_9 \widehat{x}_k = \widehat{x}_{k+9}, \qquad q_{\mathrm{mem}}(\widehat{x}_{k+9}) = q_{\mathrm{mem}}(\widehat{x}_k) + 1.$$

In particular, when q_{mem} distinguishes states, $\widehat{x}_{k+9} \neq \widehat{x}_k$. The nine ordered components describe a turn of the connection; are not nine filters applied to a motionless state. In each channel there exists a map local typed

$$\mathrm{loc}_{K,\chi} : X_\chi \longrightarrow \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729.$$

The transfer traverses the ambient fiber and locates the coordinate of the compatible extension. The turn returns the phase and advances the memory, the prefix, the carry, and the boundary.

In an isometric realization, the separation between visible publication and expressed memory is typed through

$$J : \mathcal{H}_{\mathrm{vis}} \hookrightarrow \mathcal{H}_{\mathrm{full}}, \quad J^*J = I, \qquad U_{\Gamma_9}^* U_{\Gamma_9} = I,$$
$$T = J^* U_{\Gamma_9} J, \qquad \eta = (I - JJ^*) U_{\Gamma_9} J.$$

It follows

$$U_{\Gamma_9} J = JT + \eta, \qquad J^*\eta = 0, \qquad I - T^*T = \eta^*\eta. \tag{27}$$

The term η expresses exactly the orthogonal defect produced by this compression. For composable routes $\gamma_1 : x_0 \to x_1$ and $\gamma_2 : x_1 \to x_2$, the carry $\mathrm{Carr}_R(\gamma) \in \mathsf{C}$ satisfies, with $H(\gamma), Y(\gamma) \in \mathrm{End}(\mathsf{C})$, the cocycle law

$$\mathrm{Carr}_R(\gamma_2\gamma_1) = \mathrm{Carr}_R(\gamma_2) H(\gamma_1) + Y(\gamma_2)\,\mathrm{Carr}_R(\gamma_1), \tag{28}$$

which is the algebraic form of the genealogical continuity.

Dimensional elevation and coordination of geometric regimes

The marked line provides the order and horizon. APP constructs then the two-dimensional chart in which sum and product act on a support common without losing their quotients. TRIT locally orients each interaction by the unique residual decomposition

$$a + b = r + 3c, \qquad a, b \in \mathbb{Z}, \quad r \in \{-1, 0, +1\}, \quad c \in \mathbb{Z}.$$

The Topological Phase Kernel organizes routes, sheets, boundary, signature, orientation, cylinder, record, memory, and transport. Elevation to the cube does not add a spatial metaphor: it introduces the incidences and coherences that make it possible to compare interior, crown, and publication in successive dimensions.

This sequence also prepares the articulation among three geometries. The circular structure preserves phase; the complex structure represents the quarter-turn on a real space V by an operator $\mathcal{J} : V \to V$ with $\mathcal{J}^2 = -I_V$; the hyperbolic structure is realized in the Poincaré disk, whose boundary lies at infinite hyperbolic distance. Their identifications will be effected by explicit maps, not by equality of drawings.

The geometric horizon thus anticipates the thesis of the book: a published metric, the memory of what has been traversed, and the openness of continuations are coordinated readings of an oriented structure.

The double publication originates from a single source:

$$\mathrm{ev}_\infty^{\mathrm{arq}} : X_\chi \longrightarrow \mathbb{R}, \qquad \mathrm{ev}_\infty^{\mathrm{inc}} : X_\chi \longrightarrow \mathcal{E}_{\mathrm{inc}},$$

where $\mathcal{E}_{\mathrm{inc}}$ designates the limit of the boundary incidence objects constructed in Part II. The first map publishes the Archimedean value; the second preserves the exceptional genealogy.

Causal sequence APP–TRIT–TPK, continuum, and typed publications

The following chapters construct APP, TRIT and the Topological Phase Kernel from their finite data; develop the discrete structure of the continuum and its two publications; derive the genealogies of the constants; integrate the five inseparable realizations—spectral, solenoidal, gauge, cohomological and determinantal—of the jointly constructed continuum; and then construct, through Dimensional Mechanics, the physical realizations of the sectors that have them. Archimedean publication appears at the end of each chain, as a reader of an already constructed object. This is the precise sense in which the work begins with a line and ends in $\mathbb{R}$.

Location of complete proofs. This opening fixes the objects and causal order. The complete proofs are found in the chapters devoted to the discrete measure complex, the APP gnomonic construction, TRIT oriented transport, the operator architecture of the Topological Phase Kernel, cubic completion, and double publication. Subsequent cross-references link each construction to its complete proof; the present opening fixes the common domain and the order of composition.

0.2 Projective Formalization of Unity in Successive Scales and Dimensions

0.2.1 Construction of the finite line through order, scale, and conservation of the unit

The construction begins with an oriented line and a declared scale. It does not begin with the already completed set of real numbers, but with the finite object

$$\mathcal{I}_m = \big([0, 10^m],\, \mathcal{M}_m,\, \mathcal{E}_m,\, o_m\big), \qquad m \geq 1, \tag{29}$$

where $\mathcal{M}_m$ is the set of marks, $\mathcal{E}_m$ the set of elementary intervals, and o_m an orientation. The formula brings together four distinct objects. The segment provides the ordered support; the marks publish positions; the intervals compare separations; the orientation determines the direction of the reading. Suppressing any of these coordinates changes the type of the object.

In the first chart, $[0, 10]$, the visible nonadic positions are $1, \ldots, 9$. Between them existen eight interior intervals. The step that connects the last visible state with the first of the next turn it is recorded as closure-and-carry edge. By eso the equality

$$9 \text{ visible marks} \quad \longleftrightarrow \quad 8 \text{ interior intervals} + 1 \text{ closure link} \tag{30}$$

does not identify marks with intervals. It expresses how counting and measure share a boundary without becoming the same operation.

The Euclidean division

$$n = 9q_9(n) + \rho_9(n), \qquad 0 \leq \rho_9(n) \leq 8, \tag{31}$$

is now read in two directions. The residue ρ_9 determines the published phase; the quotient q_9 preserves the accumulated height. When the phase returns to its initial value after nine steps, the quotient has advanced. The trajectory is helicoidal: one coordinate of the wheel has been recovered, but not the complete state.

Algebraic interpretation of the residue–quotient decomposition. The equality (31) is not merely an algorithm for computing remainders. It defines an extension: projection to the residue contracts the history, and the quotient preserves the information required to lift it. The elementary falsifier consists in imposing $\rho_9(n+9) = \rho_9(n)$ and $q_9(n+9) = q_9(n)$ simultaneously. The first equality is correct; the second contradicts Euclidean division.

0.2.2 Projective system of scales and cubical completion to arbitrary depth

Scaling is performed through refinement maps, not through a graphic repetition of the same rule. For $m \leq n$, let

$$r_{n,m} : \mathcal{I}_n \longrightarrow \mathcal{I}_m, \qquad r_{m,m} = I, \qquad r_{n,m} r_{\ell,n} = r_{\ell,m}. \tag{32}$$

The map $r_{n,m}$ preserves the mark published at resolution 10^{-m} and contracts the detail lying below that threshold. The composition equation ensures that forgetting two levels at once produces the same result as forgetting them successively. This is the condition that makes it possible to speak of a single history observed at different scales.

In three dimensions, the passage from the nonadic fiber to the complete decimal chart is expressed by

$$1000 = (9+1)^3 = 9^3 + 3\,9^2 + 3\,9 + 1 = 729 + 243 + 27 + 1 = 729 + 271. \tag{33}$$

The equality contains a stratification. The 729 interior states have no boundary coordinate; the next 243 states have one; the 27 states have two; the apex has three. The number 271 counts the vertices added by the decimal corona. It does not count the internal boundary of the nonadic cube, whose cardinality is $9^3 - 7^3 = 386$, nor the complete relative complex, which includes edges, faces, and cubes.

For every dimension d, let

$$\overline{C}_9^{(d)} = (E_9 \sqcup \{\star\})^d, \qquad \star \notin E_9, \tag{34}$$

and denote by $B_r(d)$ the stratum with exactly r coordinates equal to $\star$. Then

$$|B_r(d)| = \binom{d}{r} 9^{d-r}, \qquad \sum_{r=0}^{d} |B_r(d)| = 10^d. \tag{35}$$

The equation describes growth of the scale without imposing a terminal dimension. Each d has more states, but all belong to the same completion law.

0.2.3 Compatible product measure and conservation of the unit under projection

The expansion of cardinals is accompanied by a conservation of measure. Assign to each symbol of $E_9 \sqcup \{\star\}$ weight $1/10$, and let μ_d be the product measure over $\overline{C}_9^{(d)}$. If $\pi_d : \overline{C}_9^{(d)} \to \overline{C}_9^{(d-1)}$ forgets the last coordinate, then

$$(\pi_d)_* \mu_d = \mu_{d-1}, \qquad \mu_d\big(\overline{C}_9^{(d)}\big) = 1. \tag{36}$$

The first equality is the evolutionary conservation of unity. The dimension increases, the number of states changes, and the normalized mass remains equal. The boundary does not add a second unity: it redistributes the same unity among compatible strata.

This conservation has to cellular version. For the path P_m and the cubical product $Q_{m,d} = P_m^{\square d}$,

$$\#C_k(Q_{m,d}) = \binom{d}{k} (m-1)^k m^{d-k}. \tag{37}$$

In particular, the relative crown of $Q_{9,3} \subset Q_{10,3}$ has cellular vector

$$\#C_\bullet(Q_{10,3}, Q_{9,3}) = (271, 756, 702, 217), \qquad 271 - 756 + 702 - 217 = 0. \tag{38}$$

The null Euler characteristic certifies that the new vertices are accompanied by the required incidences. Reducing the corona to 271 eliminates precisely the transport that the theory must preserve.

0.2.4 Geometric curvature and observation fibers: formal separation between metric and horizon

Euclid's fifth postulate governs the global behavior of parallels. In the Euclidean formulation, it fixes a geometry in which the sum of the angles of a triangle and the distance between geodesics correspond to zero curvature. Its modification opens elliptic and hyperbolic geometries. The visible horizon of a geometric chart does not by itself constitute a proof of the postulate: it is the boundary at which the chart ceases to distinguish prolongations.

The correct relation between the two concepts is established through maps. A geometry (M, g) provides distances and geodesics; a remark chart

$$\mathrm{Obs}_K : (M, g) \longrightarrow Y_K \tag{39}$$

publishes the accessible information to resolution K. The relative horizon of $x \in M$ is the fiber

$$\mathsf{Hor}_K(x) = \mathrm{Obs}_K^{-1}\big(\mathrm{Obs}_K(x)\big). \tag{40}$$

Curvature belongs to g; indistinguishability belongs to the fiber of Obs_K. The horizon can change when the chart is refined without the curvature changing. This separation prevents identifying an observer limitation with an intrinsic property of space.

In the Poincaré disk, the Euclidean boundary lies at infinite hyperbolic distance. On the sphere, positive curvature closes the geodesics without an analogous boundary. In the Euclidean chart, parallelism remains global. HMT coordinates these regimes through the tritic parameter and the algebras

$$\mathbb{A}_s = \mathbb{R}[J]/(J^2 + sI), \qquad s \in \{+1, 0, -1\}, \tag{41}$$

but preserves its metrics and codomains. The common algebraic unit does not erase the difference geometric between cos, the parabolic branch and cosh.

0.2.5 Limit relation between infinitesimal, infinite prolongation, and projective threshold

An indefinite expansion contains two orientations of the same scaling operation. Toward precision, refinement distinguishes increasingly narrow cylinders; toward extension, height records increasingly long revolutions. Let $\mathcal{S}_K$ be the set of states surviving at level K. The complete section is

$$X_\chi = \varprojlim_K \mathcal{S}_K, \qquad x = (x_K)_K, \qquad \tau_{K+1,K}(x_{K+1}) = x_K. \tag{42}$$

Each x_K is finite; compatibility has no maximum depth. An infinitesimal is not identified with a prolongation branch: the former is a scale relation in a realization; the latter is a datum of the inverse system. Only a reader that declares the metric and the evaluation can transform the latter into the former.

The mathematics of thresholds appears when a prolongation changes regime upon crossing a boundary. If $\mathrm{Surv}_K^{(N)}$ denotes the states of level K that admit extension up to N, then

$$\mathrm{Surv}_K^{(N+1)} \subseteq \mathrm{Surv}_K^{(N)}, \qquad \mathrm{Surv}_K = \bigcap_{N \geq K} \mathrm{Surv}_K^{(N)}. \tag{43}$$

The vacancy records the threshold at which a visible continuation ceases to be compatible. It is not an unstructured void: it preserves the cause of discarding, the carry, and the boundary that determine the next level.

0.2.6 Compatible limit of finite horizons and realization of the real line

The Archimedean evaluation appears after constructing the section. For a decimal chart of base 10, let

$$\mathrm{ev}_{\mathbb{R}}(x) = a_0 + \sum_{j\geq 1} a_j 10^{-j}, \qquad a_j = \mathrm{Pub}_j(x_j). \tag{44}$$

Convergence is obtained because the compatible cylinders have diameters that tend to zero in the declared chart. The digit a_j is a coordinate; the sequence $(x_j)_j$ is the history; the real number is the limit publication. Therefore,

$$[0,10] \longrightarrow [0,1000] \longrightarrow [0,10^m] \longrightarrow X_\chi \xrightarrow{\mathrm{ev}_{\mathbb{R}}} \mathbb{R} \tag{45}$$

is a type chain, not a naive inclusion chain.

The second publication of the same x preserves the exceptional incidence. The work will traverse both directions and will finally return to $\mathbb{R}$. The return will then be a conclusion: the real line will have been explained as an evaluation of the compatible state, and not used as a premise that renders genealogy unnecessary.

0.3 Historical genealogy of the continuum problem and HMT–MD mathematical formulation

The historical problem of the continuum, value and measure

The continuum constitutes one of the foundational problems of mathematics. Arithmetic represents discrete units; geometry compares extensions; analysis completes sequences and constructs limits; measure theory assigns magnitudes to sets; physics converts those magnitudes into observables. The efficacy of these disciplines rests on the possibility of publishing a stable and reproducible result. The problem governing this work arises one level earlier: to determine what structure makes that stability possible and what information must be preserved in order to recover a value, a measure, and their symmetries from a common origin.

On the discrete line, a mark and the gap separating it from the next mark are distinct objects. The mark corresponds to the operation of counting; the interval, to the operation of measuring. The passage from 0 to 10 contains the nine visible marks $1, \ldots, 9$, the eight interior intervals between consecutive marks, and one lifted closing edge that carries the count into the next turn. The modular reading preserves the phase; the quotient preserves the attained height. When both coordinates are retained together, the circular repetition becomes a helix, and the sequence of integers preserves the history of its returns.

Triadic Modular Holography (HMT) develops this intuition as a mathematical construction. A finite system of positions, sheets, orientations, paths, and transports produces compatible families of states. Its evaluations publish digits and values; its lifts preserve residue, quotient, carry, boundary, and memory. The continuum is realized as the image of a compatible section of the system of prolongations. Its discrete structure resides in the genealogy that links all resolutions.

This formulation distinguishes three levels. A *digit* is a visible coordinate produced by a reader. A *value* is the image of a section under a specified chart. A *genealogical number* is the complete section that preserves depth, operation, orientation, sheet, residue, quotient, carry, route, boundary, memory, and survival. The decimal expansion constitutes an evaluation of that object; compatibility among its stages constitutes its continuity.

The same structure transforms the concept of symmetry. A symmetry is the evolutionary preservation of identity under a transformation with memory. A cycle may recover the visible position while simultaneously transporting the state to another height, another sheet, or a new block. Invariance belongs to the complete genealogy. The real value and exceptional symmetry therefore appear as two coordinated projections of the same antecedent: one contracts compatible cylinders, and the other preserves the incidence that the Archimedean contraction leaves outside the published coordinate.

Dimensional Mechanics (MD) prolongs this construction into the physical domain. The numerical section receives a spectral representation; persistence is realized as a particle-route; the route ledger produces a signature; the signature feeds a character and a hierarchy of towers; the dimensional chart finally publishes a magnitude. The governing chain of the work is

unit $\longrightarrow$ state with memory $\longrightarrow$ continuum, number and symmetry $\longrightarrow$ particle, constant and quantity.

The scientific objective is unitary and is developed in five Parts. The formal core constructs APP, TRIT, and the Topological Phase Kernel; the discrete structure of the continuum unfolds its sections, the double projection, and the exceptional genealogy; the genealogy of constants produces π, e, φ, α, the internal action scale, and its transducers; five specialization chains construct their internal antecedents and isolate the comparators leading to each classical recognition; Dimensional Mechanics then constructs the constitutive constants, mass, quantum statistics, information, and gravity. Each measurement is presented together with the object and operation that generate it; each metrological comparison is opened only after the internal output has been fixed.

The order of the work follows the constructive dependency: an object appears where it begins to govern subsequent results. Each statement declares its premises, its proof, and, where appropriate, the morphism of physical realization. In this way, a subsequent metrological comparison does not replace the genealogy that produced the output.

From the genealogical closure to the physical realization

The thesis of this work attains four coordinated and irreducible closures: genealogical, operatorial, matricial, and physical. It does not consist in adjoining a set theory, a theory of operator algebras, or a quantum formalism to a prior numerical construction. The four developments arise from the same causal precedence: APP constructs the dual positional and arithmetic realization; oriented TRIT distinguishes return, the torsional present, and opening; TPK preserves value, sheet, orientation, residue, quotient, carry, boundary, route, register, memory, survival, phase, and gauge. Only thereafter are the compatible section, its readers, and its representations formed. The governing diagram is, therefore,

$$\mathrm{APP} \longrightarrow \mathrm{TRIT}_{\mathrm{orientado}} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{X}_{\infty}^{\mathrm{cal}},$$

$$\mathcal{X}_{\infty}^{\mathrm{cal}} \xrightarrow{\mathfrak{R}} \mathbb{R}, \qquad \mathcal{X}_{\infty}^{\mathrm{cal}} \times C_{\mathrm{exc}} \xrightarrow{\mathfrak{E}} \mathcal{E}_{\mathrm{exc}},$$

$$C(X_m) \xrightarrow{\mathrm{diag}} M_{9^m}(\mathbb{C}) \xrightarrow{a \mapsto a \otimes I_9} \mathrm{UHF}(9^{\infty}) \xrightarrow{\pi_\tau(\,\cdot\,)''} R_{\mathrm{hyp}},$$

$$\mathsf{P}_{\mathrm{CT}}^{+} \xrightarrow{\mathfrak{R}_{\mathrm{MD}}^{\mathrm{disc},+}} \mathbf{SpecRoute} \times \mathsf{Hilb}_{\mathbb{R},J} \times \mathbf{B}\mathfrak{M}_D^{+} \times \mathbf{B}G_C.$$

The four lines do not form a single linear chain. Real evaluation and exceptional projection are sister readers of the enriched section; the tracial branch passes through the cylindrical algebras and their unital inclusions; the physical realization begins with prepared routes endowed with the structures required by each component. This separation of domains prevents the von Neumann factor from being deduced directly from a section, the exceptional projection from being identified with an action on digits, or a physical magnitude from being presented as though it were a TPK state without a realization morphism.

Genealogical Closure: Extensionality, Infinity, and Decision

The first closure determines what it means to preserve an object across all depths. Given an inverse system of finite spaces (X_m, p_m), a section $x = (x_m)_m$ is not characterized solely by the equality of its published values. The fiber-descent theorem establishes the conditions under which a finite reader descends to a quotient and distinguishes surjectivity, constancy on fibers, and uniqueness of the descended map. König's lemma guarantees the existence of a branch when the levels are finite, nonempty, and finitely branching; uniqueness further requires the complete character that selects a single compatible prolongation.

On a fixed section, the decreasing cylinders provide an exact realization of the passage $0- \; 1- \infty$: the support contracts, the height increases, the mass remains unitary, and the cylindrical measures converge weak-* to δ_x. This result coordinates the finite Kronecker delta, the conditional expectations between levels, and the Dirac delta as a point measure, without identifying the latter with a differential operator. The prefix foundation precludes infinite descending chains in each finite presentation; coinduction controls compatible prolongation. The von Neumann ordinals are lifted with a route-memory fiber, and cardinality appears as a decategorification that does not retain the entire genealogy.

The same distinction requires cylindrical power, closed power, and full power to be separated, as well as set-theoretic choice, natural choice, algebraic choice, and effective choice. Encoding in ZF/ZFC preserves the constructions and permits comparison with Extensionality, Foundation, Power Set, and Choice; it does not make the real line or the set-theoretic universe the origin of APP–TRIT–TPK. In the effective domain, decidability of each finite window, existence of the limit, uniqueness of an instance, and the impossibility of a uniform total decider are four distinct assertions. The Gödel–Turing reduction affects only the fourth: it does not invalidate particular selectors already constructed. Analogously, the Gödel–Cohen comparison separates the extension $M \mapsto M[G]$ from the internal enrichment of a state and avoids conflating the crossing of depth-dense sets with genericity over a model. Borel cylinders, comparison hierarchies, and the projective minimax passage are introduced with their hypotheses of compactness, continuity, and consistency, not as automatic consequences of inverse notation.

This closure also has an informational formulation. If an update U of the complete state is bijective, then $H(X \mid U(X)) = 0$, and the ideal logical Landauer term vanishes. If a reader q preserves only the visible shadow, the discarded information is localized in $H(X \mid q(X))$. In the operatorial formulation, a trace-preserving automorphism preserves entropy, whereas a trace-preserving conditional expectation $E_N : M \to N$ satisfies

$$S_\tau(E_N h) - S_\tau(h) = D_\tau(h \| E_N h) \geq 0.$$

The cost corresponds to forgetting the fiber, not to the reversible transport of the enriched state; this identity does not assert null total physical dissipation nor reduced computational complexity.

Operatorial Closure: From the Nonadic Unit to Continuous Dimension

The second closure operationally realizes the evolutionary conservation of unity. For the complete system, one considers

$$A_m = M_{9^m}(\mathbb{C}), \qquad \iota_m(a) = a \otimes I_9, \qquad \tau_m(a) = 9^{-m} \operatorname{Tr}(a).$$

Identity $\tau_{m+1} \circ \iota_m = \tau_m$ simultaneously preserves unity and trace. The inductive limit is the UHF algebra of supernatural type $9^\infty = 3^\infty$, and the weak closure of its tracial GNS representation is the hyperfinite factor R_{hyp} of type II_1. Values $\operatorname{rank}(P)/9^m$ become dense, and the trace of projectors in R_{hyp} realizes the entire interval $[0, 1]$: a continuous dimension emerges from a tower of discrete inclusions preserving unity.

This construction is not to be conflated with the marked branch $j_{m,r}(a) = a \otimes p_r$. The isometries of an individual fiber generate in norm the compact operators on the Hilbertian limit and, under weak closure, a factor of type I_∞. Selection of one sector preserves the mark, but not the unit of the tower; the simultaneous lifting of the nine fibers is what produces the UHF–II_1 branch. Nor may the UHF realization be identified without proof with the crossed-product realization of the profinite clock: a

canonical conjugacy requires the action, measure, amenability, ergodicity, and isotropy to be declared. The orthomodular logic of projectors, Boolean contexts, normal states, and entropic normalization

$$S_\tau(9^m\rho) = S_{\mathrm{vN}}(\rho) - m\log 9$$

are derived within this operator construction and keep separate the matrix state, its tracial density, and its statistical publication.

Topology, dimension, and composition do not collapse in the factor. The closure transversal is recorded by means of

$$\mathfrak{C}_{\mathrm{HMT}} = \big(C(\Omega_\infty), R_{\mathrm{hyp}}, \mathcal{G}_{\mathrm{TPK}}\big).$$

The commutative spectrum preserves points and cylinders; the tracial factor preserves dimension and statistics; the groupoid preserves concatenation, admissible inversion, and the provenance of routes. This threefold architecture is formulated after the double projection and the exceptional corridor. It neither founds nor replaces them: Archimedean evaluation and the Paley–Witt–Golay–Leech–$V^\natural$–Monster–Moonshine chain remain the two coordinated readings of the same enriched antecedent.

Matrix Closure: Depth, External Size and Dilation

The third closure introduces simultaneous control of three indices. If m measures genealogical depth, n the exterior size of a grid, and s the matrix level of its entries, the family $\mathfrak{M}^{(n)}_{m,s}$ is bigraded by (m, s) when n remains fixed and trigraded by (m, n, s) when the exterior size also varies. In particular,

$$\mathcal{K}_{m,s} := \mathrm{UCP}\big(C(X_m), M_s(\mathbb{C})\big)$$

has two independent operations: the genealogical restriction $\rho^s_m(\Phi) = \Phi \circ \jmath_m$ and the matrix compression

$$\mathrm{mc}_V(\Phi_1, \ldots, \Phi_k)(f) = \sum_r V_r^* \Phi_r(f) V_r, \qquad \sum_r V_r^* V_r = I_s.$$

Both commute exactly:

$$\rho^s_m(\mathrm{mc}_V(\Phi_1, \ldots, \Phi_k)) = \mathrm{mc}_V\big(\rho^{s_1}_m(\Phi_1), \ldots, \rho^{s_k}_m(\Phi_k)\big)\,.$$

The identity is functorial and distinguishes refinement of history of reduction from the observer.

Every depth-compatible family determines a unique UCP map over $C(X_\infty)$ and admits a common Stinespring dilation. In the diagonal corridor, a single projective spectral measure P satisfies

$$E^{(m)}_x = V^* P([x]_m) V$$

at every depth and on every cylinder. The minimal dilation is unique up to unitary equivalence and exactly preserves what is seen by the reader; a direct sum provides a faithful ambient realization that preserves all distinctions of the algebra. On the UHF limit, a compatible family of UCP maps likewise admits a common prolongation and dilation. The conditional expectation

$$\mathbb{E}_m = \mathrm{id} \otimes \tau_9 : M_{9^{m+1}}(\mathbb{C}) \longrightarrow M_{9^m}(\mathbb{C})$$

preserves the trace and discards the final factor in a controlled manner; its Stinespring environment records the omitted digit. In general, no uniform finite auxiliary memory exists for all depths. Moreover, faithfulness of a representation does not by itself imply APP–TPK dynamical faithfulness: the latter requires an intertwiner compatible with route, monodromy, and composition.

The matrix theory is instantiated in verifiable objects. The qutrit quantum magic squares with parameters $(9, 3)$ and $(12, 3)$ have, respectively, 81 and 144 effects, exactly unital row and column sums,

and declared simultaneous dilations; the same POVM systems produce quantum magic cubes of orders nine and twelve. The order-twelve case is organized through the fibration $12 \to 4 \times 3$, with its gauge and its explicit equivariance condition. By another route, the sum and product conditional expectations of APP generate the algebra

$$C^*(P_{\Sigma,2}, P_{\Pi,2}) \cong \mathbb{C}^4 \oplus M_2(\mathbb{C}) \oplus M_2(\mathbb{C}),$$

and at every level s the central block realizes the free matrix interval $[5I_s, 9I_s]$. These constructions distinguish quantum Latin squares, magic squares, projective measures, positive measures, and semiclassicality; no identification is obtained merely because the objects share order nine.

The common spectral antecedent of two readers is formulated only after both have been constructed. For finite maps $R_m : X_m \to \mathcal{A}_m$ and $Q_m : X_m \to \mathcal{E}_m$, the incidences

$$P_{a,e} = 1_{\{R_m=a\}} 1_{\{Q_m=e\}}$$

refine the two diagonal spectral measures and recover their marginals. The result does not prove joint injectivity or require one reader to be a compression of the other. In the noncommutative regime, two mutually unbiased qutrit PVM systems do not possess a sharp joint PVM; simultaneous realization requires compatible noise or a larger environment. This difference in type preserves the HMT double projection: the matrix theorem classifies realizations of readers and does not rewrite their foundational antecedent.

Physical Closure: Common Domain, Two Orientations, and Localization

The fourth closure constructs the domain from which a TPK route can simultaneously receive spectral, Hilbert-space, dimensional, and Cartan realizations. Let D_{sp}, D_Q, D_D, and D_C be the reference domains of those four representations, with faithful forgetful functors into the category $\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}$ of prepared states and registered routes. The fiber product

$$\mathsf{P}^{+}_{\mathrm{CT}} := \mathsf{D}_{\mathrm{sp}} \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_Q \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_D \times_{\mathsf{P}^{\mathrm{enr}}_{\mathrm{TPK}}} \mathsf{D}_C$$

imposes that the four components have exactly the same antecedent. Their canonical projections are functorial adapters and produce

$$\mathfrak{R}^{\mathrm{disc},+}_{\mathrm{MD}} = \big(\mathfrak{S}_+, \mathcal{Q}_+, \mathfrak{D}_+, \rho^{\mathrm{disc}}_{C,+}\big),$$

with values, respectively, in spectral routes, real Hilbert spaces with complex structure, the positive dimensional monoid, and the discrete Poincare group. The construction asserts the functor on the common domain; it does not assert that every TPK route automatically admits all four lifts.

On a path $\gamma = e_1 \cdots e_r$, the total variation

$$V_+(\gamma) = \sum_j w(e_j)$$

and the net oriented transport

$$V_{\mathrm{or}}(\gamma) = \sum_j \varepsilon(e_j) w(\underline{e}_j)$$

are sibling readers. The loop $ee^\vee$ proves that the former does not, in general, factor through the latter: it has zero oriented transport and positive variation. To obtain an invertible realization, the domain is restricted to those edges whose spectral and Hilbertian components are invertible, whose dimensional datum is an additive cochain, and whose Cartan cocycles are normalized and antisymmetric. Only then does the localization $\Pi_\vee(\mathsf{P}^{+}_{\mathrm{CT,rev}})$ produce the oriented functor $\mathfrak{R}^{\mathrm{disc,or}}_{\mathrm{MD}}$ and transport inversion component by component. The positive reading is not eliminated, and the oriented reading is not obtained merely by changing a sign.

This physical construction precedes the Planck and electron constructions because it supplies them with a domain, representations, and transport rules, but does not absorb their reference proofs or the General Mass Law. The number–particle–route–enriched chronological record–signature– character–towers chain preserves its causal direction; the absolute action scale, the central electron, the mass families, CKM, PMNS, and the physical sectors retain their own objects, domains, and conclusions. A metrological coincidence is compared only after the internal output has been frozen. Extensions that still require an intertwiner, a smooth limit, a proof of dynamical stability, or a physical morphism are stated with those data as exact hypotheses. The absence of any of those maps prevents the theorem from being extended to the corresponding codomain, without altering the genealogical, operatorial, and matricial theorems already proved in their domains.

The reading of the work follows, consequently, the order of dependence and not that of external recognition:

$$\begin{aligned} &\mathrm{APP} \longrightarrow \mathrm{TRIT}_{\mathrm{orientado}} \longrightarrow \mathrm{TPK} \\ &\longrightarrow \text{enriched section} \longrightarrow \begin{cases} \text{Archimedean evaluation,} \\ \text{exceptional projection,} \\ \text{cylinder algebras and tracial closure,} \\ \text{prepared routes and physical realization.} \end{cases} \end{aligned}$$

Each output preserves its domain, hypotheses, and precise obstructions. What is common is not a forced equality between codomains, but provenance from the same enriched state. This is the precise meaning of holographic closure: no terminal publication exhausts the genealogy that produces it, and no subsequent closure can replace the double direction –Archimedean and exceptional– that preserves the unit with memory.

Historical perspective and development of the theory

The history of mathematics can be read as a successive enlargement of the operations admitted on the unit. The integer made counting possible; the rational incorporated division; the real closed processes of approximation; the complex turned rotation into an algebraic operation. Each enlargement fixed a domain, an equivalence, and a representation. Equality published the result with enormous efficacy and at the same time absorbed much of the specific route that had produced it.

Geometry followed an analogous development. Euclidean construction fixed incidence and measure; non-Euclidean geometries showed the coexistence of formally coherent curvature regimes [44, 105]. The trigonometric circle, the complex plane, and the hyperbolic disk coordinate rotation, periodicity, and transport through different state spaces. HMT places beneath these realizations a common ternary state and constructs from it the elliptic, parabolic, and hyperbolic branches.

Mechanics incorporated a relational dependence into the unit. The law of the lever linked weight, arm, and equilibrium; Mach's critique of absolute motion brought the relation among body, frame, and totality to the fore [6, 85]; relativity formalized kinematic invariances, local equivalence, and the geometry of the gravitational field [42]; quantum theory introduced an action scale and propagation through path amplitudes [104, 48]. The HMT–MD program assembles these requirements within a prior problem: constructing the state that preserves position, orientation, operation, memory, and prolongation before publishing a number or a magnitude.

The three terms of the name specify the method. *Holography* denotes preservation of the genealogy and of the prolongation rule between resolutions. *Modular* denotes the coordination of the chart modulo nine, the orientation modulo three, the residue–quotient readers, and decimal publication in base one thousand. *Triadic* denotes both the local orientation $\{-1, 0, +1\}$ and the organization of the levels linking the finite support, the numerical section, and its physical realization.

Evolutionary Conservation and the Meaning of Symmetry

HMT formulates symmetry as preservation of identity under transformation with memory. An operation can recover the same visible phase without recovering the same enriched state. If Θ denotes the transport, the relation

$$\mathrm{pr}_{\mathrm{vis}} \circ \Theta^9 = \mathrm{pr}_{\mathrm{vis}}$$

coexists with a nontrivial increment of carry or memory. Horizontal repetition is the projection of a helical evolution. Identity is preserved because its genealogy permits it to be recognized through change, not because it remains motionless.

The extreme and mean holographic ratio realizes this principle in the cubic completion.

$$999 = 729 + 243 + 27, \qquad 1000 = 729 + 243 + 27 + 1.$$

The apex +1 of the cubic completion and the terminal term $+I$ of the exponential closure are closure operations defined on distinct domains. Their structural correspondence lies in the fact that both complete an evolution and preserve the unit in the respective codomain. This conservation organizes the nonadic return, the decimal carry, the inward growth of the cylinders, and the outward growth of the incidences.

The dimensional prolongation is expressed through

$$10^d = (9 + 1)^d = \sum_{k=0}^{d} \binom{d}{k} 9^k.$$

After normalization by 10^d, the coefficients form a projectively compatible family of measures whose total mass remains equal to one. The interior, the boundary strata, and the apex redistribute that unit as the rank changes. In the cubic realization $C_9 = (\mathbb{Z}/9\mathbb{Z})^3$, the six oriented projections preserve the APP support, and the face–vertex operator produces a space of rank four. The signature $(3, 1)$ emerges from that operator and provides the finite antecedent of the subsequent spacetime reading. Dimension, boundary, and conservation of unity are here results of the same system of projections.

Algebraic Unification of Elliptic, Parabolic, and Hyperbolic Geometries

The conceptual point of departure was to articulate three realizations that mathematics ordinarily presents in distinct spaces: the complex plane, the trigonometric circle, and the Poincare hyperbolic disk. HMT unifies them through the family

$$\mathbb{A}_s = \mathbb{R}[X]/(X^2 + s), \qquad s \in \{+1, 0, -1\}.$$

The elliptic branch contains an internal root of -1 and the circular closure; the parabolic branch contains the nilpotent threshold; the hyperbolic branch contains the two idempotents and the Poincare opening. These three algebras arise from TRIT and subsequently govern the sheets, the channels, the Lorentz–Minkowski metric, and the physical reading of time.

The difference between sum and product provides the elementary operation that articulates these geometries. Sum accumulates displacements and alternatives; product composes stages and folds inputs onto a common class when noninvertible elements intervene. APP preserves both evaluations on a common support. Its spectral separation and the block projectors $P_{\pm}$ fix the intrinsic modes; the conditional projectors $P_{\Sigma,d}$ and $P_{\Pi,d}$, together with their commutator, construct a finite precursor of Heisenberg incompatibility. The subsequent physical reading transforms that separation into the conjugate angular coordinates A and C^*, oriented channels, and holonomy.

Construction of the formal kernel

APP is constructed from the positions $1, \dots, 9$ in two coordinates. The kernel 8×8, the publication of the null class by means of 9 and the gnomon of seventeen cells completan the chart 9×9. The identification of opposite sides produces the torus

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2$$

and its displacements generate the Cayley graph. The evaluations Σ and Π act on the same vertices and paths.

TRIT is the ternary oriented state. In an elevation

$$a + b = r + 3c,$$

the residue r publishes the output and the quotient c preserves how it was obtained. The triple differentiates orientation, threshold and memory. TPK is the operational system of genealogical dynamics that incorporates the tritic selector of the operating mode, transports the state and simultaneously preserves the two APP sheets with their position, orientation, phase, carry, boundary, path, record and survival. Its nonadic, ternary and positional readers, its twelve-phase system and its lifts form a single tree of domains and codomains. Mathematical dependencies are the typed arrows of that tree; each map is presented with its domain, codomain and a reproducible calculation.

With greater precision, APP is the quintuple

$$\mathcal{A}_9 = \big(X_9, \Gamma_{\mathrm{APP}}, \Sigma, \Pi, \mathrm{Path}(\Gamma_{\mathrm{APP}})\big), \qquad \Gamma_{\mathrm{APP}} = \mathrm{Cay}\big(X_9, \{\pm e_1, \pm e_2\}\big),$$

with evaluations

$$\Sigma(i,j) = \mathrm{dr}_9(i+j), \qquad \Pi(i,j) = \mathrm{dr}_9(ij), \qquad \mathrm{dr}_9(n) = 1 + ((n-1) \bmod 9).$$

The lift simultaneously preserves $i + j = R^{+}_{ij} + 9Q^{+}_{ij}$ and $ij = R^{\times}_{ij} + 9Q^{\times}_{ij}$; the published value and quotient information belong to distinct coordinates of the same state.

The lift of TRIT, $\widehat{\tau} = (r, c)$, preserves residue and carry. The fiber over the visible symbol 0 contains $(0,-1)$, $(0,0)$, and $(0,+1)$, whose prolongation trees may differ. This multiplicity is the minimal form in which the same visible coordinate supports distinct histories.

TPK is organized into eight operator classes before its particular realizations are presented: support and state; internal selection; transport; readers and quotients; memory and boundary; periodicity and return; prolongation; and outputs. This classification separates the carrier objects, the maps updating the state, the readers publishing its coordinates, and the functors contracting the section toward an Archimedean, exceptional, or classificatory codomain. Each TPK operator thus receives a domain, a codomain, a rule, and its invariants before receiving an abbreviated name.

The nonadic phases are distributed among three operator fibers: $\{1, 4, 7\}$ activates additive evaluation, $\{2, 5, 8\}$ activates multiplicative evaluation, and $\{3, 6, 9\}$ records the threshold. The transition $9 \to 1$ restores the published phase and lifts the dodecaphase memory; the visible cycle is therefore the projection of a helix of enriched states.

Once the three objects have been presented, the work develops its consequences. The central block

$$B_c = 9P_{+} + 5P_{-}$$

fixes the local exchange coefficient 2 and the spectral gap $9 - 5 = 4$; modular aggregation produces $51 - 45 = 6$, and the unfolding over the nine positions produces $54 = 9 \cdot 6$. The mixed-signature form and $SO^{+}(1,1)$ construct the finite Lorentzian geometry. The cubic completion constructs the extreme and mean holographic ratio, the discrete area law, and the propagation boundary.

Uniform algorithm at finite depth and correlated coinductive publication of π, e, φ, α

Numerical generation is governed by the funnel

$$104\,976 \to 468\,U_6 \to 243\,w_6 \to w_{30} \to R_{36} \to G_9.$$

The channels of π, e, φ and α preserve different typed readers: angular closure, self-proportional propagation, autoscale and signed dodecaphasic coupling. The internal relation Ext, coinductive survival and the exhaustive partition of the fiber produce at each level a unique prolongable cylinder compatible with the preceding truncation; the nested family determines a unique enriched section of every depth. Only afterward do the Leibniz brackets, the factorial semigroup and Perron–Fibonacci locate the already generated blocks Archimedeanly. The runs of one thousand and ten thousand digits are extensive finite certificates of that uniform construction, not its logical foundation.

The initial prolongation constructs

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36},$$

and the internal census selects before the evaluation

$$w_\pi = 010211, \qquad w_e^{(\mathrm{Euler})} = 201101, \qquad w_\varphi = 121200.$$

The superscript specifies that $w_e^{(\mathrm{Euler})}$ belongs to the reader of Euler's number e; it is an object distinct from the electronic path Γ_e of Dimensional Mechanics. For each prescribed finite depth, Ext, TPK transport and compatible survival first produce exactly one cylinder $C_{\chi,n}$ among the 729 refinements. The rational reader is then applied to the already generated cylinder: it constructs its internal bracket and verifies $j_{\min} = j_{\max}$ as an Archimedean localization certificate, without selecting the output or supplying target digits to the generator. The theorem 8.54 proves, for $\chi \in \{\pi, e, \varphi\}$, nonemptiness, uniqueness and compatibility of these survivors at every finite depth; therefore, the partitions construct

$$c_\chi = (C_{\chi,n})_{n\geq 0} \in \varprojlim_n \{C_{\chi,n}\}.$$

The cylinders are nested, their diameters converge to zero, and the EF–G_9 lift preserves the enriched fiber. This separates the uniform algorithm parameterized by depth, the coinductive section it determines, and its finite runs of one thousand and more than ten thousand digits, which act as extensive certificates and not as the logical foundation of the theorem.

The three sections realize distinct structural functions. π organizes closure, orientation, and monodromic boundary; e organizes self-proportional propagation and prefix evolution; φ organizes Perron–Fibonacci self-scaling and its stable mode φ^{-2}. The oriented operator $\mathscr{R}(x, y) = x/y^2$ publishes the conjugate readings π/φ^2 and φ/π^2, which reappear in the physical areal–volumetric hinge.

The terminal state supplies the block and signed record that feed the dodecaphasic closure of α_{HMT}. The carry recurrence in base one thousand and the equation $E_{21/22}$ constitute two internal pathways with distinct sources. Next, number theory organizes the complementary constants through extraction operators: finite parts, Laurent jets, L functions, prime products, Gauss dynamics, Rogers–Ramanujan and Feigenbaum renormalization. The text distinguishes a common antecedent from equality of value; for example, φ, φ^{-1} and φ^2 share an algebraic genealogy without becoming the same number.

The complete genealogy of the first path is

$$\begin{aligned} 104\,976 \to 468\,U_6 \to 243\,w_6 \to w_{30} \to R_{36} \to G_9,\\ G_9 \to x_{\mathrm{term}} \to (B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}) \to K. \end{aligned}$$

The seal K and the twelve terminal triads feed the carry

$$s_m = P_m + E_m - \Phi_m - K_m + c_{m+1},$$
$$A_m = s_m \bmod 1000, \qquad c_m = \frac{s_m - A_m}{1000}.$$

with $c_{13} = 0$. The resulting integral identity fixes

$$\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}}) = \frac{729735256928380099728510547238 0663}{10^{36}}.$$

This identity publishes the exact thirty-six-digit rational window; the compatible recurrence at arbitrary depth constructs $\alpha_{\mathrm{HMT}} = \varprojlim_N A^{(N)}$, which is not reduced to a single window. The second pathway solves the vacancy equation $E_{21/22}$ through an analytic kernel with a simple positive root α_E. The graded TPK transport prolongs that kernel into a compatible family whose limiting root is α_B; integer closure determines $\alpha_A := \varprojlim_N \rho_N(\alpha_{12})$. The truncation squares of both families commute and determine the same surviving cylinder at each depth, so

$$\boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}.$$

The equality after Tr_9 is only the first finite certificate of this exact identity; it does not constitute its criterion, bound its extension or select the prolongations. Each pathway preserves its own boundary condition within the same enriched state.

Number theory extends the same criterion of object, operator, and extraction. Euler–Mascheroni appears as a finite part; the Stieltjes constants as Laurent coefficients; Apery as the evaluation of $\mathcal{Z}_3(3)$; Glaisher–Kinkelin through regularized derivation; Euler–Kronecker through an Eisenstein character; Meissel–Mertens through a prime trace; Catalan through $L(2, \chi_{-4})$; and Khinchin through Gauss dynamics. Rogers–Ramanujan, the prime clocks, and the Feigenbaum approximants belong to distinct operator constructions. The combinations $e + \pi$, $e\pi$, and π^e are formed after their arguments have been constructed and preserve the arithmetic domain corresponding to each statement.

The radical $(3) \subset \mathbb{Z}/9\mathbb{Z}$ organizes the visible network 3–6–9 and the orbit $369 \to 693 \to 936$. Over the same arithmetic, the power–vacancy theorem

$$V_9(n) = \left\lceil n \log_{10}\left(\frac{10}{9}\right) \right\rceil$$

gives the exact evaluation

$$\mathrm{ord}_{10}\left(9^{9^9}\right) = 369\,693\,099, \qquad \#\,\mathrm{cifras}\left(9^{9^9}\right) = 369\,693\,100.$$

This figure is not the census of 396 elementary boundary events per channel: the former measures the decimal order of a nonadic power; the latter counts states in an emission calendar.

Double projection as the sole thesis

The real continuum is the Archimedean shadow of an enriched section. The projection $\mathcal{P}_{\mathrm{arq}}$ contracts compatible cylinders and publishes the value. The projection $\mathcal{P}_{\mathrm{exc}}$ preserves support, orientation, carry, and memory. Both proceed from the same state; therefore, number and exceptional symmetry form a single causal thesis.

The incidence branch constructs Paley, Witt, the ternary Golay code and the Steiner systems. From the common code C_W, the lift $W_{12} \to W_{24}$ remains distinct of the branch

$$C_W \to N(A_2^{12}) \to \Lambda_{24} \to V_\Lambda \to V^\natural \to \mathbb{M}, \qquad [g] \longmapsto T_g.$$

The configuration of the twenty-seven lines, the Schläfli graph, and $W(E_6)$ receive their own incidence operators. The definition of the lattice VOA, the orbifold involution, and the replicable functions show how genealogical identity is preserved when changing codomain. This structure also provides the rank screens and the mathematical interface with T-duality, strings, and M-theory.

Level-five modular arithmetic enters through the Rogers–Ramanujan continued fraction $R(q)$. The Klein–Ramanujan identity expresses $j(\tau)$ rationally in $R(q)^5$, and the limit $R(q) \to \varphi^{-1}$ links pentadic self-scaling with the modular branch. On the canonical branch of order two,

$$t_2 = q^{-1} \prod_{n\geq 1} (1+q^n)^{-24}, \qquad T_{2A} = t_2 + 24 + \frac{2^{12}}{t_2}, \qquad j = \frac{(t_2+256)^3}{t_2^2}.$$

The lattice VOA $V_\Lambda = M(1) \otimes \mathbb{C}[\Lambda]$, the involution $\theta = -I$, and the fixed–twisted orbifold realize the lattice output in the domain of vertex operators. The classical FLM identification fixes $V^\natural$ and $\mathrm{Aut}(V^\natural) = \mathbb{M}$. HMT supplies the antecedent and the incidence maps that reach that construction; the VOA identification theorems retain their own mathematical domain.

The finite root and the real structure are coordinated through the integral presentation.

$$Q_\mathbb{Z} = \mathbb{Z}[u]/(u^2+1),$$

not by means of an inclusion between fields of different characteristics. The Witt endomorphism $A_W^2 = -I_6$ and the real operator $J_\mathrm{e}^2 = -I$ are specialized representations of that relation. The quarter-turn $z \mapsto \mathrm{i}z$ preserves both the Euclidean metric and the Poincare metric of the disk. The identity

$$\mathrm{Exp}(\pi_{\mathrm{HMT}} J_\mathrm{e}) + I = 0$$

is applied only after the Archimedean reader has generated $\mathcal{P}_{\mathrm{arq}}(x_\pi) = \pi_{\mathrm{HMT}}$. The exceptional branch supplies the quadratic type, not the angle: value and incidence remain coordinated without either branch acting as an oracle for the other. The family $J_s^2 = -sI$, $s \in \{+1, 0, -1\}$, extends Euler to the elliptic, parabolic, and hyperbolic realizations. The final term +1 and the apex of EMRH perform closure functions in distinct and coordinated domains. This relation provides an operator expression of the evolutionary preservation of the unit without identifying objects of different types.

Planck scale, Barbero–Immirzi functional, and CKM–CP mixing

The double projection causally precedes the angular and physical constructions. The Smith normal form of H_4 produces a cokernel of order sixteen and the transfer

$$\Sigma_H = \varphi \alpha_{\mathrm{HMT}}^{16}$$

proves $\lfloor \log_{10} \Sigma_H \rfloor = -34$ and thereby fixes the internal scale $10^{-34}\mathcal{U}_S$. The action line contains two coordinates,

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S.$$

Temporal periodicity of order 108 supplies a self-dual Planck closure. In the circular realization, with $\ell_0 := c_{\mathrm{int}} t_0$,

$$T_{108} = 108 t_0, \qquad R_{108} = \frac{54}{\pi}\ell_0, \qquad \theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi}\right)^2,$$

and the quantum satisfies

$$R_{108} = \bar{\lambda}_\mathrm{C} = r_\mathrm{g} = \ell_\mathrm{P}^{\mathrm{circ}}.$$

The broken line

$$Z_a(m) = \frac{m_{\mathrm{P},a}^\circ}{m} P_+ + \frac{m}{m_{\mathrm{P},a}^\circ} P_-, \qquad N_{\mathrm{sp}}(Z_a(m)) = 1,$$

interchanges Compton and gravity under $m \mapsto (m^{\circ}_{\mathrm{P},a})^2/m$. Its fixed point is the Planck scale. The electron section constitutes a subsequent genealogical realization on that line and not an identification of the electron with a classical black hole. The direct angular coordinate A and its conjugate angular coordinate C^* subsequently construct the channels $q_{\pm}$. The hexad–octad inclusion produces the Barbero–Immirzi functional, the area operator, and its spectrum. The same rank-three incidence constructs CKM, the CP phase, and the Jarlskog invariant. These results belong to the mathematical closure of HMT; their field interpretations are resumed in MD.

The Smith normal form explicitly fixes

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4), \qquad |\operatorname{coker} H_4| = 16,$$

and the action line distinguishes $\hbar_{\mathrm{pre}}$, $\hbar_{\mathrm{ret}}$ and $h_{\mathrm{ret}} = 2\pi\hbar_{\mathrm{ret}}$. The chart $\mathcal{U}_S \mapsto \mathrm{J\,s}$ publishes then the unit metrological; the order -34 belongs to the internal section that precedes to esa chart.

The combinatorial inclusion of a hexad into its associated octad produces

$$6\binom{6}{2} = 90, \qquad 8\binom{6}{2} = 120, \qquad \frac{90-120}{24\binom{6}{2}} = -\frac{1}{12}.$$

On these spaces, the dodecaphasic fundamental chain brings together twelve sectors and a single oriented return seam. Its linear reader produces $12S_{90} - S_{120}$ and, therefore, the weights $12 : -1$ of the functional $\Gamma_{6\to 8}$. The coefficient of $(1-q)^{-1}$, equal to $1/24$, positivity and minimality constitute subsequent arithmetic checks of the pair produced. The Holst specialization $\gamma = \Gamma_{6\to 8}$ is realized at the triadic boundary through

$$\widehat{A}_{\mathrm{HMT}} = \gamma_{\mathrm{HMT}} a_0 \sum_{e\in\partial A} N_e, \qquad \mathrm{Spec}(\widehat{A}_{\mathrm{HMT}}) = \{n\gamma_{\mathrm{HMT}} a_0 : 0 \le n \le 72\}.$$

The collective intertwiner satisfies $J_{6\to 8} D_{\mathrm{inc}} = D_{\mathrm{area}} J_{6\to 8}$ on the collective incidence subspaces. The area operator, its spectrum, and the triadic, bilayer, and modular entropies thus constitute the internal closure that realizes the Barbero–Immirzi parameter. The rank-three rational transformation constructs, in a sister branch, the CKM angles, the CP phase, and the Jarlskog invariant before experimental comparison.

Genealogical Closure of the Number and Physical-Spectral Realization

The first four Parts culminate where a conventional exposition usually begins: they define number as a compatible section and value as its projection. Dimensional Mechanics preserves that definition and adopts a physical–spectral reader. It first reconstructs the APP–TRIT–TPK kernel in physical–spectral form. APP is realized as a two-dimensional torus and distinguishes additive, multiplicative, areal, volumetric, and torsional sheets. TRIT receives the semantics

$$\begin{aligned} +1 &= \text{return, memory and past,}\\ 0 &= \text{threshold and present,}\\ -1 &= \text{opening and compatible future.} \end{aligned}$$

TPK transports the route, the record, and the holonomy. Exact periodicity constructs the finite dynamics; a physical time crystal adds a Hamiltonian, robust subharmonicity, and stability. The conjugate angular coordinates A and C^* spectrally realize the sum–product difference.

The gnomonic completion here acquires an explicit geometric function. The L carries the Euclidean chart onto which the inertial and gravitational readers project to a unit quotient. This chart constitutes the realization of the local equivalence principle. The enriched state prior to projection keeps the areal and volumetric sheets separate, and the Ambivalence Principle fixes their ratio $\pi_{\mathrm{HMT}}/\varphi^2_{\mathrm{HMT}}$. Together with the negative- and positive-curvature charts, this yields an AdS–Euclidean–dS atlas: the first realizes the

correspondence between interior and boundary, the second governs local physics, and the third satisfies $\ddot{a}/a = H^2 > 0$ and geometrically explains accelerated expansion. The three charts coexist because they are realizations of the same TRIT triad, linked by TPK transport.

The particle is defined on this grammar. A particle-route is a persistent section endowed with orientation, sheet, occupation, action, propagator, record, and anti-section. The mass law is first formulated on each multisection F:

$$\widehat{\mathbf{M}}_F^{\beta,r} = \mathbf{m}_\star^{\mathrm{ret}} \otimes R_{\mathrm{act}}^{\widehat{K}_F^r/2}\, \widehat{\mathcal{A}}_F^{(0)}\, R_{\mathrm{act}}^{\widehat{K}_F^r/2}, \qquad r \in \{D, \Omega\},$$

where

$$\mathbf{m}_\star^{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34} \mathcal{U}_S \frac{2\pi}{108 t_0}\, c_{\mathrm{int}}^{-2}$$

fixes the absolute mass section and $\widehat{\mathcal{A}}_F^{(0)}$ gathers signature, character, and all the towers of $\langle 90, 120\rangle$. The complete atlas is thus the domain of the law; each species subsequently selects its realization within the corresponding fiber.

The central electron is the first rank-one scalar reduction of this definition. The global torsion entering its reader is

$$\Delta_4 = \frac{\pi - e \log \pi}{270} \left(1 + \frac{\pi}{729}\right).$$

Its bidirectional closure produces

$$\begin{aligned} R_{\mathrm{act}} &= \frac{H_5}{\eta_{\mathrm{ret}}}, & \kappa_e &= 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4, \\ \mathfrak{e}_e^\beta &= \mathfrak{e}_e^{(0)} R_{\mathrm{act}}^{\kappa_e}, \\ \mathfrak{e}_e^\beta &= 0.510998950690000 80860825716 48\ldots \text{ MeV}, & m_e^\beta &= \mathfrak{e}_e^\beta / c^2. \end{aligned}$$

The identity $\Sigma_H = \varphi \alpha_{\mathrm{HMT}}^{16}$ simultaneously supplies the scale $10^{-34}\mathcal{U}_S$ to the two action coordinates; the quotient R_{act} preserves the relative refinement and cancels that common scale. Thus, the internal action scale, the bidirectional correction, and the energy chart in MeV occupy successive levels of a single derivation. The first quantity is the published mass energy; the second is the mass obtained through the explicit chart $E = mc^2$. This distinction precludes identifying an energy coordinate with a unit of mass. Vacancies construct polarization and current; the response of the sheets constructs the permittivity and permeability of the vacuum. The SI chart publishes

$$\begin{aligned} \mu_0^{\mathrm{HMT}} &= 1.256637062121047789\ldots \times 10^{-6}\, \mathrm{H\,m^{-1}}, \\ \varepsilon_0^{\mathrm{HMT}} &= 8.854187812793002329\ldots \times 10^{-12}\, \mathrm{F\,m^{-1}}. \end{aligned}$$

The atlas then situates the quarks and remaining species, defining color, flavor, charge, spin, statistics, and representation within the same genealogy.

In this classification, *colour* is the ternary fibre that organizes the three realizations of a quark route and whose neutral composition satisfies $0 + 1 + 2 = 0 \pmod 3$. *Flavour* is the coordinate that distinguishes, within the same representation, the sections transported by the mixing operator. *Spin* labels the representation of the cover of the rotation group carried by the section. The holonomy of the oriented band realizes its closures $2\pi/4\pi$ and distinguishes phase return from orientation return. Statistics follows from the grading and from the symmetric or exterior realizations; once CCR or CAR is fixed, it publishes Bose–Einstein or Fermi–Dirac occupation and, in the latter case, the Pauli exclusion principle. A virtual particle is a finite prolongation that conserves route, record, and signature up to a declared horizon; a prolongable material section conserves the corresponding global compatibility.

Operational domain of paths, fibers, and physical realizations

The construction proves that the internal genealogy reaches the complete physical domain. The domain distinguishes 81 positions, 56 families, 13 multisections, and 324 oriented routes, together with the null sector. Each realization preserves, according to its codomain, position or fiber, family, route, orientation, phase word, register, signature, character, refinement operators, chart, and comparison. External values are joined by identifier after the internal output has been frozen.

The construction chain that governs those rows is

$$\begin{aligned}\text{surviving section} \to \text{observable route} \to \text{record} \to \sigma \in \mathbb{Z}^5,\\ \sigma \to \chi_0 \to \chi_{\text{full}} \to \text{towers} \to \text{dimensional section.}\end{aligned}$$

The two bidirectional readers publish

$$K_D = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2}\right), \qquad K_\Omega = (\Omega, 54, P_6),$$

and act as diagonal operators on each fiber. In the central cell, both reduce to $(80, 54, 6)$; in the noncentral fibers, their spectra preserve the distinct routes before the selection of a physical realization. The operatorial comparison presents first the HMT output, then the chart, and finally the Standard Model or PDG reference with its unit, scheme, uncertainty, and residual.

The scientific output assumes the type corresponding to each sector. The electron cell publishes the closed scalar beta mass; the photon and gluons publish the null chart; the noncentral fibres preserve their operators and spectra. The finite flavour–generation–colour morphism to a persistent route is already constructed, and the twelve nominal routes $e, \mu, \tau, u, d, s, c, b, t, W, Z, H$ publish their angular signatures and their scalar characters before external comparison. In leptons and quarks, the operators K_D/K_Ω also refine the fibre; they are not the requirement that retroactively creates its scalarization. W, Z, and H preserve their native CT–108 reader even though they do not form part of the operatorial atlas of thirteen multisections. The topological sectors publish fusion and braiding; the virtual sections publish their prolongation horizon. This heterogeneity preserves the proper codomain of each class and makes the table a complete comparison of typed results, values, and realization boundaries.

Quantum, information, gravity and cosmology

The propagation of paths constructs the finite sum over paths, the Clifford–Dirac representation and the Schrodinger evolution. Fixed the Hamiltonian of the internal calendar, the evolution satisfies

$$i\hbar_{\text{int}}\dot{\psi} = H_{\text{clk}}\psi,$$

and its finite propagator admits the expansion

$$(U^R)_{fi} = \sum_{\gamma: i \to f,\, |\gamma| = R} \prod_{\ell \in \gamma} U_\ell.$$

The product preserves the order of transitions within a history, and the sum accumulates alternative histories with common endpoints. The grading of the exchange is realized concretely on $\mathbb{T}^2_{27} \times \{\text{N}, \text{S}, \text{E}, \text{W}\}$ through

$$U_{\text{micro}} = SD_JC_4, \qquad U_{12}^{\text{reg}} = U_{\text{micro}}^{12}.$$

This propagator is unitary; its powers enumerate the finite routes exactly, and its discrete transform produces 27^2 Fourier blocks. The construction is not thereby identified with a continuous functional integral. The grading fixes the exchange datum; the representation of the permutation group determines the symmetric or exterior completion. Once the CCR or CAR relations are given, the variational principle and entropy maximization produce the Bose–Einstein and Fermi–Dirac distributions, and the latter realizes

Pauli exclusion. In the Möbius basis, one visible turn of 2π changes sheet and accumulates $h/2$; the double visible-phase return of 4π restores orientation and accumulates h. Per radian of internal phase, the transport remains equal to $\hbar$.

The Boltzmann constant appears as a transducer between action and ternary information. The internal construction fixes the product $k_B\Theta_{\mathrm{clk}}$ and its structural function; the BIPM definition of the kelvin then fixes the numerical coordinate of k_B in the SI chart:

$$k_B\Theta_{\mathrm{clk}}\log 3 = \hbar_{\mathrm{int}}\frac{2\pi}{108t_0}, \qquad k_B^{\mathrm{SI}} = 1.380649\times 10^{-23}\ \mathrm{J\,K^{-1}}.$$

The ensembles realize Gibbs and the KMS condition. Null Landauer corresponds to bijective transport of the complete fiber; preparation, projection, and reset receive separate balances when the coupling discards a fiber. The thermal reading first constructs the internal transducer and then applies the unit chart.

Bilayer responses produce directly impedance, velocity, permeability and permittivity through

$$\widehat{Z} = \sqrt{\widehat{\mu}/\widehat{\varepsilon}}, \qquad \widehat{c} = (\widehat{\mu\varepsilon})^{-1/2}.$$

The same causal precedence governs the electromagnetic reading: the internal constitutive operator precedes the realization of $\varepsilon_0, \mu_0, Z_0$ and c in the International System of Units.

The gravitational branch first constructs, from the outputs of the enriched state, the action scale, the gravitational selector and the section G_a. The Palatini–Cartan–Holst variational formulation then receives these outputs, together with γ_{HMT}, and admits the constrained Hamiltonian transform

$$H_{\mathrm{tot}} = \int_\Sigma (\lambda^i G_i + N^a V_a + N\mathcal{H}).$$

The subsequent equivalence between covariant action, constrained Hamiltonian system and Einstein–Schrödinger evolution preserves co-tetrad, connection, curvature and torsion within the same scheme. The torsion-free collective sector carries the gravitational excitation; local torsion induced by spin density supplies the material channel. The type, transducer and chart of G precede this dynamical realization and are not selected through it.

The solenoidal and gauge branches receive realizations of the common finite operator

$$\mathcal{L}_{\mathrm{cyc}}^{\mathrm{TPK}} = 2I - C - C^{-1} = 3(I - P_0) = 3I - J,$$

$$\mathfrak{R}_{\mathrm{sol}}(\mathcal{L}_{\mathrm{cyc}}^{\mathrm{TPK}}) = \mathcal{L}_{\mathrm{H}}^{(0)}, \qquad \mathfrak{R}_{\mathrm{gau}}(\mathcal{L}_{\mathrm{cyc}}^{\mathrm{TPK}}) = \mathcal{L}_{\mathrm{H}}^{(1)}.$$

The hydrodynamic branch transports it through the Galerkin–register intertwiner, with coercivity and residual declared; the gauge branch transports it through the gauge functional and the transfer–gap operator. The finite proof and the bridges to the continuous equations are presented with their distinct hypotheses. The self-inertial frames, the Machian factorization, and sheet cosmology are developed after this local and collective construction, where they acquire a domain, a reader, and a typed physical interpretation.

Method of proof and contrast

Each result is presented through its object, domain, map, derivation, premises, certificate, and scope. Reproducible calculations accompany the proof and do not replace it. Metrological charts are applied after the internal scalar or operator has been constructed. CODATA and PDG comparisons are opened after the HMT output has been sealed. This order preserves the causal direction of the program: the structure generates the digit and the magnitude; the external reference measures the agreement attained by HMT.

The work is organized into five causally ordered Parts. The first four construct the formal core, the discrete continuum, the genealogy of the constants, and the five specialization chains; the fifth realizes

that architecture in magnitudes, particles, fields, and physical geometry. This sequence expresses the mathematical dependence among structure, evaluation, closure, and dimensional realization.

Composition of the treatise and scope of the statements

Part I constructs APP from the nonadic cell, presents TRIT as an oriented lift, and defines the Topological Phase Kernel with its fibers, transports, memory, clock, joint nonadic connection, and compatible prolongation. The horizon line opens this construction through the notions of scale, boundary, and measure.

Part II develops the discrete structure of the continuum. The double projection separates Archimedean evaluation from incidential publication. From Paley–Witt, the Steiner–Golay design branch and the Niemeier–Leech–$V^\natural$–Monster–Moonshine lattice branch are distinguished. Within that same structure appear the internal square root of -1, the three quadratic realizations, and the spectral–polar, solenoidal, gauge, cohomological, and determinantal substructures, typed by their own maps and terminals.

Part III establishes the genealogy of the fundamental constants: the correlated coinductive publication of $\pi, e, \varphi, \alpha_{\mathrm{HMT}}$, the specific readers and the two internal pathways of α_{HMT}, $-1/12$, the action scale, Planck, Boltzmann, the Barbero–Immirzi parameter, CKM–CP, the vacuum constitutives, the gravitational constant and the atlas of mathematical and physical constants.

Part IV applies the five substructures constructed in Part II in chapters of identical editorial rank. Each chapter sets out the internal result, the specialized comparator, its premises, and the exact criterion of publication. The conclusion in the corresponding conventional formulation is deduced only when the comparator identity has been verified throughout its domain.

Part V realizes APP–TRIT–TPK through the physical readers: torus and sheets, temporal semantics, curvatures, channels, and holonomy. On that grammar it defines the particle-route, the bidirectional electron, the mass families, the constitutive laws, statistics, information, mixing, variational gravity, self-inertia, sheet cosmology, and the interface with M-theory.

The appendices gather auxiliary proofs, complete censuses, seeds, decimal strings, extensive tables, auxiliary derivations, and reproducible calculations. The main body preserves the sequence of definition, construction, theorem, interpretation, and result. Each claim distinguishes its mathematical domain, its starting structure, its realization chart, and its external test. This separation permits the exact closures, physical realizations, and extension programs to be presented together while preserving for each the degree of proof proper to it.

Part I

Formal Core of Triadic Modular Holography: APP, TRIT, and TPK

Chapter 1

Construction and operatorial architecture of the APP–TRIT–TPK formal kernel: arithmetic support, ternary orientation, and genealogical dynamics

1.1 Arithmetic construction of APP

The name *All Possible Paths*, abbreviated APP, designates the arithmetic structure of trajectories built on a grid of nine rows and nine columns. Its main presentation is the multiplication table of the integers from one to nine, reduced by means of the positive digital root. Addition is involved both in the accumulation that produces each row and in a second evaluation of the same positions. The trajectories traverse this single support and preserve the order of the operations performed.

The development begins with the visible construction of APP and continues with the operations needed to preserve its arithmetic information. The remainder and quotient recover each integer evaluation; the carry determines how these recoveries compose; the translation record distinguishes the return to a position from the accumulated circulation. These are foundations of the generative dynamics. The TRIT, an oriented ternary unit with values $-1, 0, +1$, will provide the regime of each transition; the *Topological Phase Kernel*, TPK, or topological phase kernel, will compose selection, transport and memory updating. Its operator definition is based on the objects constructed here.

1.1.1 Construction of the APP matrix through multiplication and digital root

1.1.1.1 Arrangement of the integers from one to nine

Definition 1.1 (Ordered nonadic support)**.** Define $D_9 = \{1, 2, \ldots, 9\}$ and the two-dimensional support $\mathcal{X}_9 = D_9 \times D_9$. A position is an ordered pair $x = (i, j)$; the first coordinate identifies the row and the second, the column. Rows increase southward and columns eastward.

The support contains $9^2 = 81$ positions. The distinction between position and evaluation is essential: several positions can receive the same arithmetic result while retaining different coordinates. For example, $(2, 3)$ and $(3, 2)$ have equal sum and product, while the orientation of their coordinates distinguishes them.

In row i, the accumulation of i repeated j times determines the entry in column j:

$$P(i, j) = \underbrace{i + \cdots + i}_{j \text{ summands}} = ij.$$

The integer table is thus obtained first. Each column increment adds the row index; each row increment adds the column index.

Table 1.1: Integer multiplicative evaluation: $P(i, j) = ij$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	1	2	3	4	5	6	7	8	9
2	2	4	6	8	10	12	14	16	18
3	3	6	9	12	15	18	21	24	27
4	4	8	12	16	20	24	28	32	36
5	5	10	15	20	25	30	35	40	45
6	6	12	18	24	30	36	42	48	54
7	7	14	21	28	35	42	49	56	63
8	8	16	24	32	40	48	56	64	72
9	9	18	27	36	45	54	63	72	81

The positive digital root is calculated by repeatedly adding the decimal digits until an integer from 1 to 9 is obtained. For example,

$$16 \longmapsto 1+6=7, \qquad 20 \longmapsto 2+0=2, \qquad 25 \longmapsto 2+5=7, \qquad 81 \longmapsto 8+1=9.$$

Applying it to each of the eighty-one entries produces the main APP matrix. Using the notation ρ_9 for this reduction, we write $\Pi(i,j) = \rho_9(ij)$.

Table 1.2: Principal APP matrix: multiplication reduced by positive digital root, $\Pi(i,j) = \rho_9(ij)$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	1	2	3	4	5	6	7	8	9
2	2	4	6	8	1	3	5	7	9
3	3	6	9	3	6	9	3	6	9
4	4	8	3	7	2	6	1	5	9
5	5	1	6	2	7	3	8	4	9
6	6	3	9	6	3	9	6	3	9
7	7	5	3	1	8	6	4	2	9
8	8	7	6	5	4	3	2	1	9
9	9	9	9	9	9	9	9	9	9

The first row reproduces $1,\dots,9$; the second distributes the increment two in the order $2,4,6,8,1,3,5,7,9$; the third traverses $3,6,9$ three times. The last row and the last column have value 9. These patterns arise from the operation applied to each entry and from the convention that represents the zero class modulo nine by 9. Rows whose indices are coprime to nine traverse all nine residues; the remaining rows concentrate several positions on the same residue. The proof and the information preserved by this concentration are developed in the following sections.

The block of rows $4,5$ and columns $4,5$ can already be read directly:

$$\begin{pmatrix} 16 & 20 \\ 20 & 25 \end{pmatrix} \xrightarrow{\rho_9} \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Its selection by congruence, its spectral decomposition and its geometric realizations will be the subject of section 3.1. This localization fixes from now on the positions that produce the block.

1.1.1.2 Positions, intervals and central inversion

The sequence $1,\dots,9$ contains eight intervals between consecutive integers. Adding the cyclic transition $9 \to 1$ yields nine links. This convention makes it possible to specify the relationship between length, number of positions and combinatorial period. When the endpoints 0 and 10 are also considered on a linear scale, the reference support changes: it is advisable to state explicitly which endpoints and which intervals are involved in each construction.

With both endpoints, the linear subdivision is written

$$[0,1],\ [1,2],\ [2,3],\ [3,4],\ [4,5],\ [5,6],\ [6,7],\ [7,8],\ [8,9],\ [9,10].$$

These are ten segments determined by eleven integer marks. The inversion $i \mapsto 10-i$ exchanges the endpoints and preserves the central mark 5; on the nine interior integers it induces the pairs $(1,9)$, $(2,8)$, $(3,7)$ and $(4,6)$, as well as the fixed integer 5. The same inversion will act on each coordinate of the two-dimensional support.

Before evaluating sum or product, the positional table is

Table 1.3: The eighty-one positions before their arithmetic evaluation.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	(1, 1)	(1, 2)	(1, 3)	(1, 4)	(1, 5)	(1, 6)	(1, 7)	(1, 8)	(1, 9)
2	(2, 1)	(2, 2)	(2, 3)	(2, 4)	(2, 5)	(2, 6)	(2, 7)	(2, 8)	(2, 9)
3	(3, 1)	(3, 2)	(3, 3)	(3, 4)	(3, 5)	(3, 6)	(3, 7)	(3, 8)	(3, 9)
4	(4, 1)	(4, 2)	(4, 3)	(4, 4)	(4, 5)	(4, 6)	(4, 7)	(4, 8)	(4, 9)
5	(5, 1)	(5, 2)	(5, 3)	(5, 4)	(5, 5)	(5, 6)	(5, 7)	(5, 8)	(5, 9)
6	(6, 1)	(6, 2)	(6, 3)	(6, 4)	(6, 5)	(6, 6)	(6, 7)	(6, 8)	(6, 9)
7	(7, 1)	(7, 2)	(7, 3)	(7, 4)	(7, 5)	(7, 6)	(7, 7)	(7, 8)	(7, 9)
8	(8, 1)	(8, 2)	(8, 3)	(8, 4)	(8, 5)	(8, 6)	(8, 7)	(8, 8)	(8, 9)
9	(9, 1)	(9, 2)	(9, 3)	(9, 4)	(9, 5)	(9, 6)	(9, 7)	(9, 8)	(9, 9)

1.1.1.3 Representation of the zero remainder and preservation of the quotient

Definition 1.2 (Positive remainder and nonadic quotient)**.** For each integer $n \geq 1$, define

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n-1}{9} \right\rfloor. \tag{1.1}$$

The pair $\big(\rho_9(n), q_9(n)\big)$ is the complete nonadic record of n.

The choice of representatives $1, \ldots, 9$ assigns the integer 9 to the zero residue class. Thus, 9, 18 and 27 have the same positive remainder and respective quotients 0, 1 and 2. The residue coordinate describes a class; the quotient determines the integer lift within that class.

Proposition 1.3 (Exact arithmetic restitution)**.** *The map*

$$\mathbb{N}_{>0} \longrightarrow D_9 \times \mathbb{N}_0, \qquad n \longmapsto \big(\rho_9(n), q_9(n)\big) \tag{1.2}$$

is bijective. Its inverse is $(r, q) \mapsto r + 9q$. In particular,

$$n = \rho_9(n) + 9q_9(n). \tag{1.3}$$

Proof. Euclidean division of $n - 1$ by 9 produces a unique pair (q, t) with $q \geq 0$, $0 \leq t \leq 8$ and $n - 1 = 9q + t$. Setting $r = t + 1$ yields $n = r + 9q$ with $r \in D_9$. This is precisely the pair defined in (1.1). Conversely, given $r \in D_9$ and $q \in \mathbb{N}_0$, the integer $n = r + 9q$ satisfies $n - 1 = (r - 1) + 9q$. Its Euclidean division returns the same remainder $r - 1$ and the same quotient q. Both inverse compositions are thereby proved. □

This restitution fixes the meaning of preserving arithmetic information at the initial stage: exactly the data needed to recover the integer are preserved. The orientation of an operation and the record of a sequence of operations will be incorporated with their own coordinates. The quotient of an isolated evaluation therefore has a precise scope within the complete construction.

Example 1.4 (Two lifts of a residue class)**.** The integers 10 and 19 are represented as $(1, 1)$ and $(1, 2)$. Their first coordinate coincides; the second makes it possible to recover $1 + 9 = 10$ and $1 + 18 = 19$ respectively.

1.1.1.4 Digital root and decimal evaluation

Proposition 1.5 (Expression for the digital root)**.** *The iterated sum of the decimal digits of a positive integer n terminates at* $\rho_9(n)$.

Proof. Write $n = \sum_{k=0}^{m} d_k 10^k$, with $0 \le d_k \le 9$. Since $10 \equiv 1 \pmod 9$, we have $n \equiv \sum_k d_k \pmod 9$. For $n \ge 10$, at least one digit with positive index is nonzero, so that

$$n - \sum_k d_k = \sum_{k \ge 1} d_k (10^k - 1) > 0.$$

The iteration strictly decreases while the integer has more than one digit. It terminates at an integer in D_9 and preserves the class modulo nine. Uniqueness of the positive representative identifies the result with $\rho_9(n)$. □

The integer zero admits the conventional digital root 0. The positive representation of the residue group, in turn, represents its class by 9. Both conventions are fixed by their domains: the digital root acts on integers; the positive section selects representatives of residue classes. This clarification becomes relevant when decimal blocks with leading zeros appear.

1.1.2 Additive and multiplicative evaluations of APP

1.1.2.1 Joint definition of the two evaluations

Definition 1.6 (Enriched arithmetic evaluation of APP)**.** For $(i, j) \in \mathcal{X}_9$, define

$$S(i,j) = i + j, \qquad P(i,j) = ij, \tag{1.4}$$

$$\Sigma(i,j) = \rho_9(i+j), \qquad \Pi(i,j) = \rho_9(ij), \tag{1.5}$$

$$q_+(i,j) = q_9(i+j), \qquad q_\times(i,j) = q_9(ij). \tag{1.6}$$

The simultaneous evaluation is

$$\mathcal{A}(i,j) = \big((\Sigma(i,j), q_+(i,j)), (\Pi(i,j), q_\times(i,j))\big). \tag{1.7}$$

The state at this stage also retains the position (i, j).

The values of S range over the integers from 2 to 18; those of P lie between 1 and 81. The operation is performed first in the integers and then decomposed into remainder and quotient. This order makes it possible to recognize which content comes from the integer calculation and which content corresponds to its modular representation.

Multiplication here admits its construction by iterated addition:

$$P(i,1) = i, \qquad P(i,j+1) = P(i,j) + i, \qquad P(i,j) = \underbrace{i + \cdots + i}_{j \text{ summands}}.$$

By induction on j, this recurrence produces ij. Each row of the multiplicative table is therefore obtained by successively adding its index. The additive evaluation is constructed by adding the two position indices just once. Both operations arise from the integers of the support, with explicitly distinct rules.

For $2 \le k \le 10$, the equation $i + j = k$ has $k - 1$ solutions in D_9^2. For $11 \le k \le 18$, it has $19 - k$. In multiplication, the multiplicity of a value m is

$$\#\{i \in D_9 : i \mid m \text{ and } m/i \in D_9\}.$$

These multiplicities count positions with a given evaluation and preserve the difference between the number of positions and the number of distinct values.

Table 1.4: Integer additive evaluation: $S(i, j) = i + j$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	2	3	4	5	6	7	8	9	10
2	3	4	5	6	7	8	9	10	11
3	4	5	6	7	8	9	10	11	12
4	5	6	7	8	9	10	11	12	13
5	6	7	8	9	10	11	12	13	14
6	7	8	9	10	11	12	13	14	15
7	8	9	10	11	12	13	14	15	16
8	9	10	11	12	13	14	15	16	17
9	10	11	12	13	14	15	16	17	18

Corollary 1.7 (Simultaneous restitution of the two evaluations)**.** *At each APP position, the evaluated integers are recovered exactly by*

$$S = \Sigma + 9q_+, \qquad P = \Pi + 9q_\times. \tag{1.8}$$

Proof. Apply proposition 1.3 to the positive integers $i + j$ and ij at the same position (i, j). □

1.1.2.2 Residue atlas and quotient records

The residue multiplicative matrix already presented is now completed with the additive residues and the two quotient records. These three tables, together with the main APP matrix, display the coordinates of (1.7) separately. Reading them jointly reconstructs the two integer tables. This breakdown makes visible a property decisive for subsequent development: equality of residues can coexist with differences in quotient.

Table 1.5: Positive representatives of additive evaluation: $\Sigma(i, j) = \rho_9(i + j)$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	2	3	4	5	6	7	8	9	1
2	3	4	5	6	7	8	9	1	2
3	4	5	6	7	8	9	1	2	3
4	5	6	7	8	9	1	2	3	4
5	6	7	8	9	1	2	3	4	5
6	7	8	9	1	2	3	4	5	6
7	8	9	1	2	3	4	5	6	7
8	9	1	2	3	4	5	6	7	8
9	1	2	3	4	5	6	7	8	9

Proposition 1.8 (Records of the center and residue coincidence)**.** *The positions* $(5, 5)$ *and* $(8, 2)$ *have the same residue pair* $(\Sigma, \Pi) = (1, 7)$ *and different multiplicative records:*

$$\mathcal{A}(5, 5) = ((1, 1), (7, 2)), \tag{1.9}$$

$$\mathcal{A}(8, 2) = ((1, 1), (7, 1)). \tag{1.10}$$

Proof. At $(5, 5)$, the evaluations are $10 = 1 + 9$ and $25 = 7 + 18$. At $(8, 2)$, they are $10 = 1 + 9$ and $16 = 7 + 9$. Dividing the difference by nine produces the indicated quotients. □

Table 1.6: Quotients of additive evaluation: $q_+(i, j) = q_9(i + j)$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	0	0	0	0	0	0	0	0	1
2	0	0	0	0	0	0	0	1	1
3	0	0	0	0	0	0	1	1	1
4	0	0	0	0	0	1	1	1	1
5	0	0	0	0	1	1	1	1	1
6	0	0	0	1	1	1	1	1	1
7	0	0	1	1	1	1	1	1	1
8	0	1	1	1	1	1	1	1	1
9	1	1	1	1	1	1	1	1	1

Table 1.7: Quotients of multiplicative evaluation: $q_\times(i, j) = q_9(ij)$.

$i\backslash j$	1	2	3	4	5	6	7	8	9
1	0	0	0	0	0	0	0	0	0
2	0	0	0	0	1	1	1	1	1
3	0	0	0	1	1	1	2	2	2
4	0	0	1	1	2	2	3	3	3
5	0	1	1	2	2	3	3	4	4
6	0	1	1	2	3	3	4	5	5
7	0	1	2	3	3	4	5	6	6
8	0	1	2	3	4	5	6	7	7
9	0	1	2	3	4	5	6	7	8

The multiplicative record of the center is therefore $(7, 2)$: a remainder and a quotient. This typed identification must accompany any subsequent use of these digits. A decimal concatenation, a coordinate of the support and a remainder–quotient pair designate different objects and admit different operations.

1.1.2.3 Transposition and central inversion

The transposition $\sigma(i, j) = (j, i)$ preserves both evaluations by commutativity. Its fixed points are the nine diagonal positions; the other seventy-two positions are distributed into thirty-six two-element orbits. On the cardinal directions, it exchanges north with west and east with south.

The central inversion $\rho_c(i, j) = (10-i, 10-j)$ satisfies $\rho_c^2 = \mathrm{id}$. The fixed-point equation is equivalent to $2i = 10$ and $2j = 10$, yielding the unique fixed point $(5, 5)$. This property is an internal geometric characterization of the center. Subsequent physical interpretations must preserve the concrete operation from which it arises.

The joint evaluation (S, P) determines the multiset $\{i, j\}$, since both numbers are the roots of $t^2 - St + P$. Retaining the ordered pair adds the orientation of the coordinates and distinguishes the two orders when $i \neq j$.

1.1.3 Cardinal transport and circulation record

1.1.3.1 Translation group of the support

We identify each coordinate of D_9 with its class in $\mathbb{Z}/9\mathbb{Z}$. The support thus acquires the structure of the additive group

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2.$$

The positive representation again selects the integers $1, \ldots, 9$. The four elementary displacements are

$$\nu(N) = (-1, 0), \quad \nu(E) = (0, 1), \quad \nu(S) = (1, 0), \quad \nu(O) = (0, -1). \tag{1.11}$$

The transition in direction a is $x \mapsto x + \nu(a)$ in X_9. Each transition has the inverse determined by the opposite direction. Upon crossing an edge of the matrix representation, reduction returns a position in the same support; the integer displacement remains part of the record.

Write T_N, T_E, T_S, T_O for the four translations. The sum of opposite vectors is zero; therefore,

$$T_N \circ T_S = T_S \circ T_N = \mathrm{id}, \qquad T_E \circ T_O = T_O \circ T_E = \mathrm{id}\,.$$

Interior cases and boundary crossings are displayed in the following table. At each crossing, the difference between the integer coordinate reached and its positive representative is a multiple of nine.

Table 1.8: Interior transitions and boundary crossings in the matrix representation of APP.

Direction	Vector	Caso interior	Boundary crossing
N	$(-1, 0)$	$(5, 5) \to (4, 5)$	$(1, 5) \to (0, 5) \equiv (9, 5)$
E	$(0, 1)$	$(5, 5) \to (5, 6)$	$(5, 9) \to (5, 10) \equiv (5, 1)$
S	$(1, 0)$	$(5, 5) \to (6, 5)$	$(9, 5) \to (10, 5) \equiv (1, 5)$
O	$(0, -1)$	$(5, 5) \to (5, 4)$	$(5, 1) \to (5, 0) \equiv (5, 9)$

Congruence of pairs is interpreted coordinate by coordinate modulo nine. The intermediate pair belongs to the integer lift of the displacement.

The corresponding Cayley graph has eighty-one vertices and four outgoing edges at each vertex. It therefore contains 324 directed edges and 162 undirected edges. The directed count preserves the distinction between a transition and its inverse.

Its cellular realization is obtained by arranging nine columns and nine rows of squares and performing the periodic identifications of opposite edges. With ninety degrees between the two directions of the

planar representation, the resulting lattice has 81 vertices, 162 edges and 81 two-dimensional cells. Its Euler characteristic is $81 - 162 + 81 = 0$. The toroidal description belongs to this cellular realization of the support and its identifications; the arithmetic definition remains given by X_9 and its translations.

1.1.3.2 Sequences of displacements and integer lift

Let $w = a_1 \cdots a_r$ be a sequence of directions of length r. Given an initial position x_0, its trajectory is defined by

$$x_k = x_0 + \sum_{\ell=1}^{k} \nu(a_\ell) \quad \text{in } X_9, \qquad 0 \le k \le r.$$

The accumulated integer displacement is

$$d(w) = \sum_{\ell=1}^{r} \nu(a_\ell) = \big(\#S - \#N, \#E - \#O\big) \in \mathbb{Z}^2. \tag{1.12}$$

There are $81 \cdot 4^r$ pairs of initial position and cardinal sequence of length r. This count corresponds to the complete cardinal alphabet; the TPK admissibility criteria will act on this support with their additional records.

For $r = 0$, the empty sequence acts as the identity: each position retains its initial value and the accumulated displacement is $(0, 0)$. There are exactly eighty-one pairs of initial position and empty sequence. Under concatenation, the empty sequence is the identity element.

Theorem 1.9 (Positional return and number of turns)**.** *The trajectory of w returns to its initial position if and only if $d(w) \in 9\mathbb{Z}^2$. For a closed trajectory, the vector*

$$\mathrm{wind}(w) = \frac{d(w)}{9} \in \mathbb{Z}^2 \tag{1.13}$$

records the oriented turns in the two periodic directions. It is additive under concatenation of closed trajectories. Reversing the trajectory changes its sign.

Proof. The equality $x_r = x_0$ in $(\mathbb{Z}/9\mathbb{Z})^2$ is equivalent to divisibility by nine of both coordinates of $d(w)$. The sum of displacements is additive under concatenation. The inverse trajectory is obtained by reversing the order of the directions and replacing each with its opposite; its displacement is $-d(w)$. Division by nine preserves these identities. □

Example 1.10 (Two returns with different records)**.** The sequence E^9 and the sequence EO return to the initial position. Their turn vectors are, respectively, $(0, 1)$ and $(0, 0)$. The terminal point coincides in both cases, while the circulation record distinguishes the two paths.

The turn vector preserves net circulation. The complete order of transitions contains additional information: the sequences EO and NS have the same zero vector and different transitions. The progressive construction of the state will retain each record according to the operation to be recovered. In this way, terminal position, net circulation and ordered trajectory retain clearly differentiated functions.

1.1.4 Carry composition and change of section

1.1.4.1 The cocycle of the positive section

Let $s_9 : \mathbb{Z}/9\mathbb{Z} \to D_9$ be the section of positive representatives. For two classes a, b, define

$$c_9(a, b) = \frac{s_9(a) + s_9(b) - s_9(a + b)}{9}. \tag{1.14}$$

The numerator is divisible by nine. Since the first two quantities are between one and nine and the third represents their sum, $c_9(a, b)$ belongs to $\{0, 1\}$. The identity

$$s_9(a) + s_9(b) = s_9(a + b) + 9c_9(a, b)$$

expresses the carry produced when adding positive representatives.

Theorem 1.11 (Associative compatibility of the carry)**.** *For arbitrary $a, b, c \in \mathbb{Z}/9\mathbb{Z}$,*

$$c_9(a, b) + c_9(a + b, c) = c_9(b, c) + c_9(a, b + c). \tag{1.15}$$

Proof. We multiply the expression on the left by nine and substitute (1.14). The terms $s_9(a + b)$ cancel, leaving

$$s_9(a) + s_9(b) + s_9(c) - s_9(a + b + c).$$

The same substitution in the expression on the right cancels $s_9(b+c)$ and produces the identical expression. Division by nine proves the equality. □

The identity expresses the independence of the total carry from the two parenthesizations of a triple sum. Repeating it yields compatibility of any finite sum with its modular reduction. The record makes explicit the term connecting the integer calculation with the residue operation.

1.1.4.2 Positive residue and usual residue normalizations

The usual section s_0 takes values in $\{0, \dots, 8\}$. If $\delta_0(a)$ equals one for the zero class and zero for the others, the two sections are related by

$$s_9(a) = s_0(a) + 9\delta_0(a). \tag{1.16}$$

We define c_0 by the same expression as (1.14), replacing s_9 with s_0.

Proposition 1.12 (Exact transformation of the carry)**.** *The two cocycles satisfy*

$$c_9(a, b) = c_0(a, b) + \delta_0(a) + \delta_0(b) - \delta_0(a + b). \tag{1.17}$$

In particular, $c_9(0, a) = 1$ and $c_0(0, a) = 0$.

Proof. We substitute $s_9 = s_0 + 9\delta_0$ at the three occurrences of the section in (1.14). The terms in s_0 produce c_0 and the remaining terms produce the displayed difference of indicators. For $a = 0$, the identity is evaluated directly. □

The change of section modifies the cocycle by a coboundary. This formulation identifies exactly which term changes when the zero class is represented by 9 or by 0. Restitution of the integer remains consistent under both conventions when the quotient is transformed simultaneously.

To make the boundary cases explicit, set $\varepsilon(a, b) = c_9(a, b) - c_0(a, b)$. Formula (1.17) produces the following partition:

Table 1.9: Correction of the carry under a change of section.

Condition on the classes	$\varepsilon(a, b)$
$a = b = 0$	$1 + 1 - 1 = 1$
Exactly one of a, b is zero	1
$a \neq 0, b \neq 0, a + b = 0$	-1
$a \neq 0, b \neq 0, a + b \neq 0$	0

The first row makes explicit the overlap of the zero conditions; the four rows are disjoint and cover all pairs of classes.

1.1.5 Integer balances and multiplicative structure

1.1.5.1 The six totals of the arithmetic atlas

Proposition 1.13 (Totals of the evaluations and their records)**.** *The sum over the eighty-one positions satisfies*

$$\sum S = 810, \qquad \sum P = 2025, \tag{1.18}$$

$$\sum \Sigma = 405, \qquad \sum \Pi = 459, \tag{1.19}$$

$$\sum q_+ = 45, \qquad \sum q_\times = 174. \tag{1.20}$$

Proof. The sum $1 + \cdots + 9$ equals 45. By separation of the two coordinates,

$$\sum_{i,j} (i + j) = 9 \cdot 45 + 9 \cdot 45 = 810, \qquad \sum_{i,j} ij = 45^2 = 2025.$$

Each row of the residue additive evaluation contains a permutation of the nine representatives, with sum 45. Therefore, $\sum \Sigma = 9 \cdot 45 = 405$.
In residue multiplication, the rows with indices $1, 2, 4, 5, 7, 8$ are permutations and sum to 45. The rows with indices 3 and 6 contain each of the representatives $3, 6, 9$ three times and sum to 54. The row with index 9 contains nine entries of value 9 and sums to 81. This yields $\sum \Pi = 6 \cdot 45 + 2 \cdot 54 + 81 = 459$.
Finally, we sum (1.8): $\sum q_+ = (810 - 405)/9 = 45$ and $\sum q_\times = (2025 - 459)/9 = 174$. □

Table 1.10: Cumulative row evaluations of the APP support.

i	$\sum_j S$	$\sum_j \Sigma$	$\sum_j q_+$	$\sum_j P$	$\sum_j \Pi$	$\sum_j q_\times$
1	54	45	1	45	45	0
2	63	45	2	90	45	5
3	72	45	3	135	54	9
4	81	45	4	180	45	15
5	90	45	5	225	45	20
6	99	45	6	270	54	24
7	108	45	7	315	45	30
8	117	45	8	360	45	35
9	126	45	9	405	81	36
Grand total	810	405	45	2025	459	174

1.1.5.2 Difference between addition and multiplication

The difference between the two evaluations decomposes at each position as

$$P - S = (\Pi - \Sigma) + 9(q_\times - q_+). \tag{1.21}$$

Summing the complete atlas yields

$$2025 - 810 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129. \tag{1.22}$$

The total residue contrast is 54; the quotient contrast is 129 and contributes 1161 to the total integer contrast 1215. The local equality determines the global one without changing the meaning of any of the records.

This decomposition makes it possible to track the residue value and its integer lift separately. When these data participate in subsequent operators, the provenance of the coefficients will be fixed by the evaluation and the sum that produced them. The appearance of 54 acquires a specific arithmetic meaning here, prior to any subsequent dimensional interpretation.

1.1.5.3 Units, radical ideal and ternary extraction

In the ring $R = \mathbb{Z}/9\mathbb{Z}$, a residue is invertible exactly when it is coprime to nine. Therefore,

$$R^\times = \{1, 2, 4, 5, 7, 8\}, \qquad 1^{-1} = 1, \quad 2^{-1} = 5, \quad 4^{-1} = 7, \quad 8^{-1} = 8.$$

The multiplicative rows corresponding to these indices are permutations. For indices 3 and 6, the image has three residues; for index 0, positively represented by 9, it has one.

The inverses are checked by composition. The additive translation $b \mapsto a + b$ is inverted by $c \mapsto c - a$; both compositions return the initial argument. If a is a unit, the multiplicative map $b \mapsto ab$ is inverted by $c \mapsto a^{-1}c$, since $a^{-1}(ab) = b$ and $a(a^{-1}c) = c$. The six indicated units are verified through the products $1 \cdot 1 = 1$, $2 \cdot 5 = 10 \equiv 1$, $4 \cdot 7 = 28 \equiv 1$ and $8 \cdot 8 = 64 \equiv 1$; the two intermediate pairs also provide the inverses of 5 and 7.

Proposition 1.14 (Radical structure of nonadic multiplication)**.** *The ideal* $\mathfrak{m} = (3) = \{0, 3, 6\}$ *satisfies* $\mathfrak{m}^2 = 0$*. Multiplication by three has kernel and image both equal to* $\mathfrak{m}$*. The map*

$$R/\mathfrak{m} \longrightarrow \mathfrak{m}, \qquad x + \mathfrak{m} \longmapsto 3x \tag{1.23}$$

is an isomorphism of vector spaces over $\mathbb{F}_3$*.*

Proof. The product of two multiples of three is a multiple of nine; hence $\mathfrak{m}^2 = 0$. The equality $3x = 0$ in R is equivalent to $x \in \mathfrak{m}$ and the values of $3x$ range over $\mathfrak{m}$. If $x - y \in \mathfrak{m}$, then $3(x - y) = 0$; thus, (1.23) is well defined. Its kernel is zero and its image contains all three elements of the codomain. Additivity and compatibility with scalars in $\mathbb{F}_3$ follow immediately from multiplication in R. □

The operation in (1.23) preserves the linear structure. The product of two elements of $\mathfrak{m}$ is zero, whereas the quotient $R/\mathfrak{m}$ is the field with three elements. This distinction determines the algebraic type of the isomorphism.

The visible sequence $3, 6, 9$ admits two ternary evaluations. Its direct reduction modulo three is $(0, 0, 0)$. Extracting the factor three identifies $3k$ with its coordinate k mod 3 and produces $(1, 2, 0)$. The first operation calculates the class of the original integer; the second calculates the internal coordinate of the ideal. Their distinction prepares the typing of the ternary reader without anticipating its dynamics.

1.1.6 Operator realization of the evaluations

1.1.6.1 Additive resolution of the identity

The operator representation is constructed from the residue evaluations already defined. Let $\mathcal{H}_9 = \mathbb{C}^9$, with orthonormal basis $(e_r)_{r \in R}$, and let $P_r = e_r e_r^*$ be the projector onto the direction of e_r. To position $(a, b) \in R^2$ we assign the additive projector $P^+_{ab} = P_{a+b}$.

Proposition 1.15 (Operator identity by rows and columns)**.** *Each entry* P^+_{ab} *is a rank-one orthogonal projector and*

$$\sum_{b \in R} P^+_{ab} = I_9, \qquad \sum_{a \in R} P^+_{ab} = I_9. \tag{1.24}$$

Proof. Orthonormality implies $P_r^2 = P_r = P_r^*$ and $\sum_r P_r = I_9$. For fixed a, the translation $b \mapsto a + b$ permutes all residues; analogously for fixed b. Both sums are therefore the sum of the nine basis projectors. □

The realization expresses the Latin property of the additive table through a resolution of the identity. The Hilbert space acts here as the codomain of an explicit representation of the constructed arithmetic.

1.1.6.2 Multiplicities of the multiplicative operator

We define $P^{\times}_{ab} = P_{ab}$ and $T_a = \sum_b P^{\times}_{ab}$, where the subscript ab denotes the product of residues. For $a \in R^{\times}$, we obtain $T_a = I_9$. For $a = 3$ or $a = 6$,

$$T_a = 3(P_0 + P_3 + P_6), \tag{1.25}$$

and for $a = 0$, we obtain $T_0 = 9P_0$.

These identities are proved by counting the preimages of each residue under $b \mapsto ab$. In the two rows with ternary image, the residues $0, 3, 6$ each have three preimages. In the zero row, the residue 0 has nine. Consequently, the ranks of T_a are respectively 9, 3 and 1; its nonzero eigenvalues are 1, 3 and 9. In all three cases, the trace retains the value 9.

The operator thus records both the concentration of multiplicities and the total number of contributions. Equality of traces coexists with differences in rank and spectrum. This distinction provides a complete example of preservation of an aggregate quantity with transformation of its operator distribution.

1.1.7 Decimal blocks and compatibility between moduli

1.1.7.1 Base-thousand decomposition

For $N \in \mathbb{N}_0$, Euclidean division by one thousand produces

$$N = 1000Q + B, \qquad 0 \le B < 1000. \tag{1.26}$$

The block B has the width-three decimal notation

$$B = 100a + 10b + c, \qquad a, b, c \in \{0, \dots, 9\}.$$

The width is preserved even when leading zeros appear: the block 001 has three digit positions and integer value one. The index of the block in a sequence and the quotient Q preserve the scale information required by refinement.

In the first APP table, sums and products are less than one thousand. Their remainder modulo one thousand coincides with their integer value. Reduction modulo nine has a different function: it produces the evaluations Σ and Π and their quotients. Comparison of the two moduli therefore begins with the concrete operations that each performs.

1.1.7.2 Exact identity between quotients

Theorem 1.16 (Compatibility of nonadic and decimal records)**.** *Let $N > 0$ and let (1.26) be its Euclidean division by one thousand. Then*

$$\rho_9(N) = \rho_9(Q + B), \qquad q_9(N) = 111Q + q_9(Q + B). \tag{1.27}$$

Proof. Since $N > 0$, we have $Q + B > 0$. The identity $1000 = 999 + 1$ gives

$$N = 999Q + (Q + B) = 9 \cdot 111Q + (Q + B).$$

We apply nonadic restitution to the last term:

$$N = \rho_9(Q + B) + 9\big(111Q + q_9(Q + B)\big).$$

The remainder belongs to D_9 and the quotient is a nonnegative integer. Uniqueness in proposition 1.3 identifies them with $\rho_9(N)$ and $q_9(N)$. □

Example 1.17 (Crossing the decimal threshold)**.** For $N = 1001$, division by one thousand produces $Q = 1$, $B = 1$. The formula gives $\rho_9(N) = \rho_9(2) = 2$ and $q_9(N) = 111$. The final block considered in isolation has remainder one; incorporating the quotient recovers the remainder two of the complete integer.

For $N = 1000$, we obtain $(\rho_9, q_9) = (1, 111)$; for $N = 999$, we obtain $(9, 110)$. The transition between the two integers simultaneously changes the positive representative and the quotient.

1.1.7.3 Recomposition of a finite sequence of blocks

Corollary 1.18 (Sum of blocks and restitution of scale)**.** *Let* $N = \sum_{k=0}^{m} B_k 1000^k > 0$*, with* $0 \le B_k < 1000$*, and let* $S_B = \sum_k B_k$*. Then*

$$\rho_9(N) = \rho_9(S_B), \tag{1.28}$$

$$q_9(N) = q_9(S_B) + \sum_{k=1}^{m} B_k \frac{1000^k - 1}{9}. \tag{1.29}$$

Proof. Subtracting S_B from the expansion of N produces $\sum_{k\ge1} B_k(1000^k - 1)$. Each coefficient $1000^k - 1$ is divisible by nine. Substituting $S_B = \rho_9(S_B) + 9q_9(S_B)$ and applying uniqueness of restitution yields both identities. □

The remainder depends on the sum of the blocks; the second formula also preserves their position through powers of one thousand. The order and scale of the expansion are explicit in the integer record. This identity delimits the function of modulus one thousand in the present chapter. The selection of blocks by the calendar, the tritic orientation and the coinductive extension correspond to the TPK operations that will be developed on this basis.

1.1.8 Dependencies established for the tritic stage

The construction has produced an ordered support of eighty-one positions, two simultaneous integer evaluations and their reversible decompositions. It has also produced the cardinal translations, the circulation record, the carry cocycle and the internal ternary structure of the multiplicative ideal. The projector realization and the compatibility of decimal blocks are obtained after these operations and retain their explicit domains.

At this stage, exact reconstruction concerns the arithmetic evaluations; restitution of a complete trajectory requires its ordered record. This hierarchy determines the transition to the enriched state: each new operation must indicate which coordinates it uses, what it modifies and what it preserves. The introduction of TRIT can then be based on the ternary reduction and integer lift already defined; the introduction of TPK can act on concrete transitions and records.

The subsequent development of the regions and constants will be inserted into that generative sequence. Its exposition must preserve the difference between the operator that generates an output and the formula that allows it to be recognized or evaluated in a later language. The arithmetic basis is proved here in the detail needed to track both functions without interchanging them.

1.2 TRIT: ternary orientation, carry and quadratic representation

The construction of APP jointly preserves position, the additive and multiplicative evaluations and their nonadic decompositions. The oriented ternary reduction now acts on these data. Its task is twofold: to distinguish the three operational classes of an evaluation and to preserve the integer coordinate that allows it to be restored. This distinction is subsequently involved in the phase selection of the topological phase kernel, called TPK after its initials in English, *Topological Phase Kernel*.

The term *trit* designates a ternary unit. In the balanced convention of HMT its values are $-1, 0, +1$. The same alphabet admits different functions depending on the domain: reading an arithmetic evaluation,

Table 1.11: Balanced decomposition of the nine positions on an APP line.

n	1	2	3	4	5	6	7	8	9
$r_3(n)$	1	−1	0	1	−1	0	1	−1	0
$c_3(n)$	0	1	1	1	2	2	2	3	3

Coincidence of ternary representatives preserves three distinct positions in each class; their quotients restore the integers.

selecting an operational mode or indexing a quadratic realization. Each function is defined with its domain and the information it preserves.

The development begins with the integer evaluations of APP. Quadratic realizations appear later as representations of the tritic type already determined. The concrete construction of their generators and the Euler extension are developed in chapter 12.1, after introducing the calendar and the TPK mode selection.

1.2.1 Balanced ternary reduction of APP evaluations

At a position (i, j), with $i, j \in \{1, \dots, 9\}$, the integer evaluations are $S(i, j) = i + j$ and $P(i, j) = ij$. Each preserves its positive remainder modulo nine and its quotient. Ternary reduction is applied to the corresponding evaluation and produces another pair of coordinates.

Definition 1.19 (Oriented ternary decomposition)**.** Let

$$\mathcal{T} = \{-1, 0, +1\}, \qquad c_3(n) = \left\lfloor \frac{n+1}{3} \right\rfloor, \qquad r_3(n) = n - 3c_3(n), \quad n \in \mathbb{Z}.$$

The decomposition and restitution maps are

$$\mathcal{B}_3 : \mathbb{Z} \longrightarrow \mathcal{T} \times \mathbb{Z}, \qquad \mathcal{B}_3(n) = (r_3(n), c_3(n)),$$

$$\mathcal{L}_3 : \mathcal{T} \times \mathbb{Z} \longrightarrow \mathbb{Z}, \qquad \mathcal{L}_3(r, c) = r + 3c.$$

The first component is the balanced ternary representative; the second is the extension quotient.

Proposition 1.20 (Exact restitution and uniqueness)**.** *The maps $\mathcal{B}_3$ and $\mathcal{L}_3$ are inverses. In particular, for every integer n,*

$$n = r_3(n) + 3c_3(n), \qquad r_3(n) \in \mathcal{T},$$

and this expression is unique.

Proof. If $c = \lfloor (n+1)/3 \rfloor$, then $3c \le n+1 < 3c+3$. Therefore $-1 \le n-3c < 2$, and the integer $r = n-3c$ belongs to $\mathcal{T}$. If $r + 3c = s + 3d$, with $r, s \in \mathcal{T}$, the integer $r - s$ is a multiple of three and lies between -2 and 2. Thus, $r = s$ and $c = d$. Finally, for any pair (r, c), $\lfloor (r + 3c + 1)/3 \rfloor = c$, since $0 \le r + 1 \le 2$. This proves both inverse compositions. □

The oriented section of the quotient $\mathbb{Z}/3\mathbb{Z}$ is fixed by

$$[0]_3 \longmapsto 0, \qquad [1]_3 \longmapsto +1, \qquad [2]_3 \longmapsto -1.$$

Replacing 2 with -1 is accompanied by the necessary quotient: $2 = -1 + 3$. The integer evaluation remains recoverable in the pair.

For example, at $(i, j) = (5, 5)$, the sum equals 10 and the product equals 25. Both ternary readings give +1, while their complete decompositions are

$$\mathcal{B}_3(10) = (1, 3), \qquad \mathcal{B}_3(25) = (1, 8).$$

Table 1.12: Additive carry of the balanced ternary section.

$\chi(r,s)$	$s=-1$	$s=0$	$s=+1$
$r=-1$	-1	0	0
$r=0$	0	0	0
$r=+1$	0	0	1

The two extremes encode $-1-1=1-3$ and $1+1=-1+3$.

The common signature identifies a residue type; the sheet and quotient distinguish the two evaluations. The APP state also preserves the position that produced them.

1.2.1.1 Compatibility between moduli nine and three

Write the nonadic decomposition of an evaluation as

$$n = R_9(n) + 9q_9(n), \qquad R_9(n) \in \{1, \dots, 9\}.$$

Reducing its positive representative ternarily yields

$$R_9(n) = r_3(R_9(n)) + 3c_3(R_9(n)).$$

Substituting,

$$r_3(n) = r_3(R_9(n)), \qquad c_3(n) = c_3(R_9(n)) + 3q_9(n). \tag{1.30}$$

Uniqueness of the balanced decomposition proves both identities. The visible reduction modulo three can be performed on the nonadic remainder, while the complete reconstruction also transports the previous quotient.

In the product $5 \cdot 5 = 25$, the nonadic decomposition is $25 = 7 + 9 \cdot 2$. Since $7 = 1 + 3 \cdot 2$, the preceding formula gives $25 = 1 + 3(2 + 3 \cdot 2) = 1 + 3 \cdot 8$. Both reading orders restore the same integer because the quotients compose explicitly.

1.2.2 Arithmetic of ternary states with carry

Preserving the pairs makes it possible to transfer the APP operations to balanced coordinates. The transfer determines the additive carry and the cross terms of the product.

Definition 1.21 (Balanced additive carry)**.** For $r, s \in \mathcal{T}$, let

$$r \oplus s = r_3(r+s), \qquad \chi(r,s) = \frac{r + s - r_3(r+s)}{3}.$$

The integer $\chi(r,s)$ is the carry produced when normalizing the sum of the two representatives.

Proposition 1.22 (Recoverable operations)**.** *If $n = r + 3c$ and $m = s + 3d$, with $r, s \in \mathcal{T}$, then*

$$(r,c) \boxplus (s,d) = \big(r \oplus s, c + d + \chi(r,s)\big), \tag{1.31}$$

$$(r,c) \boxtimes (s,d) = \big(rs, rd + sc + 3cd\big) \tag{1.32}$$

are, respectively, the decompositions of $n+m$ and nm.

Proof. The sum decomposes as

$$n + m = r + s + 3(c+d) = r_3(r+s) + 3\big(c + d + \chi(r,s)\big).$$

In the product,

$$nm = (r + 3c)(s + 3d) = rs + 3(rd + sc + 3cd).$$

The integer rs belongs to $\mathcal{T}$. Both expressions are normalized; uniqueness in proposition 1.20 identifies their components. □

These laws distinguish accumulation and multiplication in the record. The sum aggregates the quotients and adds the residue carry. The product also combines each representative with the quotient of the other evaluation. This arithmetic content is maintained when the operations are incorporated into a TPK transition.

Example 1.23 (Sum and product of two evaluations)**.** From $2 = -1 + 3$ and $4 = 1 + 3$ follows

$$(-1, 1) \boxplus (1, 1) = (0, 2), \qquad (-1, 1) \boxtimes (1, 1) = (-1, 3).$$

Restitution produces 6 and 8, respectively. In the second operation, the quotient is $(-1)\cdot 1+1\cdot 1+3\cdot 1\cdot 1 = 3$.

Proposition 1.24 (Cocycle identity and associativity)**.** *For $r, s, t \in \mathcal{T}$,*

$$\chi(r, s) + \chi(r \oplus s, t) = \chi(s, t) + \chi(r, s \oplus t). \tag{1.33}$$

The operations $\boxplus$ and $\boxtimes$, together with their identity elements and additive inverses transported by $\mathcal{B}_3$, make $\mathcal{T} \times \mathbb{Z}$ a ring isomorphic to $\mathbb{Z}$.

Proof. When normalizing $(r + s) + t$, the total quotient is the first side of (1.33); when normalizing $r + (s + t)$, it is the second. The final representatives coincide because they represent the same class modulo three. Uniqueness of the complete decomposition requires the quotients to coincide as well. By proposition 1.22, $\mathcal{L}_3$ is a bijection preserving sum and product. It therefore transports associativity, distributivity and commutativity of the integer operations. Its identity elements are $(0, 0)$ and $(1, 0)$. □

The cocycle proof expresses a concrete compatibility of the record: normalization can be performed in stages without changing the final evaluation. If the sequence of operations is of interest, the record also preserves the order of the normalizations performed.

1.2.3 Ternary refinement and recovery at arbitrary depth

The decomposition is iterated on the quotient. Given $n_0 \in \mathbb{Z}$, define recursively

$$r_k = r_3(n_k), \qquad n_{k+1} = c_3(n_k), \qquad k \geq 0.$$

Each transition satisfies $n_k = r_k + 3n_{k+1}$. Composing these equalities produces a restitution at any prescribed depth.

Proposition 1.25 (Restitution of a truncation)**.** *For every $N \geq 1$,*

$$n_0 = \sum_{k=0}^{N-1} 3^k r_k + 3^N n_N. \tag{1.34}$$

The sequence $(r_0, \ldots, r_{N-1})$, together with the terminal quotient n_N, determines n_0 exactly.

Proof. For $N = 1$, the identity is the initial decomposition. If it holds for N, substitute $n_N = r_N + 3n_{N+1}$ into the last term to obtain the formula for $N + 1$. Restitution also reconstructs the intermediate quotients, starting at n_N and applying $n_k = r_k + 3n_{k+1}$ in reverse order. □

Example 1.26 (A carry crossing three levels)**.** The evaluation 26 successively gives

$$26 = -1 + 3 \cdot 9, \qquad 9 = 0 + 3 \cdot 3, \qquad 3 = 0 + 3 \cdot 1, \qquad 1 = 1 + 3 \cdot 0.$$

Its representatives, ordered from lower to higher power, are $(-1, 0, 0, 1)$. Restitution is $26 = -1 + 27$. The zero symbol at the intermediate levels preserves a position and a determined quotient.

Proposition 1.27 (Termination for a fixed integer)**.** *Iteration of the balanced quotient reaches zero for every initial integer. Once trailing zeros are removed, the finite balanced ternary expansion of an integer is unique.*

Proof. For $|n| \geq 2$, $|c_3(n)| \leq (|n| + 1)/3 < |n|$. For $n \in \{-1, 0, 1\}$, the quotient is zero. The absolute value strictly decreases while it is at least two, so the iteration terminates. If two expansions represent the same integer, their reduction modulo three fixes the same first representative; subtracting it and dividing by three repeats the argument for all positions. □

This result concerns the arithmetic of a fixed integer. In TPK extensions, the record length increases and new evaluations can be generated. There, depth corresponds to a compatible sequence of states, whose construction requires the survival rules. Formula (1.34) provides the local restitution mechanism that those extensions must preserve.

1.2.4 Two ternary coordinates of a nonadic class

The reduction of $\mathbb{Z}/9\mathbb{Z}$ modulo three has three elements in each fiber. The additional coordinate can be written as a residue ternary quotient.

Proposition 1.28 (Nonadic coordinates with carried addition)**.** *The map*

$$\beta : \mathcal{T} \times \mathbb{F}_3 \longrightarrow \mathbb{Z}/9\mathbb{Z}, \qquad \beta(r, \bar{c}) = [r + 3c]_9$$

is a bijection of sets. Nonadic addition and multiplication take the form

$$\beta(r, \bar{c}) + \beta(s, \bar{d}) = \beta\big(r \oplus s, \overline{c + d + \chi(r, s)}\big), \tag{1.35}$$

$$\beta(r, \bar{c})\beta(s, \bar{d}) = \beta\big(rs, \overline{rd + sc}\big). \tag{1.36}$$

Proof. Changing c to $c + 3k$ changes $r + 3c$ by $9k$, so the map is well defined. If two images coincide, reduction modulo three fixes the same r. The remaining difference, divided by three, fixes the same class $\bar{c}$. Injectivity between two sets of nine elements proves bijectivity. The operations come from (1.31) and (1.32); the term $3cd$ in the multiplicative quotient vanishes upon reduction modulo three. □

The carry establishes the composition law between the two levels. For example,

$$\beta(1, 0) + \beta(1, 0) = \beta(-1, 1).$$

The second coordinate records the step performed by the integer sum before its residue reading. In particular, $\mathbb{Z}/9\mathbb{Z}$ has elements of order nine, whereas the additive group of $\mathbb{F}_3^2$ has exponent three. The preceding bijection preserves the sum through the explicit carried law.

The three APP positions $3, 6, 9$ are written

$$[3]_9 = \beta(0, 1), \qquad [6]_9 = \beta(0, 2), \qquad [9]_9 = \beta(0, 0).$$

On the ideal $3\mathbb{Z}/9\mathbb{Z}$, extraction of the second coordinate is

$$[3c]_9 \longmapsto [c]_3.$$

This is an additive bijection with $\mathbb{F}_3$. It differs from direct reduction modulo three, which assigns zero to all three elements. Moreover, the product of two elements of this ideal is zero modulo nine. Its multiplicative structure thus retains a function different from multiplication in the field $\mathbb{F}_3$.

1.2.4.1 The fiber of six ternary positions

An oriented word of length six belongs to $\mathcal{T}^6$, with $3^6 = 729$ possibilities. The choice of representatives induces a bijection with $\mathbb{F}_3^6$. Grouping positions in pairs and applying β also yields a set-theoretic bijection with $(\mathbb{Z}/9\mathbb{Z})^3$. The transported law uses the carry of each pair.

The census of words actually emitted by the TPK is performed after constructing its emitter and chronology. The ambient fiber of 729 elements fixes coordinate capacity; the set of emissions and its ternary image are determined by the operational rules. This separation makes it possible to preserve, in the subsequent census, both multiplicities and the distinct records sharing a visible word.

1.2.5 Oriented involution and transport memory

Proposition 1.29 (Compatibility with sign reversal)**.** *For all $n \in \mathbb{Z}$,*

$$\mathcal{B}_3(-n) = (-r_3(n), -c_3(n)).$$

Proof. From $n = r + 3c$ we deduce $-n = (-r) + 3(-c)$. Since $-r \in \mathcal{T}$, uniqueness of the decomposition proves the statement. □

For a sequence of signatures of length m, define

$$C_{\mathrm{rev}}(\tau_1, \ldots, \tau_m) = (-\tau_m, \ldots, -\tau_1).$$

The second application restores the initial order and signs, so that $C_{\mathrm{rev}}^2 = \mathrm{id}$. In a sequence of pairs, the same rule simultaneously transports $(r_k, c_k) \mapsto (-r_{m+1-k}, -c_{m+1-k})$. The length and each restorable evaluation are determined.

Division memory and transport memory serve different purposes. The pair $(r_3(n), c_3(n))$ reconstructs an integer evaluation. Reconstructing a trajectory also requires the initial position, orientations, sequence of modes and boundary crossings. Two paths can reach the same evaluation and preserve different transport records. The enriched state integrates both orders of information.

In the temporal interpretation adopted by HMT, +1 corresponds to return with memory, 0 to the present threshold and −1 to the opening of conjugate extensions. This assignment fixes a regime reader. Effective evolution requires the TPK transition on the complete records; its iterations determine which phase returns and which memory is incremented.

1.2.6 Quadratic algebras of the three regimes

The tritic index has an algebraic realization through a quadratic relation. Its integral formulation precedes the choice of the scalar field and allows discrete information to be separated from subsequent analytic realizations.

Definition 1.30 (Quadratic algebra of tritic type)**.** For $\tau \in \mathcal{T}$, define

$$Q_{\tau,\mathbb{Z}} = \mathbb{Z}[u]/(u^2 + \tau).$$

For a commutative ring A, its realization by change of scalars is

$$Q_{\tau,A} = A[u]/(u^2 + \tau).$$

The class of u, written J_τ, satisfies $J_\tau^2 = -\tau I$.

Division by the monic polynomial $u^2 + \tau$ provides a unique expression $aI + bJ_\tau$. The product is calculated by reducing only the quadratic term:

$$(aI + bJ_\tau)(cI + dJ_\tau) = (ac - \tau bd)I + (ad + bc)J_\tau. \tag{1.37}$$

This multiplication represents the quadratic regime. The arithmetic of balanced pairs, for its part, preserves integers and their quotients through (1.31) and (1.32).

1.2.6.1 Nine-element realizations

Over $\mathbb{F}_3$, the three algebras have nine elements and admit the following classification:

$$\mathcal{Q}_{+1,\mathbb{F}_3} \cong \mathbb{F}_9, \qquad \mathcal{Q}_{0,\mathbb{F}_3} = \mathbb{F}_3[\varepsilon]/(\varepsilon^2), \qquad \mathcal{Q}_{-1,\mathbb{F}_3} \cong \mathbb{F}_3 \times \mathbb{F}_3.$$

Proposition 1.31 (Distinction of the three finite types)**.** *The first algebra is a field; the second contains a nonzero nilpotent; the third has two nontrivial orthogonal idempotents whose sum is the identity. The three are pairwise nonisomorphic.*

Proof. The polynomial $u^2 + 1$ takes the values $1, 2, 2$ on $0, 1, 2$; it is therefore irreducible over $\mathbb{F}_3$. Its quotient is a field of degree two. In the second case, the class ε is nonzero and satisfies $\varepsilon^2 = 0$. In the third, $u^2 - 1 = (u - 1)(u + 1)$, with coprime factors. The evaluation $a + bu \mapsto (a + b, a - b)$ is an isomorphism to $\mathbb{F}_3 \times \mathbb{F}_3$. The elements $2(1 + u)$ and $2(1 - u)$ are its two coordinate idempotents. These algebraic properties distinguish the three types. □

In the development of exceptional incidence, a concretely constructed ternary operator satisfying $A_W^2 = -I$ induces the action of $\mathbb{F}_9$ on its space. If that space is $\mathbb{F}_3^6$, the dimension over $\mathbb{F}_9$ is three: the action is defined by $(a + b\iota)v = av + bA_W v$. The operator fixes multiplication by the quadratic unit. The corresponding Paley construction supplies that operator in its causal place; the present classification establishes the content of the relation it must satisfy.

1.2.6.2 Conjugation, algebraic norm and inverse

In the real realization, conjugation and the algebraic norm are

$$\overline{aI + bJ_\tau} = aI - bJ_\tau, \qquad N_\tau(aI + bJ_\tau) = a^2 + \tau b^2.$$

Proposition 1.32 (Multiplicative norm and inverse restitution)**.** *For $z, w \in \mathcal{Q}_{\tau,\mathbb{R}}$,*

$$z\bar{z} = N_\tau(z)I, \qquad N_\tau(zw) = N_\tau(z)N_\tau(w).$$

An element z is invertible exactly when $N_\tau(z) \neq 0$; in that case $z^{-1} = \bar{z}/N_\tau(z)$.

Proof. The product (1.37) gives $(aI + bJ_\tau)(aI - bJ_\tau) = (a^2 + \tau b^2)I$. Conjugation is multiplicative and the algebra is commutative, so $(zw)\overline{zw} = (z\bar{z})(w\bar{w})$. If the norm is nonzero, the formula exhibits an inverse. If $zw = I$, multiplicativity gives $N_\tau(z)N_\tau(w) = 1$, forcing $N_\tau(z) \neq 0$. □

The matrix representation

$$aI + bJ_\tau \longmapsto \begin{pmatrix} a & -\tau b \\ b & a \end{pmatrix}$$

is faithful and has determinant $a^2 + \tau b^2$. For $\tau = +1$, the form is positive definite. For $\tau = 0$, it depends only on a, while J_0 retains a nonzero linear component. For $\tau = -1$, the form has signature $(1, 1)$; the directions $I \pm J_{-1}$ are zero divisors.

In particular, the word *norm* here designates a multiplicative quadratic form. The positive norms of Hilbert spaces, used in other realizations of the state, retain their own definition.

1.2.6.3 Composition of ratios between coordinates

A direction with nonzero scalar component is represented by $I + uJ_\tau$. Multiplication produces

$$(I + uJ_\tau)(I + vJ_\tau) = (1 - \tau uv)I + (u + v)J_\tau.$$

When $1 - \tau uv \neq 0$, the ratio between the components of the product is

$$u \star_\tau v = \frac{u + v}{1 - \tau uv}. \tag{1.38}$$

The scalar factor $1 - \tau uv$ forms part of the complete product. If only the ratio is retained, that factor must be recorded when it is involved in a subsequent reconstruction. If the denominator vanishes, the product is examined in its two components: it can represent a direction with zero scalar component or the zero element.

The quadratic classification thus prepares a precise reading of the three regimes. Selection of a regime preserves its index, arithmetic preserves its carries and transport preserves the oriented sequence. The TPK composes these data through explicit operators. On that composition will be built the concrete generators and the preservation of forms that articulates the Euler extension.

1.3 Topological phase kernel and generation of the seed catalog

The two APP evaluations acquire generative efficacy when it is specified which evaluation acts, at which position it is performed, how that position moves and what information each transition preserves. The *Topological Phase Kernel*, abbreviated TPK and called in Spanish *núcleo topológico de fase*, brings these operations together in dynamics on enriched states. Its definition comprises selection, transport, arithmetic updating and preservation of the record. The finite construction developed in this chapter provides the seeds on which the regional lifts and the coinductive extension will act.

The main result of this stage is a generated and classified catalog: the initial conditions of the two cursors produce integer emissions; their ternary reading determines oriented words; the dihedral action organizes these words into orbits. Each step preserves its preimages and the relations that allow a return to the preceding description. The chain of cardinalities

$$104\,976 \longrightarrow 468 \longrightarrow 243 \subset 729, \qquad 243 \longrightarrow 43,$$

abbreviates different objects. Each object is constructed below and each count is justified, before any of them is used as data for regional selection.

1.3.1 Phase selection, transport and enriched state

1.3.1.1 Tritic selector of operational phase

The nonadic phase takes its values in $D_9 = \{1, \dots, 9\}$. The tritic selector is the function

$$M_{\mathrm{ph}} : D_9 \longrightarrow \{-1, 0, +1\}, \qquad M_{\mathrm{ph}}(g) = \begin{cases} +1, & g \in \{1, 4, 7\}, \\ -1, & g \in \{2, 5, 8\}, \\ 0, & g \in \{3, 6, 9\}. \end{cases} \tag{1.39}$$

In the emitting realization, the value +1 activates the additive evaluation, −1 activates the multiplicative evaluation and 0 records the neutral event. The cardinal orientation of the cursor is another coordinate of the state. This separation allows both the operation being read and the direction in which its evaluation point is transported to be fixed simultaneously.

For transitions numbered by $t \geq 1$, the phase preceding the reading is

$$g_t = 1 + [(t-1)]_9, \qquad \epsilon_t = M_{\mathrm{ph}}(g_t), \tag{1.40}$$

where $[n]_b$ denotes the representative of n modulo b in $\{0, \dots, b-1\}$. A window of nine transitions contains the sequence $(+1, -1, 0, +1, -1, 0, +1, -1, 0)$.

1.3.1.2 Oriented cursors and cardinal transport

Indices $I_9 = \{0, \dots, 8\}$ are used for positions and positive labels $(a, b) = (i+1, j+1)$ for APP evaluations. A finite cursor is

$$c = (i, j; d) \in \mathcal{S} := I_9^2 \times \mathcal{D}, \qquad \mathcal{D} = \{N, E, S, O\}.$$

The four directions act through

$$v_N = (-1, 0), \quad v_E = (0, 1), \quad v_S = (1, 0), \quad v_O = (0, -1).$$

The cardinal map corresponding to d is

$$T_d(i, j) = \big([i + (v_d)_1]_9, [j + (v_d)_2]_9\big).$$

Thus, M_{ph} and T_d have different domains, codomains and actions. Tritic activation selects one of the two cursors; cardinal transport modifies its position in the direction that cursor already preserves.

The integer lift of the cursor is $\widetilde{c} = (x, y; d) \in \mathbb{Z}^2 \times \mathcal{D}$, with finite position $([x]_9, [y]_9)$. Its turn counts are recovered in

$$x = 9\lfloor x/9 \rfloor + [x]_9, \qquad y = 9\lfloor y/9 \rfloor + [y]_9. \tag{1.41}$$

These two divisions concern spatial transport. The division of an additive or multiplicative evaluation constitutes a distinct arithmetic register, which will be preserved alongside them.

1.3.1.3 Composition of the transition

The state of the finite realization includes the two lifted cursors, their directions, the phase, the accumulators of the active window, the ordered list of blocks already emitted and the transition register. Each local register contains the preceding positions, the integer evaluations of both sheets, their residues and quotients, the active regime and the orientations. The prefix and boundary fields that appear in a prolongation will be incorporated into the same state with their compatibility rules.

The transition is ordered as

$$\mathcal{U}_t = \mathsf{Mem}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t. \tag{1.42}$$

Selection determines the regime and preserves the sample prior to any displacement. Transport applies the active movement and the cardinal inversion prescribed by the calendar. Updating incorporates that sample into the accumulators and the register; upon completing a window, it emits its block. The composition therefore uses a sample taken before transport even though its definitive archiving occurs at the end of the transition.

1.3.2 Initial conditions and reversible enumeration

The additive and multiplicative sheets have independent cursors. The domain of initial conditions is the ordered product

$$\Omega_{\mathrm{seed}} = \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\mathcal{S}| = 9^2 \cdot 4 = 324.$$

Consequently,

$$|\Omega_{\mathrm{seed}}| = 324^2 = 104\,976. \tag{1.43}$$

The number 81 counts positions; 324 counts oriented positions of one cursor; 104 976 counts ordered pairs of cursors. Choosing a position in APP preserves only part of an initial condition of the emitter.

The numbering is fixed

$$\mathrm{ind}(N) = 0, \quad \mathrm{ind}(E) = 1, \quad \mathrm{ind}(S) = 2, \quad \mathrm{ind}(O) = 3,$$

and one defines

$$\nu(i, j; d) = 4(9i + j) + \mathrm{ind}(d). \tag{1.44}$$

Proposition 1.33 (Exact enumeration of initial conditions)**.** *The map ν is a bijection from $\mathcal{S}$ onto $\{0, \dots, 323\}$. The index pair is encoded reversibly by $324\nu_+ + \nu_\times \in \{0, \dots, 104\,975\}$.*

Proof. Division by four recovers

$$\mathrm{ind}(d) = [\nu]_4, \qquad j = [\lfloor \nu/4 \rfloor]_9, \qquad i = \lfloor \nu/36 \rfloor.$$

The domain bounds guarantee that these three quantities belong to their index sets and reconstruct ν through (1.44). For the pair, Euclidean division by 324 recovers quotient ν_+ and residue $\nu_\times$. □

The enumeration traverses the complete domain before any regional grouping. The indices are used to locate the preimages of an emission, keeping explicit the condition that produced each trajectory.

1.3.3 Evaluation of the sheets and arithmetic register

At a positive position (a, b), the integer evaluations are $A_+(a, b) = a + b$ and $A_\times(a, b) = ab$. For $n > 0$, one maintains

$$\rho_9(n) = 1 + [n - 1]_9, \qquad q_9(n) = \lfloor (n - 1)/9 \rfloor, \qquad n = \rho_9(n) + 9q_9(n). \tag{1.45}$$

Additive activation incorporates $\rho_9(A_+)$ into the corresponding accumulator. Multiplicative activation uses an observable of the residue $\rho_9(A_\times)$, defined below.

1.3.3.1 Discrete exponent in the units modulo nine

The powers of 2 modulo 9 traverse

$$2^0, 2^1, \dots, 2^5 \equiv 1, 2, 4, 8, 7, 5 \pmod 9, \qquad 2^6 \equiv 1 \pmod 9.$$

The discrete logarithm in this group of six units is represented by

$$\ell_9(1) = 0, \quad \ell_9(2) = 1, \quad \ell_9(4) = 2, \quad \ell_9(8) = 3, \quad \ell_9(7) = 4, \quad \ell_9(5) = 5. \tag{1.46}$$

The emission law extends the observable through $\ell_9(3) = \ell_9(6) = \ell_9(9) = 0$. To preserve its provenance, the recorded sample includes the original residue and the indicator of membership in the group of units. In this way, an observed value of zero can come from the unit 1 or from one of the three noninvertible residues, and its origin remains recoverable.

1.3.3.2 Order of reading and movement

Evaluations are performed at the positions preceding the transition. If $\epsilon_t = +1$, the additive reading is accumulated and its cursor is moved. If $\epsilon_t = -1$, the multiplicative discrete exponent is accumulated and the second cursor is moved. If $\epsilon_t = 0$, the neutral counter is incremented and both positions are preserved.

At the end of steps 27 and 54, both directions are replaced by their opposites. The windows are chained together while preserving positions and orientations. At the start of each window only its three local accumulators are reset to zero; the previous register remains available.

Proposition 1.34 (Inversion of lifted transport)**.** *Let $a, b \in \{0, 1\}$ be the activation and inversion indicators of a cursor. If* opp *interchanges $N \leftrightarrow S$ and $E \leftrightarrow O$, the transformation*

$$F_{a,b}(z, d) = \left(z + a v_d, \mathrm{opp}^b(d)\right)$$

has an inverse

$$F_{a,b}^{-1}(z', d') = \big(z' - av_{\mathrm{opp}^b(d')}, \mathrm{opp}^b(d')\big).$$

Spatial reduction modulo nine intertwines this transformation with finite transport.

Proof. Applying opposition twice recovers the initial direction. Once that direction is recovered, subtracting av_d undoes the displacement. For spatial projection, the equality $[z + av_d]_9 = [[z]_9 + av_d]_9$ suffices, component by component. Direction inversion preserves this equality. □

The phase determines the indicators used by the inverse. The spatial and arithmetic registers can thus be preserved together, even when crossing the boundary of the representative I_9^2.

1.3.4 Six windows and decimal emission by blocks

1.3.4.1 Accumulation in a nonadic window

Window m, with $1 \le m \le 6$, comprises the steps $9m - 8, \dots, 9m$. Let S_m be the sum of its active positive additive residues, E_m the sum of its active discrete exponents and Z_m its number of neutral events.

Lemma 1.35 (Activation multiplicities)**.** *Each window contains three additive activations, three multiplicative activations and three neutral activations. In particular, $Z_m = 3$.*

Proof. The phases of a window traverse exactly $1, \dots, 9$. Each of the three sets of (1.39) has cardinality three. □

The six windows form 54 transitions and produce six blocks. This length belongs to the initial emitter defined here. Continuation in depth subsequently acts on the words and their compatible registers.

1.3.4.2 Decimal encoding rule

The emission law specifies the digits

$$\begin{aligned} d_{m,1} &= [S_m]_{10}, \\ d_{m,2} &= [S_m + E_m]_{10}, \\ d_{m,3} &= [3S_m + 5E_m + 7Z_m]_{10}, \\ U_m &= 100d_{m,1} + 10d_{m,2} + d_{m,3}. \end{aligned} \tag{1.47}$$

The weights $100, 10, 1$ are the hundreds, tens and units positions. The subscript 10 indicates the decimal residue, and each block satisfies $0 \le U_m \le 999$. The emitted word is the ordered sequence $\mathbf{U} = (U_1, \dots, U_6)$, with a fixed width of three digits per block.

The coefficients $3, 5, 7$ constitute the explicit weights of this emission law. Once the rule is fixed, each digit is calculated from the accumulators, and the results of this chapter follow from that rule. The number 1 appearing in its reduced form has a specific additional provenance: $7Z_m = 21 \equiv 1 \pmod{10}$.

If $s_m = [S_m]_{10}$ and $e_m = [E_m]_{10}$, one obtains

$$G(s_m, e_m) = 100s_m + 10[s_m + e_m]_{10} + [3s_m + 5e_m + 1]_{10} = U_m. \tag{1.48}$$

The letter e_m here denotes a component of the discrete-exponent signature. Its definition belongs to the finite emitter.

Proposition 1.36 (Recovery of the two signatures)**.** *The map $G : \{0, \dots, 9\}^2 \to \{0, \dots, 999\}$ is injective. For a block $U = 100a + 10b + c$ in its image, the inverse is*

$$s = a, \qquad e = [b - a]_{10}, \qquad c = [3s + 5e + 1]_{10}.$$

Consequently, the word **U** *determines the two six-component signatures* **s** *and* **e**.

Proof. The last two summands of (1.48) belong to $\{0, \dots, 99\}$, so the hundreds digit recovers s. The tens digit is $[s+e]_{10}$; subtracting s and reducing modulo ten recovers e. The units digit verifies the third congruence. Reconstruction is applied independently to the six positions of the word. □

The integer totals S_m, E_m are recovered from the recorded readings; the hundreds and tens digits recover their residues. For example, a total $S_m = 15$ produces $s_m = 5$. This difference identifies exactly what information each level of encoding preserves.

1.3.4.3 Positional encoding of the six-block word

The six blocks admit a fixed-width integer encoding,

$$\mathcal{N}(\mathbf{U}) = \sum_{m=1}^{6} U_m 1000^{6-m}, \qquad 0 \le \mathcal{N}(\mathbf{U}) < 1000^6. \tag{1.49}$$

The first block occupies the highest-weight position and the sixth, the units position in base one thousand. A block 058 occupies a complete position with integer value 58; its three-digit width is part of the decimal presentation of that position.

Proposition 1.37 (Positional recovery of emissions)**.** *The encoding* (1.49) *determines the complete word through*

$$U_m = \left[\left\lfloor \frac{\mathcal{N}(\mathbf{U})}{1000^{6-m}} \right\rfloor \right]_{1000}, \qquad 1 \le m \le 6.$$

Proof. Upon division by 1000^{6-m}, the earlier blocks produce integer multiples of 1000, block m produces U_m, and the contribution of later blocks belongs to $[0, 1)$. The integer part eliminates this last contribution and the residue modulo 1000 eliminates the earlier ones. □

This encoding preserves the six emissions. Its domain has ordered positions in base one thousand, whereas the APP domain has spatial positions modulo nine. The composition maintains both indices: m identifies an emission window and (i, j) identifies the cell visited during a transition in that window.

1.3.5 Complete calculation of an emission beginning with 501

The initial conditions are fixed

$$c_{+,0} = (0, 4; N), \qquad c_{\times,0} = (2, 3; N), \qquad \nu_+ = 16, \quad \nu_\times = 84.$$

The initial positive positions are $(1, 5)$ and $(3, 4)$. The preceding chronological index is $t = 0$, the first phase read is $g_1 = 1$ and the register is empty. These coordinates are the inputs to the calculation; the blocks are obtained by executing the recurrence.

The three active additive evaluations are

$$1 + 5 = 6, \qquad 9 + 5 = 14 = 5 + 9, \qquad 8 + 5 = 13 = 4 + 9,$$

so that $S_1 = 6 + 5 + 4 = 15$. The three active multiplicative evaluations are $3 \cdot 4 = 12$, $2 \cdot 4 = 8$ and $1 \cdot 4 = 4$. Their positive residues are $3, 8, 4$, with observables $0, 3, 2$; therefore, $E_1 = 5$. Finally $Z_1 = 3$. The decimal rule gives

$$d_{1,1} = [15]_{10} = 5, \quad d_{1,2} = [15 + 5]_{10} = 0, \quad d_{1,3} = [45 + 25 + 21]_{10} = 1,$$

and one obtains $U_1 = 501$.

The second additive reading above has arithmetic quotient 1, while its lifted cursor is at $(-1, 4; N)$, with vertical turn count -1. These are two different data in the same register. Both enter into the full recovery of the evaluation and its position.

Table 1.13: First window: preceding readings and active accumulation.

t	ϵ_t	position +	position ×	ΔS	ΔE	(S, E, Z)
1	+1	(1, 5)	(3, 4)	6	0	(6, 0, 0)
2	−1	(9, 5)	(3, 4)	0	0	(6, 0, 0)
3	0	(9, 5)	(2, 4)	0	0	(6, 0, 1)
4	+1	(9, 5)	(2, 4)	5	0	(11, 0, 1)
5	−1	(8, 5)	(2, 4)	0	3	(11, 3, 1)
6	0	(8, 5)	(1, 4)	0	0	(11, 3, 2)
7	+1	(8, 5)	(1, 4)	4	0	(15, 3, 2)
8	−1	(7, 5)	(1, 4)	0	2	(15, 5, 2)
9	0	(7, 5)	(9, 4)	0	0	(15, 5, 3)

The positions are positive labels of the cells before movement. Neutral events increment only Z.

Table 1.14: The six windows of the initial condition (16, 84).

m	steps	S_m	E_m	Z_m	s_m	U_m	$[-U_m]_3$
1	1–9	15	5	3	5	501	0
2	10–18	6	5	3	6	614	1
3	19–27	24	5	3	4	498	0
4	28–36	21	5	3	1	169	2
5	37–45	12	5	3	2	272	1
6	46–54	12	5	3	2	272	1

The resulting word and its signatures are

$$\mathbf{U} = (501, 614, 498, 169, 272, 272),$$
$$\mathbf{s} = (5, 6, 4, 1, 2, 2), \qquad \mathbf{e} = (5, 5, 5, 5, 5, 5).$$

The cardinal inversion after step 27 modifies the paths of the last three windows. The repeated block 272 corresponds to two successive windows with their own positions and chronological register.

As a second case, the minimal initial condition $(\nu_+, \nu_\times) = (0, 0)$ produces

$$\mathbf{U} = (252, 109, 252, 903, 850, 850), \quad \mathbf{s} = (2, 1, 2, 9, 8, 8), \quad \mathbf{e} = (3, 9, 3, 1, 7, 7).$$

In this case, both cursors return to their initial position and orientation after 54 transitions. The nonadic phase completes six turns, the chronological counter advances by 54 units and the register contains 54 samples. The positional reading of the return and the recorded history describe distinct properties of the execution.

1.3.6 Factorization of the finite census

The signatures $f_+(\nu) = \mathbf{s}$ and $f_\times(\nu) = \mathbf{e}$ are calculated by executing the corresponding cursor during the six windows. The independence of positions and directions between the two cursors gives

$$T_{\mathrm{em}}(\nu_+, \nu_\times) = G^{(6)}\big(f_+(\nu_+), f_\times(\nu_\times)\big), \tag{1.50}$$

where $G^{(6)}$ applies (1.48) at each position. The factorization allows 324+324 trajectories to be enumerated first and the distinct signatures to be combined afterward, preserving the multiplicity of their preimages.

1.3.6.1 Images of the two signatures

The following tables include all signatures. Their multiplicity is the number of initial conditions producing them; the minimum index locates one of those conditions. The complete preimage is defined by

$$f_\sigma^{-1}(a) = \{\nu \in \{0, \dots, 323\} : f_\sigma(\nu) = a\}.$$

The recurrence of the preceding sections determines each element of this set through a finite integer calculation.

Table 1.15: The eighteen additive signatures.

signature	multiplicity	$\nu_{\min}$	signature	multiplicity	$\nu_{\min}$
122564	18	17	564122	18	16
122898	18	24	645212	18	4
212645	18	5	654889	18	33
212988	18	0	889221	18	13
221456	18	29	889654	18	32
221889	18	12	898122	18	25
456221	18	28	898465	18	20
465898	18	21	988212	18	1
546988	18	9	988546	18	8

Table 1.16: The twenty-six multiplicative signatures.

signature	multiplicity	$\nu_{\min}$	signature	multiplicity	$\nu_{\min}$
000000	108	8	555555	24	84
177393	8	1	555717	8	14
177555	8	54	555771	8	18
177771	8	11	555933	8	24
339555	8	6	717555	8	12
339771	8	15	717717	8	21
339933	8	59	717933	8	19
393177	8	0	771177	8	9
393393	8	45	771339	8	13
393555	8	40	771555	8	16
555177	8	52	933339	8	57
555339	8	4	933555	8	26
555393	8	41	933717	8	17

Proposition 1.38 (Image and multiplicities of the emitter)**.** *The image* $\mathcal{U}_6 = \operatorname{im} T_{\mathrm{em}}$ *contains* 468 *distinct words. Their preimages are distributed among* 432 *fibers of cardinality* 144*,* 18 *of cardinality* 432 *and* 18 *of cardinality* 1944*.*

Proof. The exhaustive evaluation of the algorithm in section 1.3.9 over the indices $0, \dots, 323$ gives the two preceding tables. The first partition has 18 classes of cardinality 18, and the second 24 classes of cardinality 8, one of cardinality 24 and one of cardinality 108. The sums $18 \cdot 18 = 324$ and $24 \cdot 8 + 24 + 108 = 324$ check the total mass of both partitions. Proposition 1.36 makes the coupling of their images injective; therefore, there are $18 \cdot 26 = 468$ emissions. By (1.50), the preimage of a pair of signatures is the product

of their two preimages. One obtains $18 \cdot 24 = 432$ products of cardinality $18 \cdot 8 = 144$, 18 of cardinality $18 \cdot 24 = 432$ and 18 of cardinality $18 \cdot 108 = 1944$. Finally,

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

The enumerative part is an exact finite check of the recurrence; the factorization explains why that count covers all pairs. □

The emission in example 1.3.5 has a fiber of cardinality $18 \cdot 24 = 432$. The example with indices $(0, 0)$ has a fiber of cardinality $18 \cdot 8 = 144$. In both cases the emitted word recovers the signatures, while identifying a particular initial condition uses its index or its trajectory register.

1.3.7 Oriented ternary reading and preservation of fibers

The oriented reduction acts separately on each block:

$$\Psi : \mathcal{U}_6 \longrightarrow \mathbb{F}_3^6, \qquad \Psi(U_1, \ldots, U_6) = ([-U_1]_3, \ldots, [-U_6]_3). \tag{1.51}$$

Its sign fixes an orientation of the catalog. The balanced identification $0 \mapsto 0$, $1 \mapsto +1$, $2 \mapsto -1$ is applied afterward, component by component.

Modulus nine organizes the APP evaluations and positions; residues modulo ten form each digit; base one thousand brings together three decimal positions; modulus three determines the ternary signature of each block. These four uses have defined objects and functions. In particular, Ψ reads six blocks and produces six trits; a positional conversion of the integer formed by eighteen digits would be another operation.

For the two calculated conditions one obtains

$$\Psi(501, 614, 498, 169, 272, 272) = (0, 1, 0, 2, 1, 1),$$
$$\Psi(252, 109, 252, 903, 850, 850) = (0, 2, 0, 0, 2, 2).$$

The decimal emitter is defined before this reduction. The function of Ψ is to produce the ternary object on which orbital symmetry and regional selectors act. That function explains its position in the genealogy: it links an already calculated emission to a structural classification.

The image $\mathcal{W}_6 := \Psi(\mathcal{U}_6)$ contains exactly 243 words within the ambient set of $3^6 = 729$ words. Enumeration by the final algorithm gives the histogram

$\lvert\Psi^{-1}(w)\rvert$	1	2	3	4	5	6
number of words w	132	66	18	3	6	18.

(1.52)

The sums of both readings are

$$132 + 66 + 18 + 3 + 6 + 18 = 243, \qquad 132 + 2 \cdot 66 + 3 \cdot 18 + 4 \cdot 3 + 5 \cdot 6 + 6 \cdot 18 = 468.$$

The first counts ternary words; the second recovers the number of emissions distributed among their fibers.

Example 1.39 (Two emissions with the same ternary signature)**.** The emissions

$$(498, 501, 614, 252, 252, 109), \qquad (870, 810, 923, 252, 252, 109)$$

are distinct and both have image $(0, 0, 1, 0, 0, 2)$ under Ψ. Each has 144 initial conditions. The ternary word preserves a reading class; the emissions and their preimages distinguish the data that converge in that class.

Preservation of fibers is expressed concretely by

$$\mathcal{F}_w = \{\mathbf{U} \in \mathcal{U}_6 : \Psi(\mathbf{U}) = w\}, \qquad \Omega_{\mathbf{U}} = T_{\mathrm{em}}^{-1}(\mathbf{U}).$$

Therefore, the complete preimage of w in the initial domain is the disjoint union of the sets $\Omega_{\mathbf{U}}$, with $\mathbf{U} \in \mathcal{F}_w$. The enriched register can preserve the emission, its signatures and the initial condition together with its ternary reading. The exact inverse then refers to the recorded datum with its type; the isolated six-trit word maintains the precise scope of (1.51).

1.3.8 Dihedral action and the forty-three orbits

On six coordinates the permutations are defined

$$r(u_1, u_2, u_3, u_4, u_5, u_6) = (u_3, u_1, u_2, u_5, u_6, u_4), \tag{1.53}$$

$$s(u_1, u_2, u_3, u_4, u_5, u_6) = (u_4, u_5, u_6, u_1, u_2, u_3). \tag{1.54}$$

The first rotates the two groups of three coordinates in conjugate directions; the second interchanges the two groups. Their composition satisfies $r^3 = s^2 = 1$ and $srs = r^{-1}$. They thus generate an action of the dihedral group D_3, with six elements.

Proposition 1.40 (Equivariance and stability of the catalog)**.** *The reduction Ψ commutes with the action of D_3. The sets $\mathcal{U}_6$ and $\mathcal{W}_6$ are stable under its generators.*

Proof. The equality $\Psi(g\mathbf{U}) = g\Psi(\mathbf{U})$ is verified in each coordinate because g permutes positions and Ψ applies the same reduction to each position. Catalog stability constitutes another check: when generating its 468 elements through (1.50), one verifies that $r\mathbf{U}$ and $s\mathbf{U}$ belong to that set again. The algorithm in section 1.3.9 performs these membership checks. Equivariance then transmits stability to its ternary image. □

Proposition 1.41 (Complete orbital decomposition)**.** *The set $\mathcal{W}_6$ decomposes into* 43 *orbits:* 38 *of cardinality six and* 5 *of cardinality three.*

Proof. For each $w \in \mathcal{W}_6$ one forms

$$O(w) = \{w, rw, r^2w, sw, srw, sr^2w\}.$$

The lexicographically minimal word in that set is chosen as the representative. Two words have the same representative exactly when they belong to the same orbit. The algorithm generates the list of representatives in table 1.17; their cardinalities sum to $38 \cdot 6 + 5 \cdot 3 = 243$. Since every word in the catalog takes part in this operation and the catalog is stable, the list covers the entire image. □

Orbits inherit integer invariants from their fibers. For each word, $n(w) = |\mathcal{F}_w|$ counts emissions, while

$$M(w) = \sum_{\mathbf{U} \in \mathcal{F}_w} |\Omega_{\mathbf{U}}|$$

counts initial conditions. The symbol census $c(w) = (n_0, n_1, n_2)$ records how many times each ternary class appears. These data, together with the orientation and support of the paths, provide the predicates for subsequent regional selection. The classification thus preserves more information than the form of a representative word.

Table 1.17: Minimal representatives and cardinalities of the forty-three orbits.

representative	cardinality	representative	cardinality	representative	cardinality

1.3.9 Self-contained enumeration and control algorithm

The enumeration uses integers, finite lists and the operations already defined. The following procedure specifies its execution; σ takes the values + and $\times$.

1. For each $\nu = 0, \dots, 323$, recover $(i, j; d)$ through the inverse of (1.44). Initialize an empty list of signatures.
2. For each window $m = 1, \dots, 6$, initialize the accumulator $A = 0$. Traverse $t = 9m - 8, \dots, 9m$, calculating ϵ_t by (1.40).
3. If $\sigma = +$ and $\epsilon_t = +1$, add $\rho_9(i + j + 2)$ to A and update $(i, j) \leftarrow T_d(i, j)$. If $\sigma = \times$ and $\epsilon_t = -1$, add $\ell_9(\rho_9((i + 1)(j + 1)))$ and perform the same transport.
4. Upon completing $t = 27$ or $t = 54$, replace d by its opposite. Upon concluding the window, add $[A]_{10}$ to the signature list. Preserve the position and direction for the next window.
5. Group the 324 indices by equality of their six-component lists. These two groupings give f_+, $f_\times$ and all their preimages.
6. For each pair of distinct signatures, apply $G^{(6)}$. Assign to the emission the product multiplicity of the two preimages. Check signature recovery in each block and the sum of multiplicities 104 976.
7. Apply Ψ to each emission and group by equality of words. Count the 243 values and the multiplicities of (1.52).
8. Apply r, s to each emission and verify membership in the catalog. For each ternary word, form its six dihedral images, remove repetitions and record its lexicographic minimum. Count the 43 orbits and the two sizes in table 1.17.

Execution terminates: the first stage evaluates 648 trajectories of 54 transitions; the second combines 468 pairs of signatures; the third groups a set of 243 words. An additional direct check can execute the 104 976 pairs and check the factorization (1.50); its scope coincides with the same finite domain.

1.3.10 Preservation of the register and function of the seeds

Let $\mathsf{Sample}(q_t)$ be the sample preceding the transition and $\mathcal{M}_t$ the accumulated register. The memory update is

$$\mathcal{M}_{t+1} = \mathcal{M}_t \parallel \mathsf{Sample}(q_t), \tag{1.55}$$

where $\parallel$ denotes ordered concatenation. Induction gives

$$\mathcal{M}_n = \mathcal{M}_0 \parallel (\mathsf{Sample}(q_0), \dots, \mathsf{Sample}(q_{n-1})).$$

The accumulators are reconstructed by summing the active contributions of each segment of nine records. Their quotients, the cursor turns and the orientations remain associated with the same transitions. Execution determines that register through the recurrence; the archive preserves the specific provenance of the readings.

At the end of this stage, the complete domain of initial conditions, the decimal emission, its two recoverable signatures, the ternary image, its fibers and its orbital classification have been constructed. The censuses 104 976, 468, 243, 729 and 43 now have a domain and a mechanism of obtainment. Regional selections will receive these structures with their invariants, and lifts will act on oriented words with their provenance preserved. That continuity makes the finite catalog a constructive antecedent of the coinductive development.

1.4 Nonadic connection, calendar extension and transport memory

TPK chronology combines an observable phase, a dodecaphasic register and a memory of the transitions performed. Their relation is determined by the composition of displacements. Crossing the phase boundary increments a quotient; preserving that quotient distinguishes successive returns. This structure provides the arithmetic basis of nonadic holonomy and its bilateral representation.

It is useful to fix from the outset the three objects involved. The phase belongs to a cycle of nine positions. The finite calendar retains twelve turns of that cycle. The enriched history additionally preserves the integer number of turns and the registers of position, orientation, sheet, carry and boundary. Each reduction preserves a specific observation of the same evolution; the available information is specified through its projections.

1.4.1 Incidence of arithmetic modes

1.4.1.1 Selection, persistence and cyclic succession

Let Σ and Π be the modes corresponding to the additive and multiplicative APP evaluations. In each block of three events, the phase selector traverses the sequence $(+1, -1, 0)$. Its action on mode m is

$$+1 : m \longmapsto \Sigma, \qquad -1 : m \longmapsto \Pi, \qquad 0 : m \longmapsto m.$$

The neutral event preserves the preceding mode. Starting from the cyclic closure of the block, the three recorded modes are therefore

$$(\Sigma, \Pi, \Pi).$$

The third position preserves the multiplicative-mode label selected in the preceding event. In the emitter, that neutral event increments only the counter Z. This distinction allows the incidence to be constructed directly from the calendar transitions.

Proposition 1.42 (Modal incidence of the tritic block)**.** *Counting the consecutive pairs of the block, including its closure, and ordering the modes as* (Σ, Π) *gives*

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{1.56}$$

In a sequence of $3q$ events consisting of q repetitions of the block, the transition count is qF_{av}.

Proof. The ordered pairs are $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$. Each appears once; $\Sigma \to \Sigma$ appears zero times. These are, respectively, the upper-right, lower-right, lower-left and upper-left entries of the matrix. Each repetition adds exactly the same three pairs, including the link from the last mode of one block to the first of the next. The sum of the counts is qF_{av}. □

The lengths 9, 27 and 108 thus produce $3F_{\mathrm{av}}$, $9F_{\mathrm{av}}$ and $36F_{\mathrm{av}}$. These matrices count events of an already fixed periodic itinerary. The powers of F_{av} count concatenations admitted by its incidence. These are two distinct mathematical operations on the same matrix: summation of occurrences and composition of transitions.

1.4.1.2 Concatenation of incidences and induced recurrence

Let us define integers $a_0 = 0$, $a_1 = 1$ and $a_{n+1} = a_n + a_{n-1}$ for $n \geq 1$. Their appearance follows from multiplication of the matrix already constructed.

Proposition 1.43 (Powers of modal incidence)**.** *For every $n \geq 1$,*

$$F_{\mathrm{av}}^n = \begin{pmatrix} a_{n-1} & a_n \\ a_n & a_{n+1} \end{pmatrix}, \qquad a_{n-1}a_{n+1} - a_n^2 = (-1)^n.$$

Proof. For $n = 1$, the formula reproduces (1.56) because $a_2 = 1$. If the formula holds for n, multiplication by F_{av} gives

$$\begin{pmatrix} a_n & a_{n-1} + a_n \\ a_{n+1} & a_n + a_{n+1} \end{pmatrix} = \begin{pmatrix} a_n & a_{n+1} \\ a_{n+1} & a_{n+2} \end{pmatrix}.$$

Induction proves the first identity. Taking determinants and using $\det F_{\mathrm{av}} = -1$ gives the second. □

In particular, $F_{\mathrm{av}}^2 = F_{\mathrm{av}} + I$. This identity allows a hyperbolic generator to be normalized through

$$J_{-1} = \frac{2F_{\mathrm{av}}^2 - 3I}{\sqrt{5}} = \frac{2F_{\mathrm{av}} - I}{\sqrt{5}}, \qquad J_{-1}^2 = I. \tag{1.57}$$

Indeed, $(2F_{\mathrm{av}} - I)^2 = 4(F_{\mathrm{av}} + I) - 4F_{\mathrm{av}} + I = 5I$. The coefficient 5 comes here from the matrix identity. The quadratic representation and Euler extension use this generator after its modal construction.

The recurrence (a_n) subsequently admits identification with the Fibonacci sequence. The proof order in this subsection is explicit: tritic selector, sequence of modes, edge count, incidence and recurrence. Identification of the sequence preserves that order. Coinductive regional generation also has its own emitters, filters, lifts and survival conditions; the modal recurrence specifies one of its structural realizations.

1.4.2 Arithmetic extension of the calendar

1.4.2.1 Decomposition into phase and dodecaphasic position

We write $C_q = \mathbb{Z}/q\mathbb{Z}$ for the additive group of residues modulo q. The position of a calendar of $108 = 12 \cdot 9$ events has a unique decomposition

$$t = 9b + r, \qquad 0 \leq b < 12, \quad 0 \leq r < 9,$$

for the representative $0 \leq t < 108$. The coordinate r is the nonadic phase; b identifies the position of the turn in the dodecaphasic register. The scale 108 brings those two registers together according to the law of composition with carry.

Theorem 1.44 (Calendar extension with carry)**.** *The maps*

$$\iota : C_{12} \longrightarrow C_{108}, \quad [b] \longmapsto [9b], \qquad p : C_{108} \longrightarrow C_9, \quad [t] \longmapsto [t]_9$$

determine an exact sequence

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0. \tag{1.58}$$

In the coordinates (b, r)*, addition is given by*

$$(b, r) \oplus (b', r') = \left(\left[b + b' + \left\lfloor \frac{r + r'}{9} \right\rfloor \right]_{12}, [r + r']_9 \right). \tag{1.59}$$

This extension has no homomorphic section.

Proof. The equality $[9b] = 0$ in C_{108} is equivalent to $12 \mid b$, so ι is injective. The map p is surjective and its kernel consists exactly of the classes that are multiples of nine, the image of ι. This demonstrates exactness.

To add two representatives, one writes

$$9b + r + 9b' + r' = 9 \left(b + b' + \left\lfloor \frac{r + r'}{9} \right\rfloor \right) + [r + r']_9.$$

Reducing the first coefficient modulo twelve gives (1.59). Now suppose that a homomorphic section $s : C_9 \to C_{108}$ exists. The representative a of $s([1])$ satisfies $a \equiv 1 \pmod 9$ and $9a \equiv 0 \pmod{108}$. The second condition implies $12 \mid a$, whence $a \equiv 0 \pmod 3$; the first implies $a \equiv 1 \pmod 3$. The contradiction demonstrates the last assertion. □

1.4.2.2 Cocycle, inverse and restitution

The term

$$\kappa_9(r, s) = \left\lfloor \frac{r + s}{9} \right\rfloor, \qquad 0 \le r, s < 9,$$

records the threshold crossing. Its composition identity is

$$\kappa_9(r, s) + \kappa_9([r + s]_9, u) = \kappa_9(s, u) + \kappa_9(r, [s + u]_9). \tag{1.60}$$

Both sides are $\lfloor (r + s + u)/9 \rfloor$: it suffices to substitute $r + s = 9\kappa_9(r, s) + [r + s]_9$, or the analogous decomposition of $s + u$. The identity ensures that the accumulated quotient is independent of the parenthesization of three summands.

The inverse of (b, r) is determined by

$$-(b, r) = \begin{cases} ([-b]_{12}, 0), & r = 0, \\ ([-b - 1]_{12}, 9 - r), & 1 \le r < 9. \end{cases}$$

The additional term -1 represents the exact boundary correction when inverting an interior residue. For example, the representative $t = 17$ has coordinates $(1, 8)$. Its inverse is $(-2, 1)$ in coordinates with first component modulo twelve: $9(-2) + 1 = -17$. The inverted residue and the corrected quotient jointly restore the opposite integer.

1.4.3 Integer lift and nonadic holonomy

1.4.3.1 Finite phase and turn counter

Euclidean division extends to every $k \in \mathbb{Z}$:

$$k = 9m + r, \qquad m = \left\lfloor \frac{k}{9} \right\rfloor, \quad 0 \le r < 9.$$

The pair (m, r) determines k exactly. Its reduction $(m, r) \mapsto ([m]_{12}, r)$ recovers the finite calendar. In the integer lift, a turn of nine steps acts by

$$(r, m) \longmapsto (r, m + 1). \tag{1.61}$$

Twelve turns restore both finite coordinates and shift the integer counter by twelve units. Enriched memory includes that counter together with the ordered register of transitions.

1.4.3.2 Composition of admissible prolongations

At level k, we represent the enriched regional state by

$$\widehat{x}_k = (B_k, C_k, p_k, c_k, \Sigma_k, W_k, g_k, m_k).$$

B_k brings together the regional blocks; C_k is the compatible cylinder; p_k is the prefix; c_k records the carry; Σ_k preserves the boundary and W_k the incidence. The last coordinates are the phase and the turn counter. The prolongation operators act on this complete state, with the dependencies of each component.

Definition 1.45 (Nonadic holonomy of the prolongation system)**.** Let $\mathcal{R}_k \subseteq \widehat{X}_k \times \widehat{X}_{k+1}$ be the admissible relations produced by the TPK. The composition of one turn is

$$\Gamma_{9,k} = \mathcal{R}_{k+8} \circ \cdots \circ \mathcal{R}_k.$$

For $s \ge 1$, the composition of s turns is

$$\Gamma_{9s,k} = \Gamma_{9,k+9(s-1)} \circ \cdots \circ \Gamma_{9,k}.$$

Relational composition retains the prolongations that simultaneously satisfy the constraints of the state. An admissible trajectory singles out a sequence of such transitions. The notation distinguishes the admissibility relation, the chosen trajectory and the finite observation of its phase.

Proposition 1.46 (Phase return and memory advance)**.** *On a trajectory whose turn rule is $g_{k+9} = g_k$, $m_{k+9} = m_k + 1$, every admissible composition of s turns satisfies*

$$g_{k+9s} = g_k, \qquad m_{k+9s} = m_k + s, \qquad [m_{k+9s}]_{12} = [m_k + s]_{12}.$$

Proof. The case $s = 1$ is the turn rule. Composing an additional turn with the trajectory already constructed preserves the phase and the counter receives another unit. Induction demonstrates the first two equalities; projection modulo twelve gives the third. □

The register allows each return to be recognized as a transformation of history. The observable phase expresses a periodicity, while the counter and boundary coordinates distinguish its successive realizations. The regional prolongation proofs additionally specify which cylinders survive and which prefixes are determined.

1.4.4 Bilateral representation of phase transport

1.4.4.1 Unit shift and group of turns

The lift of the index admits a representation in $\mathcal{H}_{\mathrm{ind}} = \ell^2(\mathbb{Z})$. Its orthonormal basis is written $e_k = e_{r,m}$ when $k = 9m + r$. We define $Te_k = e_{k+1}$, that is,

$$Te_{r,m} = \begin{cases} e_{r+1,m}, & r < 8, \\ e_{0,m+1}, & r = 8. \end{cases}$$

The transformation bijectively permutes an orthonormal basis and extends by continuity to a unitary operator. The inverse takes $e_{r,m}$ to $e_{r-1,m}$ when $r > 0$ and takes $e_{0,m}$ to $e_{8,m-1}$.

Theorem 1.47 (Faithful representation of the turn counter)**.** *Let $S = T^9$. Then*

$$S^s e_{r,m} = e_{r,m+s}, \qquad s \in \mathbb{Z}.$$

The map $s \mapsto S^s$ is a faithful unitary representation of $(\mathbb{Z}, +)$.

Proof. Nine steps preserve the residue and increase the quotient by one unit. The same identity applied to the inverse provides the formula for negative exponents. The powers satisfy $S^{s+t} = S^s S^t$. If $S^s = I$, the equality $e_{r,m+s} = e_{r,m}$ forces $s = 0$ by independence of the basis vectors. This proves faithfulness. □

The index space is a realization of the counter. The TPK state space also incorporates the arithmetic and incidence data. Unitary inversion of the index applies to its bilateral covering; inversion of a complete transition uses the archive of that transition and its admissibility conditions.

1.4.4.2 Memory operator and boundary correction

Let us define, on finitely supported vectors,

$$D_M e_k = \left\lfloor \frac{k}{9} \right\rfloor e_k, \qquad \mathcal{I} e_k = e_{-k}, \qquad P_0 e_k = \begin{cases} e_k, & 9 \mid k, \\ 0, & 9 \nmid k. \end{cases}$$

This domain is dense and stable under the operations considered.

Proposition 1.48 (Memory and inversion identities)**.** *On that domain the following hold*

$$[D_M, S] = S, \qquad \mathcal{I}T\mathcal{I} = T^{-1}, \qquad \mathcal{I} D_M \mathcal{I} = -D_M - (I - P_0). \tag{1.62}$$

Proof. If $k = 9m + r$, then $D_M S e_k = (m + 1)e_{k+9}$ and $S D_M e_k = m e_{k+9}$, which proves the commutator. The composition $\mathcal{I}T\mathcal{I}$ takes e_k to e_{k-1}. Finally,

$$\left\lfloor \frac{-k}{9} \right\rfloor = \begin{cases} -m, & r = 0, \\ -m - 1, & r > 0. \end{cases}$$

The diagonal action of the last member of (1.62) coincides with that expression on each basis vector. Linearity concludes the proof. □

The correction $I - P_0$ locates the boundary contribution in the interior phases. When the path is inverted, the quotient and residue are transformed jointly. That identity expresses arithmetically the information that disappears when only the phase is observed.

1.4.5 Refinement capacity and arithmetic vacancies

1.4.5.1 Exact comparison of ternary and decimal blocks

A block of six trits has $3^6 = 729$ configurations in its ambient space. A decimal block of three digits has $10^3 = 1000$ positions. Their cardinalities define an arithmetic encoding capacity. For $n \geq 0$, let

$$C_n = \max\{a \in \mathbb{N} : 1000^a \leq 729^{n+1}\}. \tag{1.63}$$

The definition compares integers and can be evaluated exactly. In a subsequent logarithmic representation,

$$\rho = \log_{1000} 729 = \log_{10} 9, \qquad \delta = 1 - \rho, \qquad C_n = \lfloor (n+1)\rho \rfloor.$$

The ratio ρ belongs to $(0, 1)$ and is irrational. If $\rho = p/q$ with positive integers, one would have $10^p = 9^q$; the prime factorization of the two sides prevents this.

Definition 1.49 (Register of capacity vacancies)**.** We define

$$Z_n = \lfloor (n+1)\delta \rfloor, \qquad z_n = \lfloor (n+1)\delta \rfloor - \lfloor n\delta \rfloor, \quad n \geq 0.$$

The value $z_n \in \{0, 1\}$ records capacity retention at the corresponding step. One has $z_0 = 0$ at the chosen origin.

Theorem 1.50 (Balance of capacity and vacancies)**.** *For $n \geq 0$ in the first identity and $n \geq 1$ in the second,*

$$C_n + Z_n = n, \qquad C_n - C_{n-1} = 1 - z_n. \tag{1.64}$$

In particular, for $0 \leq a < b$,

$$C_b - C_a + \sum_{n=a+1}^{b} z_n = b - a.$$

Proof. The irrationality of δ implies $\lceil (n+1)\delta \rceil = \lfloor (n+1)\delta \rfloor + 1$. Therefore,

$$\lfloor (n+1)(1-\delta) \rfloor = n + 1 - \lceil (n+1)\delta \rceil = n - Z_n.$$

The difference between two consecutive equalities gives the second identity for $n \geq 1$. The telescoping sum demonstrates the formula on an interval. □

The register Z_n can be obtained through $n - C_n$, using only the integer comparison (1.63). The logarithmic functions express the same construction in analytic coordinates. The first capacity retention occurs between $n = 20$ and $n = 21$:

$$C_{19} = 19, \quad C_{20} = 20, \quad C_{21} = 20, \quad C_{22} = 21.$$

The history receives an additional block while decimal capacity remains constant. The vacancy records precisely that offset.

1.4.5.2 Distinguishing the operational indices

The phase of the finite emitter, the regional prolongation phase and decimal capacity belong to declared indices. The nonadic connection preserves the phase after nine steps of its own index; vacancy preserves a capacity during one step of the block index. The comparison between the two is expressed by

$$[C_n]_q = \big[[n]_q - [Z_n]_q \big]_q, \qquad q = 9 \text{ or } 108.$$

The phase offset depends on the accumulated vacancy register. Preserving it allows one phase reading to be transformed into the other without improperly identifying the two calendars.

The resulting structure links modal selection, carry composition, holonomy and refinement. Memory fulfills precise functions at each level: it restores quotients, distinguishes turns, records transitions and controls encoding capacity. These operations constitute the temporal and archival support on which regional readers and realizations of unit conservation act.

1.5 APP: support, operations, and paths

The acronym APP derives from *All Possible Paths*. It designates a single path structure on a finite arithmetic support: the underlying graph has eighty-one vertices, whereas the set of finite paths, taken over all lengths, is countable. Its principal arithmetic matrix is the nonadic multiplication table. Addition is the internal law whose accumulation generates each row and each column of that table, and it also acts as a comparison observable on the same support. APP thus brings together addition, multiplication, and path composition before the ternary projection or the Archimedean evaluation is performed. The following definition exhaustively fixes the universe of paths under consideration.

1.5.1 Domain, generators and preformal relations of the APP support

The support of APP is a finite arithmetic torus: each of its two coordinates ranges over the nine residue classes and returns to its origin after nine unit translations. Its eighty-one points are therefore pairs of classes modulo nine. The associated Cayley graph preserves this cyclic structure: a vertex represents a position, an oriented edge represents a unit cardinal displacement, and a finite sequence of edges represents a path. Thus, *all possible paths* denotes the set of finite cardinal words with an initial point on the torus.

Each vertex simultaneously receives two arithmetic evaluations. The *additive sheet* publishes the sum of its two coordinates, and the *multiplicative sheet* publishes their product. The term *sheet* here designates an evaluation of the same point and the same path; APP preserves a single support and two functions upon it.

The operative difference between the two sheets is exact. In a row or column, addition acts by translation and repeatedly accumulates the same increment. Multiplication by a unit also permutes the classes; multiplication by a zero divisor folds several classes onto one and the same residue. To preserve the information that this folding conceals, APP lifts each evaluation to its residue–quotient coordinates:

$$i + j = R^{+}_{ij} + 9q^{+}_{ij}, \qquad ij = R^{\times}_{ij} + 9q^{\times}_{ij}.$$

The pairs (R^{+}, q^{+}) and $(R^{\times}, q^{\times})$ recover the integer values prior to reduction. When blocks are concatenated, additive carry κ_9 records the discrepancy between adding integer representatives and first adding their residues; together with both quotients, it makes recovery compositional. Thus, additive accumulation constructs visible trajectories, whereas the residue–quotient lift unfolds the fibers created by multiplicative folding.

For a path $\gamma = (x_0, \ldots, x_r)$, the genealogy visible is the sucesion of positions and pairs of evaluations

$$\mathcal{G}_{\mathrm{vis}}(\gamma) = \big(\gamma; (\Sigma(x_k), \Pi(x_k))_{k=0}^{r}\big).$$

At each step, its enriched genealogy adjoins the quotients, carry, and transported orientation. The enriched–visible projection preserves the path and residues and forgets precisely those memory coordinates. This distinction will be the input to the complete state of TRIT and of the Topological Phase Kernel. The complete domain of (104 976) double-cursor initial conditions and the (468) emission fibers they produce are published in full in the appendix D.1; there each seed is distinguished from the emission to which it belongs, and the multiplicity of the fiber is preserved.

1.5.2 Aritmetic support, translations and observables

Let

$$\mathrm{dr}_9(n) = 1 + ((n-1) \bmod 9) \in \{1, \dots, 9\}.$$

This map chooses the representative 9 for the null class. We define $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$, on which acts the group of translations $(\mathbb{Z}/9\mathbb{Z})^2$, and fix the symmetric set of generators

$$\mathscr{D} = \{(1,0), (0,1), (-1,0), (0,-1)\}.$$

The Cayley graph

$$\Gamma_{\mathrm{APP},9} = \mathrm{Cay}(X_9, \mathscr{D})$$

has 81 vertices and four oriented edges originating at each vertex. An oriented path of length r is a sequence $\gamma = (x_0, \dots, x_r)$ in X_9 such that $x_{k+1} - x_k \in \mathscr{D}$ for every $k < r$. We denote by $\mathrm{Path}(\Gamma_{\mathrm{APP},9})$ the set of all finite paths so defined.

Definition 1.51 (APP Structure)**.** The arithmetic structure of possible paths is the tuple

$$\mathscr{A}_9 = (X_9, \Gamma_{\mathrm{APP},9}, \Sigma, \Pi, \mathrm{Path}(\Gamma_{\mathrm{APP},9})),$$

where the two vertex observables are

$$\Sigma(i,j) = \mathrm{dr}_9(i+j), \qquad \Pi(i,j) = \mathrm{dr}_9(ij), \qquad 1 \le i, j \le 9.$$

Marked cardinal and path words

To make the orientation of the torus explicit, we use coordinates (row, column), with the row increasing southward and the column increasing eastward, and write

$$\delta(N) = (-1,0), \qquad \delta(E) = (0,1), \qquad \delta(S) = (1,0), \qquad \delta(O) = (0,-1).$$

Let $\mathscr{D}_{\mathrm{card}} = \{E, N, O, S\}$, where O denotes west. Given an initial point $x_0 \in X_9$ and a word $w = d_1 \cdots d_r \in \mathscr{D}_{\mathrm{card}}^r$, its trajectory is

$$\gamma(x_0; w)_k = x_0 + \sum_{j=1}^{k} \delta(d_j) \pmod 9, \qquad 0 \le k \le r.$$

The correspondence $(x_0, w) \mapsto \gamma(x_0; w)$ is bijective between $X_9 \times \mathscr{D}_{\mathrm{card}}^r$ and the paths oriented of length r. In particular, existen exactly $81 \cdot 4^r$ paths of that length when it allowed returns and backtracks.

The word w closes in the torus precisely when

$$\#S(w) - \#N(w) \equiv 0 \pmod 9, \qquad \#E(w) - \#O(w) \equiv 0 \pmod 9.$$

For a closed word, the integer displacement computed before reduction modulo nine defines the winding vector

$$\mathrm{wind}(w) = \frac{1}{9}\big(\#S(w) - \#N(w), \#E(w) - \#O(w)\big) \in \mathbb{Z}^2.$$

Reversal of orientation reverses the order of the word, exchanges $E \leftrightarrow O$ and $N \leftrightarrow S$, and transforms $\mathrm{wind}(w)$ into its opposite. This cardinal framework is subsequently transported in the phase kernel and forms part of the definition of each trajectory.

The expressions are written here in the chart of representatives $\{1, \dots, 9\}$. The formula $\widetilde{\Sigma}(i,j) = \mathrm{dr}_9(i+j-1)$ is a translated chart. It represents the same torus only when the translation is also

applied to indices, initial conditions, positional trajectories, and labels. All the following proofs employ $\Sigma(i, j) = \mathrm{dr}_9(i + j)$ and do not alternate both charts.

APP arithmetic matrix
$\Pi(i, j) = \mathrm{dr}_9(ij)$

subconjunto coordenado de la clase nula

Ley interna de acumulación

$$\Pi(i, j) = \mathrm{dr}_9(\underbrace{i + \cdots + i}_{j \text{ sumandos}}) = \mathrm{dr}_9(ij).$$

Addition generates the multiplicative rows and, in the transverse direction, the columns. The observable $\Sigma(i, j) = \mathrm{dr}_9(i + j)$ preserves that elementary law in order to compare both readings at the same point.

$\mathcal{A}_9 = (X_9, \Gamma_{\mathrm{APP},9}, \Pi; \Sigma, \mathrm{Path}(\Gamma_{\mathrm{APP},9}))$
a single APP, one principal matrix, one internal additive law, and four oriented directions N, E, S, O.

Figure 1.1: The unique APP matrix and its internal law. The nonadic multiplication table occupies the main body; each of its rows is generated by additive accumulation. The violet shading indicates the nonunitary rows or columns; the blue line identifies the subset determined by the representative 9 of the null class; the gold frame highlights the central block 2×2.

Every point of X_9 simultaneously receives the product and sum values, but it does not thereby belong to two distinct APP matrices. The paths of $\mathrm{Path}(\Gamma_{\mathrm{APP},9})$ traverse a single support; Π publishes its main table and Σ conserves the internal operation that generates the accumulations and allows its incompatibility to be measured.

Proposition 1.52 (Structure of Rows and Columns)**.** *The matrix of Σ is a Latin square of order nine. The matrix of Π is not; nevertheless, for each $u \in (\mathbb{Z}/9\mathbb{Z})^\times = \{1, 2, 4, 5, 7, 8\}$, the row and column corresponding to u are permutations of the nine residue classes.*

Proof. With i fixed, the map $j \mapsto i + j$ is a translation of $\mathbb{Z}/9\mathbb{Z}$; the same holds when j is fixed. Hence each representative occurs exactly once in every row and column of Σ. For Π, multiplication by u permutes the classes if and only if u is a unit. The rows corresponding to $3, 6, 9$ contain repetitions, so the Latin property does not extend to the entire multiplicative matrix. □

1.5.3 Multiplicative structure of the local ring

Each row of the multiplication table is a repeated sum. Row i accumulates i along one direction; column j accumulates j along the perpendicular direction. Cell (i, j) is the intersection of both accumulations and returns $ij = ji$. The table thus represents product and commutativity through two transverse accumulations on the same lattice.

The second row is

$$2, 4, 6, 8, 1, 3, 5, 7, 9.$$

Before the modular return the even ones appear and after the odd ones. The third row is

$$3, 6, 9, 3, 6, 9, 3, 6, 9,$$

and makes the radical visible. Let

$$R := \mathbb{Z}/9\mathbb{Z}, \qquad \mathfrak{m} := (3) = \{\overline{0}, \overline{3}, \overline{6}\}.$$

Multiplication by three defines

$$M_3 : R \longrightarrow R, \qquad x \longmapsto 3x, \qquad \ker M_3 = \operatorname{im} M_3 = \mathfrak{m}.$$

By the first isomorphism theorem induces a linear identification

$$\overline{M}_3 : R/\mathfrak{m} \xrightarrow{\sim} \mathfrak{m}, \qquad \overline{x} \longmapsto 3x, \tag{1.65}$$

of vector spaces on $\mathbb{F}_3$. No is an isomorphism of rings: $\mathfrak{m}^2 = 0$, whereas the quotient is a field.

In positive representatives, the three phases of (1.65) are

$$369 \longmapsto 693 \longmapsto 936 \longmapsto 369, \tag{1.66}$$

produced by the phase shift $j \mapsto j+1$. The row corresponding to $6 \equiv -3 \pmod 9$ reverses the orientation of the same cycle. This radical orbit must not be conflated with the integer 369 693 100, which will subsequently appear as the digit count of 9^{9^9}.

In direct reduction modulo three,

$$3, 6, 9 \longmapsto 0, 0, 0.$$

If we first extract the factor three and retain its internal coordinate,

$$\eta_{\mathfrak{m}}(3a) = a \bmod 3, \qquad 3, 6, 9 \longmapsto 1, 2, 0.$$

The second map preserves the internal coordinate of the ideal generated by three. It must not be confused with the oriented ternary projection to be defined in the section devoted to the TRIT.

1.5.4 Coordinate subset of the null class

In the graph of the multiplicative observable,

$$\Pi(9, j) = \Pi(i, 9) = 9.$$

The last row and the last column form a union of seventeen positions, all with value nine. They do not constitute an intrinsic boundary of the arithmetic torus: they are the subset of the chart in which at least one coordinate represents the null class by means of 9. There are also four interior null representatives in

$$(3, 3), (3, 6), (6, 3), (6, 6).$$

The figure thus distinguishes this subset from the internal zeros of the nonunital ideal. The additional symbol used later in the cubic completion belongs to an enlarged space and is not identified with any of them.

1.5.5 Residue–quotient extension

Reduction modulo nine preserves the residue and eliminates the quotient of the Euclidean division. To study both components, we define, at each point,

$$i + j = 9q^{+}_{ij} + R^{+}_{ij}, \qquad ij = 9q^{\times}_{ij} + R^{\times}_{ij},$$

where $R^{+} = \Sigma$, $R^{\times} = \Pi$ and the q preserve the quotient. The residue–quotient extension of APP it is denoted by

$$\mathcal{A}^{\#}_{9} = (R^{+}, q^{+}; R^{\times}, q^{\times}).$$

Let $s_9 : \mathbb{Z}/9\mathbb{Z} \to \{1, \dots, 9\}$ be the section of representatives fixed by dr_9. The additive carry associated with this section is

$$\kappa_9(a, b) = \frac{s_9(a) + s_9(b) - s_9(a + b)}{9} \in \mathbb{Z}.$$

Lemma 1.53 (Cocycle Identity of the Carry)**.** *For arbitrary $a, b, c \in \mathbb{Z}/9\mathbb{Z}$,*

$$\kappa_9(a, b) + \kappa_9(a + b, c) = \kappa_9(b, c) + \kappa_9(a, b + c).$$

Proof. Both sides are equal to

$$\frac{s_9(a) + s_9(b) + s_9(c) - s_9(a + b + c)}{9}.$$ □

This cocycle records the discrepancy between summing integer representatives and first summing in the quotient. It is the compositional form of the quotient coordinate that will reappear in base 1000 concatenation.

The gross totals are

$$\sum_{i,j}(i + j) = 9\sum_i i + 9\sum_j j = 2 \cdot 9 \cdot 45 = 810,$$

and

$$\sum_{i,j} ij = \left(\sum_i i\right)\left(\sum_j j\right) = 45^2 = 2025.$$

The visible sums are obtained from the tables:

$$\sum R^+ = 405, \qquad \sum R^\times = 459.$$

Therefore, the total sums of the quotient coordinates are

$$\sum q^+ = \frac{810 - 405}{9} = 45, \qquad \sum q^\times = \frac{2025 - 459}{9} = 174.$$

Decomposition exacta of the difference integrada

$$\boxed{2025 - 810 = 1215 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129.}$$

The difference between the sums of residues is 54, whereas the difference between the sums of quotients is 129. The equality recomposes the total difference between the integer observables and proves that the quotient component contains arithmetic information not determined by the residual class.

1.6 Arithmetic Operators and Local Geometry of the Path Space

1.6.1 Localization of the excess in the nilpotent radical

The group of units of $\mathbb{Z}/9\mathbb{Z}$ is

$$(\mathbb{Z}/9\mathbb{Z})^\times = \{1, 2, 4, 5, 7, 8\},$$

and the maximal ideal is

$$\mathfrak{m} = (3) = \{0, 3, 6\} = \{9, 3, 6\}_{\text{visual}}, \qquad \mathfrak{m}^2 = 0.$$

Each unit row of Π is a permutation of $1, \dots, 9$ and sums to 45. Rows 3 and 6 sum to 54; row 9 sums to 81. Hence

$$459 = 6 \cdot 45 + 2 \cdot 54 + 81$$

and

$$459 - 405 = 2(54 - 45) + (81 - 45) = 54.$$

All the excess is located in the nonunitary sector.

The union of rows and columns $3, 6, 9$ contains 45 cells and sums to 297. Its central square 3×3 sums to $81 = 3 \cdot 27$; the outer arms, to $216 = 3 \cdot 72$. Thus,

$$297 = 216 + 81 = 3(72 + 27) = 3 \cdot 99.$$

The interpretation of 72 and 27 is obtained later from the uniquely selected central block.

1.6.2 Conditional expectation with respect to the projection $\mathbb{Z}/9\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$

The canonical reduction $\mathbb{Z}/9\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ determines the partition

$$C_1 = \{1, 4, 7\}, \qquad C_2 = \{2, 5, 8\}, \qquad C_0 = \{3, 6, 9\}.$$

The uniform conditional expectation averages each observable on the nine points of each block $C_a \times C_b$. The aggregate matrices are

$$M_\Pi = \begin{pmatrix} 4 & 5 & 6 \\ 5 & 4 & 6 \\ 6 & 6 & 9 \end{pmatrix}, \qquad M_\Sigma = \begin{pmatrix} 5 & 6 & 4 \\ 6 & 4 & 5 \\ 4 & 5 & 6 \end{pmatrix}.$$

Since each block contains nine positions,

$$9 \sum_{a,b} (M_\Pi)_{ab} = 459, \qquad 9 \sum_{a,b} (M_\Sigma)_{ab} = 405.$$

Thus, the averaging preserves the totals of both observables and relocates their difference:

$$\sum M_\Pi - \sum M_\Sigma = 51 - 45 = 6, \qquad 9 \cdot 6 = 54.$$

Theorem 1.54 (Spectrum of the aggregated multiplicative operator)**.** *The matrix operator M_Π satisfies*

$$\det M_\Pi = -9$$

and its real spectrum is

$$\operatorname{Spec}(M_\Pi) = \{-1,\ 9 - 6\sqrt{2},\ 9 + 6\sqrt{2}\}.$$

In particular, the associated quadratic form has signature $(2, 1)$.

Proof. The expansion of the determinant gives -9. The characteristic polynomial factors as

$$(\lambda + 1)\big((\lambda - 9)^2 - 72\big).$$

Its roots are those indicated and $9 - 6\sqrt{2} > 0$; therefore, there exist two positive directions and one negative direction. □

The spectral decomposition admits an integral form over an invariant sublattice. For

$$v_- = (1, -1, 0), \qquad v_+ = (1, 1, 0), \qquad v_0 = (0, 0, 1),$$

one has $M_\Pi v_- = -v_-$, whereas the restriction of M_Π to the submodule generated by v_+, v_0 is represented by

$$\begin{pmatrix} 9 & 6 \\ 12 & 9 \end{pmatrix} = 3H, \qquad H = \begin{pmatrix} 3 & 2 \\ 4 & 3 \end{pmatrix} \in SL(2,\mathbb{Z}).$$

The eigenvalues of H are

$$3 \pm 2\sqrt{2} = (1 \pm \sqrt{2})^2.$$

The three vectors v_-, v_+, v_0 generate a sublattice of index two in $\mathbb{Z}^3$, since the determinant of the matrix having them as columns equals -2. Therefore, an integral direct sum of all of $\mathbb{Z}^3$ is not asserted here: on that invariant sublattice, the aggregate operator separates an eigendirection of eigenvalue -1 and a hyperbolic submodule governed by the quadratic unit $3 + 2\sqrt{2}$; over $\mathbb{R}^3$, the spectral decomposition is complete.

1.6.3 Commutator of the arithmetic projectors and separation of their images

The difference between Σ and Π is not reducible to their global sums. For $d \geq 2$, let $\mathscr{A}_d = \{1, \ldots, 9\}^d$, and define

$$\Sigma_d(x) = \mathrm{dr}_9(x_1 + \cdots + x_d), \qquad \Pi_d(x) = \mathrm{dr}_9(x_1 \cdots x_d).$$

In the Hilbert space $\ell^2(\mathscr{A}_d)$, endowed with the uniform measure, let $P_{\Sigma,d}$ and $P_{\Pi,d}$ denote the orthogonal conditional expectations onto the functions measurable with respect to Σ_d and Π_d, respectively. The normalized joint table is

$$C_{ab}^{(d)} = \frac{N_{ab}^{(d)}}{\sqrt{n_a m_b}}, \quad N_{ab}^{(d)} = \#\{x : \Sigma_d(x) = a,\ \Pi_d(x) = b\},$$

where $n_a = \sum_b N_{ab}^{(d)}$ and $m_b = \sum_a N_{ab}^{(d)}$.

On the original two-dimensional support, the exact joint correlation is

$$N^{(2)} = \begin{pmatrix} 0 & 0 & 2 & 0 & 0 & 2 & 3 & 0 & 2 \\ 3 & 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 \\ 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 & 3 \\ 0 & 0 & 2 & 3 & 0 & 2 & 0 & 0 & 2 \\ 0 & 0 & 2 & 3 & 0 & 2 & 0 & 0 & 2 \\ 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 & 3 \\ 3 & 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 \\ 0 & 0 & 2 & 0 & 0 & 2 & 3 & 0 & 2 \\ 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 & 3 \end{pmatrix}.$$

The rows, ordered by the value of Σ, sum to nine; the columns, ordered by the value of Π, sum to $(6, 6, 12, 6, 6, 12, 6, 6, 21)$. Complete enumeration thus determines the joint correlation of the two observables before any subsequent evaluation map is introduced.

Proposition 1.55 (Switches in two and three dimensions)**.** *The two pairs of projectors satisfy*

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

In particular, the additive and multiplicative observables do not induce simultaneously compatible decompositions.

Proof. The singular values s of $C^{(d)}$ are the cosines of the principal angles between the two subspaces. In the corresponding two-dimensional block, the norm of the commutator is $s\sqrt{1 - s^2}$. The exact enumeration of the 9^d words produces, for $d = 2$, the nontrivial eigenvalues

$$s^2 \in \left\{\frac{5}{7}, \frac{1}{3}, \frac{1}{3}\right\}.$$

The maximum of $s^2(1-s^2)$ is $2/9$, whence $\sqrt{2}/3$. For $d = 3$, the same construction gives the maximum $s^2(1-s^2) = 3/16$, attained at $s^2 = 1/4$, and therefore the norm is $\sqrt{3}/4$. In both cases, the commutator is nonzero. □

Proposition 1.56 (Intersection of the observable subspaces)**.** *The exact enumeration of the words of $\mathscr{A}_d$, for $2 \le d \le 15$, verifies*

$$\operatorname{Ran} P_{\Sigma,d} \cap \operatorname{Ran} P_{\Pi,d} = \mathbb{C}\mathbf{1}.$$

In that interval of dimensions, the constant functions constitute the only subspace common to the two arithmetic decompositions.

Proof. For two orthogonal projections, the dimension of the intersection of their ranges coincides with the multiplicity of the singular value 1 in the overlap matrix $C^{(d)}$. The integer computation of the tables $N^{(d)}$, followed by the exact computation of that multiplicity, gives the value one for each $d = 2, \dots, 15$. The constant vector belongs to both ranges; it therefore generates the entire intersection. □

The sequence of norms is not extrapolated from the first two cases. In particular, for $d = 4$ the same calculation gives

$$\|[P_{\Sigma,4}, P_{\Pi,4}]\| = \sqrt{\frac{2618939}{22240656}} \simeq 0.3431538652,$$

which does not coincide with the elementary prolongation $2/(d+1)$. This case constitutes a counterexample to any formula inferred solely from $d = 2, 3$.

1.6.4 Central block and spectral decomposition

The characterization of the central block is obtained by means of a congruence condition. For two consecutive representatives $k, k+1$, consider

$$B_k = \begin{pmatrix} k^2 & k(k+1) \\ k(k+1) & (k+1)^2 \end{pmatrix} \pmod 9.$$

Theorem 1.57 (Uniqueness of the Adjacent Diagonal Block)**.** *There is a unique block B_k whose diagonal entries coincide. It is determined by $k = 4$ and is*

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Proof. The equality of the diagonals is equivalent to

$$k^2 \equiv (k+1)^2 \pmod 9,$$

that is, $2k + 1 \equiv 0 \pmod 9$. Since 2 is a unit of $\mathbb{Z}/9\mathbb{Z}$, the congruence has the unique solution $k \equiv 4 \pmod 9$. □

Therefore, the positions $4, 5$ of the multiplicative observable form

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 7I + 2R, \qquad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad R^2 = I.$$

With $P_\pm = (I \pm R)/2$,

$$B_c = 9P_+ + 5P_-.$$

Theorem 1.58 (Typed hierarchy of the sum-product separation)**.** *The central block has a local spectral gap (9-5=4). Its off-diagonal coefficient is (2). Compression by the three residue classes modulo three produces the aggregate difference (51-45=6), and unfolding across the nine positions produces the global defect*

$$9 \cdot 6 = 459 - 405 = 54.$$

The integers (4), (2), (6), and (54) belong, respectively, to the spectral jump, the local coupling, the modular compression, and the two-dimensional integration.

Proof. The decomposition $B_c = 7I + 2R = 9P_+ + 5P_-$ gives the jump and the local coefficient. The aggregated matrices M_Π, M_Σ constructed above satisfy $\sum M_\Pi = 51$ and $\sum M_\Sigma = 45$. Each aggregated entry represents nine positions, so unfolding multiplies the difference by nine and recovers the totals (459) and (405). □

Their ordered concatenations produce the blocks 72 and 27:

$$72 + 27 = 99, \qquad 72 - 27 = 45 = \det B_c.$$

The concatenation of the diagonal and antidiagonal entries produces, respectively, 77 and 22. Therefore,

$$72 + 27 = 77 + 22 = 99, \qquad 77 - 22 = 55 = 54 + 1.$$

These equalities express two exact partitions of the same block; they do not by themselves identify an external constant.

Proposition 1.59 (Local–global relationship of the radical sector)**.** *The partition by rows of the central block reproduces, with scale factor three, the partition of the radical sector:*

$$3 \cdot 72 = 216, \qquad 3 \cdot 27 = 81, \qquad 3 \cdot 99 = 297.$$

Proof. The block $C_0 \times C_0$ contains nine null representatives and sums to 81. The remaining four arms of the rows and columns of C_0 sum to 216. The identities follow from $72 + 27 = 99$. □

Moreover,

$$M_c := \frac{B_c}{\sqrt{45}} = \exp\left(\frac{1}{2}\log\frac{9}{5}\,R\right) \in SO^+(1,1).$$

If $\eta = \mathrm{diag}(1,-1)$, the normalized matrix M_c satisfies $M_c^{\mathsf{T}}\eta M_c = \eta$, $\det M_c = 1$, and belongs to $SO^+(1,1)$. This finite realization is confined to the constructed block 2×2; its space-time interpretation requires the dimensional bridge developed in the treatise on Dimensional Mechanics.

Proposition 1.60 (Spectral family APP–TRIT and reading Markov–Lorentz local)**.** *For $\tau \in \{-1, 0, +1\}$, let*

$$B_\tau = (4 + 3\tau)I + (5 - 3\tau)R.$$

Then

$$\mathrm{Spec}(B_\tau) = \{9,\ 6\tau - 1\}, \qquad B_\tau = 9P_+ + (6\tau - 1)P_-,$$

and the differential mode recovers the orientation through

$$\tau = \frac{\lambda_- + 1}{6}.$$

In particular, $B_{+1} = B_c$. Its stochastic normalization

$$P_B := \frac{1}{9}B_c = P_+ + \frac{5}{9}P_-$$

satisfies, for all $n \geq 0$,

$$P_B^n = P_+ + \left(\frac{5}{9}\right)^n P_-.$$

Therefore, the contraction of the antisymmetric mode is $\kappa_B = 5/9$ *and the spectral gap of this local chain is* $4/9$. *If*

$$\eta_c := \frac{1}{2}\log\frac{9}{5},$$

the lorentzian normalization of the same block satisfies

$$\frac{B_c}{\sqrt{45}} = \exp(\eta_c R), \qquad \boxed{\frac{5}{9} = e^{-2\eta_c}}.$$

Proof. Since R acts with eigenvalues $+1$ and -1 on $\operatorname{im} P_+$ and $\operatorname{im} P_-$, respectively, the two eigenvalues of B_τ are

$$(4+3\tau)+(5-3\tau) = 9, \qquad (4+3\tau)-(5-3\tau) = 6\tau - 1.$$

The formula for the powers follows from $P_\pm^2 = P_\pm$ and $P_+P_- = 0$. Finally, $e^{-2\eta_c} = e^{-\log(9/5)} = 5/9$. □

This coincidence identifies two exact readings of the local block: the differential memory decreases by the same quotient that encodes the speed in the decomposed realization. It does not turn B_τ into the global Markov kernel of TPK, or $5/9$ into a physical constant. Nor does it by itself extend the realization $SO^+(1,1)$ to a Minkowski space $3+1$: those steps require additional dimensional maps.

1.6.5 Discrete curvature induced by the interaction of the sum and product leaves and its commutation defect

On the torus we write, now in residues,

$$S(x,y) = x + y, \qquad P(x,y) = xy \pmod 9.$$

For every function $T : X_9 \to \mathbb{Z}/9\mathbb{Z}$, we fix the forward differences

$$\Delta_x T(x,y) = T(x+1,y) - T(x,y), \qquad \Delta_y T(x,y) = T(x,y+1) - T(x,y),$$

where the coordinates are taken modulo nine. This convention also fixes the positive orientation of each plaquette: first the direction x is traversed, then the direction y, and one returns along the opposite edges. It is important to type these two objects correctly. S and P are vertex potentials; the link variables are their discrete differences

$$A_x^T = \Delta_x T, \qquad A_y^T = \Delta_y T.$$

For an ordered mixture of potentials (T_x, T_y), we define the plaquette curvature by

$$F(T_x,T_y) = \Delta_x A_y^{T_y} - \Delta_y A_x^{T_x} = \Delta_x\Delta_y T_y - \Delta_y\Delta_x T_x.$$

Since

$$\Delta_x S = \Delta_y S = 1, \qquad \Delta_x P = y, \qquad \Delta_y P = x,$$

is obtained in the 81 plaquettes:

$$F(S,S) = F(P,P) = 0, \qquad F(S,P) = +1, \qquad F(P,S) = -1 \pmod 9.$$

The connections associated with a single observable are flat; the mixed composition of the two observables produces curvature of opposite sign according to the order. For a coordinate rectangle $R_{a,b}$ contained in

the chart, we define the additive boundary Wilson observable as the oriented sum of the link variables. Cancellation of the interior edges gives

$$W_{\partial R_{a,b}}(S,P) = ab, \qquad W_{\partial R_{a,b}}(P,S) = -ab \pmod 9,$$

which is the finite Stokes identity for this convention.

The distinction between potential and linkage is algebraically necessary. If A_x, A_y were directly substituted by S, P, terms depending on x, y would appear and the preceding constant values would not be obtained. The typed formulation is what produces the mixed cocycle used later in the finite Heisenberg closure.

Remark 1.61. The integrated difference 54 and the mixed curvature ± 1 are distinct invariants. The former compares global sums; the latter depends on the order of the two potentials and is localized on each plaquette. The formulation in terms of self-adjoint operators and commutators will be developed after the corresponding state space has been constructed.

1.6.6 Path Transition Operator Expansion

The definition of APP includes the space $\mathrm{Path}(\Gamma_{\mathrm{APP},9})$. Once a transition operator U has been fixed on the vertices of $\Gamma_{\mathrm{APP},9}$, we assume that $U_{yx} = 0$ whenever $x \to y$ is not an edge of the graph. Under this support hypothesis, its powers admit the expansion

Proposition 1.62 (Finite Path Expansion)**.** *For each $R \geq 1$ and each pair of vertices i, f,*

$$(U^R)_{fi} = \sum_{\substack{\gamma: i \to f \\ |\gamma| = R}} \prod_{k=0}^{R-1} U_{x_{k+1}, x_k}, \qquad \gamma = (x_0 = i, x_1, \ldots, x_R = f).$$

Proof. For $R = 1$ the identity is the definition of the matrix elements of U. If it holds for R, then

$$(U^{R+1})_{fi} = \sum_j U_{fj} (U^R)_{ji}.$$

Substituting the induction hypothesis concatenates to every path of length R from i to j the final edge $j \to f$; thus, every path of length $R+1$ appears exactly once. □

Consequently, APP brings together in a single structure the finite arithmetic torus, the sum and product observables, the residue–quotient decomposition, the nilpotent radical, and an oriented mixed curvature. The representative 9 of the null class fixes a visible chart of the quotient; replacing it with 0 without simultaneously transporting the chart alters the registers used by the subsequent dynamics.

1.7 Aritmetic Matrix of APP and Local Ring Structure

The section 1.8 constructed a single support X_9. APP has a single principal arithmetic matrix: nonadic multiplication published by the positive digital root. Addition does not constitute a second APP table; it is the internal accumulation law that generates the rows and columns of the multiplicative matrix and provides an auxiliary observable for comparison. This distinction will be maintained throughout the work.

1.7.1 Nonadic multiplicative matrix and digital root

For $a, b \in \mathcal{D}_9 = \{1, \dots, 9\}$, the APP entry is obtained directly through

$$\boxed{\Pi(a, b) = \mathrm{dr}_9(ab) = 1 + ((ab - 1) \bmod 9).} \tag{1.67}$$

The only APP matrix is, therefore,

Π	1	2	3	4	5	6	7	8	9
1	1	2	3	4	5	6	7	8	9
2	2	4	6	8	1	3	5	7	9
3	3	6	9	3	6	9	3	6	9
4	4	8	3	7	2	6	1	5	9
5	5	1	6	2	7	3	8	4	9
6	6	3	9	6	3	9	6	3	9
7	7	5	3	1	8	6	4	2	9
8	8	7	6	5	4	3	2	1	9
9	9	9	9	9	9	9	9	9	9

Each row can also be reconstructed by reiterated addition of its index, but that recurrence describes the internal law of the matrix and not a second sheet. The rows and columns of indices $1, 2, 4, 5, 7, 8$ traverse the nine classes; those of indices $3, 6, 9$ are exactly those that contract the support.

In the residual chart, the set of units is

$$R_9^\times = (\mathbb{Z}/9\mathbb{Z})^\times = \{[1], [2], [4], [5], [7], [8]\}.$$

The maximal ideal is

$$\mathfrak{m} = (3) = \{[0], [3], [6]\}.$$

Theorem 1.63 (Classification of multiplicative rows)**.** *For $a \in \mathcal{D}_9$, the map*

$$m_a : \mathcal{D}_9 \longrightarrow \mathcal{D}_9, \qquad b \longmapsto \Pi(a, b)$$

is bijective if and only if $[a]_9 \in R_9^\times$. If $[a]_9 \in \mathfrak{m} \setminus \{0\}$, its image has three elements. If $[a]_9 = [0]_9$, its image has a single element.

Proof. The residual reduction of m_a is multiplication by $[a]_9$. In a finite ring, that multiplication is bijective exactly when $[a]_9$ is a unit. If $[a]_9 = [3]$ or $[6]$, its image is the ideal $\mathfrak{m}$, of cardinality three. If $[a]_9 = [0]$, every entry is sent to the null class, published as 9. □

Proposition 1.64 (Internality of the additive law)**.** *The auxiliary observable*

$$\Sigma(a, b) = \mathrm{dr}_9(a + b)$$

acts by translations: for each $a, c \in \mathcal{D}_9$ there exists a unique $b \in \mathcal{D}_9$ such that $\Sigma(a, b) = c$, and analogously in the other coordinate.

Proof. In the residual chart, $[a + b]_9 = [c]_9$ has the unique solution $[b]_9 = [c - a]_9$. The positive section transports that class to a unique element of $\mathcal{D}_9$. □

The difference of geometry of fibers remains thus typed without duplicar the matrix APP: the law additive internal only translates, whereas the matrix multiplicative permutes on the units and contracts on the radical.

Proposition 1.65 (Linear structure of the radical)**.** *The map*

$$M_3 : R_9 \longrightarrow R_9, \qquad x \longmapsto 3x$$

satisfies

$$\ker M_3 = \operatorname{im} M_3 = \mathfrak{m}.$$

The induced map

$$R_9/\mathfrak{m} \longrightarrow \mathfrak{m}, \qquad [x] \longmapsto 3x$$

is an isomorphism of vector spaces over $\mathbb{F}_3$, but not a ring isomorphism.

Proof. The congruence $3x \equiv 0 \pmod 9$ is equivalent to $x \equiv 0 \pmod 3$, whence the kernel $\mathfrak{m}$. The image is $\{[0], [3], [6]\} = \mathfrak{m}$. The first isomorphism theorem gives the linear isomorphism. It is not a ring isomorphism because $\mathfrak{m}^2 = 0$ in R_9, whereas the quotient $R_9/\mathfrak{m} \cong \mathbb{F}_3$ has a nonzero unit. □

The positive section publishes the non-trivial radical cycle as

$$369 \longmapsto 693 \longmapsto 936 \longmapsto 369,$$

according to the position from which the triple is read. This notation preserves the order of the coordinates; it does not turn the ideal into three independent integers.

1.7.2 Residue-quotient extensions and nonadic carry cocycle

Let $s_0 : R_9 \to \{0, \dots, 8\}$ be the normalized residual section. The binary carry of the sum is

$$\kappa_0(a, b) = \frac{s_0(a) + s_0(b) - s_0(a + b)}{9}.$$

Lemma 1.66 (Cocyclic Identity)**.** *For $a, b, c \in R_9$,*

$$\kappa_0(a, b) + \kappa_0(a + b, c) = \kappa_0(b, c) + \kappa_0(a, b + c).$$

Proof. Multiply by nine and expand either of the two sides produces

$$s_0(a) + s_0(b) + s_0(c) - s_0(a + b + c).$$

Therefore, both are equal. □

Define $\chi_0(a) = 1$ if $a = [0]_9$ and 0 otherwise. Since

$$s_+(a) = s_0(a) + 9\chi_0(a),$$

the carryovers of the two sections are related by

$$\kappa_+(a, b) = \kappa_0(a, b) + \chi_0(a) + \chi_0(b) - \chi_0(a + b).$$

Changing the representative modifies the cocycle by a coboundary. This is the exact form for transporting memory when the null class is published as 9 instead of 0.

1.7.3 Integrated censuses of residues and quotients

Summing over all pairs $(i, j) \in \mathcal{D}_9^2$, one obtains

$$\sum_{i,j}(i+j) = 810, \qquad \sum_{i,j} ij = 2025.$$

The positive residues satisfy

$$\sum_{i,j} R^{+}_{i,j} = 405, \qquad \sum_{i,j} R^{\times}_{i,j} = 459.$$

By the raised identities,

$$\sum_{i,j} Q^{+}_{i,j} = \frac{810-405}{9} = 45, \qquad \sum_{i,j} Q^{\times}_{i,j} = \frac{2025-459}{9} = 174.$$

Theorem 1.67 (Exact separation of the sum-product excess)**.** *The integrated difference between product and sum decomposes uniquely into a published part and a quotient part:*

$$\boxed{2025 - 810 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129.}$$

Proof. We subtract, term to term, the identities $ij = R^{\times}_{i,j} + 9Q^{\times}_{i,j}$ and $i + j = R^{+}_{i,j} + 9Q^{+}_{i,j}$, and sum on the eighty and a pairs. The censuses preceding dan the equality. The uniqueness proceeds of the division Euclidean in each pair. □

The value 54 is not the complete difference between two supposed matrices. It is the visible defect between the multiplicative matrix and the additive accumulator in the positive chart. The term $9 \cdot 129$ is the contribution that remains in the quotients. Omitting it would confuse publication with genealogy.

1.7.4 Bivariate central block of APP and decomposition into 2 spectral modes

For $k \in \mathbb{Z}/9\mathbb{Z}$, consideramos the block symmetric

$$B_k = \begin{pmatrix} k^2 & k(k+1) \\ k(k+1) & (k+1)^2 \end{pmatrix} \pmod 9.$$

The diagonals coincide exactly when

$$k^2 \equiv (k+1)^2 \pmod 9 \quad \Longleftrightarrow \quad 2k + 1 \equiv 0 \pmod 9.$$

Since $2^{-1} = 5 \pmod 9$, the unique solution is $k = 4$. Thus appears the block

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Let

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad P_{\pm} = \frac{1}{2}(I \pm R).$$

Then

$$B_c = 7I + 2R = 9P_{+} + 5P_{-}.$$

Theorem 1.68 (Uniqueness and spectrum of the central block)**.** *The block B_c is the unique adjacent block in the family B_k with equal diagonals. Its eigenvalues on the symmetric and antisymmetric subspaces are, respectively,* 9 *and* 5*.*

Proof. The congruence before proves the uniqueness. Since that R acts by $+1$ on $\operatorname{im} P_+$ and by -1 on $\operatorname{im} P_-$, the matrix $7I + 2R$ acts by 9 and 5, respectively. □

The two ordered readings of its digits give

$$72 + 27 = 99, \qquad 72 - 27 = 45 = \det B_c,$$

and the two diagonals give

$$77 + 22 = 99, \qquad 77 - 22 = 55 = 54 + 1.$$

These identities are internal controls of the block; they do not by themselves define the global defect.

1.7.5 Discrete curvature of the interaction between additive and multiplicative leaves

On the residual chart we write

$$S(x, y) = x + y, \qquad P(x, y) = xy.$$

For a function $T : X_9 \to R_9$, let

$$\Delta_x T(x, y) = T(x + 1, y) - T(x, y), \qquad \Delta_y T(x, y) = T(x, y + 1) - T(x, y).$$

We define the ordered curvature of a pair of laws by

$$\mathcal{F}(T_x, T_y) := \Delta_x \Delta_y T_y - \Delta_y \Delta_x T_x.$$

Proposition 1.69 (Orientations of the mixed composition)**.** *The following hold*

$$\mathcal{F}(S, S) = 0, \qquad \mathcal{F}(P, P) = 0,$$

and, for mixed compositions,

$$\mathcal{F}(S, P) = +1, \qquad \mathcal{F}(P, S) = -1 \quad \text{in } R_9.$$

Proof. The mixed second differences of the linear law S vanish. For $P(x, y) = xy$, both pure mixed differences equal one and cancel when compared in the same order. Combining a linear law and a bilinear one leaves a single unit whose sign changes when the order of the sheets is reversed. □

The curvature not creates another matrix APP. Is recorded that the order $\Sigma \to \Pi$ and the order $\Pi \to \Sigma$ are orientations opposite, whereas the sectors pure remain flat. This triad $-1, 0, +1$ will be typed in the unit TRIT.

1.7.6 Obstructions of the arithmetic matrix of APP: translations, local radical, central block, mixed curvature, and conservation of carry

Comparison Criterion 1.70 (Refutation criteria for the APP matrix)**.** The unit is refuted if:

1. the internal additive law ceases to act by translations;
2. a nonunitary multiplicative row is declared bijective;
3. $R_9/\mathfrak{m}$ is identified with $\mathfrak{m}$ as a ring;
4. the exceso 1215 it replaces by 54 without conservar quotients;
5. the central block is chosen without resolving $2k + 1 = 0 \pmod 9$;

6. reversal of the mixed order does not change the sign of the curvature;
7. the carry it eliminates to the cambiar between the sections s_0 and s_+.

APP is now constructed as support, category of trajectories, nonadic multiplicative matrix, internal additive law, local radical, carry cocycle, and mixed orientation. The following unit will not summarize these structures: it will take the triad of orientations that has just emerged and construct the complete TRIT state with its three quadratic regimes.

1.8 Gnomonic completion and arithmetic support of APP

This unit constructs the APP support from the nonadic cell of the section 1.9. It does not presuppose a continuous plane, an infinite lattice, or a numerical constant. The starting object is finite: two ordered copies of the positive chart of $\mathbb{Z}/9\mathbb{Z}$. Completion of its interior interstices produces exactly eighty-one states, and the residual translation law turns that square support into a discrete torus.

Throughout the unit, APP denotes a mathematical structure and not an image. Henceforth, the acronym APP names this structure; the properties that follow depend on its objects and morphisms, not on a verbal expansion of the acronym.

1.8.1 Conjugation between the positive and residual charts of the same class modulo 9

We define

$$\mathcal{D}_9 := \{1, 2, \dots, 9\}, \qquad \mathcal{D}_8 := \{1, 2, \dots, 8\}.$$

The residual publication application is

$$\lambda_9 : \mathcal{D}_9 \longrightarrow \mathbb{Z}/9\mathbb{Z}, \qquad \lambda_9(a) = [a]_9.$$

Therefore, $\lambda_9(9) = [0]_9$. Its inverse as a set map is the positive section

$$s_+([a]_9) = \begin{cases} a, & [a]_9 \neq [0]_9, \quad 1 \leq a \leq 8, \\ 9, & [a]_9 = [0]_9. \end{cases}$$

The two expressions 9 and $[0]_9$ are not two phases: they are two representatives of the same element in different charts.

For two coordinates we will write

$$\lambda_9^{\times 2} : \mathcal{D}_9^2 \longrightarrow X_9 := (\mathbb{Z}/9\mathbb{Z})^2, \qquad (a, b) \longmapsto ([a]_9, [b]_9).$$

This map is a bijection of sets. The chart $\mathcal{D}_9^2$ makes the positive marks visible; the group X_9 makes the residual sum and the translations visible.

Lemma 1.71 (State-preserving chart change)**.** *The maps $\lambda_9^{\times 2}$ and $s_+^{\times 2}$ are inverses. In particular, the positive representation and the residual representation contain exactly the same eighty-one states.*

Proof. In each coordinate, $\lambda_9 \circ s_+ = \mathrm{id}_{\mathbb{Z}/9\mathbb{Z}}$ and $s_+ \circ \lambda_9 = \mathrm{id}_{\mathcal{D}_9}$ hold. The Cartesian product of these identities gives the two required identities. □

1.8.2 Decomposition of the APP orthogram into inner core and gnomonic complement

The inner core is

$$\mathcal{N}_8 := \mathcal{D}_8 \times \mathcal{D}_8, \qquad |\mathcal{N}_8| = 8^2 = 64.$$

In the plane of indices, $\mathcal{N}_8$ is the square that not uses the mark of closure in no coordinate. For publish also the null class it must completar the ninth row and the ninth column. We define the complement gnomonic disjoint by

$$\mathcal{G}_9 := (\{9\} \times \mathcal{D}_9) \sqcup (\mathcal{D}_8 \times \{9\}).$$

The corner $(9, 9)$ belongs to the first piece; for that reason the second uses $\mathcal{D}_8$ and not $\mathcal{D}_9$. Consequently,

$$|\mathcal{G}_9| = 9 + 8 = 17, \qquad \mathcal{D}_9^2 = \mathcal{N}_8 \sqcup \mathcal{G}_9, \qquad 81 = 64 + 17.$$

Proposition 1.72 (Minimality of the Completion)**.** *Let Y be a subset of $\mathcal{D}_9^2$ that contains $\mathcal{N}_8$ and whose projection onto each coordinate is all of $\mathcal{D}_9$. If, in addition, Y contains all pairs required to translate one coordinate while the other remains arbitrary, then $\mathcal{G}_9 \subseteq Y$. Therefore, the addition of seventeen states is the minimal completion compatible with the two translations.*

Proof. To transport the first coordinate through the closure class while the second remains at an arbitrary value $b \in \mathcal{D}_9$, all pairs $(9, b)$ are necessary. Nine states are obtained. To transport the second coordinate through closure while the first assumes an arbitrary value $a \in \mathcal{D}_8$, the remaining eight pairs $(a, 9)$ are necessary. The corner $(9, 9)$ was already counted in the first family. In total, $9 + 8 = 17$ states are necessary, exactly those of $\mathcal{G}_9$. □

The hypothesis of compatibility with the two translations is essential. It would suffice to add a single mark per coordinate for both projections to be surjective, but that set would not contain the boundary states needed to move one coordinate while holding the other fixed. APP requires the complete product, not two disconnected axes.

1.8.3 Exact realization of the interstitial interval via APP cells and boundary coordinates

Let P_9 be the ordered path with nine marks and eight interior edges

$$E(P_9) = \{e_1, \ldots, e_8\}.$$

Closing the endpoints incorporates an edge e_9 and produces the cycle C_9:

$$E(C_9) = E(P_9) \sqcup \{e_9\}.$$

The pairs of interior interstices form $E(P_9)^2$. The pairs of interstices of the complete cycle form $E(C_9)^2$. The difference is

$$E(C_9)^2 \setminus E(P_9)^2 = (\{e_9\} \times E(C_9)) \sqcup (E(P_9) \times \{e_9\}). \tag{1.68}$$

The decomposition is disjoint because the corner (e_9, e_9) is reserved for the first piece.

Theorem 1.73 (Equivalence of the mark model and the interstice model)**.** *The map*

$$\beta : E(C_9)^2 \longrightarrow \mathcal{D}_9^2, \qquad \beta(e_i, e_j) = (i, j),$$

is bijective. Its restrictions satisfy

$$\beta(E(P_9)^2) = \mathcal{N}_8, \qquad \beta(E(C_9)^2 \setminus E(P_9)^2) = \mathcal{G}_9.$$

Therefore, the identity $81 = 64 + 17$ *simultaneously counts pairs of published marks and pairs of closed interstices.*

Proof. Each edge of C_9 has a unique index in $\mathcal{D}_9$. The map $(i, j) \mapsto (e_i, e_j)$ is the explicit inverse of β. If $i, j \leq 8$, the pair belongs to $E(P_9)^2$ and its image belongs to $\mathcal{D}_8^2$. If at least one of the indices is nine, the pair belongs to the complement of equation (1.68); separating the case $i = 9$ from the case $i \leq 8$, $j = 9$ produces exactly the two pieces of $\mathcal{G}_9$. □

1.8.4 Toroidal closure and translations

Let

$$\mathbf{e}_1 = ([1]_9, [0]_9), \qquad \mathbf{e}_2 = ([0]_9, [1]_9).$$

The set of elementary directions is

$$\mathscr{D}_{\mathrm{APP}} := \{+\mathbf{e}_1, -\mathbf{e}_1, +\mathbf{e}_2, -\mathbf{e}_2\}.$$

We define the oriented Cayley graph.

$$\Gamma_{\mathrm{APP}} := \mathrm{Cay}(X_9, \mathscr{D}_{\mathrm{APP}}).$$

Its vertices are the eighty-one elements of X_9. For every $x \in X_9$ and $d \in \mathscr{D}_{\mathrm{APP}}$, there is an oriented edge $x \xrightarrow{d} x + d$. The inverse edge bears the label $-d$.

In the positive chart, unit translation is written by means of the published successor and its carry:

$$u_+(a) = \begin{cases} a + 1, & a < 9, \\ 1, & a = 9, \end{cases} \qquad \kappa_+(a) = \begin{cases} 0, & a < 9, \\ 1, & a = 9. \end{cases}$$

The raised identity is

$$a + 1 = u_+(a) + 9\kappa_+(a). \tag{1.69}$$

Upon applying λ_9, the carry term vanishes, leaving

$$\lambda_9(u_+(a)) = \lambda_9(a) + [1]_9.$$

Lemma 1.74 (Compatibility between closure, residue, and elevation)**.** *The addition of* e_9*, the identification* $9 \sim [0]_9$*, and the translation* $x \mapsto x + \mathbf{e}_i$ *describe three compatible operations in distinct domains. The residual quotient publishes the return; the carry of equation* (1.69) *preserves the elevation that the quotient omits.*

Proof. Topological closure incorporates the edge joining the endpoints of the path. The residual chart identifies the published endpoint with the null class. If $a < 9$, the successor has zero carry; if $a = 9$, the lifted equality is $10 = 1 + 9$. Both cases descend to the same residual sum, but the value of κ_+ distinguishes them. □

Corollary 1.75 (Toroidal support)**.** *Identifying opposite sides of the chart* $\mathcal{D}_9^2$ *yields a geometric realization of the group* X_9*. Each elementary translation is defined at every vertex and has an inverse.*

1.8.5 APP Path Category: Objects, Prolongation Morphisms and Compatible Composition

Definition 1.76 (Oriented trajectory)**.** A trajectory of length $n \geq 0$ is a pair

$$\gamma = (x_0; d_1, \ldots, d_n), \qquad x_0 \in X_9, \qquad d_k \in \mathscr{D}_{\mathrm{APP}}.$$

Its vertices are

$$x_k = x_0 + \sum_{r=1}^{k} d_r, \qquad 0 \leq k \leq n.$$

The source is $s(\gamma) = x_0$ and the target is $t(\gamma) = x_n$. For $n = 0$ the identity trajectory in x_0 is obtained.

If $t(\gamma) = s(\delta)$, its concatenation is

$$\delta \circ \gamma = (x_0; d_1, \ldots, d_n, e_1, \ldots, e_m),$$

where $e_1, \ldots, e_m$ are the directions of δ. Concatenation is associative, and paths of zero length are identities. We thus obtain the free category

$$\mathsf{Path}(\Gamma_{\mathrm{APP}}).$$

Proposition 1.77 (Finiteness of Support and Countability of Trajectories)**.** *The APP state set is finite, of cardinality* 81. *For a fixed source, there are* 4^n *direction words of length n. The union of all finite trajectories is countable.*

Proof. The first assertion follows from $|X_9| = 9^2$. At each of the n steps there are four independent choices, whence 4^n. Finally, $\bigcup_{n\geq 0} X_9 \times \mathscr{D}_{\mathrm{APP}}^n$ is a countable union of finite sets. □

This proposition separates two levels that will not be identified: APP has a finite support, but admits trajectories of arbitrary length. The prolongation of a route does not create new vertices of the support; it creates new genealogy over them.

1.8.6 Multiplicative matrix and internal additive law on a single support

For $n \in \mathbb{Z}_{>0}$, the root digital positive is

$$\mathrm{dr}_9(n) := 1 + ((n-1) \bmod 9).$$

On the positive chart we define the principal matrix and the internal law.

$$\Sigma(a,b) := \mathrm{dr}_9(a+b), \qquad \Pi(a,b) := \mathrm{dr}_9(ab).$$

Both maps have the same domain $\mathcal{D}_9^2$ and the same codomain $\mathcal{D}_9$, but they do not have the same status: Π publishes the unique APP matrix, and Σ generates its accumulations. Their residual versions are

$$\bar{\Sigma}([a]_9, [b]_9) = [a+b]_9, \qquad \bar{\Pi}([a]_9, [b]_9) = [ab]_9.$$

The change of chart is compatible with both operations:

$$\lambda_9 \circ \Sigma = \bar{\Sigma} \circ \lambda_9^{\times 2},$$
$$\lambda_9 \circ \Pi = \bar{\Pi} \circ \lambda_9^{\times 2}.$$

To preserve the integer quotient, lifts are introduced.

$$a + b = R_{a,b}^{+} + 9Q_{a,b}^{+}, \qquad 1 \leq R_{a,b}^{+} \leq 9, \tag{1.70}$$

$$ab = R^{\times}_{a,b} + 9Q^{\times}_{a,b}, \qquad 1 \le R^{\times}_{a,b} \le 9. \tag{1.71}$$

Here

$$R^{+}_{a,b} = \Sigma(a,b), \qquad R^{\times}_{a,b} = \Pi(a,b),$$

and the quotients are uniquely determined by

$$Q^{+}_{a,b} = \frac{a+b-R^{+}_{a,b}}{9}, \qquad Q^{\times}_{a,b} = \frac{ab-R^{\times}_{a,b}}{9}.$$

Definition 1.78 (APP genealogical)**.** The APP structure at this stage is the tuple

$$\mathrm{APP} := \big(X_9, \Gamma_{\mathrm{APP}}, \mathsf{Path}(\Gamma_{\mathrm{APP}}), \Sigma, \Pi, R^{+}, Q^{+}, R^{\times}, Q^{\times}\big).$$

The genealogy of a trajectory preserves, for each vertex visited, the position, incoming direction, multiplicative entry, additive accumulation, and their respective residues and quotients.

Theorem 1.79 (Causal construction of the APP support)**.** *The chain*

$$\mathcal{D}_9 \longrightarrow \mathcal{D}_8^2 \longrightarrow \mathcal{D}_8^2 \sqcup \mathcal{G}_9 \longrightarrow \mathcal{D}_9^2 \xrightarrow{\lambda_9^{\times 2}} X_9 \longrightarrow \Gamma_{\mathrm{APP}} \longrightarrow \mathsf{Path}(\Gamma_{\mathrm{APP}}) \longrightarrow (\Sigma, \Pi)$$

constructs, without loss of cardinality, the support, motion, paths, APP multiplicative matrix and its internal additive law.

Proof. The proposition 1.72 constructs the complete chart from the kernel. The theorem 1.73 identifies its interstitial model. The lemma 1.71 transports the eighty-one states to X_9. The Cayley graph incorporates the four reversible translations without changing the vertices. The free category incorporates all finite concatenations. Finally, Σ and Π are distinct total maps on the same domain; the equations equations (1.70) y (1.71) preserve the part that residual reduction does not publish. □

1.8.7 Decomposition of the APP orthogram into kernel 8×8, gnomon of 17 states, and chart 9×9 with opposite sides identified

The Figure 1.1 must be read in three layers: the inner square of sixty-four states, the gnomon of seventeen states, and the identification of opposite sides. The nine-by-nine chart thereby completes the eight-by-eight core by means of the closure gnomon. The multiplicative matrix and the internal additive law are evaluated at every vertex of the same state, preserve distinct residue–quotient lifts, and do not constitute two APP squares.

1.8.8 Obstructions to the fidelity of the APP support: cardinals $81/17$, reversible translations, and separation of the sum and product sheets

Comparison Criterion 1.80 (Refutation criteria for the APP support)**.** The construction is refuted if any of the following facts occurs:

1. the complete support has cardinality other than 81;
2. the gnomonic complement does not have cardinal 17;
3. a state of X_9 lacks any of the four translations;
4. it identify Σ and Π because coincide in a value;
5. Q^{+} or $Q^{\times}$ is eliminated upon returning through a boundary;
6. trajectories of different lengths are presented as new support vertices;

7. it interpreta 9 and $[0]_9$ as phases independent.

The unit has constructed APP up to its complete genealogical evaluation. It has not yet oriented the difference between the matrix and its accumulator, has not introduced the TRIT, and has not defined the Topological Phase Kernel. The following unit will study the algebraic structure of rows and columns, the sector of units, and the carry cocycle that prepares that orientation.

1.9 Construction of the nonadic cell from marked segments and interstices

The construction begins before every constant and before every choice of physical unit. The inaugural datum is not an already constituted real number, but an ordered segment, a family of marks, and the adjacency relation between consecutive marks. This separation is necessary because a mark, an interval, the length of that interval, and the numeral that publishes that length are objects of different types.

1.9.1 Decimal residual projection of the finite positional chart of APP

Definition 1.81 (Marked segment of order ten)**.** Let

$$\mathsf{M}_{10} := \{m_0, m_1, \dots, m_{10}\}$$

a set totally ordered by $m_0 < m_1 < \cdots < m_{10}$. Its adjacency graph is the path

$$\mathsf{P}_{10} : \quad m_0 \longrightarrow m_1 \longrightarrow \cdots \longrightarrow m_{10}.$$

We shall denote by

$$\mathsf{I}_k := (m_k, m_{k+1}), \qquad 0 \le k \le 9,$$

the abstract interstice between two consecutive marks. The family of interstices is $\mathsf{E}_{10} := \{\mathsf{I}_0, \dots, \mathsf{I}_9\}$.

The open notation (m_k, m_{k+1}) does not yet presuppose the real line. It indicates only the ordered pair of endpoints and the edge joining them. When the Archimedean chart is chosen

$$\chi_{10}(m_k) = k,$$

the abstract interstice I_k is published by the semiopen interval $[k, k+1)$. Therefore, the index k, the edge I_k, and the interval $[k, k+1)$ will not be identified in the text: the first is a label, the second is a combinatorial element, and the third is its realization in a chart.

Lemma 1.82 (Census of Marks and Gaps)**.** *The segment* P_{10} *contains eleven marks and ten interstices. More generally, a path with* $n+1$ *marks has exactly* n *edges.*

Proof. The map

$$\{0, \dots, n-1\} \longrightarrow E(\mathsf{P}_n), \qquad k \longmapsto (m_k, m_{k+1}),$$

is bijective. The particular assertion is obtained with $n = 10$. □

The endpoint m_0 fixes the origin of the chart, and m_{10} fixes its threshold. Neither by itself constitutes an additional interstice. This elementary remark prevents three subsequent confusions: counting endpoints as cells, confusing closure with a new phase state, and treating zero as a tenth phase independent of the nonadic cycle.

1.9.2 Construction of the nonadic cell of 9 phases via residual projection

The decimal chart distinguishes the anchor $[0, 1)$ of the periodic cell. The nine positive marks

$$\mathsf{D}_9 := \{1, 2, 3, 4, 5, 6, 7, 8, 9\}$$

it utilizaran as representantes publicos of $\mathbb{Z}/9\mathbb{Z}$, haciendo corresponder the mark 9 with the class residual $\overline{0}$. We define

$$\lambda_9 : \mathsf{D}_9 \longrightarrow \mathbb{Z}/9\mathbb{Z}, \qquad \lambda_9(a) = \overline{a}.$$

Proposition 1.83 (Positive chart of the nonadic classes)**.** *The map λ_9 is bijective. Its inverse is the positive section*

$$s_+(\overline{a}) = \begin{cases} a, & 1 \le a \le 8, \\ 9, & \overline{a} = \overline{0}. \end{cases}$$

In particular, the public representation 9 *and the residual representation* 0 *represent the same class, but belong to different charts.*

Proof. The nine classes of $\mathbb{Z}/9\mathbb{Z}$ have unique representatives in $\{0, 1, \ldots, 8\}$. Replacing the representative 0 by 9 produces another complete transversal, so λ_9 is bijective and s_+ is its inverse. □

The phase cell is not obtained by arbitrarily erasing the origin. The segment $[0, 1)$ fixes the decimal chart from which the cycle is observed; the nine phases are the nine classes published as $1, \ldots, 9$. In the lifted chart, the step that closes the cell is represented by $[9, 10)$; in the residual chart, that same step returns from $\overline{0}$ to $\overline{1}$. Closure and change of representative are not the same operation.

1.9.3 Position and height coordinates induced by the Euclidean division

Definition 1.84 (Nonadic Coordinates)**.** For each integer $n \ge 1$, we define

$$\rho_9(n) := 1 + ((n-1) \bmod 9), \qquad q_9(n) := \left\lfloor \frac{n-1}{9} \right\rfloor.$$

The first coordinate is called phase position; the second, turn height or memory quotient.

Theorem 1.85 (Unique nonadic decomposition)**.** *Every integer $n \ge 1$ admits a unique expression*

$$n = 9q + \rho, \qquad q \in \mathbb{Z}_{\ge 0}, \quad \rho \in \mathsf{D}_9.$$

In esa escritura $q = q_9(n)$ and $\rho = \rho_9(n)$.

Proof. We apply Euclidean division to $n - 1$: there exist unique $q \ge 0$ and $r \in \{0, \ldots, 8\}$ such that $n - 1 = 9q + r$. Taking $\rho = r + 1$ gives $n = 9q + \rho$, with $1 \le \rho \le 9$. The uniqueness of q, r implies that of q, ρ. □

Corollary 1.86 (Phase return with memory increment)**.** *For every $n \ge 1$,*

$$\rho_9(n + 9) = \rho_9(n), \qquad q_9(n + 9) = q_9(n) + 1.$$

Consequently, a full rotation preserves the visible phase and changes the raised state.

Proof. If $n = 9q + \rho$, then $n + 9 = 9(q + 1) + \rho$; uniqueness of theorem 1.85 gives the two identities. □

The one-step evolution is written unambiguously as

$$(q,\rho) \longmapsto \begin{cases} (q,\rho+1), & 1 \le \rho < 9, \\ (q+1,1), & \rho = 9. \end{cases}$$

The second line is not a restart. It recovers the initial phase label and increases the quotient that records how many turns have been performed.

1.9.4 Circular projection periodicity and injectivity of the nonadic helical lifting

Let

$$\vartheta_9(\rho) = \frac{2\pi(\rho-1)}{9}.$$

The phase projection onto the unit circle is

$$\mathcal{R}_9(n) = \big(\cos\vartheta_9(\rho_9(n)), \sin\vartheta_9(\rho_9(n))\big).$$

To simultaneously preserve position and height we introduce the helical immersion.

$$\mathcal{H}_9(n) = \left(\cos\vartheta_9(\rho_9(n)), \sin\vartheta_9(\rho_9(n)), q_9(n) + \frac{\rho_9(n)-1}{9}\right).$$

Proposition 1.87 (The circular projection does not determine the state)**.** *The map $\mathcal{R}_9$ is periodic with period nine. The map $\mathcal{H}_9$ is injective. In particular,*

$$\mathcal{R}_9(n+9) = \mathcal{R}_9(n), \qquad \mathcal{H}_9(n+9) \neq \mathcal{H}_9(n).$$

Proof. The first equality follows from corollary 1.86. The third coordinate of $\mathcal{H}_9(n+9)$ exceeds that of $\mathcal{H}_9(n)$ by one unit, hence both points are distinct. Finally, n is recovered from the third coordinate by multiplying by nine and adding one to the phase part; therefore, $\mathcal{H}_9$ is injective. □

This proposition is the minimal model of the principle that will run through the entire work:

phase return ≠ state return.

The nonadic connection of the Topological Phase Kernel will preserve more fields than the elementary helix —sheet, orientation, carry, boundary, terminal, and route memory—, but it will not alter this inaugural distinction.

1.9.5 Correspondence between Discrete Cardinality and Projective Measure

Definition 1.88 (Counting)**.** The count of a finite set X is its cardinality $|X|$. It requires neither an orientation, a scale, nor an additional reader.

Definition 1.89 (Measured data)**.** A discrete measurement datum is a triple

$$(x, \mathcal{L}, C),$$

where x is a state, $\mathcal{L}$ is a typed reader, and C is a publication chart compatible with the codomain of $\mathcal{L}$. Its visible output is

$$C(\mathcal{L}(x)).$$

The same set may have a single cardinality and admit multiple measures, because the local cochain, the orientation of integration, or the publication chart may vary. Conversely, two distinct states may publish the same coordinate. The work will therefore always preserve two levels:

$$\text{state with genealogy} \quad \longrightarrow \quad \text{published coordinate.}$$

Comparison Criterion 1.90 (Refutation criteria for the inaugural unit)**.** The construction is refuted if any of the following facts occurs:

1. ten independent phases are counted in the residue cell;
2. the mark 9 is identified with the integer 0 without declaring the change of chart;
3. the passage $9 \to 1$ forces $q \mapsto 0$;
4. two distinct integers have the same pair (q_9, ρ_9);
5. a physical unit is attributed to the cell before defining the dimensional transducer.

1.9.6 Autonomous arithmetic domain of the nonadic cell and causal precedence with respect to APP–TRIT–TPK and the constants analiticas

The unit constructed so far contains only:

$$\mathsf{P}_{10}, \quad \mathsf{D}_9, \quad \lambda_9, \quad (q_9, \rho_9), \quad \mathcal{R}_9, \quad \mathcal{H}_9.$$

It does not yet contain APP, TRIT, the Topological Phase Kernel, or an analytic constant. The following unit will take two copies of the nonadic cell, construct its gnomonic completion, and prove how the bidimensional support appears over which the multiplicative matrix of APP and its internal additive law act.

1.10 Cyclotomic skeleton of APP and binomial completion of the unit

The defect between the APP matrix and its internal accumulator is not an isolated number. Its law in Cartesian length, its decomposition into orbits of order three, and the completion of the nonadic cell produce three different objects that must remain typed:

$$\text{scalar defect} \quad D_d, \qquad \text{cyclotomic module} \quad W_{\mathrm{APP}}, \qquad \text{completion} \quad \overline{C}_9.$$

The first counts; the second preserves orientation and rank; the third adds boundary strata. Equalities between their cardinals do not authorize identifying their elements.

1.10.1 Cyclotomic Defect Invariance at Fixed Modulus Under Length Variation

For each integer $d \geq 1$, let

$$B_d := \{1, \ldots, 9\}^d.$$

The nonary digital root is represented by

$$\mathrm{dr}_9(n) = \begin{cases} n \bmod 9, & n \not\equiv 0 \pmod 9, \\ 9, & n \equiv 0 \pmod 9. \end{cases}$$

We define the additive accumulation and the multiplicative matrix evaluation on the same domain:

$$A_d(x_1, \ldots, x_d) = \mathrm{dr}_9\left(\sum_{j=1}^{d} x_j\right),$$

$$M_d(x_1, \ldots, x_d) = \mathrm{dr}_9\left(\prod_{j=1}^{d} x_j\right).$$

Their visible masses and their defect are

$$S_\Sigma(d) := \sum_{x \in B_d} A_d(x), \qquad S_\Pi(d) := \sum_{x \in B_d} M_d(x),$$

$$D_d := S_\Pi(d) - S_\Sigma(d).$$

Here d counts Cartesian positions. The module 9 does not vary, and no physical dimension has yet been introduced.

Lemma 1.91 (Mass of the additive accumulator)**.** *For every $d \geq 1$,*

$$S_\Sigma(d) = 45\, 9^{d-1}.$$

Proof. Once the first $d-1$ coordinates and a published residue $r \in \{1, \dots, 9\}$ have been fixed, there exists a unique last coordinate that makes the sum have residue r. Each visible value thus has 9^{d-1} preimages. Summing the weights $1 + \cdots + 9 = 45$ gives the formula. □

Lemma 1.92 (Census of the multiplicative matrix)**.** *For each of the six unit residues there are 6^{d-1} preimages for each fixed product value. The residues 3 and 6 have $d6^{d-1}$ preimages each. The zero residue, published as 9, has*

$$9^d - 6^d - 2d6^{d-1}$$

preimages. Consequently,

$$S_\Pi(d) = 9^{d+1} - 9(d+3)6^{d-1}.$$

Proof. The unit group of $\mathbb{Z}/9\mathbb{Z}$ has six elements. Upon fixing $d-1$ units, the last is determined by the prescribed unit product, giving 6^{d-1} solutions for each of the six classes.

To obtain a product of ternary valuation exactly one, one chooses which of the d coordinates belongs to one of the two classes 3, 6, while the others are units. Once the product 3 or 6 is fixed, the last unit is determined; hence $d6^{d-1}$ for each class. All remaining tuples have product zero modulo 9. Subtracting the two preceding counts from 9^d gives their multiplicity. The sum weighted by the visible representatives yields the final identity. □

Theorem 1.93 (Internal dimensional law of APP)**.** *For every $d \geq 1$,*

$$\boxed{D_d = 4\, 9^d - 9(d+3)6^{d-1}.}$$

In particular,

$$D_1 = 0, \qquad D_2 = 54,$$

and

$$\sum_{d \geq 1} D_d z^d = \frac{54z^2(1-3z)}{(1-9z)(1-6z)^2}.$$

Moreover,

$$\frac{D_d}{9^d} = 4 - (d+3)\left(\frac{2}{3}\right)^{d-1} \longrightarrow 4.$$

Proof. The formulas from the two lemmas are subtracted. For the generating function, one uses

$$\sum_{d \geq 1} 9^d z^d = \frac{9z}{1-9z}, \qquad \sum_{d \geq 1} (d+3)6^{d-1} z^d = \frac{z(4-18z)}{(1-6z)^2},$$

and the common numerator is reduced. The normalized formula follows by dividing by 9^d; the exponential term multiplied by $d+3$ converges to zero. □

The equality $D_2 = 54$ reproduce the census $459 - 405$, but the formula before and the law of modulo variable $\Delta_{3^m}^{\mathrm{pl}} = m3^{2m-1}$ are enunciados distintos: the first varia d manteniendo the modulo 9; the second varia the modulo.

1.10.2 Cyclotomic operator of APP and action on the 12 A_2-type fibers

Let

$$G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}.$$

Proposition 1.94 (Coxeter of type A_2)**.** *They are verified.*

$$C^3 = I_2, \qquad C^{\mathsf{T}} G_{A_2} C = G_{A_2}, \qquad \det(XI_2 - C) = X^2 + X + 1.$$

Therefore C preserves the form A_2, has order exactly three, and has no nonzero fixed vector.

Proof. The multiplication gives

$$C^2 = \begin{pmatrix} -1 & 1 \\ -1 & 0 \end{pmatrix}, \qquad C^3 = I_2.$$

Direct substitution into $C^{\mathsf{T}} G_{A_2} C$ yields G_{A_2}. Finally, 1 is not a root of X^2+X+1, hence $\ker(C-I_2) = 0$. □

1.10.3 Decomposition of APP into 12 fibers of type A_2

Consider the action

$$a : \mathbb{Z}/9\mathbb{Z} \longrightarrow \mathbb{Z}/9\mathbb{Z}, \qquad a(r) = 4r.$$

Since $4^3 \equiv 1 \pmod 9$, its restriction to the units has two free orbits:

$$\mathcal{O}_1 = (1, 4, 7), \qquad \mathcal{O}_2 = (2, 8, 5).$$

For an orbit $\mathcal{O} = (r, 4r, 7r)$, we define the augmentation module

$$A(\mathcal{O}) := \ker\left(\mathbb{Z}[\mathcal{O}] \xrightarrow{\Sigma} \mathbb{Z}\right).$$

At the base

$$b_1 = e_r - e_{4r}, \qquad b_2 = e_{4r} - e_{7r},$$

the restricted Euclidean form has Gram matrix G_{A_2}, and the cycle $r \mapsto 4r \mapsto 7r \mapsto r$ acts by C.

For $x = (x_1, x_2, x_3) \in (\mathbb{Z}/9\mathbb{Z})^3$, the three unordered pairs are

$$\{1, 2\}, \quad \{2, 3\}, \quad \{3, 1\}.$$

Over each pair, two typed laws are evaluated:

$$\ell_{ij}^{\Sigma}(x) = x_i + x_j, \qquad \ell_{ij}^{\Pi}(x) = x_i x_j.$$

Since

$$\ell_{ij}^{\Sigma}(ax) = a\ell_{ij}^{\Sigma}(x), \qquad \ell_{ij}^{\Pi}(ax) = a^{-1}\ell_{ij}^{\Pi}(x),$$

the sum carries the orientation C and the product the inverse orientation C^{-1}.

Definition 1.95 (Cyclotomic module of APP)**.** It is defined

$$\boxed{W_{\mathrm{APP}} := \bigoplus_{\{i,j\}} \bigoplus_{\mu\in\{\Sigma,\Pi\}} \bigoplus_{O\in\{O_1,O_2\}} A(O).}$$

There are $3 \cdot 2 \cdot 2 = 12$ summands, each of rank two; therefore

$$W_{\mathrm{APP}} \cong A_2^{12}, \qquad \operatorname{rank} W_{\mathrm{APP}} = 24.$$

The par–law–orbit labels are part of the object.

For $u \in \mathbb{Z}/9\mathbb{Z}$, we write

$$\beta_O(u) = \begin{cases} (1,0), & u = r, \\ (0,1), & u = 4r, \\ (-1,-1), & u = 7r, \\ (0,0), & u \notin O, \end{cases}$$

in the basis (b_1, b_2). The state map is

$$\Psi(x)_{ij,\mu,O} := \beta_O(\ell_{ij}^{\mu}(x)).$$

Theorem 1.96 (Equivariance and rank of the state skeleton)**.** *Let $\rho(a)$ be the action using C on the six additive fibers and C^{-1} on the six multiplicative fibers. Then*

$$\boxed{\Psi(ax) = \rho(a)\Psi(x)}$$

for the 729 *states of* $(\mathbb{Z}/9\mathbb{Z})^3$*. The rational submodule generated by the images has rank* 24*.*

Proof. Under the additive law, multiplying all coordinates by 4 advances one position in each orbit; under the multiplicative law, it multiplies the value by $4^2 \equiv 7 \equiv 4^{-1} \pmod 9$ and therefore reverses the cycle. This proves componentwise equivariance.

In order for the rank not to remain hidden in a computational statement, we fix the coordinate order.

$$(12,\Sigma,O_1), (12,\Sigma,O_2), (12,\Pi,O_1), (12,\Pi,O_2),$$

followed by the same order for the pairs 23 and 31, and, within each fiber, the two coordinates (b_1, b_2). Consider the states

$$001, 002, 004, 005, 010, 011, 012, 013, 014, 015, 016, 020,$$
$$022, 023, 040, 050, 101, 102, 104, 105, 110, 120, 140, 150.$$

The integer matrix M_Ψ whose rows are its twenty-four images has entries in (-1,0,1). Bareiss's fraction-free elimination yields the following successive leading principal minors

$$1, 1, 1, -1, -1, -1, -1, 1, -1, 1, 1, 1, 1, -2, -1, 1, 1, 1, 2, 1, 4, -6, 12, 9.$$

In particular,

$$\det M_\Psi = 9 \neq 0.$$

These twenty-four images are linearly independent. Since the codomain already has rank 24, they generate $W_{\mathrm{APP}} \otimes \mathbb{Q}$. □

The proof exhibits a finite reproducible certificate; it does not deduce full rank from the mere surjectivity of each component projection.

1.10.4 Derivation of the sum-product defect 459−405=54 in the central block of APP

Let

$$\mathcal{M} := \mathbb{Z}[\mathbb{Z}/9\mathbb{Z}]$$

and, for $\mu \in \{\Sigma, \Pi\}$,

$$\nu_\mu := \sum_{x,y\in\mathbb{Z}/9\mathbb{Z}} e_{\ell^\mu(x,y)}.$$

The census of the two tables gives

$$\delta_{\Pi\Sigma} := \nu_\Pi - \nu_\Sigma = 12e_0 + 3e_3 + 3e_6 - 3\sum_{u\in(\mathbb{Z}/9\mathbb{Z})^\times} e_u.$$

Its coefficients are constant on the orbits of a; therefore

$$(I - a)\delta_{\Pi\Sigma} = 0.$$

We define the increase projection

$$T : \mathcal{M} \longrightarrow A(\mathcal{O}_1) \oplus A(\mathcal{O}_2),$$

$$T(\nu) = \left(((I - a)\nu)|_{\mathcal{O}_1}, ((I - a)\nu)|_{\mathcal{O}_2}\right).$$

Then

$$T(\delta_{\Pi\Sigma}) = 0.$$

However, the visible reader

$$w(e_0) = 9, \qquad w(e_r) = r \quad (1 \le r \le 8)$$

satisfies

$$w(\delta_{\Pi\Sigma}) = 54.$$

Corollary 1.97 (Isotopic Obstruction)**.** *The scalar* 54 *belongs to the C_3-invariant sector and cannot be recovered by means of a linear functional that factors exclusively through the augmentation modules. In particular,*

$$\sum_x \Psi(x) = 0$$

and, for every linear functional L on $W_{\mathrm{APP}} \otimes \mathbb{Q}$,

$$L\left(\sum_x \Psi(x)\right) = 0 \neq 54.$$

This obstruction prevents presenting 54 as a retrospective linear sum of the twelve fibers. The subsequent APP–Fock coupling preserves the orientation and uses an additional object; it does not contradict the corollary.

1.10.5 Cubic completion of the nonad cell

Let E_9 be the underlying set of $\mathbb{Z}/9\mathbb{Z}$, and let $\star \notin E_9$ be a boundary state. We define

$$C_9 := E_9^3, \qquad \overline{C}_9 := (E_9 \sqcup \{\star\})^3.$$

The symbol $\star$ is not the zero class: it indicates that a coordinate has reached the closure stratum.

Theorem 1.98 (Binomial stratification of the unit cube)**.** *The stratum with exactly r coordinates equal to $\star$ contains*

$$\binom{3}{r} 9^{3-r}$$

elements. Therefore,

$$\boxed{1000 = 729 + 243 + 27 + 1 = 729 + 271.}$$

Upon removing only the apex $(\star, \star, \star)$, there remains

$$999 = 729 + 243 + 27 = 729 + 270.$$

Proof. The r boundary coordinates are chosen in $\binom{3}{r}$ ways; each remaining coordinate admits nine values. The four strata are disjoint and exhaust the Cartesian product. The sum is the expansion of $(9+1)^3$. □

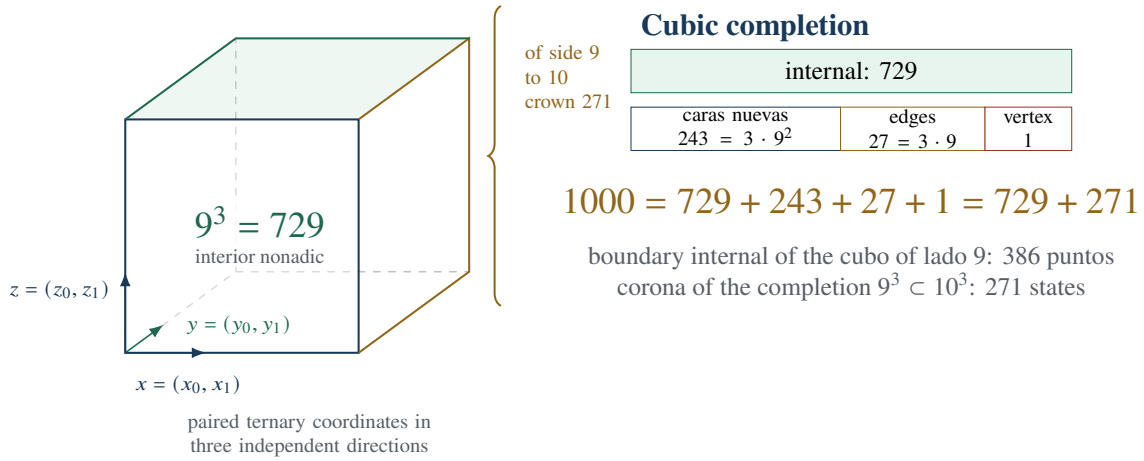

Figure 1.2: Cubic completion of the nonadic cell. The interior of cardinality 729 and the boundary strata of cardinalities 243, 27, and 1 are disjoint parts of a single object.

This stratification receives in HMT the name of extreme and mean holographic ratio. Mathematically it is the typed binomial completion of the nonadic cell; the name does not replace its definition.

For every $d \geq 1$, let

$$\overline{C}_9^{(d)} = (E_9 \sqcup \{\star\})^d.$$

Asignemos peso $1/10$ to each symbol of a coordinate and tomemos the measure product μ_d.

Theorem 1.99 (Projective compatibility of the measure)**.** *The projection that forgets the last coordinate satisfies*

$$(\pi_d)_* \mu_d = \mu_{d-1}.$$

Moreover,

$$10^d = \sum_{r=0}^{d} \binom{d}{r} 9^{d-r}, \qquad \mu_d(\overline{C}_9^{(d)}) = 1.$$

The number of states increases with d, while the normalized total mass is conserved.

Proof. For every cylinder $A \times (E_9 \sqcup \{\star\})$,

$$\mu_d(A \times (E_9 \sqcup \{\star\})) = \mu_{d-1}(A) \sum_{u \in E_9 \sqcup \{\star\}} \frac{1}{10} = \mu_{d-1}(A).$$

The cilindros generate the algebra finite of subconjuntos, what that determines the measure image. The identity cardinal again becomes the binomio of Newton. □

1.10.6 Morphism from the central block of APP to its Euclidean realization

The already constructed central block is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Row reading and diagonal reading give

$$72 + 27 = 77 + 22 = 99,$$

$$72 - 27 = 45 = \det B_c, \qquad 77 - 22 = 55 = 54 + 1.$$

The relation with the completion is not obtained by concatenating symbols, but by the Euclidean division.

$$729 = 10 \cdot 72 + 9, \qquad 271 = 10 \cdot 27 + 1.$$

Theorem 1.100 (Uniqueness of the Decimal Lift)**.** *For $L_d(n) = 10n + d$, with $d \in \{0, \dots, 9\}$, there exists a single pair (d, d') such that*

$$L_d(72) = 729, \qquad L_d(72) + L_{d'}(27) = 1000, \qquad d + d' = 10.$$

It is the pair

$$(d, d') = (9, 1).$$

Proof. The first equality is $720 + d = 729$, hence $d = 9$. The second becomes $729 + 270 + d' = 1000$, whence $d' = 1$. The third is verified, and the uniqueness of quotient and remainder rules out any other solution. □

Thus the causal diagram is obtained.

$$B_c \longrightarrow (72, 27) \longleftarrow ((72, 9), (27, 1)) \longleftarrow (729, 271).$$

The block and its reading belong to APP; the dividends and remainders belong to the completion. The diagram shares quotients; it does not invert causality.

1.10.7 Incidence of the cube and separation with respect to sextets and octets

Let M_d be the incidence matrix of the $2d$ codimension-one faces of a hypercube on its 2^d vertices. Each face contains 2^{d-1} vertices; two opposite faces are disjoint, and two transversal faces share 2^{d-2} vertices.

Theorem 1.101 (Hypercube incidence spectrum)**.**

$$\mathrm{Spec}(M_d M_d^{\mathsf{T}}) = \left\{ d 2^{d-1\ (1)}, 2^{d-1\ (d)}, 0^{(d-1)} \right\}.$$

Para $d = 3$,

$$\mathrm{Spec}(M_3 M_3^{\mathsf{T}}) = \{12, 4, 4, 4, 0, 0\}.$$

Proof. The row space decomposes into: the constant line; the d differences of each pair of opposite faces; and the (d-1) combinations of pair sums whose total sum is zero. The intersections described above cause the Gram matrix to act by $d2^{d-1}$, 2^{d-1}, and 0, respectively. □

The three-dimensional cube has six faces, eight vertices, and twelve edges. Those cardinals anticipate an incidence pattern (6/8), but a face is not a hexad and the set of vertices is not an octad. The exceptional identification requires a subsequent transporter that preserves supports and gauge.

1.10.8 Range 6 of the incidence operator and multiplicity of its resonant mode

Define the strata that preserve exactly k nonadic coordinates in rank d:

$$\mathcal{I}_k(d) := \binom{d}{k} 9^k.$$

The defects of APP are

$$D_{\text{vis}} = 54, \qquad D_{\text{tot}} = 1215, \qquad D_{\text{coc}} = 129, \qquad 1215 = 54 + 9 \cdot 129.$$

Theorem 1.102 (Uniqueness of the Binomial Resonance)**.** *The unique positive integer d that simultaneously satisfies*

$$\mathcal{I}_1(d) = 54, \qquad \mathcal{I}_2(d) = 1215$$

is $d = 6$. In that range,

$$\frac{\mathcal{I}_2(6) - \mathcal{I}_1(6)}{9} = 129.$$

Proof. The first equality is $9d = 54$, which forces $d = 6$. Then

$$\mathcal{I}_2(6) = 81\binom{6}{2} = 81 \cdot 15 = 1215,$$

and

$$\frac{1215 - 54}{9} = 129.$$

There remains no other possible rank because the first equality already determines d. □

1.10.9 Obstructions of the cyclotomic skeleton of APP: fibers A_2^{12}, completion $729 + 271$, rank resonance 6, and cubic incidence

Comparison Criterion 1.103 (Typed falsification of the unit)**.** The construction is refuted if any of the following facts occurs:

1. the law of D_d not reproduce $D_1 = 0$ and $D_2 = 54$;
2. variation of length is fused with variation of modulus;
3. C ceases to preserve G_{A_2} or acquires a fixed vector;
4. the labels pair–sheet–orbit not produce twelve fibers;
5. the smallest certificate of Ψ has zero determinant;
6. a functional that factors through the augmentation module recovers 54;
7. the symbol of boundary $\star$ it identifica with the zero residue;
8. the four strata do not sum to 1000;

9. a cubic face is identified with a hexad without an incidence transporter.

The unit has constructed, without recognizing them retrospectively, the module A_2^{12}, the completion $729 + 271$, the projective measure, and the rank-six resonance. These structures will feed, in distinct ways, the generation of constants and the exceptional branches.

1.11 TRIT as a ternary oriented unit: internal geometries, temporal order, and dynamic conditions of time crystal

The mixed curvature of APP produced three oriented values: zero on the pure sheets and opposite signs when the sum–product order is exchanged. The TRIT types that triad and preserves, in addition to the visible residue, the quotient required to reconstruct the lifted integer. This unit explicitly separates four levels: ternary class, balanced representative, carry, and quadratic regime.

Definition 1.104 (Topological Information Unit TRIT)**.** The *TRIT* is the elementary oriented unit whose state space is $\mathsf{TRIT} = \{-1, 0, +1\}$. Its native logarithmic capacity is $\log 3$, and its expression in binary units is $\log_2 3$. Unlike a bit, its three states do not reduce to a cardinal encoding: they respectively type opening, threshold, and return, and preserve the carry quotient required to reconstruct the transition that produced the visible residue.

1.11.1 Oriented ternary system and balanced representation of TRIT states

We define the oriented set

$$\mathsf{TRIT} := \{-1, 0, +1\}.$$

The balanced chart is the bijection of sets.

$$\mathrm{bal} : \mathbb{F}_3 \longrightarrow \mathsf{TRIT}, \qquad [0]_3 \mapsto 0, \qquad [1]_3 \mapsto +1, \qquad [2]_3 \mapsto -1.$$

It is not of an equality of types. $\mathbb{F}_3$ carries sum and product of field; TRIT carries order and orientation. Every operation transported between both must indicate the chart used.

The orientation of the nine phases is

$$\varepsilon_9(r) = \begin{cases} +1, & r \in \{1, 4, 7\}, \\ -1, & r \in \{2, 5, 8\}, \\ 0, & r \in \{3, 6, 9\}. \end{cases}$$

His complete table is

r	1	2	3	4	5	6	7	8	9
$\varepsilon_9(r)$	+1	−1	0	+1	−1	0	+1	−1	0

.

Periodicity of three does not eliminate the nonadic phase: the phases $1, 4, 7$, for example, have the same orientation and different positions in the circuit.

1.11.2 Balanced ternary division algorithm and uniqueness of the quotient–residue pair

Theorem 1.105 (Local ternary lifting)**.** *For each $n \in \{-4, -3, \ldots, 4\}$ there exists a single pair $(r, c) \in \mathsf{TRIT}^2$ such that*

$$n = r + 3c.$$

Proof. The existence is verified in the table.

n	−4	−3	−2	−1	0	1	2	3	4
r	−1	0	+1	−1	0	+1	−1	0	+1
c	−1	−1	−1	0	0	0	+1	+1	+1

.

If $r + 3c = r' + 3c'$, then $r - r' = 3(c' - c)$. Since $r - r' \in \{-2, -1, 0, 1, 2\}$, the only possible multiple of three is zero; therefore $r = r'$ and $c = c'$. □

The visible projection $(r, c) \mapsto r$ has three local states over the value zero:

$$0^- := (0, -1), \qquad 0^0 := (0, 0), \qquad 0^+ := (0, +1).$$

They publish the same residue, but reconstruct $-3, 0, +3$. This triple fiber is the minimal form of a distinction that will reappear in the enriched state of the Topological Phase Kernel.

Corollary 1.106 (Balanced Iteration)**.** *Every integer N admits a finite balanced ternary expansion*

$$N = r_0 + 3r_1 + \cdots + 3^m r_m, \qquad r_j \in \mathsf{TRIT}.$$

It is obtained by iterating the division $N_k = r_k + 3N_{k+1}$, where r_k is the balanced representative of N_k mod 3.

Proof. Euclidean division modulo three yields a residue in $\{0, 1, 2\}$; replacing 2 with -1 increases the quotient by one and produces $r_k \in \mathsf{TRIT}$. The absolute value of the quotient decreases outside a finite set, so the process terminates. Uniqueness follows by comparing the first differing digit and reducing modulo three. □

1.11.3 Carry cocycle of the oriented ternary composition

For $r, s \in \mathsf{TRIT}$, we define $r \oplus s \in \mathsf{TRIT}$ and $\kappa_3(r, s) \in \mathbb{Z}$ by the unique equality

$$r + s = (r \oplus s) + 3\kappa_3(r, s).$$

The table is

$\oplus$	-1	0	$+1$
-1	$+1$	-1	0
0	-1	0	$+1$
$+1$	0	$+1$	-1

,

κ_3	-1	0	$+1$
-1	-1	0	0
0	0	0	0
$+1$	0	0	$+1$

.

Proposition 1.107 (Ternary cocyclic identity)**.** *For $r, s, t \in \mathsf{TRIT}$,*

$$\kappa_3(r, s) + \kappa_3(r \oplus s, t) = \kappa_3(s, t) + \kappa_3(r, s \oplus t).$$

Proof. Both sides are the total quotient that appears when writing $r + s + t$ as a balanced representative plus a multiple of three. The uniqueness of the lift proves the equality. □

If (r, c) and (s, d) are states levantados, its sum is

$$(r, c) \boxplus (s, d) := \big(r \oplus s,\ c + d + \kappa_3(r, s)\big).$$

The proposition 1.107 proves that $\boxplus$ is associative and that the reconstruction $\mathrm{rec}_3(r, c) = r + 3c$ satisfies

$$\mathrm{rec}_3(x \boxplus y) = \mathrm{rec}_3(x) + \mathrm{rec}_3(y).$$

1.11.4 Orientation and Temporal Order Involution

For to tritic word $\tau = (\tau_1, \dots, \tau_n)$, define

$$C_{\mathrm{rev}}(\tau_1, \dots, \tau_n) := (-\tau_n, \dots, -\tau_1).$$

Lemma 1.108 (Oriented reversal)**.** *The map C_{rev} is an involution. It interchanges the sectors $+1$ and -1 and fixes the sector 0.*

Proof. Applying it twice reverses the order twice and changes every sign twice. The initial word is thereby recovered. The remaining assertions are immediate in each component. □

When a time-oriented parameter is fixed, the TPK convention is

$$+1 : \text{return with memory}, \qquad 0 : \text{present threshold}, \qquad -1 : \text{prolongation opening}.$$

This assignment does not add a fourth temporal state. The direction is preserved in the sign and the exact position is preserved in the nonadic phase.

1.11.5 Unified classification of the 3 quadratic algebras of the TRIT

For $\tau \in \mathsf{TRIT}$, define

$$\mathbb{A}_\tau := \mathbb{R}[J_\tau]/(J_\tau^2 + \tau I).$$

The three cases are:

τ	J_τ^2	regime	$\exp(tJ_\tau)$
$+1$	$-I$	elliptic	$\cos t\, I + \sin t\, J_{+1}$
0	0	parabolic	$I + tJ_0$
-1	$+I$	hyperbolic	$\cosh t\, I + \sinh t\, J_{-1}$

.

Theorem 1.109 (Uniform quadratic exponential)**.** *If $J_\tau^2 = -\tau I$, then*

$$\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau,$$

where

τ	$+1$	0	-1
$C_\tau(t)$	$\cos t$	1	$\cosh t$
$S_\tau(t)$	$\sin t$	t	$\sinh t$

.

Proof. We separate the exponential series into even and odd powers. The relations $J_{+1}^{2m} = (-1)^m I$, $J_0^2 = 0$, and $J_{-1}^{2m} = I$ respectively produce the cosine and sine series, the linear truncation, and the hyperbolic series. □

On $\mathbb{F}_3$ the analogues appear

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1), \qquad \mathbb{D}_3 = \mathbb{F}_3[\epsilon]/(\epsilon^2), \qquad \mathbb{S}_3 = \mathbb{F}_3[j]/(j^2 - 1).$$

The first is a field of nine elements; the second contains a nonzero nilpotent; the third decomposes through the idempotents $(1 \pm j)/2$ and is isomorphic to $\mathbb{F}_3 \times \mathbb{F}_3$. The coincidence of cardinality does not identify these three algebras.

The integral source of the elliptic regime is

$$\mathbb{Q}_{\mathbb{Z}} := \mathbb{Z}[u]/(u^2 + 1).$$

Reduction modulo three sends u to ι and produces $\mathbb{F}_9$. The extension of scalars to $\mathbb{R}$ and a $u \mapsto J_{+1}$ representation produce the real elliptic realizer. There is therefore no untyped map $\mathbb{F}_9 \to \mathbb{R}$: both realizations follow from a common integral source.

1.11.6 Matrix representations of the TRIT selected by the sign of J_τ^2

Let

$$C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad C^3 = I,$$

and let us define

$$J_e := \frac{2C + I}{\sqrt{3}} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & -2 \\ 2 & -1 \end{pmatrix}.$$

A direct multiplication gives

$$(2C + I)^2 = -3I, \qquad J_e^2 = -I.$$

The parabolic realizer is

$$J_p := N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad N^2 = 0.$$

For the hyperbolic regime we take

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad A := F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix},$$

and

$$J_h := \frac{2A - 3I}{\sqrt{5}} = \frac{1}{\sqrt{5}} \begin{pmatrix} -1 & 2 \\ 2 & 1 \end{pmatrix}.$$

Then

$$(2A - 3I)^2 = 5I, \qquad J_h^2 = I.$$

The bilinear form

$$G = \begin{pmatrix} 2 & 1 \\ 1 & -2 \end{pmatrix}$$

satisfies

$$A^T G A = G.$$

Moreover,

$$\cosh(2 \log \varphi) = \frac{3}{2}, \qquad \sinh(2 \log \varphi) = \frac{\sqrt{5}}{2},$$

for which

$$A = \exp(2 \log \varphi \, J_h) = \cosh(2 \log \varphi) I + \sinh(2 \log \varphi) J_h.$$

This identity will be recovered causally in the biography of φ; here only the matrix representation is verified.

The three exponential controls are

$$\exp(\pi J_e) + I = 0, \qquad \exp(J_p) = I + J_p, \qquad \exp(2 \log \varphi \, J_h) = F_{\mathrm{av}}^2.$$

The presence of π and φ in these verification identities does not authorize using them as constructors of those constants. Their constructors will appear later from the nonadic genealogy.

1.11.7 Local coupling APP–TRIT

With the exchange

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

we define, for $\tau \in \mathsf{TRIT}$,

$$B_\tau = (4 + 3\tau)I + (5 - 3\tau)R.$$

Since $P_\pm = (I \pm R)/2$,

$$B_\tau = 9P_+ + (6\tau - 1)P_-.$$

Theorem 1.110 (Spectral Recovery of Orientation)**.** *The spectrum of B_τ is*

$$\mathrm{Spec}(B_\tau) = \{9, 6\tau - 1\}.$$

The differential eigenvalue λ_- uniquely determines the TRIT:

$$\tau = \frac{\lambda_- + 1}{6}.$$

Moreover, the block central of APP is B_{+1}.

Proof. The projectors P_+ and P_- diagonalize R with eigenvalues $+1$ and -1. The spectral formula is obtained by substitution. The second identity solves for τ. For $\tau = +1$, $B_{+1} = 7I + 2R = \left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$, which is the unique block of theorem 1.68. □

Therefore, the TRIT not it anade as retrospective label: can be recovered of the differential mode of a family constructed on the internal exchange of APP.

1.11.8 Obstructions of TRIT: residue–representative–carry separation, involutivity, and spectral recovery of τ

Comparison Criterion 1.111 (Refutation Criteria for the TRIT)**.** The unit is refuted if:

1. it identify class residual, representative balanceado and carry;
2. it is asserted that 0^-, 0^0, and 0^+ are the same state;
3. the composition $\boxplus$ ceases to reconstruct the integer sum;
4. C_{rev} is not involutive;
5. the three algebras are identified because they have the same cardinal;
6. some realizer fails to satisfy $J_\tau^2 = -\tau I$;
7. the value of τ is chosen after observing the outcome and is not recovered from the spectrum of B_τ.

APP provides the support, the multiplicative matrix, and the internal additive law; TRIT provides orientation, lift, and quadratic type. The next unit will construct the Topological Phase Kernel as the transport category of these data, without confusing the internal selector with the complete state.

1.12 TPK: base observable, enriched state, and typed separation of its projections

APP has supplied a support, a multiplicative matrix, and an internal additive law; TRIT has supplied a lifted orientation. The Topological Phase Kernel, hereinafter TPK, specifies how those data are transported jointly, which coordinates are preserved when a route is closed, and which readers can be published without identifying the publication with the state. Its mathematical object is a category over a base of paths, endowed with an explicit family of fibers and prolongation relations.

1.12.1 Bivariate category of APP paths as the basis of the TPK enriched state

Let $\mathsf{P}_{\mathrm{APP}}$ be the category libre constructed in the section 1.8. We define

$$\mathsf{P}_{\mathrm{APP}}^{(2)} := \mathsf{P}_{\mathrm{APP}} \times \mathsf{P}_{\mathrm{APP}}.$$

An object is a pair of positions $(p^{\Sigma}, p^{\Pi}) \in X_9^2$. A morphism is a pair of trajectories; one of them may be the identity. The first component is evaluated by Σ, the second by Π. They are not two lattices: they are two typed cursors over the same APP support.

The set of cardinal directions is

$$\mathscr{D}_{\mathrm{card}} := \{N, E, S, O\},$$

with shifts

$$\delta(N) = (-1, 0), \quad \delta(E) = (0, 1), \quad \delta(S) = (1, 0), \quad \delta(O) = (0, -1) \quad \text{in } X_9.$$

The orientation involution is

$$\overline{N} = S, \quad \overline{S} = N, \quad \overline{E} = O, \quad \overline{O} = E.$$

1.12.2 Non-split extension $\mathbf{C}_{12} \to \mathbf{C}_{108} \to \mathbf{C}_9$ and dodecaphase record of the nonadic phase

The complete clock of this stage is

$$\Theta_{108} := \mathbb{Z}/108\mathbb{Z}.$$

For $\theta \in \Theta_{108}$, let $\widetilde{\theta} \in \{0, \dots, 107\}$ be its normalized representative. We define three distinct coordinates:

$$\begin{aligned} g_0(\theta) &= [\widetilde{\theta} + 1]_9 \in C_9, \\ r(\theta) &= 1 + (\widetilde{\theta} \bmod 9) \in \mathcal{D}_9, \\ \beta(\theta) &= \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12} \in C_{12}. \end{aligned}$$

The first is the phase class, the second its positive label, and the third the dodecaphasic sector. The map β is a block map; it is not the canonical reduction $\theta \bmod 12$.

The signature and the active sheet are

$$\tau(\theta) := \varepsilon_9(r(\theta)) \in \mathsf{TRIT},$$

and

$$\mu(\theta) = \begin{cases} \Sigma, & \tau(\theta) = +1, \\ \Pi, & \tau(\theta) = -1, \\ \varnothing, & \tau(\theta) = 0. \end{cases}$$

The symbol $\varnothing$ denotes a threshold step in which neither cursor moves; it does not denote the absence of a state.

Definition 1.112 (Observable configuration)**.** The observable base is

$$\mathcal{Q}_{\mathrm{obs}} := X_9^2 \times \mathscr{D}_{\mathrm{card}}^2 \times \Theta_{108}.$$

An element is written

$$q = (p^{\Sigma}, p^{\Pi}, d^{\Sigma}, d^{\Pi}, \theta).$$

It contains two positions, two cardinal orientations, and a calendar index.

1.12.3 Sheet selector $M_{\mathrm{ph}} : \mathcal{D}_9 \to \mathsf{TRIT}$ and joint evolution of position, orientation, and calendar

The function

$$M_{\mathrm{ph}} : \mathcal{D}_9 \longrightarrow \mathsf{TRIT}, \qquad M_{\mathrm{ph}}(r) = \varepsilon_9(r)$$

is the internal sheet selector. It selects which evaluation acts; it does not by itself displace any position.

We define the orientation inversion indicator by

$$\eta_{27}(\theta) = \begin{cases} -1, & \widetilde{\theta} + 1 \in \{27, 54, 81, 108\}, \\ +1, & \text{otherwise.} \end{cases}$$

The new directions are

$$d^{\nu,+} = \begin{cases} \overline{d^{\nu}}, & \eta_{27}(\theta) = -1, \\ d^{\nu}, & \eta_{27}(\theta) = +1, \end{cases} \qquad \nu \in \{\Sigma, \Pi\}.$$

The positions evolve via

$$(p^{\Sigma,+}, p^{\Pi,+}) = \begin{cases} (p^{\Sigma} + \delta(d^{\Sigma}), p^{\Pi}), & \tau(\theta) = +1, \\ (p^{\Sigma}, p^{\Pi} + \delta(d^{\Pi})), & \tau(\theta) = -1, \\ (p^{\Sigma}, p^{\Pi}), & \tau(\theta) = 0. \end{cases}$$

Definition 1.113 (Observable evolution)**.** The map

$$F_{\mathrm{obs}} : \mathcal{Q}_{\mathrm{obs}} \longrightarrow \mathcal{Q}_{\mathrm{obs}}$$

is defined by

$$F_{\mathrm{obs}}(q) = (p^{\Sigma,+}, p^{\Pi,+}, d^{\Sigma,+}, d^{\Pi,+}, [\theta + 1]_{108}).$$

The category libre of the graph $q \to F_{\mathrm{obs}}(q)$ it is denoted by $\mathsf{P}_{\mathrm{obs}}$.

Each arrow of $\mathsf{P}_{\mathrm{obs}}$ induces a pair of trajectories in APP, so there exists a functor

$$B : \mathsf{P}_{\mathrm{obs}} \longrightarrow \mathsf{P}_{\mathrm{APP}}^{(2)}.$$

If $\tau = +1$, the second component of B is the identity; if $\tau = -1$, the first is the identity; if $\tau = 0$, both are the identity.

Proposition 1.114 (Separation between selection, motion, and remark)**.** *The selector M_{ph}, the translations $T_d(p) = p + \delta(d)$, and any temporal sampling have distinct domains and codomains. They are not interchangeable operators.*

Proof. M_{ph} takes a phase label and returns a tritic orientation. T_d is an automorphism of X_9. A sampling acts on a sequence or a category of arrows. Identifying two of them would violate typing. F_{obs} composes them in a declared order without erasing that distinction. □

1.12.4 Decomposition of the enriched state in 6 families fibradas

Over each $q \in Q_{\mathrm{obs}}$ we fix the total fiber

$$\mathcal{F}_q = \mathsf{O}_q \times \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{S}_q \times \mathsf{B}_q \times \Lambda_q.$$

Each factor has its own type and function.

1.12.4.1 Joint determination of the orientation and sheet of the enriched state

$$\mathsf{O}_q \subseteq \mathscr{D}^2_{\mathrm{card}} \times \{+1, -1\}.$$

The two directions coincide with those stored in q; the last coordinate records the sheet orientation when the realization requires it. The sheet label does not replace the cardinal directions.

1.12.4.2 Euclidean decomposition of the state into compatible residue and quotient

The first lift fiber is

$$\mathsf{H}^{(1)} = \mathcal{D}_9 \times \mathbb{Z}, \qquad \mathrm{rec}_9(r, u) = r + 9u.$$

For each integer n there exist unique

$$r = \mathrm{dr}_9(n), \qquad u = \frac{n - r}{9}.$$

A greater depth consists of a declared tower of these fibers and their truncation maps. The term “Hensel” does not replace the definition of that tower.

1.12.4.3 Carry operator and joint update of residue, quotient, and memory

C_q is an abelian group. In the readers of decimal blocks one takes $\mathsf{C}_q = \mathbb{Z}$. The increment is not an independent coordinate, but a cochain over the arrows:

$$\kappa(r) \in \mathsf{C}_{q'} \quad \text{for } r : q \to q'.$$

1.12.4.4 Construction of the full signature from orientation, carry, and boundary

The signature is derived via a typed application.

$$\mathrm{Sig}_q : \mathsf{H}_q \times \mathsf{C}_q \times \Lambda_q \longrightarrow \mathsf{S}_q.$$

In the nonadic boundary realization, individual conservation is maintained,

$$q_\partial, a_\partial, c_\partial \in \mathbb{F}_3^6, \qquad \mathrm{colw} \in \mathbb{Z}^6_{\geq 0}, \qquad \rho_W, r_\partial \in \mathbb{F}_3^3.$$

These coordinates are margin, axial combination, cubic condition, column weights, Witt residual class, and ternary return. They do not condense into a single word if a subsequent proof uses any of them.

1.12.4.5 Cylindrical compatibility and boundary signature of the enriched state

$$\mathsf{B}_q := \mathsf{Cyl}_q \times \mathsf{Fr}_q.$$

The cylinder localizes a family of prefixes; the boundary determines which extensions are compatible. Survival will be a relation between states endowed with both data, not a number added a posteriori.

1.12.4.6 Genealogical transport record

Λ_q contains the transport records whose endpoint is q. A prolongation $r : q \to q'$ acts by concatenation:

$$\lambda \longmapsto r \circ \lambda.$$

The genealogical register preserves the route; its observable endpoint does not determine it.

1.12.5 Cardinal operator T_d of transport between enriched fibers with conservation of path and memory

For each arrow $r : q \to q'$ maps are declared

$$\mathsf{H}(r) : \mathsf{H}_q \to \mathsf{H}_{q'}, \quad \mathsf{C}(r) : \mathsf{C}_q \to \mathsf{C}_{q'}, \quad \Lambda(r) : \Lambda_q \to \Lambda_{q'}.$$

They respect identities and composition, and $\mathsf{C}(r)$ is a homomorphism. The carry satisfies

$$\kappa(r_2 \circ r_1) = \kappa(r_2) + \mathsf{C}(r_2)\big(\kappa(r_1)\big). \tag{1.72}$$

Therefore, the transport of the determined coordinates is

$$\begin{aligned} h' &= \mathsf{H}(r)(h), \\ c' &= \mathsf{C}(r)(c) + \kappa(r), \\ \lambda' &= \Lambda(r)(\lambda), \\ \sigma' &= \mathrm{Sig}_{q'}(h', c', \lambda'). \end{aligned}$$

Lemma 1.115 (Associativity of the transported carry)**.** *The equation equation (1.72) guarantees that transporting a state by r_1 and then by r_2 produces the same carry as transporting it by $r_2 \circ r_1$.*

Proof. The successive transport gives

$$\mathsf{C}(r_2)\big(\mathsf{C}(r_1)c + \kappa(r_1)\big) + \kappa(r_2).$$

By functoriality of C, the first term is $\mathsf{C}(r_2 r_1)c$; the sum of the other two is $\kappa(r_2 r_1)$ by equation (1.72). □

1.12.6 Typed prolongation relation Ext_r between enriched fibers

Orientation and boundary are not imposed by means of a universal function. For each arrow $r : q \to q'$, a relation is declared

$$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}.$$

The two conditions are required.

$$\Delta_q \subseteq \mathrm{Ext}_{\mathrm{id}_q}, \qquad \mathrm{Ext}_{r_2} \circ \mathrm{Ext}_{r_1} \subseteq \mathrm{Ext}_{r_2 \circ r_1}.$$

The first preserves identities; the second preserves composition. A relation may admit several local extensions and leave only one after a larger horizon.

Definition 1.116 (The Topological Phase Kernel)**.** An object of the TPK is a tuple

$$x = (q, o, h, c, \sigma, C, b, \lambda)$$

such that

$$\begin{gathered} q \in Q_{\mathrm{obs}}, \quad o \in \mathsf{O}_q, \quad h \in \mathsf{H}_q, \quad c \in \mathsf{C}_q, \quad \lambda \in \Lambda_q, \\ \sigma = \mathrm{Sig}_q(h, c, \lambda), \qquad (C, b) \in \mathsf{Cyl}_q \times \mathsf{Fr}_q. \end{gathered}$$

We associate to each object its fiber component.

$$\mathbf{f}(x) := (o, h, c, \sigma, (C, b), \lambda) \in \mathcal{F}_q.$$

A morphism $x \to x'$ is a triple (r, x, x') in which $r : q \to q'$ belongs to $\mathsf{P}_{\mathrm{obs}}$, the transportable coordinates satisfy the preceding laws, and $(\mathbf{f}(x), \mathbf{f}(x')) \in \mathrm{Ext}_r$. Composition is

$$(r_2, x', x'') \circ (r_1, x, x') = (r_2 r_1, x, x''),$$

and the identity of x is (id_q, x, x).

Theorem 1.117 (Categorical structure of the TPK)**.** *The definition 1.116 defines a category and the map*

$$p : \mathsf{TPK} \longrightarrow \mathsf{P}_{\mathrm{obs}}, \qquad p(x) = q, \qquad p(r, x, x') = r,$$

is a functor.

Proof. Route composition is associative. The lemma 1.115 proves compatibility of the carry coordinate; the declared functoriality of H, C, and Λ proves compatibility of the other determined coordinates. The stability of Ext guarantees that the composite remains admissible, and its diagonal condition provides the identities. The map p preserves identities and composition by construction. □

1.12.7 Observable quotients of the enriched state and conserved genealogical fields

The elementary projections are

$$\phi(x) = g_0(\theta), \qquad \tau(x) = \varepsilon_9(r(\theta)), \qquad \mu(x) = \mu(\theta).$$

The projection to the local TRIT state is

$$\pi_{\mathrm{TRIT}}(x) = \big(\tau, \mu, o, h, c, \sigma, \lambda, \phi\big).$$

It forgets the cylinder, the boundary, and part of q; it does not define another container. Two states may have the same image under π_{TRIT} and differ in the forgotten information.

1.12.8 Criterion of route survival via conservation of the projected boundary

Let $\mathcal{X}_{\mathrm{TPK}}^{(n)}$ be the family of states at depth n. For $N \geq n$, we define

$$\mathrm{Surv}_n^{(N)} = \left\{ x_n : \begin{array}{l} \text{there exist } x_{n+1}, \ldots, x_N \text{ with} \\ (x_j, x_{j+1}) \in \mathrm{Ext}_{r_j} \ \text{ for } n \leq j < N \end{array} \right\}.$$

Proposition 1.118 (Survival filtration)**.** *For $N \geq n$,*

$$\mathrm{Surv}_n^{(N+1)} \subseteq \mathrm{Surv}_n^{(N)}.$$

If the scheme is defined to all depth, the states indefinitely prolongable are

$$\mathrm{Surv}_n = \bigcap_{N \geq n} \mathrm{Surv}_n^{(N)}.$$

Proof. A prolongation to $N + 1$ truncates to a prolongation to N, which proves the inclusion. The intersection expresses exactly prolongability for every finite horizon. □

1.12.9 Insertion of the 6 fibered families of the enriched state into the operator hierarchy of TPK

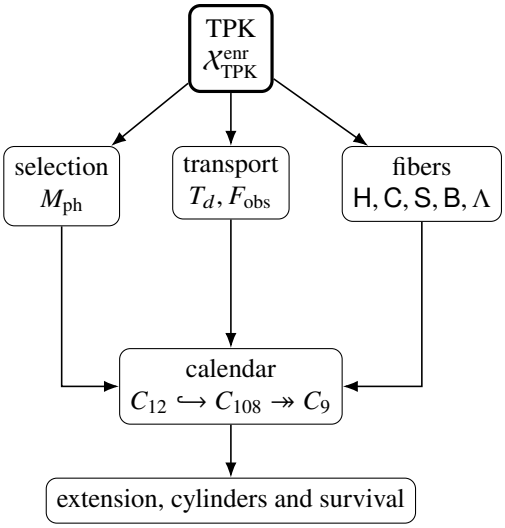

Figure 1.3: Operator containment of the Topological Phase Kernel. The selector, transport, readers, and fibers are not parallel containers: they are maps or coordinates of the same enriched state.

1.12.10 Obstructions of the enriched state of the TPK: typing of the selector, carry cochain, compatible extension, and genealogical conservation

Comparison Criterion 1.119 (Refutation Criteria for the Enriched State)**.** The definition is refuted if:

1. the selector M_{ph} it usa as translation;
2. θ, $g_0(\theta)$, $r(\theta)$, and $\beta(\theta)$ are identified;
3. a signature is allowed to be chosen independently of (h, c, λ);
4. the composition of carries incumple equation (1.72);
5. Ext_r is replaced by an unproved functional choice;
6. a projection that has forgotten the cylinder, boundary, or genealogical record is called a complete state;
7. the phase return erases any of the coordinates of fiber.

This unit has defined the container. The next will enumerate its readers, operators, odometer, and calendars, and will prove why the returns of nine, twenty-seven, and one hundred eight steps are not restarts of the state.

1.13 Typed hierarchy of the 34 heterogeneous canonical constructions and causal dynamics of TPK updating

The Topological Phase Kernel is neither a reduction modulo three nor a clock with one hundred and eight positions. It is a category of enriched states equipped with operators of selection, transport, reading, memory, periodicity, prolongation, and publication. To prevent an abbreviation from replacing the object, each operator is recorded by its type and by the information it preserves.

1.13.1 Typed schema of the 34 canonical TPK constructions: domain, codomain, action, invariants, and memory

Definition 1.120 (Operator specification)**.** A canonical realization of the TPK is a sextuple

$$O = (D_O, C_O, f_O, I_O, L_O, M_O), \tag{1.73}$$

where:

1. $f_O : D_O \to C_O$ is its rule;
2. I_O is the family of conserved relations;
3. L_O declares the information published or lost;
4. M_O enumerates the memory that remains in the enriched state.

Two realizations represent the same operator only when there exists a typed equivalence that intertwines rules and invariants. Sharing a period, cardinality, or visible output is not sufficient.

1.13.2 Typed L_0–L_7 hierarchy of the 34 heterogeneous canonical TPK constructions

The inventory is partitioned into:

C1. supports and states;

C2. internal selection;

C3. transporte;

C4. readers and quotients;

C5. memory and boundary;

C6. periodicity and return;

C7. prolongation;

C8. salidas.

The class is determined by domain, codomain, and function, not by the name of a number associated with it.

1.13.3 Functional grouping of the 34 canonical constructions in 14 families of composition APP–TRIT–TPK

Grouping	Operators or spaces	Function and invariants
State and route memory	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}, \mathcal{F}_q$	Preserve position, sheet, orientation, residue, quotient, carry, signature, boundary, cylinder, prefix, provenance and memory.
Internal selection	$M_{\mathrm{ph}} : \{1,\dots,9\} \to \{-1,0,+1\}$	Activate the additive, multiplicative evaluation or the threshold step; does not move the state.
Transporte espacial	$T_N, T_E, T_S, T_O, F_{\mathrm{loc}}, F_{\mathrm{obs}}$	Perform cardinal translations, sheet feedback, and timeline of two cursors.
Lectores modulares	$\rho_9, q_9, \rho_3^{\mathrm{or}}, c_3, q_{1000}, r_{1000}$	Publish phase, orientation and decimal block preserving the lift quotients.
Block and memory	$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}, \mathcal{N}_{27}$	The former composes twenty-seven transports; the latter filters memory events. An equal index does not imply an equal operator.
Twelve-phase state	$\mathcal{R}_{12}, C_{12}, \Theta_{108}, \Gamma_{108}$	Distinguish enriched record, sector, cyclic law, and ordered support.
Periodicity and depths	$C_{12} \hookrightarrow C_{108} \twoheadrightarrow C_9, w_{108}, w_{1080}$	Preserves the non-splittable extent, words of different lengths and the vertical memory.
Channels 90/120	$\mathcal{F}_6, \mathcal{F}_8, \mathcal{I}_{6\to 8}, S_{90}, S_{120}$	Separate finite incidences, analytic tails, and their normalizations.
Bidirectionality	$P_{\pm}, \mathrm{rev}, \mathrm{Ext}_{\pm}, N_{\pm}, \beta, C_M$	Perform exchange, route inversion, future and past prolongation, valence, balance, and conjugation.
Emission and coinduction	$L_0, L_1, R_{36}, G_9, \varprojlim \mathrm{Cyl}_m$	Lift the seed, open the boundary, and organize finite and compatible extensions.
Numeric Readers	$\mathscr{C}_\pi, \mathscr{P}_e, F_{\mathrm{av}}$	They construct rational forks, factorial propagation, and Fibonacci self-scaling.
Exceptional Projection	Γ_{A_W}, weight, projective support	Transport the same emission to ternary incidence without selecting Archimedean numbers.
Atlas and realization	route signature, atlas 81/56/13/324, C_M	Classify stories and characters before applying a dimensional chart.
Finite validation	censuses, structural necessity tests, integrity identities and independence controls	Checks coverage at the executed depth and separates construction, independent verification, and comparison data.

The eight classes describe mathematical nature; the fourteen groupings describe execution function. They are two gradings of the same inventory.

1.13.4 Mathematical classes, domains, codomains, and causal dependencies of the 34 canonical constructions

$$\mathfrak{O}_{\mathrm{TPK}} := (\mathfrak{o}_1, \dots, \mathfrak{o}_{34}). \tag{1.74}$$

#	Symbol	Domain and codomain	Rule or function
1	$\mathcal{A}_9$	$(\mathbb{Z}/9)^2$, matrix and internal law	Additive-multiplicative arithmetic cell.
2	(ρ_9, q_9)	$\mathbb{Z}_{>0} \to \{1, \dots, 9\} \times \mathbb{Z}_{\geq 0}$	Nonadic division with positive representative and quotient.
3	$\rho_3^{\mathrm{or}}, c_3$	$\mathbb{Z} \to \{-1, 0, +1\} \times \mathbb{Z}$	Lift ternary oriented $n = \rho_3^{\mathrm{or}}(n) + 3c_3(n)$.
4	$\iota_{1000} := (q_{1000}, r_{1000})$	$\mathbb{Z} \to \mathbb{Z} \times \{0, \dots, 999\}$	Euclidean division $N = 1000q_{1000} + r_{1000}$.
5	T_d	$X_9 \to X_9$, $d \in \{N, E, S, O\}$	Cardinal oriented translation.
6	F_{loc}	$\mathcal{Q}_{\mathrm{loc}} \times \mathscr{D}_{\mathrm{card}} \to \mathcal{Q}_{\mathrm{loc}}$	Local position feedback and sheet.
7	$T_{\min}$	$\Omega_{\mathrm{seed}} \to \mathcal{U}_6$	Minimum emitter of the two cursors, including the coordinate signature.
8	G	$\operatorname{im} s_\Sigma \times \operatorname{im} s_\Pi \to \{0, \dots, 999\}^6$	Coordinate-by-coordinate decimal coupling.
9	Ψ_6	$\mathcal{U}_6 \to \mathbb{F}_3^6$	Tertiary reduction of the catalog.
10	$\mathcal{R}_3$	$\mathcal{Q}_{\mathrm{loc}} \times \mathscr{D}_{\mathrm{card}}^3 \to \{-1, 0, +1\}$	Local three-step observable factor.
11	$\mathcal{K}_{27}$	$\mathcal{Q}_{\mathrm{obs}} \to \mathcal{Q}_{\mathrm{obs}}$	Composition F_{obs}^{27}.
12	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$	enriched states category	Preserve all the typed coordinates of the nucleus.
13	$\mathcal{H}$	relation on enriched states	Hensel Transition that retains residue and quotient.
14	$C_{3,1000}$	crossed states (N, L, D, K, A, B)	Exact update of ternary-decimal cylinders.
15	Σ_{B}	boundary memories → signature joint	Publish the block orientation preserving its genealogical record.
16	EF–G_9	extension relation	Filter compatible extensions and organize the nonadic genealogy.
17	Γ_9	enriched histories ⟶ histories	Holonomy of a phase twist with boundary memory.
18	X_χ	$\varprojlim_m \mathrm{Surv}_m^{(\chi)}$	Global section when non-emptiness, compatibility, and uniqueness are demonstrated in full depth.
19	$\mathcal{P}_{\mathrm{APP}}^{(2)}$	bivariate path category	Transports simultaneously the multiplicative evaluation and the additive accumulation.
20	F_{obs}	$\mathcal{Q}_{\mathrm{obs}} \to \mathcal{Q}_{\mathrm{obs}}$	Deterministic observable chronology with two cursors.
21	$\mathcal{A}_{42}$	alphabet of forty-two triads	Extended decimal support of finite emission.
22	Ext_r	$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}$	Typed relation of fiber prolongation.
23	$\mathcal{K}_{\mathrm{ph}}$	$\mathcal{U}_6 \times C_9$ about itself	Transfer of phase-compatible explicit continuation.
24	(P, H, Q)	$\mathcal{X}_\times \to \mathcal{X}_\times$	Advance, half-turn, and quarter-turn of seeds.
25	$(c_{\mathrm{mode}}, c_{\mathrm{or}})$	caminos → $\mathbb{Z}^2$	Mode and orientation change cocycles.
26	E_{20}	finite states → twenty blocks	Finite triadic prolongation with sourcebook.
27	$\mathcal{R}_{12}$	history enriched → record of twelve sectors	Timed system with route, signature, carry, and genealogical record.
28	R_{sgn}	terminal state → $U_{12}^{\mathrm{sgn}} \subseteq \mathbb{Z}^{12}$	Reader of the signed harmonic observable.
29	$\mathcal{H}_{12}$	$\mathbb{Z}^{12} \to \mathbb{Z}^{12}$	Transformation by three orbits of step three; inverse $\mathcal{H}_{12}/4$ over the pertinent image.
30	$\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q)$	$\mathbb{Z}^{12} \to \mathbb{Z}^{25}$	Transversal extractor set of arities three and four.
31	C_α	blocks and carries → blocks	Dodecaphasic closure recurrence in base thousand.
32	$(L_{\mathrm{tick}}, \chi_{\mathrm{mass}})$	enriched history → temporal character	Posterior dimensional interface; does not participate in the numeric constructor of this work.
33	$\mathcal{W}_\pm$	bidirectional lattice of index twelve	Reading in both directions preserving orientation and origin.
34	$\mathcal{A}_{\mathrm{species}}$	extension families → atlas	Posterior realization interface, not a primitive fourth.

1.13.5 Update of the enriched state through $U_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$

Definition 1.121 (Complete canonical state)**.** Let

$$\mathcal{E} := \mathbb{Z}_{\mathrm{quo}} \times \mathbb{Z}_{\mathrm{car}} \times \mathsf{Mem} \times \mathsf{Term} \times \mathsf{Cyl} \times \mathsf{Fr} \times \mathsf{Pref} \times \Lambda.$$

The canonical enriched state at instant t is

$$x_t = (p_t, m_t, \sigma_t, b_t, r_t; q_t, c_t, \eta_t, s_t, C_t, \partial_t, N_t, \lambda_t) \in X_9 \times \{\Sigma, \Pi\} \times \mathsf{TRIT} \times C_{12} \times C_9 \times \mathcal{E}. \tag{1.75}$$

The state abbreviations used in other units are projections of this tuple. In particular, the quotient q_t, carry c_t, terminal s_t, cylinder C_t, boundary ∂_t, prefix N_t, and ledger λ_t are not omitted.

Let ρ_t be the observable arrow determined by x_t. The transport laws of U005 and the transition $C_{3,1000}$ determine a memory endomorphism

$$\begin{aligned} \mathbf{E}_t &: \mathcal{E} \longrightarrow \mathcal{E}, \\ (q, c, \eta, s, C, \partial, N, \lambda) &\longmapsto \begin{pmatrix} \mathsf{H}(\rho_t)q, \mathsf{C}(\rho_t)c + \kappa(\rho_t), \mathsf{M}(\rho_t)\eta, \\ \mathsf{T}(\rho_t)s, \mathsf{Cyl}(\rho_t)C, \mathsf{Fr}(\rho_t)\partial, \\ \mathsf{Pref}(\rho_t)N, \Lambda(\rho_t)\lambda \end{pmatrix}. \end{aligned} \tag{1.76}$$

Each component published in (1.76) has the domain indicated by its fiber; $\kappa(\rho_t)$ is the carry cochain.

We define three endomorphisms of the canonical product. If $\sigma' = M_{\mathrm{ph}}(g(t))$ and $m' = \mu(\sigma', m)$, then

$$\mathsf{Sel}_t(p, m, \sigma, b, r; e) := (p, m', \sigma', b, r; e), \tag{1.77}$$

$$\mathsf{Tra}_t(p, m, \sigma, b, r; e) := (T_{d(t)}p, m, \sigma, b, r; e), \tag{1.78}$$

$$\mathsf{Upd}_t(p, m, \sigma, b, r; e) := (p, m, \sigma, b', r'; \mathbf{E}_t(e)), \tag{1.79}$$

where (b', r') is the destination of $\rho_t : (b, r) \to (b', r')$. The causal update is a composition of maps, not the composition of a map with a tritic value:

$$\boxed{\mathcal{U}_t := \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t.} \tag{1.80}$$

Theorem 1.122 (Closure of causal update)**.** *The map $\mathcal{U}_t$ is an endomorphism of the complete canonical state. Readers, prolongations, and projections are applied after $\mathcal{U}_t$ only when their domain has been produced.*

Proof. Sel_t changes only the mode and the TRIT; Tra_t changes only the APP position; and Upd_t applies the typed product (1.76) and the phase arrow. All three codomains are the same product of definition 1.121; their composition is therefore defined and preserves all state coordinates. □

1.13.6 Typed separation between operators, states, projections, and publications of the TPK

The inventory imposes

$$\mathcal{S}_4 \neq D_4 \neq \mathrm{sd}_4, \qquad \mathcal{R}_{12} \neq C_{12} \neq \Theta_{108} \neq \Gamma_{108}, \qquad F_{\mathrm{obs}} \neq \mathcal{K}_{\mathrm{ph}}, \tag{1.81}$$

and

$$U_{12}^{\mathrm{cat}} \neq U_{12}^{\mathrm{sgn}}, \qquad \mathcal{E}_{\mathrm{dod}} \neq D_{\mathrm{raw}}^{90,120} \neq \mathcal{K}_{6\to 8}. \tag{1.82}$$

They are type incompatibilities, not mere value inequalities.

Comparison Criterion 1.123 (Audit of operatorial completeness)**.** An execution is operatorially complete only if:

1. declares the inputs of $\mathfrak{O}_{\mathrm{TPK}}$ used;
2. is recorded the domain and the codomain of each composition;
3. preserves the causal order of (1.80);
4. distinguishes dynamics, transfer, reading, prolongation, and output;
5. permits reconstruction from λ_t of every block change and every carry;

6. does not promote a finite check to an infinite section without proving non-emptiness, compatibility, and uniqueness at every depth.

Any symbol used without a type, or any fusion prohibited by (1.81) and (1.82), constitutes a verifiable failure.

1.14 Tritic incidence 90/120 and typed separation of the temporal, nilpotent, and angular operators

The integers 90 and 120 appear in several strata of the construction. Their numerical coincidence does not establish an identity of objects. Likewise, the letter epsilon denotes three constructions with incompatible domains. The purpose of this unit is to fix their types before using them and to indicate precisely which realizations require structures that have not yet been constructed.

1.14.1 Temporal, nilpotent, and angular operators: domains and codomains

1.14.1.1 Action of the tritic temporal selector over $\{-1,0,+1\}$*: opening, threshold, and return with memory*

The internal calendar selector is

$$\varepsilon_9 : \{1,\dots,9\} \longrightarrow \{-1,0,+1\}, \qquad \varepsilon_9(r) = \begin{cases} +1, & r \in \{1,4,7\}, \\ -1, & r \in \{2,5,8\}, \\ 0, & r \in \{3,6,9\}. \end{cases} \tag{1.83}$$

Its codomain is the oriented TRIT. It determines which sheet acts and does not itself shift any position.

1.14.1.2 Nilpotent parabolic generator $J_0^2 = 0$ *and evolution at the temporal threshold*

The class

$$\varepsilon_{\mathrm{nil}} \in Q_{\mathrm{n}} := \mathbb{F}_3[\varepsilon_{\mathrm{nil}}]/(\varepsilon_{\mathrm{nil}}^2) \tag{1.84}$$

satisfies

$$\varepsilon_{\mathrm{nil}} \neq 0, \qquad \varepsilon_{\mathrm{nil}}^2 = 0. \tag{1.85}$$

It is an element of a degenerate quadratic algebra; it is not a temporal selector.

1.14.1.3 Angular residue induced after temporal selection and orientation preservation

The symbol

$$\varepsilon_{\mathrm{res}}^{\circ} \in \mathbb{R} \tag{1.86}$$

designates, when its geometric parameters are introduced, the residue of an angular identity. At this stage only its type remains reserved. It is not obtained from ε_9 or from $\varepsilon_{\mathrm{nil}}$, and it does not intervene in the construction of π, e, φ or α.

Proposition 1.124 (No identification of the epsilon symbols)**.** *There is no well-typed equality between*

$$\varepsilon_9, \qquad \varepsilon_{\mathrm{nil}}, \qquad \varepsilon_{\mathrm{res}}^{\circ}.$$

Proof. The first object is a function between finite sets; the second, a nilpotent element of an algebra over $\mathbb{F}_3$; the third, a real scalar with angular unit. Their domains, codomains, and laws of composition are distinct. □

1.14.2 Typed residences of the indices 90/120 in 6 non-equivalent operator objects

Definition 1.125 (Dodecaphasic Extractor)**.** The integral extractor

$$\mathcal{E}_{\mathrm{dod}} := (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25} \tag{1.87}$$

reads differences of arities three and four and a sum coordinate. The subscripts are not angular lengths.

Definition 1.126 (Raw difference of sequences)**.** For $|q| < 1$, define

$$S_m^{\mathrm{raw}}(q) := \frac{q^m}{1 - q^{3m}}, \qquad D_{\mathrm{raw}}^{90,120}(q) := S_{90}^{\mathrm{raw}}(q) - S_{120}^{\mathrm{raw}}(q). \tag{1.88}$$

This object is an analytic function of q; it is not a finite census.

Definition 1.127 (Marked families of incidence)**.** Once a hexad H, its image $\ell(H)$ in a binary dodecad D, and the lifted octad O_H have been constructed, one will define

$$\mathcal{F}_6(H) := \ell(H) \times \binom{\ell(H)}{2}, \tag{1.89}$$

$$\mathcal{F}_8(H) := O_H \times \binom{\ell(H)}{2}. \tag{1.90}$$

By construction,

$$|\mathcal{F}_6(H)| = 6\binom{6}{2} = 90, \qquad |\mathcal{F}_8(H)| = 8\binom{6}{2} = 120. \tag{1.91}$$

The inclusion $\ell(H) \hookrightarrow O_H$ inducira

$$\mathcal{I}_{6\to 8} : \mathcal{F}_6(H) \hookrightarrow \mathcal{F}_8(H). \tag{1.92}$$

The equations (1.89) y (1.90) fix the type from now on. Their effective existence will be proved after constructing C_W, W_{12}, the binary datum G_{24}, D, ℓ, and W_{24}. That branch is not anticipated here.

Definition 1.128 (Normalized Queue Combination)**.** For parameters $q_-, q_+ \in (0, 1)$, let

$$S_m(q) := \frac{q^m}{1 - q^{3m}}, \qquad \Delta S_m := S_m(q_-) - S_m(q_+). \tag{1.93}$$

The functional

$$\mathcal{K}_{6\to 8} := 12\,\Delta S_{90} - \Delta S_{120} \tag{1.94}$$

is an analytic combination of tails. Its coefficient twelve belongs to its normalization and does not turn it into the record $\mathcal{R}_{12}$.

Definition 1.129 (Semigroup of Degrees and Moments)**.** The additive semigroup generated by both degrees is

$$\mathfrak{S}_{90,120} := \langle 90, 120\rangle = \{90a + 120b : a, b \in \mathbb{N}_0\}. \tag{1.95}$$

For $n \in \mathfrak{S}_{90,120}$, the oriented moment is

$$s_n := q_-^n - q_+^n. \tag{1.96}$$

The moments are differential monomials indexed by a semigroup; the series of (1.93) are infinite sums of those moments over specific progressions.

1.14.3 Normalized defect 1−90/120=1/4 of the tritic incidence

When the inclusion $\mathcal{I}_{6\to 8}$ has been constructed, its difference of cardinalities will be

$$|\mathcal{F}_6(H)| - |\mathcal{F}_8(H)| = 90 - 120 = -30.$$

If normalization is declared

$$24\binom{6}{2} = 360,$$

we obtain

$$\frac{90-120}{24\binom{6}{2}} = \frac{6-8}{24} = -\frac{1}{12}. \tag{1.97}$$

The inclusion determines -30; the rational $-1/12$ depends moreover of the declared normalization. No it what must present as if the cardinality by if alone fixed the denominator.

1.14.4 Domain invariants, orientation, and memory of the 90/120 realizations

Theorem 1.130 (Separation of the six objects)**.** *The objects*

$$\mathcal{E}_{\mathrm{dod}}, \quad D_{\mathrm{raw}}^{90,120}, \quad \mathcal{I}_{6\to 8}, \quad \mathcal{K}_{6\to 8}, \quad \mathfrak{S}_{90,120}, \quad \varepsilon_{\mathrm{res}}^{\circ} \tag{1.98}$$

are mutually distinct by type: they are, respectively, an integer reader, an analytic function, a finite morphism, a combination of series, an index semigroup, and a real angular scalar.

Proof. The conclusion is obtained by comparing their domains and codomains:

$$\mathbb{Z}^{12} \to \mathbb{Z}^{25}, \quad \mathbb{D} \to \mathbb{C}, \quad \mathcal{F}_6(H) \to \mathcal{F}_8(H), \quad (0,1)^2 \to \mathbb{R}, \quad \mathbb{N}_0^2 \to \mathbb{N}_0, \quad \{*\} \to \mathbb{R}.$$

There are no two identical signatures. □

Comparison Criterion 1.131 (Refutation criteria)**.** The classification is refuted if any of its domains or codomains is altered, if the census of (1.91) does not reproduce 90 and 120, if $-1/12$ is attributed to the inclusion without declaring the normalization, or if the angular residual is presented as an output of the constants generator of this monograph.

1.15 Local transport factor and ternary-decimal transition

This unit separates three operations involved in the transport of the Topological Phase Kernel that do not share a domain: the cardinal realization of a trit, the stroboscopic sampling of a sequence, and the exact update of a pair of ternary–decimal cylinders. The first is a finite dynamics; the second is a temporal reader; the third preserves the integers that make it possible to decide compatibility without floating-point arithmetic.

1.15.1 Oriented transition local operator and APP sheet update

Let

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2, \qquad \mathscr{D}_{\mathrm{card}} = \{N, E, S, O\},$$

with

$$\delta(N) = (-1, 0), \quad \delta(E) = (0, 1), \quad \delta(S) = (1, 0), \quad \delta(O) = (0, -1).$$

The visible evaluations of APP are

$$L_\Sigma(x, y) = \rho_9((x+1) + (y+1)), \qquad L_\Pi(x, y) = \rho_9((x+1)(y+1)),$$

where $\rho_9(n) = 1 + ((n-1) \bmod 9)$. We further define

$$\rho_3^{\mathrm{or}}([0]) = 0, \qquad \rho_3^{\mathrm{or}}([1]) = +1, \qquad \rho_3^{\mathrm{or}}([2]) = -1.$$

Definition 1.132 (Local factor of APP–TRIT)**.** The local state space is

$$\mathcal{Q}_{\mathrm{loc}} = X_9 \times \{\Sigma, \Pi\}, \qquad |\mathcal{Q}_{\mathrm{loc}}| = 162.$$

For $q = (p, m)$, $d \in \mathscr{D}_{\mathrm{card}}$, we set

$$p_d = p + \delta(d), \qquad a_d(q) = \rho_3^{\mathrm{or}}([L_m(p_d)]_3),$$

and

$$\mu(a, m) = \begin{cases} \Sigma, & a = +1, \\ \Pi, & a = -1, \\ m, & a = 0. \end{cases}$$

The local transition is

$$F_d^{\mathrm{loc}}(p, m) = (p_d, \mu(a_d(p, m), m)).$$

The position it is modified before evaluating the sheet. The null trit preserves the last active mode; not eliminates the sheet nor reinitializes the history.

For a cardinal word $u = d_1 d_2 d_3$, let

$$q_j = F_{d_j}^{\mathrm{loc}}(q_{j-1}), \qquad q_0 = q,$$

and let us denote by

$$R_3(q, u) \in \{-1, 0, +1\}$$

the trit produced in the third displacement.

Definition 1.133 (Remark on step three)**.** On an oriented sequence $a = (a_t)_{t \geq 1}$ we define

$$\mathrm{Obs}_3(a) = (a_3, a_6, a_9, \ldots).$$

The map R_3 takes a state and a cardinal word of length three; Obs_3 takes a sequence and publishes a subsequence. They are operators of different types.

Theorem 1.134 (Exact surjectivity of the sampled factor)**.** *For every $q \in \mathcal{Q}_{\mathrm{loc}}$ and every $b \in \{-1, 0, +1\}$, the fiber*

$$\mathcal{R}_3(q, b) = \{u \in \mathscr{D}_{\mathrm{card}}^3 : R_3(q, u) = b\}$$

is non-empty and satisfies

$$\boxed{8 \leq |\mathcal{R}_3(q, b)| \leq 40.}$$

In particular, the $162 \cdot 3 = 486$ *state–output fibers are non-empty.*

Proof. From each of the 162 states, the $4^3 = 64$ cardinal words are enumerated, and the recurrence of definition 1.132 is applied literally. The exhaustive census of the 486 pairs (q, b) has a minimum of eight, a maximum of forty, and no zero value. The statement is therefore a finite identity on the defined system, not a mixing hypothesis. □

Corollary 1.135 (Realization of an arbitrary oriented sequence)**.** *Remark. For every sequence $(b_k)_{k \geq 1} \in \{-1, 0, +1\}^{\mathbb{N}}$ there exists a cardinal history whose observation satisfies*

$$(a_3, a_6, a_9, \ldots) = (b_1, b_2, b_3, \ldots).$$

Proof. Fixing a total order on $\mathscr{D}^3_{\mathrm{card}}$, at stage k the first element of $\mathcal{R}_3(q_{k-1}, b_k)$ is taken. The terminal state of the block again belongs to Q_{loc}, so that the choice may be iterated indefinitely. □

The corollary proves that the sampled factor can be realized. It does not select the sections of π, e, φ, fix the two intermediate trits or replace the compatibility of the enriched state.

1.15.2 Cylindrical systems of the 2 arithmetic readers and truncation compatibility

A ternary word of length L, interpreted as the integer N, determines

$$I_3(N, L) = \left[\frac{N}{3^L}, \frac{N+1}{3^L}\right).$$

A prefix of K decimal triads, interpreted as the integer D, determines

$$I_{1000}(D, K) = \left[\frac{D}{1000^K}, \frac{D+1}{1000^K}\right).$$

We introduce the cross residues

$$A = N1000^K - D3^L, \qquad B = (N+1)1000^K - D3^L = A + 1000^K.$$

Lemma 1.136 (Integer compatibility criterion)**.** *The cylinders $I_3(N, L)$ and $I_{1000}(D, K)$ intersect if and only if*

$$\boxed{A < 3^L, \qquad B > 0.}$$

Equivalently,

$$N1000^K < (D+1)3^L, \qquad (N+1)1000^K > D3^L.$$

Proof. Two half-open intervals $[a, b)$ and $[c, d)$ intersect exactly when $a < d$ and $c < b$. Multiplication by $3^L 1000^K > 0$ produces the two inequalities. Subtracting $D3^L$ and $N1000^K$, respectively, gives the form in A, B. □

1.15.3 Completion operator $C_{3,1000}$: ternary extension and preservation of the unit in 10^3 positions

A new block of six trits is represented by

$$u \in \{0, \dots, 3^6 - 1\} = \{0, \dots, 728\}.$$

The ternary update is

$$N' = 729N + u, \qquad L' = L + 6.$$

Decimal publication has two cases. If the refined cylinder does not yet determine a new triad, then $K' = K$, $D' = D$. If it determines $\delta \in \{0, \dots, 999\}$, then

$$K' = K + 1, \qquad D' = 1000D + \delta.$$

Definition 1.137 (Crossed state and exact transition)**.** The cylinder state is the sextuple

$$\mathfrak{c} = (N, L, D, K, A, B)$$

subject to

$$A = N1000^K - D3^L, \qquad B = A + 1000^K.$$

The transition $C_{3,1000}$ adjoins u and, when corresponds, δ, and updates

$$(N, L, D, K, A, B) \longmapsto (N', L', D', K', A', B')$$

through means of

$$A' = \begin{cases} 729A + u1000^K, & K' = K, \\ 729000A + u1000^{K+1} - \delta\, 729\, 3^L, & K' = K + 1, \end{cases} \qquad B' = A' + 1000^{K'}.$$

The prolongation is admissible exactly when

$$A' < 3^{L'}, \qquad B' > 0.$$

Theorem 1.138 (Accuracy and Sufficiency of the Cross State)**.** *The transition of the definition 1.137 exactly preserves the identities*

$$A' = N'1000^{K'} - D'3^{L'}, \qquad B' = (N' + 1)1000^{K'} - D'3^{L'}.$$

Consequently, (A', B', L', K') *suffices to decide the compatibility of the new pair of cylinders, while* (N', D') *preserves its reconstructive provenance.*

Proof. If a decimal triplet does not appear,

$$N'1000^K - D3^{L+6} = (729N + u)1000^K - 729D3^L = 729A + u1000^K.$$

Si aparece δ,

$$\begin{aligned} N'1000^{K+1} - D'3^{L+6} &= (729N + u)1000^{K+1} - (1000D + \delta)7293^L \\ &= 729000A + u1000^{K+1} - \delta\, 729\, 3^L. \end{aligned}$$

In both cases, increasing N' by one unit adds $1000^{K'}$, which yields B'. The criterion of the lemma 1.136 concludes. □

Proposition 1.139 (Compatibility with concatenation)**.** *Successively applying* $C_{3,1000}$ *to two blocks produces the same pair* (N'', D'') *and the same cross-residues as appending at once the two ternary words and the decimal triads published in the same order.*

Proof. The recurrences $N \mapsto 729N + u$ and $D \mapsto 1000D + \delta$ are the laws of positional concatenation in bases 729 and 1000. The theorem 1.138 identifies A, B with functions of those four integers; hence its stagewise update coincides with the evaluation subsequent to concatenation. □

1.15.4 Factorization of the TPK transition as $U_t = \mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$

The correct sequence is

$$(q, u) \xmapsto{R_3} b, \qquad (a_t)_{t\geq 1} \xmapsto{\mathrm{Obs}_3} (a_{3k})_{k\geq 1}, \qquad (\mathfrak{c}, u, \delta) \xmapsto{C_{3,1000}} \mathfrak{c}'.$$

R_3 proves local realizability; Obs_3 publishes a subsequence; $C_{3,1000}$ transports compatibility between two bases. None of the three can replace the survival relation of the full TPK.

Comparison Criterion 1.140 (Refutation criteria)**.** The construction is refuted in its domain if any of the following facts occurs:

1. any of the 486 fibers $\mathcal{R}_3(q, b)$ is empty or remains outside of the interval $[8, 40]$;
2. the null trit changes the active mode;

3. R_3 is identified with Obs_3;
4. the recurrence of A' does not reproduce its direct definition;
5. a declared compatible prolongation violates $A' < 3^{L'}$ or $B' > 0$;
6. the decision depends on a numerical tolerance absent from the integer inequalities.

1.16 Record dodecafasico integral, extension ciclica and decomposition 1 + 5 + 6

The observable period of one hundred eight positions contains twelve sectors of nine positions. This equality of cardinalities does not suffice to describe the temporal state: the ordered support, cyclic law, sector index, and enriched register of transports, orientations, carries, and incidences must be distinguished. This unit constructs the four objects and proves the integral reconstruction of the twelve memory coordinates.

1.16.1 Cyclic coordinate on the time-oriented 12-sector support

For $m \in \{1, \dots, 12\}$, define

$$E_m := \{9(m-1)+1, \dots, 9m\}. \tag{1.99}$$

The ordered support and the cyclic group are

$$\Gamma_{108} := E_1 \sqcup \cdots \sqcup E_{12}, \qquad \Theta_{108} := \mathbb{Z}/108\mathbb{Z}. \tag{1.100}$$

Γ_{108} preserves position, order and pertenencia to block; Θ_{108} preserves the law of translation. No are the same object.

For $\theta \in \Theta_{108}$, let $\widetilde{\theta} \in \{0, \dots, 107\}$ be its representative. We define

$$\beta(\theta) := \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12}, \qquad r(\theta) := 1 + (\widetilde{\theta} \bmod 9). \tag{1.101}$$

The first coordinate locates the duodecaphase sector; the second publishes the positive position $1, \dots, 9$ within the sector.

1.16.2 nonsplit extension $0 \to C_{12} \to C_{108} \to C_9 \to 0$ and carry cocycle

Let $C_n = \mathbb{Z}/n\mathbb{Z}$. The applications

$$\iota : C_{12} \longrightarrow C_{108}, \quad \iota([b]_{12}) = [9b]_{108}, \qquad p : C_{108} \longrightarrow C_9, \quad p([\theta]_{108}) = [\theta]_9 \tag{1.102}$$

form the sequence

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0. \tag{1.103}$$

For the set-theoretic section

$$s([r]_9) := [\widetilde{r}]_{108}, \qquad 0 \le \widetilde{r} < 9,$$

the defect of additivity is

$$c(r, r') := \left[\left\lfloor \frac{\widetilde{r} + \widetilde{r}'}{9} \right\rfloor\right]_{12}, \qquad s(r) + s(r') = s(r + r') + \iota(c(r, r')). \tag{1.104}$$

Theorem 1.141 (Accuracy, non-division, and cohomological class)**.** *The sucesion* (1.103) *is exacta and not it escinde. For the action trivial,*

$$H^2(C_9, C_{12}) \simeq C_{12}/9C_{12} \simeq C_3, \tag{1.105}$$

and the cocycle (1.104) *represents its generating class.*

Proof. The image of ι is the subgroup of multiples of nine, which coincides with $\ker p$; p is surjective. This proves exactness. If the extension were split, C_{108} would be isomorphic to $C_{12} \times C_9$, but

$$\exp(C_{108}) = 108, \qquad \exp(C_{12} \times C_9) = \operatorname{mcm}(12, 9) = 36.$$

The cocycle identity is the Euclidean division of $\widetilde{r} + \widetilde{r'}$ by nine. For a cyclic group with trivial action, $H^2(C_9, C_{12}) \simeq C_{12}/9C_{12}$; the unit carry projects to $[1]$, which generates the quotient of order three. □

The non-splitting typifies the return:

$$g_0(\theta + 9) = g_0(\theta), \qquad \beta(\theta + 9) = \beta(\theta) + 1 \pmod{12}.$$

Nine iterations close the visible phase and shift one sector; one hundred eight close both coordinates of the clock. The enriched state further preserves the vertical memory, cylinder, boundary, and genealogy.

1.16.3 Enhanced temporal registration: joint encoding of phase, sheet, boundary, and memory

Definition 1.142 (Oriented dodecaphonic register)**.** For an enriched history, let τ_m be the ordered subroute on E_m, σ_m its orientation, κ_m the carry crossing the block boundary, and Λ_m its local incidence ledger. The complete record is

$$\mathcal{R}_{12} := \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12}. \tag{1.106}$$

Thus four levels are distinguished:

$$\boxed{\mathcal{R}_{12} \neq C_{12} \neq \Theta_{108} \neq \Gamma_{108}.} \tag{1.107}$$

The first is an enriched register; the second, a sector index; the third, a group of translations; the fourth, an ordered support. There exist projections between them, but no identifications.

Let $q_{\mathrm{mem}} \in \mathbb{Z}_{\geq 0}$ be the unbounded number of nonadic turns. The duodecaphase coordinate is only its residue

$$\beta = [q_{\mathrm{mem}}]_{12}.$$

After one hundred and eight steps,

$$\beta \longmapsto \beta, \qquad q_{\mathrm{mem}} \longmapsto q_{\mathrm{mem}} + 12.$$

The calendar returns; the vertical memory is not reset.

1.16.4 Extraction of the signed dodecaphase state from the enriched time record

Let $(d_t)_{t=1}^{108}$ be the digital record on Γ_{108}. We define

$$\mathcal{D}_{\mathrm{evt}} := \{2, 4, 6, 8\}, \qquad \Sigma_{12} := (+, +, +, -, -, -, +, +, +, -, -, -). \tag{1.108}$$

For $m = 0, \ldots, 11$, let

$$e_m := \Sigma_{12}(m + 1)\, \#\{t \in E_{m+1} : d_t \in \mathcal{D}_{\mathrm{evt}}\} \in \mathbb{Z}. \tag{1.109}$$

The application preserves the local census and the sectorial orientation as separate factors.

We pair the two semicrowns by means of

$$p_i := e_i + e_{i+6}, \qquad a_i := e_i - e_{i+6}, \qquad 0 \leq i \leq 5. \tag{1.110}$$

We define the total census, the five differences with respect to the sixth pair, and the six antisymmetries:

$$s_C := \sum_{i=0}^{5} p_i, \qquad M_i := p_i - p_5 \quad (0 \le i \le 4), \qquad A_6 := (a_0, \dots, a_5). \tag{1.111}$$

Definition 1.143 (Integral reader 1 + 5 + 6)**.** The linear reader is

$$\mathcal{L}_{12} : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{12}, \qquad \mathcal{L}_{12}(e) := (s_C, M_0, \dots, M_4, a_0, \dots, a_5). \tag{1.112}$$

The coordinate distribution is

$$\underbrace{1}_{s_C} + \underbrace{5}_{M_0,\dots,M_4} + \underbrace{6}_{a_0,\dots,a_5} = 12. \tag{1.113}$$

Theorem 1.144 (Exact reconstruction and integral image)**.** *The reader $\mathcal{L}_{12}$ is injective. On its image,*

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i \quad (0 \le i \le 4), \tag{1.114}$$

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2} \quad (0 \le i \le 5). \tag{1.115}$$

An output tuple belongs to $\operatorname{im} \mathcal{L}_{12}$ *if and only if*

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6 \tag{1.116}$$

and, for the reconstructed p_i,

$$p_i \equiv a_i \pmod 2 \qquad (0 \le i \le 5). \tag{1.117}$$

Proof. From $M_i = p_i - p_5$ is obtained

$$s_C = \sum_{i=0}^{4} (p_5 + M_i) + p_5 = 6p_5 + \sum_{i=0}^{4} M_i,$$

which gives the first equation of (1.114); the others are immediate. Adding and subtracting $p_i = e_i + e_{i+6}$ and $a_i = e_i - e_{i+6}$ produces (1.115). Divisibility by six and the six parity congruences are precisely the necessary and sufficient conditions for all reconstructed coordinates to be integers. □

Division by six appears after the oriented census, not during it. The integrality conditions for this unit are exactly (1.116) and (1.117); no Smith normal form is attributed here to a matrix that has not previously been defined.

1.16.5 Genealogical distinction between 2 dodecaphasic words of equal period

The distinction must be preserved.

$$U_{12}^{\mathrm{cat}} := U_6 \| U_6, \qquad U_{12}^{\mathrm{sgn}} := \mathcal{H}_{12}(K). \tag{1.118}$$

The first concatenates two catalog emissions of length six. The second is a signed coordinate reversibly linked to K by the operator $\mathcal{H}_{12}$. Their common length does not imply the same provenance, semantics, or transport law.

Comparison Criterion 1.145 (Falsification criteria)**.** The construction is refuted if the sequence (1.103) is not exact, if its cohomology class is trivial, if a tuple in the image violates (1.116) or (1.117), if the inverse formulas do not recover the twelve initial integers, or if the return of β is interpreted as a reset of q_{mem}.

1.17 Cyclotomic phase functor–length and modular elevation of paths

The odometric quotient $O_{9,12}$ simultaneously preserves the nonadic position, the dodecaphase register, and the integral length of each arrow. In this unit, its phase is realized over fibers A_2, and the cardinal lift that replaces each edge with four oriented edges is proved. The cyclotomic representation and the absolute length will be retained as distinct coordinates.

1.17.1 Coxeter representation of order 3 on the dodecaphasic fibers of type A_2

Let

$$G_{A_2} := \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad C := \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}. \tag{1.119}$$

By the proposition 1.94,

$$C^3 = I_2, \qquad C^{\mathsf{T}} G_{A_2} C = G_{A_2}, \qquad \det(XI_2 - C) = X^2 + X + 1. \tag{1.120}$$

Thus, C realizes the character cyclotomic of C_3 on A_2.

For each $b \in \mathbb{Z}/12\mathbb{Z}$, let $A_{2,b}$ be a copy of A_2, let

$$\iota_b : A_{2,b} \xrightarrow{\sim} A_2$$

an integral identification, and let $P_b \in O(G_{A_2})$ be a frame that depends on b, but not on the residue r. We define

$$\rho_b := \iota_b^{-1} P_b C P_b^{-1} \iota_b, \qquad \rho_b^3 = \mathrm{id}_{A_{2,b}}. \tag{1.121}$$

The independencia respect of r liga the character to the fiber dodecaphasic; r preserves the position internal of the turn nonadic.

1.17.2 Odometer category of the TPK: cylinders, truncations, and sequence morphisms

Recall that $O_{9,12}$ has objects

$$(b, r) \in \mathbb{Z}/12\mathbb{Z} \times \{0, \dots, 8\}.$$

For $n \in \mathbb{N}$, the flecha unique of length n is

$$\gamma_{(b,r),n} : (b, r) \longrightarrow (b + \kappa_r(n), [r + n]_9), \qquad \kappa_r(n) := \left\lfloor \frac{r+n}{9} \right\rfloor. \tag{1.122}$$

The composition relies on

$$\kappa_r(n + m) = \kappa_r(n) + \kappa_{[r+n]_9}(m). \tag{1.123}$$

The length $\ell(\gamma_{(b,r),n}) = n$ is additive.

Definition 1.146 (Cyclotomic Phase–Length Functor)**.** Let $\mathbf{Rep}_{\mathbb{C}}(C_3)$ be the category of complex representations of C_3, and let $\mathbf{B}\mathbb{N}$ be the monoidal category with a single object whose endomorphisms are $(\mathbb{N}, +)$. We define

$$\mathfrak{F}_{\mathrm{cyc}} : O_{9,12} \longrightarrow \mathbf{Rep}_{\mathbb{C}}(C_3) \times \mathbf{B}\mathbb{N} \tag{1.124}$$

by

$$\mathfrak{F}_{\mathrm{cyc}}(b, r) = (A_{2,b} \otimes_{\mathbb{Z}} \mathbb{C}, \rho_b)$$

and

$$\mathfrak{F}_{\mathrm{cyc}}(\gamma) := \left(\iota_{b'}^{-1} P_{b'} C^{\ell(\gamma)} P_b^{-1} \iota_b, \ell(\gamma) \right) \tag{1.125}$$

for $\gamma : (b, r) \to (b', r')$.

Theorem 1.147 (Functoriality and separation of the records)**.** *The assignment of the definition 1.146 is a functor. Its first component preserves only the length class modulo three; the second preserves the*

complete integer and, by reduction, determines that class. The cyclotomic component does not allow the absolute length to be reconstructed.

Proof. If $\gamma_1 : (b_0, r_0) \to (b_1, r_1)$ and $\gamma_2 : (b_1, r_1) \to (b_2, r_2)$ have lengths n_1, n_2, the intermediate trivialization cancels:

$$\begin{aligned}&\left(\iota_{b_2}^{-1} P_{b_2} C^{n_2} P_{b_1}^{-1} \iota_{b_1}\right)\left(\iota_{b_1}^{-1} P_{b_1} C^{n_1} P_{b_0}^{-1} \iota_{b_0}\right)\\ &\quad = \iota_{b_2}^{-1} P_{b_2} C^{n_1+n_2} P_{b_0}^{-1} \iota_{b_0}.\end{aligned} \tag{1.126}$$

The second component composes by addition. Since C^n depends only on $[n]_3$, whereas $\ell = n$ preserves the integer, the two coordinates are not identified. □

If

$$Q : \mathsf{TPK} \longrightarrow O_{9,12}$$

is the odometer functor of U006, the typed realization is

$$\mathfrak{F}_{\mathrm{cyc}} \circ Q : \mathsf{TPK} \longrightarrow \mathbf{Rep}_{\mathbb{C}}(C_3) \times \mathbf{B}\mathbb{N}. \tag{1.127}$$

1.17.3 Modular elevation of cardinal paths

Let $\mathcal{A}_{N,d}$ be the category libre of paths cardinal of $(\mathbb{Z}/N\mathbb{Z})^d$. Let

$$N \geq 2, \quad u \geq 1, \quad \gcd(u, N) = 1, \quad k := \mathrm{ord}_N(u), \quad q := \frac{u^k - 1}{N}.$$

Definition 1.148 (Cardinal Substitution by u)**.** The functor

$$\mathcal{S}_u : \mathcal{A}_{N,d} \longrightarrow \mathcal{A}_{N,d}$$

sends an object p to up and each oriented edge to the ordered concatenation of u copies with the same direction.

Theorem 1.149 (Modular lifting to endomorphism of paths)**.** *For every object p, path γ, and*

$$\kappa_{N,r}(n) := \left\lfloor \frac{r+n}{N} \right\rfloor,$$

we have

$$\mathcal{S}_u^k(p) = p, \tag{1.128}$$

$$\ell(\mathcal{S}_u^k \gamma) = u^k \ell(\gamma), \tag{1.129}$$

$$\kappa_{N,r}(u^k n) - \kappa_{N,r}(n) = qn. \tag{1.130}$$

Proof. The category is free, so the images of objects and generators determine a unique functor. Each map multiplies the length by u. Since $u^k = 1 + qN$, the objects return modulo N, and

$$\left\lfloor \frac{r + n + qNn}{N} \right\rfloor = \left\lfloor \frac{r+n}{N} \right\rfloor + qn.$$

□

In the nonadic case,

$$(N, u, k, q) = (9, 4, 3, 7), \qquad 4^3 = 64 = 1 + 7 \cdot 9. \tag{1.131}$$

Therefore,

$$\boxed{\mathcal{S}_4^3(e) \text{ preserves the endpoints and contains seven nonadic turns oriented per initial edge.}} \tag{1.132}$$

The endpoints and the residual position return under three maps; the enriched state need not return. Without a proof of invertibility, $\mathcal{S}_4^3$ is a vertical endomorphism of paths, not a monodromy.

Remark 1.150 (Separation with respect to clock dilation). $\mathcal{S}_4$ replaces objects and edges in a path category. The map D_4 of U006C will multiply the coordinate Θ_{108} by four. They share an integer factor, but not a domain, codomain, or composition law.

Comparison Criterion 1.151 (Criteria of refutation)**.** The block remains refuted if fails any of the identities (1.120), (1.123), (1.126) or (1.131); also remains badly typed if it identify the phase C^n, the length n, the substitution $\mathcal{S}_4$ and the dilation D_4.

1.18 Quaternary dilation of the register, observable obstruction, and refined semiconjugacy

The cardinal substitution $\mathcal{S}_4$ constructed in the preceding unit acts on paths. In this unit, a second operation, arithmetic in nature, is defined on the register $\mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$, and a third, categorical operation subdivides each observable transition into four microtransitions. The aim is not to merge them, but to prove the exact relationship between their realizations.

1.18.1 Dilation on the product register

Let

$$Q_{12,9} := \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}.$$

For $r \in \mathbb{Z}/9\mathbb{Z}$, we denote its normalized representative by $\widetilde{r} \in \{0, \dots, 8\}$.

Definition 1.152 (Quaternary dilation of the register)**.** We define

$$D_4(b, r) := \left(\left[4b + \left\lfloor \frac{4\widetilde{r}}{9} \right\rfloor \right]_{12}, [4r]_9 \right). \tag{1.133}$$

The total coordinate is

$$\Theta : Q_{12,9} \xrightarrow{\sim} \mathbb{Z}/108\mathbb{Z}, \qquad \Theta(b, r) := [9b + \widetilde{r}]_{108}. \tag{1.134}$$

Proposition 1.153 (Realization by modular multiplication)**.** *In the total coordinate,*

$$\boxed{\Theta \circ D_4 \circ \Theta^{-1}(\theta) = [4\theta]_{108}.} \tag{1.135}$$

In particular,

$$\operatorname{im}(D_4) = 4\mathbb{Z}/108\mathbb{Z} \simeq \mathbb{Z}/27\mathbb{Z}, \tag{1.136}$$

and the induced restriction on the image has order nine.

Proof. For $\theta = 9b + \widetilde{r}$,

$$4\theta = 9 \left(4b + \left\lfloor \frac{4\widetilde{r}}{9} \right\rfloor \right) + (4\widetilde{r} \bmod 9).$$

This is exactly the quotient–residue decomposition of (1.133). The image consists of the classes that are multiples of four. Dividing by four yields $\mathbb{Z}/27\mathbb{Z}$, and

$$\begin{aligned} &4^1 \equiv 4, \quad 4^2 \equiv 16, \quad 4^3 \equiv 10, \\ &4^4 \equiv 13, \quad 4^5 \equiv 25, \quad 4^6 \equiv 19, \\ &4^7 \equiv 22, \quad 4^8 \equiv 7, \quad 4^9 \equiv 1 \pmod{27}. \end{aligned}$$

No preceding power is one; therefore $\mathrm{ord}_{27}(4) = 9$. □

1.18.2 Exact carry identity

For $r \in \{0, \dots, 8\}$ and $n \in \mathbb{N}$, define

$$\kappa_r(n) := \left\lfloor \frac{r+n}{9} \right\rfloor, \qquad r' := [r+n]_9.$$

Theorem 1.154 (Quaternary carry cocycle)**.** *We have*

$$\boxed{\kappa_{[4r]_9}(4n) = 4\kappa_r(n) + \left\lfloor \frac{4\widetilde{r'}}{9} \right\rfloor - \left\lfloor \frac{4\widetilde{r}}{9} \right\rfloor.} \tag{1.137}$$

The last difference is the coboundary produced by the choice of representatives $r \mapsto \widetilde{r}$.

Proof. Write

$$r + n = 9\kappa_r(n) + \widetilde{r'}.$$

When multiplied by four,

$$4r + 4n = 36\kappa_r(n) + 4\widetilde{r'}.$$

Separating quotient and residue modulo nine and subtracting the quotient already contained in $4\widetilde{r}$ yields (1.137). □

Corollary 1.155 (Third iteration)**.** *For every $(b, r) \in Q_{12,9}$,*

$$\boxed{D_4^3(b, r) = ([4b + 7\widetilde{r}]_{12}, r).} \tag{1.138}$$

Proof. By proposition 1.153,

$$\Theta(D_4^3(b, r)) = [4^3(9b + \widetilde{r})]_{108} = [64(9b + \widetilde{r})]_{108}.$$

Since $64 = 1 + 7 \cdot 9$, the residue modulo nine is again r, whereas the block coordinate becomes $[4b + 7\widetilde{r}]_{12}$. □

The return of r is not return of the complete register. The difference $7\widetilde{r}$ preserves the memory of the internal representative traversed.

1.18.3 Obstruction in the observable quotient

In the observable configuration of definition 1.112, we write

$$q = (p^\Sigma, p^\Pi, d^\Sigma, d^\Pi, \theta) \in Q_{\mathrm{obs}}.$$

The positional projection is

$$\pi_{\mathrm{pos}}(q) := (p^\Sigma, p^\Pi) \in X_9^2. \tag{1.139}$$

The temporal signature is

$$\tau(q) := \varepsilon_9(r(\theta)) \in \{-1, 0, +1\}.$$

We define the oriented observable shift

$$a(q) := \begin{cases} (\delta(d^\Sigma), 0), & \tau(q) = +1, \\ (0, \delta(d^\Pi)), & \tau(q) = -1, \\ (0, 0), & \tau(q) = 0. \end{cases} \tag{1.140}$$

Then

$$\pi_{\mathrm{pos}}(F_{\mathrm{obs}}q) = \pi_{\mathrm{pos}}(q) + a(q),$$

with the address update and clock defined in U005.

Theorem 1.156 (Obstruction to the ordinary observable endofunctor)**.** *There is no endofunctor of the ordinary observable space that simultaneously satisfies:*

1. *multiplying the geometric position by four;*
2. *replace each transition by four genuine microtransitions;*
3. *preserving sheet and orientation in each microtransition;*
4. *sending a complete duodecaphase fiber to a single duodecaphase fiber.*

The obstruction persiste in a step of umbral with $a(q) = 0$.

Proof. Let

$$\mathcal{B}_b := \{(b, r) : 0 \le r \le 8\}.$$

Replace one elementary iteration with four force

$$h(\theta + 1) = h(\theta) + 4$$

and, by induction,

$$h(\theta) = 4\theta + c \pmod{108}.$$

Take $0 \le \widetilde{c} < 108$ and write $\widetilde{c} = 9c_b + c_0$, with $0 \le c_0 < 9$. If the whole fiber $\mathcal{B}_b$ were sent to a single fiber, the destination block index would have to be independent of r; however, it contains

$$4b + c_b + \left\lfloor \frac{4r + c_0}{9} \right\rfloor \pmod{12}, \tag{1.141}$$

which is not constant in r. Moreover, the neutral transition operator satisfies $P_0^{\mathrm{TPK}} = I$, distinct from the cyclotomic trivializations P_b; the ordinary calendar $(+1, -1, 0)$ causes four elementary iterations to visit both arithmetic modes and the neutral mode. □

1.18.4 Minimal temporal subdivision compatible with semiconjugation

Definition 1.157 (Subdivided observable state)**.** Let

$$\widetilde{Q}_4 := Q_{\mathrm{obs}} \times \{0, 1, 2, 3\}, \qquad \widetilde{\pi}(q, j) := 4\pi_{\mathrm{pos}}(q) + j\, a(q). \tag{1.142}$$

We define

$$\widetilde{F}(q, j) := \begin{cases} (q, j + 1), & 0 \le j < 3, \\ (F_{\mathrm{obs}}q, 0), & j = 3, \end{cases} \qquad \iota_4(q) := (q, 0). \tag{1.143}$$

Theorem 1.158 (Four-step semiconjugacy)**.** *The inclusion ι_4 satisfies*

$$\boxed{\widetilde{F}^4 \circ \iota_4 = \iota_4 \circ F_{\mathrm{obs}}.} \tag{1.144}$$

The intermediate positions are exactly

$$4\pi_{\mathrm{pos}}(q) + j\, a(q), \qquad j = 0, 1, 2, 3.$$

Proof. Starting from $(q, 0)$, the first three applications increment only the microinstant index. The fourth applies F_{obs} and returns the index to zero. This gives

$$(q,0) \mapsto (q,1) \mapsto (q,2) \mapsto (q,3) \mapsto (F_{\mathrm{obs}}q, 0).$$

The formula for the positions is the definition of $\widetilde{\pi}$. The refinement makes visible a determined subdivision; it does not add a dynamic decision. □

1.18.5 Subdivided category and cyclotomic elevation

Let $\mathrm{sd}_4\,\mathsf{P}_{\mathrm{obs}}$ be the category obtained by replacing each generator $\gamma : q \to F_{\mathrm{obs}}q$ with the chain

$$(q,0) \to (q,1) \to (q,2) \to (q,3) \to (F_{\mathrm{obs}}q, 0). \tag{1.145}$$

The functor

$$\mathrm{sd}_4 : \mathsf{P}_{\mathrm{obs}} \longrightarrow \mathrm{sd}_4\,\mathsf{P}_{\mathrm{obs}}$$

sends each generator to that string. The collapse functor

$$\mathrm{col}_4 : \mathrm{sd}_4\,\mathsf{P}_{\mathrm{obs}} \longrightarrow \mathsf{P}_{\mathrm{obs}}$$

recompose the four microarrows and satisfies

$$\mathrm{col}_4 \circ \mathrm{sd}_4 = \mathrm{id}_{\mathsf{P}_{\mathrm{obs}}}. \tag{1.146}$$

In a chain that remains in the fiber b, the first three microarrows act by ρ_b; the fourth incorporates the interfiber transport if a dodecaphase crossing occurs. By $\rho_b^3 = I$, the ordered product of the four actions coincides with the cyclotomic morphism of the original arrow.

Proposition 1.159 (Cyclotomic Invariance under Subdivision)**.** *There exists a typed lift*

$$\widetilde{\mathfrak{F}}_{\mathrm{cyc}} : \mathrm{sd}_4\,\mathsf{P}_{\mathrm{obs}} \longrightarrow \mathbf{Rep}_{\mathbb{C}}(C_3) \times \mathbf{B}\mathbb{N}$$

such that, for every arrow γ of $\mathsf{P}_{\mathrm{obs}}$,

$$\boxed{\widetilde{\mathfrak{F}}_{\mathrm{cyc}}\big(\mathrm{sd}_4\,\gamma\big) = \big(\mathfrak{F}_{\mathrm{cyc}} \circ Q\big)(\gamma).} \tag{1.147}$$

Proof. The successive powers of ρ_b are assigned to the internal microarrows, and transport between the frames of the source and target fibers is assigned to the fourth. The composition of the first three factors is the identity because $\rho_b^3 = I$. The remaining factor is exactly the morphism that $\mathfrak{F}_{\mathrm{cyc}} \circ Q$ assigns to the collapsed arrow. The subdivided category is free on those microarrows, so the assignment extends uniquely. □

1.18.6 Commutators of 3 quaternary operations and separation of their actions

The architecture contains three distinct operations:

1. $\mathcal{S}_4$, cardinal substitution of objects and paths;
2. D_4, multiplication by four in Θ_{108};
3. sd_4, functorial subdivision of an observable transition.

Their compatibilities are given, respectively, by

$$4^3 = 1 + 7 \cdot 9, \qquad \Theta D_4 = 4\Theta, \qquad \widetilde{F}^4 \iota_4 = \iota_4 F_{\mathrm{obs}}.$$

Sharing the integer four converts none into another.

Comparison Criterion 1.160 (Refutation criteria)**.** The construction is refuted if any of the identities (1.135), (1.137), (1.138), (1.144), or (1.147) fails; likewise if an observable realization satisfies the four conditions of theorem 1.156 without preserving a register equivalent to the microinstant.

1.19 Modular readers, odometer, and dodecaphasic calendar

The enriched state of the TPK is not identified with any of its readings. This unit defines the readers modulo nine, modulo three, and modulo one thousand, the phase–sector odometer, the predictive quotient of thirty-six states, and the cyclic extension of one hundred eight positions. Each construction declares what it publishes and what memory it preserves.

1.19.1 Typed scheme of the modular readers of the TPK: domain, codomain, publication, and conserved memory

Definition 1.161 (Operator specification)**.** A canonical TPK operator is recorded by means of a sextuple

$$O = (D_O, C_O, f_O, I_O, L_O, M_O),$$

where D_O is the domain, C_O the codomain, f_O the rule, I_O the preserved invariants, L_O the information published or forgotten, and M_O the memory that remains in the enriched state.

Two symbols with equal cardinality or equal period do not represent the same operator unless there exists an equivalence intertwining their domains, rules, and invariants. This convention will prevent confusing the predictive quotient C_{36}^{pred}, the boundary R_{36}, and a cardinal defect of value thirty-six.

1.19.2 Nonadic reader of the enriched state: phase, transition and memory-return

For $n \geq 1$, define

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n-1}{9} \right\rfloor.$$

Then

$$n = 9q_9(n) + \rho_9(n).$$

The card of ρ_9 is

$$\big(\mathbb{Z}_{>0}, \mathcal{D}_9, \rho_9, n \equiv \rho_9(n) \pmod 9, \text{positive phase}, q_9(n)\big).$$

The positive digital root numerically coincides with ρ_9, but its semantics is distinct: one is presented as a section of the quotient; the other, as an iterated sum of digits.

1.19.3 Triticale reader with quotient and carry transport

The balanced division is written

$$n = r_3(n) + 3c_3(n), \qquad r_3(n) \in \mathsf{TRIT}, \quad c_3(n) \in \mathbb{Z}.$$

Its card is

$$\big(\mathbb{Z}, \mathsf{TRIT} \times \mathbb{Z}, n \mapsto (r_3(n), c_3(n)), \mathrm{rec}_3(r, c) = r + 3c, r_3, c_3\big).$$

The publication may display only r_3, but the TPK preserves c_3 if a subsequent composition requires reconstruction.

1.19.4 Reader positional by blocks in base 10^3

The Euclidean division defines

$$N = 1000q_{1000}(N) + r_{1000}(N), \qquad 0 \le r_{1000}(N) < 1000.$$

Its card is

$$\big(\mathbb{Z}, \mathbb{Z} \times \{0, \dots, 999\}, N \mapsto (q_{1000}, r_{1000}), \mathrm{rec}_{1000}(q, r) = 1000q + r, r_{1000}, q_{1000}\big).$$

Proposition 1.162 (Concatenation and residual reading)**.** *If* $u_1, \dots, u_m \in \{0, \dots, 999\}$ *and*

$$D_m = 1000D_{m-1} + u_m, \qquad D_0 = 0,$$

then

$$D_m = \sum_{j=1}^{m} u_j 1000^{m-j}.$$

Moreover,

$$D_m \equiv \sum_{j=1}^{m} u_j \pmod 9$$

because $1000 \equiv 1 \pmod 9$.

Proof. The first equality is obtained by induction on m. The second follows by reducing it modulo nine. □

The congruence does not reconstruct the order of the blocks. The genealogical register preserves the sequence $(u_1, \dots, u_m)$; the residual reader publishes only its sum modulo nine.

1.19.5 Odometer category of the TPK: cylindrical objects and composition by truncation

Definition 1.163 (Nonadic odometer–dodecaphasic)**.** The category $O_{9,12}$ has objects

$$(b, r) \in C_{12} \times \{0, \dots, 8\}.$$

An arrow of length $n \in \mathbb{N}$ is

$$(b, r) \xrightarrow{n} \left(b + \left\lfloor \frac{r+n}{9} \right\rfloor, r + n \bmod 9\right).$$

The composition sums lengths.

Let

$$\kappa_r(n) = \left\lfloor \frac{r+n}{9} \right\rfloor.$$

Lemma 1.164 (Cocycle of the odometer)**.** *If* $r_1 = r + n_1 \bmod 9$*, then*

$$\kappa_r(n_1 + n_2) = \kappa_r(n_1) + \kappa_{r_1}(n_2).$$

Proof. We write $r + n_1 = 9\kappa_r(n_1) + r_1$, with $0 \le r_1 < 9$. Adding n_2 and again dividing by nine yields the identity. □

For a state x whose base contains θ, we define

$$Q_0(x) = (\beta(\theta), \widetilde{\theta} \bmod 9).$$

A TPK arrow has length equal to the number of observable generators that compose it.

Theorem 1.165 (Phase–length functor)**.** *The assignment sending a state x to $Q_0(x)$ and an arrow of length n to the odometric arrow of length n defines a functor*

$$Q : \mathsf{TPK} \longrightarrow O_{9,12}.$$

Proof. Each generator increases θ by one unit. After n steps, the phase residue increases by n modulo nine and the sector increases by $\lfloor (r+n)/9 \rfloor$. The identity has zero length and the lemma 1.164 proves compatibility with composition. □

After nine steps,

$$(b, r) \longmapsto (b+1, r).$$

After one hundred and eight,

$$(b, r) \longmapsto (b, r).$$

These identities belong to the odometric quotient. They do not assert that the cylinder, boundary, genealogical register, or vertical memory have returned.

1.19.6 Memory quotient of order 1 and predictive sufficiency of the modal projection

Let

$$X_{9,12} = \{(a, m) : a \in \mathbb{Z}/9\mathbb{Z}, 0 \le m < 12\}$$

with successor

$$S(a, m) = \begin{cases} (a, m+1), & m < 11, \\ (a+1 \bmod 9, 0), & m = 11. \end{cases}$$

We define the observables

$$\beta_{\mathrm{pred}}(a, m) = 4a \pmod{12}, \qquad d_{\mathrm{pred}}(a, m) = 1 + (m + \beta_{\mathrm{pred}}(a, m) \pmod{12}).$$

For an observable q, the inclusive future word of horizon h is

$$Q_h^q(x) = (q(x), q(Sx), \ldots, q(S^h x)).$$

Theorem 1.166 (Minimum predictive quotient)**.** *The observables β_{pred}, d_{pred}, and the pair $(\beta_{\mathrm{pred}}, d_{\mathrm{pred}})$ produce the same stable quotient*

$$\pi_{36}(a, m) = (a \bmod 3, m).$$

It has thirty-six states and fibers of cardinality three. The minimal horizons are 11*,* 8*, and* 0*, respectively.*

Proof. For a finite system (X, T), let

$$E_h = \mathrm{Eq}(Q_h^q).$$

Then

$$E_{h+1} = E_h \cap (T \times T)^{-1}(E_h).$$

The decreasing chain stabilizes and its limit is the largest T-compatible equivalence contained in $\mathrm{Eq}(q)$. In the declared system, the exact enumeration produces the following number of classes:

h	0	1	2	3	4	5	6	7	8	9	10	11
$\#(X/E_h^{\beta})$	3	6	9	12	15	18	21	24	27	30	33	36

,

and

h	0	1	2	3	4	5	6	7	8
$\#(X/E_h^{d})$	12	15	18	21	24	27	30	33	36.

The pair already distinguishes the thirty-six classes at horizon zero. In all cases, the stable classes preserve m and a mod 3; the three possibilities for a with the same residue modulo three form each fiber. □

We denote this object by C_{36}^{pred}. No is the boundary R_{36}, that will contain three ordered channels of six trits, nor a census of thirty-six elements of another construction.

1.19.7 Central extension of the calendar

We define

$$\iota : C_{12} \longrightarrow C_{108}, \qquad \iota([b]_{12}) = [9b]_{108},$$

and

$$p : C_{108} \longrightarrow C_9, \qquad p([\theta]_{108}) = [\theta]_9.$$

The exact sequence is obtained.

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0. \tag{1.148}$$

A section of sets $s([r]_9) = [r]_{108}$, $0 \le r < 9$, induces the cocycle

$$c(r, r') = \left[\left\lfloor \frac{r + r'}{9} \right\rfloor\right]_{12}.$$

Proposition 1.167 (The extension does not split)**.** *The sucesion equation (1.148) not is isomorfa to the extension product* $C_{12} \times C_9$.

Proof. The exponent of C_{108} is 108. The exponent of $C_{12} \times C_9$ is $\mathrm{mcm}(12, 9) = 36$. Two isomorphic finite groups have the same exponent; therefore, they are not isomorphic. □

Theorem 1.168 (Necessity and exact period of one hundred eight positions)**.** *The translation* $\theta \mapsto \theta + 1$ *on* C_{108} *has order exactly* 108. *Consequently, an iteration n returns the complete calendar if and only if* $108 \mid n$.

Proof. The n-th power sends $[\theta]$ to $[\theta + n]_{108}$. It is the identity for every θ exactly when $[n]_{108} = 0$, that is, when $108 \mid n$. □

In particular, 1008 is not another return of the calendar:

$$1008 \equiv 36 \pmod{108}.$$

After 1008 steps, the phase modulo nine returns, but the coordinate of C_{108} has shifted by thirty-six positions. Naturally, $216, 324, \ldots$ also return the calendar, but they are repetitions of the fundamental circuit of length 108.

1.19.8 Unbounded Growth of Memory Depth Under Phase Returns

Let $q_{\mathrm{mem}} \in \mathbb{Z}_{\ge 0}$ be the unbounded number of nonadic turns, and let

$$\beta = [q_{\mathrm{mem}}]_{12}.$$

Then a nine-step turn satisfies

$$q_{\mathrm{mem}} \longmapsto q_{\mathrm{mem}} + 1, \qquad \beta \longmapsto \beta + 1 \pmod{12}.$$

After one hundred eight steps,

$$\beta \longmapsto \beta, \qquad q_{\mathrm{mem}} \longmapsto q_{\mathrm{mem}} + 12.$$

The calendar returns; the vertical memory does not.

Corollary 1.169 (Hierarchy of returns)**.** *In the phase quotient,* 9 *steps constitute one turn. The composite morphisms*

$$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}, \qquad F_{\mathrm{obs}}^{54}, \qquad F_{\mathrm{obs}}^{108}$$

contain, respectively, three, six, and twelve nonadic turns. None erases the genealogical record or the boundary by definition.

1.19.9 Minimal type system of the enriched state and compatibilities between its readers

The following table answers explicitly which internal objects already exist in the TPK before introducing seeds:

Objeto u operador	Dominio y codominio	Función
X_9	$(\mathbb{Z}/9)^2$	soporte APP
T_N, T_E, T_S, T_O	$X_9 \to X_9$	traslaciones cardinales
M_{ph}	$\mathcal{D}_9 \to \mathsf{TRIT}$	selección de hoja
F_{obs}	$Q_{\mathrm{obs}} \to Q_{\mathrm{obs}}$	sucesor observable
(ρ_9, q_9)	$\mathbb{Z}_{>0} \to \mathcal{D}_9 \times \mathbb{Z}_{\geq 0}$	fase y altura
(r_3, c_3)	$\mathbb{Z} \to \mathsf{TRIT} \times \mathbb{Z}$	orientación y carry
(q_{1000}, r_{1000})	$\mathbb{Z} \to \mathbb{Z} \times \{0, \ldots, 999\}$	bloque decimal y cociente
Q	$\mathsf{TPK} \to O_{9,12}$	fase y longitud
C_{36}^{pred}	cociente de $X_{9,12}$	memoria predictiva mínima
C_{108}	calendario cíclico	extensión no escindida
q_{mem}	$\mathbb{Z}_{\geq 0}$	memoria vertical no acotada
Ext_r	$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}$	prolongaciones compatibles

1.19.10 Obstructions of the readers and the TPK calendar: Euclidean quotients, C_{36}^{pred}, extension C_{108}, and vertical memory

Comparison Criterion 1.170 (Reader Refutation Criteria and Calendar)**.** The unit is refuted if:

1. a residual reader is presented as a complete transition;
2. the quotient of some subsequently used Euclidean division is omitted;
3. C_{36}^{pred} is identified with R_{36};
4. it is asserted that the extension C_{108} is the product $C_{12} \times C_9$;
5. complete return is declared for a number not divisible by 108;
6. the return of β fuerza $q_{\mathrm{mem}} = 0$;
7. $\mathcal{K}_{27}$ is presented as a distinct clock and not as a power of the transport.

1.20 Complete operatorial structure of APP and arithmetic-geometric hierarchy

The operatorial development of APP fixes the hierarchy $4 \to 2 \to 6 \to 54$, the arithmetic projectors, the central block, and the local geometry of paths. These consequences remain subordinated to the already constructed formal kernel and do not introduce a second origin of APP.

The next unit will construct the quadruple subdivision, the cyclotomic functor, and the internal channels of ninety and one hundred twenty positions. Only afterward will the exhaustive space of seeds be introduced.

1.21 Typed architecture, inventory, and memory conservation of the Topological Phase Kernel

1.21.1 Categorical structure of the TPK: enriched states, transport morphisms, and operatorial classification

The TPK is the categorical container that transports over APP the oriented states of TRIT. Its definition precedes the inventory of realizations: first objects, morphisms, composition, and operatorial classes are fixed; only afterward are the operators that realize each class introduced.

Definition 1.171 (TPK as a category over the observable base with fiber family)**.** Let $\mathsf{P}_{\mathrm{obs}}$ be the category of observable paths over the Cayley graph of APP. For each configuration q the fiber is fixed

$$\mathcal{F}_q = \mathsf{O}_q \times \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{S}_q \times \mathsf{B}_q \times \Lambda_q,$$

whose factors retain, respectively, orientation and sheet; residue and quotient; carry; signature; cylinder and boundary; and transport register. A TPK object is a pair $x = (q, f)$, with $f \in \mathcal{F}_q$. A morphism $\Gamma : x \to y$ is a route $\gamma : q \to q'$ of $\mathsf{P}_{\mathrm{obs}}$ together with the fiber transport that preserves the declared extension relations between f and f'. The identity is the empty route with identity transport, and composition is the concatenation of routes with composition of the fiber transports. The projection

$$p : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathsf{P}_{\mathrm{obs}}$$

sends each state to its observable configuration and each morphism to the path that transports. This definition fixes a category over the base and a family of fibers; the existence is not presupposed the existence of Cartesian lifts for every flecha of $\mathsf{P}_{\mathrm{obs}}$.

Definition 1.172 (Ontological–operational classification of the TPK)**.** The internal structure of the TPK is organized into eight classes distinguished by type of domain, codomain, and function:

1. **Support and state.** The base is $\mathsf{P}_{\mathrm{obs}}$ and the carrier is $\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \to \mathsf{P}_{\mathrm{obs}}$. This class contains objects; the next seven contain maps between objects or readers of those objects.

2. **Internal selection.** The phase function

$$M_{\mathrm{ph}} : \{1, \ldots, 9\} \longrightarrow \{+1, -1, 0\}$$

produces the scalar value that the operator Sel_t receives to activate the additive evaluation, the multiplicative evaluation or the threshold step. It is Sel_t, not M_{ph} in isolation, that acts on the sheet coordinate; neither modifies the position in APP by itself.

3. **Transport.** For each cardinal direction d, $T_d : X_9 \to X_9$, $p \mapsto p + \delta(d)$, it transports the position. The evolution $F_{\mathrm{obs}} : Q_{\mathrm{obs}} \to Q_{\mathrm{obs}}$ composes selection, translation, orientation, and phase advance.

4. **Readers and quotients.** ρ_9 publishes the nonadic class; (r_3, c_3) conserves tritic residue and quotient; and (q_{1000}, r_{1000}) separates decimal block and carry. They are reading maps, not state transitions.

5. **Memory and boundary.** The transports of $\mathsf{H}_q, \mathsf{C}_q, \mathsf{S}_q, \mathsf{B}_q$ and Λ_q update quotient, carry, signature, cylinder, boundary, and record. Their visible projections may coincide even though the enriched states differ.

6. **Periodicity and return.** The extension

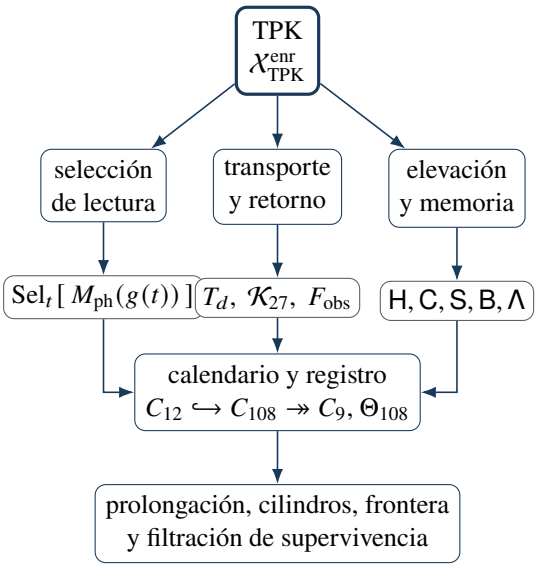
$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0$$

types sector, calendar, and visible phase. The nonadic return restores the phase; the periodicity of one hundred eight iterations restores the calendar; neither erases by definition the boundary memory. The loop $\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$ is a composite morphism, not another clock.

7. **Prolongation.** The relations $\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}$ select compatible continuations. The cylinders and their inverse system publish finite survival and, under the stated compatibility hypotheses, a global section.

8. **Outputs.** The evaluation functors contract the same enriched state toward the Archimedean output, the exceptional-incidence output, or the classifiers of the atlas. These outputs are codomains of reading; they do not constitute new containers alongside TPK.

Each operator appearing below is determined by the sextuple (D, C, f, I, L, M): domain D, codomain C, rule f, preserved invariants I, published or lost information L, and retained memory M. Equality of cardinalities, periods, or historical names does not identify two operators with distinct sextuples. Once this classification has been fixed, the following diagram summarizes five functional groupings of realizations that refine the eight operator classes of TPK:



The diagram fixes a containment, not a succession of theories. In particular, the internal selector, the cardinal translations, the stroboscopic observation, and the modular readers preserve the types fixed in the definition 1.172. Remark. The TPK coordinates their compositions and conserves their provenance in a single enriched state.

Proposition 1.173 (Separation of selection, motion, and remark)**.** *The selection* $\mathrm{Sel}_t\,[\,M_{\mathrm{ph}}(g(t))\,]$*, the cardinal transport* $\mathrm{Lift}(T_d)$ *and the sampling* Obs_3 *are noninterchangeable operations: the first chooses the active evaluation; the second modifies the position and winding; the third publishes a temporal subsequence. Their composition within the TPK determines an observable route, while the fiber* $\mathcal{F}_q$ *preserves the data needed to distinguish prolongations with the same endpoint.*

Proof. The types are different: M_{ph} takes values in the ternary activation set, Sel_t updates the sheet coordinate, $\mathrm{Lift}(T_d)$ transports the state on the torus and Obs_3 acts on sequences. An identification between two of these objects would violate domain or codomain typing. The extension by fibers also incorporates residue–quotient, carry, boundary and record, so projection to the path endpoint is an explicit forgetful map. □

Canonical nomenclature

The public name of the container is *TPK*. When it is necessary to name the transported data, *enriched TPK state* or $\mathcal{X}^{\mathrm{enr}}_{\mathrm{TPK}}$ will be used. The function M_{ph} designates exclusively the internal phase value received by Sel_t.

1.21.2 Fundamental operators of the TPK: domains, actions, invariants, and memory

The definition 1.172 first fixed the eight ontological–operatorial classes: support and state; selection; transport; readers and quotients; memory and boundary; periodicity and return; prolongation; and outputs. This section defines their realizations. For each operator, the sextuple (D, C, f, I, L, M) of domain, codomain, rule, invariants, published or lost information, and preserved memory is declared. The subsequent nominal census groups symbols already defined by these six data and does not replace their domains or rules.

Definition 1.174 (Typed Record for a TPK Operator)**.** A canonical operator is a sextuple

$$O = (D_O, C_O, f_O, I_O, L_O, M_O),$$

where $f_O : D_O \to C_O$ is the action rule, I_O is the family of relations it preserves, L_O declares the published coordinates and the equivalence relation induced by forgetting, and M_O enumerates the data that remain in the enriched state after publication. Two realizations represent the same operator only when a typed equivalence exists that intertwines their rules and invariants; sharing a period, cardinality, or visible output is insufficient.

1.21.2.1 Modular readers built

The nonadic reduction is fixed by the published representative.

$$\rho_9(n) = 1 + ((n-1) \bmod 9) = n - 9\left\lfloor \frac{n-1}{9} \right\rfloor, \tag{1.149}$$

so that the null class is written as 9. For $n \geq 1$, the digital root satisfies

$$\mathrm{dr}_9(n) = \rho_9(n),$$

but the two expressions preserve distinct semantics: the first is a section of the quotient; the second publishes the iterated sum of digits. The tritic lift writes uniquely

$$n = r_3(n) + 3c_3(n), \qquad r_3(n) \in \{-1, 0, +1\}, \quad c_3(n) \in \mathbb{Z}, \tag{1.150}$$

and simultaneously preserves oriented residue and carry quotient. Finally, the decimal-block reader is the Euclidean division

$$N = 1000q_{1000}(N) + r_{1000}(N), \qquad 0 \leq r_{1000}(N) < 1000, \tag{1.151}$$

therefore basis 1000, residue modulo 1000 and carry q_{1000} are three data related and not a same object.

1.21.2.2 Classification of Operator Realizations by Domain and Function

The preceding definitions govern the reading of the table. Its fourteen functional groupings refine the eight operator classes and summarize the realizations that share a function; a class may therefore occupy more than one row. The table does not operate as a replacement definition. Symbols that share a cardinal remain separated by domain and codomain.

Functional grouping	Operators and Spaces	Domain, Action and Invariants
State and route memory	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$, fiber $\mathcal{F}_q$, route memory	They preserve position, leaf, orientation, residue, quotient, carry, signature, boundary, cylinder, prefix, genealogy, and memory.
Sheet selection	$M_{\mathrm{ph}} : \{1, \dots, 9\} \to \{-1, 0, +1\}$	It activates the additive evaluation, the multiplicative evaluation, or the threshold passage; it does not by itself move the state.
Transporte espacial	T_N, T_E, T_S, T_O, reversible two-cursor engine, F_{obs}	It realizes the translations of the Cayley graph, updates sheet and orientation and preserves each transition of the path.
Lectores modulares	ρ_9, (r_3, c_3), (q_{1000}, r_{1000})	Publish nonadic phase, tritic orientation and decimal block without erasing the lift quotients.
Block and memory	$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$, memory filter $\mathcal{N}_{27}$	The first composes twenty-seven transports; the second selects the memory events. Equal cardinality does not imply an equal operator.
Twelve-phase state	$\mathcal{R}_{12}$, centers $\theta_m = 30m - 10$ degrees, refinement $\mathcal{R}_{120}$	Organize the twelve phases, their opposition, and the angular refinement in increments of three degrees.
Periodicity and depths	$C_{12} \hookrightarrow C_{108} \twoheadrightarrow C_9, \Pi_{108}^{\mathrm{cur}}, w_{108}, w_{1080}, \Gamma_0(1080)$	It distinguishes the total periodicity of order 108, the cursor projection, the words of 108 and 1080 trits, and modular level 1080.
Channels (90/120)	mask C_m, S_{90}, S_{120}, orbital grammar, supertrace, and invariants ν_{120}, ν_{270}	It separates the two genealogies, their geometric tails, their weights, and the coordinates that they extract from the state.
Bidirectionality	$P_{\pm}$, route inversion, $\mathrm{Ext}_{\pm}$, $N_{\pm}$, β, $C_M = -\mathrm{rev}$	It implements, respectively, spectral exchange, spatial outward passage and return, future/past prolongation, valence, balance, and word conjugation.
Emission and coinduction	L_0, L_1, R_{36}, G_9, partition $3^6 = 729$, $\varprojlim \mathrm{Cyl}_m$	It lifts the seed, opens the boundary, and exhaustively enumerates the finite prolongations. The numerical limit and the enriched lift belong to distinct types.
Numeric Readers	$\mathscr{C}_\pi$, $\mathscr{P}_e$, F_{av}	Through rational forks, factorial recurrence, and Fibonacci self-scaling, they construct the published sections of π, e, φ.
Exceptional Projection	Witt vector lifting, weight enumerator, and non-selective shadow	Transports the same state to ternary incidence without intervening in the Archimedean selection of digits.
Atlas and realization	route signature, atlas (81/56/13/324), involution C_M, electronic center, and fiber operators	Convert the route state into classifiers, characters, and operators before applying any dimensional chart.
Finite validation	exhaustive censuses, ablations, and causal independence	It checks coverage and uniqueness at the computed depth, and verifies that no target prefix intervenes in the generating map.

1.21.2.3 Functional Index of the Canonical Operators

The preceding classification organizes the realizations by function. The following table gathers the operators after the categorical definition and the constructed readers. Each row declares domain, codomain, rule, and invariants; the symbols make it possible to recognize a single definition throughout its different realizations without identifying operators of different types.

#	Canonical Operator	Symbol	Capa tipada
1	Additive–multiplicative arithmetic cell of order nine	$\mathcal{A}_9$	arithmetic support
2	Residual decomposition and nonadic quotient	(ρ_9, q_9)	reduction and elevation
3	Ternary oriented reduction	ρ_3^{or}	reduction and elevation
4	Ternary-decimal positional reader of base thousand	ι_{1000}	reduction and elevation
5	Cardinal Action Oriented on the Arithmetic Torus	$T_d,\ d \in \{N, E, S, O\}$	transporte cardinal
6	Additive–multiplicative local feedback	F_{loc}	transporte cardinal
7	Minimum emitter of two cursors	$T_{\min}$	finite emission
8	Decimal Arithmetic Sign Coupler	G	finite emission
9	Ternary projection of the catalog	Ψ_6	finite emission
10	Local Surjectivity of Cardinal Transport	$\mathcal{R}_3$	transporte cardinal
11	Transportation loop of twenty-seven iterations	$\mathcal{K}_{27}$	transporte cardinal
12	Enriched state of the topological phase core	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$	estado enriquecido
13	Hensel State Transition	$\mathcal{H}$	estado enriquecido
14	Exact Transition of Ternary-Decimal Cylinders	$C_{3,1000}$	estado enriquecido
15	Joint boundary signature	Σ_{B}	estado enriquecido
16	Relationship of extension and nonadic survival	EF–G_9	prolongation and monodromy
17	Nonadic monodromy with boundary holonomy	$\mathcal{M}_9$	prolongation and monodromy
18	Global Section of the Inverse Survivor System	$X_\chi = \varprojlim_m \mathrm{Surv}_m^{(\chi)}$	prolongation and monodromy
19	Bivariant Category of Arithmetic Paths	$\mathcal{P}_{\mathrm{APP}}^{(2)}$	transporte cardinal
20	Observable chronology of two cursors	F_{obs}	transporte cardinal
21	Decimal Alphabet of Forty-Two Trinities	$\mathcal{A}_{42}$	finite emission
22	Typed extension relation of fibers	Ext_r	estado enriquecido
23	Nonadic transfer of compatible fibers	K_{ph}	prolongation and monodromy
24	Refinement of Seeds by Advancement and Rotation	(P, H, Q)	transporte cardinal
25	Mode and Orientation Cocycles	$(c_{\mathrm{mode}}, c_{\mathrm{or}})$	estado enriquecido
26	Triadic prolongation of twenty blocks	E_{20}	prolongation and monodromy
27	Dodecaphonic oriented system	$\mathcal{R}_{12}$	dodecaphonic reading
28	Signed harmonic dodecaphonic observable	U_{12}^{sgn}	dodecaphonic reading
29	Harmonic transformation by three-step orbits	$\mathcal{H}_{12}$	dodecaphonic reading
30	Cyclic difference transversal extractor	$\mathcal{E}_{3,4}$	dodecaphonic reading
31	Dodecaphasic closure recurrence in base thousand	C_α	close in base thousand
32	Enhanced history transducer to angular character	$(L_{\mathrm{tick}}, \chi_{\mathrm{mass}})$	interfaz dimensional
33	Bidiirectional lattice of index twelve	$\mathcal{W}_\pm$	interfaz dimensional
34	Nonadic Atlas of Extension Families	$\mathcal{A}_{\mathrm{species}}$	interfaz dimensional

The symbol L_{tick} denotes the iteration and return reader. Its codomain is the temporal memory of the state; it does not define an independent physical time unit.

The internal selector function

$$M_{\mathrm{ph}} : \mathcal{D}_9 \longrightarrow \{+1, -1, 0\}$$

belongs to the TPK; its tabulated vector is

$$m_{\mathrm{ph}} := \big(M_{\mathrm{ph}}(1), \ldots, M_{\mathrm{ph}}(9)\big)^{\mathsf{T}}.$$

The function M_{ph}, the vector m_{ph} and the state operator are objects of different types. The scalar value $M_{\mathrm{ph}}(g(t))$ enters as the second argument of the selector Sel_t; it is not composed directly with the state. Cardinal transport T_d occupies another factor of the transition $\mathcal{U}_t$ and performs movement on APP through its lift $\mathrm{Lift}(T_d)$. This separation preserves a single container, distinguishes phase selection from transport, and preserves the complete architecture by types.

Finite depth and enriched limit

The enumeration, censuses, and contraction of numerical cylinders are exact results in their domains. The existence and uniqueness of an enriched section jointly subject to all survival predicates follow when the lifting fibers are nonempty, singletons, and compatible at every depth. A calculation on a finite window verifies the fibers in that window, but does not by itself imply the quantifier over all depths.

Theorem 1.175 (Composition of the internal dynamics)**.** *A transition observable of the TPK is the composition typed*

$$\mathrm{Tra}_t(y,d) := \mathrm{Lift}(T_d)(y), \qquad \mathrm{Upd}_t := \mathrm{Rec}_t \circ \mathrm{Mem}_t,$$

$$\mathcal{U}_t(x) = \mathrm{Upd}_t\big(\mathrm{Tra}_t\big(\mathrm{Sel}_t\big(x, M_{\mathrm{ph}}(g(t))\big), d(t)\big)\big)$$

on $\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$, followed, when appropriate, by a modular reader, a cylindrical extension, or one of the two projections. Each factor acts on a distinct component of the state; for that reason the selector, the movement, the clock, the memory, and the publication cannot collapse into a single modular reduction.

The preceding table enumerates the operator families. Equivalences among local realizations must intertwine their domains, rules, and invariants. Subsequent developments select compositions of these operations; they introduce no fourth primitive object alongside APP, TRIT, and TPK.

1.22 Transport, selection, and prolongation in the Topological Phase Kernel

The acronym TPK designates the *Topological Phase Kernel*, or the topological phase kernel.[1] It does not denote a single 108-step algorithm, a table of results, or the catalog of 468 emissions. It is the system of operators that enables the additive and multiplicative readings to coexist over the APP path category without identifying their genealogies.

The word *topological* has a precise content here. The support of APP is the Cayley graph of the quotient group

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2$$

with its cardinal edges. A closed route admits a winding class after being lifted to cover $\mathbb{Z}^2$. TPK transports that class, the route orientation, and phase holonomy. Two paths ending in the same cell may therefore represent distinct states. The phase kernel is precisely the information that remains invisible when publishing only the final cell or its residue.

The dynamical basis is the free category $\mathsf{P}_{\mathrm{APP}}$ of the cardinal graph of APP. Since the two arithmetic evaluations do not induce the same partition, transport resides on the bivariate category

$$\mathsf{P}_{\mathrm{APP}}^{(2)} = \mathsf{P}_{\mathrm{APP}} \times \mathsf{P}_{\mathrm{APP}}.$$

The first component is evaluated through the additive sheet Σ and the second through the multiplicative sheet Π. This separation is constitutive, but it does not duplicate APP: it records two ordered readings of one and the same matrix of paths. The multiplicative component is the principal table; the additive component preserves the law of accumulation that generates its rows and makes it possible to measure what information a visible projection eliminates.

[1] The denomination likewise preserves the authorial dedication to Tan Peng Kian.

1.22.1 Residual reductions and decimal representation

The architecture uses three reductions, each with a distinct purpose:

$$\mathbb{Z} \xrightarrow{(\rho_9, q_9)} \{1, \dots, 9\} \times \mathbb{Z}, \qquad \rho_3^{\mathrm{or}} : \mathbb{Z}/3\mathbb{Z} \longrightarrow \{-1, 0, +1\},$$

$$(d_1, d_2, \dots) \in \{0, \dots, 999\}^{\mathbb{N}} \xrightarrow{\iota_{1000}} \sum_{m \geq 1} d_m 1000^{-m}.$$

The ternary orientation is

$$\rho_3^{\mathrm{or}}([0]) = 0, \qquad \rho_3^{\mathrm{or}}([1]) = +1, \qquad \rho_3^{\mathrm{or}}([2]) = -1.$$

The first separates the visible residue from the nonadic quotient; the second assigns the oriented type of the transition; the third groups the Archimedean reading into decimal triads, whose register preserves the carry. None can replace another. In particular, reduction modulo three does not reconstruct the quotient modulo nine, and a decimal triad is not a six-trit word. Addition accumulates displacements; multiplication folds classes and contracts the noninvertible rows. The need for TPK arises because the two readings share a support but do not share a partition, period, or quotient.

1.22.2 Correspondence between TPK symbols, domains, and compositions

Historical names are fixed here by object, not by numerical similarity. This table forms part of the public definition of TPK.

Name	Object	Function within the core
nonadic coordinate	$\rho_9(n)$ together with $q_9(n)$	Separa the representative visible modulo 9 of the quotient that preserves the memory of the cruce of boundary. No is a root digital.
ternary temporal selector	$M_{\mathrm{ph}}(t) = \varepsilon(t) \in \{+1, -1, 0\}$	At $1, 4, 7$ it activates additive accumulation; at $2, 5, 8$ it activates multiplicative accumulation; at $3, 6, 9$ it maintains both cursors and records the threshold. It does not denote the spatial directions.
transporte cardinal	T_N, T_E, T_S, T_O	It shifts the position on the APP torus and preserves the path word and its winding. It is independent of the temporal selector.
ternary reader	ρ_3^{or}	It converts the three residual classes into orientation $0, +1, -1$. It does not by itself reconstruct the nonadic quotient.
reader in base thousand	ι_{1000}	It groups the Archimedean publication into decimal triads and transports their carries. It is a positional reader, not a congruence "modulo 1000".
return of twenty-seven	$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$	It composes twenty-seven positional and oriented updates. Its fourth iterate restores the observable phase, while the complete register preserves the accumulated memory.
dodecaphonic register	$\Lambda \in \mathcal{R}_{12}$	It preserves six positions, five differences, and one total. It is the support of the reversible transport $1 + 5 + 6 = 12$.
bidirectional reading	q_+, q_- and its conjugate weights	It simultaneously preserves the outward and return orientations. In Dimensional Mechanics, a signature (n_A, s_C) first produces $W_\pm = 6n_A \pm s_C$; only afterward does $s_C/6$ appear in the angular character.

The temporal selector, cardinal transport, and ternary orientation are therefore three distinct maps. Their separation preserves the difference between *when* a reading is activated, *in which direction* the route advances, and *with which orientation* the step is recorded. TPK contains all three and preserves their relations.

1.22.3 Cardinal Action and Arithmetic Feedback

Let

$$\nu_N = (-1, 0), \quad \nu_E = (0, 1), \quad \nu_S = (1, 0), \quad \nu_O = (0, -1)$$

the four generators cardinal. For $d \in \{N, E, S, O\}$,

$$T_d(i, j) = (i, j) + \nu_d \pmod 9.$$

The letter O means west. These directions are displacements over APP and not names of the channels π, e, φ.

A word $w = d_1 \cdots d_r$ determines

$$\gamma(x_0; w)_k = x_0 + \sum_{j=1}^{k} \nu_{d_j} \pmod 9.$$

When it closes, its lift preserves

$$\mathrm{wind}(w) = \frac{1}{9}\big(\#S - \#N, \#E - \#O\big) \in \mathbb{Z}^2.$$

The bidirectional reading preserves word, orientation, and sheet. Its formal reversal inverts the order and exchanges $N \leftrightarrow S$, $E \leftrightarrow O$. Its eventual reading as advance–delay is a later physical interface, not part of this route definition.

The locally observable state is

$$s_t = (i_t, j_t, m_t), \qquad m_t \in \{\Sigma, \Pi\}.$$

The active sheet is evaluated,

$$a_t = \rho_3^{\mathrm{or}}\big(m_t(i_t, j_t)\big),$$

and the mode is updated via

$$m_{t+1} = \begin{cases} \Sigma, & a_t = +1, \\ \Pi, & a_t = -1, \\ m_t, & a_t = 0. \end{cases}$$

Thus, each cardinal step modifies both the position and the future arithmetic reading. The path is not superimposed on a previously constructed word: it is the positional history that produces it.

Theorem 1.176 (Surjectivity of the sampled three-step factor)**.** *For each of the* $162 = 9^2 \cdot 2$ *states* (i, j, m) *and each target oriented trit* $b \in \{-1, 0, +1\}$*, there exists a route* $u \in \{N, E, S, O\}^3$ *whose third step emits* b*. In the* 486 *state–target cases, the number of admissible routes is between* 8 *and* 40*. Consequently, for every target succession* $(b_k)_{k \geq 1}$*, there exists a cardinal history whose output satisfies*

$$(a_3, a_6, a_9, \ldots) = (b_1, b_2, b_3, \ldots).$$

The two intermediate trits a_{3k-2} *and* a_{3k-1} *of each block are not prescribed by this assertion.*

Proof. The $4^3 = 64$ three-step routes from each state are enumerated. The included exhaustive certificate records, for each of the $162 \cdot 3$ cases, the route executed, the final state, and the total number of witnesses; its indices $0, 1, 2$ are transported by ρ_3^{or} to $0, +1, -1$. All counts are positive; the minimum is 8 and the maximum is 40. After each block, the same result is applied to the state reached. The choice, for example, of the first witness in lexicographic order recursively produces a history for any target sequence. □

Surjectivity concerns the factor observed every three steps, not the word emitted at unit time. This theorem establishes that sampled capacity of the route support. The selection of the sections π, e, φ belongs to the enriched EF–G9 relation defined later: capacity for realization and selection that is genealogical are two distinct operators.

1.22.4 Chronological evolution of the cursor pair and determination of the observable state

The calendar is formulated over

$$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}, \qquad \beta(\theta) = \left[\left[\frac{\widetilde{\theta}}{9}\right]\right]_{12}, \qquad r(\theta) = 1 + (\theta \bmod 9),$$

where $\widetilde{\theta} \in \{0, \dots, 107\}$. The active signature is

$$\varepsilon(r) = \begin{cases} +1, & r \in \{1, 4, 7\}, \\ -1, & r \in \{2, 5, 8\}, \\ 0, & r \in \{3, 6, 9\}. \end{cases}$$

The observable space of two cursors is

$$Q_{\mathrm{obs}} = X_9^2 \times \{N, E, S, O\}^2 \times \Theta_{108}.$$

If $\varepsilon = +1$, the additive cursor advances; if $\varepsilon = -1$, the multiplicative cursor advances; if $\varepsilon = 0$, neither advances. The two orientations are reversed after steps $27, 54, 81, 108$. This rule defines a permutation

$$F_{\mathrm{obs}} : Q_{\mathrm{obs}} \longrightarrow Q_{\mathrm{obs}}.$$

Positions and orientations are restored after 54 steps and the complete phase after 108:

$$F_{\mathrm{obs}}^{108} = I.$$

Therefore, the chronology of a single route is reversible and does not by itself select a distribution on the continuations; selection of all compatible prolongations belongs to the fiber transfer operator defined below.

1.22.5 Finite emitter associated with the cursor pair and generation of admissible states

A cursor seed is

$$\mathcal{S} = \mathbb{T}_9^2 \times \{N, E, S, O\}, \qquad |\mathcal{S}| = 324.$$

Minimal TPK receives an additive cursor $P \in \mathcal{S}$ and a multiplicative cursor $M \in \mathcal{S}$. Their six-window signatures are $s(P)$ and $e(M)$. In each coordinate one applies

$$G(s, e) = 100s + 10\big((s + e) \bmod 10\big) + \big((3s + 5e + 1) \bmod 10\big).$$

The figure of hundreds recovers s; known s, the of tens recovers e. Therefore G is injective on the effective signatures. The emitter factorizes as

$$\mathcal{S}^2 \xrightarrow{s \times e} \operatorname{im} s \times \operatorname{im} e \xrightarrow{G} \mathcal{U}_6,$$

with

$$|\mathcal{S}^2| = 104\,976, \qquad |\operatorname{im} s| = 18, \qquad |\operatorname{im} e| = 26, \qquad |\mathcal{U}_6| = 18 \cdot 26 = 468.$$

The factorization $468 = 18 \cdot 26$ is therefore a decomposition of the object: each emission conserves an additive and a multiplicative signature.

The projection

$$\Psi_6 : \mathcal{U}_6 \longrightarrow \mathbb{F}_3^6, \qquad \Psi_6(U) = -U \pmod 3,$$

has an image of 243 words. The chain typed is

$$104\,976 \text{ seeds} \longrightarrow 468 \text{ decimal emissions } U_6 \longrightarrow 243 \text{ ternary words } w_6.$$

The ambient space $\mathbb{F}_3^6$ contains 729 words; it is not identified with the effective image of 243. Nor are U_6 and w_6 the same type.

The emitter minimo repite, in the chart dodecaphasic of catalogo,

$$U_{12}^{\mathrm{cat}} = U_6 \| U_6.$$

Its visible period six explains why it cannot replace the signed state U_{12}^{sgn}. This difference is not an insufficiency of TPK: it separates the catalogue projection from the enriched history.

Each emitted decimal block belongs to an exact alphabet of $7 \cdot 6 = 42$ triads. If $\overline{d_1 d_2 d_3}$ is one of them,

$$\boxed{d_3 \equiv 5d_2 - 2d_1 + 1 \pmod{10}.}$$

The sweep of the 104 976 seeds produces no triad outside this law. It is therefore useful to distinguish the complete chain of quotients:

$$\mathcal{S}^2 \longrightarrow \Omega_{\mathrm{seed}} \longrightarrow \mathcal{U}_6 \xrightarrow{\Psi_6} \operatorname{im}\Psi_6 \subset \mathbb{F}_3^6.$$

The microscopic presentations, the 468 decimal emissions, the 243 ternary words, and the environment of 729 words are four distinct objects.

Orbital Commutativity of Typed Morphisms. Let $W_{243} := \operatorname{im}\Psi_6 \subset \mathbb{F}_3^6$. The complete funnel and its dihedral quotient are represented without turning inclusions into selections:

$$\underbrace{\mathcal{S}^2}_{104\,976 \text{ semillas}} \xrightarrow[\text{fiber census}]{\text{emission}} \underbrace{\mathcal{U}_6}_{468\ U_6} \xrightarrow[\text{visible projection}]{\Psi_6} \underbrace{W_{243}}_{243\ w_6} \hookrightarrow \underbrace{\mathbb{F}_3^6}_{729 \text{ palabras}}, \qquad W_{243} \xrightarrow{/D_3^{\mathrm{cat}}} \underbrace{\mathcal{O}_{43}}_{43 \text{ orbits}}.$$

(TPK-embudo)

The first arrow groups initial conditions by the emission they produce; the second forgets the decimal presentation; the third is an inclusion in the algebraic ambient space; the last is a quotient by the action D_3^{cat} on W_{243}. In particular, there is no implicit quotient $729 \to 43$. The exact census is

$$243 = 38 \cdot 6 + 5 \cdot 3,$$

that is, thirty-eight orbits of size six and five of size three. These 43 orbital classes are not the 43 complete nonadic turns per channel of the thousand-digit G9 witness either: the first 43 belongs to the finite quotient $W_{243}/D_3^{\mathrm{cat}}$; the second is a depth counter of a certified run.

1.22.6 Configuration of the enriched state of the TPK: sheet, orientation, residue, quotient, carry, boundary, route, and memory

The complete dynamic unit is a history, not an isolated word. At depth m we write

$$v_m = \big(B_m, \boldsymbol{\delta}_m, \boldsymbol{x}_m, \boldsymbol{C}_m, \Sigma_m, \omega_m, \ell_m, g(m), \Lambda_m\big),$$

where

$$B_m = (u_m^{\pi}, u_m^{e}, u_m^{\varphi}) \in (\mathbb{F}_3^6)^3.$$

Their components have distinct functions:

1. B_m is the joint visible block of the three channels;
2. $\boldsymbol{\delta}_m$ retains the new decimal triads and the associated carry;

3. $\boldsymbol{x}_m$ is the deep Hensel state;
4. $\boldsymbol{C}_m$ contains the ternary and decimal cylinders and their integer residues;
5. Σ_m is the signature joint of boundary;
6. ω_m and ℓ_m conserve orientation and bidirectional sheet;
7. $g(m) \in \mathbb{Z}/9\mathbb{Z}$ is the nonadic phase;
8. Λ_m is the dodecaphasic record oriented.

Definition 1.177 (Operatorial presentation and TPK category)**.** The operator inventory of the enriched state of TPK is

$$\mathfrak{T}_{\mathrm{HMT}} = \left(\mathcal{A}_9, \widehat{\mathbb{T}}, T_{N,E,S,O}, T_{\min}, H, C_{3,1000}, \Sigma_B, EF, \mathcal{G}_9, \mathcal{R}_{12}\right)$$

that transports histories $(v_0, \ldots, v_m)$ and their truncations. Its formal carrier is the category TPK over the observable base: its objects are enriched states, and its morphisms are the prolongations Ext_r stable under identity and concatenation, defined below. The inventory does not replace that category. The visible projection eliminates components of v_m; it does not define an equivalence with the complete state.

This definition contains exactly what disappears when cursors are reset or only the residue is conserved: the path, the sheet, the quotient, the carry, the orientation, and the boundary. TPK is, for that reason, the point at which modular arithmetic ceases to be an operation without history.

1.22.7 Ternary-decimal cylinders and state of extension

Let N be the integer determined by a ternary prefix of length L, and let D be the integer determined by K decimal triads. We define

$$A = N1000^K - D3^L, \qquad B = (N+1)1000^K - D3^L.$$

The cylinders intersect exactly when

$$\boxed{A < 3^L, \qquad B > 0.}$$

When incorporating a ternary block $u \in \{0, \ldots, 728\}$,

$$N' = 729N + u.$$

If no appears a new triad decimal,

$$A' = 729A + u1000^K.$$

Si aparece $\delta \in \{0, \ldots, 999\}$,

$$D' = 1000D + \delta,$$

$$A' = 729000A + u1000^{K+1} - \delta\, 729\, 3^L.$$

In both cases,

$$B' = A' + 1000^{K+\Delta K}.$$

These integer recurrences transport the decimal datum without turning it into an external target of the update.

The Hensel state preserves the information that does not appear in the residue. The active matrix is

$$A_H = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad \det A_H = 1,$$

and the residue–quotient division is

$$y = xA_H, \qquad u = y \bmod 3, \qquad x^+ = \frac{y-u}{3}.$$

For the three channels, the joint cocycles are additionally formed

$$q = (\pi + e + \varphi) \bmod 3, \qquad c = \frac{\pi + e + \varphi - q}{3},$$

$$a = (\pi + e - \varphi) \bmod 3, \qquad h = \frac{\pi + e - \varphi - a}{3}.$$

The second-order update corrects the next state with c and h. Two branches with the same visible block are therefore not necessarily the same state: they may differ in their Hensel extension and in their cylinders. Since $\det A_H = 1$, the reduction of A_H belongs to $\mathrm{GL}_6(\mathbb{F}_3)$. Hence, before cylinders, boundaries, or survival are imposed, the residual Hensel chart covers exactly $\mathbb{F}_3^6$. This raw coverage does not imply coverage of the filtered system.

Formally, over each observable configuration q a fiber is fixed

$$\mathcal{F}_q = \mathsf{O}_q \times \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{S}_q \times \mathsf{B}_q \times \Lambda_q,$$

corresponding, respectively, to orientation and sheet, residue and quotient, carry, signature, cylinder and boundary, and transport record. For a cardinal arrow $r : q \to q'$, the admissible prolongation does not reduce to a function on residues; it is the relation

$$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}, \qquad \mathrm{Ext}_{r_2} \circ \mathrm{Ext}_{r_1} \subseteq \mathrm{Ext}_{r_2 \circ r_1}.$$

The carry increment is a cocycle:

$$\kappa(r_2 \circ r_1) = \kappa(r_2) + \mathsf{C}(r_2)\big(\kappa(r_1)\big).$$

Thus the forgetful map is typed: projecting an extension to its observable route eliminates components of $\mathcal{F}_q$, but does not authorize identifying both objects.

1.22.8 Compound returns and transport calendars

The length of a trace does not determine its type. The academic presentation separates the composite return, calendar, trace, and atlas according to their respective preserved states.

The symbol $\mathcal{K}_{27}$ is reserved for the composition of twenty-seven updates of a positional and oriented transport loop. The integer 27 is its composition length; this does not turn it into a trace of 108 iterations or into an infinite emitter. Another construction, historical in origin, groups four loops whose joint periods reach 108; that joint rotor is not denoted by $\mathcal{K}_{27}$ in isolation.

Object	Estado conservado	Significado de 108
Contador simplificado	position and velocity	its real period is 18; it is a historical control.

Object	Estado conservado	Significado de 108
Rotor set of four loops	four routes, reading, rotation, and motion	the individual periods are 54, 54, 36, 36; the joint state has period 108.
Raw clocked trace	four positions, orientations, and phase	the dynamic content repeats at 54.
Trace of $T_{\min}$	two positions and two directions	the state returns to 54 and the output is $U_6 \| U_6$.
Reinitialized pseudocode	cursors reset each window	collapses to $(222, 222, 222, 333, 333, 333)^2$; it does not represent the enriched state of TPK.
Rutas condicionadas	path and prescribed word	108 is horizon, not period.
Sectorial odometer	$\mathbb{Z}/9\mathbb{Z} \times \{0, \dots, 11\}$	the complete state has period 108; the sectorial observable, 36.
Projection raw	quotient by forgetfulness of $X_{\mathrm{TPK}}^{\mathrm{enr}}$	does not possess by itself the signed reading.
Traza enriquecida	all the fields of v_m during 108 updates	is the temporal restriction of the enriched state of TPK.
Atlas of Routes	81 cells/56 signatures or 324 oriented seeds	is a taxonomy, not an orbit of 108 states.

The loop $\mathcal{K}_{27}$ is the finite transport operator of twenty-seven updates. The windows, joint rotor, and calendrical projection receive distinct symbols, so that the shared length does not replace the domain or composition of each object.

1.22.9 Fiber transfer and spin memory

The factorization $\mathcal{U}_6 \simeq \mathcal{S}_+ \times \mathcal{S}_\times$ allows one to define, with respect to the uniform count, the conditional expectations

$$(E_+ f)(s, e) = \frac{1}{18} \sum_{s' \in \mathcal{S}_+} f(s', e), \qquad (E_\times f)(s, e) = \frac{1}{26} \sum_{e' \in \mathcal{S}_\times} f(s, e').$$

E_+ renews the additive fiber and preserves the multiplicative one; $E_\times$ realizes the dual operation. They are the only Markov projectors that completely marginalize the active coordinate, preserve the inactive one, and preserve the uniform count.

Let $\tau = (+1, -1, 0)^3$ be the phase word on C_9, and $P_{+1} = E_+$, $P_{-1} = E_\times$, $P_0 = I$. The nonadic transfer is

$$\mathcal{K}_{\mathrm{ph}}\big((u, r), (v, r+1)\big) = P_{\tau(r)}(u, v).$$

It is doubly stochastic, irreducible, of period 9, and has a unique stationary distribution $1/(9 \cdot 468)$. Moreover,

$$\mathcal{K}_{\mathrm{ph}}^9 = E_+ E_\times, \qquad (E_+ E_\times)(u, v) = \frac{1}{468}.$$

This equality expresses the simultaneous renewal of all compatible continuations, not the deterministic successor of a single path.

Three geometric operations on the seeds preserve additional information: P, advance in the active orientation; H, a half-turn; and Q, a quarter-turn. The pair (P, H) refines the 26 product signatures into 28 classes. In particular, the signature 555555 splits into three sheets of eight representatives, and

$$18 \cdot 28 = 504 = 468 + 36.$$

The term 36 counts additional sheets of the refinement and is not the object R_{36}. The pair (P, Q) produces 162 classes of two elements, transitively permuted by

$$J(i, j, d) = \left(7 - i,\ 7 - j,\ \overline{d}\right) \pmod 9.$$

In a trace of 108 steps, there appear 36 signs of each type, 72 effective changes between the two sheets, and four orientation reversals; the total signed cocycle is zero. These counts are invariants of the evolution record and link nonadic dynamics with the dodecaphase record.

1.22.10 Tertiary prolongation and joint boundary

Relative to the named seeds, boundaries, and readers of the published profile, the initial visible words are

$$w_6^{\pi} = 010211, \qquad w_6^{e} = 201101, \qquad w_6^{\varphi} = 121200.$$

After five blocks, the prefixes are

$$\begin{aligned} w_{30}^{\pi} &= 010211|012222|010211|002111|110221, \\ w_{30}^{e} &= 201101|121221|102011|012222|102011, \\ w_{30}^{\varphi} &= 121200|112202|121020|010210|010200. \end{aligned}$$

The first deep boundary is

$$R_{36} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}.$$

For each channel the prefix $w_{36}^{\chi} := w_{30}^{\chi}|u_5^{\chi}$ is defined; R_{36} is the ordered triple of the three sixth blocks. Neither is an emitter nor a terminal state.

For $B_k = (u_k^{\pi}, u_k^{e}, u_k^{\varphi})$, the signatures

$$q_k = u_k^{\pi} + u_k^{e} + u_k^{\varphi}, \qquad a_k = u_k^{\pi} + u_k^{e} - u_k^{\varphi}$$

determine

$$u_k^{\varphi} = 2(q_k - a_k), \qquad u_k^{\pi} + u_k^{e} = q_k - u_k^{\varphi} \quad \text{in } \mathbb{F}_3^6.$$

Thus, φ is the fixed axis and the residual freedom is the internal distribution π/e. In the ninth phase,

$$B_9 = (100100|020112|010122)$$

admits three local outputs with the same axis φ and the same aggregate $\pi + e$; all three survive one horizon and only

$$B_{10} = (101222|112221|112002)$$

survives the second. This is the executable3 $\to$ 1 descent of EF–G9. The published branch continues through twenty blocks per channel: w_{30} and R_{36} are prefix and boundary, not closure.

1.22.11 Relation of extension and nonadic monodromy

Let $\mathcal{H}_m$ be the set of admissible enriched histories of depth m, and let

$$p_{n,m} : \mathcal{H}_n \longrightarrow \mathcal{H}_m$$

the truncation. For $N \geq m$,

$$\mathrm{Surv}_m^{(N)} = p_{N,m}(\mathcal{H}_N), \qquad \mathrm{Surv}_m = \bigcap_{N \geq m} \mathrm{Surv}_m^{(N)}.$$

The EF–G9 relation conserves the extensions that belong to this stable core. The phase satisfies

$$g(m+9) = g(m),$$

but the transported state satisfies, in general,

$$v_{m+9} \neq v_m.$$

The return acts on the fiber of states of a same phase; does not reset the history.

Definition 1.178 (Number HMT)**.** An HMT number of channel χ is solely a compatible global section

$$x = (x_m)_{m \geq 0} \in X_\chi := \varprojlim_m \mathrm{Surv}_m^{(\chi)}.$$

The reader and the published value are not part of the section.

A presentation or measurement of the number is a pair (x, L), where L is a declared reader whose domain contains x. When L is the Archimedean reader of cylinders, $L(x)$ is the published value; x conserves in addition orientation, quotient, carry, and boundary.

Theorem 1.179 (Existence of a global prolongation)**.** *Let $h \in \mathcal{H}_m$. If the prolongation tree of h is finitely branching and has at least one node at every depth, then there exists an infinite history whose truncations prolong h. If, in addition, each stable level is a singleton and the unique states are compatible, the global section is unique.*

Proof. The non-empty finite levels form a finitely ramified tree. König's lemma provides an infinite branch. The compatibility of the truncations identifies that branch with an element of the inverse limit. If each level contains a single state, there is no second compatible branch. □

The preceding theorem is abstract and conditional: by itself it asserts neither nonemptiness nor the stable uniqueness of a concrete channel. For π, e, φ, those hypotheses are subsequently discharged through the executable rational filtration of theorem 8.54. This placement preserves here only the inverse-limit principle and does not anticipate its application.

1.22.12 Composition of the fundamental operators

The above operators lead to the enriched terminal state without flattening its coordinates:

$$\begin{aligned} \mathrm{APP} &\longrightarrow \mathrm{TRIT} \longrightarrow \text{oriented route} \longrightarrow \text{enriched TPK state} \\ &\longrightarrow \text{cylinders and survival} \longrightarrow x_{\mathrm{term}}. \end{aligned}$$

The dodecaphonic closure then receives two coordinated evaluations of the same state:

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} \left(B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}\right), \qquad U_{12}^{\mathrm{sgn}} \overset{\mathcal{H}_{12}}{\longleftrightarrow} K,$$

$$(P, E, \Phi, K, c_{13} = 0) \longleftrightarrow \alpha_{12}.$$

No arrow $B_{\mathrm{term}} \to U_{12}^{\mathrm{sgn}}$ appears: both coordinates follow from x_{term}. The subsequent passage to Dimensional Mechanics likewise creates no other machine; it prolongs the preserved genealogy through an enriched chronological record, signature, character, and towers.

1.23 Construction and operatorial architecture of the APP–TRIT–TPK formal kernel: arithmetic support, ternary orientation, and genealogical dynamics

Triadic Modular Holography, abbreviated HMT, begins with a finite structure of positions and operations. The order of construction matters: the positions receive arithmetic evaluations, the transitions acquire a ternary signature and the dynamics preserves the information necessary to prolong them. Only afterward are the numerical realizations formed. A constant recognized at the end of this process does not replace the rule that produced its region or the history that determines its evaluation.

The name *All Possible Paths*, APP, expresses the role of paths on the support. It is adopted as the name of the construction, with a conceptual reference to the path formulation of quantum mechanics; it does not imply that its arithmetic law is Feynman's path integral. The *Topological Phase Kernel*, TPK,[2] designates the composition of selection, transport, memory update and prolongation. The acronyms are retained only after the objects they represent have been defined.

1.23.1 APP: positional support and arithmetic evaluations

Consider the nine interior marks of a graduated line between zero and ten,

$$D_9 = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}.$$

Their horizontal and vertical arrangement produces the eighty-one positions of D_9^2. The interior marks must not be confused with the ten unit intervals of the reference line. This arrangement fixes an alphabet and two directions; it does not yet use a real expansion to decide a trajectory.

The cyclic identification of the positions leads to the support

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2.$$

The chart of positive representatives preserves the symbol nine for the zero class. For every positive integer one defines

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \frac{n - \rho_9(n)}{9}, \qquad n = \rho_9(n) + 9q_9(n). \tag{1.152}$$

The positive digital root is therefore a choice of representative of the residual class. It does not by itself preserve the integer before reduction; the coordinate q_9 provides precisely the missing information.

At each position (i, j), the accumulation of i repeated j times produces ij. The two integer evaluations and their projections are

$$S(i,j) = i + j, \qquad P(i,j) = ij, \qquad \Sigma(i,j) = \rho_9(i+j), \quad \Pi(i,j) = \rho_9(ij).$$

The symmetry $(i, j) \mapsto (j, i)$ interchanges the directions of accumulation and preserves both evaluations. It is a property of a single support, not a subsequent identification between two independent matrices.

Definition 1.180 (Lifted arithmetic evaluation)**.** The evaluation of APP that preserves the two sheets is

$$\mathcal{A}(i,j) = \big((R^+_{ij}, q^+_{ij}), (R^\times_{ij}, q^\times_{ij})\big) = \big((\rho_9(i+j), q_9(i+j)), (\rho_9(ij), q_9(ij))\big). \tag{1.153}$$

The term *sheet* here indicates an evaluation on the same support: additive or multiplicative. The two quotient coordinates belong to the arithmetic state and are not discarded when reducing the residues.

Proposition 1.181 (Reconstruction of the evaluations)**.** *Los dos pares de* (1.153) *determinan exactamente* $i + j$ *e* ij*. Los residuos aislados no determinan esas evaluaciones enteras ni sus cocientes.*

[2] The authors also dedicate the initials TPK to Tan Pengkiang. This dedication is independent of the mathematical definition.

	1	2	3	4	5	6	7	8	9
1	1	2	3	4	5	6	7	8	9
2	2	4	6	8	1	3	5	7	9
3	3	6	9	3	6	9	3	6	9
4	4	8	3	7	2	6	1	5	9
5	5	1	6	2	7	3	8	4	9
6	6	3	9	6	3	9	6	3	9

8	8	7	6	5	4	3	2	1	9
9	9	9	9	9	9	9	9	9	9

One support: 81 positions.

Two evaluations:
$S(i, j) = i + j$, $P(i, j) = ij$.

Each row is generated by accumulation:
$P(i, j + 1) - P(i, j) = i$.

La carta representa 0 (mod 9) por 9.

El bloque señalado es
$B_c = \left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$,
con autovalores 9 y 5.

Figure 1.4: Tabla multiplicativa de APP en representantes positivos. Las filas y columnas no unitarias se distinguen por trama gris; el marco identifica el bloque diagonal adyacente de diagonales iguales. La tabla dibujada es un observable del toro aritmético; sus bordes de representación no constituyen una frontera topológica intrínseca del toro.

Proof. La primera afirmación es (1.152) aplicada a cada hoja. Para la segunda, $10 = 1 + 9$ y $19 = 1 + 2 \cdot 9$ tienen el mismo residuo y distinto cociente. En el soporte bidimensional, las posiciones $(5, 5)$ y $(8, 2)$ dan la misma suma y el mismo residuo producto, pero productos $25 = 7 + 18$ y $16 = 7 + 9$. La proyección residual identifica datos que la evaluación levantada distingue. □

1.23.1.1 Grafo de Cayley, topología toroidal y grado de enrollamiento

Las traslaciones cardinales están dadas, en coordenadas de fila y columna, por

$$\nu_N = (-1, 0), \quad \nu_E = (0, 1), \quad \nu_S = (1, 0), \quad \nu_O = (0, -1), \qquad T_d(x) = x + \nu_d.$$

The first coordinate increases southward and the second eastward. The graph

$$\mathcal{G}_9 = \mathrm{Cay}(X_9, \{\nu_N, \nu_E, \nu_S, \nu_O\})$$

is the two-dimensional cyclic grid: it has eighty-one vertices and four outgoing oriented edges per vertex. It is a Cayley graph for the *additive* structure of the support. Multiplication of residues has zero divisors and does not make all rows of APP into a multiplicative group.

A cardinal word $w = d_1 \cdots d_r$ and an origin x_0 determine

$$x_k = x_0 + \sum_{j=1}^{k} \nu_{d_j} \pmod 9.$$

There are $81 \cdot 4^r$ oriented paths of length r, including returns and backtracking. When the path closes, its integer displacement before reduction defines

$$\mathrm{wind}(w) = \frac{1}{9}\big(\#S(w) - \#N(w), \#E(w) - \#O(w)\big) \in \mathbb{Z}^2. \tag{1.154}$$

Reversing the path changes the sign of this vector. Returning to the same residual position therefore does not require the winding to be zero. This is the first example of a difference that will reappear in the phase return: one coordinate may close while another records a nontrivial evolution.

1.23.1.2 Transport quotient and cocycle identity

Let $s_9 : \mathbb{Z}/9\mathbb{Z} \to D_9$ be the section of positive representatives. The transport quotient associated with additive composition, also called *carry* in positional arithmetic, is

$$c_9(a,b) = \frac{s_9(a) + s_9(b) - s_9(a+b)}{9}.$$

The compositional character of this memory is expressed by an exact identity.

Lemma 1.182 (Cocycle identity)**.** *For $a, b, c \in \mathbb{Z}/9\mathbb{Z}$,*

$$c_9(a,b) + c_9(a+b,c) = c_9(b,c) + c_9(a,b+c).$$

Proof. Both sums are equal to

$$\frac{s_9(a) + s_9(b) + s_9(c) - s_9(a+b+c)}{9}.$$

The associativity of the sum of lifted representatives requires precisely this additional term when composing in the quotient. □

With positive representatives, this cocycle is not normalized at the identity: $c_9(0,a) = 1$. If s_0 takes representatives in $\{0,\dots,8\}$, its normalized carry c_0 satisfies

$$c_9(a,b) = c_0(a,b) + \mathbf{1}_{a=0} + \mathbf{1}_{b=0} - \mathbf{1}_{a+b=0}.$$

The difference is the change of section; it does not alter the cocycle identity. The subsequent decomposition of the calendar into phase and window will use representatives from zero to eight.

The totals of both evaluations distinguish the visible contribution and the one preserved in the quotient:

$$\sum S = 810, \quad \sum P = 2025, \quad \sum \Sigma = 405, \quad \sum \Pi = 459,$$
$$\sum q^{+} = 45, \qquad \sum q^{\times} = 174.$$

It follows that

$$2025 - 810 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129. \tag{1.155}$$

The sum–product difference is not exhausted by the visible defect 54. The identity also preserves the quotient defect 129. Removing it would change the arithmetic being transported, even if the residual table remained identical.

1.23.1.3 Ternary reduction and multiplicative radical

The ring $R = \mathbb{Z}/9\mathbb{Z}$ has unit group $\{1,2,4,5,7,8\}$ and maximal ideal

$$\mathfrak{m} = (3) = \{0,3,6\}, \qquad \mathfrak{m}^2 = 0.$$

Every additive row is a permutation of the nine representatives. A multiplicative row is one exactly when its index is a unit. Rows three and six contain three repeated values; row nine contains only the representative of the zero class. Thus the multiplicative folding already distinguishes, before any continuous geometry, the units from the nilpotent sector.

The map $x \mapsto 3x$ has kernel and image both equal to $\mathfrak{m}$. It induces an isomorphism of vector spaces over $\mathbb{F}_3$,

$$R/\mathfrak{m} \longrightarrow \mathfrak{m}, \qquad [x] \longmapsto 3x,$$

but not a ring isomorphism. In particular, the visible sequence $3, 6, 9$ admits two different readings: its direct reduction modulo three is $0, 0, 0$, whereas extracting the factor three followed by reducing its internal coordinate gives $1, 2, 0$. This second operation preserves a coordinate of the ideal; it is not the same projection as directly reducing the original number.

1.23.1.4 Latin realization of the additive evaluation

The difference between the two evaluations can also be expressed through operators. Let $(e_r)_{r\in\mathbb{Z}/9\mathbb{Z}}$ be the orthonormal basis of $\mathbb{C}^9$. The assignment $v_{ab} = e_{a+b}$ produces an orthonormal basis in each row and column. The projectors $P_{ab} = v_{ab}v_{ab}^*$ satisfy

$$\sum_b P_{ab} = I_9 = \sum_a P_{ab}, \qquad P_{ab}^2 = P_{ab}.$$

Indeed, each translation $b \mapsto a + b$ permutes the nine residues. A realization of a Latin square by rank-one projectors is obtained, in the terminology of quantum Latin squares [152, 154]. This construction starts from the additive sheet already defined and makes explicit the map to its operator representation.

The multiplicative evaluation preserves other content: for $a = 3$, the vectors e_{3b} repeat the residues $0, 3, 6$, and

$$\sum_{b\in\mathbb{Z}/9\mathbb{Z}} |e_{3b}\rangle\langle e_{3b}| = 3\big(|e_0\rangle\langle e_0| + |e_3\rangle\langle e_3| + |e_6\rangle\langle e_6|\big).$$

The multiplicity is recorded in the operator and characterizes the multiplicative radical. Thus the toroidal support, the Latin property and the operator resolution of the identity are properties that require different definitions. The quantum magic squares studied by De las Cuevas, Drescher and Netzer require positive entries and row and column sums equal to the identity; their theory also distinguishes dilations with commutative entries[153]. This reference provides a precise language for comparing realizations of APP.

1.23.2 TRIT: orientation and quadratic regimes

Definition 1.183 (Ternary signature and local lift)**.** The TRIT signature uses the balanced identification

$$\mathbb{F}_3 \longrightarrow \widehat{\mathbb{T}}, \qquad 0 \mapsto 0, \quad 1 \mapsto +1, \quad 2 \mapsto -1.$$

For $n \in \mathbb{Z}$, its lift preserves $n = r + 3c$, where $r \in \widehat{\mathbb{T}}$ and $c \in \mathbb{Z}$. In a transition of bounded local amplitude, the three states $(0, -1), (0, 0), (0, +1)$ may have the same zero residue and different carries.

The signature does not replace the trajectory. A residual zero does not mean an absence of orientation, phase or quotient information. Nor does it by itself introduce a physical quantity. Its function is to distinguish algebraically the transport classes that will be realized next.

1.23.2.1 Three quadratic regimes and a common exponential

Once the ternary signature has been obtained, its quadratic realization is defined by

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \tau), \qquad \tau \in \widehat{\mathbb{T}}. \tag{1.156}$$

If J_τ is the class of X, then $J_\tau^2 = -\tau I$. The structure distinguishes the elliptic type $\tau = +1$, the parabolic type $\tau = 0$ and the hyperbolic type $\tau = -1$. The real realization does not generate the signature: it expresses the types that oriented reduction has already produced.

Proposition 1.184 (Exponentiation of the three types)**.** *In each algebra* (1.156)*,*

$$\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau, \tag{1.157}$$

where

$$C_\tau(t) = \sum_{n\geq 0} \frac{(-\tau)^n t^{2n}}{(2n)!}, \qquad S_\tau(t) = \sum_{n\geq 0} \frac{(-\tau)^n t^{2n+1}}{(2n+1)!}.$$

The three realizations are

τ	J_τ^2	$\exp(tJ_\tau)$
$+1$	$-I$	$\cos t\, I + \sin t\, J_\tau$
0	0	$I + tJ_\tau$
-1	I	$\cosh t\, I + \sinh t\, J_\tau$.

Proof. Separating the even and odd terms of the exponential series and substituting $J_\tau^{2n} = (-\tau)^n I$ and $J_\tau^{2n+1} = (-\tau)^n J_\tau$ gives the formulas. For $\tau = 0$, all terms of degree at least two vanish. In the other two cases the trigonometric or hyperbolic series are recovered. □

The exponential is common to the three regimes: it is not assigned exclusively to the parabolic branch. The invariants

$$C_\tau(t)^2 + \tau S_\tau(t)^2 = 1$$

follow from $\exp(tJ_\tau)\exp(-tJ_\tau) = I$. The same algebraic principle preserves unity across realizations that differ in their quadratic type.

In the hyperbolic regime, $P_\pm = (I \pm J_{-1})/2$ are complementary projectors and

$$\exp(tJ_{-1}) = e^t P_+ + e^{-t} P_-.$$

Growth and contraction appear jointly in two eigendirections. In the elliptic regime, the parameter describes a rotation; in the parabolic regime, a nilpotent translation. The temporal interpretation adopted by HMT associates $+1$ with the return with memory, 0 with the threshold and -1 with bidirectional opening. This interpretation requires an order of parametrization; it does not add a fourth algebraic type.

1.23.2.2 Balanced division and composition of lifts

Ternary reduction allows an integer evaluation of APP to be expressed in a visible coordinate and a prolongation coordinate. Its function does not consist merely in abbreviating the notation of an integer: it provides a composition rule that determines how the quotient is modified when evaluations are added or multiplied. The balanced choice also makes explicit the compatibility of that rule with sign reversal.

Definition 1.185 (Balanced ternary coordinates)**.** For $n \in \mathbb{Z}$, let

$$q_3(n) = \left\lfloor \frac{n+1}{3} \right\rfloor, \qquad r_3(n) = n - 3q_3(n).$$

The map

$$\mathcal{B} : \mathbb{Z} \longrightarrow \widehat{\mathbb{T}} \times \mathbb{Z}, \qquad n \longmapsto (r_3(n), q_3(n))$$

is called the balanced ternary decomposition. Its inverse is $\mathcal{L}(r, c) = r + 3c$.

Indeed, $r_3(n) \in \{-1, 0, +1\}$. If two pairs represent the same integer, $r + 3c = s + 3d$, then $r - s$ is a multiple of 3 and belongs to the interval $[-2, 2]$; necessarily $r = s$ and $c = d$. The representation is therefore unique. Division can be repeated on $q_3(n)$, so that each level preserves the datum necessary to reconstruct the preceding one. The quotient is not a perturbation of the residue: it constitutes its complementary coordinate.

The signature obtained from an evaluation F, with $F = S$ or $F = P$ in APP, is $r_3 \circ F$. When reduction acts on the phase cursor, the same balanced section produces the classes $\{1, 4, 7\}$, $\{2, 5, 8\}$ and $\{3, 6, 9\}$, with values $+1, -1, 0$. The TPK selector defined next uses these classes to determine the operational mode. Reading an evaluation and selecting a mode thus have the same ternary reduction, but different domains and functions.

Proposition 1.186 (Arithmetic of balanced pairs)**.** *Let $n = r + 3c$ and $m = s + 3d$, with $r, s \in \widehat{\mathbb{T}}$. Define*

$$\chi(r,s) = \frac{r + s - r_3(r+s)}{3}.$$

The integer operations are transported to pairs through

$$(r,c) \boxplus (s,d) = \big(r_3(r+s),\, c + d + \chi(r,s)\big), \tag{1.158}$$

$$(r,c) \boxtimes (s,d) = \big(rs,\, rd + sc + 3cd\big). \tag{1.159}$$

The map $\mathcal{L}$ preserves both operations.

Proof. The equality $r + s = r_3(r+s) + 3\chi(r,s)$ gives

$$n + m = r_3(r+s) + 3\big(c + d + \chi(r,s)\big).$$

On the other hand,

$$nm = rs + 3(rd + sc + 3cd).$$

Since the product of two balanced representatives again belongs to $\{-1, 0, +1\}$, it requires no additional residue reduction. Uniqueness of the decomposition proves both formulas. □

For example, $2 = (-1) + 3$ and $4 = 1 + 3$. Their sum and product are reconstructed as

$$(-1,1) \boxplus (1,1) = (0,2), \qquad (-1,1) \boxtimes (1,1) = (-1,3).$$

The resulting evaluations are 6 and 8. Adding quotients suffices in this additive example; the product involves the cross terms rd, sc and $3cd$. The discrepancy between the two operations also lies in the prolongation coordinate, not only in the residue.

The term χ is a cocycle of the balanced section. If $r \oplus s = r_3(r+s)$, it satisfies

$$\chi(r,s) + \chi(r \oplus s, t) = \chi(s,t) + \chi(r, s \oplus t).$$

Both sides represent the quotient of the same sum of three integers. This identity guarantees that regrouping the operations does not change the reconstructed evaluation. At the same time, projection onto the first component suppresses that accounting: $1 + 1 = -1 + 3$, whereas the residual reading preserves only -1. The eliminated information is determined, in this case, by $\chi(1,1) = 1$.

The relation with the modulus 9 preserves a second discrete scale. The map

$$\beta : \widehat{\mathbb{T}} \times \mathbb{F}_3 \longrightarrow \mathbb{Z}/9\mathbb{Z}, \qquad (r, \bar{c}) \longmapsto r + 3c \pmod 9$$

is well defined and bijective. Changing the representative of $\bar{c}$ adds a multiple of 9; conversely, equality of images first fixes r by reduction modulo 3 and then $\bar{c}$. The sum transported by this bijection contains the term $\chi(r,s)$ of (1.158), now reduced modulo 3. Thus the two ternary levels are not composed through an independent sum of coordinates: normalization of the first level modifies the second.

In particular, the classes 3, 6 and 0 of $\mathbb{Z}/9\mathbb{Z}$ have first component 0, but second component 1, 2 and 0, respectively. The distinction already observed between direct reduction and extraction of the ideal coordinate appears as a property of β. Preserving that coordinate prevents the zero residual sector from being artificially turned into a single position. The modulus 1000, used later to organize decimal blocks, serves another positional representation function; its quotient is preserved through the corresponding division. A change of base preserves the integer when it retains residue and quotient, whereas the coincidence of residues in different bases does not by itself identify their transport states.

1.23.2.3 Reversal, residual class and nonvisible coordinates

Additive inversion lifts unambiguously:

$$\mathcal{B}(-n) = (-r_3(n), -q_3(n)).$$

In particular, 3, 0 and −3 have coordinates $(0, 1)$, $(0, 0)$ and $(0, -1)$. They share a zero signature, but represent different evaluations. In a transition restricted to a quotient of maximum amplitude 1, they are the three possibilities of the visible fiber over zero; in a general integer lift, that fiber contains all pairs $(0, c)$, with $c \in \mathbb{Z}$.

The quotient coordinate recovers the evaluated integer, but does not by itself recover the trajectory that produced it. Two APP paths may share evaluation, residue and quotient, and differ in orientation, mode sequence or winding. Thus the decomposition $\mathcal{B}$ is integrated into the transport state, instead of replacing it. The arithmetic memory of a division and the memory of a trajectory are related coordinates, not synonyms.

For a signature sequence of length n, oriented reversal is

$$C_{\mathrm{rev}}(\tau_1, \dots, \tau_n) = (-\tau_n, \dots, -\tau_1).$$

Applying it twice restores the sequence. The operation reverses the order of the positions and the sign of each signature; it preserves its length and the zero positions in reverse order. In the adopted parametrization, it interchanges the return with memory, associated with +1, and bidirectional opening, associated with −1, maintaining the threshold 0. The transport of the remaining data of a trajectory is specified through the corresponding involution of TPK.

This reversal of signatures must be distinguished from conjugation within a quadratic algebra. The former may change the type τ; the latter, which is constructed next, acts within the type already fixed. The distinction prevents a sign reversal from being credited with an algebraic equivalence between different regimes.

1.23.2.4 Quadratic product, conjugation, and algebraic norm

An element of $\mathbb{A}_\tau$ has a unique expression $aI + bJ_\tau$. The relation $J_\tau^2 = -\tau I$ determines its product:

$$(aI + bJ_\tau)(cI + dJ_\tau) = (ac - \tau bd)I + (ad + bc)J_\tau. \tag{1.160}$$

This is a real realization of the type already selected. The coordinates a, b are not residues of APP, and the product (1.160) does not replace (1.159); it expresses another operation, in the declared quadratic codomain.

Definition 1.187 (Conjugation and algebraic norm)**.** Conjugation of type τ and its algebraic norm are

$$\overline{aI + bJ_\tau} = aI - bJ_\tau, \qquad N_\tau(aI + bJ_\tau) = a^2 + \tau b^2.$$

Proposition 1.188 (Multiplicativity and invertibility)**.** *For $z, w \in \mathbb{A}_\tau$,*

$$z\bar{z} = N_\tau(z)I, \qquad N_\tau(zw) = N_\tau(z)N_\tau(w).$$

Moreover, z is invertible if and only if $N_\tau(z) \neq 0$, and in that case

$$z^{-1} = \frac{\bar{z}}{N_\tau(z)}.$$

Proof. The product of $aI + bJ_\tau$ and $aI - bJ_\tau$ is $(a^2 + \tau b^2)I$. Conjugation is multiplicative and the algebra is commutative, so $(zw)\overline{zw} = (z\bar{z})(w\bar{w})$. If the norm does not vanish, the indicated formula provides the inverse. Conversely, if $zw = I$, multiplicativity implies $N_\tau(z)N_\tau(w) = 1$. □

The quadratic form N_τ is positive definite only in the elliptic type. For $\tau = 0$, it equals a^2, and the element J_0 is nonzero although its square and norm are zero. For $\tau = -1$, it equals $a^2 - b^2$; the nonzero elements $I + J_{-1}$ and $I - J_{-1}$ have zero norm and their product vanishes. The algebraic norm here is a multiplicative quadratic form: it does not presuppose a positive vector space norm.

The three types can be faithfully realized through

$$aI + bJ_\tau \longmapsto \begin{pmatrix} a & -\tau b \\ b & a \end{pmatrix}.$$

The determinant of this matrix is $N_\tau(aI + bJ_\tau)$. Thus the complex structure, the dual number structure and the split real structure are represented with the same matrix expression. Each preserves its law and its zero divisors. The form of signature $(1, 1)$ in the last case has a Lorentzian interpretation in dimension $1 + 1$; identifying a physical metric additionally requires a specific space, field and transport rule.

1.23.2.5 Multiplicative conservation and composition of evolutions

The exponential already obtained belongs to the set of elements of norm one:

$$N_\tau\big(\exp(tJ_\tau)\big) = 1.$$

This conservation is maintained when composing parameters. Indeed, all the factors are functions of the same generator, and

$$\exp(tJ_\tau)\exp(sJ_\tau) = \exp((t + s)J_\tau).$$

Comparing the two components yields the addition laws

$$C_\tau(t + s) = C_\tau(t)C_\tau(s) - \tau S_\tau(t)S_\tau(s), \tag{1.161}$$

$$S_\tau(t + s) = S_\tau(t)C_\tau(s) + C_\tau(t)S_\tau(s). \tag{1.162}$$

Conjugation changes t to $-t$ and coincides with inversion within this subgroup. It does not change τ: it reverses an evolution of the chosen regime.

In the elliptic type, the preserved form is $a^2 + b^2$, and the exponential trajectory traverses the circle of norm one. In the hyperbolic type, the eigencoordinates are $u = a + b$, $v = a - b$, with $uv = N_{-1}(z)$. The exponential gives

$$(u, v) = (e^t, e^{-t}), \qquad uv = 1.$$

The growth of one coordinate is accompanied by the contraction of the other. Conservation expresses a relation between both coordinates; it does not state that each one remains constant.

In the parabolic type,

$$(I + tJ_0)(I + sJ_0) = I + (t + s)J_0, \qquad (I + tJ_0)^{-1} = I - tJ_0.$$

Evolution does not stop because $J_0^2 = 0$. Nilpotency eliminates the terms of order at least two, but preserves the linear term that transports the parameter. The visible symbol 0, the zero element of the algebra and the nonzero generator J_0 are distinct. This distinction is necessary to describe the threshold without identifying it with an absence of state or dynamics.

Proposition 1.189 (Composition of affine coordinates)**.** *In the chart where the scalar component does not vanish, represent a direction by $I + uJ_\tau$. If $1 - \tau uv \neq 0$, the direction of its product with $I + vJ_\tau$ has coordinate*

$$u \star_\tau v = \frac{u+v}{1-\tau uv}.$$

Proof. We have

$$(I + uJ_\tau)(I + vJ_\tau) = (1 - \tau uv)I + (u+v)J_\tau.$$

Dividing by the scalar component gives the stated expression. □

The affine chart preserves the ratio between components, not the scalar factor divided out. When $1 - \tau uv = 0$, the product must be examined before changing charts: it may have a defined direction with zero scalar component, or be the zero element in the presence of zero divisors. The composition law still belongs to the full algebra; the singularity of a coordinate does not automatically amount to a singularity of the object. This formula will reappear in the elliptic regional reading. Its use requires retaining the denominator and, where appropriate, the normalization factor.

1.23.2.6 Transport of type and subsequent realizations

The algebras $\mathbb{A}_{+1}$, $\mathbb{A}_0$ and $\mathbb{A}_{-1}$ are not isomorphic as unital real algebras. The first is a field; the second contains a nonzero nilpotent; the third has nontrivial idempotents and is isomorphic to $\mathbb{R} \times \mathbb{R}$. Thus the change of signature that organizes a route cannot be interpreted as an undifferentiated isomorphism between the three realizations. TPK preserves the regime index, the domains and the effective operator acting at each transition.

Within the electronic chapter, the pair of projections of the APP sheets produces a normalized commutator whose square is $-I$. The same block contains an involution of square I and two nilpotent directions. The joint realization will be proved on that specific pair of projections; the preceding classification explains why the three quadratic relations can appear in the same matrix algebra without being identified with one another.

In the exceptional prolongation, the Paley matrix reduced modulo 3 satisfies $A_W^2 = -I_6$. The relation endows the ternary space with a structure of dimension 3 over $\mathbb{F}_9$. Its link with a real operator root is expressed through the integral presentation

$$\mathbb{Z}[u]/(u^2+1).$$

The base changes to $\mathbb{F}_3$ and to $\mathbb{R}$ produce representations of that same relation. Each preserves its characteristic, its dimension and its incidence information. The development of the respective operators establishes the link, not the equality of their cardinalities.

The conservation of norm one therefore describes the quadratic realizations of evolutions. The conservation of quotients, orientation and trajectory belongs to the transported arithmetic state. Both properties play a role in the construction, with different functions: one determines the identities of the representations; the other allows the operations that originate them to be composed, reconstructed and prolonged.

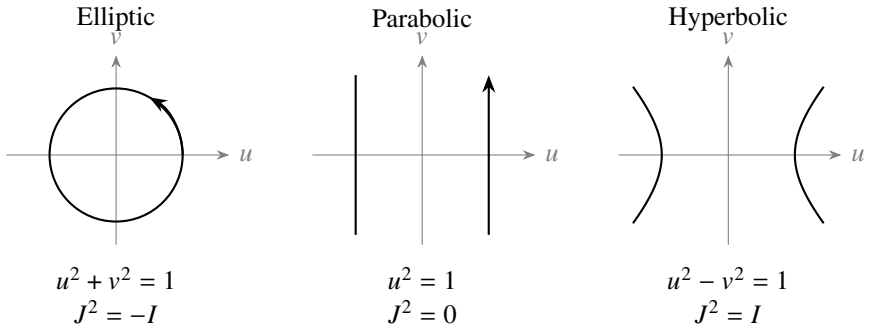

Figure 1.5: Quadratic realizations of TRIT. For $J_\tau = \left(\begin{smallmatrix} 0 & -\tau \\ 1 & 0 \end{smallmatrix}\right)$, the exponential preserves $u^2 + \tau v^2$. Parabolic degeneration preserves u and transports v linearly. The three diagrams represent orbits of quadratic forms; their geometric type corresponds to the algebraic relation of the generator.

1.23.3 TPK: topological phase kernel

The dynamics uses the phase selector

$$M_{\mathrm{ph}}(r) = \begin{cases} +1, & r \in \{1,4,7\}, \\ -1, & r \in \{2,5,8\}, \\ 0, & r \in \{3,6,9\}. \end{cases}$$

Its value decides which evaluation operates. Cardinal transport shifts the corresponding cursor; the register preserves the preceding value, the new quotient, the orientation and the transition. Therefore, selection and transport are distinct functions: a ternary sign is not a displacement of the torus.

We shall denote by $\widehat{X}$ the space of arithmetic states with trajectory memory. An element contains the positions and directions of the two cursors, the active mode, the TRIT signature, the phase, the residues and quotients of both evaluations, the carries, the constructed prefix and the boundary data. When a refinement cylinder is introduced, it forms part of the state. The notation avoids replacing the object with a reduced version that preserves only the visible symbol.

Definition 1.190 (TPK update)**.** Let Sel_t be mode selection through M_{ph}, Tra_t lifted cardinal transport and Mem_t the update of the registers. The transition is

$$\mathcal{U}_t = \mathsf{Mem}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t. \tag{1.163}$$

Each map preserves the fields that it does not modify and updates the others through Euclidean division and concatenation of the trajectory.

The notation (1.163) expresses the order of composition; it does not replace the effective rules. The following section fully specifies its finite two-cursor realization. Afterward, prolongation will not be obtained by erasing its memory and repeating the first emission, but by transporting the prefixes and their compatible boundaries. In this way, APP provides the evaluations, TRIT distinguishes their regimes and TPK composes their evolution.

1.23.3.1 Dynamic state, observables and dependence of the operations

The topological phase kernel organizes the evolution of the two APP sheets with the orientation determined by TRIT. Its definition includes the state on which it acts, the transition rules and the relations that make the prolongations compatible. The equation (1.163) acquires operational content by specifying which coordinates each of its factors receives and modifies. Position belongs to the toroidal support; phase belongs to the calendar; orientation determines transport; the quotients record the arithmetic

evaluation before its reduction. These coordinates are related through the transition and preserve different mathematical functions.

The observable projection of a state is

$$q = (x_+, d_+, x_\times, d_\times, \theta) \in Q_{\mathrm{obs}} := (X_9 \times \mathcal{D})^2 \times \Theta_{108}, \qquad \mathcal{D} = \{N, E, S, O\}, \quad \Theta_{108} = \mathbb{Z}/108\mathbb{Z}. \tag{1.164}$$

The subscripts distinguish the additive and multiplicative cursors. In the fibers of complete states over q, the ordered trajectory, the integer evaluations of both sheets, their residues and quotients, and the orientation and boundary registers are preserved. In a precision prolongation, the prefix and the compatible cylinder are added. Therefore, two states with the same projection q may preserve different registers.

The dependence of the operations has three levels. At the local level, the selector activates a sheet, transport modifies its position and the update calculates the new arithmetic coordinates. At the trajectory level, these transitions are composed and preserve the registers of the preceding steps. At the refinement level, extension relations determine which continuation preserves the prefix, the signature and the boundary of the antecedent. The finite calendar describes the phase of these operations; holonomy describes their composition on the history.

1.23.3.2 Tritic selection and lifted cardinal transport

Let $\bar\theta \in \{0, \dots, 107\}$ be the calendar representative. The operational phase and the dodecaphasic sector are

$$r(\theta) = 1 + (\bar\theta \bmod 9), \qquad \beta(\theta) = \left[\left\lfloor \frac{\bar\theta}{9} \right\rfloor\right]_{12}. \tag{1.165}$$

The selector already defined can be written $\varepsilon_9 = M_{\mathrm{ph}}$. Its vector of values, in the ordered chart of D_9, is

$$m_{\mathrm{ph}} = (1, -1, 0, 1, -1, 0, 1, -1, 0).$$

The function $M_{\mathrm{ph}} : D_9 \to \widehat{\mathbb{T}}$ and this vector are two presentations of the same selector, with their respective domains.

Define the activation indicators

$$a_+(\theta) = \mathbf{1}_{\{1,4,7\}}(r(\theta)), \qquad a_\times(\theta) = \mathbf{1}_{\{2,5,8\}}(r(\theta)).$$

The transport of the cursors is then

$$x'_+ = x_+ + a_+(\theta)\nu_{d_+}, \qquad x'_\times = x_\times + a_\times(\theta)\nu_{d_\times} \quad \text{in } X_9. \tag{1.166}$$

In phases $3, 6, 9$ both positions remain unchanged; the neutral event is part of the chronology and its register. The cardinal directions determine the vectors ν_d, while the phase signature determines which of those vectors is applied.

The integer lift preserves the boundary crossing. If $s : X_9 \to D_9^2$ chooses the positive representatives and $x' = x + a\nu_d$, with $a \in \{0, 1\}$, one defines

$$b_d(x, a) = \frac{s(x) + a\nu_d - s(x')}{9} \in \mathbb{Z}^2. \tag{1.167}$$

Divisibility by 9 follows from equality in X_9. If $z \in \mathbb{Z}^2$ records the preceding crossings, the update is $z' = z + b_d(x, a)$. In this way,

$$s(x') + 9z' = s(x) + 9z + a\nu_d.$$

The integer transport datum remains reconstructible after reducing the position on the torus.

Proposition 1.191 (Conservation of the lifted displacement)**.** *For a cardinal trajectory of n steps, whose activation indicators are a_t, one has*

$$s(x_n) + 9z_n = s(x_0) + 9z_0 + \sum_{t=0}^{n-1} a_t \nu_{d_t}.$$

The same equality is preserved when concatenating two compatible trajectories.

Proof. The one-step identity is (1.167). Summing it over the n steps cancels the intermediate coordinates. Dividing the summation interval into two segments produces exactly the concatenation law. In a closed trajectory, the difference $z_n - z_0$ is the winding number defined previously. □

The same principle governs APP evaluations. If a sheet takes the integer value N_t, its register simultaneously preserves $N_t = R_t + 9q_t$. The difference between two steps satisfies

$$N_{t+1} - N_t = (R_{t+1} - R_t) + 9(q_{t+1} - q_t).$$

The spatial crossing memory z_t and the arithmetic quotient q_t have different definitions; their joint conservation maintains the geometric and arithmetic provenance of each transition.

1.23.3.3 Two-cursor chronology and composite returns

The cardinal involution $\jmath$ interchanges N with S and E with O. After applying (1.166), both directions are reversed when a block of 27 steps ends. Writing

$$h(\theta) = \mathbf{1}_{\{0,27,54,81\}}((\bar{\theta} + 1) \bmod 108),$$

the complete rule on the observable projection is

$$F_{\mathrm{obs}}(q) = \big(x'_+, \jmath^{h(\theta)} d_+, x'_\times, \jmath^{h(\theta)} d_\times, \theta + 1\big). \tag{1.168}$$

The reading that forms the emission uses the positions before transport, according to the explicit recurrence in section 4.3. The observable update and the emission are therefore composed in a fixed order.

Proposition 1.192 (Reversibility and period of the observable calendar)**.** *The map F_{obs} is a permutation of $\mathcal{Q}_{\mathrm{obs}}$ and satisfies $F_{\mathrm{obs}}^{108} = I$. In a block of* 54 *steps, positions and directions are restored; the coordinate of Θ_{108} advances by* 54*.*

Proof. Given the final state, the preceding phase is first recovered by subtracting one in Θ_{108}. That phase determines whether the directions were reversed and which cursor moved. Applying the corresponding involution and subtracting the cardinal vector uniquely recovers the initial state.

Each interval of 27 steps contains nine activations of each cursor. The next block preserves the activations and reverses the directions, so the integer displacements cancel in 54 steps. The rule has period 54 in its position and orientation increments; the same cancellation holds with any origin of the calendar. After 108 steps, θ is also restored. □

We reserve

$$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27} : \mathcal{Q}_{\mathrm{obs}} \longrightarrow \mathcal{Q}_{\mathrm{obs}}$$

for the iterate of 27 transitions. Its fourth iterate is the identity on the observable state defined in (1.164). Projection of the history onto the calendar allows this finite check to be performed. The trajectory register, its evaluations and the new prefixes are preserved in the dynamic state on which $\mathcal{U}_t$ acts; observable equality does not reset them.

1.23.3.4 Affine transport of memory and composition of states

The observable projection admits fibers of arithmetic and geometric data. Over a configuration q, we write a state in the form

$$x = (q, o, h, c, \sigma, C, b, \lambda).$$

Here o preserves the orientation and the sheet; h, the residues and quotients; c, the additive transport memory; σ, the boundary signature; C, the precision cylinder; b, its boundary label; and λ, the recorded trajectory. The signature is determined by a map

$$\mathrm{Sig}_q : \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{Hist}_q \longrightarrow \mathsf{S}_q, \qquad \sigma = \mathrm{Sig}_q(h, c, \lambda).$$

The symbols $\mathsf{H}_q, \mathsf{C}_q, \mathsf{Hist}_q$ and S_q denote, respectively, the sets of residue–quotient data, the abelian group of transport memory, the recorded trajectories and the boundary signatures. The realizations of this signature are specified with their components in the regional and terminal constructions. This dependence prevents treating the signature as a free parameter once the data producing it are fixed.

The elementary residue and quotient chart is explicit. For $n \in \mathbb{Z}$, let

$$r = 1 + ((n-1) \bmod 9), \qquad u = \frac{n-r}{9}.$$

Then $n = r + 9u$, with $r \in D_9$ and $u \in \mathbb{Z}$. Uniqueness follows because two representatives of D_9 congruent modulo 9 are equal. This chart provides local integer reconstruction. The precision towers additionally incorporate the truncation maps and the cylinders developed in 4.3 and 10.5.

Let $\gamma : q \to q'$ be an observable trajectory. The transport of the fibers is expressed through maps

$$\mathsf{H}(\gamma) : \mathsf{H}_q \to \mathsf{H}_{q'}, \qquad \mathsf{C}(\gamma) : \mathsf{C}_q \to \mathsf{C}_{q'}, \qquad \mathsf{Hist}(\gamma) : \mathsf{Hist}_q \to \mathsf{Hist}_{q'}.$$

The maps respect identities and composition, and $\mathsf{C}(\gamma)$ is a homomorphism of abelian groups. The increment $k_{\mathrm{tr}}(\gamma) \in \mathsf{C}_{q'}$ satisfies

$$\begin{aligned} k_{\mathrm{tr}}(\mathrm{id}_q) &= 0, \\ k_{\mathrm{tr}}(\gamma_2 \circ \gamma_1) &= k_{\mathrm{tr}}(\gamma_2) + \mathsf{C}(\gamma_2) k_{\mathrm{tr}}(\gamma_1). \end{aligned} \tag{1.169}$$

The symbol k_{tr} here designates the transport cocycle; the rational coordinate κ of the register K retains its notation in the chapter on dodecaphasic closure.

The transportable coordinates are updated by

$$\begin{aligned} h' &= \mathsf{H}(\gamma) h, \quad & c' &= \mathsf{C}(\gamma) c + k_{\mathrm{tr}}(\gamma), \\ \lambda' &= \gamma \circ \lambda, \quad & \sigma' &= \mathrm{Sig}_{q'}(h', c', \lambda'). \end{aligned} \tag{1.170}$$

The second equation is an affine action: the linear term transports the preceding memory and the cocycle adds the increment produced by the trajectory. In the realization of spatial crossing for each cursor separately, $\mathsf{C}(\gamma) = I$ and $k_{\mathrm{tr}}(\gamma)$ is the sum of the vectors of (1.167). This concrete instance links the abstract law to the cardinal operations already defined.

Proposition 1.193 (Compatibility of the update with concatenation)**.** *The update* (1.170) *by* γ_1*, followed by the update by* γ_2*, coincides with the update by* $\gamma_2 \circ \gamma_1$*.*

Proof. For the affine coordinate, two updates give

$$c'' = \mathsf{C}(\gamma_2)\mathsf{C}(\gamma_1) c + \mathsf{C}(\gamma_2) k_{\mathrm{tr}}(\gamma_1) + k_{\mathrm{tr}}(\gamma_2).$$

The functoriality of C and (1.169) turns this expression into $\mathsf{C}(\gamma_2 \circ \gamma_1)c + k_{\mathrm{tr}}(\gamma_2 \circ \gamma_1)$. The assertion for h follows from the composition of H, and for λ, from the associativity of the trajectories. The final signature coincides because it is evaluated on the same three reconstructed coordinates. □

The cylinder and its boundary complete this law through the relations Ext_γ, defined in 1.23.3.7. Their elements determine which of the preceding updates preserve an admissible prolongation. The states, together with the triples (γ, x, x') admitted by these relations, form a category over the observable trajectories:

$$(\gamma_2, x', x'') \circ (\gamma_1, x, x') = (\gamma_2 \circ \gamma_1, x, x'').$$

The identity of x is (id_q, x, x). Composition preserves both arithmetic transport and boundary prolongability. This is the structure in which returns with memory and successive refinements are carried out.

1.23.3.5 Dodecaphasic register, phase and accumulated memory

The 108 transitions are distributed in the ordered windows

$$E_m = \{9m - 8, \ldots, 9m\}, \qquad 1 \le m \le 12.$$

The register preserves the phase origin, the orientation and the data produced during each window. Its map is

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12},$$

where τ_m is the subroute of the window, σ_m its orientation, κ_m the integer boundary increment and Λ_m the local incidence register. The chart that will be developed in 11.4.2 is adopted; its window indices correspond to $m = \beta + 1$. The domain comprises the compatible histories of TPK and the codomain, their oriented temporal registers. The composition of segments and their increments is governed by (1.170). The group C_{12} instead describes the translation of the window index; Θ_{108} preserves the step calendar. This distinction makes it possible to specify what is transformed and what is observed upon completing a cycle.

In the coordinates $\theta = 9b + r$, with $0 \le r < 9$, advancing by 9 steps preserves r and increases b by one. The addition of phases introduces the quotient

$$c_0(r, r') = \left\lfloor \frac{r + r'}{9} \right\rfloor,$$

whose cocycle identity ensures associativity of composition. The finite calendar preserves $[b]_{12}$; a turn register preserves $b \in \mathbb{Z}$, or $b \in \mathbb{N}_0$ for a history with fixed origin. Section 4.3 proves the nonsplit exact sequence (4.33). Its function is to describe the relation between these coordinates, before using them in the construction of the signed state.

The signed register receives the phase and memory data through the composition developed in section 11.4:

$$R_{\mathrm{sgn}} = \Pi_H \circ \mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12}. \tag{1.171}$$

Its domain is the terminal state with memory; its output belongs to $\mathbb{Z}^{12}$. The reversible transformation between that signed state and K, as well as the rational reading of K, are proved in the corresponding chapter. The register operations precede these transformations. Reconstructing a register from its cyclic differences verifies its recoverability; dynamic provenance must be preserved through the events that produced it.

For the encoded trace (d_t) preserved by the register, the event reader counts the codes $\{2, 4, 6, 8\}$ of each window with the orientation $(+, +, +, -, -, -, +, +, +, -, -, -)$. These codes and the cardinal symbols of $\mathcal{D}$ are distinct coordinates of the register. Chapter 11.4 develops this reader, the integral decomposition

$1+5+6$, the congruences that characterize its image and its exact inverse. The inversion proof establishes which data that chart preserves; the definition of $\mathcal{R}_{12}$ specifies the oriented history on which it acts.

1.23.3.6 Phase incidence and internal construction of the channels

The selector determines three subsets of D_9:

$$H_+ = \{1,4,7\}, \qquad H_- = \{2,5,8\}, \qquad H_0 = \{3,6,9\}.$$

Let $H_{\mathrm{act}} = H_+ \sqcup H_-$ be the set of active phases and let $O_{\mathrm{ph}} = D_9 \setminus \{9\}$ be the chart before the marked return. Denote by $P_2(H_{\mathrm{act}})$ the set of unordered pairs of active phases. The internal incidence is given by

$$\mathcal{F}_6^{\mathrm{ph}} = H_{\mathrm{act}} \times P_2(H_{\mathrm{act}}), \qquad \mathcal{F}_8^{\mathrm{ph}} = O_{\mathrm{ph}} \times P_2(H_{\mathrm{act}}), \qquad \Theta_{\mathrm{ph}} = D_9 \times P_2(H_{\mathrm{act}}). \tag{1.172}$$

The indices describe the number of positions of the first component. The construction uses the phases and the calendar origin already fixed; subsequent exceptional realizations will transport these incidences to their own domains.

Proposition 1.194 (Cardinalities and oriented phase incidence)**.** *The sets in* (1.172) *have cardinalities* $90, 120, 135$*, respectively. If*

$$\partial_{\mathrm{ph}} = \Theta_{\mathrm{ph}} \times \{-1,+1\}, \qquad E_{\mathrm{ph}} = \partial_{\mathrm{ph}} \sqcup \{\infty\}, \qquad L_{\mathrm{ph}} = H_0 \times P_2(H_{\mathrm{act}}),$$

then

$$|\partial_{\mathrm{ph}}| = 270, \quad |E_{\mathrm{ph}}| = 271, \quad |L_{\mathrm{ph}}| = 45, \quad |\partial_{\mathrm{ph}} \sqcup L_{\mathrm{ph}}| = 315.$$

Simultaneously translating the phase origin and the marked return preserves all these cardinalities and their inclusions.

Proof. There are six active phases, so $|P_2(H_{\mathrm{act}})| = \binom{6}{2} = 15$. The products by $6, 8, 9$ give $90, 120, 135$. Orientation doubles 135; the return mark adds one element; the three neutral phases give $3 \cdot 15 = 45$. A calendar translation transports each factor through a bijection and takes the marked point to its image. The products and disjoint unions thus preserve incidence. □

The cardinality 271 here has a realization through phase incidence. The cubic completion of section 4.3 has its own construction of the crown $1000 - 729$. The correspondence between both realizations must preserve the maps and marks that identify them, in addition to the cardinality. Likewise, the selector ε_9, the incidence $(90, 120)$ and the extractor $\mathcal{E}_{108}^{90,120}$ preserve the domains and operations that have just been distinguished.

1.23.3.7 Reversal of trajectories and conjugate prolongations

Bidirectionality begins with an operation on trajectories, before assigning scalar values to them. For $\gamma = (x_0; d_1, \ldots, d_n)$, with endpoint x_n, we define

$$\operatorname{rev}\gamma = (x_n; \jmath d_n, \ldots, \jmath d_1).$$

The origin of the reversed trajectory is the endpoint of the original. Composition satisfies

$$\operatorname{rev}^2\gamma = \gamma, \qquad \operatorname{rev}(\gamma_2 \circ \gamma_1) = \operatorname{rev}\gamma_1 \circ \operatorname{rev}\gamma_2,$$

and the integer displacement changes sign. These identities are obtained by reversing the order of the steps and replacing each cardinal vector with its opposite. For a loop it follows that $\operatorname{wind}(\operatorname{rev}\gamma) = -\operatorname{wind}(\gamma)$.

On the registers, reversal also requires transporting the order of their components and the orientation of their events. Route reversal and a signature conjugation are distinguishable operations: their composition

is specified when applied to a concrete register. In particular, the regional involution that interchanges the closure and propagation components preserves the autoscale axis; its formula is presented in section 10.5.14. This regional operation acts on a different domain from the reversal of a cardinal trajectory.

Extensions over a route $r : q \to q'$ are expressed through relations between fibers of compatible states. If $\mathcal{F}_q$ denotes the fiber of complete states over q, one requires

$$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}, \qquad \Delta_{\mathcal{F}_q} \subseteq \mathrm{Ext}_{\mathrm{id}_q},$$

$$\mathrm{Ext}_{r_2} \circ \mathrm{Ext}_{r_1} \subseteq \mathrm{Ext}_{r_2 \circ r_1}.$$

Their composition preserves the evaluations of both sheets, the orientation, the quotients, the prefix and the boundary. Reversal of the route does not by itself imply that every extension relation is a bijection. The conjugate prolongation is defined on the domain where the transport of these data satisfies the corresponding compatibilities.

1.23.3.8 Nonadic holonomy and continuity of refinement

One phase turn composes the transitions on the state with memory:

$$\Gamma_{9,k} = \mathcal{U}_{k+8} \circ \cdots \circ \mathcal{U}_k. \tag{1.173}$$

On an individualized history, this functional composition realizes the holonomy relation; on the complete domain one preserves $\Gamma_{9,k} \subseteq \widehat{X}_k \times \widehat{X}_{k+9}$, with the admissible prolongations developed later. The cyclic base has nine phases, while the fiber preserves the trajectory, the quotients and the boundary. The monodromy is the action of one turn of that base on the fibers; the holonomy $\Gamma_{9,k}$ expresses its realization through the effective transitions of TPK.

If g observes the phase and M the number of preserved turns,

$$g(\Gamma_{9,k}x) = g(x), \qquad M(\Gamma_{9,k}x) = M(x) + 1.$$

The first identity expresses phase closure and the second identifies the new temporal depth. Coinductive prolongation also preserves its cylinders and prefixes. The restrictions between depths compose an inverse system; a compatible section gathers its antecedents without replacing them with the latest observation. The development of this arithmetic of histories and its unity occupies 4.3.8–4.3.10; the construction of the regions and their readers is carried out in section 10.5.

Phase transfer on emissions already constructed has another domain. Let $\mathcal{A}_+$ and $\mathcal{A}_\times$ be the alphabets of additive and multiplicative signatures, of cardinalities 18 and 26. Their product identifies the catalog $\mathcal{U}_6$. For $f : \mathcal{A}_+ \times \mathcal{A}_\times \to \mathbb{R}$, the sheet averages are

$$(E_+ f)(s,e) = \frac{1}{18} \sum_{s' \in \mathcal{A}_+} f(s',e), \qquad (E_\times f)(s,e) = \frac{1}{26} \sum_{e' \in \mathcal{A}_\times} f(s,e').$$

These emissions and their cardinalities are constructed through the recurrence in section 4.3. Once they have been obtained, the transfer operator is defined on $\mathcal{U}_6 \times C_9$ by

$$P_+ = E_+, \quad P_- = E_\times, \quad P_0 = I, \qquad \mathcal{K}_{\mathrm{ph}}((u,r),(v,r+1)) = P_{M_{\mathrm{ph}}(r)}(u,v),$$

with zero weight for the remaining phase transitions. The index r uses the positive representative of the cyclic class. The phase order $(+1,-1,0)^3$ then produces the renewal

$$\mathcal{K}_{\mathrm{ph}}^{9}\big|_r = E_+ E_\times.$$

Indeed, both averages are idempotent, commute and average different factors; their composition assigns weight $1/(18 \cdot 26) = 1/468$ to each emission. This equality characterizes a subsequent transfer observable. The transport of histories remains given by (1.173), with its memory and its boundary.

The resulting hierarchy establishes the function of the following chapters. The finite emission constructs the domain and the regions; the extension relations preserve their prefixes; the nonadic connection prolongs them; the dodecaphasic register determines the data involved in K and in the closure of α. The numerical realization and the incidence realization receive that preceding structure. This order allows each consequence to be presented in its chapter while preserving, from the formal kernel, the objects that make it possible.

1.23.4 Accumulated memory and transport resolvents

The return of the calendar does not eliminate the increments produced during the path. To express this difference in operator terms, one first constructs an accumulative register of trajectory events and then its generating series. The reduction of memory variables will be carried out on that transport, also preserving the source and the output reader.

1.23.4.1 Oriented events and register update

Let (d_t) be the sequence of integer direction codes preserved by a TPK trajectory. The code d_t and the cardinal direction of the cursor are distinct coordinates; no identification between their alphabets is assumed. We number the windows from zero

$$I_m = \{9m + 1, \dots, 9m + 9\}, \qquad m \geq 0.$$

During the first cycle, I_m is window E_{m+1} of the dodecaphase record. Its orientation is $\sigma = (1, 1, 1, -1, -1, -1, 1, 1, 1, -1, -1, -1)$. For a prolonged history, $\sigma_m \in \{-1, 1\}$ is the sign retained in the corresponding window. The signed event is

$$a_m = \sigma_m \sum_{t \in I_m} \mathbf{1}_{\{2,4,6,8\}}(d_t), \qquad |a_m| \leq 9. \tag{1.174}$$

Each summand is incorporated when its transition occurs. This definition counts the events of the trace; it does not choose directions through a value that is to be obtained later.

Let $\mathbf{e}_0, \dots, \mathbf{e}_{11}$ be the basis of $\mathbb{Z}^{12}$ and $S\mathbf{e}_j = \mathbf{e}_{j+1 \bmod 12}$. We write $R = S^{-1}$. The accumulated register in fixed coordinates satisfies

$$z_{m+1} = z_m + a_m \mathbf{e}_{m \bmod 12}.$$

A prefix without accumulated history starts at $z_0 = 0$; at another origin, z_0 preserves the previous register. The frame accompanying the calendar is $y_m = S^{-m} z_m$.

Proposition 1.195 (Update and return with memory)**.** *The register in the moving frame satisfies*

$$y_{m+1} = R y_m + \eta_m, \qquad \eta_m = a_m R \mathbf{e}_0. \tag{1.175}$$

For all $n \geq 1$,

$$y_n = R^n y_0 + \sum_{j=0}^{n-1} R^{n-1-j} \eta_j. \tag{1.176}$$

In particular,

$$y_{12} = y_0 + \sum_{j=0}^{11} a_j \mathbf{e}_j. \tag{1.177}$$

Proof. Multiplying the update of z_m by $S^{-(m+1)}$ gives $y_{m+1} = S^{-1}y_m + a_m S^{-1}\mathbf{e}_0$, because $S^{-m}\mathbf{e}_{m \bmod 12} = \mathbf{e}_0$. Formula (1.176) is obtained by induction. For $n = 12$, $R^{12} = I$ and $R^{11-j}\eta_j = a_j R^{12-j}\mathbf{e}_0 = a_j\mathbf{e}_j$, which proves (1.177). □

Thus twelve windows restore the frame and preserve the event vector. The count alone does not recover the order of all steps within each window; that order remains in the recorded trajectory.

To specify the balance, define

$$D_3 = I - S^3, \quad D_4 = I - S^4, \quad B = D_3^{\mathsf{T}} D_3 + D_4^{\mathsf{T}} D_4,$$

$$\mathcal{M}(y) = \tfrac{1}{2} y^{\mathsf{T}} B y, \qquad q(y) = \sum_{j=0}^{11} y_j.$$

The first is a quadratic form of the register; the second records the sum of its coordinates. They are not identified here with physical energy or charge.

Proposition 1.196 (Balance produced by the event)**.** *The update* (1.175) *satisfies*

$$\begin{aligned} \mathcal{M}(y_{m+1}) - \mathcal{M}(y_m) &= a_m (B y_m)_0 + 2a_m^2, \\ q(y_{m+1}) - q(y_m) &= a_m. \end{aligned} \tag{1.178}$$

Proof. Expanding the products, $B = 4I - S^3 - S^{-3} - S^4 - S^{-4}$; therefore $R^{\mathsf{T}} B R = B$ and $B_{00} = 4$. Since $y_{m+1} = R(y_m + a_m\mathbf{e}_0)$, the quadratic difference is $a_m \mathbf{e}_0^{\mathsf{T}} B y_m + \frac{1}{2} a_m^2 B_{00}$. The coordinate sum is invariant under the permutation R, which gives the second equality. □

1.23.4.2 Generating series and uniform control of memory

The series preserves all increments, not only their sum at the end of a cycle. With a formal variable u, let

$$Y(u) = \sum_{m \geq 0} y_m u^m, \qquad H_\eta(u) = \sum_{m \geq 0} \eta_m u^m.$$

Proposition 1.197 (Resolvent and tail bound)**.** *The formal identity*

$$Y(u) = (I - uR)^{-1}\big(y_0 + u H_\eta(u)\big). \tag{1.179}$$

holds. Both series converge for $|u| < 1$. If $\ell : \mathbb{R}^{12} \to \mathbb{R}$ is linear, $L = \|\ell\|_{1\to\mathbb{R}}$, $M_0 = \|y_0\|_1$, and $0 < r < 1$, then, for every integer $N \geq 0$ and $|u| \leq r$,

$$\left| \sum_{m > N} \ell(y_m) u^m \right| \leq L r^{N+1} \left(\frac{M_0 + 9(N+1)}{1 - r} + \frac{9r}{(1-r)^2} \right). \tag{1.180}$$

The series of derivatives converges uniformly on each disk $|u| \leq r < 1$.

Proof. Multiplying (1.175) by u^{m+1} and summing gives $Y - y_0 = uRY + uH_\eta$. The constant term of $I - uR$ is invertible, so its formal inverse is $\sum_{k \geq 0} u^k R^k$. Moreover, R preserves the ℓ^1 norm and $\|\eta_m\|_1 \leq 9$, whence $\|y_m\|_1 \leq M_0 + 9m$. For the tail, sum the majorants $L(M_0 + 9m) r^m$, using

$$\sum_{m > N} r^m = \frac{r^{N+1}}{1 - r}, \qquad \sum_{m > N} m r^m = r^{N+1} \left(\frac{N+1}{1-r} + \frac{r}{(1-r)^2} \right).$$

Finally, $\sum_{m \geq 1} L m (M_0 + 9m) r^{m-1} < \infty$ majorizes the derivative series and proves its uniform convergence. □

The variable u counts windows of nine transitions. Its identification with the variable of another reader requires preserving that clock and the map relating the two readings.

1.23.4.3 Memory elimination: operator, source and reader

On a domain where the update is fixed as $U : X \to X$, the free vector space $V = \mathbb{Q}^{(X)}$ on the states admits the operator $T\delta_x = \delta_{U(x)}$. The clock is included in x if the transition depends on it. This linear extension preserves distinct states even when they share an observable phase.

Consider a decomposition $V = V_0 \oplus V_1$, where V_1 is the auxiliary sector to be eliminated, and write

$$T = \begin{pmatrix} A & B_1 \\ C & D \end{pmatrix}, \qquad v = \begin{pmatrix} v_0 \\ v_1 \end{pmatrix}, \qquad \ell = (\ell_0, \ell_1).$$

Here $A : V_0 \to V_0$, $B_1 : V_1 \to V_0$, $C : V_0 \to V_1$, and $D : V_1 \to V_1$. The following identities are formal; they also hold wherever the resolvents converge.

Proposition 1.198 (Schur reduction with source and reader)**.** *Let*

$$D_u = (I - uD)^{-1}, \qquad \mathscr{F}(u) = I - uA - u^2 B_1 D_u C.$$

The retained component of $(I - uT)^{-1}v$ *is*

$$w_0 = \mathscr{F}(u)^{-1}\big(v_0 + uB_1 D_u v_1\big), \qquad w_1 = D_u(v_1 + uCw_0). \tag{1.181}$$

Its complete reading satisfies

$$\begin{aligned} \ell(I - uT)^{-1}v = (\ell_0 + u\ell_1 D_u C)\mathscr{F}(u)^{-1}(v_0 + uB_1 D_u v_1) \\ + \ell_1 D_u v_1. \end{aligned} \tag{1.182}$$

Proof. The two equations of $(I - uT)w = v$ are $w_0 = v_0 + uAw_0 + uB_1 w_1$ and $w_1 = v_1 + uCw_0 + uDw_1$. Solving the second and substituting it into the first gives (1.181); applying ℓ_0 and ℓ_1 to both components gives (1.182). All the formal inverses exist because their constant terms are identities. □

The term $u^2 B_1 D_u C = \sum_{k\geq 0} u^{k+2} B_1 D^k C$ describes an exit to memory, k steps within it and a return. By contrast, $u\ell_1 D_u C$ reads the memory before that return. Thus reducing only the operator does not necessarily preserve the observation: source and reader must also be transformed.

The difference is visible in the cycle already constructed. If P retains $\mathbf{e}_0$, then $PRP = 0$, but

$$\big\langle \mathbf{e}_0, (I - uR)^{-1}\mathbf{e}_0 \big\rangle = \frac{1}{1 - u^{12}}, \qquad \big\langle \mathbf{e}_{11}, (I - uR)^{-1}\mathbf{e}_0 \big\rangle = \frac{u}{1 - u^{12}}. \tag{1.183}$$

Indeed, $R^n \mathbf{e}_0 = \mathbf{e}_{-n \bmod 12}$: the two series collect, respectively, $n \equiv 0$ and $n \equiv 1 \pmod{12}$. The resolvent of the compression is I, whereas the compression of the resolvent preserves the omitted returns. This example corresponds to the twelve-window register, not to the entirety of the TPK state.

1.23.4.4 Composition of segments and coherence of reduction

Let three composable affine transports be $F_i(y) = R_i y + b_i$, with compatible domains and codomains. The memory produced by the complete path is

$$F_3 F_2 F_1(y) = R_3 R_2 R_1 y + b_3 + R_3 b_2 + R_3 R_2 b_1. \tag{1.184}$$

The proof is the successive substitution of the three affine formulas. Grouping the first two segments or the last two first produces the same expression; the factors transport each increment from the point where it originated. In (1.175), $R_i = R$ and b_i is the event of its window.

Eliminating several layers preserves a similar coherence. To make it explicit, now decompose $V = V_0 \oplus V_1 \oplus V_2$ and write

$$T = \begin{pmatrix} A & B_1 & B_2 \\ C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{pmatrix}, \qquad Q_2 = (I - uD_{22})^{-1}.$$

Eliminating the third component leaves the four blocks

$$\begin{aligned} A' &= A + uB_2Q_2C_2, & B_1' &= B_1 + uB_2Q_2D_{21}, \\ C_1' &= C_1 + uD_{12}Q_2C_2, & D_{11}' &= D_{11} + uD_{12}Q_2D_{21}. \end{aligned} \tag{1.185}$$

Proposition 1.199 (Transitivity of elimination)**.** *If $D_* = (D_{ij})_{i,j=1}^2$, the complement obtained in two stages coincides with that obtained by eliminating both memories together:*

$$\begin{aligned} I - uA' - u^2B_1'(I - uD_{11}')^{-1}C_1' = I - uA \\ - u^2(B_1\ B_2)(I - uD_*)^{-1}\begin{pmatrix} C_1 \\ C_2 \end{pmatrix}. \end{aligned} \tag{1.186}$$

Proof. Solving the third equation of $(I - uT)w = v$ and substituting it into the first two produces (1.185). Then eliminating the second component gives the left-hand side of (1.186). Solving the two memory equations simultaneously gives the right-hand side, by Proposition 1.198. The formal solution is unique because $I - uT$ has constant term I. Both procedures also transform the source and the reader according to (1.181)–(1.182). □

The balance (1.178) describes the increments of the register. The preceding identities allow them to be transported when reusing memory in the dodecaphasic closure; they do not by themselves determine additional analytic coefficients.

1.23.5 Operator architecture of transport, memory, and prolongation

The topological phase kernel organizes the evolution of the two APP evaluations on oriented histories. Its structure brings together a path support, local update rules, prolongation relations, temporal records, and reading maps. Each component has its own domain. This hierarchy allows the observable position, the transport quotient, and the memory of the crossed boundaries to be preserved within a single construction. The composition in equation (1.163) thus acquires a precise realization at each of these levels.

1.23.5.1 Bivariate paths and lifted transport

Let $\mathsf{P}_{\mathrm{APP}}$ be the free category of the cardinal graph on $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$. Its objects are the APP positions; its morphisms are cardinal words, with composition by concatenation. The category

$$\mathsf{P}_{\mathrm{APP}}^{(2)} = \mathsf{P}_{\mathrm{APP}} \times \mathsf{P}_{\mathrm{APP}}$$

preserves, in order, the path of the additive sheet and that of the multiplicative sheet. Both paths traverse the same arithmetic support and keep their evaluations distinct.

In the chart $I_9 = \{0, \dots, 8\}$, the generators are

$$\nu_N = (-1, 0), \quad \nu_E = (0, 1), \quad \nu_S = (1, 0), \quad \nu_O = (0, -1), \qquad T_d(x) = [x + \nu_d]_9.$$

For $w = d_1 \cdots d_r$, the lift to the integer covering space preserves

$$\widetilde{x}_k = \widetilde{x}_0 + \sum_{j=1}^{k} \nu_{d_j}, \qquad x_k = [\widetilde{x}_k]_9.$$

When $x_r = x_0$, the winding class is

$$\mathrm{wind}(w) = \frac{1}{9}(\#S - \#N, \#E - \#O) \in \mathbb{Z}^2. \tag{1.187}$$

The final position and winding are two different readings of the same route. The second records the displacement of the lift even when the first has returned.

Path reversal has a determined domain and codomain:

$$\mathrm{rev} : \mathrm{Hom}(x, y) \longrightarrow \mathrm{Hom}(y, x), \qquad d_1 \cdots d_r \longmapsto \overline{d}_r \cdots \overline{d}_1,$$

where $\overline{N} = S$, $\overline{E} = O$. It satisfies $\mathrm{rev}^2 = I$, reverses the order of composition, and changes the sign of (1.187). This is the precise operation that must be transported when comparing conjugate orientations of a route.

1.23.5.2 Full state and preservation through updates

The description of $\widehat{X}$ is organized over the positions and directions of the two cursors. Over each observable configuration q, the arithmetic fiber is written

$$\mathcal{F}_q = \mathsf{O}_q \times \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{S}_q \times \mathsf{B}_q \times \Lambda_q. \tag{1.188}$$

The coordinates O_q preserve orientation and sheet; H_q, the remainders and quotients of the evaluations; C_q, compatible carries; S_q, the boundary signature; B_q, the prefix and its cylinders; and Λ_q, the ordered transport record. The fiber is restricted by the corresponding arithmetic, incidence, and truncation identities. The full state also preserves the route that produced it and the origin from which its phases are read.

Mode selection has type

$$M_{\mathrm{ph}} : D_9 \longrightarrow \{-1, 0, +1\}, \qquad \mathsf{Sel}_t : \widehat{X} \longrightarrow \widehat{X}_t^{\mathrm{sel}}.$$

The second map incorporates the value of the first into the state and activates the corresponding sheet. Lifted transport

$$\mathsf{Tra}_t : \widehat{X}_t^{\mathrm{sel}} \longrightarrow \widehat{X}_t^{\mathrm{tra}}$$

applies T_d to the active cursor, concatenates its route letter, and preserves the selected sheet. Finally,

$$\mathsf{Upd}_t : \widehat{X}_t^{\mathrm{tra}} \longrightarrow \widehat{X}$$

updates the evaluations and records. In this notation, Upd_t is the update Mem_t of (1.163), made explicit in its components.

Each integer evaluation a is preserved through $a = \rho_9(a) + 9q_9(a)$; each ternary evaluation, through its oriented remainder and carry. For a concatenation $r_2 r_1$, carry transport satisfies the cocycle law

$$k_{\mathrm{tr}}(r_2 r_1) = k_{\mathrm{tr}}(r_2) + \mathsf{C}(r_2) k_{\mathrm{tr}}(r_1), \tag{1.189}$$

where $\mathsf{C}(r_2)$ is the transport action of the second route on the carry coordinate of the first. In the ordered record, updating is performed by adjoining the event produced:

$$\Lambda_{t+1} = \Lambda_t \| (\mathrm{sheet}, d_t, \mathrm{residue}, \mathrm{quotient}, \mathrm{carry}, \mathrm{orientation}, \mathrm{boundary})_t.$$

Preservation has a dynamic meaning here: earlier contributions remain recoverable within the record being prolonged. Their coordinates may change when the state is transported.

1.23.5.3 Affine action on transport memory

For a trajectory $r : q \to q'$, the maps

$$\mathsf{H}(r) : \mathsf{H}_q \to \mathsf{H}_{q'}, \qquad \mathsf{C}(r) : \mathsf{C}_q \to \mathsf{C}_{q'}$$

respect identity and concatenation; C_q is the abelian group of transport memory, and $\mathsf{C}(r)$ its homomorphism. The increment $k_{\mathrm{tr}}(r) \in \mathsf{C}_{q'}$, with $k_{\mathrm{tr}}(\mathrm{id}_q) = 0$, is the cocycle of (1.189). This symbol distinguishes the transport increment from the rational coordinates of the dodecaphasic record.

In a chart with data (h, c, λ), the update has the explicit form

$$h' = \mathsf{H}(r)h, \qquad c' = \mathsf{C}(r)c + k_{\mathrm{tr}}(r), \qquad \lambda' = r \circ \lambda. \tag{1.190}$$

The signature is evaluated through $\mathrm{Sig}_{q'}(h', c', \lambda')$. Its residence in the fiber $\mathsf{S}_{q'}$ preserves its dependence on those data.

Proposition 1.200 (Composition of affine memory)**.** *Updating by r_1, followed by updating by r_2, agrees with updating by $r_2 r_1$.*

Proof. Two memory updates give

$$c'' = \mathsf{C}(r_2)\mathsf{C}(r_1)c + \mathsf{C}(r_2)k_{\mathrm{tr}}(r_1) + k_{\mathrm{tr}}(r_2).$$

Compatibility of C with concatenation and identity (1.189) turn this expression into $\mathsf{C}(r_2 r_1)c + k_{\mathrm{tr}}(r_2 r_1)$. The coordinate h satisfies the same compatibility by functoriality of H; the trajectory does so by associativity. The signature agrees because it is evaluated on the same data. □

The spatial chart of each cursor provides an elementary realization of that law. For $x \in I_9^2$ and a cardinal direction d,

$$a_d(x) = \frac{x + \nu_d - T_d(x)}{9} \in \mathbb{Z}^2, \qquad x' = T_d(x), \qquad c' = c + a_d(x).$$

Here $\mathsf{C}(r) = I$, and $k_{\mathrm{tr}}(r)$ sums the integer boundary crossings. For a route of length n, the telescoping sum gives

$$x_n = x_0 + \sum_{j=1}^{n} \nu_{d_j} - 9 \sum_{j=1}^{n} a_{d_j}(x_{j-1}).$$

On a loop, the last sum equals $\mathrm{wind}(r)$. The residual position returns while the lift preserves the number and orientation of its crossings. The remaining memory components retain their own transport maps and prolongation relations.

1.23.5.4 Chronology of the two cursors and observable return

The finite calendar lives in $\Theta_{108} = \mathbb{Z}/108\mathbb{Z}$. For $0 \le \widetilde{\theta} < 108$, set

$$r(\theta) = 1 + (\widetilde{\theta} \bmod 9), \qquad \beta(\theta) = \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12}, \qquad \varepsilon_9(r) = M_{\mathrm{ph}}(r).$$

The presentation (1.164) groups position and direction by cursor. This extension groups the two positions first and then the two directions. Both charts are identified through the permutation of factors

$$\begin{aligned} \mathfrak{p}_{\mathrm{obs}} :\ & (X_9 \times \mathcal{D})^2 \times \Theta_{108} \longrightarrow X_9^2 \times \mathcal{D}^2 \times \Theta_{108}, \\ & (x_+, d_+, x_\times, d_\times, \theta) \longmapsto (x_+, x_\times, d_+, d_\times, \theta), \end{aligned} \tag{1.191}$$

with $\mathcal{D} = \{N, E, S, O\}$. The inverse restores each direction alongside its cursor. If superscripts agr and sep distinguish these two expressions of the observable successor, then

$$\mathfrak{p}_{\mathrm{obs}} F_{\mathrm{obs}}^{\mathrm{agr}} = F_{\mathrm{obs}}^{\mathrm{sep}} \mathfrak{p}_{\mathrm{obs}}.$$

Indeed, the selector depends on the same phase, the cardinal vector is applied to the same cursor, and direction reversal occurs at the same instant; only the coordinate order changes. We retain Q_{obs} and F_{obs} for the space and map so identified. This presentation permutation leaves the events and memory coordinates of the history unchanged.

The observable space is

$$Q_{\mathrm{obs}} = X_9^2 \times \{N, E, S, O\}^2 \times \Theta_{108}.$$

Write a state as $q = (x_+, x_\times, d_+, d_\times, \theta)$. The active sheet is first evaluated at the current position. The positions are then updated by

$$(x'_+, x'_\times) = \begin{cases} (T_{d_+} x_+, x_\times), & \varepsilon_9(r) = +1, \\ (x_+, T_{d_\times} x_\times), & \varepsilon_9(r) = -1, \\ (x_+, x_\times), & \varepsilon_9(r) = 0. \end{cases} \tag{1.192}$$

If $\widetilde{\theta} + 1$ is a multiple of 27, $(d_+, d_\times)$ is replaced by $(\overline{d}_+, \overline{d}_\times)$. In all cases θ is incremented modulo 108. These rules define the successor $F_{\mathrm{obs}} : Q_{\mathrm{obs}} \to Q_{\mathrm{obs}}$. The emission realization in section 4.3 applies exactly this order of evaluation, transport, and reversal.

Proposition 1.201 (Observable return and preservation of history)**.** *The map F_{obs} is a permutation. The operator $\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$ satisfies $\mathcal{K}_{27}^4 = I$. A complete history of one hundred eight updates also preserves the events and carry accumulated during that turn.*

Proof. Knowing the later phase recovers the preceding phase. The rule indicates whether a direction reversal occurred; undoing it and applying inverse cardinal transport to the active cursor recovers the previous state. Each segment of twenty-seven transitions contains nine activations of each sheet. From an endpoint of a segment, each cursor makes nine displacements in the same direction, whose sum is zero in X_9; it then reverses its orientation. Two segments restore the orientations, and four also restore the calendar. The identity is transported to any phase by invertibility of F_{obs}. The full record preserves the concatenation of the one hundred eight events and their counter, which have been updated at every transition. □

The periodicity of this permutation belongs to the observable quotient. In the full history, the integer window counter increases by twelve over the same interval. Exact sequence (4.33) expresses the reduction of the counter to its dodecaphasic coordinate and preserves its defect of additivity.

1.23.5.5 Bidirectional electronic transport and arithmetic record

The central representation uses a cell shared by the two APP evaluations. Its coordinates belong to $D_9 = \{1, \ldots, 9\}$, and the inversion $(r, c) \mapsto (10 - r, 10 - c)$ has the unique fixed point $(5, 5)$. The visible state is written (r, c, h, v, n), with $h, v \in \{-1, 1\}$ and integer chronological index $n \geq 0$. The tritic selector repeats $(+1, -1, 0)$. On the additive sheet, $r + c$ is read and the column is translated in direction h; on the multiplicative sheet, rc is read and the row is translated in direction v. The threshold preserves position. Both orientations are reversed upon completing each interval of twenty-seven updates.

To express reading and carry with the same positive convention, define

$$[z]_9^+ = 1 + ((z - 1) \bmod 9), \qquad q_9(z) = \frac{z - [z]_9^+}{9}.$$

Evaluation precedes displacement. If a_n is the integer read, the event preserves $(a_n, [a_n]_9^+, q_9(a_n))$, the sheet, previous position, orientation, and boundary crossing. The tritic symbol is $[a_n]_9^+ \bmod 3$. The spatial lift retains, for example, the integer $q_9(c+h)$ when c is replaced by $[c+h]_9^+$.

The shared-cell representation and the two-cursor representation of (1.192) have different visible states. Their records are related to the TPK state through their respective representation maps. For the central trajectory, the full update on the shared cell producing the electronic word is used here.

Proposition 1.202 (Invertible update with preserved quotients)**.** *Add to the visible state two integer records $Q_+, Q_\times$ and two winding numbers W_r, W_c. Each active reading increments its sheet's record by $q_9(a_n)$; each displacement increments the corresponding winding by its boundary crossing. This update has an explicit inverse on its image.*

Proof. The later index determines the preceding mode and whether an orientation reversal has just occurred. This reversal is undone first. If the mode was additive, the previous column is recovered as $[c-h]_9^+$; if multiplicative, the row is recovered as $[r-v]_9^+$. The neutral mode preserves both coordinates. The recovered cell again determines the integer read, its remainder, quotient, and boundary crossing. Subtracting these increments from $Q_+, Q_\times, W_r, W_c$ and reversing the chronological index recovers the preceding state exactly. Composing these inverses recovers an entire finite history. Event concatenation also preserves the order of readings. □

The registers $Q_+, Q_\times$ are an explicit additive expression of quotient history. The construction is integrated into the memory fibre alongside its other coordinates. Its composition law, for concatenable histories u, v, is

$$Q_s(uv) = Q_s(u) + Q_s(v), \qquad s \in \{+, \times\},$$

where the second history begins at the first one's final state. Algebraic inversion of an update subtracts its increments; subsequently traversing a spatial return path records new evaluations. This distinction simultaneously preserves transport reversibility and history duration.

Proposition 1.203 (Central return and exact accumulation)**.** *Starting from $(r, c, h, v, n) = (5, 5, 1, 1, 0)$ and zero initial records, the spatial projection and its orientations return after fifty-four updates. Over that interval,*

$$(\Delta W_r, \Delta W_c) = (0, 0), \qquad (\Delta Q_+, \Delta Q_\times) = (10, 46).$$

After $54N$ updates, for every integer $N \geq 0$, one has $(Q_+, Q_\times) = (10N, 46N)$, while the spatial coordinates and their orientations return. The integer index takes the value $54N$; the dodecaphasic calendar modulo 108 returns for even N.

Proof. Each pair of active modes displaces each coordinate once. In twenty-seven updates, both complete a turn of nine positions and return to the central diagonal; h, v are then reversed. The next block traverses the opposite turn. Spatial crossings cancel between the two blocks.

In each block, the additive readings run through $2k$, $1 \leq k \leq 9$, whose positive quotient sums to five. The multiplicative readings of the positive block run through $k[k+1]_9^+$. Their integer sum and remainder sum are

$$\sum_{k=1}^{9} k[k+1]_9^+ = 249, \qquad \sum_{k=1}^{9} [k[k+1]_9^+]_9^+ = 42.$$

The second identity follows from the list $(2, 6, 3, 2, 3, 6, 2, 9, 9)$. By Euclidean division, the quotient sum is $(249-42)/9 = 23$. Substitution $k \mapsto [k-1]_9^+$ shows that the negative block contains the same multiset of products. The two blocks therefore produce ten and forty-six units in the respective records. The spatial projection and its orientations return to their initial values. The activation and reversal rules repeat upon shifting the index by 54, and the increments do not depend on the accumulated records. The preceding additive law proves the formula for every N by induction. □

The tritic reading and window orientation provide, on the same trajectory,

$$\gamma_e = \big((100000220)^3(120200000)^3\big)^2, \qquad \tau_e = (+,+,+,-,-,-,+,+,+,-,-,-).$$

Powers represent concatenations. The discrepancy and window readers developed in (16.39) and (16.40) both compute $(80, 54, 6)$. Evaluation is obtained from the trajectory before incorporating α, the action section or a mass. Quotient memory preserves information additional to that triple: over one hundred and eight updates it records $(20, 92)$, with zero net spatial winding. Each expression thus retains the type of the observable producing it.

1.23.5.6 Bidirectionality of the product reader and quotient memory

The product reading preserves four arithmetic coordinates before expressing a signature. For $x = (i, j) \in D_9^2$, $D_9 = \{1, \dots, 9\}$, define

$$N(x) = ij, \qquad r(x) = 1 + ((ij - 1) \bmod 9), \qquad q(x) = \frac{N(x) - r(x)}{9},$$

and the discrete reader

$$\ell(1, 2, 4, 8, 7, 5) = (0, 1, 2, 3, 4, 5), \qquad \ell(3) = \ell(6) = \ell(9) = 0.$$

Thus $N = r + 9q$ simultaneously preserves the integer product, positive residue, and arithmetic quotient. The function $f_\ell(x) = \ell(r(x))$ is the coordinate used by the regional signature. The functions N, r, q, and f_ℓ have a positional domain; the transport direction remains in the oriented seed.

Advance, half-turn, and reading before transport. Let $\mathcal{X}_\times = D_9^2 \times \{N, E, S, O\}$. The cardinal vectors are $\nu_N = (-1, 0)$, $\nu_E = (0, 1)$, $\nu_S = (1, 0)$, $\nu_O = (0, -1)$. Positional addition is reduced to positive representatives modulo nine. Define

$$P(x, d) = (x + \nu_d, d), \qquad H(x, d) = (x, \bar{d}), \qquad \nu_{\bar{d}} = -\nu_d.$$

These operators satisfy $P^9 = I$, $H^2 = I$, and $HPH = P^{-1}$.

In the first fifty-four TPK transitions, the product channel is activated in phases $2, 5, 8$ of each nonadic window. Each activation reads the position before advance. After transitions 27 and 54, H is applied. Thus the eighteen positions read are, for a seed s,

$$P^0 s, P^1 s, \dots, P^8 s, \quad HP^9 s,\ PHP^9 s, \dots, P^8 HP^9 s,$$

with the understanding that the positional reading omits only direction. For any positional function f, put $f_n = f(P^n s)$, with indices modulo nine. The word of raw readings is

$$\mathcal{R}_f(s) = (f_0, f_1, \dots, f_8,\ f_0, f_8, f_7, \dots, f_1). \tag{1.193}$$

The six window sums, each comprising three activations, are

$$A_j^f(s) = f_{3j} + f_{3j+1} + f_{3j+2}, \qquad 0 \le j < 3, \tag{1.194}$$

$$A_{3+j}^f(s) = f_{-3j} + f_{-3j-1} + f_{-3j-2}, \qquad 0 \le j < 3. \tag{1.195}$$

For $f = f_\ell$, the signature is $E_{\mathrm{sig}}(s) = ([A_0^f]_{10}, \dots, [A_5^f]_{10})$. The decimal quotient of each accumulator is $c_j^{10} = \lfloor A_j^f / 10 \rfloor$, and it preserves $A_j^f = [A_j^f]_{10} + 10c_j^{10}$.

Proposition 1.204 (Half-turn and permutation of half-cycles)**.** *For every oriented seed and every positional function f,*

$$\mathcal{R}_f(Hs) = \mathrm{rot}_9\,\mathcal{R}_f(s), \qquad A_j^f(Hs) = A^f_{j+3 \bmod 6}(s).$$

The same permutation transports the decimal residues and quotients of the accumulators. It applies, in particular, to N, r, q, and f_ℓ.

Proof. The relation $P^nH = HP^{-n}$ and equality $f(Hs) = f(s)$ give $f(P^nHs) = f(P^{-n}s) = f_{-n}$. Substitution into (1.193) exchanges its two groups of nine entries. Summation in groups of three produces the window identity. Euclidean division by ten is performed componentwise and respects the permutation. □

Advance also has an exact law on the accumulators:

$$A_j^f(Ps) - A_j^f(s) = f_{3j+3} - f_{3j}, \qquad 0 \le j < 3, \tag{1.196}$$

$$A^f_{3+j}(Ps) - A^f_{3+j}(s) = f_{1-3j} - f_{-2-3j}, \qquad 0 \le j < 3. \tag{1.197}$$

The proof consists in cancelling the two common summands of each window. Transporting a signature therefore requires the boundary evaluations appearing in these differences, in addition to the sums already expressed.

Chronological inversion and boundary terms. Let $\gamma = (x_0, \dots, x_n)$ be a recorded trajectory, and let $\gamma^\dagger = (x_n, \dots, x_0)$ be its chronological inversion, with each edge oriented in the opposite direction. For a positional function f, the reading before each advance is

$$C_f(\gamma) = \sum_{t=0}^{n-1} f(x_t).$$

Then

$$C_f(\gamma^\dagger) = C_f(\gamma) + f(x_n) - f(x_0). \tag{1.198}$$

If $n = 3m$ and A_j^f groups three consecutive edges,

$$A_j^f(\gamma^\dagger) = A^f_{m-1-j}(\gamma) + f(x_{3(m-j)}) - f(x_{3(m-j-1)}). \tag{1.199}$$

Both formulas follow because the reverse trajectory reads the arrival endpoints of the original edges. The interior summands coincide; the difference preserves the endpoints.

For an antisymmetric edge observable $a(x, y) = -a(y, x)$, its word does transform according to

$$\mathcal{R}_a(\gamma^\dagger) = -\,\mathrm{rev}\,\mathcal{R}_a(\gamma).$$

This identity acts on oriented edges. Identities (1.198)–(1.199) act on positional readings. The half-turn H changes the initial direction and preserves calendar order; chronological inversion reverses the complete record. Their domains and reading rules are specified separately.

Occupation cocycle and memory preserved on outward and return paths. For a cardinal edge $x \to y$, with positive representatives $\widetilde{x}, \widetilde{y}$, the covering crossing is

$$b(x, y) = \frac{\widetilde{x} + \nu_d - \widetilde{y}}{9} \in \mathbb{Z}^2.$$

The identity $b(y, x) = -b(x, y)$ holds. In the free category of recorded paths, define the additive reader

$$\mathfrak{m}(\gamma) = \left(\sum_{t=0}^{n-1} b(x_t, x_{t+1}),\ C_q(\gamma),\ n \right). \tag{1.200}$$

Concatenation satisfies $\mathfrak{m}(\gamma_2 \circ \gamma_1) = \mathfrak{m}(\gamma_1) + \mathfrak{m}(\gamma_2)$. It is an additive cocycle on recorded trajectories: the record preserves outward and return edges as different events.

By (1.198),

$$\mathfrak{m}(\gamma^\dagger \circ \gamma) = \big(0,\ 2C_q(\gamma) + q(x_n) - q(x_0),\ 2n\big), \tag{1.201}$$

where $\gamma^\dagger \circ \gamma$ denotes the temporal concatenation of the outward path followed by the return. The oriented sum of crossings cancels; arithmetic occupation and length remain. This reader does not descend to the quotient that identifies a path followed by its inverse with the empty trajectory, since that quotient eliminates the events preserved by the second and third coordinates.

There is also a purely boundary-based even reading:

$$V_b(\gamma) = \sum_{t=0}^{n-1} b(x_t, x_{t+1}) b(x_t, x_{t+1})^{\mathsf{T}}, \qquad V_b(\gamma^\dagger \circ \gamma) = 2V_b(\gamma).$$

The odd and even readings record distinct properties of the same edges; both are computed before the path is forgotten.

Exact application to the signature fiber 555555**.** The finite enumeration of $\mathscr{X}_\times$ contains 324 seeds, 26 signatures, and 24 seeds with signature 555555. The stable partition under P, H refines this fiber into three classes of eight elements. They can be labeled by their signature after one advance:

$$\mathscr{C}_{177}, \quad \mathscr{C}_{717}, \quad \mathscr{C}_{771}.$$

The half-turn action is

$$H\mathscr{C}_{177} = \mathscr{C}_{177}, \qquad H\mathscr{C}_{717} = \mathscr{C}_{771}, \qquad H\mathscr{C}_{771} = \mathscr{C}_{717}.$$

The attached finite certificate verifies these identities on all representatives. In the twenty-four seeds, the six raw accumulators of f_ℓ are exactly five. Hence the decimal quotients c_j^{10} vanish on this fiber. The additional information is observed in the positions, integer evaluations, and arithmetic quotients, which have readings different from that signature.

The fixed transverse coordinate a of the cardinal path is 4 or 5 in these seeds. During one turn of nine advances, each value of the moving coordinate $u \in D_9$ is traversed once. Since $\gcd(a, 9) = 1$, the positive residues $r(au)$ permute D_9. This gives, without using a physical constant,

$$\sum_{u=1}^{9} au = 45a, \qquad \sum_{u=1}^{9} r(au) = 45, \qquad \sum_{u=1}^{9} q(au) = 5(a-1).$$

The subsequent return traverses the same positions in the opposite direction. Over the eighteen activations,

$$\sum N = 90a, \qquad \sum r = 90, \qquad \sum q = 10(a-1) = \begin{cases} 30, & a = 4, \\ 40, & a = 5. \end{cases} \tag{1.202}$$

The accumulated integer product is, respectively, 360 or 450. The net winding is zero; the sum of quotients and the eighteen incidences preserve the history of the reading. Each of the three signature classes contains representatives of both transverse values. The same signature and the same transport class of that finite quotient can therefore coexist with distinct arithmetic occupations.

These results connect preserved memory with concrete operations: permutation of half-cycles, boundary differences, arithmetic quotients, and incidence records. The physical-mathematical identification of any subsequent reader preserves its own maps; the identities proved here belong to the internal dynamics of the product channel.

1.23.5.7 Arithmetic memory of the multiplicative channel

Preservation of the regional signature extends to the full arithmetic evaluation of APP. For an oriented position $x = (i, j, d) \in \{1, \dots, 9\}^2 \times \{N, E, S, O\}$, let $\chi(x) = (a, b, \epsilon)$, where a is the fixed coordinate, b the moving coordinate, and ϵ its orientation:

$$\chi(i,j,N) = (j,i,-1), \quad \chi(i,j,S) = (j,i,+1), \qquad \chi(i,j,E) = (i,j,+1), \quad \chi(i,j,O) = (i,j,-1).$$

The axis label $\iota \in \{i, j\}$ preserves which of the two original coordinates moves. Writing $\langle b \rangle_9 = 1 + ((b-1) \bmod 9)$, the operators and evaluation are

$$\overline{P}(a,b,\epsilon) = (a, \langle b+\epsilon \rangle_9, \epsilon), \qquad \overline{H}(a,b,\epsilon) = (a,b,-\epsilon), \tag{1.203}$$

$$n(a,b) = ab, \qquad r(a,b) = \langle ab \rangle_9, \qquad q(a,b) = \frac{ab - r(a,b)}{9}. \tag{1.204}$$

Proposition 1.205 (Exact representation of arithmetic transport)**.** *The identities $\chi P = \overline{P}\chi$ and $\chi H = \overline{H}\chi$ hold. The representation χ has* 162 *states and is the coarsest of the representations stable under P, H that preserve the integer product or, equivalently, the pair (r, q). Additionally preserving ι recovers the* 324 *original oriented positions.*

Proof. Advance modifies only b, and the half-turn only ϵ, proving the two transport identities. The nine observations $n_k = n(\overline{P}^k \chi(x))$, $0 \le k < 9$, run through $a, 2a, \dots, 9a$. Thus one recovers $a = \min_k n_k$, $b = n_0/a$, and the sign through $(n_1/a - n_0/a) \bmod 9 \in \{1, 8\}$. Every stable equivalence that preserves n preserves these nine observations and therefore distinguishes all states (a, b, ϵ). The identity $n = r + 9q$ proves equivalence of the two evaluations. Each fiber of χ contains the two transposed routes: $(i, j, d) \mapsto (j, i, d^\top)$, with $N^\top = O, O^\top = N, E^\top = S, S^\top = E$. The axis label distinguishes these two preimages and allows position and direction to be reconstructed. □

The TRIT selector activates the product at $t \equiv 2, 5, 8 \pmod 9$, before each advance. The half-turn acts at the end of every 27 instants. If y_{t-1} denotes the preceding arithmetic state, the increment and its accumulated memory are determined by

$$\eta_q(t) = \mathbf{1}_{\{t \equiv 2 \ (3)\}} q(y_{t-1}), \qquad \lambda_q(t) = \lambda_q(t-1) + \eta_q(t), \quad \lambda_q(0) = 0. \tag{1.205}$$

The bound $0 \le q(a, b) \le a - 1$ holds. To invert an update, one first undoes the corresponding half-turn, then the advance, and finally subtracts the quotient recovered from the preceding state. The record retains phase, axis, event order, and memory; λ_q is an additive cocycle of this transport.

Each block of 27 contains nine advances and traverses the moving coordinate once. Hence the return of position and orientation at 54, and of phase at 108, coexist with

$$\lambda_q(108N) = NQ_\times^+(a), \qquad Q_\times^+(a) = \frac{180a - 4\sum_{b=1}^{9} r(a,b)}{9}, \qquad N \ge 0. \tag{1.206}$$

Indeed, each block sums the products $a, 2a, \dots, 9a$; summing $n = r + 9q$ over the four blocks gives the formula. If a is coprime to 9, the residues sum to 45, and $Q_\times^+(a) = 20(a-1)$. In window j, counted from $j = 0$, the relative calendar sign is $\sigma_j = (-1)^{\lfloor j/3 \rfloor}$, and the effective orientation is $\epsilon_j = \epsilon_0 \sigma_j$. The charge signed by σ_j vanishes; the charge weighted by the effective orientation likewise vanishes after multiplication by ϵ_0. The ledger preserves the initial orientation, the accumulated charge, and its

increments. These quantities belong to the multiplicative cursor; the readers of a trajectory that alternates between both sheets act on the record of that trajectory.

The finite emission, its coupling of signatures, and ternary reduction have successive types:

$$\mathcal{S}^2 \xrightarrow{s\times e} \operatorname{im} s \times \operatorname{im} e \xrightarrow{G} \mathcal{U}_6 \xrightarrow{\Psi_6} W_6 \hookrightarrow \mathbb{F}_3^6.$$

Section 4.3 proves factorization of the 104 976 seeds into $18 \cdot 26 = 468$ emissions and the 243 visible words of the 729-element ambient space. The maps G and Ψ_6 are those of (4.31) and (4.32); the register preserves arithmetic preimages alongside this finite expression.

1.23.5.8 Compatibility of quotients and refinement cylinders

Extension compares states that simultaneously preserve remainders, quotients and boundaries. In the register's six-coordinate linear chart, the matrix

$$A_H = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad \det A_H = 1,$$

gives the division map

$$\mathcal{H} : \mathbb{Z}^6 \longrightarrow \{0,1,2\}^6 \times \mathbb{Z}^6, \qquad x \longmapsto (u, x^+), \quad y = xA_H, \quad u = [y]_3, \quad x^+ = (y-u)/3. \tag{1.207}$$

Rows are interpreted as vectors. The pair (u, x^+) preserves $y = u + 3x^+$ and recovers $x = (u + 3x^+)A_H^{-1}$. The ternary orientation of u is then obtained through ρ_3^{or}, preserving the preceding quotient. This makes the reversible content of this local chart explicit.

The cylindrical chart relates a ternary prefix of length L and integer index N to K decimal triads of index D. The corresponding half-open cylinders have rational endpoints

$$I_3(N,L) = \left[\frac{N}{3^L}, \frac{N+1}{3^L}\right), \qquad I_{1000}(D,K) = \left[\frac{D}{1000^K}, \frac{D+1}{1000^K}\right).$$

Define the boundary integers

$$a = N1000^K - D3^L, \qquad b = (N+1)1000^K - D3^L.$$

Lemma 1.206 (Integer update of compatible cylinders)**.** *The preceding cylinders intersect if and only if $a < 3^L$ and $b > 0$. Adjoining a ternary block $u \in \{0,\dots,728\}$ gives $N' = 729N + u$ and $L' = L + 6$. For $\Delta K \in \{0,1\}$, the boundaries are updated by*

$$\begin{aligned} \Delta K = 0: &\quad a' = 729a + u1000^K, \\ \Delta K = 1: &\quad D' = 1000D + \delta, \quad a' = 729000a + u1000^{K+1} - \delta\, 729\, 3^L, \end{aligned}$$

where $\delta \in \{0,\dots,999\}$ is the triad of the compatible prolongation. In both cases, $b' = a' + 1000^{K+\Delta K}$.

Proof. Two half-open intervals intersect exactly when each left endpoint is less than the other's right endpoint. Multiplying those two inequalities by $3^L 1000^K$ gives $a < 3^L$, $b > 0$. Substituting N', L', and D' into $a' = N'1000^{K+\Delta K} - D'3^{L'}$ produces the two recurrences. Subtracting the definitions of b' and a' gives the last identity. □

These operations act on integer prefixes and their compatible restrictions. The Archimedean reading appears when the resulting cylinder system is evaluated. The prolongation domain also incorporates orientation, carry, and the joint boundary signature of (1.188); interval comparison is one component of this joint compatibility.

1.23.5.9 Extension relations and joint nonadic connection

For an observable route $r : q \to q'$, prolongation has type

$$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}, \qquad \mathrm{Ext}_{r_2} \circ \mathrm{Ext}_{r_1} \subseteq \mathrm{Ext}_{r_2 r_1}\,.$$

The identities satisfy $\Delta_{\mathcal{F}_q} \subseteq \mathrm{Ext}_{\mathrm{id}_q}$. It preserves the truncations, sheets, orientations, carries, and boundary incidences of the two histories. The identities and admissible concatenations form the category of TPK states and prolongations. This relational structure admits local fibers with more than one continuation and allows their persistence to be imposed jointly.

Let $\mathcal{H}_m$ be the set of admissible histories of depth m, with truncations $p_{n,m}$. Survival is expressed by

$$\mathrm{Surv}_m^{(N)} = p_{N,m}(\mathcal{H}_N), \qquad \mathrm{Surv}_m = \bigcap_{N \geq m} \mathrm{Surv}_m^{(N)}, \qquad X_\chi = \varprojlim_m \mathrm{Surv}_m^{(\chi)}\,.$$

The compatible section simultaneously preserves all its prefixes. The local connection relations $\mathcal{R}_k$ compose into

$$\Gamma_{9,k} = \mathcal{R}_{k+8} \circ \cdots \circ \mathcal{R}_k, \qquad \Gamma_{9,k} : \widehat{X}_k \dashrightarrow \widehat{X}_{k+9}. \tag{1.208}$$

The indicated domain is that of compatible histories. On an individualized history, the nine relations represent its effective transport; the system retains all admissible prolongations before this individualization.

The return law is written

$$g(\Gamma_{9,k}x) = g(x), \qquad q_{\mathrm{mem}}(\Gamma_{9,k}x) = q_{\mathrm{mem}}(x) + 1.$$

Phase returns and history extends. The prefixes $w_6, w_{12}, w_{18}, w_{24}, w_{30}$, boundary R_{36} and charts G_9 are states, extensions or presentations of this construction, with types distinct from the holonomy Γ_9. Their regional realization is developed in Section 10.5; turn composition and its representations are proved in 10.55–10.57.

1.23.5.10 Phase incidence and arithmetic origin of the channels

The selector M_{ph} induces the classes

$$H_+ = \{1,4,7\}, \quad H_- = \{2,5,8\}, \quad H_0 = \{3,6,9\}, \quad H_{\mathrm{act}} = H_+ \sqcup H_-.$$

The phase origin fixes the terminal representative $\star_{\mathrm{ph}} = 9$ and the set $O_{\mathrm{ph}} = D_9 \setminus \{\star_{\mathrm{ph}}\}$. Write $P_2(H_{\mathrm{act}})$ for the unordered pairs of active phases and define

$$\mathcal{F}_6^{\mathrm{ph}} = H_{\mathrm{act}} \times P_2(H_{\mathrm{act}}), \qquad \mathcal{F}_8^{\mathrm{ph}} = O_{\mathrm{ph}} \times P_2(H_{\mathrm{act}}), \qquad \Theta_{\mathrm{ph}} = D_9 \times P_2(H_{\mathrm{act}}).$$

Theorem 1.207 (Incidence of the phase semicorona)**.** *At the declared window origin,*

$$|\mathcal{F}_6^{\mathrm{ph}}| = 90, \qquad |\mathcal{F}_8^{\mathrm{ph}}| = 120, \qquad |\Theta_{\mathrm{ph}}| = 135.$$

The oriented boundary, pointed return, and lateral closure,

$$\partial_{\mathrm{ph}} = \Theta_{\mathrm{ph}} \times \{-1,+1\}, \quad E_{\mathrm{ph}} = \partial_{\mathrm{ph}} \sqcup \{\infty\}, \quad L_{\mathrm{ph}} = H_0 \times P_2(H_{\mathrm{act}}), \quad P_{\mathrm{ph}} = \partial_{\mathrm{ph}} \sqcup L_{\mathrm{ph}},$$

satisfy

$$|\partial_{\mathrm{ph}}| = 270, \quad |E_{\mathrm{ph}}| = 271, \quad |L_{\mathrm{ph}}| = 45, \quad |P_{\mathrm{ph}}| = 315.$$

Translation of the origin transports all these sets by bijections and preserves their incidences.

Proof. There are six active phases and $\binom{6}{2} = 15$ unordered pairs. Products by $6, 8, 9$ give $90, 120, 135$. Orientation doubles the last set, the pointed return adds one element, and the three neutral phases contribute $3 \cdot 15 = 45$ lateral incidences. The C_9 action simultaneously transports the selector, the terminal representative, and each factor of the Cartesian products. □

The difference of active cardinalities is $120 - 90 = 30$. The normalized defect therefore has the exact expression

$$\frac{30}{120} - \frac{30}{90} = -\frac{1}{12}. \tag{1.209}$$

Here 90 and 120 are cardinalities of incidences produced by the phase rule. The subsequent hexadic–octadic realization transports this incidence to its combinatorial objects. The angular coordinates of these objects are established through their realization maps.

1.23.5.11 Temporal record, signed extraction, and reversible coordinates

Let $E_m = \{9(m-1)+1, \dots, 9m\}$. Restricting a history to twelve windows preserves in each its subroute τ_m, orientation σ_m, boundary carry κ_m, and local record Λ_m:

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12}.$$

The domain of $\mathcal{R}_{12}$ is histories; the elements of the group C_{12} are sector classes, and Θ_{108} preserves their calendar. This distinction keeps the data preserved by each realization visible.

The signed extraction of section 11.4 factors through

$$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,mem}} \xrightarrow{\mathcal{R}_{12}} \mathcal{R}_{12}^{\mathrm{mem}} \xrightarrow{\mathcal{E}_{108}^{90,120}} \mathbb{Z}^{12} \times \mathbb{Z}^{12} \times \mathbb{Z} \xrightarrow{\Pi_H} \mathbb{Z}^{12}. \tag{1.210}$$

The second map expresses the channels $(b^{90}, b^{120}, Q_{\mathrm{TPK}})$; the third constructs the signed vector U. The rule $\varepsilon_9 = M_{\mathrm{ph}}$ belongs to phase selection, whereas $\mathcal{E}_{108}^{90,120}$ acts on the complete channel register. Their domains and outputs distinguish them.

Equations (11.104) and (11.105) give the arithmetic action of Π_H. The transformation $\mathcal{H}_{12}$, constructed from the three step-three orbits, then reversibly relates U to the record K. The cyclic differences and total charge provide subsequent readings of the same record. This preserves the common provenance of the regional coordinates and the signed coordinate before the integer closure determining α.

1.23.5.12 Reduced transfer and memory preserved by the dynamics

Once the emission factorization has been constructed, $\mathcal{U}_6 \simeq \mathcal{A}_+ \times \mathcal{A}_\times$, with $|\mathcal{A}_+| = 18$ and $|\mathcal{A}_\times| = 26$, there are two projections on functions of the catalog:

$$(E_+ f)(s,e) = \frac{1}{18} \sum_{s' \in \mathcal{A}_+} f(s',e), \qquad (E_\times f)(s,e) = \frac{1}{26} \sum_{e' \in \mathcal{A}_\times} f(s,e').$$

The signature alphabets $\mathcal{A}_+, \mathcal{A}_\times$ are distinct from the seed sets of the two cursors. Each projection averages the active coordinate and preserves the other. With $P_{+1} = E_+$, $P_{-1} = E_\times$, $P_0 = I$, the transfer kernel on $\mathcal{U}_6 \times C_9$ is

$$\mathcal{K}_{\mathrm{ph}}((u,r),(v,r+1)) = P_{M_{\mathrm{ph}}(r)}(u,v).$$

The two projections commute and are idempotent. Thus their composition during one phase turn satisfies

$$\mathcal{K}_{\mathrm{ph}}^{9}\big|_r = E_+ E_\times, \qquad (E_+ E_\times)(u,v) = \frac{1}{468}. \tag{1.211}$$

This operator is an expression of reduced memory on emissions already constructed. The holonomy Γ_9 additionally preserves the coordinates of the history on which this expression is performed.

In an isometric realization U_{Γ_9} of transport, and for an isometric inclusion J of the observed coordinate, its two components are

$$T = J^* U_{\Gamma_9} J, \qquad \eta = (I - JJ^*) U_{\Gamma_9} J.$$

One obtains directly

$$U_{\Gamma_9} J = JT + \eta, \qquad J^* \eta = 0, \qquad I - T^* T = \eta^* \eta.$$

The component η is computed from the same realized update and the declared projection. The telescoping identity (4.36) preserves both the contributions expressed in the orthogonal complement and the terminal term. This separation is the operator basis for the subsequent distinction between recorded information, entropy of an observation, and dimensional realization of action.

Chapter 2

Cohomological rank of carry memory: independent cocycles, dimensional lift, and projective preservation of unity

2.1 Cohomology of the helicoidal carry: evaluation of cocycles and minimum dimension of cumulative memory

A periodic coordinate records the visible position; the carry records how many times the trajectory has crossed its boundary. The former returns, whereas the latter accumulates. This distinction turns periodicity into a lift: two instants may share a visible phase yet belong to distinct states because they retain different winding numbers.

In the nonadic alphabet, for $n \in \mathbb{Z}_{\geq 1}$, let us define

$$r(n) = 1 + ((n-1) \bmod 9), \qquad q(n) = \left\lfloor \frac{n-1}{9} \right\rfloor,$$

and the helical lift

$$H_9(n) = (r(n), q(n)). \tag{2.1}$$

Then

$$H_9(n+9) = H_9(n) + (0,1) :$$

the phase returns and memory changes. If $c_k \in \mathbb{Z}$ is the carry of step $k \to k+1$, its discrete integral

$$Q_N = Q_0 + \sum_{k=0}^{N-1} c_k \tag{2.2}$$

constitutes the cumulative coordinate of the lift. Its independence is algebraic; a later metric realization may represent it by means of a transverse or orthogonal direction.

2.1.1 Independent cocycles and minimum number of memory coordinates

Let G be the directed graph of visible states, and let $c_1, \ldots, c_d \in Z^1(G;\mathbb{Z})$ be integer cocycles. For a route γ, define

$$Q_j(\gamma) = \sum_{e \in \gamma} c_j(e), \qquad \widetilde{\gamma} = \big(q_{\mathrm{vis}}(\gamma), Q_1(\gamma), \ldots, Q_d(\gamma)\big).$$

On an open route this evaluation retains the representative of the cocycle and the endpoints. Indeed, with the convention $(\mathrm{d}\phi)(e) = \phi(t(e)) - \phi(s(e))$,

$$Q_j^{c_j + \mathrm{d}\phi}(\gamma) = Q_j^{c_j}(\gamma) + \phi(t\gamma) - \phi(s\gamma). \tag{2.3}$$

Therefore, for an open path, the representative and its endpoints are fixed, and the memory preserves those data. If γ is a cycle, the boundary term vanishes and $Q_j(\gamma)$ depends solely on the class $[c_j] \in H^1(G;\mathbb{Z})$.

Theorem 2.1 (Cohomological criterion for dimensional rank)**.** *Suppose that the classes of $c_1, \ldots, c_d$ generate a free submodule of rank d in $H^1(G;\mathbb{Z})$. Let*

$$Q : Z_1(G;\mathbb{Z}) \longrightarrow \mathbb{Z}^d$$

its evaluation on cycles. If a family of m additive counters is obtained by means of a homomorphism $A : \mathbb{Z}^d \to \mathbb{Z}^m$, such that

$$\widehat{Q} := A \circ Q : Z_1(G;\mathbb{Z}) \longrightarrow \mathbb{Z}^m,$$

and permits reconstruction of the evaluations, that is, there exists $B : \mathbb{Z}^m \to \mathbb{Z}^d$ with $Q = B \circ \widehat{Q}$, then

$$\boxed{m \geq d}.$$

Therefore, the lift requires at least d independent memory coordinates in addition to the visible coordinate.

Proof. The pairing $H^1(G;\mathbb{Z}) \times H_1(G;\mathbb{Z}) \to \mathbb{Z}$ and the independence of $[c_1], \ldots, [c_d]$ imply $\operatorname{rk}\operatorname{im} Q = d$. Since $Q = B \circ \widehat{Q}$,

$$d = \operatorname{rk}\operatorname{im} Q \leq \operatorname{rk}\operatorname{im} \widehat{Q} \leq m.$$

No homomorphism into fewer than d integer counters admits an additive inverse on the submodule generated by the evaluations Q_j. The stronger condition $B \circ A = I_{\mathbb{Z}^d}$ is sufficient, but the bound requires only reconstruction of Q on the evaluations performed by the cycles. □

The genealogical dimension here quantifies degrees of freedom necessary to recover the transport. The theorem does not yet identify that rank with a physical spatial dimension: it provides the minimum domain on which a metric realization may act without erasing the independent cocycles.

2.1.2 Nonadic tower and projective conservation of unity

Let

$$C_9^{(d)} = (\mathbb{Z}/9\mathbb{Z})^d.$$

For to mark $\star \in \mathbb{Z}/9\mathbb{Z}$, define the inclusion

$$h_{d,\star} : C_9^{(d)} \longrightarrow C_9^{(d+1)}, \qquad h_{d,\star}(x) = (x, \star),$$

and the projection

$$\pi_{d+1,d}(x_1, \ldots, x_{d+1}) = (x_1, \ldots, x_d).$$

Proposition 2.2 (Conservation by Dimensional Elevation)**.** *We have*

$$\pi_{d+1,d} \circ h_{d,\star} = \mathrm{id}_{C_9^{(d)}}.$$

Consequently, the cell of dimension d reappears exactly as a coordinate section of the cell of dimension $d + 1$: an affine slice, and a subgroup when $\star = 0$. The term codimension-one face *is reserved for an expressly declared additional cubical realization. For the normalized uniform measures μ_d,*

$$(\pi_{d+1,d})_* \mu_{d+1} = \mu_d.$$

Proof. The first identity follows by eliminating the newly added final coordinate. For a point $x \in C_9^{(d)}$, the fiber of $\pi_{d+1,d}$ contains nine points, each with mass $9^{-(d+1)}$; its total mass is $9^{-d} = \mu_d(\{x\})$. □

The first equality expresses structural conservation; the second, normalized conservation. Lifting does not replace the preceding layer: it includes it as a section and distributes the new coordinate over its fibers. In dimension three, $|C_9^{(3)}| = 729$; its decimal completion and the disjoint decomposition

$$1000 = 729 + 243 + 27 + 1$$

remain in the residence of cubic completion, where interior, faces, edges, and added vertex are distinguished.

2.1.3 From the cumulative coordinate to the metric

Cocycle lifting and the choice of a metric are successive operations. The former constructs independent memory coordinates; the latter declares a quadratic form that measures their variations. In APP, the central block

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 9P_+ + 5P_-$$

produce the reference normalization

$$M_c := \frac{B_c}{\sqrt{45}} \in SO^+(1,1),$$

proved in proposition 1.60. On the cubic screen, the physical realization selects the corresponding Lorentzian signature, and the TPK temporal reader orients its dynamics. The causal chain is

$$\begin{aligned} \text{return with carry} &\longrightarrow \text{cumulative cocycle} \longrightarrow \text{memory rank} \\ &\longrightarrow \text{quadratic form} \longrightarrow \text{realized metric.} \end{aligned}$$

Separation between the internal cohomological range and its spatiotemporal realization. The nonadic helix and the integral of carry provide the premises for the cohomological rank criterion and its lower bound. The cell tower and conservation of measure follow from the finite projection. Identifying genealogical rank with a spacetime dimension requires the declared metric functor in Dimensional Mechanics.

Chapter 3

Spectral, geometric, and operatorial realizations of the APP–TRIT–TPK kernel

3.1 Geometry of APP and structure of its trajectories

The main APP matrix makes it possible to recognize its regularities visually. Its geometric content is determined by the operations relating its positions: translation, inversion, composition of trajectories and simultaneous evaluation of sum and product. These operations produce distinct and compatible realizations. The Cayley graph describes adjacency; periodic identification of the edges produces a toroidal surface; the integer lift preserves winding; the interaction of the two evaluations determines an oriented discrete curvature. The central block, selected within the matrix itself, also admits a spectral realization and a Lorentzian normalization.

Each construction is introduced with its domain. This preserves the relationship between the finite support, its cellular realization, the spaces of functions on it and the bilinear forms obtained from its operators. This distinction makes it possible to use the full geometric content of APP without substituting one realization for another.

3.1.1 Cayley graph and arithmetic structure of trajectories

3.1.1.1 From the positional support to the directed graph

Identifying the representatives $1, \dots, 9$ with the classes modulo nine transforms the positional support of section 1.1 into the additive group

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2.$$

The projection $\mathcal{X}_9 \to X_9$ is bijective: each class of each coordinate has a unique representative in D_9. The four cardinal displacements determine the symmetric set

$$\mathscr{D} = \{(-1, 0), (0, 1), (1, 0), (0, -1)\}.$$

The orientation of the coordinates is the one fixed earlier: first coordinate southward and second eastward.

Definition 3.1 (Cardinal graph of APP)**.** The directed graph $\mathscr{G}_9$ has vertex set X_9 and an edge $x \to x + v$ for each $x \in X_9$ and $v \in \mathscr{D}$. In Cayley graph notation,

$$\mathscr{G}_9 = \mathrm{Cay}(X_9, \mathscr{D}).$$

The inverse edge of $x \to x + v$ is $x + v \to x$, associated with $-v$.

Proposition 3.2 (Connectivity, degree and translation symmetry)**.** *The graph $\mathscr{G}_9$ is connected, has* 81 *vertices,* 324 *directed edges and* 162 *undirected edges. Each translation $T_a : x \mapsto x + a$ is a graph automorphism and acts freely on the vertices.*

Proof. The classes of $(1, 0)$ and $(0, 1)$ generate X_9. From any vertex, another can be reached through a sequence of these displacements or their inverses; this proves connectivity. The four vectors in $\mathscr{D}$ are distinct modulo nine and none is zero. Therefore, each vertex has four outgoing edges and the total number of directed edges is $81 \cdot 4 = 324$. Each undirected edge appears exactly twice, once in each direction, giving 162.

If $y - x \in \mathscr{D}$, then $(y + a) - (x + a) = y - x \in \mathscr{D}$. Thus, T_a preserves the edges and their orientation; its inverse is T_{-a}. Finally, $T_a(x) = x$ implies $a = 0$, which is the freeness of the action. □

The group structure used in this result is addition of positions. The multiplicative observable Π remains defined on the same vertices and retains the radical described in proposition 1.14. The two operations

therefore play distinct roles: addition defines the translations of the graph; multiplication assigns to each position its main evaluation and multiplicities.

3.1.1.2 Trajectories, concatenation and order of records

An oriented path of length r is specified by an origin x_0 and a sequence $w = a_1 \cdots a_r$ of directions. Its position at time k is

$$x_k = x_0 + \sum_{j=1}^{k} \nu(a_j) \quad \text{in } X_9.$$

The difference $x_k - x_{k-1}$ recovers the direction a_k, since the four generators are distinct. This establishes a bijection between the pairs (x_0, w) and the oriented trajectories of length r. The count $81 \cdot 4^r$ includes exactly the trajectories with backtracking and returns admitted by this definition.

Definition 3.3 (Composition of APP trajectories)**.** A trajectory $\gamma : x \to y$ and another $\delta : y \to z$ are composed by concatenating their lists of edges. The empty trajectory at each position is the identity. The two evaluations of a trajectory are the ordered sequences

$$\Sigma[\gamma] = (\Sigma(x_0), \ldots, \Sigma(x_r)), \qquad \Pi[\gamma] = (\Pi(x_0), \ldots, \Pi(x_r)).$$

The complete arithmetic record adds the quotients q_+ and $q_\times$ to each position.

Concatenation is associative because list concatenation is associative. The preceding objects and operations constitute the path category of the graph. Reversing the path reverses the order of the edges and changes each direction to its opposite. Concatenating a trajectory with its inverse preserves a list of outward and return transitions; passing to the quotient that cancels immediate backtracking yields, by contrast, an identity. This distinction expresses exactly what information the recorded trajectory retains and what information its reduced class preserves.

The APP structure can be brought together as

$$\mathcal{A}_{\mathrm{APP}} = \big(X_9, \mathcal{G}_9, \Sigma, \Pi, \mathrm{Path}(\mathcal{G}_9)\big),$$

accompanied by the remainder–quotient lift defined in (1.7). The term *sheet* designates one of the two evaluations on this common support. If two cursors are used, each trajectory also retains the identifier of the sheet on which it is evaluated. This differentiation is the basis of the subsequent coupling of the two emissions.

3.1.2 Toroidal realization and lifting of paths

3.1.2.1 Periodic identification of the grid

The cellular realization is constructed on the integer lattice of the plane: its vertices are integer pairs; its edges join pairs that differ by a cardinal generator; its faces are unit squares. Cells translated by vectors in $9\mathbb{Z}^2$ are identified. The quotient contains nine positions per direction and its edge graph is precisely $\mathcal{G}_9$.

Proposition 3.4 (Toroidal surface of APP)**.** *The preceding cellular realization is a closed orientable surface homeomorphic to the two-dimensional torus. Its cellular decomposition has* 81 *vertices,* 162 *edges and* 81 *faces, and its Euler characteristic is zero.*

Proof. The square of side length nine, with opposite sides identified by translations, is a fundamental domain. Identifying one pair of opposite sides first yields a cylinder; identifying the two ends of the cylinder by the remaining translation yields the torus. The orientation of the squares in the plane is preserved under translations and descends to the quotient.

The vertex classes are the pairs of residues modulo nine, so there are 81 of them. From each class emanate a positive horizontal edge and a positive vertical edge; each geometric edge has a unique

description of this type, so there are 162. The square classes are identified by their initial vertex and number 81. Consequently,

$$\chi = 81 - 162 + 81 = 0.$$

The identification eliminates the boundary of the fundamental domain: an edge of that boundary is joined to its opposite and belongs to two faces. The link of each vertex is a cycle of four edges, as in the planar grid. This locally verifies the closed-surface structure. □

The edges of the printed table act as cuts of a fundamental domain. Their arithmetic role comes from the chosen representatives. In particular, the last row and the last column correspond to zero-class coordinates. These cuts allow periodicity to be represented on a page without making them an intrinsic boundary of the toroidal surface.

Proposition 3.5 (Distribution of multiplicative zero representatives)**.** *The evaluation* Π *takes the value nine at exactly twenty-one positions. Seventeen belong to the union of the last row and the last column; the remaining four are*

$$(3,3), \quad (3,6), \quad (6,3), \quad (6,6).$$

Proof. The condition $\Pi(i,j) = 9$ is equivalent to $9 \mid ij$. If one coordinate is nine, it holds for any value of the other. The last row and the last column comprise $9 + 9 - 1 = 17$ positions. If both coordinates are between one and eight, divisibility by nine requires both to be multiples of three, since neither already contains the factor nine. The only possibilities are $i, j \in \{3, 6\}$, which give the four indicated positions. The two sets are disjoint and their union has 21 positions. □

Multiplicative vanishing thus distinguishes the coordinate cut and the interior radical sector of the representation. Each position also retains its additive evaluation and quotients; the visible value nine has twenty-one different positional origins.

3.1.2.2 Integer lift and boundary-crossing record

Fix an integer representative $\widetilde{x}_0 \in D_9^2$ of the origin. The lift of a trajectory is constructed without modular reduction:

$$\widetilde{x}_k = \widetilde{x}_0 + \sum_{j=1}^{k} \nu(a_j) \in \mathbb{Z}^2.$$

Its reduction modulo nine is x_k. Denote by $s_9(x_k) \in D_9^2$ the coordinatewise positive representative. There exists a unique vector $q_k \in \mathbb{Z}^2$ such that

$$\widetilde{x}_k = s_9(x_k) + 9q_k.$$

The vector q_k counts the displacements between fundamental domains of the lift.

Proposition 3.6 (Exact accumulation of crossings)**.** *For each transition, the vector*

$$\kappa_k = \frac{s_9(x_{k-1}) + \nu(a_k) - s_9(x_k)}{9} \in \mathbb{Z}^2$$

satisfies $q_k = q_{k-1} + \kappa_k$*. In a trajectory of length* r*,*

$$\sum_{k=1}^{r} \kappa_k = \frac{s_9(x_0) + d(w) - s_9(x_r)}{9}.$$

If the trajectory is closed, this sum is its winding vector $\mathrm{wind}(w)$.

Proof. The congruence $s_9(x_{k-1}) + \nu(a_k) \equiv s_9(x_k) \pmod 9$ proves that κ_k is integral. Substituting $\widetilde{x}_{k-1} = s_9(x_{k-1}) + 9q_{k-1}$ into the lifting rule yields

$$\widetilde{x}_k = s_9(x_k) + 9(q_{k-1} + \kappa_k).$$

Uniqueness of the decomposition gives the first identity. Summing the expressions for κ_k cancels the intermediate positions, leaving the second. For a closed path, $s_9(x_r) = s_9(x_0)$; the result is $d(w)/9$, according to theorem 1.9. □

Example 3.7 (Lift of a horizontal turn)**.** From $(5, 5)$, nine eastward displacements produce the integer columns

$$5, 6, 7, 8, 9, 10, 11, 12, 13, 14.$$

Their positive representatives are

$$5, 6, 7, 8, 9, 1, 2, 3, 4, 5.$$

In the step from 9 to 1, the second component of κ_k equals one; in the other steps it equals zero. The final residue position coincides with the initial one, while the final lift is $(5, 14)$ and the winding is $(0, 1)$.

The crossing integer preserves the accumulated circulation. The ordered sequence of crossings and positions preserves additional data, such as the instant when the cut is crossed. The two records have different applications within the enriched state. Preserving them makes it possible to transport a history that repeatedly traverses the same set of positions.

3.1.2.3 Complex realization and Kähler structure of the continuous torus

The cellular realization admits an explicit geometric extension:

$$\mathbb{T}_{9,\mathrm{an}} = \mathbb{R}^2/(9\mathbb{Z})^2.$$

The map sending an integer position to its class in this quotient includes the 81 APP vertices as a finite grid. Real space is used here as the realization codomain of the arithmetic object already constructed. The developments of the genealogical continuum will separately establish their own construction of values.

In the local coordinates (u, v) inherited from the plane, define

$$g = \mathrm{d}u^2 + \mathrm{d}v^2, \qquad J(a, b) = (-b, a), \qquad \omega = \mathrm{d}u \wedge \mathrm{d}v.$$

These structures are invariant under lattice translations. They therefore descend to the torus.

Proposition 3.8 (Kähler structure of the toroidal realization)**.** *The triple (g, J, ω) defines a flat Kähler structure on $\mathbb{T}_{9,\mathrm{an}}$. It satisfies*

$$J^2 = -I, \qquad g(JX, JY) = g(X, Y), \qquad \omega(X, Y) = g(JX, Y), \qquad \mathrm{d}\omega = 0.$$

Proof. The formula for J gives $J^2(a, b) = (-a, -b)$ and preserves the inner product. If $X = (a, b)$ and $Y = (c, d)$, then

$$g(JX, Y) = -bc + ad = \omega(X, Y).$$

The constant coefficients of ω imply $\mathrm{d}\omega = 0$. The complex coordinate $z = u + \mathrm{i}v$ provides the complex structure; changes between the coordinates of two fundamental domains are translations $z \mapsto z + 9m + 9\mathrm{i}n$, which are holomorphic. Consequently, J is integrable. The metric has constant coefficients in these local coordinates, so its Riemannian curvature vanishes. □

The Kähler property belongs to this differential realization. The graph retains its combinatorial description and the 81 vertices retain their arithmetic evaluations. The explicit choice of g and J shows

how the two levels are related and makes it possible to identify the additional datum used by the continuous realization.

3.1.3 Interaction of the evaluations and discrete curvature

3.1.3.1 Vertex potentials and link differences

We now work with the observables taking values in $R = \mathbb{Z}/9\mathbb{Z}$. To avoid confusing them with their integer representatives, we write

$$\overline{S}(x, y) = x + y, \qquad \overline{P}(x, y) = xy.$$

The map s_9 recovers the visible tables: $\Sigma = s_9 \circ \overline{S}$ and $\Pi = s_9 \circ \overline{P}$. In this subsection, subtractions and products of values are performed in R.

For $T : X_9 \to R$, define

$$\Delta_x T(x, y) = T(x + 1, y) - T(x, y), \qquad \Delta_y T(x, y) = T(x, y + 1) - T(x, y).$$

Each difference is a variable associated with the corresponding link. An ordered choice of potentials (T_x, T_y) determines the variables

$$A_x = \Delta_x T_x, \qquad A_y = \Delta_y T_y.$$

The circulation around the positively oriented plaquette is

$$\begin{aligned} F(T_x, T_y)(x, y) &= A_x(x, y) + A_y(x + 1, y) \\ &\quad - A_x(x, y + 1) - A_y(x, y) \\ &= \Delta_x \Delta_y T_y - \Delta_y \Delta_x T_x. \end{aligned} \tag{3.1}$$

The formula simultaneously fixes the orientation and order of the potentials.

Proposition 3.9 (Oriented curvature of the mixed evaluations)**.** *In every APP plaquette, we have*

$$F(\overline{S}, \overline{S}) = F(\overline{P}, \overline{P}) = 0, \qquad F(\overline{S}, \overline{P}) = 1, \qquad F(\overline{P}, \overline{S}) = -1.$$

Proof. The differences of the two potentials are

$$\Delta_x \overline{S} = 1, \quad \Delta_y \overline{S} = 1, \qquad \Delta_x \overline{P} = y, \quad \Delta_y \overline{P} = x.$$

Differencing them again yields $\Delta_x \Delta_y \overline{S} = \Delta_y \Delta_x \overline{S} = 0$ and $\Delta_x \Delta_y \overline{P} = \Delta_y \Delta_x \overline{P} = 1$. Substitution into (3.1) produces the four values. All identities are polynomial in the residue ring, so they remain valid in plaquettes crossing the cut of the positive representation. □

In the same plaquette, selecting sum in the horizontal direction and product in the vertical direction produces an oriented unit of circulation. Interchanging the two selections reverses its sign. The result is obtained from the actual order of the evaluations and their differences, before any physical reading.

Theorem 3.10 (Discrete Stokes identity)**.** *Let $R_{a,b}$ be a rectangle of $a \times b$ plaquettes in a lift of the grid. The oriented sum of its boundary links satisfies*

$$W_{\partial R_{a,b}}(\overline{S}, \overline{P}) = ab, \qquad W_{\partial R_{a,b}}(\overline{P}, \overline{S}) = -ab \quad \text{in } R.$$

Proof. We sum the first expression in (3.1) over the ab plaquettes. Each interior link is traversed once in each direction, with the same potential and opposite values, and its contributions cancel. Exactly the outer boundary links remain, with the induced orientation. The curvature of each plaquette is respectively 1 or -1, so the total sum is ab or $-ab$ modulo nine. □

For a one-plaquette rectangle the circulation is one unit; for a three-by-three rectangle its sum is nine and its residue class is zero. The difference between accumulated integer circulation and its modular evaluation again makes the lifting record relevant. The discrete curvature in this subsection and the Riemannian curvature of the Kähler realization act on different objects: the former measures the mixing of two arithmetic potentials on the links; the latter belongs to the declared metric on the continuous surface.

3.1.4 Selection and spectral decomposition of the central block

3.1.4.1 Intrinsic selection by congruence

In the main matrix, consider the blocks of two consecutive rows and two consecutive columns with matching indices. For $1 \le k \le 8$, their integer evaluations are

$$\widetilde{B}_k = \begin{pmatrix} k^2 & k(k+1) \\ k(k+1) & (k+1)^2 \end{pmatrix}.$$

Their entrywise reduction by ρ_9 defines B_k.

Theorem 3.11 (Uniqueness of the adjacent block with equal diagonals)**.** *The equality condition for the two diagonal entries of B_k selects only $k = 4$. The resulting block is*

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Proof. Equality of positive representatives is equivalent to equality of their classes. Therefore,

$$\rho_9(k^2) = \rho_9((k+1)^2) \quad \Longleftrightarrow \quad 2k + 1 \equiv 0 \pmod 9.$$

The inverse of two modulo nine is five. Multiplying the congruence by five gives $k \equiv -5 \equiv 4 \pmod 9$. Among the indices $1, \dots, 8$, only 4 appears. The four entries are the reductions of $16, 20, 20, 25$, producing $7, 2, 2, 7$. □

The condition selecting this block depends only on adjacent APP entries. The fixed point $(5, 5)$ of central inversion and the block of positions $\{4, 5\} \times \{4, 5\}$ have different types: the former is a position; the latter brings together four evaluations. Their relationships are maintained through the indices, without identifying the point with the matrix.

3.1.4.2 Symmetric and antisymmetric modes

We define the exchange involution and its two projectors:

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad P_+ = \frac{I + R}{2}, \qquad P_- = \frac{I - R}{2}.$$

The vectors $(1, 1)$ and $(1, -1)$ generate their respective eigenspaces. Since $R^2 = I$, we have $P_\pm^2 = P_\pm$, $P_+P_- = 0$ and $P_+ + P_- = I$.

Proposition 3.12 (Exact decomposition of the block)**.** *The selected block satisfies*

$$B_c = 7I + 2R = 9P_+ + 5P_-, \qquad \det B_c = 45, \qquad \operatorname{tr} B_c = 14.$$

Its eigenvalue difference is four and its exchange coefficient is two.

Proof. Substituting $I = P_+ + P_-$ and $R = P_+ - P_-$ into $7I + 2R$ yields $9P_+ + 5P_-$. The eigenvalues are therefore nine and five; their product is 45 and their sum 14. The difference is $9 - 5 = 4$, while the coefficient of the operator R is the two in the antidiagonal entries. □

The ordered decimal concatenation of each row produces the blocks 72 and 27. Concatenation of the diagonals produces 77 and 22. These readings satisfy

$$72 + 27 = 77 + 22 = 99, \qquad 72 - 27 = 45, \qquad 77 - 22 = 55 = 54 + 1.$$

The equality $72 - 27 = \det B_c$ relates two explicit evaluations of the same block: decimal concatenation and determinant. Each reading retains its rule; equality of their results is a verifiable identity between these rules.

3.1.5 Conservative normalizations of the block and Lorentzian realization

3.1.5.1 Stochastic normalization and differential contraction

The sum of each row and each column of B_c equals nine. Division by nine defines the doubly stochastic matrix

$$P_B = \frac{1}{9} B_c = \begin{pmatrix} 7/9 & 2/9 \\ 2/9 & 7/9 \end{pmatrix} = P_+ + \frac{5}{9} P_-.$$

Its entries are positive and its row and column sums are one.

Proposition 3.13 (Iteration of the two modes)**.** *For every $n \geq 0$,*

$$P_B^n = P_+ + \left(\frac{5}{9}\right)^n P_-.$$

If $v = (a, b)^\mathsf{T}$, the sum of its components is preserved and their difference is multiplied by $(5/9)^n$.

Proof. Orthogonality of the projectors eliminates all cross products in the power. Their positive powers are themselves, yielding the formula. Moreover,

$$v = \frac{a+b}{2}(1, 1)^\mathsf{T} + \frac{a-b}{2}(1, -1)^\mathsf{T}.$$

The first component is fixed and the second is multiplied by $(5/9)^n$. This simultaneously proves preservation of the sum and contraction of the difference. □

This reading describes a local transformation of two components. Its factor $5/9$ and gap $1 - 5/9 = 4/9$ come from the spectrum of the selected block. The global TPK operator uses additional states and records; the two scales retain their own domains.

3.1.5.2 Determinantal normalization and two-dimensional Minkowski form

Let $\eta = \mathrm{diag}(1, -1)$ and define

$$M_c = \frac{B_c}{\sqrt{45}}.$$

The normalization is fixed by the determinant just obtained from the block.

Theorem 3.14 (Local Lorentzian realization of APP)**.** *The matrix M_c satisfies*

$$M_c^\mathsf{T} \eta M_c = \eta, \qquad \det M_c = 1.$$

It preserves the future component of the timelike cone of the form $t^2 - x^2$ and belongs to $SO^+(1, 1)$. If

$$\theta_c = \frac{1}{2} \log \frac{9}{5},$$

then

$$M_c = \exp(\theta_c R), \qquad \frac{5}{9} = \exp(-2\theta_c).$$

Proof. Direct multiplication gives

$$B_c^{\mathsf{T}} \eta B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} \begin{pmatrix} 7 & 2 \\ -2 & -7 \end{pmatrix} = \begin{pmatrix} 45 & 0 \\ 0 & -45 \end{pmatrix} = 45\eta.$$

Dividing by 45 proves invariance of the form. Since $\det B_c = 45$, dividing each of the two columns by $\sqrt{45}$ gives $\det M_c = 1$.

For $t > |x|$, we have $7t + 2x \geq 7t - 2|x| > 0$. The first coordinate of $M_c(t, x)$ is positive and the timelike form is preserved, so it remains in the same component of the cone.

Finally, the spectral decomposition produces

$$M_c = \sqrt{\frac{9}{5}}\, P_+ + \sqrt{\frac{5}{9}}\, P_-.$$

Since $R = P_+ - P_-$, its exponential is $e^{\theta_c} P_+ + e^{-\theta_c} P_-$. The definitions of θ_c identify the two coefficients exactly. The last identity follows from $-2\theta_c = -\log(9/5)$. □

The same integer matrix therefore admits two explicit normalizations. Normalization by the row sum preserves the uniform mode and contracts the differential mode. Normalization by the square root of the determinant preserves an indefinite form. The relation $5/9 = e^{-2\theta_c}$ links the two readings of the block. The proved realization has dimension $1 + 1$; subsequent incidence constructions and dimensional maps determine its physical extensions.

3.1.6 Reduction by ternary classes and aggregate spectral structure

3.1.6.1 Averaging of the two evaluations

The projection from classes modulo nine to classes modulo three determines

$$C_1 = \{1, 4, 7\}, \qquad C_2 = \{2, 5, 8\}, \qquad C_0 = \{3, 6, 9\}.$$

Each set $C_a \times C_b$ contains nine positions. For a real evaluation T on D_9^2, we define its aggregate matrix by

$$(M_T)_{ab} = \frac{1}{9} \sum_{i \in C_a} \sum_{j \in C_b} T(i, j), \qquad a, b \in \{1, 2, 0\}.$$

The index order $(1, 2, 0)$ is fixed in rows and columns.

Proposition 3.15 (Aggregate APP matrices)**.** *Averaging the residue tables gives*

$$M_\Pi = \begin{pmatrix} 4 & 5 & 6 \\ 5 & 4 & 6 \\ 6 & 6 & 9 \end{pmatrix}, \qquad M_\Sigma = \begin{pmatrix} 5 & 6 & 4 \\ 6 & 4 & 5 \\ 4 & 5 & 6 \end{pmatrix}.$$

The totals are preserved through

$$9 \sum_{a,b} (M_\Pi)_{ab} = 459, \qquad 9 \sum_{a,b} (M_\Sigma)_{ab} = 405.$$

Proof. For multiplication, the block $C_1 \times C_1$ contains each value $1, 4, 7$ three times, so its average is $(1 + 4 + 7)/3 = 4$. The block $C_1 \times C_2$ contains each value $2, 5, 8$ three times and has average five. The blocks of a unit class with C_0 contain each value $3, 6, 9$ three times and have average six. The block $C_2 \times C_2$ has average four and the block $C_0 \times C_0$ consists of nine values of nine. Symmetry completes the matrix.

In addition, the block $C_a \times C_b$ distributes the three representatives of the class $a + b$ modulo three uniformly. The averages of the classes C_1, C_2, C_0 are respectively four, five and six. Evaluating $a + b$ in the fixed order yields M_Σ. The nine blocks partition the 81 positions and each average is multiplied by nine to recover its sum. This proves the two identities for totals. □

We obtain $\sum M_\Pi = 51$ and $\sum M_\Sigma = 45$. The difference six corresponds to the aggregate structure; restoring the multiplicity of nine positions per block recovers $9 \cdot 6 = 54$. This calculation connects ternary aggregation with the global contrast in section 1.1.5.

3.1.6.2 Form of signature two plus one and hyperbolic sublattice

Theorem 3.16 (Exact spectrum of the aggregate multiplicative matrix)**.** *The characteristic polynomial and spectrum of M_Π are*

$$\det(\lambda I - M_\Pi) = (\lambda + 1)((\lambda - 9)^2 - 72),$$
$$\mathrm{Spec}(M_\Pi) = \{-1, 9 - 6\sqrt{2}, 9 + 6\sqrt{2}\}.$$

Its determinant is -9 and the quadratic form $v \mapsto v^{\mathsf{T}} M_\Pi v$ has signature $(2, 1)$.

Proof. The vector $v_- = (1, -1, 0)$ satisfies $M_\Pi v_- = -v_-$. The plane generated by $v_+ = (1, 1, 0)$ and $v_0 = (0, 0, 1)$ is invariant, since

$$M_\Pi v_+ = 9v_+ + 12v_0, \qquad M_\Pi v_0 = 6v_+ + 9v_0.$$

The matrix of the restriction in that basis is $\left(\begin{smallmatrix} 9 & 6 \\ 12 & 9 \end{smallmatrix}\right)$ and its characteristic polynomial is $(\lambda - 9)^2 - 72$. Adding the factor $\lambda + 1$ from the first direction gives the formula. The two roots of the quadratic factor are positive because $81 > 72$. The direction with eigenvalue -1 is negative and the other two are positive. The product of the eigenvalues is $-(81 - 72) = -9$. □

The restriction to the invariant plane is written

$$\begin{pmatrix} 9 & 6 \\ 12 & 9 \end{pmatrix} = 3H, \qquad H = \begin{pmatrix} 3 & 2 \\ 4 & 3 \end{pmatrix}, \qquad \det H = 1.$$

The eigenvalues of H are $3 \pm 2\sqrt{2} = (1 \pm \sqrt{2})^2$. The matrix whose columns are v_-, v_+, v_0 has determinant of absolute value two. These vectors therefore generate a sublattice of index two in $\mathbb{Z}^3$. The decomposition is complete as a real decomposition; its integral version explicitly retains this index.

3.1.6.3 Localization of the contrast in the nonunit sector

The sector formed by the rows and columns with indices $3, 6, 9$ comprises $27 + 27 - 9 = 45$ positions. Their intersection $C_0 \times C_0$ has nine entries of value nine and sums to 81. The remaining four blocks, $C_0 \times C_1$, $C_0 \times C_2$, $C_1 \times C_0$ and $C_2 \times C_0$, each sum to 54 and contribute 216. Thus,

$$297 = 216 + 81 = 3 \cdot 72 + 3 \cdot 27 = 3(72 + 27).$$

The partition by ternary classes and the concatenations of the central block produce these identities through their respective procedures. The factor three remains explicit; the value 297 belongs to a sum over 45 positions and the value 99 belongs to a concatenation of pairs from the block.

The numbers appearing throughout the development thus acquire precise meanings: four is the local spectral separation; two, the exchange coefficient; six, the difference of aggregate averages; fifty-four, the global residue contrast. Their relationships are proved through the operations connecting each level.

3.1.7 Operator realization of trajectories

Let $\mathcal{H}_X = \ell^2(X_9)$, with the orthonormal basis $(e_x)_{x\in X_9}$, and let U be an operator whose matrix elements satisfy $U_{yx} = 0$ when $x \to y$ is not an edge of $\mathcal{G}_9$. The hypothesis expresses locality with respect to the graph already constructed. Once that operator is fixed, the composition of its transitions has an exact expansion.

Theorem 3.17 (Finite path expansion of the transition)**.** *For $r \geq 1$ and positions $i, f \in X_9$,*

$$(U^r)_{fi} = \sum_{\substack{\gamma: i\to f \\ |\gamma|=r}} \prod_{k=0}^{r-1} U_{x_{k+1},x_k}, \qquad \gamma = (x_0 = i, x_1, \ldots, x_r = f).$$

Proof. For $r = 1$, the statement coincides with the entry U_{fi}, and entries outside the graph are zero by hypothesis. Assume the formula holds for r. Matrix multiplication gives

$$(U^{r+1})_{fi} = \sum_{j\in X_9} U_{fj}(U^r)_{ji}.$$

We substitute the inductive expression for $(U^r)_{ji}$. Each term is a trajectory of length r from i to j, followed by the final edge $j \to f$. Every trajectory of length $r+1$ has a unique penultimate vertex j and a unique truncation of length r. The sum therefore traverses each trajectory exactly once, with the product of its transition elements. □

The expansion expresses the composition of a declared operator through APP trajectories. The complete record of a TPK transition also incorporates the selected sheet, the tritic signature, the carry, the phase and memory. The support and operator expansion of this chapter provide the domains on which this enriched update is constructed. The dependency order remains explicit: first positions and evaluations, then trajectories and their realizations, and upon them the law of selection and transport with memory.

3.2 TRIT as an oriented ternary state: carry memory, temporal order, and 3 quadratic regimes

TRIT preserves within a single state the published residue, the carry cocycle, orientation, and compositional memory. Its 3 algebraic regimes are not editorial layers: they are correlative realizations of the quadratic operator $J_\tau^2 = -\tau I$, linked to the 2 orientations of time and to the threshold state.

3.3 Ternary local state and transport orientation

TRIT is the ternary coordinate that preserves the local orientation of a transition. Its definition precedes any temporal interpretation: the three values distinguish algebraic types of transport and acquire a reading of past, threshold, or future only when an ordered parameter is fixed.

3.3.1 Oriented ternary signature and state space

The space of visible signatures is

$$\widehat{\mathbb{T}} = \{-1, 0, +1\}.$$

Its elements are oriented symbols, not results of an operation in $\mathbb{Z}$. The balanced map

$$\mathbb{F}_3 \longrightarrow \widehat{\mathbb{T}}, \qquad 0 \mapsto 0, \quad 1 \mapsto +1, \quad 2 \mapsto -1,$$

allows passage from the ternary residue to the oriented signature.

Definition 3.18 (Complete state of the TRIT and carry fiber)**.** In a local step whose amplitude requires at most one carry, the balanced ternary decomposition is written

$$\widehat{\tau} = (r, c), \qquad a + b = r + 3c, \qquad r, c \in \{-1, 0, +1\}.$$

The first coordinate r is the visible residue, and the second c preserves the quotient that made that reading possible. In particular, the fiber over visible zero contains three distinct states:

$$0^+ = (0, +1), \qquad 0^0 = (0, 0), \qquad 0^- = (0, -1), \qquad \mathrm{vis}(0^+) = \mathrm{vis}(0^0) = \mathrm{vis}(0^-) = 0.$$

This local separation between residue and quotient is what, in the subsequent Bockstein–Hensel lift, takes the matrix form

$$x_k A = u_k + 3x_{k+1}.$$

There u_k publishes the residue of level k, while x_{k+1} transports the memory necessary to recover the lift x_k. Therefore, a visible zero does not by itself determine the state or its admissible future. This assertion is algebraic: it does not convert $0^\pm$ into an infinitesimal, an energy, a physical torsion, or a temporal interval.

A visible trit does not determine the set of admissible continuations. The complete transport state space contains the fields

$$x = (t, \mu, o, h, c, \sigma, \lambda, g).$$

Here $t \in \widehat{\mathbb{T}}$ is the visible signature; $\mu \in \mathsf{M} := \{\Sigma, \Pi, \varnothing\}$, the label of the additive, multiplicative, or neutral observable; o, the orientation; h, the extension coordinate; c, the accumulated carry; σ, the boundary signature; λ, the trajectory register; and $g \in \mathbb{Z}/9\mathbb{Z}$, the phase. The projection $x \mapsto t$ removes all other components.

Remark 3.19 (Distinction between symbol and state). Two states may display the same trit and have different continuations. Nor does a ternary word by itself determine the observable label, orientation, carry, or monodromy. This distinction explains why five regions of π may share a word w_π without becoming a single region.

3.4 Quadratic algebras and transport regimes

3.4.1 3 associated quadratic algebras

For $\tau \in \widehat{\mathbb{T}}$, let $\bar{\tau} \in \{-1, 0, +1\} \subset \mathbb{R}$ be its image under the preceding balanced identification. We consider the unital real algebra

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \bar{\tau}),$$

in which J denotes the class of X and I the unit. This convention separates the TRIT symbol from its scalar value. According to the sign, three types are obtained:

$$\begin{aligned} \tau = +1 \quad &: \quad J^2 = -I, \quad \text{elliptic or complex type,} \\ \tau = 0 \quad &: \quad J^2 = 0, \quad \text{parabolic or nilpotent type,} \\ \tau = -1 \quad &: \quad J^2 = +I, \quad \text{hyperbolic or split type.} \end{aligned}$$

Exponentials exhibit the difference:

$$e^{tJ} = \begin{cases} \cos t + J \sin t, & J^2 = -I, \\ 1 + tJ, & J^2 = 0, \\ \cosh t + J \sinh t, & J^2 = +I. \end{cases}$$

The three algebras are, respectively, the complex extension, the algebra of dual numbers, and the split real algebra. Their exponential subgroups produce elliptic, parabolic, and hyperbolic evolutions without introducing any additional continuous geometry into the definition of TRIT. The concrete real realizations selected by the APP Coxeter object, the nilpotent generator, and the TPK sheet incidence are constructed, without duplicating this abstract classification, in section 3.5.6.

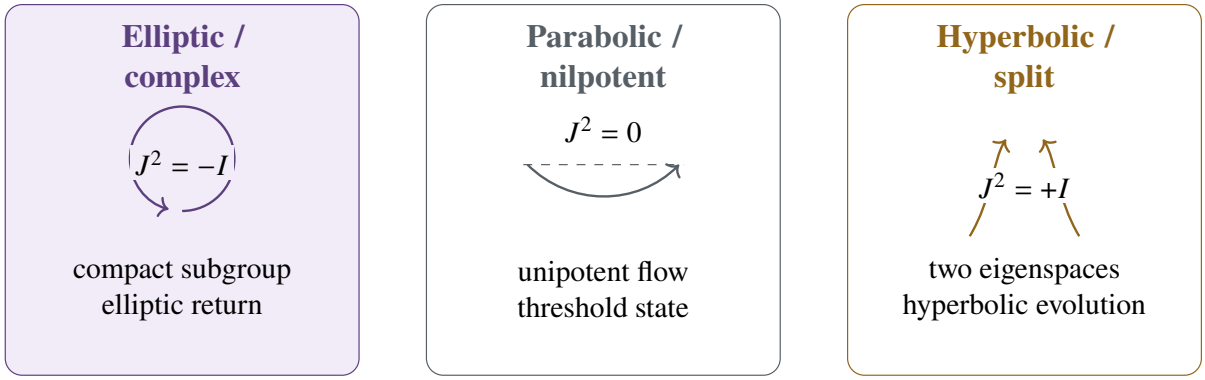

Figure 3.1: Three algebraic types associated with the oriented ternary state. The first line records the algebraic identities; the second, their interpretation with respect to an ordered parametrization.

3.4.2 Compatibility and parameterized trajectories

The expression *All Possible Paths* invites one to imagine paths traversed in time. HMT places the object one step earlier. Let Ω_{HMT} be a set of local states endowed with an admissible transition relation $\rightsquigarrow$, a TRIT signature, and transport data to be typed in the following section. If $\mathcal{T}$ is a discretely ordered set, a parametrized trajectory is a map

$$\gamma : \mathcal{T} \longrightarrow \Omega_{\mathrm{HMT}}$$

that satisfies $\gamma(t) \rightsquigarrow \gamma(t^+)$ for every successor t^+. The ordering of $\mathcal{T}$ converts compatibility into a parameterized sequence. Before an order is chosen, there is only a compatible family indexed by the corresponding graph or poset; it is not called a section unless a projection $p : E \to \mathcal{T}$ with $p \circ \gamma = \mathrm{id}_{\mathcal{T}}$ has been declared. Consequently, a finite sum over paths can be read as a sum over temporalizations of a structure that, at its primary level, presupposes no external time.

3.4.3 Ordered parameterization of compatibility

An ordered parametrization permits return, threshold, and opening to be interpreted as three relative positions in an evolution. The convention used in Figure 3.1 is

$$\begin{aligned} J^2 = -I &\quad\rightsquigarrow\quad \text{return and reverse orientation,} \\ J^2 = 0 &\quad\rightsquigarrow\quad \text{threshold state,} \\ J^2 = +I &\quad\rightsquigarrow\quad \text{decomposition into two eigendirections.} \end{aligned}$$

In the adopted temporal parametrization, $+1$ represents return, memory, and past; 0, threshold and present; and -1, bidirectional opening and future. This ordered reading does not alter the three preceding quadratic types. The exact involution, typed for each $n \geq 1$,

$$C_{\mathrm{rev}} : \widehat{\mathbb{T}}^n \longrightarrow \widehat{\mathbb{T}}^n, \qquad C_{\mathrm{rev}}(\tau_1, \ldots, \tau_n) = (-\tau_n, \ldots, -\tau_1)$$

exchanges $+1$ and -1, preserves 0, and satisfies $C_{\mathrm{rev}}^2 = \mathrm{id}_{\widehat{\mathbb{T}}^n}$. Thus, temporal orientation is not introduced as a fourth state: it results from the parametrization of the signature together with an involution that conserves the threshold.

3.4.4 Spectral decomposition of the hyperbolic type

In the hyperbolic type, the projectors

$$P_{\pm} = \frac{I \pm J}{2}$$

separate two proper directions. The involution that changes orientation exchanges them. Algebraically, $P_+P_- = 0$, $P_+ + P_- = I$, and $JP_{\pm} = \pm P_{\pm}$. Therefore the hyperbolic type contains two complementary proper subspaces and an exact operation that permutes them.

Remark 3.20 (Complete structure of the TRIT state). TRIT is not a substitute for the signs $-, 0, +$. It is the minimal observable of a state with an observable label, orientation, and path record. Its three associated algebras make it possible for one and the same support to admit elliptic closures, parabolic thresholds, and hyperbolic openings before a temporal evaluation is fixed.

3.5 Quadratic algebras of order 9

The identity $A_W^2 = -I_6$, obtained in the preceding section by reducing the Paley conference matrix, contains more information than a modular orthogonality relation. It determines a scalar extension of degree two, turns the six-dimensional ternary space into a three-dimensional space over the field of nine elements, and permits the ternary Golay code to be written as the graph of a quadratic unit. This section develops those consequences and distinguishes them from the characteristic-nine arithmetic used by the Hensel branch.

3.5.1 Estructura of $\mathbb{F}_9$ inducida by Paley

The polynomial $X^2 + 1$ has no roots in $\mathbb{F}_3$: its values in $0, 1, 2$ are $1, 2, 2$. It is therefore irreducible, and the quotient

$$\mathbb{F}_9 := \mathbb{F}_3[\iota]/(\iota^2 + 1)$$

is a field of nine elements.

Theorem 3.21 (Structure quadratic induced by A_W)**.** *Let $V = \mathbb{F}_3^6$, written by means of row vectors, and let $J(v) = vA_W$. The rule*

$$(a + b\iota)v := av + bJ(v), \qquad a, b \in \mathbb{F}_3,$$

turns V into a vector space of dimension three over $\mathbb{F}_9$. In the coordinates fixed by the Paley construction,

$$\mathbb{F}_3^6 \cong \mathbb{F}_9^3.$$

Proof. The equality $J^2 = -I$ makes the evaluation $\mathbb{F}_3[X] \to \mathrm{End}_{\mathbb{F}_3}(V)$, $X \mapsto J$, vanish on the ideal $(X^2 + 1)$. The action therefore factorizes through the field $\mathbb{F}_9$. Since $[\,\mathbb{F}_9 : \mathbb{F}_3\,] = 2$ and $\dim_{\mathbb{F}_3} V = 6$, one obtains $\dim_{\mathbb{F}_9} V = 3$. □

The isomorphism depends on the coordinate system that fixes A_W. The assertion does not follow from the mere cardinal $3^6 = 9^3$: the matrix exhibits multiplication by all scalars $a + b\iota$ and therefore provides the complete linear structure.

3.5.2 The ternary code as an isotropic graph

The code's generating application is

$$c(q) = (q, qA_W).$$

After identifying J with multiplication by ι, its image admits the writing

$$C_W = \{(q, \iota q) : q \in \mathbb{F}_9^3\},$$

where both components are regarded, by restriction of scalars, as vectors of $\mathbb{F}_3^6$.

Proposition 3.22 (Isotropic maximality)**.** *With respect to the standard bilinear form of $\mathbb{F}_3^{12}$, the subspace C_W is totally isotropic and maximal among the totally isotropic subspaces.*

Proof. The generator matrix $G = (I_6 \mid A_W)$ satisfies

$$GG^{\mathsf{T}} = I_6 + A_W A_W^{\mathsf{T}} = I_6 + 2I_6 = 0.$$

The generated space is therefore totally isotropic. It has dimension six, half the dimension of the nondegenerate ambient space, and is therefore maximal; indeed, it coincides with its orthogonal dual. □

The root of $-I$ thus appears as a finite incidence transformation. The analytic complex field is not introduced into the system: a quadratic structure over $\mathbb{F}_3$ is obtained, sufficient to organize the polarity, the code, and its two eigenspaces after extending scalars.

3.5.3 Characteristic 9 and characteristic 3

Two sets of 729 states enter the construction:

$$(\mathbb{Z}/9\mathbb{Z})^3 \qquad \text{and} \qquad \mathbb{F}_9^3.$$

They are not isomorphic as additive groups or as rings. The first has characteristic nine and contains elements of order nine; the second has characteristic three and its entire additive group has exponent three.

For $a, b \in \mathbb{F}_3$, choosing representatives $\widetilde{a}, \widetilde{b} \in \{0, 1, 2\}$, let

$$\beta(a, b) = \widetilde{a} + 3\widetilde{b} \pmod 9.$$

The coordinate map induced by β is a bijection of sets between $\mathbb{F}_3^6$ and $(\mathbb{Z}/9\mathbb{Z})^3$, but does not preserve addition. Indeed, if

$$\kappa(a, c) := \left\lfloor \frac{\widetilde{a} + \widetilde{c}}{3} \right\rfloor,$$

then

$$\beta(a, b) + \beta(c, d) = \beta\big(a + c,\ b + d + \kappa(a, c)\big),$$

with the coordinates of the second member reduced modulo three. For example,

$$\beta(2, 0) + \beta(2, 0) = \beta(1, 1),$$

whereas coordinatewise addition in $\mathbb{F}_3^2$ would give $(1, 0)$. The second coordinate of $\beta(1, 1)$ preserves the quotient of Euclidean division; this term is precisely the datum lost under componentwise reduction.

This distinction types the two readings of the cardinal 729. The realization $(\mathbb{Z}/9\mathbb{Z})^3$ preserves residue and quotient; the realization $\mathbb{F}_9^3$ converts each ternary pair into a scalar of a quadratic extension. One prolongs arithmetic with division memory; the other organizes exceptional incidence.

Proposition 3.23 (Two typed readings of the same ternary support)**.** *Once the set-theoretic section used in β, the basis, the polarization, and the operator J of theorem 3.21 are fixed, there exists the diagram of set bijections*

$$\boxed{(\mathbb{Z}/9\mathbb{Z})^3 \xleftarrow{\beta^{\times 3}} \mathbb{F}_3^6 \xrightarrow{\iota_J} \mathbb{F}_9^3.}$$

The left arrow transports the nonadic sum twisted by the carry cocycle κ; the right arrow transports the linear structure over $\mathbb{F}_9$ determined by $J^2 = -I$. The two arrows share the coordinate support $\mathbb{F}_3^6$, but do not identify their algebraic laws.

Proof. The formula

$$\beta(a,b)+\beta(c,d)=\beta\big(a+c,b+d+\kappa(a,c)\big)$$

proves that $\beta^{\times 3}$ is a bijection with twisted addition and is not an isomorphism from the componentwise sum of $\mathbb{F}_3^6$. By theorem 3.21, the choice of J turns that same six-dimensional ternary space into a three-dimensional space over $\mathbb{F}_3[J]\cong\mathbb{F}_9$, thereby defining ι_J. □

The proposition is a synthesis demonstrated with explicit starting structure. It does not assert a canonical identification between $(\mathbb{Z}/9\mathbb{Z})^3$ and $\mathbb{F}_9^3$: the first contains additive elements of order nine, whereas the second has additive exponent three. The cocycle measures precisely the information that would be lost by confusing both laws.

3.5.4 Classification of Quadratic Algebras

Over a field of characteristic other than two, a unital quadratic algebra is classified by the type of its defining polynomial. Over $\mathbb{F}_3$ the three representatives may be chosen as

$$Q_{\mathrm{e}}=\mathbb{F}_3[t]/(t^2+1)\cong\mathbb{F}_9,$$

$$Q_{\mathrm{n}}=\mathbb{F}_3[\varepsilon]/(\varepsilon^2),\qquad Q_{\mathrm{s}}=\mathbb{F}_3[r]/(r^2-1)\cong\mathbb{F}_3\times\mathbb{F}_3.$$

Theorem 3.24 (Classification of the quadratic algebras over $\mathbb{F}_3$)**.** *The relations*

$$J^2=-I,\qquad N^2=0,\qquad R^2=I$$

define actions of Q_{e}, Q_{n}, and Q_{s}, respectively. These three algebras have nine elements and are mutually nonisomorphic: the first is a field; the second contains nonzero nilpotents; the third contains nontrivial idempotents.

Proof. Each relation makes the evaluation of $\mathbb{F}_3[t]$ factor through the corresponding ideal. The irreducibility of t^2+1 proves that Q_{e} is a field. In Q_{n}, the class ε is nonzero and satisfies $\varepsilon^2=0$. In Q_{s}, since $2^{-1}=2$ in $\mathbb{F}_3$, the elements

$$e_+=2(1+r),\qquad e_-=2(1-r)$$

are nontrivial orthogonal idempotents and sum to the unit. Being a field, possessing a nonzero nilpotent, and possessing nontrivial idempotents are properties invariant under isomorphism. □

Three copies of the two-dimensional regular representation yield three six-dimensional actions on $\mathbb{F}_3$. The relation $J^2=-I$ corresponds to Paley polarity; relation $N^2=0$ describes the linearization of an extension with quotient; relation $R^2=I$ separates two summands through the idempotents $e_\pm$. This classification supplies the finite algebraic framework in which the elliptic, nonreduced, and split structures are distinguished without appeal to a continuous geometry.

The construction does not replace $\mathbb{C}$: the field $\mathbb{F}_9$ does not possess the topology, completeness, or complex analytic structure. The exact result is different: a square root of $-I$ and the corresponding extension of scalars emerge from the incidence matrix already constructed within the ternary system.

3.5.5 Integral quadratic form and finite and real specializations

The finite root and the real operator root are coordinated through a common integral presentation. Let

$$Q_{\mathbb{Z}}:=\mathbb{Z}[u]/(u^2+1). \tag{3.2}$$

Its change of basis are

$$Q_{\mathbb{Z}}\otimes_{\mathbb{Z}}\mathbb{F}_3\cong\mathbb{F}_3[u]/(u^2+1)\cong\mathbb{F}_9,$$

and

$$Q_{\mathbb{Z}} \otimes_{\mathbb{Z}} \mathbb{R} \cong \mathbb{R}[u]/(u^2+1).$$

Theorem 3.25 (Two realizations of an integral quadratic form)**.** *The finite representation $u \mapsto A_W$ on $\mathbb{F}_3^6$ and the real representation $u \mapsto J_{\mathrm{e}}$ on V_{e}, constructed in the theorem 3.26, realize, after their respective changes of basis, the same integral relation*

$$u^2 + 1 = 0.$$

Proof. The equality $A_W^2 + I_6 = 0$ makes the evaluation $\mathbb{F}_3[u] \to \mathrm{End}_{\mathbb{F}_3}(\mathbb{F}_3^6)$ factor through (u^2+1). In the same way, $J_{\mathrm{e}}^2 + I = 0$ makes $\mathbb{R}[u] \to \mathrm{End}_{\mathbb{R}}(V_{\mathrm{e}})$ factor. The two representations follow from specializations of $Q_{\mathbb{Z}}$; no unital homomorphism $\mathbb{F}_9 \to \mathbb{R}$ exists or is used. □

The common source coordinates relations; it does not identify modules of distinct characteristics. The finite branch preserves incidence; the real branch incorporates the analytic structure required for the operator exponential.

3.5.6 3 generators concrete of the TRIT regimes

The section 3.4 fixes the three abstract quadratic types $J^2 = -I$, $J^2 = 0$, and $J^2 = I$, while the theorem 3.24 provides their finite models on $\mathbb{F}_3$. Those objects must not be confused with the subsequent real realizations. Here three real spaces and three concrete operators are fixed, each obtained from its declared causal antecedent.

Let

$$V_{\mathrm{e}} = A_2 \otimes_{\mathbb{Z}} \mathbb{R}, \qquad V_{\mathrm{p}} = \mathbb{R}^2, \qquad V_{\mathrm{h}} = \mathbb{R}^2.$$

On V_{e} acts the Coxeter C of the proposition 1.94. On V_{p} it fixes

$$N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Finally, the theorem 6.20 constructs

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad A := F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$$

on V_{h}.

Theorem 3.26 (Three concrete realizations of the TRIT regimes)**.** *Define*

$$J_{\mathrm{e}} := \frac{2C + I}{\sqrt{3}}, \qquad J_{\mathrm{p}} := N, \qquad J_{\mathrm{h}} := \frac{2A - 3I}{\sqrt{5}}.$$

Then

$$J_{\mathrm{e}}^2 = -I_{V_{\mathrm{e}}}, \qquad J_{\mathrm{p}}^2 = 0, \qquad J_{\mathrm{h}}^2 = I_{V_{\mathrm{h}}}.$$

Therefore, for $t \in \mathbb{R}$,

$$\exp(tJ_{\mathrm{e}}) = \cos t\, I + \sin t\, J_{\mathrm{e}}, \qquad \exp(tJ_{\mathrm{p}}) = I + tJ_{\mathrm{p}},$$

$$\exp(tJ_{\mathrm{h}}) = \cosh t\, I + \sinh t\, J_{\mathrm{h}}.$$

Furthermore, in the elliptic branch,

$$C = -\frac{1}{2} I + \frac{\sqrt{3}}{2} J_{\mathrm{e}},$$

and, for $n \in \mathbb{Z}$,

$$C^n = \cos\left(\frac{2\pi n}{3}\right) I + \sin\left(\frac{2\pi n}{3}\right) J_{\mathrm{e}}.$$

In the hyperbolic branch, the form

$$G = \begin{pmatrix} 2 & 1 \\ 1 & -2 \end{pmatrix}$$

has signature $(1,1)$ *and satisfies*

$$A^{\mathsf{T}} G A = G, \qquad \det A = 1, \qquad \operatorname{tr} A = 3.$$

If

$$\eta := \operatorname{arcosh} \frac{3}{2} = 2 \log \varphi,$$

then

$$A = \cosh(\eta) I + \sinh(\eta) J_{\mathrm{h}}, \qquad A^n = \cosh(n\eta) I + \sinh(n\eta) J_{\mathrm{h}}.$$

Proof. The polinomio caracteristico of the Coxeter is $X^2 + X + 1$; by Cayley–Hamilton,

$$C^2 + C + I = 0.$$

From here,

$$(2C + I)^2 = 4C^2 + 4C + I = -3I,$$

and, therefore, $J_{\mathrm{e}}^2 = -I$. The identity for C^n follows from $C = -\frac{1}{2} I + \frac{\sqrt{3}}{2} J_{\mathrm{e}}$.

Direct multiplication gives $N^2 = 0$. Hence, the exponential series truncates exactly:

$$\exp(tN) = I + tN.$$

For the third branch,

$$A^{\mathsf{T}} G A = G, \qquad \det G = -5 < 0,$$

so that G is nondegenerate and has signature $(1,1)$. Likewise,

$$(2A - 3I)^2 = 5I,$$

therefore $J_{\mathrm{h}}^2 = I$. As

$$\cosh(2 \log \varphi) = \frac{3}{2}, \qquad \sinh(2 \log \varphi) = \frac{\sqrt{5}}{2},$$

we obtain

$$A = \frac{3}{2} I + \frac{\sqrt{5}}{2} J_{\mathrm{h}} = \cosh(\eta) I + \sinh(\eta) J_{\mathrm{h}}.$$

The formula for A^n follows from the exponential law. The three general expressions are obtained, in each case, by separating the even and odd powers in the exponential series. □

Corollary 3.27 (Extended Euler equation by the tritic parameter)**.** *For* $\tau \in \{+1, 0, -1\}$*, let* J_τ *be one of the preceding generators, normalized by*

$$J_\tau^2 = -\tau I.$$

Define the functions of the quadratic family.

$$C_\tau(t) = \begin{cases} \cos t, & \tau = +1, \\ 1, & \tau = 0, \\ \cosh t, & \tau = -1, \end{cases} \qquad S_\tau(t) = \begin{cases} \sin t, & \tau = +1, \\ t, & \tau = 0, \\ \sinh t, & \tau = -1. \end{cases}$$

Then the three branches satisfy a single exponential identity:

$$\boxed{\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau.} \tag{3.3}$$

In particular,

$$\exp(\pi J_{+1}) + I = 0, \qquad \exp(J_0) = I + J_0, \qquad \exp\bigl(2\log\varphi\, J_{-1}\bigr) = F_{\mathrm{av}}^2.$$

The first equality is Euler's matrix closure; the second realizes the parabolic threshold transport; the third incorporates Fibonacci self-scaling through the eigenvalues φ and $-\varphi^{-1}$.

Proof. The identity (3.3) is obtained by separating the even and odd powers of the exponential series and using $J_\tau^2 = -\tau I$. The three specializations follow from $J_{+1}^2 = -I$, $J_0^2 = 0$, and from the already proved equality $F_{\mathrm{av}}^2 = \exp(2\log\varphi\, J_{-1})$. □

3 **exact realizations of the quadratic regimes of the TRIT** The elliptic, parabolic, and hyperbolic branches realize, respectively, the internal Coxeter element of A_2, the nilpotent generator, and the incidence F_{av} induced by the TPK calendar. The matrix identities are exact in the declared spaces and gauges.

Realization conditions of the 3 **quadratic regimes of TRIT and obstructions of algebraic nondegeneration** The isolated TRIT type organizes the three quadratic possibilities, but it does not by itself select the operators C, N, and F_{av}: the selection uses, respectively, the APP Coxeter element, the nilpotent transport model, and the TPK descent of modes. The appearance of π in the elliptic spectral formula belongs to the analytic expression of the cycle and does not replace the regional generation of π_{HMT}. The identity $A^{\mathsf{T}}GA = G$ constructs an exact Lorentz transformation in dimension $1+1$; it does not by itself identify this screen with physical spacetime $3+1$. A failure of

$$(2C + I)^2 = -3I, \qquad N^2 = 0, \qquad (2A - 3I)^2 = 5I, \qquad A^{\mathsf{T}}GA = G$$

would refute the corresponding realization.

3.6 Operator genealogy of arithmetic and discrete calculus: composition, contraction of fibers, and lifts with memory

Arithmetic publishes results; a genealogical theory must additionally preserve the conditions that made each result possible. This distinction does not add a new operation to sum, product, power, root, logarithm, differentiation, or integration. It specifies what structure each contracts and what data a lift must transport in order to distinguish antecedents identified by the same output. APP exhibits the first case on a common support; TRIT locally orients the transition; TPK preserves provenance throughout composition.

3.6.1 Published operation and genealogical lifting

Let X and Y be sets and let $f : X \to Y$ be a map that publishes an operation. An *operation memory* is a set M_f together with a map

$$\widetilde{f} : X \longrightarrow Y \times M_f, \qquad \mathrm{pr}_Y \circ \widetilde{f} = f. \tag{3.4}$$

The first component publishes the output; the second records the data that the reader elects to preserve. The lift is *complete on the fibers* if, for every $y \in Y$, the restriction

$$\mathrm{pr}_{M_f} \circ \widetilde{f}\big|_{f^{-1}(y)} : f^{-1}(y) \longrightarrow M_f$$

is injective. This condition expresses exactly that two antecedents with the same visible output remain distinguishable by their memory. In HMT realizations, no single token is required to preserve the entire history: the complete memory may be distributed among sheet, quotient, carry, phase, orientation, boundary, and the enriched chronological register.

If $f : X \to Y$ and $g : Y \to Z$ possess fixed lifts, their composition admits the canonical lift associated with those lifts,

$$\widetilde{g \circ f} : X \longrightarrow Z \times M_f \times M_g, \qquad \widetilde{g \circ f}(x) = \big(g(f(x)), m_f(x), m_g(f(x))\big), \tag{3.5}$$

where m_f and m_g are the memory components. Concatenation does not erase the provenance of the first stage in order to replace it with the second: it coordinates them. This is the operator principle that the TPK realizes on paths.

Lemma 3.28 (Composition of complete surveys)**.** *If $\widetilde{f}$ and $\widetilde{g}$ are complete over the fibers of f and g, respectively, then $\widetilde{g \circ f}$ is complete over the fibers of $g \circ f$.*

Proof. Let $x_1, x_2 \in X$ with $g(f(x_1)) = g(f(x_2))$ and with equal memory components in (3.5). Equality of the memories $m_g(f(x_1)) = m_g(f(x_2))$, together with the completeness of $\widetilde{g}$ on that fiber of g, implies $f(x_1) = f(x_2)$. The equality $m_f(x_1) = m_f(x_2)$ and the completeness of $\widetilde{f}$ then imply $x_1 = x_2$. □

3.6.2 Sum and product: alternatives and composition

In a path algebra, the sum combines alternatives with compatible endpoints,

$$a_1\gamma_1 + a_2\gamma_2,$$

while the product concatenates stages when the end of the first coincides with the origin of the second,

$$\gamma_2\gamma_1, \qquad t(\gamma_1) = s(\gamma_2).$$

Addition preserves the linear coexistence of histories; multiplication constructs a composite history and, when only its value is published, may forget the factorization that produced it. On the APP chart, the evaluations Σ and Π act on the same state (i, j) but organize distinct fibers. In the central block B_c of APP, the spectral separation developed in the following chapter measures precisely that local incompatibility; it is not a discrepancy between two independent tables, nor is it presented as a global distance among all readers.

On the additive sheet, translation $T_a(x) = x + a$ is reversible on the residual group. On the multiplicative sheet, $M_a(x) = ax$ is invertible in $\mathbb{Z}/9\mathbb{Z}$ exactly when $\gcd(a, 9) = 1$. The nonunitary classes $\overline{0}, \overline{3}, \overline{6}$, published in the positive chart as $9, 3, 6$, fold fibers and make visible the need to preserve quotient and provenance. Sum and product thus constitute the two inaugural readers of a single path geometry.

Lemma 3.29 (Affine conjugation in the unit sector)**.** *Let $R = \mathbb{Z}/9\mathbb{Z}$. For $a \in R^\times$ and $b \in R$, the maps $T_b(x) = x + b$ and $M_a(x) = ax$ satisfy*

$$M_a T_b M_a^{-1} = T_{ab}. \tag{3.6}$$

If $a \in (3)$, M_a ceases to be invertible and conjugation is not defined: its image remains contained in the radical and several branches of the additive sheet are identified.

Proof. For $a \in R^\times$, $M_a T_b M_a^{-1}(x) = a(a^{-1}x + b) = x + ab = T_{ab}(x)$. If $a \in (3)$, the kernel of M_a is nontrivial; hence there is no M_a^{-1}, and the conjugation expression is ill-typed. The case $a = 3$ explicitly realizes the folding through $\ker M_3 = \operatorname{im} M_3 = (3)$. □

3.6.3 Power, logarithm, and root

Let x be an element of a monoid, or of an associative algebra, and let $n \geq 1$. The power records iteration of a composition:

$$x^n = \underbrace{x \cdots x}_{n \text{ factores}}.$$

The exponent is the depth of that iteration, and the orbit of x determines which outputs are identified. In the positive real domain, if $b > 0$, $b \neq 1$, and $x > 0$, then

$$\log_b(x^n) = n \log_b x.$$

In the complex domain, the same identity requires a compatible branch and requires the iteration not to cross its cut. The logarithm coordinates the depth n only after the generator x has also been fixed and $\log_b x \neq 0$ has been required. Base, generator, domain, branch, and cut form part of the reader.

The root inverts a power as a fibered problem,

$$y^n = x.$$

The fiber may be empty, a singleton, or multiple. Selecting a root requires branch, orientation, phase, or boundary data. The subsequent construction of an internal operator $J_E \in \mathrm{End}(V)$, with $J_E^2 = -I_V$, exemplifies this principle: the symbol $\sqrt{-1}$ publishes a coordinate, whereas the operator, its domain, and its action preserve the structure that supports it.

3.6.4 Discrete Calculus on Compatible Cylinders: Differentiation and Integration Operators

Let P_n be a connected oriented path and let A be an abelian group. In the discrete measure complex, the combinatorial coboundary

$$d : C^0(P_n; A) \longrightarrow C^1(P_n; A), \qquad (df)(e) = f(t(e)) - f(s(e)),$$

has as its kernel exactly the constant 0-cochains. Reconstructing f from df requires a boundary condition, for example, the value at a reference vertex.

The coboundary depends on incidence and orientation, but not on a length. If A is also a real vector space and $\ell : E(P_n) \to \mathbb{R}_{>0}$ is an edge length, the metric derivative is defined by

$$D_\ell f(e) = \frac{(df)(e)}{\ell(e)}.$$

For a route $\gamma = (e_1, \ldots, e_r)$ compatible with the orientations,

$$\sum_{k=1}^{r} D_\ell f(e_k)\, \ell(e_k) = f(t(\gamma)) - f(s(\gamma)). \tag{3.7}$$

Integration thus accumulates a cochain along a route and recovers the endpoint difference when the cochain is exact. Coboundary, metric derivative, and integral depend on distinct data: incidence and orientation; length and scale; path and boundary section.

This dependence explains why the passage from counting marks to measuring intervals is structural. The derivation lives on interstitial relations; integration composes those relations; the cycle adds the topological carrier of holonomy; TPK transport determines which memory survives the revolution.

3.6.5 Hierarchy of fibers and function of the TPK

The hierarchy can be condensed without identifying its levels:

Operation	Primary action	Fiber contracted by the output	Memory of reconstruction
Sum	aggregation or translation	alternatives with the same evaluation	origin, coefficients and support
Product	composition or scale	nonunitary factorizations and classes	order of factors, quotient and sheet
Power	iteration	composition orbits	exponent, order, and initial point
Root	multivalued inversion	antecedents of a power	branch, phase, orientation, and boundary
Logarithm	depth coordinate	periods and determinations	base, generator, domain, branch, and cutoff
Cobordism and metric derivative	local difference and normalization	modo constante	incidence, orientation, length, scale and reference
Integration	path accumulation	paths with equal published value	path, measure, boundary and holonomy

TPK conserves these coordinates within transportable states and not as a list added to the result. Its file (D, C, f, I, L, M) declares for each operator the domain, codomain, rule, invariants, the information published or lost, and the conserved memory. The transition

$$\text{visible operation} \longrightarrow \text{lift with memory} \longrightarrow \text{compatible section}$$

provides the link between the inaugural arithmetic, reconstruction of the continuum, and the subsequent definition of genealogical number. The number–particle boundary will preserve the same architecture when adding a dimensional realization to the surviving section.

Autonomous arithmetic domain of the nonadic cell and causal precedence with respect to APP–TRIT–TPK and the constants analiticas The priority of sum and product in APP, the conservation of phase, sheet, carry, and boundary by TPK, and the transition from section to route constitute the premises of the lift (3.4), the notion of completeness over fibers, and the table of memories. An operation is not identified with its physical realization: each subsequent step preserves its domain, its chart, and its source.

3.7 APP–TRIT–TPK Composition: arithmetic support, ternary orientation, and memory-based transport

3.7.1 APP as fiber arithmetic

APP is not an illustrative table: it is the arithmetic support on which the difference between aggregation and composition becomes visible. In $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$, summation accumulates displacements and alternative histories; multiplication composes stages and, when a factor is not invertible, folds distinct inputs onto the same residue. The residue–quotient lift unfolds those fibers and preserves the genealogy contracted by the modular publication.

Let $q(a, b) = a + b \pmod 9$. The published datum $q(a, b)$ does not determine the pair (a, b). The fiber

$$q^{-1}(r) = \{(a, b) : a + b \equiv r \pmod 9\}$$

is memory of the alternatives. For multiplication, the contraction is even more pronounced: the nonunit classes $(0, 3, 6)$ produce fibers of distinct sizes. APP therefore publishes a geometry of operations before any physical interpretation.

The active central block is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 7I + 2S = 9P_+ + 5P_-, \qquad P_\pm = \frac{I \pm S}{2}.$$

Its local spectral jump is $9 - 5 = 4$; the coupling coefficient is 2. The value 54 belongs to a later unfolding and, in the electronic fiber, to $D_1(\Gamma_e)$. Equating them because they occur in a numerical chain would erase their types.

3.7.2 Local Lorentz geometry and Minkowski plane $1 + 1$

Normalization

$$M_c = \frac{B_c}{\sqrt{45}} = \exp\left(\frac{1}{2}\log\frac{9}{5}\,S\right)$$

realizes an element of $SO^+(1, 1)$. APP thus contains, prior to continuous physics, a decomposition into P_+, P_- modes, a gap, a coupling, and a velocity. The result is not yet Minkowski space-time: it is the algebraic structure that will make a Lorentzian representation possible.

3.7.3 TRIT as orientation and local memory

TRIT introduces the sign that the modular publication omits. In a triadic sum.

$$a + b = r + 3c,$$

the residue r publishes the result, and the carry c preserves how it was obtained. The states $(+1, 0, -1)$ should not be interpreted solely as 3 colors. In the temporal parametrization they act, respectively, as return with memory of the past, present threshold, and bidirectional opening toward the future; in the algebraic realization they distinguish counterflow, fixation, and flow; in the geometric realization they label the hyperbolic, parabolic, and elliptic branches of a quadratic family. Compatibility among these readings requires maps, not a verbal identification.

Definition 3.30 (Enhanced TRIT state)**.** A TRIT state is a pair (r, c) endowed with orientation. The first component is publishable; the second belongs to the memory fiber. Change of reader may forget c, but TPK transport cannot do so.

This separation makes it possible to formalize present, past, and future without converting them into three absolute instants. The present is the locus of coupling between two orientations; past and future are senses of transport. Route inversion exchanges both senses and leaves the coupling point as a section of boundary.

3.7.4 TPK as the dynamics of selection, transport, memory, return, and deployment.

TPK brings together support, orientation, and memory. Its objects are finite or coinductive prepared sections; its morphisms are recorded routes compatible with the readers. Each route contains

$$\Gamma = (\text{origin}, \text{target}, \text{sheet}, \text{orientation}, \text{carry}, \text{boundary}, \text{record}).$$

Composition concatenates paths and composes memories. Inversion reverses the order and orientation. The readers, the 108-phase calendar, boundary, and record are internal operators, not added external observers.

A published operation $f : X \to Y$ admits a lift

$$\widetilde{f} : X \longrightarrow Y \times M_f, \qquad \pi_Y \circ \widetilde{f} = f.$$

Given fixed lifts of f and g, the composition has an associated canonical lift

$$\widetilde{g \circ f} : X \longrightarrow Z \times M_f \times M_g.$$

Memory is not a comment on the operation: it is part of its enriched codomain.

Proposition 3.31 (Genealogy of the operations)**.** *In TPK, sum, product, power, root, logarithm, derivation, and integration admit a common reading:*

Operation	*Action*	*Preserved Memory*
Sum	*aggregation of alternatives*	*origin and carry*
Product	*stage composition*	*order and folded fiber*
Power	*monoid iteration*	*depth and orbit*
Root	*multivalued inversion*	*branch and orientation*
Logarithm	*iteration coordinate*	*generator and caliber*
Derivation	*differ by scale*	*border and orientation*
Integration	*composition of increments*	*path and boundary conditions*

Exponentiation does not introduce an operation ontologically disconnected from addition and product: it iterates composition. The root inverts that iteration and must preserve the branch selection. The logarithm records depth. This hierarchy explains why nonadic powers and their vacancies are informative for APP: the raised operation preserves layers of memory that an isolated digital root contracts.

3.7.5 Temporal periodicity of 108 phases and returns at 27, 54, and 108 iterations

The observable calendar has three distinct thresholds. After 27 iterations, the position returns and the orientation is reversed; after 54, position and orientation are restored; after 108, the complete observable phase is restored. The memory of the positive semigroup, however, is not erased. Schematically,

$$F_{\text{obs}}^{27}(x, o) = (x, -o), \qquad F_{\text{obs}}^{54}(x, o) = (x, o), \qquad F_{\text{obs}}^{108}(x, o, \phi) = (x, o, \phi).$$

This hierarchical order will be crucial for separating outward propagation, return, orientation, and complete cycle. A finite observable period can coexist with nonperiodic genealogical memory.

Type controls

It is inadmissible to identify TPK with a list of 34 operators; to call the structure a "fibered category" without Cartesian lifts; to place the carry simultaneously as a cellular coboundary and as a 2-cocycle without separating their complexes; or to convert the block $SO^+(1, 1)$ into physical spacetime before constructing the metric representation.

3.8 Hopf fibration, Villarceau circles, double covering, and Möbius holonomy

3.8.1 Complex structure and Hopf fibration

Let $S^3 \subset \mathbb{C}^2$ and

$$h(z_0, z_1) = \left(2\Re(z_0\overline{z}_1), 2\Im(z_0\overline{z}_1), |z_0|^2 - |z_1|^2\right) \in S^2.$$

On the Hopf torus

$$T_\eta = \{(z_0, z_1) : |z_0| = \cos\eta, |z_1| = \sin\eta\},$$

the curves

$$\gamma_+(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{it}),$$
$$\gamma_-(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{-it})$$

have distinct behaviors: γ_+ is a Hopf fiber and γ_- projects with degree two. Under stereographic projection, the homology classes $(1,1)$ and $(1,-1)$ produce the two diagonal Villarceau families.

The total complex conjugation

$$K(z_0, z_1) = (\overline{z}_0, \overline{z}_1)$$

preserves each unoriented family and reverses its orientation. It does not interchange the two families. Partial conjugation can interchange them, but it is neither a complex-linear map nor the standard global antiunitary. This correction is essential to avoid manufacturing a particle–antiparticle symmetry from the toroidal drawing.

3.8.2 Double covering and spinor return

The map $SU(2) \to SO(3)$ is a double cover. A loop of 2π in $SO(3)$ can lift to $-I$ in $SU(2)$; the loop of 4π recovers I. The sign structure does not turn a circle into a Möbius band. Obtaining a band requires a real line bundle whose holonomy character is -1.

Let $L_\chi \to S^1$ be the associated bundle to

$$\chi : \pi_1(S^1) \longrightarrow \{\pm 1\}, \qquad \chi(1) = -1.$$

Its total space is a Möbius band. The route $C_M = -\,\mathrm{rev}$ provides the sign candidate; the Villarceau circle provides the loop; the physical intertwiner must prove that the former is the holonomy of the latter.

3.8.3 Spectral decomposition of the oriented memory operator and derivation of the ratio (5:2)

With $B_c = 7I + 2S$, define the oriented memory operator

$$B^{\varepsilon}_{\mathrm{mem}} = 5I + 2\varepsilon S, \qquad \varepsilon = \pm 1.$$

For $\varepsilon = +1$,

$$\mathrm{Spec}(B^{+}_{\mathrm{mem}}) = \{7, 3\}, \qquad \det B^{+}_{\mathrm{mem}} = 21.$$

Interpreting the values $(7, 3)$ as the outer and inner equatorial boundaries in a common positive chart yields

$$R + r = 7\ell, \qquad R - r = 3\ell,$$

and therefore

$$R = 5\ell, \qquad r = 2\ell, \qquad \sin\beta = \frac{r}{R} = \frac{2}{5}.$$

The Villarceau angle is

$$\beta = \arcsin\frac{2}{5} = 23.5781784782\ldots^{\circ}.$$

The algebraic theorem $\{7, 3\} \leftrightarrow (5, 2)$ is exact. The geometric premise interpreting the spectrum as the two boundaries of a torus is a declared interface. It must not be concealed, nor may the angle be used as a target.

The realization of the full block B_c retains another reading: $R : r = 7 : 2$ and $\beta = \arcsin(2/7)$. These are not rival values; they belong to two functors: total block and memory mode. The physical priority of the latter must be decided by the intertwiner with the dynamics, not by decimal proximity to another constant.

3.8.4 Conjugate Angular Coordinates and Phase Unit Normalization in the Hopf Fibration

HMT's native angle is a phase $u \in \mathbb{R}/\mathbb{Z}$. The readers publish

$$\theta_{\mathrm{rad}} = 2\pi u, \qquad \theta_{\mathrm{deg}} = 360u.$$

Radians and degrees are distinct charts of the same circular element. The radian is not more "ontological" by virtue of being dimensionless; its naturality follows from arc length. Degrees provide another absolute coordinate of the full turn. Any relation with α^{-1}, φ, or CKM must first be formulated as an invariant quotient or holonomy and only thereafter evaluated in an angular chart.

The exact identity already available

$$\tanh^2(2\log\varphi) = \frac{5}{9}$$

connects the Perron–Fibonacci channel to the spectral quotient of B_c. Its complement is $4/9$, the normalized gap. This relation is structural. It does not imply that every angle constructed with φ is a physical angle.

3.8.5 Brouwer, Möbius, and degree

Brouwer's fixed-point theorem, fractional linear Mobius transformations, and the Mobius band are three distinct objects. They are related only after fixing domain, action, and bundle. The elliptic advance and retardation orbits may be modeled as two sections of a bundle with sign holonomy; the Mobius transformation describes the conformal action in the chart; Brouwer's theorem guarantees a fixed point for continuous maps of the disk. None of these statements replaces the realization diagram.

Result and boundary

The degree-two character of the Hopf curve, the orientation of the total conjugation, and the algebraic construction $7, 3 \mapsto 5, 2$ are proved. The toroidal reading (5:2), Möbius holonomy, and the particle–antiparticle interpretation form a chain of interfaces that must share a single intertwiner. The volume does not force that intertwiner through an angular coincidence.

3.9 Finite Hilbertian realization of the path system and its conditional projectors

3.9.1 Matrix realization of each depth

For $d \geq 1$, define

$$C_9^{(d)} = (\mathbb{Z}/9\mathbb{Z})^d, \qquad H_d = \ell^2(C_9^{(d)}), \qquad A_d = B(H_d) \cong M_{9^d}(\mathbb{C}).$$

The canonical basis $\{\delta_x : x \in C_9^{(d)}\}$ preserves the discrete label of each state. The uniform measure induces the normalized trace

$$\tau_d(a) = \frac{1}{9^d}\,\mathrm{Tr}(a).$$

The factorization

$$C_9^{(d+1)} = C_9^{(d)} \times \mathbb{Z}/9\mathbb{Z}$$

produce a unitary identification

$$H_{d+1} \cong H_d \otimes \mathbb{C}^9.$$

This is the exact input to the operator tower. This does not identify $(\mathbb{Z}/9)^3$ with $\mathbb{F}_3^6$ as groups: they share 729 elements, but their operations and carry cocycles are distinct.

3.9.2 Weyl–Heisenberg Representation of Phase and Displacement on the Triadic Fiber

Let $\omega = e^{2\pi i/9}$. On $H_1 = \ell^2(\mathbb{Z}/9\mathbb{Z})$, we define

$$(Xf)(r) = f(r-1), \qquad (Zf)(r) = \omega^r f(r).$$

Then

$$X^9 = Z^9 = I, \qquad ZX = \omega XZ.$$

The group generated by $X, Z, \omega I$ is the finite Heisenberg group of order $9^3 = 729$.

Theorem 3.32 (Stone–von Neumann finite)**.** *Every irreducible unitary representation of the finite Heisenberg group in which the center acts by means of the primitive character ωI is unitarily equivalent to the preceding representation.*

Proof. Let v be an eigenvector of Z. The vectors

$$v, Xv, \ldots, X^8 v$$

have eigenvalues distinct from Z, since $ZX^k v = \omega^k X^k Zv$. They are orthogonal and span an invariant subspace. By irreducibility, they form a basis of the entire representation. In that basis, X is the cyclic shift and Z the diagonal phase. □

Structural obstruction

Uniqueness fails if the primitive central character is not fixed or if reducible representations are allowed. This finite theorem must not be confused with the continuous version for the canonical commutation relations.

3.9.3 Conditional projectors and pre-Heisenberg incompatibility

The additive and multiplicative sheets of APP define information subspaces and their orthogonal projectors $P_{\Sigma,d}, P_{\Pi,d}$. The constructed identities satisfy

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

Noncommutativity is not deduced from a quantum analogy: it is a finite matrix theorem. Its "pre-Heisenberg" reading is subsequent to that calculation.

Proposition 3.33. *The preceding projectors do not jointly belong to the same Boolean subalgebra of projections.*

Proof. In an abelian subalgebra all projectors commute. The displayed commutators are nonzero. □

3.9.4 Hilbertian structure of the matrix publication and preserved genealogical memory

Hilbert space provides linear superposition, orthogonal projection, and spectral calculus. HMT supplies the genealogical index of the basis and distinguishes which operator represents a transition, a measurement, or a shadow. The realization does not replace TPK: it represents it.

Premises and derivation

The APP projectors and the Weyl–Heisenberg pair are part of the preceding construction. The organization H_d, A_d and the uniqueness proof are established here by applying the corresponding classical theorem to the HMT objects.

3.10 Finite symplectic structure of APP and nonadic fibration of observables

Symplectic geometry is not part of the published theorems on De las Cuevas–Netzer magic squares. The legitimate link passes through a neighboring, standard route: Weyl operators, discrete phase space and mutually unbiased bases [52, 100]. In HMT, that route acquires a nonadic lift and fiber memory.

3.10.1 The alternating form and the Weyl commutation

On $V_3 = \mathbb{F}_3^2$ we define

$$\langle (q,p),(q',p')\rangle_{\mathrm{sp}} = qp' - pq'. \tag{GMC-5.1}$$

If $X|k\rangle = |k+1\rangle$, $Z|k\rangle = \omega^k|k\rangle$, and $\omega = e^{2\pi i/3}$, the operators $W_{q,p} = X^q Z^p$ satisfy, under these conventions,

$$W_u W_v = \omega^{-\langle u,v\rangle_{\mathrm{sp}}} W_v W_u. \tag{GMC-5.2}$$

Therefore, two operators commute exactly when their labels are orthogonal for the alternating form. In dimension two, the maximal isotropic sublines are the four points of

$$\mathbb{P}^1(\mathbb{F}_3) = \{[1:0],[0:1],[1:1],[1:2]\}. \tag{GMC-5.3}$$

Each generates a maximal abelian context of $M_3(\mathbb{C})$; its spectral projectors constitute a PVM. Contexts associated with distinct lines produce the four MUB bases of (GMC-2.13).

Proposition 3.34 (Qutrit decomposition by directions)**.** *Let $\mathcal{D}_a$ be the four diagonal subalgebras determined by the lines of* (GMC-5.3) *and $\mathcal{D}_a^0$ their traceless parts. Then*

$$M_3(\mathbb{C}) = \mathbb{C}I \oplus \bigoplus_{a\in\mathbb{P}^1(\mathbb{F}_3)} \mathcal{D}_a^0 \tag{GMC-5.4}$$

as an orthogonal sum for the Hilbert–Schmidt product. The dimension count is $9 = 1 + 4\cdot 2$.

Proof. Each $\mathcal{D}_a^0$ has dimension two. Unbiasedness implies $\mathrm{Tr}(A^*B) = 0$ for $A \in \mathcal{D}_a^0$ and $B \in \mathcal{D}_b^0$, $a \neq b$. All are orthogonal to I. The dimensions sum to nine, the dimension of $M_3(\mathbb{C})$. □

This identity explains why the twelve projections are not twelve arbitrary independent pieces: they are four resolutions of the identity whose centered parts decompose the entire qutrit operator space.

3.10.2 The lift $12 \to 4\times 3$

On the modulo nonadic $V_9 = (\mathbb{Z}/9\mathbb{Z})^2$ it preserves the forma alternante

$$\langle (a,b),(c,d)\rangle_9 = ad - bc \pmod 9. \tag{GMC-5.5}$$

The projective line $\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})$ consists of the primitive vectors modulo multiplication by a unit. It can be represented as

$$\{[1:t] : t \in \mathbb{Z}/9\mathbb{Z}\} \sqcup \{[3u:1] : u \in \mathbb{Z}/3\mathbb{Z}\}, \tag{GMC-5.6}$$

and has $9 + 3 = 12$ points. Reduction modulo three gives the diagram

$$\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \xrightarrow{r} \mathbb{P}^1(\mathbb{F}_3), \qquad |r^{-1}(a)| = 3. \tag{GMC-5.7}$$

The basis a of a qutrit context and the outcome k of its PVM likewise form a set 4×3. A *calibration* is a bijection

$$\Xi : \mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \longrightarrow \{P_{a,k} : a \in \mathbb{P}^1(\mathbb{F}_3),\ k \in \mathbb{F}_3\} \tag{GMC-5.8}$$

that sends each fiber of r to the three outcomes of the context lying over a.

Structural obstruction

The fibration is canonical; assigning the internal order of each fiber to the three outputs k is a gauge. A bijection is not yet an equivariance. To promote Ξ to an intertwiner, one must prove that the relevant linear, projective, and antiunitary actions are transported in every fiber. The preliminary gauge fails an antiunitary check in one fiber; that failure is preserved as a falsifier, not concealed.

3.10.3 Depth, carry, and memory over the discrete phase space

The Weyl geometry over $\mathbb{F}_3^2$ explains commutation, contexts, and MUB. HMT adds three levels that are not recovered from the symplectic form by itself:

1. the lift of a ternary direction to three points of $\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})$;
2. the sheet, carry and orientation that distinguish states with the same reduction;
3. the TPK route that transports those coordinates and can return to the phase without returning to the state.

The potential contribution to the qutrit literature is not "another construction of four MUBs," which is already known. It is a geometry of *context roots*: each ternary context has three nonadic antecedents, and those antecedents may carry dynamics and monodromy. The order-twelve square of Theorem 26.9 is the first normalized shadow of that atlas.

3.10.4 Typed separation between the qutrit overlap $1/3$ and the HMT reader $1/\pi$

In a pair of MUB qutrit bases,

$$\operatorname{Tr}(P_{a,k}P_{b,\ell}) = \frac{1}{3}. \tag{GMC-5.9}$$

In the HMT reader defined here, the relation between a real sheet and a volumetric reading can take the quotient

$$\frac{\pi}{\pi^2} = \frac{1}{\pi}. \tag{GMC-5.10}$$

The two expressions are not interchangeable: $1/3$ is an overlap between projectors in dimension three; $1/\pi$ is a scalar weight of another reader. The difference does not prevent their coordination. For a fixed PVM $\{P_0, P_1, P_2\}$, we define a measurement with nine effects:

$$F_k^{(\pi)} = \frac{3}{\pi}P_k \quad (k = 0, 1, 2), \qquad F_r^{(\pi)} = \frac{1 - 3/\pi}{6}I_3 \quad (r = 3, \dots, 8). \tag{GMC-5.11}$$

It is a POVM because $3/\pi < 1$ and

$$\sum_{r=0}^{8} F_r^{(\pi)} = \frac{3}{\pi}I_3 + \left(1 - \frac{3}{\pi}\right) I_3 = I_3. \tag{GMC-5.12}$$

If Q is a rank-one projector of a distinct MUB context,

$$\operatorname{Tr}(QF_k^{(\pi)}) = \frac{3}{\pi}\operatorname{Tr}(QP_k) = \frac{3}{\pi}\cdot\frac{1}{3} = \frac{1}{\pi}. \tag{GMC-5.13}$$

Matrix bridge result

The formula (GMC-5.11) exactly transforms the MUB probability $1/3$ into the reader $1/\pi$ through the gauge $3/\pi$, without identifying the two numbers. The six residual effects preserve the unit and complete a POVM of nine outcomes, from which another cyclic QMS $(9, 3)$ is obtained. This

construction does not yet identify the geometric provenance of the residual mass; it fixes the exact operator type that it must have.

3.10.5 Symplectic group and equivariance equation

In dimension two over $\mathbb{F}_3$, the symplectic group coincides with $SL(2,\mathbb{F}_3)$ and permutes the four lines. Its action lifts projectively, by means of the Clifford group, on the PVM qutrits. Let G_{HMT} be a group or groupoid of transformations of the nonadic atlas and U_g the candidate unitary or antiunitary operator in the qutrit chart. The condition that turns a calibration into a dynamical bridge is

$$\Xi(g\cdot\ell) = U_g\,\Xi(\ell)\,U_g^{*}, \qquad g\in G_{\mathrm{HMT}},\quad \ell\in\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}). \tag{GMC-5.14}$$

If g is an arrow and not merely a global symmetry, the equation must include the source and target and is formulated as a natural transformation. The verification of (GMC-5.14) is the step that separates a fortunate labeling from a structural transduction.

Premises and derivation

The symplectic and MUB identities rely on the finite-phase literature [52, 100]. They are not attributed to the papers on magic squares by De las Cuevas–Netzer. The nonadic fibration, calibration, and route readers constitute the original contribution of the HMT construction studied here.

3.11 Spatial return and conservation of winding in the calendar of twenty-seven transitions

The two periodic APP coordinates arise from two transported integer coordinates. The residual reading identifies positions that differ by multiples of nine; the integer quotients preserve the turns of that transport. The TPK calendar provides a complete example in which the residual position returns and the lifted cursor preserves a nonzero horizontal displacement.

3.11.1 Lifted coordinates and boundary cocycle

For $z\in\mathbb{Z}$, let

$$\rho_9(z) = 1 + ((z-1) \bmod 9), \qquad q_9(z) = \left\lfloor \frac{z-1}{9} \right\rfloor.$$

Euclidean division, also for negative coordinates, gives

$$z = \rho_9(z) + 9q_9(z), \qquad 1\le \rho_9(z)\le 9. \tag{3.8}$$

The transport carry of an increment $a\in\mathbb{Z}$ is

$$c(z,a) = q_9(z+a) - q_9(z).$$

From (3.8) we deduce

$$\rho_9(z+a) + 9c(z,a) = \rho_9(z) + a, \tag{3.9}$$

$$c(z,a+b) = c(z,a) + c(z+a,b). \tag{3.10}$$

The second identity follows by canceling $q_9(z+a)$ on the right-hand side. The second increment is evaluated from the endpoint of the first; that dependence preserves the boundary crossing information.

Let $D=\{N,E,S,O\}$, with displacements

$$\delta(N) = (-1,0), \quad \delta(E) = (0,1), \quad \delta(S) = (1,0), \quad \delta(O) = (0,-1).$$

For a direction word $w = d_1 \cdots d_n$, define $\Delta(w) = \sum_j \delta(d_j)$ and, from $o = (o_1, o_2)$,

$$\mathrm{Ext}(o, w) = o + \Delta(w), \qquad \nu(o, w) = \big(c(o_1, \Delta_1(w)), c(o_2, \Delta_2(w))\big).$$

The vector ν records both windings.

Proposition 3.35 (Composition and reversal of turns)**.** *For two concatenable routes u, v one has*

$$\nu(o, uv) = \nu(o, u) + \nu(\mathrm{Ext}(o, u), v).$$

If w^{-1} reverses the order and replaces each direction with its opposite, then

$$\mathrm{Ext}(\mathrm{Ext}(o, w), w^{-1}) = o, \qquad \nu(\mathrm{Ext}(o, w), w^{-1}) = -\nu(o, w).$$

For a spatially closed route in APP,

$$\nu(o, w) = \Delta(w)/9 \in \mathbb{Z}^2.$$

Proof. The sum of displacements is additive under concatenation. Applying (3.10) in each coordinate proves the first identity. Reversal gives $\Delta(w^{-1}) = -\Delta(w)$ and recovers the initial endpoint. Subtracting the quotients in reverse order changes the sign of ν. Finally, spatial closure is equivalent to $\rho_9(o_i + \Delta_i) = \rho_9(o_i)$ for both coordinates; the first equality of (3.10) then gives $9\nu_i = \Delta_i$. □

The cycles of nine southward moves and nine eastward moves, from $(1, 1)$, have turns $(1, 0)$ and $(0, 1)$, respectively. They are two independent cycles of the periodic APP surface.

3.11.2 Update of the two cursors

A lifted observable cursor is $c = (x, y, d) \in \mathbb{Z}^2 \times D$. The phase p belongs to $\mathbb{Z}/108\mathbb{Z}$ and is represented by $0, \ldots, 107$. In the additive sheet, displacement is activated when $p \equiv 0 \pmod 3$; in the multiplicative sheet, when $p \equiv 1 \pmod 3$. Define

$$a_+(p) = \mathbf{1}_{\{p \equiv 0 \ (3)\}}, \qquad a_\times(p) = \mathbf{1}_{\{p \equiv 1 \ (3)\}}, \qquad \varepsilon(p) = \mathbf{1}_{\{p+1 \equiv 0 \ (27)\}}.$$

The observable operator acts through

$$c'_s = \big(x_s + a_s(p)\delta_1(d_s),\ y_s + a_s(p)\delta_2(d_s),\ \mathrm{op}^{\varepsilon(p)}\, d_s\big), \qquad p' = p + 1 \pmod{108}, \tag{3.11}$$

where $s \in \{+, \times\}$ and op interchanges N with S and E with O. Displacement uses the preceding direction and then the half-cycle transition updates the orientation.

The inverse first recovers $p = p' - 1 \pmod{108}$, restores $d_s = \mathrm{op}^{\varepsilon(p)}\, d'_s$ and subtracts $a_s(p)\delta(d_s)$ from the coordinates. Since $\mathrm{op}^2 = I$, both compositions are the identity.

Theorem 3.36 (Effective spatial return in the first half-crown)**.** *Start from $c_+(0) = c_\times(0) = (1, 1, E)$ and $p(0) = 0$. After twenty-seven transitions of (3.11), one obtains*

$$c_+(27) = c_\times(27) = (1, 10, O), \qquad p(27) = 27.$$

Both residual positions return to $(1, 1)$, while the horizontal quotient increases by one and the vertical quotient remains unchanged.

Proof. For $0 \le n \le 27$, the number of additive activations before transition n is $\lfloor (n + 2)/3 \rfloor$; the number of multiplicative activations is $\lfloor (n + 1)/3 \rfloor$. Before the phase transition from 26 to 27 there is no direction reversal. By induction on n, the coordinates are

$$x_+(n) = x_\times(n) = 1, \qquad y_+(n) = 1 + \left\lfloor \frac{n+2}{3} \right\rfloor, \qquad y_\times(n) = 1 + \left\lfloor \frac{n+1}{3} \right\rfloor.$$

The directions are E for $0 \le n < 27$ and O for $n = 27$. The decomposition in each group of three transitions is

n	$y_+(n)$	$y_\times(n)$	direction
$3k$	$1+k$	$1+k$	E
$3k+1$	$2+k$	$1+k$	E
$3k+2$	$2+k$	$2+k$	E

$(0 \le k \le 8)$,

and the final endpoint is $(y_+, y_\times, d) = (10, 10, O)$. There are nine activations in each sheet. The final transition has preceding phase 26, of class two modulo three; it therefore reverses the directions and maintains the coordinates that have already reached ten.

Finally, $\rho_9(10) = 1$, $q_9(10) = 1$, $\rho_9(1) = 1$ and $q_9(1) = 0$. The residual position coincides with the initial one, and the spatial winding is $(0, 1)$. □

The return in this example is spatial. The recorded direction and phase are $(O, 27)$ at the end and $(E, 0)$ at the start. The example expressly preserves the three data: residual position, orientation and phase; their equality or difference is established for each one.

3.11.3 Cursor recovery and compatibility at every depth

Proposition 3.37 (Recovery of the lifted cursor)**.** *The residual position, the direction and the two integer quotients uniquely determine the cursor $c = (x, y, d)$.*

Proof. The two identities (3.8) recover x and y and the direction is preserved in the observable projection. If these five data coincide for two cursors, their three components coincide and the cursors are therefore equal. □

Let P be the projection of the two cursors onto their positions modulo nine, preserving their directions and the phase. The finite update T_{fin} uses the same activation and orientation indicators, with residual addition in the coordinates. If T is (3.11), then

$$PT = T_{\mathrm{fin}} P, \qquad PT^n = T_{\mathrm{fin}}^n P \quad (n \ge 0).$$

The first equality results from compatibility of reduction modulo nine with addition and preservation of direction and phase; the second is proved by induction on n.

The ordered archive of observable states can be prolonged through $(q, \mathcal{A}) \mapsto (Tq, \mathcal{A} \| q)$. After n transitions it preserves its initial prefix and its length increases by n. This operation keeps the current state, the winding and the register of its preceding states separate. In the complete enriched construction, the observable factor is composed with the other cylinder, incidence and memory readings through their declared projections.

Part II

discrete structure of the continuum: surviving sections, double projection and incidence hierarchies

Chapter 4

Inverse path system of compatible trajectories: orientation, boundary, carry, and memory under refinement

4.1 Arithmetic Genealogy of Measure and Nonadic Configuration of the Inverse System

4.1.1 The Continuum Problem and the Genealogy of Measure

This opening develops the number–measure dimension of the treatise's inaugural thesis: the discrete structure constructs the continuum and the real chart subsequently publishes its coordinate, without intervening as a generating domain.

The history of the continuum can be read as the history of a separation and of its successive reconciliations. Ancient arithmetic organized pluralities; geometry compared lengths, areas, and volumes. The Greek theory of proportions made it possible to reason with incommensurable magnitudes: the diagonal of the unit square existed as an exact construction even when its length could not be published as a ratio of integers. Books V and VII of the *Elements* therefore preserved two domains, magnitude and number, united by rules of comparison but endowed with distinct operations [44, 113].

Modern analysis brought that reconciliation to a decisive form. Cauchy sequences, Dedekind cuts, and set theory made $\mathbb{R}$ a complete ordered field, capable of publishing continuous magnitudes in a single arithmetic language. Cantor distinguished cardinality from order; Dedekind made continuity a structural property of the number system; Weierstrass established the local discipline of limits and approximation [115, 114, 97]. The resulting real continuum is one of the most powerful constructions in the history of mathematics: it identifies presentations that converge to the same value and makes possible calculus, analytic geometry, and the quantitative formulation of physical theories.

Triadic Modular Holography poses a question prior to that identification: *what finite and prolongable structure produces the value published by the real line?* Its primary object is the compatible genealogy of an evaluation. A digit is the output of a positional reader; a value is the scalar coordinate obtained by contracting a family of cylinders; an HMT number is the section that additionally preserves phase, orientation, arithmetic sheet, lifting quotient, carry, boundary, and route memory. The Archimedean evaluation thus takes the form

$$\mathrm{ev}_{\mathbb{R}} : X_{\infty}^{\mathrm{HMT}} \longrightarrow \mathbb{R},$$

and their fibers gather stories that share a coordinate without thereby losing their operational identity.

This formulation changes the explanatory order of measurement. Counting determines the cardinality of a finite set; measuring couples a state, a reader, and a chart, restricts their compatible continuations, and publishes an observable. If X is the state space, A the apparatus or reader, and $C \subset X \times A$ the compatibility condition, the minimal scheme is

$$(x, a) \in C \longmapsto O(x, a) \longmapsto \mathcal{U}\big(O(x, a)\big),$$

where O conserves the type of the observable and $\mathcal{U}$ expresses it in the chosen chart. The final digit constitutes the visible coordinate of the complete coupling. This distinction will be the mathematical basis of the theory of the observer and of Dimensional Mechanics in Part V.

The epistemological consequence is precise. Ordinary physical metrology assigns coordinates to observables, and theories subsequently relate those coordinates by means of equations; HMT first constructs the state, the route, and the reader from which the coordinate descends. The fundamental constants then assume the status of results of a genealogy, and experimental comparison is applied to the output. In the same movement, an HMT symmetry expresses the conservation of unity through a transformation: the value records the published coordinate, and the exceptional projection records the

organization that has survived transport. Structure and number become two verifiable aspects of the same discrete evolution.

4.1.1.1 Marks, intervals, and the nonad cell

The finite construction begins on the line of integers. The origin 0, the decimal threshold 10, and the cell of positive representatives are fixed

$$E_9 = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}.$$

The elements of E_9 perform two related but distinct functions: they are the nine phase marks of the path P_9, and they are also the nine positive integer coordinates $d(0, r) = r$ measured from the origin. This second reading adds no edges to the path. The nine marks determine exactly the eight half-open interior intervals

$$J_r = [r, r + 1), \qquad 1 \le r \le 8.$$

The closure edge is represented in the lifted chart by $[9, 10)$; its nonadic projection returns to the first phase and preserves the carry of the next turn. The origin 0 belongs solely to the expanded decimal chart and does not add an interior interval to P_9. Marks, coordinates, intervals, and closure are thus typed before any operation is applied.

For each $n \ge 1$, nonadic Euclidean division defines

$$\rho_9(n) = 1 + ((n - 1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n - 1}{9} \right\rfloor,$$

$$n = 9q_9(n) + \rho_9(n). \tag{4.1}$$

The coordinate ρ_9 gives the position on a nine-phase wheel; q_9 preserves the accumulated height. The successor acts by

$$(q, r) \longmapsto \begin{cases} (q, r + 1), & 1 \le r < 9, \\ (q + 1, 1), & r = 9. \end{cases}$$

Therefore, n and $n + 9$ share a phase and occupy consecutive heights. The geometric realization

$$\mathcal{H}_9(n) = \left(\cos \frac{2\pi(\rho_9(n) - 1)}{9}, \sin \frac{2\pi(\rho_9(n) - 1)}{9}, q_9(n) + \frac{\rho_9(n) - 1}{9} \right)$$

makes this structure visible: projected onto the plane it is a wheel; conserved in the three coordinates it is a helix. The return $9 \to 1$ recovers the angle and elevates the history. This is the elementary form of the distinction that will govern the entire TPK:

$$\boxed{\text{phase return} \neq \text{state return.}}$$

4.1.1.2 Construction of APP via decomposition of 1 cell into 2 coordinates

The Cartesian product of two nonadic cells constructs a two-dimensional chart. Its inner kernel contains $8^2 = 64$ positions. The ninth row and the ninth column publish the null residual class through the label 9 and form a gnomon of seventeen cells:

$$81 = 64 + (9 + 8) = 64 + 17.$$

The modular identification of opposite sides converts the square chart into the torus

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2,$$

and the cardinal translations endow it with a Cayley graph. The geometric operation is, consequently, a precise sequence: kernel 8×8, gnomonic completion 9×9, toroidal identification, and transport by the graph.

On each vertex $(i, j) \in X_9$ act two evaluations of the same support: the additive sheet Σ and the multiplicative sheet Π. Their exact incompatibility supplies dynamics because a route must preserve which sheet acted, which residue it published and which quotient it produced. APP constructs the support and its two evaluations; TRIT locally orients the transition; TPK transports the complete state, simultaneously preserves both sheets and, through M_{ph}, types the mode and TRIT phase of the transition; it also preserves the memory of elevation and decides the survival of prolongations. The inaugural architecture is fixed by the chain

$$\boxed{E_9 \longrightarrow \mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK}.}$$

The importance of this beginning lies in its capacity for prolongation. The same difference between position and height that turns the wheel into a helix is reproduced in the periodicity of $108 = 12 \cdot 9$ iterations, in the oriented cyclic system of twelve phases, in the architecture of levels and thresholds of the TPK prolongation $w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$, in the derivation of π, e, φ and α_{HMT}, and in the double projection towards the real value and exceptional incidence. The discrete structure of the continuum designates precisely this continuity of a finite genealogy across arbitrary depths.

Hypothesis, domain, and conclusion

The history of number, magnitude and continuum belongs to the classical mathematical context. The decomposition (4.1), the nonadic torus, the APP sheets and memory transport are results of the HMT corpus. The helical embedding $\mathcal{H}_9$ is a geometric formalization of that decomposition. Evaluation on all of $\mathbb{R}$ is established by the coverage and Archimedean closure theorem of the genealogical continuum theorem 18.17; the genealogy of the constructed values is formulated in the inverse system of compatible sections.

4.2 Genealogical construction of the continuum

4.2.1 Generative composition APP→TRIT→TPK and construction of the enriched state

The construction begins with three irreducible and causally ordered objects. The object of *All Possible Paths* (hereafter, APP) constructs the common nonadic support, its graph of all finite paths, and the two sum–product evaluation sheets. The tritic unit (hereafter, $\widehat{\mathbb{T}}$) is the minimal local unit of topological, geometric, informational, and, once ordered, temporal relation: its visible signature has three states, and its lift preserves the carry that a binary or residual reading would lose. The *Topological Phase Kernel* (hereafter, TPK) is the transport category that composes these units into routes and preserves, within the same state, sheet, orientation, boundary, genealogical ledger, memory, phase, and survival.

Object	Construction	Invariantes transportados
APP	positive chart, finite torus, Cayley graph, paths, and leaves Σ, Π	marker, cell, neighborhood, sum, product, quotient and closure
TRIT	ternary signature visible and local topological-temporal lift	residue, carry, sheet, orientation, threshold and reversal
TPK	category of paths, fibers, and compatible extensions	cylinder, boundary, genealogical record, memory, phase, holonomy and survival

The exact construction of APP is established on a marked segment and a finite chart; the real line appears afterward as a limiting publication. The reference interval, its marks, and the oriented path that traverses them are:

$$I_{10} = [0, 10], \qquad \mathcal{M}_{10} = I_{10} \cap \mathbb{Z} = \{0, 1, \dots, 10\}, \qquad \mathsf{P}_{10} : 0 \longrightarrow 1 \longrightarrow \cdots \longrightarrow 9 \longrightarrow 10, \tag{4.2}$$

The endpoints fix the edge and the nine interior marks $I_{10}^{\circ} \cap \mathbb{Z}$ form the positive alphabet. The exact mathematical object of departure is the chart

$$\mathcal{D}_9 = \{1, \dots, 9\}, \qquad \mathcal{D}_8 = \{1, \dots, 8\}, \qquad \lambda_9 : \mathcal{D}_9 \xrightarrow{\sim} \mathbb{Z}/9\mathbb{Z}, \qquad \lambda_9(9) = [0]_9. \tag{4.3}$$

The mark 9 is simultaneously the last positive representative and the publication of the null class. For every $n \geq 1$, the positive digital root and quotient are separated by means of

$$\mathrm{dr}_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n-1}{9} \right\rfloor, \qquad n = 9q_9(n) + \mathrm{dr}_9(n). \tag{4.4}$$

To the path $1 \to 2 \to \cdots \to 9$ we add the unique closing edge $9 \to 1$. The successor and its memory are separated:

$$u_+(a) = \begin{cases} a+1, & a < 9, \\ 1, & a = 9, \end{cases} \qquad \kappa_+(a) = \begin{cases} 0, & a < 9, \\ 1, & a = 9, \end{cases} \qquad a + 1 = u_+(a) + 9\kappa_+(a). \tag{4.5}$$

For that reason $9 \to 1$ closes the phase, increases the memory, and prolongs the genealogical state.

The square of the chart produces the finite torus and its movement graph:

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2, \qquad \Gamma_{\mathrm{APP}} = \mathrm{Cay}\big(X_9, \{\pm e_1, \pm e_2\}\big), \qquad \mathrm{Path}(\Gamma_{\mathrm{APP}}). \tag{4.6}$$

Identifying opposite sides preserves the cardinality of the chart and adds the continuation law. The core of $8^2 = 64$ interstices is completed by the minimal gnomon that publishes the zero class in both coordinates:

$$\mathcal{D}_9^2 = \mathcal{D}_8^2 \sqcup \mathcal{G}_9, \qquad 81 = 64 + (9 + 8) = 64 + 17. \tag{4.7}$$

The same law is prolonged to charts of greater depth; the scale changes, but the closure, the shared edge, and the memory of the turn preserve their type.

The associated volumetric completion is expressed through the strata identity.

$$10^3 = (9 + 1)^3 = 729 + 243 + 27 + 1. \tag{4.8}$$

The interior volume, faces, edges, and point closure are thus typed as distinct layers of the same completed unit. The evaluations act on the 81 cells of the positive chart

$$\Sigma, \Pi : \mathcal{D}_9^2 \longrightarrow \mathcal{D}_9, \qquad \Sigma(i, j) = \mathrm{dr}_9(i + j), \qquad \Pi(i, j) = \mathrm{dr}_9(ij),$$

Their residues and quotients raised are defined by

$$R^+(i, j) := \Sigma(i, j), \quad Q^+(i, j) := \frac{i + j - R^+(i, j)}{9},$$
$$R^\times(i, j) := \Pi(i, j), \quad Q^\times(i, j) := \frac{ij - R^\times(i, j)}{9},$$

and, therefore,

$$\widehat{\Sigma}(i, j) := \big(R^+(i, j), Q^+(i, j)\big), \qquad \widehat{\Sigma}, \widehat{\Pi} : \mathcal{D}_9^2 \longrightarrow \mathcal{D}_9 \times \mathbb{Z}_{\geq 0}.$$
$$\widehat{\Pi}(i, j) := \big(R^\times(i, j), Q^\times(i, j)\big),$$

The bijection $\lambda_9^{\times 2} : \mathcal{D}_9^2 \to X_9$ transports these operations and their lifts to the torus. Therefore, APP is the tuple

Multiplicative leaf of the APP chart: $\Pi(i,j) = \mathrm{dr}_9(ij)$

	1	2	3	4	5	6	7	8	9
1	1	2	3	4	5	6	7	8	**9**
2	2	4	6	8	1	3	5	7	**9**
3	3	6	9	3	6	9	3	6	**9**
4	4	8	3	7	2	6	1	5	**9**
5	5	1	6	2	7	3	8	4	**9**
6	6	3	9	6	3	9	6	3	**9**
7	7	5	3	1	8	6	4	2	**9**

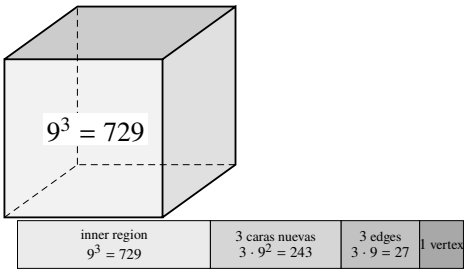
Cube of Extreme and Mean Holographic Ratio



$10^3 = 729 + 243 + 27 + 1 = 729 + 271$
growth corona $9^3 \subset 10^3$: 271 states
internal boundary of the cube of side 9: 386 points

Figure 4.1: Two finite publications of the support. Left: the product table with positive digital root and its closure gnomon. Right: the EMRH cubic completion, which distinguishes interior, faces, edges, and vertex. The growth corona 271 and the internal boundary 386 are two typed counts: the former measures the enlargement $9^3 \subset 10^3$ and the latter the boundary of the cube of side 9.

$$\mathrm{APP} = \big(\mathcal{D}_9, \lambda_9, X_9, \Gamma_{\mathrm{APP}}, \mathrm{Path}(\Gamma_{\mathrm{APP}}), \Sigma, \Pi, \widehat{\Sigma}, \widehat{\Pi}\big), \tag{4.9}$$

The table constitutes a two-dimensional representation of this complete tuple. The additive sheet is Latin; the multiplicative sheet conserves the ternary radical of the ring $\mathbb{Z}/9\mathbb{Z}$

$$R_9 := \mathbb{Z}/9\mathbb{Z}, \qquad \mathfrak{m} := ([3]_9) = \{[0]_9, [3]_9, [6]_9\} \triangleleft R_9, \qquad \mathfrak{m}^2 = (0). \tag{4.10}$$

The internal rotation is the automorphism

$$\rho : \mathfrak{m}^3 \longrightarrow \mathfrak{m}^3, \qquad \rho(x_1, x_2, x_3) = (x_2, x_3, x_1),$$

whose distinguished orbit is

$$([3]_9, [6]_9, [0]_9) \xrightarrow{\rho} ([6]_9, [0]_9, [3]_9) \xrightarrow{\rho} ([0]_9, [3]_9, [6]_9) \xrightarrow{\rho} ([3]_9, [6]_9, [0]_9).$$

The direct reduction sends $3, 6, 9$ to $0, 0, 0$. The internal coordinate of the ideal, by contrast, conserves the extracted factor:

$$\eta_{\mathfrak{m}} : (\mathfrak{m}, +) \xrightarrow{\sim} (\mathbb{Z}/3\mathbb{Z}, +), \qquad \eta_{\mathfrak{m}}([3a]_9) := [a]_3, \qquad ([3]_9, [6]_9, [0]_9) \xmapsto{\eta_{\mathfrak{m}}^{\times 3}} ([1]_3, [2]_3, [0]_3), \tag{4.11}$$

so that the $3, 6, 9$ sector remains intact and its internal coordinate is read as $1, 2, 0$. This map belongs to the radical of APP; the temporal TRIT projection constitutes the subsequent calendrical reader. The three calendrical classes remain separated as

$$C_+ = \{1, 4, 7\}, \qquad C_- = \{2, 5, 8\}, \qquad C_0 = \{3, 6, 9\}.$$

The incompatibility between the two leaves becomes a measurable invariant. On $\mathscr{A}_3 = \mathcal{D}_9^3$, with uniform measure $\nu_3(x) = 9^{-3}$, let $\mathcal{H}_3 = L^2(\mathscr{A}_3, \nu_3)$. We define

$$\Sigma_3, \Pi_3 : \mathscr{A}_3 \longrightarrow \mathcal{D}_9, \qquad \Sigma_3(x) = \mathrm{dr}_9(x_1 + x_2 + x_3), \qquad \Pi_3(x) = \mathrm{dr}_9(x_1 x_2 x_3),$$

and the orthogonal projectors

$$P_{\Sigma,3} := \mathbb{E}_{\nu_3}[\,\cdot \mid \sigma(\Sigma_3)], \qquad P_{\Pi,3} := \mathbb{E}_{\nu_3}[\,\cdot \mid \sigma(\Pi_3)] \in \mathcal{B}(\mathcal{H}_3).$$

The joint enumeration of the 9^3 words then determines

$$\left\|[P_{\Sigma,3}, P_{\Pi,3}]\right\| = \frac{\sqrt{3}}{4}, \qquad B_c = 7I + 2R = 9P_+ + 5P_-, \qquad 459 - 405 = 54.$$

The first number reappears as the electronic prefactor; the second organizes the central block; the third records the global sum–product defect.

4.2.2 TRIT: local topological unit and temporal relation unit

HMT first fixes the visible signature

$$\mathrm{TRIT}_{\mathrm{vis}} = \{-1, 0, +1\}, \qquad \tau \in \mathrm{TRIT}_{\mathrm{vis}}. \tag{4.12}$$

In contrast to the binary unit, the TRIT preserves three local regimes. In the uniform distribution, its information and entropy are distinguished as

$$I_{\mathrm{TRIT}} = \log 3 \text{ nats} = \log_2 3 \text{ bits}, \qquad S_{\mathrm{TRIT}} = k_B I_{\mathrm{TRIT}}. \tag{4.13}$$

The bit remains the binary unit; the TRIT is the minimal unit capable of simultaneously distinguishing return, threshold, and opening. The equality (4.13) quantifies the information of the triad; the cost $k_B\Theta \log 3$ belongs to the subsequent thermal reset reader. Dimensional Mechanics also preserves the arithmetic antecedent of that signature. For $(i, j) \in \mathcal{D}_9^2$, the associated lifted arithmetic cell is

$$c_{\mathrm{MD}}(i, j; \tau) = \big(i, j; R^+, Q^+, R^\times, Q^\times; \tau\big). \tag{4.14}$$

The residues $R^+, R^\times$ are the visible publication of the two sheets; the quotients $Q^+, Q^\times$ conserve the exact memory of Euclidean division; and τ orients the transition. The visible signature occupies the first level; the cell that bears it adds the arithmetic antecedents, and the enriched state then completes boundary, route, phase, and survival.

It is useful to distinguish four strata. The visible signature is τ; the residue–carry pair is its local lift; c_{MD} is the APP arithmetic cell equipped with that signature; and the TPK state adds extension, boundary, genealogical ledger, phase, and survival. This hierarchy preserves the distinct identity of the observed coordinate, its lift, the carrier cell, and the enriched history that transports it.

In the balanced ternary chart, the lifted local integer $n \in \{-4, -3, \ldots, 3, 4\}$ decomposes uniquely as

$$\widehat{n} = (r, \kappa), \qquad n = r + 3\kappa, \qquad r, \kappa \in \{-1, 0, +1\}. \tag{4.15}$$

The visible signature is $\tau = r$; κ conserves the carry that the projection $n \mapsto r$ would forget. The fiber over the visible zero contains three distinct states,

$$0^+ = (0, +1), \qquad 0^0 = (0, 0), \qquad 0^- = (0, -1),$$

because $n = -3, 0, 3$ have the same visible residue and different carries. This is the minimal topological lift of MD: an oriented APP transition is endowed with the information required to invert it and to decide which prolongations remain compatible.

The signature also has a sheet-memory rule. If m_k is the active arithmetic mode, then

$$m_{k+1} = \begin{cases} \Sigma, & \tau_k = +1, \\ \Pi, & \tau_k = -1, \\ m_k, & \tau_k = 0. \end{cases} \tag{4.16}$$

Zero encodes retention of the previous sheet. For that reason the word $(+1, -1, 0)$ publishes the sequence (Σ, Π, Π): the third state conserves the active multiplicative mode.

The temporal relation is obtained by orderly parametrizing these cells. Each signature carries a quadratic algebra.

$$\mathbb{A}_\tau = \mathbb{R}[X]/(X^2 + \tau), \qquad J_\tau = [X], \tag{4.17}$$

so that

τ	J_τ^2	ordered temporal relation
$+1$	$-I$	elliptic return, memory and past,
0	0	parabolic threshold and present,
-1	$+I$	bidirectional hyperbolic opening and future.

The TRIT precedes external time: it first classifies the algebraic and topological type of the transport; an ordered parameterization then publishes it as a temporal relation. The twofold direction is typed by the exact involution

$$C_{\mathrm{rev}}(\tau_1, \dots, \tau_n) = (-\tau_n, \dots, -\tau_1), \qquad C_{\mathrm{rev}}^2 = I, \tag{4.18}$$

which exchanges return and opening and preserves the threshold. On the hyperbolic sheet, $P_\pm = (I \pm J_{-1})/2$ separate the two eigendirections, and reversal exchanges their orientations. Topology and time are thus the two coordinated readings of the TRIT.

The combinatorial involution C_{rev} and an operatorial conjugation C belong, however, to distinct domains. In a separate dynamic realization, endowed with $H = H^*$, $CJ_EC^{-1} = -J_E$, and $CHC^{-1} = H$, we fix an internal action scale $\hbar_{\mathrm{int}} > 0$ and write $h_{\mathrm{int}} := 2\pi\hbar_{\mathrm{int}}$. Then

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}}), \qquad CU(t)C^{-1} = U(-t). \tag{4.19}$$

The intertwiner that transports TRIT words to the dynamical realization fixes the correspondence between C_{rev} and C. The twofold local orientation provides the domain of that construction.

4.2.3 TPK: category of transport and phase evolution

The *Topological Phase Kernel* is the transport category over the observable base of APP that composes digits, words, operators, and prolongation relations within a single enriched state. Its internal architecture is distributed among eight operator classes, differentiated by domain, codomain, and function:

(i) observable support and enriched state;

(ii) internal sheet selector $M_{\mathrm{ph}} : \{1, \dots, 9\} \to \{+1, -1, 0\}$;

(iii) cardinal translations and visible evolution F_{obs};

(iv) readers and quotients nonadic, tritico and of block 1000;

(v) memory, carry, cylinder, boundary, and genealogical register;

(vi) periodicity and return $C_{12} \hookrightarrow C_{108} \twoheadrightarrow C_9, \mathcal{K}_{27}$, and channels 90/120;

(vii) prolongations Ext_r, cylinders, survival, and natural bidirectional extension;

(viii) Archimedean-output, calibrated-exceptional, and dimensional functors.

The return of 27 steps is the composite morphism.

$$\mathcal{K}_{27} := F_{\mathrm{obs}}^{27}, \qquad \mathcal{K}_{27}^4 = F_{\mathrm{obs}}^{108}. \tag{4.20}$$

Its fourth iterate restores the observable phase of the calendar, while the memory and the complete TPK state continue along their trajectory; $\mathcal{K}_{27}$ is the internal return morphism of C_{108}. The calendar

C_{108}, the nonadic connection, the bilateral extension, and the readers occupy typed places within this architecture. Let $\mathsf{P}_{\mathrm{APP}}$ be the free category of the directed graph of APP, and let $\mathsf{P}_{\mathrm{APP}}^{(2)} = \mathsf{P}_{\mathrm{APP}} \times \mathsf{P}_{\mathrm{APP}}$ be its simultaneous sum–product reading. Let, moreover,

$$\mathcal{Q}_{\mathrm{obs}} = X_9^2 \times \{N, E, S, O\}^2 \times \Theta_{108}, \qquad \Theta_{108} = \mathbb{Z}/108\mathbb{Z},$$

where, for the representative $\widetilde{\theta} \in \{0, \dots, 107\}$,

$$r(\theta) = 1 + (\widetilde{\theta} \bmod 9), \qquad g_0(\theta) = [\widetilde{\theta}]_9,$$

$$\tau(\theta) = \begin{cases} +1, & r(\theta) \in \{1,4,7\}, \\ -1, & r(\theta) \in \{2,5,8\}, \\ 0, & r(\theta) \in \{3,6,9\}, \end{cases} \qquad \mu(\theta) = \begin{cases} \Sigma, & \tau(\theta) = +1, \\ \Pi, & \tau(\theta) = -1, \\ \varnothing, & \tau(\theta) = 0. \end{cases}$$

The calendar label $\mu = \varnothing$ marks the threshold, and the dynamic memory m_k of (4.16) retains the last active sheet. A configuration $q = (p^{\Sigma}, p^{\Pi}, d^{\Sigma}, d^{\Pi}, \theta)$ preserves the two positions, the two cardinal directions, and the calendar index. The visible evolution F_{obs} activates the sheet indicated by TRIT, transports the corresponding position, and advances θ. Let $\mathsf{P}_{\mathrm{obs}}$ denote the free category generated by the arrows $q \to F_{\mathrm{obs}}(q)$. Each arrow induces a pair of APP paths and defines the base functor

$$B : \mathsf{P}_{\mathrm{obs}} \longrightarrow \mathsf{P}_{\mathrm{APP}}^{(2)}. \tag{4.21}$$

Over each q lies the typed fibre

$$\mathcal{F}_q = \mathsf{O}_q \times \mathsf{H}_q \times \mathsf{C}_q \times \mathsf{S}_q \times \mathsf{B}_q \times \Lambda_q, \tag{4.22}$$

Its six factors conserve, respectively, orientation and sheet; residue and quotient; carry; signature; cylinder and boundary; and ordered register of transport. Memory and survival are properties of the composition and of the prolongation relations.

For a route $r : q \to q'$, the relation

$$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'} \tag{4.23}$$

contains all admissible continuations and satisfies

$$\Delta_q \subseteq \mathrm{Ext}_{\mathrm{id}_q}, \qquad \mathrm{Ext}_{r_2} \circ \mathrm{Ext}_{r_1} \subseteq \mathrm{Ext}_{r_2 \circ r_1}.$$

Transports respect identities and composition:

$$\begin{gathered} \mathsf{H}(\mathrm{id}_q) = I, \quad \mathsf{C}(\mathrm{id}_q) = I, \quad \Lambda(\mathrm{id}_q) = I, \quad \kappa(\mathrm{id}_q) = 0, \\ \mathsf{H}(r_2 \circ r_1) = \mathsf{H}(r_2)\mathsf{H}(r_1), \quad \mathsf{C}(r_2 \circ r_1) = \mathsf{C}(r_2)\mathsf{C}(r_1), \quad \Lambda(r_2 \circ r_1) = \Lambda(r_2)\Lambda(r_1). \end{gathered} \tag{4.24}$$

Along with these functorial laws, the transported coordinates obey

$$\begin{aligned} h' &= \mathsf{H}(r)(h), \\ c' &= \mathsf{C}(r)(c) + \kappa(r), \\ \lambda' &= \Lambda(r)(\lambda), \\ \sigma' &= \mathrm{Sig}_{q'}(h', c', \lambda'), \end{aligned} \qquad \kappa(r_2 \circ r_1) = \kappa(r_2) + \mathsf{C}(r_2)\kappa(r_1). \tag{4.25}$$

The last identity is the carry cocycle that makes the composition with memory associative.

The TPK is then the category TPK whose objects are

$$x = (q, o, h, c, \sigma, C, b, \lambda), \qquad (o, h, c, \sigma, (C, b), \lambda) \in \mathcal{F}_q, \tag{4.26}$$

and whose morphisms $x \to x'$ are the triples (r, x, x') such that the coordinates satisfy (4.25) and $(f_x, f_{x'}) \in \mathrm{Ext}_r$, where $f_x \in \mathcal{F}_q$ and $f_{x'} \in \mathcal{F}_{q'}$. Composition is

$$(r_2, x', x'') \circ (r_1, x, x') = (r_2 \circ r_1, x, x''), \tag{4.27}$$

the identity is (id_q, x, x), and the functor

$$p : \mathsf{TPK} \longrightarrow \mathsf{P}_{\mathrm{obs}}, \qquad p(x) = q, \qquad p(r, x, x') = r, \tag{4.28}$$

publishes the visible configuration without identifying states of the same fiber. The definition fixes a category over a base; it does not presuppose that it is a categorical fibration nor that every arrow admits a Cartesian lift. The local projections remain separated by type:

$$\pi_{\mathrm{TRIT}} : \mathrm{Ob}(\mathsf{TPK}) \longrightarrow \mathrm{TRIT}_{\mathrm{vis}}, \qquad \pi_{\mathrm{TRIT}}(x) = \tau(\theta),$$

$$\pi_{\mathrm{loc}}(x) = \big(\pi_{\mathrm{TRIT}}(x), \mu(\theta), o, h, c, \sigma, \lambda, g_0(\theta)\big).$$

The first recovers only the visible TRIT signature. The second further preserves the calendrical sheet label, orientation, the residue–quotient pair, carry, transport signature, genealogical register, and phase, but still forgets the cylinder, its boundary label, and other coordinates of q. This is why neither the visible TRIT nor its local register replaces the enriched state of the TPK.

The name encompasses three inseparable functions. *Topological* refers to the category of paths, incidence, boundary, and prolongation by cylinders; *Phase* refers to the nonadic index, the oriented calendar, and holonomy; *Kernel* names the persistent transport kernel that remains before the state is contracted by a reader. Formally, the object is the preceding category: an additional topology on objects or morphisms, or its identification with the linear kernel of a map, requires independent data.

Consequently, two routes with the same visible endpoint may remain objects distinct by sheet, quotient, carry, boundary, cylinder, phase, or register. The TPK does not choose a scalar output: it conserves the common antecedent from which the Archimedean, exceptional, and dimensional publications depart.

4.3 Development of the formal kernel: initial conditions, geometry and refinement

The support of eighty-one positions does not coincide with the domain of initial conditions of the dynamics. An initial condition must also specify an orientation; and the additive and multiplicative sheets have independent cursors. This distinction allows emission to be reconstructed exhaustively without selecting a numerical region in advance.

4.3.1 Initial states and the emission recurrence

For enumeration we use indices $I_9 = \{0, \dots, 8\}$, related to the positive labels by $i \mapsto i + 1$. Let

$$\mathcal{S} = I_9^2 \times \{N, E, S, O\}, \qquad \Omega_{\mathrm{seed}} = \mathcal{S}_+ \times \mathcal{S}_\times.$$

Each initial condition $\omega = (s_+, s_\times)$ determines two positions and two directions. The domain comprises all ordered pairs, so

$$|\mathcal{S}| = 324, \qquad |\Omega_{\mathrm{seed}}| = 324^2 = 104\,976. \tag{4.29}$$

The census of residual-emitter signatures in Section 155 enumerates these conditions by identifiers and presents their fibers; the law transforming them is defined here. The rows of an emission table are fibers of this initial-condition domain.

The finite realization uses six windows of nine transitions. At each instant t, the phase signature is $M_{\mathrm{ph}}(1+((t-1) \bmod 9))$. If it equals $+1$, the positive residue $\Sigma(i+1, j+1) = \rho_9(i+j+2)$ of the first cursor is read and that cursor is then shifted; if it equals -1, the positive residue $\Pi(i+1, j+1) = \rho_9((i+1)(j+1))$

of the second cursor is read and the second is then shifted. Zero increments the neutral counter. At the end of transitions twenty-seven and fifty-four, the cardinal orientations are reversed. Integer evaluations and their quotients are preserved in the register, but the emitter uses the residue readings specified here.

In the unit sector, the multiplicative reader uses the base-two discrete logarithm in $(\mathbb{Z}/9\mathbb{Z})^{\times}$:

$$\ell_9(1) = 0, \quad \ell_9(2) = 1, \quad \ell_9(4) = 2, \quad \ell_9(8) = 3, \quad \ell_9(7) = 4, \quad \ell_9(5) = 5.$$

For finite emission it is extended by zero to the nonunit sector. This extension is an observable, not an identification of the elements $3, 6, 9$ with the multiplicative unit. The sheet and its membership in the radical sector remain in the trajectory register.

Let S_m be the sum of the three positive additive residues Σ of window m, E_m the sum of the three discrete exponents of the multiplicative residues Π and $Z_m = 3$ the number of neutral events. Thus, S_m does not sum the integer evaluations $S = i + j$, whose quotients remain in the register. With $[a]_{10} \in \{0, \dots, 9\}$, the decimal emission rule is

$$\begin{aligned} d_{m,1} &= [S_m]_{10}, \\ d_{m,2} &= [S_m + E_m]_{10}, \\ d_{m,3} &= [3S_m + 5E_m + 7Z_m]_{10}, \\ U_m &= 100d_{m,1} + 10d_{m,2} + d_{m,3}. \end{aligned} \tag{4.30}$$

The integer coefficients and calendar of this recurrence are an explicit part of the declared emission law. No values of π, φ, e or α are received. The distinction between an emission rule and a constant recognized from its output prevents the genealogy from being hidden in a table of decimals.

If $s_m = [S_m]_{10}$ and $e_m = [E_m]_{10}$, the same rule is written

$$U_m = 100s_m + 10[s_m + e_m]_{10} + [3s_m + 5e_m + 1]_{10}. \tag{4.31}$$

The final one is the residue of $7Z_m = 21$ modulo ten. The oriented ternary reduction of the catalogue adopts the convention

$$\Psi(U_1, \dots, U_6) = ([-U_1]_3, \dots, [-U_6]_3). \tag{4.32}$$

The sign of this chart is explicit: changing it modifies the words and requires subsequent orientations to be transported. Balanced identification of each component of $\mathbb{F}_3$ with TRIT is performed after (4.32).

Proposition 4.1 (Injective factorization of emission)**.** *The word $U = (U_1, \dots, U_6)$ determines the two signatures $s = (s_1, \dots, s_6)$ and $e = (e_1, \dots, e_6)$. The emission image has $18 \cdot 26 = 468$ elements. The ternary projection has 243 distinct values in the ambient space of 729 words.*

Proof. The hundreds digits of U_m recover s_m. If b_m is its tens digit, then $e_m = [b_m - s_m]_{10}$. The units digit checks the third congruence of (4.31). Coupling is therefore injective on the product of signatures.

Enumerating the 324 conditions for one cursor through the preceding recurrence produces eighteen additive signatures, each with eighteen preimages, and twenty-six multiplicative signatures, of which twenty-four have eight preimages, one has twenty-four, and one has one hundred and eight. Section 155 collects the signatures, their multiplicities, and the exact rule recovering their initial conditions. Injectivity of the coupling gives $18 \cdot 26$ emissions and multiplicities

$$\underbrace{432}_{18\cdot 24} \text{ fibers of } 144, \qquad 18 \text{ fibers of } 432, \qquad 18 \text{ fibers of } 1944.$$

The sum is $432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976$. Applying (4.32) to the 468 emissions produces exactly 243 words. This last number is the cardinality of the image, not of the space $\mathbb{F}_3^6$. □

This factorization explains the difference between finite exhaustiveness and unlimited depth. The domain (4.29) is complete for the declared support and emitter; it does not contain in advance every prefix of every prolongation. Depth belongs to the system of compatible extensions constructed on those conditions.

4.3.2 Calendar closure and memory advance

The calendar of one hundred and eight transitions consists of twelve nonadic windows. Its group structure is more precise than an informal product of two periods:

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0, \quad \iota([b]) = [9b], \quad p([t]) = [t]_9. \tag{4.33}$$

If $t = 9b + r$ with $0 \le r < 9$, adding two phases produces the carry

$$(b, r) + (b', r') = \left(b + b' + \left\lfloor \frac{r + r'}{9} \right\rfloor,\ [r + r']_9 \right),$$

where the first coordinate is reduced modulo twelve. Composition preserves the term linking the two coordinates.

Proposition 4.2 (Nonsplitting of the calendar)**.** *The sequence* (4.33) *is exact and admits no section that is a group homomorphism.*

Proof. The kernel of reduction modulo nine is the subgroup of multiples of nine, the image of ι. If the extension split, commutativity would give $C_{108} \cong C_{12} \times C_9$. The first group has exponent 108, whereas the second has exponent $\operatorname{mcm}(12, 9) = 36$, a contradiction. □

Nine transitions restore the nonadic phase and advance one window; one hundred and eight restore the finite calendar. Neither fact requires erasing the trajectory or restoring the prefix of a prolongation. The nonadic holonomy Γ_9 denotes the transport of one turn on states with memory, so

$$g(\Gamma_9 x) = g(x), \qquad M(\Gamma_9 x) = M(x) + 1. \tag{4.34}$$

Phase equality and memory increment are compatible and constitute two observations of the same transport.

4.3.2.1 Temporal parametrization of compatibility and tritic orientation

The temporal interpretation of TRIT is established on transitions of the complete state. Let $x \xrightarrow{\text{adm}} y$ be the admissibility relation determined by TPK operations on $\widehat{X}$. A trajectory parametrized by a discretely ordered set $\mathcal{T}$ is a map

$$\gamma : \mathcal{T} \longrightarrow \widehat{X}, \qquad \gamma(t) \xrightarrow{\text{adm}} \gamma(t^+),$$

where t^+ is the successor of t. The compatibility relation precedes choice of the parameter: the order allows its transitions to be expressed as an evolution. When the term section is used, the projection $p : E \to \mathcal{T}$ and condition $p \circ \gamma = \mathrm{id}_{\mathcal{T}}$ are also declared. This specifies the state space, temporal order and information transported.

The signature τ selects a quadratic regime and admits a temporal reading relative to that parametrization. Type +1, with $J_{+1}^2 = -I$, represents return and memory; type 0, with $J_0^2 = 0$, represents the transition threshold; type −1, with $J_{-1}^2 = I$, represents opening in two eigendirections. In the model's temporal terminology, these functions correspond, respectively, to past, present and future. The correspondence refers to the operational position of a transition within a history: preserved antecedent, update and admissible prolongation.

This interpretation acquires content through three distinct operations. Restricting a trajectory recovers the already constructed prefix. The update $\mathcal{U}_t$ composes selection, transport and recording in the observed transition. Prolongation considers the continuations that preserve that prefix's boundary conditions. If $\mathcal{P}_n(x)$ denotes the set of admissible continuations of length n from x, removing the last step defines

$$r_n : \mathcal{P}_{n+1}(x) \longrightarrow \mathcal{P}_n(x).$$

An unlimited continuation is a family $(\gamma_n)_{n\geq 1}$ satisfying $r_n(\gamma_{n+1}) = \gamma_n$. The inverse system thus preserves the restrictions each depth imposes on the preceding ones. Existence of a compatible family is established in the corresponding prolongation domain; merely establishing the sets $\mathcal{P}_n(x)$ does not replace that proof.

Bidirectionality therefore combines reconstruction of antecedents with compatibility of continuations. On the sequence of signatures, the involution C_{rev} reverses the order and changes the sign of each component. The trajectory is additionally acted on by the position, sheet and boundary transformations specified by transport. The inverted signature is an observation of the conjugate trajectory, not a replacement for its remaining coordinates. The threshold remains distinguished: the visible value 0 retains its transition function even when its quotient or historical register is nonzero.

The relation to exponential geometries is equally precise. In each fixed regime, $\exp(tJ_\tau)$ composes parameters and preserves the algebraic norm. Elliptic closure belongs to that local representation. The phase return of Γ_9, by contrast, acts on the trajectory with memory, according to (4.34). A trajectory can recover its phase and preserve a new antecedent: the historical datum has changed even though the phase observation is the same. The parabolic threshold retains a linear shift; hyperbolic opening separates two eigendirections of expansion and contraction. These three realizations provide composition laws, while TPK determines their selection and effective concatenation.

The aperiodic suspension of Section 10.5 will make this distinction explicit through a finite phase factor, an irrational rotation and a memory degree. The link between TRIT and temporality is thus expressed by operations on trajectories and their quadratic representations. Its content goes beyond a classification of signs: it preserves the regime, direction of transport and relation between antecedent, transition and continuation.

The monodromy representation of this return is developed in Section 10.5.11. There the holonomy of the state is distinguished from its representation on phase and counter. The symbolic suspension of Section 10.5.13 defines the aperiodic time-crystal model, and Section 10.5.15 composes that temporality with the three Euler realizations.

4.3.3 Observable compression and orthogonal conservation

An isometric realization allows what a reduced observation loses to be expressed quantitatively. Let $U : \mathcal{H} \to \mathcal{H}$ be an isometric realization of the transport of one turn, $U^*U = I$, and $J : \mathcal{H}_{\mathrm{vis}} \to \mathcal{H}$ an isometric inclusion. Define

$$T = J^*UJ, \qquad D = (I - JJ^*)UJ.$$

Then

$$UJ = JT + D, \qquad J^*D = 0, \qquad I - T^*T = D^*D. \tag{4.35}$$

The last equality follows by taking the adjoint product of the first and using orthogonality. Contraction of the visible component does not by itself constitute destruction of information in the total state.

Proposition 4.3 (Conservation at a finite horizon)**.** *If $I - T^*T = D^*D$, then, for every $n \geq 1$,*

$$I = \sum_{r=0}^{n-1} T^{*r} D^* D T^r + T^{*n} T^n. \tag{4.36}$$

Proof. Multiplying $D^*D = I - T^*T$ by T^{*r} and T^r and summing produces a telescoping sum. The interior terms cancel and $I - T^{*n}T^n$ remains. □

The last summand preserves the terminal state. Suppressing it before justifying a limit would alter the equality. This distinction is the operational content of preservation of unity in compression: the norm is distributed among the visible component, memory and terminal, without being replaced by a single residue.

4.3.4 Local development: commutation, Lorentzian signature, and discrete curvature

The adjacent diagonal block with equal diagonals modulo nine is unique. Indeed,

$$k^2 \equiv (k+1)^2 \pmod 9 \quad \Longleftrightarrow \quad 2k+1 \equiv 0 \pmod 9$$

gives $k = 4$. Its visible matrix is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 7I + 2R, \quad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad R^2 = I.$$

With $P_\pm = (I \pm R)/2$, we obtain $B_c = 9P_+ + 5P_-$. The unity of stochastic normalization and preservation of an indefinite form are two realizations of this block:

$$\frac{B_c}{9} = P_+ + \frac{5}{9}P_-, \qquad \frac{B_c}{\sqrt{45}} = \exp(\eta R), \quad \eta = \frac{1}{2}\log\frac{9}{5}.$$

For $Q = \mathrm{diag}(1,-1)$, the second matrix satisfies $B_c^{\mathsf{T}} Q B_c = 45Q$. This yields a local realization in $SO^+(1,1)$; proving it does not require introducing a four-dimensional spacetime beforehand.

Uniform averaging over the classes $C_1 = \{1,4,7\}$, $C_2 = \{2,5,8\}$, $C_0 = \{3,6,9\}$ gives

$$M_\Pi = \begin{pmatrix} 4 & 5 & 6 \\ 5 & 4 & 6 \\ 6 & 6 & 9 \end{pmatrix}, \quad M_\Sigma = \begin{pmatrix} 5 & 6 & 4 \\ 6 & 4 & 5 \\ 4 & 5 & 6 \end{pmatrix}.$$

The characteristic polynomial of M_Π is

$$(\lambda + 1)((\lambda - 9)^2 - 72),$$

whence its quadratic form has signature $(2,1)$. The local spectral gap $9 - 5 = 4$, coefficient 2, aggregate difference $51 - 45 = 6$ and integrated defect $9 \cdot 6 = 54$ describe distinct levels of the same arithmetic comparison. They are not interchangeable indices of the same operator.

Discrete curvature can be described directly before this spectral realization. In residues, let $S(x,y) = x + y$, $P(x,y) = xy$ and Δ_x, Δ_y be the forward differences. The link variables are potential differences, $A_x^T = \Delta_x T$, $A_y^T = \Delta_y T$, and we fix

$$F(T_x, T_y) = \Delta_x \Delta_y T_y - \Delta_y \Delta_x T_x.$$

Since $\Delta_x S = \Delta_y S = 1$, $\Delta_x P = y$, and $\Delta_y P = x$,

$$F(S,S) = F(P,P) = 0, \qquad F(S,P) = +1, \quad F(P,S) = -1 \pmod 9. \tag{4.37}$$

Sum and product, taken separately, induce flat connections; the ordered mixture changes the sign of plaquette curvature. On summing over a rectangle with sides a, b, interior edges cancel and the oriented boundary sum equals $\pm ab$ modulo nine. An exact relation thus appears between composition order and boundary orientation.

4.3.5 Cubic completion and two notions of boundary

The enlargement of the cubic support of side nine to that of side ten admits an exact positional stratification:

$$10^3 = 9^3 + 3 \cdot 9^2 + 3 \cdot 9 + 1 = 729 + 243 + 27 + 1. \tag{4.38}$$

The first term corresponds to the three interior coordinates; the second, to one new coordinate; the third, to two; and the last, to the vertex of three new coordinates. The enlargement shell contains 271 positions. By contrast, the internal boundary of the discrete cube of side nine contains $9^3 - 7^3 = 386$. The difference between these counts is a difference of domain, not a conflict of values.

Dividing (4.38) by 1000 gives a normalized partition of unity. Cube incidence distinguishes six faces, twelve edges and eight vertices. The subsequent link with Steiner hexads and octads requires the corresponding combinatorial maps; cube cardinalities do not replace them. This completion here provides the relation between bases 729 and 1000, while exceptional prolongation will be developed after numerical generation, the dodecaphasic register and the constructions of α.

4.3.5.1 Stratification of the completion and restoration of the apex

The completion admits a set-theoretic description making its operation explicit. Let E_9 be the set of nine residue classes, positively represented by $1, \dots, 9$, and let $*$ be an additional element. The symbol $*$ is distinct from the zero class, already represented by 9. Consequently, enlargement from E_9 to $\widehat{E} = E_9 \sqcup \{*\}$ increases cardinality from nine to ten without modifying the internal modular identification. The cubic completion is $\widehat{C} = \widehat{E}^3$, and the initial cube is $C = E_9^3$.

Definition 4.4 (Strata of combinatorial codimension)**.** For $0 \le r \le 3$, define

$$S_r = \{(x_1, x_2, x_3) \in \widehat{E}^3 : \#\{j : x_j = *\} = r\}.$$

The apex of the completion is $a_* = (*, *, *)$, and the punctured completion is $\widehat{C}^\circ = \widehat{C} \setminus \{a_*\}$.

Proposition 4.5 (Exact decomposition of the completion)**.** *The strata are disjoint and satisfy*

$$\widehat{C} = S_0 \sqcup S_1 \sqcup S_2 \sqcup S_3, \qquad |S_r| = \binom{3}{r} 9^{3-r}, \tag{4.39}$$

$$|\widehat{C}^\circ| = 729 + 243 + 27 = 999, \qquad |\widehat{C}| = 999 + 1 = 1000. \tag{4.40}$$

The punctured enlargement contains 270 *elements additional to the initial cube; the complete enlargement contains* 271.

Proof. An element of S_r is obtained by choosing the r coordinates containing $*$, in $\binom{3}{r}$ ways, and assigning to the remaining ones one of the nine classes of E_9. Classification by the number of additional coordinates is exhaustive and its classes are disjoint. The unique element of S_3 is a_*. Removing it subtracts one unit from the total cardinality; restoring it recovers the complete Cartesian product. □

The expression *holographic extreme and mean ratio*, abbreviated EMRH in the corpus, here denotes this articulation between the initial body, enlargement strata and unit restitution. Its immediate content is the exact partition of a finite product and its normalization. The number 999 represents a determined object, the punctured completion; 1000 represents its closure by restitution of the apex. The added unit therefore has an explicit incidence residence.

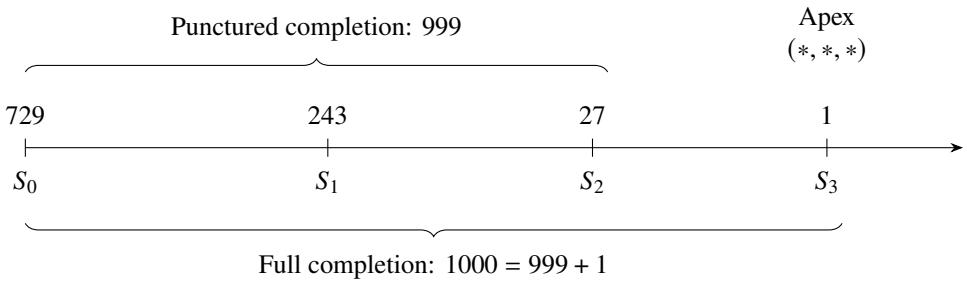


Figure 4.2: Strata of the cubic completion. The arrangement represents the set-theoretic decomposition, not a metric scale. The 243 elements of S_1 are three coordinate strata of 81 elements; the 27 of S_2 are three strata of 9. The apex completes the partition.

4.3.5.2 Preservation of unity and dimensional compatibility

Normalization is not limited to dividing an isolated identity. In dimension d, the product $\widehat{E}^d$ carries the uniform measure $\mu_d(\{x\}) = 10^{-d}$. The coordinate projection $p_d : \widehat{E}^{d+1} \to \widehat{E}^d$ removes the last coordinate.

Proposition 4.6 (Projective compatibility of normalized measures)**.** *For all $d \geq 1$,*

$$(p_d)_* \mu_{d+1} = \mu_d, \qquad \mu_d(\widehat{E}^d) = 1.$$

The mass of the stratum with r additional coordinates is $\binom{d}{r} 9^{d-r}/10^d$, and the sum of the masses of all strata is one.

Proof. Each point of $\widehat{E}^d$ has ten preimages. Their total mass is $10\,10^{-(d+1)} = 10^{-d}$. Equality for any subset is obtained by summing over its points. The stratified formula follows from the same count as (4.39); the binomial expression $(9 + 1)^d$ gives total normalization. □

In dimension three, removing the apex leaves mass $999/1000$, and restoring it adds $1/1000$. Renormalizing before restitution would define another measure: the distinction is operationally relevant. In particular, conservation of probability mass, preservation of transport registers and thermodynamic dissipation are assertions about different objects. The proposition proves the first and provides the compatible support for studying the second; the third requires a specified dynamic and energetic realization.

The internal geometric boundary also remains distinct. On the Cartesian representative $\{1, \ldots, 9\}^3$, removing $\{2, \ldots, 8\}^3$ leaves 386 points. This boundary belongs to the initial cube, whereas $\widehat{C} \setminus C$ belongs to its enlargement. Cubic completion, base-one-thousand positional expansion and the exceptional incidence reading share support data; their respective maps determine what information from those data each representation uses.

4.3.6 Cubic incidence and Lorentzian realization

Cubic completion provides a relation between interior and boundary. Its geometry can be developed through incidence of the six faces with the eight vertices. Label the faces by (i, ε), $i \in \{1, 2, 3\}$, $\varepsilon \in \{+1, -1\}$, and the vertices by $\nu \in \{+1, -1\}^3$. The incidence matrix is

$$M_{(i,\varepsilon),\nu} = \mathbf{1}_{\{\nu_i = \varepsilon\}}.$$

Let $u = (1, \ldots, 1)^\mathsf{T} \in \mathbb{R}^6$, R_F be face opposition and $P_u = uu^\mathsf{T}/6$, $P_- = (I - R_F)/2$.

Proposition 4.7 (Four-dimensional incidence quotient)**.** *The incidence Gram matrix satisfies*

$$MM^\mathsf{T} = 12P_u + 4P_-.$$

Its eigenvalues $12, 4, 0$ *have multiplicities* $1, 3, 2$. *Consequently,*

$$Q_\square = \mathbb{R}^6/\ker(MM^{\mathsf{T}}) \simeq \mathbb{R}u \oplus E_-, \qquad E_- = \operatorname{im} P_-.$$

Proof. A face contains four vertices; two opposite faces have empty intersection, and two distinct nonopposite faces share two vertices. The matrix $12P_u + 4P_-$ has precisely those entries. The uniform space has dimension one; differences between opposite faces span a three-dimensional space orthogonal to the uniform one. Its complement has dimension two and belongs to the kernel. □

The decomposition $1 + 3$ comes from incidence. The temporal choice is declared through the bilinear form

$$B_\square([x], [y]) = \langle x, (P_- - P_u)y\rangle.$$

It is well-defined on the quotient, because both projectors annihilate the kernel. In the basis

$$t = [u]/\sqrt{6}, \qquad d_i = [e_{i,+} - e_{i,-}]/\sqrt{2},$$

its matrix is $\operatorname{diag}(-1, 1, 1, 1)$. The domain, decomposition and sign convention producing the Minkowski realization are made explicit. The positive Gram matrix determines the quotient; the temporal assignment determines the indefinite form on it.

The operator

$$W_\square = \sqrt{6}P_u + \sqrt{2}P_-, \qquad W_\square e_{i,\varepsilon} = t + \varepsilon d_i$$

sends the six face labels to null directions, since $B_\square(t + \varepsilon d_i, t + \varepsilon d_i) = -1 + 1 = 0$. Inversion of a direction and face opposition thus have a specific geometric realization.

4.3.6.1 Soldering, inversion and subdivision

The cellular realization uses an invertible transport $U_m(a)$, preserving the Lorentzian form, between the fibers at the endpoints of an oriented dual edge a, a face label $\lambda_m(a)$ and an orientation $\sigma_m(a)$. With $\ell_m = \ell_0/9^m$, the soldering map is

$$\beta_m(a) = \ell_m \sigma_m(a) W_{\square, s(a)} e_{\lambda_m(a)}.$$

Compatible reversal satisfies

$$\beta_m(\bar{a}) = -U_m(a)\beta_m(a).$$

Identify the origin fibers at two consecutive levels through the declared refinement isometry. If the nine subsegments $a_1, \dots, a_9$, of level $m + 1$, preserve the label and orientation when transported to that common fiber, then

$$\beta_m(a) = \sum_{j=1}^{9} U_{m+1}(a_1 \cdots a_{j-1})^{-1} \beta_{m+1}(a_j). \tag{4.41}$$

Each transported term equals $\ell_m/9$ times the same null direction, proving the identity. The compatibility hypothesis determines which subdivisions realize this refinement. The equation combines direction, scale and transport, instead of limiting the geometric correspondence to a count of dimensions.

With orientation and Lorentzian form also fixed, Hodge duality on $\Lambda^2 Q_\square^*$ satisfies $\star^2 = -I$. In dimension four, the sign is $(-1)^{2(4-2)+1} = -1$. This yields a real complex structure on two-forms and, after complexification, the eigenspaces of values $+i$ and $-i$. The electromagnetic realization will use this domain after constructing the electronic section and declaring its coupling.

4.3.7 Compatibility between modular and positional reductions

The block decimal base enters through a Euclidean division simultaneously preserving remainder and quotient:

$$n = 1000q + r, \qquad 0 \le r < 1000.$$

Since $1000 \equiv 1 \pmod 9$ and $1000 \equiv 1 \pmod 3$,

$$n \equiv q + r \pmod 9, \qquad n \equiv q + r \pmod 3.$$

Therefore, reduction of a block requires the quotient's contribution to recover the integer's class. The numbers 0 and 1000 have the same remainder modulo 1000, but different classes modulo 9 and modulo 3. This is an operator reason to preserve memory during a change of resolution.

Ternary refinement and determination of a decimal prefix can be coordinated through a single integer residue. If $N/3^L$ is a cylinder endpoint and $D/1000^r$ a decimal endpoint, define

$$A = 1000^r N - D3^L.$$

On adding six ternary symbols, $N' = 729N + \nu$, $L' = L + 6$, with $0 \le \nu < 729$. If the decimal prefix remains fixed, we obtain

$$A' = 729A + \nu 1000^r.$$

If a decimal block δ is also incorporated, then $D' = 1000D + \delta$, $r' = r + 1$, and

$$A' = 729000A + \nu 1000^{r+1} - 729\delta 3^L. \tag{4.42}$$

Both identities are proved by substituting the definitions. Endpoint comparison is thus reduced to integer operations retaining the contribution of each prolongation. This compatibility allows a region to be refined before its real coordinate is evaluated.

4.3.8 The number as a compatible section and the value as a reading

Distinguishing state from observation specifies what object is prolonged as resolution increases. At depth n, let X_n be the set of admissible states produced by APP–TRIT–TPK. Their data include position, sum and product sheets, residues and quotients, regime, orientation, carry, phase, route, boundary, memory, and survival. These are not independent coordinates: earlier arithmetic evaluations and transports impose their relations. A prolongation preserves these relations in each antecedent, even while adding new steps and memory data. This is the meaning of the arithmetic of histories developed in (Sections 4.3 and 10.5.11).

Let $r_{m,n} : X_m \to X_n$, for $m \ge n$, be the depth restrictions, with $r_{n,n} = \mathrm{id}$ and $r_{\ell,n} = r_{m,n} \circ r_{\ell,m}$. Each restriction preserves the prefix and the information already determined in it.

Definition 4.8 (Compatible numerical section)**.** An HMT number is a compatible history of the state system:

$$x = (x_n)_{n\ge 0} \in X_\infty := \varprojlim_n X_n, \qquad r_{m,n}(x_m) = x_n. \tag{4.43}$$

A reader is an additional operation on a specified domain of these histories. A digit is a finite observation; a scalar value is an evaluation of the reader. The pair formed by the section and its reader constitutes a read presentation, not a redefinition of the section's identity.

In the Archimedean domain X_∞^{Arch}, the reader associates a closed cylinder with each prefix, preserves their nesting and makes their diameter tend to zero. It thus determines

$$\mathrm{ev}_{\mathbb{R}} : X_\infty^{\mathrm{Arch}} \longrightarrow \mathbb{R}, \qquad \{\mathrm{ev}_{\mathbb{R}}(x)\} = \bigcap_n I_n(x). \tag{4.44}$$

The specific construction of these cylinders and determination of their boundaries are developed in Section 10.5. Definition (4.43) does not by itself assert that the image of (4.44) is the whole line: a coverage assertion requires its own theorem. Nor does equality of values establish, without an injectivity result, equality of their histories. This separation allows precision to be discussed as depth while preserving the difference between the arithmetic antecedent and its scalar realization.

4.3.9 Composition of histories and memory multiplier

Fix a sector of states at depth n and a category C whose arrows are its admissible histories. Composition is written $vu = v \circ u$: first u is traversed, then v. Elementary steps come from TPK selection, transport and update. A local tritic fiber admits the expression $\mathbb{R}[J_x]/(J_x^2 + \tau(x)1_x)$, where $\tau(x) \in \{+1, 0, -1\}$. Regime and orientation belong to the transported state; a transition between regimes is not equivalent to identifying their quadratic algebras.

The following formulation makes an algebraic sector of that composition precise. For each object x, a unital associative real algebra A_x is given, which may be noncommutative. For each $u : x \to y$, a unital homomorphism $\rho_u : A_x \to A_y$ is given. We assume a strict action:

$$\rho_{\mathrm{id}_x} = \mathrm{id}_{A_x}, \qquad \rho_v \rho_u = \rho_{vu}. \tag{4.45}$$

For each composable pair $u : x \to y$, $v : y \to z$, fix an invertible central multiplier $\Omega(v, u) \in Z(A_z)^\times$. We require the normalization $\Omega(\mathrm{id}_y, u) = \Omega(u, \mathrm{id}_x) = 1_y$ and, for each composable triple, the identity

$$\rho_w\big(\Omega(v, u)\big)\Omega(w, vu) = \Omega(w, v)\Omega(wv, u). \tag{4.46}$$

These are explicit hypotheses on transports and their coefficients, not a consequence of calling the dynamics holonomic. When applying this presentation to a TPK sector, its ρ_u and $\Omega(v, u)$ must be identified. Transitions expressed through bimodules require that structure to be preserved and are not replaced by (4.45).

The space of finite sums

$$\mathcal{H}(C, A, \rho, \Omega) = \bigoplus_{u \in \mathrm{Mor}(C)} A_{t(u)} T_u$$

receives the bilinear product

$$(aT_v)(bT_u) = a\rho_v(b)\Omega(v, u)T_{vu}, \tag{4.47}$$

if the arrows are composable, and zero otherwise. Here $t(u)$ denotes the terminal state. The sum combines histories with coefficients; the product concatenates histories while preserving the register multiplier.

Proposition 4.9 (Sectorial associativity with a central multiplier)**.** *Under* (4.45) *and* (4.46)*, the product* (4.47) *is associative. If the object set is finite, its unit is* $\sum_x 1_x T_{\mathrm{id}_x}$.

Proof. For $u : x \to y$, $v : y \to z$, $w : z \to t$, let $a \in A_y$, $b \in A_z$, $c \in A_t$. The two coefficients of T_{wvu} are

$$\begin{aligned} ((cT_w)(bT_v))(aT_u) &: \quad c\rho_w(b)\Omega(w, v)\rho_{wv}(a)\Omega(wv, u), \\ (cT_w)((bT_v)(aT_u)) &: \quad c\rho_w(b)\rho_w\rho_v(a)\rho_w(\Omega(v, u))\Omega(w, vu). \end{aligned}$$

The strict action equates $\rho_w\rho_v(a)$ with $\rho_{wv}(a)$. Centrality of $\Omega(w, v)$ allows it to be moved to the right of that factor; (4.46) then equates the remaining products. The coefficients a, b, c are not permuted. If the triple is not composable, both parenthesizations are zero because of their initial and terminal states. Bilinearity completes the proof. The local identities and normalization of Ω verify the indicated unit. □

Calendar carry provides an effective example. In the category with one object and arrows C_9, take coefficients $A = \mathbb{R}[z, z^{-1}]$, identity action and

$$\Omega(b,a) = z^{c_0(a,b)}, \qquad c_0(a,b) = \left\lfloor \frac{a+b}{9} \right\rfloor, \quad 0 \le a, b < 9.$$

The two carry sums of a triple are $\lfloor (a+b+c)/9 \rfloor$; hence (4.46) holds. The formal variable z records the turn without assigning it a numerical value. Subsequently imposing $z^{12} = 1$ recovers the dodecaphasic register of the calendar (4.33); retaining z without that relation distinguishes successive turns. The example realizes the memory of this calendar, without identifying it with the entirety of TPK memory.

4.3.10 Double variance of refinement and preservation of unity

Restricting states prolongs observables in the opposite direction. Consider the function algebras, with pointwise product, $D_n = \mathrm{Fun}(X_n, \mathbb{R})$. Precomposition defines

$$r^*_{m,n} : D_n \longrightarrow D_m, \qquad r^*_{m,n} f = f \circ r_{m,n}. \tag{4.48}$$

These are unital morphisms; they are also injective when the corresponding restrictions are surjective. The direct limit $D_{\mathrm{cyl}} = \varinjlim_n (D_n, r^*_{n+1,n})$ brings together observations of finite depth. This algebra is not identified here with the entire route algebra: prolonging transport operators also requires their compatibilities with refinement.

Lemma 4.10 (Unit and naturality of evaluation)**.** *If e_x is the indicator of $x \in X_n$, then*

$$r^*_{m,n} e_x = \sum_{y:\, r_{m,n}(y) = x} e_y, \qquad r^*_{m,n} 1_n = 1_m, \tag{4.49}$$

and, for every $f \in D_n$, $y \in X_m$,

$$\langle r^*_{m,n} f, y \rangle = \langle f, r_{m,n} y \rangle.$$

Each section $x \in X_\infty$ determines a well-defined evaluation $D_{\mathrm{cyl}} \to \mathbb{R}$, given by $[f] \mapsto f(x_n)$ for $f \in D_n$.

Proof. The fibers of $r_{m,n}$ partition X_m. Their indicators are orthogonal and sum to 1_m, proving (4.49). Naturality is the definition of precomposition. Finally, $(r^*_{m,n} f)(x_m) = f(x_n)$, so two compatible representatives give the same evaluation in the direct limit. □

The global unit is the constant function one over all possibilities; the individual section selects a compatible history. Preserving the former does not mean immobilizing the latter. Refinement may increase the number of extensions and the depth of each history while maintaining unity and all evaluations of its antecedents.

4.3.11 Phase return, Weyl representation and two readings

The law (4.34) acquires an operator realization in the bilateral suspension to be constructed in Section 10.5. There T is the one-step advance, V_9 observes the nonadic phase, W_δ the rotation phase and D_M the memory degree. Writing $\widehat{\Gamma}_9 = T^9$ for the turn in this representation, the Weyl relations (10.53) imply, on finitely supported vectors,

$$\begin{aligned} V_9 \widehat{\Gamma}_9 &= \widehat{\Gamma}_9 V_9, \qquad W_\delta \widehat{\Gamma}_9 = e^{2\pi i 9\delta} \widehat{\Gamma}_9 W_\delta, \\ [D_M, \widehat{\Gamma}_9] &= \widehat{\Gamma}_9. \end{aligned} \tag{4.50}$$

The first equality follows from $\zeta_9^9 = 1$; the second, from nine applications of the covariance of W_δ; the third expresses the unit memory increment. Finite phase returns, while irrational rotation and memory distinguish the next state. The characters and parameter δ are subsequently realized from the numerical construction specified there: they do not retrospectively select the seeds. This representation describes observables and translations of the suspension; it does not replace all coordinates or all operators of TPK.

The double reading prolongs the same distinction between history and observable. In its Archimedean domain, (4.44) is applied; in the calibrated incidence domain, the maps Q_n of Section 21.11.1 preserve the words and boundary frames. The equality proved there $r_{n,m}Q_n = Q_m p_{n,m}$ determines their prolongation Q_∞. On the common domain of both readings one may jointly consider $\mathrm{ev}_{\mathbb{R}}(x)$ and $Q_\infty(x)$: the first retains the value; the second, the transported incidence preserved by its codomain. The section precedes both. This articulation allows the passage from arithmetic of histories to constants and the exceptional reading without turning their realizations into new initial data.

Chapter 5

Unitary construction of the discrete structure of the continuum: spectral transport, solenoidal balance, gauge incidence, cellular coherence and determinant line

The five constructions are generated correlatively on a single APP–TRIT–TPK state. They are consubstantial operations of the continuum, not an exhaustive enumeration of its properties, five independent branches, or a retrospective selection determined by subsequent applications.

5.1 Common state, prolongation tree, and genealogical measure

A single enriched state prior to any internal discrimination

The object of this chapter is the complete finite state produced by APP, oriented by TRIT, and transported by TPK. From it are constructed the groupoid of reversible symmetries, the tree of all admissible prolongations, the multisection of complete histories, and its canonical measure. No specialized domain is introduced: the domain is the total set of states effectively generated by the same APP–TRIT–TPK mechanism. Nor is any sheet, continuation, or subsequent reading selected.

5.1.1 Finite data produced by APP

For each depth $k \geq 0$, let A_k denote the finite set of cellular prefixes produced by APP, and let

$$\rho^{\mathrm{APP}}_{k+1,k} : \mathsf{A}_{k+1} \longrightarrow \mathsf{A}_k \tag{5.1}$$

the erasure of the last refinement. This erasure conserves the already constructed prefix. The neutral cell of APP gives a prolongation

$$\eta^{\mathrm{APP}}_k : \mathsf{A}_k \longrightarrow \mathsf{A}_{k+1}, \qquad \rho^{\mathrm{APP}}_{k+1,k}\eta^{\mathrm{APP}}_k = I_{\mathsf{A}_k}. \tag{5.2}$$

We write

$$\varepsilon^0_k(a) : a \longrightarrow \eta^{\mathrm{APP}}_k(a) \tag{5.3}$$

for the emission that realizes that prolongation. Thus, its destination, $\eta^{\mathrm{APP}}_k(a)$, and the operation that produces it, $\varepsilon^0_k(a)$, are kept separate. η^{APP}_k is not interpreted as an absence of history: it records a length-one refinement with neutral emission and materially preserves the preceding state.

Each $a \in \mathsf{A}_k$ simultaneously bears the two sheets of APP,

$$\mathrm{Sh}_k(a) = \big(\Sigma_k(a), \Pi_k(a)\big) \in \mathsf{H}^{\Sigma}_k \times \mathsf{H}^{\Pi}_k, \tag{5.4}$$

and not a chosen element of the pair. For an elementary emission $\epsilon : a \to a'$, APP further produces two typed Euclidean divisions,

$$\delta^{\diamond}(\epsilon) = \mathrm{res}^{\diamond}(\epsilon) + 9\,\mathrm{quo}^{\diamond}(\epsilon), \qquad \mathrm{res}^{\diamond}(\epsilon) \in \{0, \ldots, 8\}, \quad \mathrm{quo}^{\diamond}(\epsilon) \in \mathbb{Z}, \tag{5.5}$$

where $\diamond \in \{\Sigma, \Pi\}$. The label $\diamond$ merely indicates which leaf is being read; both divisions remain in the same ledger.

The cellular source and target of ϵ determine its oriented boundary

$$\partial\epsilon := t(\epsilon) - s(\epsilon). \tag{5.6}$$

The neutral emission satisfies

$$\mathrm{res}^{\diamond}(\varepsilon_k^0(a)) = 0, \qquad \mathrm{quo}^{\diamond}(\varepsilon_k^0(a)) = 0, \qquad \partial\varepsilon_k^0(a) = 0. \tag{5.7}$$

Definition 5.1 (Directed graph of APP emissions)**.** Let $\mathsf{E}_k(a)$ be the finite set of APP emissions of length one that depart from $a \in \mathsf{A}_k$. We conserve the emissions with multiplicity: two operations with the same target but with different residue, quotient, or provenance are different elements of $\mathsf{E}_k(a)$. By (5.2),

$$\varepsilon_k^0(a) \in \mathsf{E}_k(a), \qquad 1 \le \#\mathsf{E}_k(a) < \infty. \tag{5.8}$$

5.1.2 Tritic extension of the incidence datum: balanced orientation and genealogical carry cocycle

The signed incidence of an APP emission is an integer $\Delta(\epsilon)$. The balanced representative modulo three uniquely gives

$$\Delta(\epsilon) = \mathrm{or}(\epsilon) + 3\kappa(\epsilon), \qquad \mathrm{or}(\epsilon) \in \{-1, 0, +1\}, \quad \kappa(\epsilon) \in \mathbb{Z}. \tag{5.9}$$

Thus, orientation and carry are not conditions imposed on a history: they are total functions of the APP data.

To make the composition visible, let $\mathsf{C}_\epsilon : \mathsf{M}_{s(\epsilon)} \to \mathsf{M}_{t(\epsilon)}$ be the memory transport induced by the emission. The native carry of a composition satisfies

$$\kappa(\epsilon_2\epsilon_1) = \kappa(\epsilon_2) + \mathsf{C}_{\epsilon_2}\kappa(\epsilon_1), \tag{5.10}$$

whenever $t(\epsilon_1) = s(\epsilon_2)$. For the identity and the neutral emission,

$$\kappa(I_a) = 0, \qquad \kappa(\varepsilon_k^0(a)) = 0, \qquad \mathsf{C}_{I_a} = I_{\mathsf{M}_a}. \tag{5.11}$$

Lemma 5.2 (Associativity of the carry ledger)**.** *For three composable emissions, the evaluation of* $\kappa(\epsilon_3\epsilon_2\epsilon_1)$ *does not depend on the parenthesization.*

Proof. Applying (5.10) twice to the left parenthesization gives

$$\kappa(\epsilon_3) + \mathsf{C}_{\epsilon_3}\kappa(\epsilon_2) + \mathsf{C}_{\epsilon_3}\mathsf{C}_{\epsilon_2}\kappa(\epsilon_1).$$

The right parenthesization produces the same expression because the transport of memory is functorial: $\mathsf{C}_{\epsilon_3\epsilon_2} = \mathsf{C}_{\epsilon_3}\mathsf{C}_{\epsilon_2}$. □

The oriented reversal of a reversible emission is denoted by $\overline{\epsilon}$. TRIT acts by

$$\mathrm{or}(\overline{\epsilon}) = -\mathrm{or}(\epsilon), \qquad \partial\overline{\epsilon} = -\partial\epsilon, \qquad \mathsf{C}_{\overline{\epsilon}} = \mathsf{C}_\epsilon^{-1}. \tag{5.12}$$

The inverse carry is determined, not chosen, by

$$\kappa(\overline{\epsilon}) = -\mathsf{C}_\epsilon^{-1}\kappa(\epsilon), \tag{5.13}$$

for $\kappa(\overline{\epsilon}\epsilon) = 0$.

5.1.3 TPK transport of the 2 leaves and of memory

TPK chronology is part of the type of each emission and is not reconstructed a posteriori by counting letters. Here we recover the action of the ometer of definition 1.163 y theorem 1.165. Let

$$C_9 := \mathbb{Z}/9\mathbb{Z}, \qquad \widetilde{O}_9 := \mathbb{Z}_{\ge 0} \times C_9, \qquad O_{9,12} := \mathbb{Z}/12\mathbb{Z} \times C_9. \tag{5.14}$$

The unrolled phase-and-memory state is $\mathsf{Q}_k = (w_k, r_k) \in \widetilde{\mathcal{O}}_9$; its reduction $(w, r) \mapsto ([w]_{12}, r)$ recovers $\mathcal{O}_{9,12}$. The canonical seed of the clock is

$$\mathsf{Q}_0(a_0) := (0, [0]_9) \qquad (a_0 \in \mathsf{A}_0); \tag{5.15}$$

the other choices of origin are their coherent translations by C_9 and do not change the update law. For $\bar{r} \in \{0, \dots, 8\}$, we set

$$\chi_9(r) := \left\lfloor \frac{\bar{r} + 1}{9} \right\rfloor. \tag{5.16}$$

Every emission ϵ that lleva depth k to depth $k + 1$ acts in the odometro by

$$\sigma_9(w, r) := (w + \chi_9(r), r + [1]_9), \qquad \mathsf{Q}_{k+1}(\epsilon_* \widehat{x}_k) = \sigma_9 \mathsf{Q}_k(\widehat{x}_k). \tag{5.17}$$

Its phase component is, by typed definition,

$$\mathrm{ph}(\epsilon) : r_k \longmapsto r_k + [1]_9, \qquad \mathrm{ph}(\epsilon_n \cdots \epsilon_1) : r_k \longmapsto r_k + [n]_9. \tag{5.18}$$

We write $g_k := r_k \in C_9$ for the published phase and $q_k^{(9)} := w_k$ for the vertical memory, and $\beta_k := [w_k]_{12}$ for its duodecaphase reduction. The iteration of (5.17) is

$$\sigma_9^n(w, r) = \left(w + \left\lfloor \frac{\bar{r} + n}{9} \right\rfloor, r + [n]_9 \right). \tag{5.19}$$

In efecto, the sumandos $\chi_9(r), \chi_9(r + [1]_9), \dots, \chi_9(r + [n - 1]_9)$ cuentan exactly the cruces of the representative 8 to the representative 0, that are $\lfloor (\bar{r} + n)/9 \rfloor$. In particular,

$$\sigma_9^9(w, r) = (w + 1, r), \qquad g_{k+9} = g_k, \qquad q_{k+9}^{(9)} = q_k^{(9)} + 1. \tag{5.20}$$

Even the neutral emission of APP realizes $g_k \mapsto g_{k+1}$: it is neutral in residue, quotient, carry, and boundary, but records that an extension has occurred. The phase word

$$\boldsymbol{\tau}_k^{(N)} := (g_k, g_{k+1}, \dots, g_N), \qquad g_{j+1} = g_j + [1]_9, \tag{5.21}$$

and the memory $q^{(9)}$ type the phase return and the state change as distinct objects.

5.1.3.1 Simultaneous Renewal of the Complete Fiber

The preceding odometer conserves the chronology of each extension. The same nonadic turn also has the internal Markov realization, already constructed over the APP–TPK catalogue, which simultaneously renews the two coordinates of the complete fiber. It is essential to conserve both realizations and not to identify a generic edge of the tree with an emission of the catalogue without a typing map.

Proposition 5.3 (Internal Markov Realization of the Nonadic Connection)**.** *Let the APP seed domain, its observable emission, and its multiplicities be*

$$T_{\min} : \Omega_{\mathrm{seed}} \twoheadrightarrow \mathcal{U}_6, \qquad m(u) := \#T_{\min}^{-1}(u),$$

and the factorization produced by the TPK

$$\mathcal{U}_6 \simeq \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\mathcal{S}_+| = 18, \qquad |\mathcal{S}_\times| = 26.$$

On functions in $\mathcal{U}_6$, the two conditional expectations act by

$$(E_+ f)(s, e) = \frac{1}{18} \sum_{s' \in \mathcal{S}_+} f(s', e), \qquad (E_\times f)(s, e) = \frac{1}{26} \sum_{e' \in \mathcal{S}_\times} f(s, e').$$

For

$$\tau = (+1, -1, 0, +1, -1, 0, +1, -1, 0), \qquad P_{+1} = E_+, \quad P_{-1} = E_\times, \quad P_0 = I,$$

the catalog transfer and its elevation to all seeds are

$$\begin{aligned} \mathcal{K}_{\mathrm{ph}}\big((u,r),(v,r+1)\big) &= P_{\tau(r)}(u,v), \qquad (5.22)\\ L_0(\omega,\omega') &= \mathbf{1}_{\{\omega=\omega'\}},\\ L_+(\omega,\omega') &= \frac{E_+(T_{\min}\omega, T_{\min}\omega')}{m(T_{\min}\omega')},\\ L_\times(\omega,\omega') &= \frac{E_\times(T_{\min}\omega, T_{\min}\omega')}{m(T_{\min}\omega')},\\ \widehat{\mathcal{K}}_{\mathrm{ph}}\big((\omega,r),(\omega',r+1)\big) &= L_{\tau(r)}(\omega,\omega'). \qquad (5.23) \end{aligned}$$

For $u = T_{\min}\omega$, it holds phase by phase that

$$\sum_{\omega' : T_{\min}\omega' = v} \widehat{\mathcal{K}}_{\mathrm{ph}}\big((\omega,r),(\omega',r+1)\big) = \mathcal{K}_{\mathrm{ph}}\big((u,r),(v,r+1)\big). \qquad (5.24)$$

In particular,

$$\boxed{\mathcal{K}_{\mathrm{ph}}^{9}\big|_r = E_+E_\times, \qquad (E_+E_\times)(u,v) = \frac{1}{468}.} \qquad (5.25)$$

Proof. In a phase + or ×, summing (5.23) over $T_{\min}^{-1}(v)$ exactly cancels the denominator $m(v)$; in a zero phase, L_0 projects onto the identity. This proves (5.24). The operators E_+, $E_\times$, and I are idempotent and commute, and each appears three times in the nonadic word. Therefore

$$\prod_{r \in C_9} P_{\tau(r)} = E_+^3 E_\times^3 I^3 = E_+E_\times.$$

The composition first renews one coordinate of cardinal 18 and then the other of cardinal 26, so that each target receives $1/(18 \cdot 26) = 1/468$. □

Remark 5.4 (Two internal realizations, without fictitious identification). The transfer $\mathcal{K}_{\mathrm{ph}}$ is the global realization of the complete catalog, and σ_9 is the chronological action on each state of the tree. One is not substituted for the other. An edge-by-edge equality would require an additional map

$$\mathrm{Cat}_{k,x} : \mathrm{Out}(x) \longrightarrow \mathcal{U}_6$$

that verified the corresponding sum identity on fibers. That map is not used in this volume. The complete monodromy (5.25) proceeds from the APP–TPK catalogue, while the genealogy of each history remains in the tree and its ledger.

TPK assigns to each admissible emission a typed transport of the leaf pair,

$$U_\epsilon : \mathsf{H}^{\Sigma}_{s(\epsilon)} \times \mathsf{H}^{\Pi}_{s(\epsilon)} \longrightarrow \mathsf{H}^{\Sigma}_{t(\epsilon)} \times \mathsf{H}^{\Pi}_{t(\epsilon)}, \qquad (5.26)$$

with

$$U_{I_a} = I, \qquad U_{\epsilon_2\epsilon_1} = U_{\epsilon_2}U_{\epsilon_1}. \qquad (5.27)$$

The codomain of U_ϵ remains the complete pair. No operation in this chapter replaces (Σ, Π) by one of its coordinates.

Let $m \in \mathsf{M}_{s(\epsilon)}$ be an accumulated memory. The TPK action over it is the affine transformation

$$\mathsf{U}_\epsilon(m) := \mathsf{C}_\epsilon m + \kappa(\epsilon). \qquad (5.28)$$

Lemma 5.5 (TPK Action on Memory)**.** *The transformations* U_ϵ *satisfy*

$$\mathsf{U}_{I_a} = I, \qquad \mathsf{U}_{\epsilon_2\epsilon_1} = \mathsf{U}_{\epsilon_2}\mathsf{U}_{\epsilon_1}. \tag{5.29}$$

Proof. The identity follows from (5.11). For the composition,

$$\begin{aligned}\mathsf{U}_{\epsilon_2}\mathsf{U}_{\epsilon_1}(m) &= \mathsf{C}_{\epsilon_2}\big(\mathsf{C}_{\epsilon_1}m + \kappa(\epsilon_1)\big) + \kappa(\epsilon_2)\\ &= \mathsf{C}_{\epsilon_2\epsilon_1}m + \kappa(\epsilon_2) + \mathsf{C}_{\epsilon_2}\kappa(\epsilon_1)\\ &= \mathsf{C}_{\epsilon_2\epsilon_1}m + \kappa(\epsilon_2\epsilon_1),\end{aligned}$$

where the last equality is (5.10). □

A finite route is a composable word.

$$\gamma = \epsilon_1\epsilon_2\cdots\epsilon_k. \tag{5.30}$$

Its boundary, transport, carry, and memory are

$$\partial\gamma := \sum_{j=1}^{k}\partial\epsilon_j, \tag{5.31}$$

$$U_\gamma := U_{\epsilon_k}\cdots U_{\epsilon_1}, \tag{5.32}$$

$$\kappa(\gamma) := \kappa(\epsilon_k) + \sum_{j=1}^{k-1}\mathsf{C}_{\epsilon_k}\cdots\mathsf{C}_{\epsilon_{j+1}}\kappa(\epsilon_j), \tag{5.33}$$

$$m(\gamma; m_0) := \mathsf{U}_{\epsilon_k}\cdots\mathsf{U}_{\epsilon_1}(m_0). \tag{5.34}$$

In (5.31), the interior endpoints cancel, leaving

$$\partial\gamma = t(\epsilon_k) - s(\epsilon_1). \tag{5.35}$$

5.1.4 The common state and its total domain

Definition 5.6 (Elementary ledger)**.** For an emission that appears between two consecutive enriched prefixes, we denote by $\mathsf{Q}^-(\epsilon) = (w^-(\epsilon), r^-(\epsilon))$ the odometer of the source prefix and by

$$\mathsf{Q}^+(\epsilon) := \sigma_9\mathsf{Q}^-(\epsilon) = (w^-(\epsilon) + \chi_9(r^-(\epsilon)), r^-(\epsilon) + [1]_9) \tag{5.36}$$

that of the destination prefix. Thus the odometer is not applied to a bare APP cell. The emission record is

$$\lambda(\epsilon) := \big(s(\epsilon), t(\epsilon), \mathrm{res}^\Sigma(\epsilon), \mathrm{quo}^\Sigma(\epsilon), \mathrm{res}^\Pi(\epsilon), \mathrm{quo}^\Pi(\epsilon), \mathrm{or}(\epsilon), \kappa(\epsilon), \partial\epsilon, \mathsf{Q}^-(\epsilon), \mathsf{Q}^+(\epsilon)\big). \tag{5.37}$$

The ledger of γ is the word ordered

$$\mathrm{Led}(\gamma) := \big(\lambda(\epsilon_1), \ldots, \lambda(\epsilon_k)\big). \tag{5.38}$$

Preserving this word, and not only its sum, distinguishes two histories with the same terminal output.

5.1.4.1 Complete reader of the TPK state

The depth K of TPK blocks and the depth k of the extension tree are distinct types. In this subsection, K denotes exclusively the depth of the TPK state already generated by the operator mechanism; it is not identified with k or with a generic edge.

Definition 5.7 (Compact nonadic memory reader)**.** The TPK enriched state of depth K is

$$v_K = \big(B_K, \boldsymbol{\delta}_K, \boldsymbol{x}_K, \boldsymbol{C}_K, \Sigma_K, \omega_K, \ell_K, g(K), \Lambda_K\big), \qquad B_K = (u_K^{\pi}, u_K^{e}, u_K^{\varphi}). \tag{5.39}$$

Its compact reader does not add coordinates: it publishes them from that same state,

$$\mathfrak{r}_9(v_K) := \big(B_K, C_K, p_K, c_K, \Sigma_K, W_K, g(K)\big), \tag{5.40}$$

where

$$\begin{aligned} C_K &:= \boldsymbol{C}_K = \big(C_K^{\chi}\big)_{\chi\in\{\pi,e,\varphi\}},\\ C_K^{\chi} &:= (N_K^{\chi}, L_K^{\chi}, r_K^{\chi}, D_K^{\chi}, A_K^{\chi}, B_K^{\chi}),\\ p_K &:= (B_0, \dots, B_K),\\ c_K &:= (\boldsymbol{\delta}_K, \boldsymbol{x}_K, \kappa(\gamma_{0:K}^{\mathrm{TPK}})), \end{aligned} \tag{5.41}$$

and the oriented shadow of Witt is preserved as

$$W_K := \big((u_K^{\chi}, u_K^{\chi} A_W)\big)_{\chi\in\{\pi,e,\varphi\}}, \qquad A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1\\ 1 & 0 & 1 & 2 & 2 & 1\\ 1 & 1 & 0 & 1 & 2 & 2\\ 1 & 2 & 1 & 0 & 1 & 2\\ 1 & 2 & 2 & 1 & 0 & 1\\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}, \qquad A_W^2 = -I_6. \tag{5.42}$$

The route $\gamma_{0:K}^{\mathrm{TPK}}$ is the word of extensions encoded by Λ_K; its prefix of length j is the one that produces v_j. The signature is the output of the explicit internal primitive

$$\Sigma_B : \mathsf{B}_{\mathrm{TPK}} \times \mathsf{C}_{\mathrm{TPK}} \times \mathbb{Z}[\mathsf{A}] \times \Omega_{12} \times \mathsf{L}_{\mathrm{TPK}} \longrightarrow \mathsf{S}_{\mathrm{TPK}}, \quad (B, c, \partial\gamma, \omega, \ell) \longmapsto \Sigma_B(B, c, \partial\gamma, \omega, \ell), \tag{5.43}$$

with $\Sigma_B(g \cdot -) = g \cdot \Sigma_B(-)$ for each TPK symmetry. Its explicit starting structure is $(B_K, c_K, \partial\gamma_{0:K}^{\mathrm{TPK}}, \omega_K, \ell_K)$. It is not replaced by an external signature nor inferred retrospectively from a numerical reader.

The action of step $K \mapsto K+1$ is written without omitting the deep state. For each $\chi \in \{\pi, e, \varphi\}$,

$$y_K^{\chi} = x_K^{\chi} A_H, \qquad u_{K+1}^{\chi} = y_K^{\chi} \bmod 3, \qquad x_{K+1}^{\chi} = \frac{y_K^{\chi} - u_{K+1}^{\chi}}{3}, \tag{5.44}$$

with

$$A_H = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1\\ 2 & 1 & 2 & 2 & 1 & 1\\ 1 & 0 & 0 & 1 & 0 & 2\\ 0 & 0 & 1 & 1 & 1 & 0\\ 2 & 2 & 2 & 0 & 2 & 1\\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad \det A_H = 1.$$

If

$$\mathrm{ind}_3(u_1, \dots, u_6) := \sum_{j=1}^{6} \overline{u}_j \, 3^{6-j} \in \{0, \dots, 728\},$$

the update of the prefix and its 729 subcylinders is

$$N_{K+1}^{\chi} = 729 N_K^{\chi} + \mathrm{ind}_3(u_{K+1}^{\chi}), \qquad L_{K+1}^{\chi} = L_K^{\chi} + 6, \tag{5.45}$$

$$I^{\chi}_{K,u} := \left[\frac{729N^{\chi}_{K} + u}{3^{L^{\chi}_{K}+6}}, \frac{729N^{\chi}_{K} + u + 1}{3^{L^{\chi}_{K}+6}} \right), \qquad 0 \le u < 729. \tag{5.46}$$

The decimal cylinder and the associated carry are updated by the two integer cases of the same operator $C_{3,1000}$. If a new decimal triad is not published,

$$r^{\chi}_{K+1} = r^{\chi}_{K}, \qquad D^{\chi}_{K+1} = D^{\chi}_{K}, \qquad A^{\chi}_{K+1} = 729A^{\chi}_{K} + \mathrm{ind}_3(u^{\chi}_{K+1})1000^{r^{\chi}_{K}}, \qquad B^{\chi}_{K+1} = A^{\chi}_{K+1} + 1000^{r^{\chi}_{K}}. \tag{5.47}$$

The primitive $C_{3,1000}$ produces the option datum

$$d^{\mathrm{dec}}_{K+1,\chi} \in \{\bot\} \sqcup \{0, \dots, 999\};$$

in the first case it equals $d^{\mathrm{dec}}_{K+1,\chi} = \bot$. If a triad occurs, we write $d^{\mathrm{dec}}_{K+1,\chi} = \delta^{\chi}_{K+1} \in \{0, \dots, 999\}$ and

$$\begin{aligned} r^{\chi}_{K+1} &= r^{\chi}_{K} + 1, \qquad D^{\chi}_{K+1} = 1000D^{\chi}_{K} + \delta^{\chi}_{K+1}, \\ A^{\chi}_{K+1} &= 729000A^{\chi}_{K} + \mathrm{ind}_3(u^{\chi}_{K+1})1000^{r^{\chi}_{K}+1} - 729\delta^{\chi}_{K+1}3^{L^{\chi}_{K}}, \\ B^{\chi}_{K+1} &= A^{\chi}_{K+1} + 1000^{r^{\chi}_{K}+1}. \end{aligned} \tag{5.48}$$

The register $\boldsymbol{\delta}_{K+1}$ adds those triads and the two joint cocycles

$$\begin{aligned} q_{K+1} &= (u^{\pi}_{K+1} + u^{e}_{K+1} + u^{\varphi}_{K+1}) \bmod 3, \quad c^{\mathrm{joint}}_{K+1} = \frac{u^{\pi}_{K+1} + u^{e}_{K+1} + u^{\varphi}_{K+1} - q_{K+1}}{3}, \\ a_{K+1} &= (u^{\pi}_{K+1} + u^{e}_{K+1} - u^{\varphi}_{K+1}) \bmod 3, \quad h^{\mathrm{joint}}_{K+1} = \frac{u^{\pi}_{K+1} + u^{e}_{K+1} - u^{\varphi}_{K+1} - a_{K+1}}{3}, \\ \boldsymbol{\delta}_{K+1} &= \boldsymbol{\delta}_{K} \star \big((d^{\mathrm{dec}}_{K+1,\chi})_{\chi}, c^{\mathrm{joint}}_{K+1}, h^{\mathrm{joint}}_{K+1}\big). \end{aligned} \tag{5.49}$$

Thus C_{K+1}, $\boldsymbol{\delta}_{K+1}$, and $\boldsymbol{x}_{K+1}$ have material actions, not merely names. The other coordinates are simultaneously updated by

$$p_{K+1} = p_{K} \star B_{K+1}, \tag{5.50}$$

$$\kappa(\gamma^{\mathrm{TPK}}_{0:K+1}) = \kappa(\varepsilon^{\mathrm{TPK}}_{K+1}) + \mathsf{C}_{\varepsilon^{\mathrm{TPK}}_{K+1}}\kappa(\gamma^{\mathrm{TPK}}_{0:K}), \tag{5.51}$$

$$c^{\mathrm{comp}}_{K+1} := (\boldsymbol{\delta}_{K+1}, \boldsymbol{x}_{K+1}, \kappa(\gamma^{\mathrm{TPK}}_{0:K+1})), \tag{5.52}$$

$$\Sigma_{K+1} = \Sigma_{B}\big(B_{K+1}, c^{\mathrm{comp}}_{K+1}, \partial\gamma^{\mathrm{TPK}}_{0:K} + \partial\varepsilon^{\mathrm{TPK}}_{K+1}, \omega_{K+1}, \ell_{K+1}\big), \tag{5.53}$$

$$W_{K+1} = \big((u^{\chi}_{K+1}, u^{\chi}_{K+1}A_{W})\big)_{\chi}, \qquad g(K+1) = g(K) + [1]_9. \tag{5.54}$$

Since A_H is invertible modulo three and $A^2_W = -I_6$, the residue and shadow updates do not collapse distinct blocks. Truncation preserves the complete sequences

$$(B_0, \dots, B_K),\ (C_0, \dots, C_K),\ (p_0, \dots, p_K),\ (c_0, \dots, c_K),\ (\Sigma_0, \dots, \Sigma_K),\ (W_0, \dots, W_K)$$

and simultaneously removes its last entry. Hence the reader $\mathfrak{r}_9$ commutes with the erasure of a block.

Proposition 5.8 (Universal scope and certified scope of non-rebooting)**.** *On every horizontal circuit of nine steps, the following are preserved*

$$g(K+9) = g(K), \qquad q_{\mathrm{mem}}(K+9) = q_{\mathrm{mem}}(K) + 1,$$

and the prefix is prolonged with nine emissions, so the state is not reset. In the certified joint section $\chi \in \{\pi, e, \varphi\}$, $0 \le K < 387$, it also holds that

$$(p_K, C_K) \neq (p_{K+9}, C_{K+9}), \qquad (B_K, \mathbf{N}_K, W_K) \neq (B_{K+9}, \mathbf{N}_{K+9}, W_{K+9}), \qquad \mathbf{N}_K := (N_K^{\pi}, N_K^{e}, N_K^{\varphi}). \tag{5.55}$$

Proof. The two universal identities are the exact iteration of (5.17); the prefix preserves the nine entries adjoined by (5.50). For the joint section, the recurrence (5.45) compares the 387 nonadic pairs of each of the three channels and produces (5.55); this is the assertion certified in theorem 8.54. Finally, $u \mapsto (u, uA_W)$ is injective, so the change of block also preserves the change of its complete shadow. This last inequality is not extended to an arbitrary neutral prolongation outside the certified section. □

Definition 5.9 (APP–TRIT–TPK state of depth k)**.** For a route $\gamma = \epsilon_1 \cdots \epsilon_k$ born in an APP cell a_0, the common enriched state is

$$\widehat{x}_k(\gamma) := \Big(a_0, \dots, a_k; \mathrm{Sh}_0, \dots, \mathrm{Sh}_k; \mathbf{res}_k, \mathbf{quo}_k; \mathbf{or}_k, \kappa_k; \mathsf{Q}_k; g_k; q_k^{(9)}; \beta_k; m_k; \partial\gamma; \gamma; \mathrm{Led}(\gamma)\Big), \tag{5.56}$$

where

$$\begin{aligned} \mathbf{res}_k &:= \big((\mathrm{res}^{\Sigma}(\epsilon_j), \mathrm{res}^{\Pi}(\epsilon_j))\big)_{1\le j\le k}, \\ \mathbf{quo}_k &:= \big((\mathrm{quo}^{\Sigma}(\epsilon_j), \mathrm{quo}^{\Pi}(\epsilon_j))\big)_{1\le j\le k}, \\ \mathbf{or}_k &:= \big(\mathrm{or}(\epsilon_j)\big)_{1\le j\le k}, \qquad \kappa_k := \big(\kappa(\epsilon_j)\big)_{1\le j\le k}, \\ m_k &:= m(\gamma; m_0). \end{aligned}$$

The intermediate sheets are obtained by $\mathrm{Sh}_j = U_{\epsilon_j}\,\mathrm{Sh}_{j-1}$.

The simultaneous presence of the route and the ledger prevents identifying distinct words that terminate in the same cell. The state is not a list of cardinals: each coordinate has the type and composition equations of the preceding sections.

Definition 5.10 (Total depth finite domain)**.** Let

$$\widehat{\mathcal{X}}_k^{\mathrm{tot}} := \left\{ \widehat{x}_k(\epsilon_1 \cdots \epsilon_k) : \begin{array}{l} a_0 \in \mathsf{A}_0, \\ \epsilon_j \in \mathsf{E}_{j-1}(a_{j-1}), \\ s(\epsilon_j) = a_{j-1},\ t(\epsilon_j) = a_j \end{array} \right\}. \tag{5.57}$$

No condition from a later publication is added to (5.57). Being an element of the domain means exactly having been produced by the total actions (5.5), (5.9), and (5.17)– (5.28).

The common truncation deletes the last emission and all and only the entries of the ledger that it produced:

$$\rho_{k+1,k} : \widehat{\mathcal{X}}_{k+1}^{\mathrm{tot}} \longrightarrow \widehat{\mathcal{X}}_k^{\mathrm{tot}}, \qquad \rho_{k+1,k}\widehat{x}_{k+1} = \widehat{x}_k. \tag{5.58}$$

Let $\varepsilon_k^0(x)$ be the neutral emission (5.3) applied to the APP endpoint of x. The neutral prolongation defines

$$\eta_k : \widehat{\mathcal{X}}_k^{\mathrm{tot}} \longrightarrow \widehat{\mathcal{X}}_{k+1}^{\mathrm{tot}}, \qquad \eta_k(x) := (\varepsilon_k^0(x))_* x, \qquad \rho_{k+1,k}\eta_k = I. \tag{5.59}$$

Proposition 5.11 (Finiteness, non-emptiness, and surjectivity)**.** *For every k, the set $\widehat{\mathcal{X}}_k^{\mathrm{tot}}$ is finite and nonempty, and $\rho_{k+1,k}$ is surjective.*

Proof. APP produces a nonempty finite set at depth zero. At each step, every state has a finite set of emissions through (5.8); by induction, there are only finitely many words of length k. The sequence of neutral prolongations produces at least one word of each length. Finally, (5.59) is a right inverse of truncation, so the latter is surjective. □

5.1.5 Finite reversible symmetry groupoid

The reversible operations of APP, TRIT, and TPK act on the entire state. Let U be the group of coherent families $g = (g_k)_{k\ge 0}$ generated by those operations, where

$$\rho_{k+1,k} g_{k+1} = g_k \rho_{k+1,k}, \qquad g_{k+1}\eta_k = \eta_k g_k. \tag{5.60}$$

We denote by U_k its image in $\mathrm{Sym}(\widehat{\mathcal{X}}_k^{\mathrm{tot}})$. This image is finite because it acts on a finite set. The action of g_k on

$$\widehat{x} = (a_{\le k}; \mathrm{Sh}_{\le k}; \mathbf{res}, \mathbf{quo}; \mathbf{or}, \kappa; \mathsf{Q}_k; g_k; q_k^{(9)}; \beta_k; m; \partial\gamma; \gamma; \mathrm{Led}(\gamma))$$

is

$$\begin{aligned} g_k \cdot \widehat{x} := \big(&g_k a_{\le k}; U_{g_k}\,\mathrm{Sh}_{\le k}; \mathbf{res}(g_k\gamma), \mathbf{quo}(g_k\gamma); \mathbf{or}(g_k\gamma), \kappa(g_k\gamma);\\ &\mathsf{Q}(g_k\gamma); g(g_k\gamma); q^{(9)}(g_k\gamma); \beta(g_k\gamma); \mathsf{U}_{g_k}(m); (g_k)_*\partial\gamma; g_k\gamma; \mathrm{Led}(g_k\gamma)\big). \end{aligned} \tag{5.61}$$

All the terms on the right-hand side are recalculated by means of the APP, TRIT, and TPK rules; they are not copied as independent labels.

Definition 5.12 (Common action groupoid)**.** The finite groupoid of depth k is

$$\mathfrak{G}_k := \mathsf{U}_k \ltimes \widehat{\mathcal{X}}_k^{\mathrm{tot}}. \tag{5.62}$$

Its objects are the common states. An arrow $(g_k, \widehat{x})$ has source $\widehat{x}$, target $g_k \cdot \widehat{x}$, identity $(I, \widehat{x})$, and inverse $(g_k^{-1}, g_k \cdot \widehat{x})$.

Lemma 5.13 (The action preserves all equations of state)**.** *The action* (5.61) *preserves the pair of sheets, the APP divisions, the TRIT orientation, the carry, the phase odometer, the vertical memory, its dodecaphase reduction, the affine memory, the boundary, the route, and the ledger, in their respective types. Moreover,*

$$I \cdot \widehat{x} = \widehat{x}, \qquad (g_{2,k} g_{1,k}) \cdot \widehat{x} = g_{2,k} \cdot (g_{1,k} \cdot \widehat{x}). \tag{5.63}$$

Proof. The APP divisions are unique, so the action on an emission redetermines its residues and quotients. The balanced decomposition (5.9) is likewise unique. Composition of the carry is associative by lemma 5.2; the action on memory is associative by lemma 5.5; and the boundary is functorial by (5.35). Finally, the action on the ordered word induces the action on its ledger entry by entry. Coherence with the odometer recalculates Q, g, and $q^{(9)}$ from the transformed route and preserves (5.17). These identities prove (5.63). □

5.1.6 Finite tree of all prolongations

For $x \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$, let $\mathrm{Out}(x)$ be the set of all admissible TPK emissions of length one from the endpoint of x. An emission belongs to $\mathrm{Out}(x)$ only when its action jointly updates all coordinates of (5.56). In particular,

$$1 \le d(x) := \#\,\mathrm{Out}(x) < \infty, \qquad \varepsilon_k^0(x) \in \mathrm{Out}(x). \tag{5.64}$$

Definition 5.14 (Truncated prolongation tree)**.** Given $N \ge k$ and $x \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$, we define $\mathcal{T}_{k,N}(x)$ as the rooted tree whose vertices at height j, $0 \le j \le N - k$, are the words

$$h = (\epsilon_{k+1}, \dots, \epsilon_{k+j}), \qquad \epsilon_{n+1} \in \mathrm{Out}(x_n), \qquad x_{n+1} = (\epsilon_{n+1})_* x_n, \tag{5.65}$$

with the empty word as root. An edge appends an emission. Two words reaching the same terminal state remain distinct vertices if their ledgers differ.

The last condition is essential: the tree records genealogies and not the quotient that remembers only the target. Its terminal level is

$$\mathrm{Term}_{k,N}(x) := \{h \in \mathscr{T}_{k,N}(x) : |h| = N - k\}. \tag{5.66}$$

Each h preserves the complete terminal state.

$$\mathrm{ter}_N(h) := \big(x_N, m_N, \partial(\gamma h), \gamma h, \mathrm{Led}(\gamma h)\big). \tag{5.67}$$

Proposition 5.15 (Finiteness and non-emptiness at every horizon)**.** *For all x, k, and $N \geq k$, the tree $\mathscr{T}_{k,N}(x)$ is finite and* $\mathrm{Term}_{k,N}(x) \neq \varnothing$.

Proof. The root has a finite positive number of successors by (5.64). Applying the same argument at each level yields, by induction, finiteness at every finite horizon. The word formed by neutral emissions $(\varepsilon^0_k, \varepsilon^0_{k+1}, \ldots, \varepsilon^0_{N-1})$ is a terminal vertex, so level (5.66) is nonempty. □

The erasure of the last emission defines

$$\pi_{N+1,N} : \mathrm{Term}_{k,N+1}(x) \longrightarrow \mathrm{Term}_{k,N}(x). \tag{5.68}$$

Lemma 5.16 (Terminal surjectivity)**.** *The map $\pi_{N+1,N}$ is surjective for every $N \geq k$.*

Proof. Let $h \in \mathrm{Term}_{k,N}(x)$, with terminal state v_h. Adding the emission $\varepsilon^0_N(v_h)$ produces $h' \in \mathrm{Term}_{k,N+1}(x)$ and $\pi_{N+1,N}(h') = h$. □

5.1.7 Nonadic Connection: Phase, Holonomy, and Memory

A word of nine emissions is not called a holonomy merely because it has length nine. The horizontal connection determined by the phase functor is first preserved. For $r \in C_9$, we define

$$\begin{aligned}\mathscr{R}_{r,k} := \big\{(x, \epsilon, \epsilon_* x) : x \in \widehat{\mathcal{X}}^{\mathrm{tot}}_k, \quad \epsilon \in \mathrm{Out}(x),\\ \mathsf{Q}_k(x) = (w, r), \quad \mathsf{Q}_{k+1}(\epsilon_* x) = \sigma_9(w, r)\big\}.\end{aligned} \tag{5.69}$$

The last equality does not restrict the domain: it is the total action (5.17) of every elementary TPK emission. The connection simultaneously transports sheet, memory and ledger:

$$\nabla_{\mathrm{TPK}}(\epsilon) := \big(\mathrm{ph}(\epsilon), U_\epsilon, \mathsf{U}_\epsilon, \lambda(\epsilon)\big). \tag{5.70}$$

Its composition is calculated by means of (5.27), (5.29), and the concatenation of the ledger.

The apex of the nonadic turn is now the set of phase-compatible horizontal lifts.

$$\begin{aligned}\mathsf{Z}^{\Gamma}_{9,k} := \coprod_{r \in C_9} \big\{(x, \epsilon_1, \ldots, \epsilon_9) : x_0 = x, \quad x_i = (\epsilon_i)_* x_{i-1},\\ (x_{i-1}, \epsilon_i, x_i) \in \mathscr{R}_{r+i-1,k+i-1}, \quad 1 \leq i \leq 9\big\},\end{aligned} \tag{5.71}$$

where the subscripts of $r + i - 1$ are read in C_9. The summand is uniquely determined by $r = g_k(x)$, so the coproduct does not duplicate witnesses. The source and target maps are

$$\widehat{\mathcal{X}}^{\mathrm{tot}}_k \xleftarrow{s_{9,k}} \mathsf{Z}^{\Gamma}_{9,k} \xrightarrow{t_{9,k}} \widehat{\mathcal{X}}^{\mathrm{tot}}_{k+9}, \qquad s_{9,k}(x, \epsilon) = x, \quad t_{9,k}(x, \epsilon) = (\epsilon_9 \cdots \epsilon_1)_* x. \tag{5.72}$$

The relational holonomy is

$$\Gamma_{9,k} := \{(s_{9,k} z, t_{9,k} z) : z \in \mathsf{Z}^{\Gamma}_{9,k}\} = \mathrm{Hol}_{C_9}(\nabla_{\mathrm{TPK}}). \tag{5.73}$$

Lemma 5.17 (The ninth level of the tree realizes the holonomy)**.** *The map that forgets the intermediate states already determined by the emissions induces a bijection*

$$\mathsf{Z}^{\Gamma}_{9,k} \xrightarrow{\cong} \coprod_{x\in\widehat{\chi}^{\mathrm{tot}}_k} \mathrm{Term}_{k,k+9}(x). \tag{5.74}$$

Proof. Each edge of $\mathrm{Out}(x_i)$ satisfies (5.17); hence a terminal word of length nine determines the nine elements of (5.69). Reciprocally, a horizontal lift of (5.71) is a composable word of the tree. The two operations conserve the emissions and are inverse. Thus (5.74) is a theorem derived from the connection, not its definition. □

Proposition 5.18 (Phase return, memory advance and no restart)**.** *For every $z = (x, \epsilon_1, \dots, \epsilon_9)$ of the apex,*

$$g(t_{9,k}z) = g(s_{9,k}z), \tag{5.75}$$
$$q^{(9)}(t_{9,k}z) = q^{(9)}(s_{9,k}z) + 1, \tag{5.76}$$
$$\mathrm{Led}(t_{9,k}z) = \mathrm{Led}(s_{9,k}z) \star \big(\lambda(\epsilon_1), \dots, \lambda(\epsilon_9)\big). \tag{5.77}$$

In particular, the phase identification $g(t_{9,k}z) = g(s_{9,k}z)$ does not induce an identification of states: after transporting both registers to the same type of comparison, their vertical memories differ by one unit. The published phase returns, not the enriched state.

Proof. The first two identities are (5.20). The third is the definition of ledger concatenation. Since the vertical memory differs by one unit, the complete states are distinct even if some additional visible coordinate could coincide. □

Proposition 5.19 (Isometric compression of the same holonomy)**.** *Let $U_{\Gamma_9} : \mathcal{H}_{\mathrm{full}} \to \mathcal{H}_{\mathrm{full}}$ be an isometric realization of the preceding holonomy and let $J : \mathcal{H}_{\mathrm{vis}} \to \mathcal{H}_{\mathrm{full}}$ be the isometric inclusion of the visible register, with $E := J^*$ and $P := JE$. We define*

$$T := EU_{\Gamma_9}J, \qquad \eta := (I - P)U_{\Gamma_9}J. \tag{5.78}$$

Then

$$\boxed{U_{\Gamma_9}J = JT + \eta, \qquad I - T^*T = \eta^*\eta.} \tag{5.79}$$

Proof. Inserting $I = P + (I - P)$ before $U_{\Gamma_9}J$ gives

$$U_{\Gamma_9}J = JEU_{\Gamma_9}J + (I - P)U_{\Gamma_9}J = JT + \eta.$$

The two summands belong to orthogonal subspaces. Since U_{Γ_9} and J are isometries,

$$I = (U_{\Gamma_9}J)^*(U_{\Gamma_9}J) = T^*T + \eta^*\eta,$$

which is the second identity. □

Proposition 5.20 (Totality and Equivariance of Holonomy)**.** *The map $s_{9,k}$ is surjective. The nine neutral prolongations form the section*

$$\begin{gathered} x_0 := x, \qquad \varepsilon^0_{k+i} := \varepsilon^0_{k+i}(x_i), \qquad x_{i+1} := (\varepsilon^0_{k+i})_* x_i \quad (0 \le i < 9), \\ \eta^{(9)}_k(x) := (x, \varepsilon^0_k, \dots, \varepsilon^0_{k+8}) \in \mathsf{Z}^{\Gamma}_{9,k}, \qquad s_{9,k}\eta^{(9)}_k = I. \end{gathered} \tag{5.80}$$

Every coherent symmetry a whose action on the odometer satisfies $\mathsf{Q}\,a = \bar{a}\,\mathsf{Q}$ and $\bar{a}\,\sigma_9 = \sigma_9\,\bar{a}$ induces

$$a^{Z}(x, \epsilon_1, \dots, \epsilon_9) := (ax, a\epsilon_1, \dots, a\epsilon_9)$$

and satisfies

$$s_{9,k}a^{Z} = a_k s_{9,k}, \qquad t_{9,k}a^{Z} = a_{k+9}t_{9,k}. \tag{5.81}$$

Proof. The neutral word exists in every source and satisfies the phase action (5.17); this proves the section and surjectivity. The condition $\bar{a}\sigma_9 = \sigma_9\bar{a}$ sends horizontal relations to horizontal relations. Acting entry by entry preserves composition, carry, memory, boundary, and ledger; reading the first or the final state before or after acting gives (5.81). □

5.1.8 Total survival and complete multisection

Definition 5.21 (Produced survival)**.** A state $x \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$ survives when

$$\mathrm{Term}_{k,N}(x) \neq \varnothing \qquad \text{for every } N \geq k. \tag{5.82}$$

We denote by Surv_k the set of such states.

Theorem 5.22 (The total domain is survivor)**.** *For every depth,*

$$\mathrm{Surv}_k = \widehat{\mathcal{X}}_k^{\mathrm{tot}}. \tag{5.83}$$

In particular, survival does not define a subset supposed before constructing the state.

Proof. The inclusion $\mathrm{Surv}_k \subseteq \widehat{\mathcal{X}}_k^{\mathrm{tot}}$ belongs to the definition. The opposite inclusion is exactly the nonemptiness at every horizon proved in proposition 5.15. □

Definition 5.23 (Multisection of complete prolongations)**.** The complete multisection over x is the inverse limit

$$\mathrm{Msect}(x) := \varprojlim_{N \geq k} \big(\mathrm{Term}_{k,N}(x), \pi_{N+1,N}\big). \tag{5.84}$$

Its elements are all the compatible infinite histories that prolong x. None of them receives priority within (5.84).

Theorem 5.24 (No material emptiness of the multisection)**.** *For every $x \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$,*

$$\mathrm{Msect}(x) \neq \varnothing. \tag{5.85}$$

Moreover, every finite coordinate of a history in $\mathrm{Msect}(x)$ *preserves both leaves, orientation, carry, memory, boundary, path, and ledger of the state that it prolongs.*

Proof. The terminal sets are finite and nonempty by proposition 5.15, and their bonding maps are surjective by lemma 5.16. A compatible element can be constructed recursively: one begins at the root and, at every step, retains a prolongation of the preceding prefix. The neutral prolongation guarantees that the process never stops. Compatibility of the coordinates follows from the fact that each edge of the tree acts through the unique state action defined in (5.56). □

5.1.9 Canonical measure generated by the tree

The measure is not introduced as an external weight on the outputs. It is obtained by counting the admissible emissions at each vertex before choosing a continuation.

Definition 5.25 (Local weight and horizon measure)**.** For $v \in \widehat{\mathcal{X}}_j^{\mathrm{tot}}$ and $\epsilon \in \mathrm{Out}(v)$, we set

$$p_v(\epsilon) := \frac{1}{d(v)} \in \mathbb{Q}_{>0}. \tag{5.86}$$

If $h = (\epsilon_{k+1}, \dots, \epsilon_N) \in \mathrm{Term}_{k,N}(x)$ and x_j is the prefix that precedes ϵ_{j+1}, we define

$$\mu_{x,N}(h) := \prod_{j=k}^{N-1} p_{x_j}(\epsilon_{j+1}) = \prod_{j=k}^{N-1} \frac{1}{d(x_j)}. \tag{5.87}$$

Lemma 5.26 (Normalization)**.** *For every horizon $N \geq k$,*

$$\sum_{h \in \mathrm{Term}_{k,N}(x)} \mu_{x,N}(h) = 1. \tag{5.88}$$

Proof. At height one, $\sum_{\epsilon \in \mathrm{Out}(x)} d(x)^{-1} = 1$. Assuming the normalization at height $N - k$, each terminal prefix h, with final state v_h, contributes at the next level

$$\sum_{\epsilon \in \mathrm{Out}(v_h)} \mu_{x,N}(h) p_{v_h}(\epsilon) = \mu_{x,N}(h).$$

Summing over all prefixes proves the identity by induction. □

Proposition 5.27 (Projective consistency)**.** *Finite measures satisfy*

$$(\pi_{N+1,N})_* \mu_{x,N+1} = \mu_{x,N}. \tag{5.89}$$

Proof. For $h \in \mathrm{Term}_{k,N}(x)$, the mass of its fiber is

$$\begin{aligned} \sum_{\pi_{N+1,N}(h')=h} \mu_{x,N+1}(h') &= \mu_{x,N}(h) \sum_{\epsilon \in \mathrm{Out}(v_h)} p_{v_h}(\epsilon) \\ &= \mu_{x,N}(h). \end{aligned}$$

This is precisely the equality of point measures equivalent to (5.89). □

The cylinders of the multisection are

$$[h]_{x,N} := \{\omega \in \mathrm{Msect}(x) : \omega|_N = h\}. \tag{5.90}$$

Theorem 5.28 (Canonical Measure of Extensions)**.** *There exists a unique measure of cilindros μ_x on* $\mathrm{Msect}(x)$ *such that*

$$\mu_x([h]_{x,N}) = \mu_{x,N}(h). \tag{5.91}$$

It is normalized, has support on the whole multisection, and is obtained only from the finite sets of APP–TRIT–TPK prolongations.

Proof. The consistency of proposition 5.27 makes (5.91) independent of the horizon at which a cylinder is represented. The normalization follows from lemma 5.26. Two cylinders are either disjoint or one contains the other; hence the finite masses uniquely define an additive measure on the cylinder algebra. The multisection is a limit of finite discrete sets, and the cylinders form its compact basis; the measure

extends uniquely to the σ-algebra they generate. Finally, $p_v(\epsilon) > 0$ for every admissible emission, so every nonempty cylinder has positive mass and the support is the entire multisection. □

5.1.10 Naturality under symmetries and truncations

A coherent family $g = (g_j)_{j\geq 0} \in \mathsf{U}$ transports an outgoing emission of depth j by means of

$$(g_{j+1}, g_j)_* : \mathrm{Out}(x) \longrightarrow \mathrm{Out}(g_j \cdot x), \qquad \epsilon \longmapsto g_{j+1}\epsilon g_j^{-1}. \tag{5.92}$$

The TPK relations make (5.92) a bijection that preserves multiplicities. Acting on each entry yields a tree isomorphism

$$g_{*,N} : \mathscr{T}_{k,N}(x) \xrightarrow{\cong} \mathscr{T}_{k,N}(g_k \cdot x). \tag{5.93}$$

Theorem 5.29 (Naturalness of the tree, the multisection, and the measure)**.** *For every coherent reversible symmetry $g = (g_j)_{j\geq 0}$,*

$$\pi_{N+1,N} g_{*,N+1} = g_{*,N} \pi_{N+1,N}, \tag{5.94}$$

$$g_* \,\mathrm{Msect}(x) = \mathrm{Msect}(g_k \cdot x), \tag{5.95}$$

$$(g_{*,N})_* \mu_{x,N} = \mu_{g_k \cdot x, N}, \qquad (g_*)_* \mu_x = \mu_{g_k \cdot x}. \tag{5.96}$$

Proof. The first equality states that entrywise action commutes with deleting the final entry. Passing to the inverse limit yields (5.95). Since (5.92) is bijective, $d(g_j \cdot v) = d(v)$; by (5.87), a word and its image have the same weight. This proves the first equality of measures in (5.96). The second follows on the cylinders from (5.91), and the cylinders determine the measure. □

The truncations of the state and those of the tree also form the square.

$$\begin{array}{ccc} \mathrm{Term}_{k,N+1}(x) & \xrightarrow{\pi_{N+1,N}} & \mathrm{Term}_{k,N}(x) \\ {\scriptstyle \mathrm{ter}_{N+1}}\downarrow & & \downarrow{\scriptstyle \mathrm{ter}_N} \\ \widehat{\mathcal{X}}^{\mathrm{tot}}_{N+1} & \xrightarrow{\rho_{N+1,N}} & \widehat{\mathcal{X}}^{\mathrm{tot}}_{N}. \end{array} \tag{5.97}$$

Commutativity is literal: both paths erase the last emission and its last ledger entry.

5.1.11 Inverse limit $\widehat{\Omega}$ of complete histories and common APP–TRIT–TPK enriched state

The surjections (5.58) produce the object of complete histories

$$\widehat{\Omega} := \varprojlim_{k} \big(\widehat{\mathcal{X}}^{\mathrm{tot}}_k, \rho_{k+1,k}\big). \tag{5.98}$$

An element $\widehat{x} = (\widehat{x}_k)_{k\geq 0}$ contains, at each depth, the same pair of transported sheets, the produced orientations and carries, the accumulated memory, the boundaries, the route, and the complete ledger. Its fiber of continuations from any prefix is $\mathrm{Msect}(\widehat{x}_k)$, equipped with $\mu_{\widehat{x}_k}$.

Theorem 5.30 (Common enriched state APP–TRIT–TPK)**.** *The system*

$$\mathfrak{C}^{\mathrm{gen}} := \left(\begin{array}{l} \{\widehat{\mathcal{X}}^{\mathrm{tot}}_k, \rho_{k+1,k}, \eta_k\}_{k\geq 0}, \widehat{\Omega}, \{\mathfrak{G}_k\}_{k\geq 0}, \{\mathscr{T}_{k,N}\}_{N\geq k}, \\ \mathrm{Msect}, \mathrm{Surv}, \{\mu_x\}, \{\mathfrak{r}_9(v_K)\}_{K\geq 0}, \mathcal{K}_{\mathrm{ph}}, \widehat{\mathcal{K}}_{\mathrm{ph}}, \\ \mathrm{Sh}, \mathrm{or}, \kappa, \mathsf{Q}, g, q^{(9)}, \beta, m, \partial, \gamma, \mathrm{Led}, \\ \{\mathsf{Z}^{\Gamma}_{9,k}, s_{9,k}, t_{9,k}, \Gamma_{9,k}\}_{k\geq 0} \end{array} \right) \tag{5.99}$$

is defined for every state produced by APP–TRIT–TPK. It is non-empty, natural under reversible symmetries, and compatible with refinement. In particular:

1. *the two leaves are transported together;*
2. *orientation and carry it calculan by the division TRIT;*
3. *the memory obeys the affine TPK action;*
4. *the phase obeys the TPK odometer, returns after nine emissions, and the vertical memory advances by one unit;*
5. *the Markov realization of that turn satisfies* $\mathcal{K}_{\mathrm{ph}}^{9} = E_{+}E_{\times}$ *and uniformly renews the complete fiber of* $468 = 18 \cdot 26$ *emissions;*
6. *the compact reader conserves block, cylinder, prefix, carry, signature, Witt shadow, and phase, with their updates and truncations;*
7. *boundary, path, and ledger are composed without erasing the endpoints or the order of the emissions;*
8. *every state survives and has a nonempty multisection of complete prolongations;*
9. *the canonical measure is projective and has support on all those prolongations.*

Proof. Totality and finiteness follow from proposition 5.11. The sheet, carry, and memory identities are proved in lemmas 5.2 y 5.5; the phase, vertical memory, and nonadic holonomy, including its fiber realization and its state reader, are proved in propositions 5.3, 5.8 y 5.18 a 5.20; the boundary preserves its endpoints by (5.35). Total survival and nonemptiness of the multisections are theorems 5.22 y 5.24. The existence, consistency, and support of the measure are proposition 5.27 y theorem 5.28. Finally, compatibility with the symmetries and truncations is proved in theorem 5.29 and (5.97). □

5.1.12 Structural necessity and origin

Proposition 5.31 (Falsifiers of the common enriched state)**.** *Any of the following operations replaces* $\mathfrak{C}^{\mathrm{gen}}$ *with another object and blocks the transfer of the preceding theorems:*

1. *elegir* Σ *or* Π *and descartar the another sheet;*
2. *conserving the residue and erasing the quotient;*
3. *preserving the TRIT sign and erasing its carry;*
4. *replacing the ordered ledger with its terminal value;*
5. *identifying two words because they reach the same cell;*
6. *choosing a continuation and replacing the multisection with it;*
7. *declaring survival without exhibiting prolongations to each horizon;*
8. *uniformly normalizing only the last level, ignoring the degrees of the prefixes and losing projective consistency;*
9. *using a subsequent reading to decide which states enter* $\widehat{\mathcal{X}}_{k}^{\mathrm{tot}}$.

Proof. The first six points eliminate coordinates or relations that appear in the definition of the state, tree, or multisection. The seventh eliminates the proof of theorem 5.22. The eighth may violate (5.89) when the terminal degrees are not constant. The last replaces the total domain (5.57) with a retrospective selection. □

The APP cells, the pair of sheets, the TRIT lift, the TPK extensions, the carry cocycle, memory, boundary, route, and preservation of the register constitute the starting structures. Upon them, the finite

groupoid, the word tree, the multisection, and the normalized local measure are brought together in a single domain. The theorems of total survival, nonemptiness, consistency, and naturality certify this joint construction.

5.2 Intrinsic Correlative Operations of the Same Continuum

Tesis rectora

The symbols sp, sol, gau, coh and det that appear in this chapter mark five correlative operations over a single APP–TRIT–TPK state. Each operation receives the same surviving extension, the same orientation, the same carry, the same memory, the same boundary, and the same route. The following sections are successive mathematical stages of a single construction and not autonomous expositions.

5.2.1 Generating edge and common genealogical state

We do not repeat here the state, tree, or measure constructed in the preceding chapter. We take $\widehat{x} = \widehat{x}_k(\gamma) \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$ from (5.56) and all its admissible emissions $\alpha \in \mathrm{Out}(\widehat{x})$. If $\widehat{y} = \alpha_* \widehat{x}$, we write

$$\mathrm{Ch}_k(\widehat{x}) := \{(\alpha, \alpha_* \widehat{x}) : \alpha \in \mathrm{Out}(\widehat{x})\}, \qquad d_k(\widehat{x}) := \#\,\mathrm{Ch}_k(\widehat{x}). \tag{5.100}$$

The finiteness and non-emptiness of this set are already (5.64); survival at all horizons, the complete multisection, and its measure are theorems 5.22, 5.24 y 5.28. A second non-emptiness is not again assumed or proved.

Each pair $(\alpha, \widehat{y})$ of (5.100) preserves the unique record

$$\begin{aligned} \mathfrak{e}_\alpha := \big(&\alpha, \mathrm{Ext}_{\gamma_\alpha}; \mathrm{Sh}_{s(\alpha)}, \mathrm{Sh}_{t(\alpha)}; \\ &\mathrm{res}^{\Sigma,\Pi}(\alpha), \mathrm{quo}^{\Sigma,\Pi}(\alpha); \\ &\mathrm{or}(\alpha), \kappa(\alpha), \mathsf{C}_\alpha; \mathsf{Q}(s(\alpha)), \mathsf{Q}(t(\alpha)), g(s(\alpha)), g(t(\alpha)), q^{(9)}(s(\alpha)), q^{(9)}(t(\alpha)); \\ &m(\gamma\alpha; m_0), \partial\alpha, \gamma\alpha, \mathrm{Led}(\gamma\alpha); \\ &\{\mathrm{Term}_{k+1,N}(\widehat{y})\}_{N \geq k+1}, \mathrm{Msect}(\widehat{y}), \mu_{\widehat{y}}\big). \end{aligned} \tag{5.101}$$

Here $\mathrm{Ext}_{\gamma_\alpha}$ denotes the complete relation that the admissible emission already satisfies; it introduces no additional filter. The subsequent operations are coordinated applications of $\mathfrak{e}_\alpha$ and do not reconstruct the record from their outputs.

5.2.2 Intrinsic Correlative Actions on the Common Generator

The internal marks are fixed without changing their source: sp denotes transport and grading of the two sheets; sol, signed increment, balance, and memory; gau, incidence and carry curvature; coh, ports, rectangular difference, and cellular complex; and det, based complex, correlative filling, and determinant line. The following formulas display their couplings over the same $\mathfrak{e}_\alpha$; their actions literally share source, target, route, and ledger.

The double APP evaluation provides, on the same support, the labels Σ and Π. For an extension α, their multiplicities are calculated from the complete ledger, without an external counter:

$$N_\diamond(\alpha) := \sum_{\epsilon \ \mathrm{en} \ \gamma\alpha} \mathbf{1}_{\{\mathrm{res}^\diamond(\epsilon) \neq 0\}}, \qquad \diamond \in \{\Sigma, \Pi\}. \tag{5.102}$$

Let there also be the total oriented coefficient

$$\Delta_{\gamma_\alpha} := \sum_{\epsilon \ \mathrm{en} \ \gamma\alpha} \mathrm{or}(\epsilon) \in \mathbb{Z}.$$

The signed action is

$$b_\alpha := \Delta_{\gamma_\alpha}\big(N_\Sigma(\alpha) - N_\Pi(\alpha)\big), \qquad b_\alpha^{\pm} := \frac{|b_\alpha| \pm b_\alpha}{2}. \tag{5.103}$$

By construction,

$$b_\alpha = b_\alpha^{+} - b_\alpha^{-}, \qquad |b_\alpha| = b_\alpha^{+} + b_\alpha^{-}, \qquad b_\alpha^{+} b_\alpha^{-} = 0. \tag{5.104}$$

The same set of extensions simultaneously produces the ports

$$I_k(\widehat{x}_k) := \mathrm{Ch}_k(\widehat{x}_k) \times \{\Sigma\}, \qquad J_k(\widehat{x}_k) := \mathrm{Ch}_k(\widehat{x}_k) \times \{\Pi\}. \tag{5.105}$$

A visible leaf is not assumed to contain more prolongations than the other: each surviving extension is evaluated on both leaves of the same support. By (5.64), both sets of ports are nonempty.

For $A_N = \mathbb{Z}/3^N\mathbb{Z}$, the cellular action on generators is

$$\begin{aligned} \kappa_{k,N} &: A_N^{I_k} \oplus A_N^{J_k} \longrightarrow A_N^{I_k \times J_k}, \\ \kappa_{k,N}(u,v)_{(\alpha,\Sigma),(\beta,\Pi)} &:= u_{(\alpha,\Sigma)} - v_{(\beta,\Pi)}. \end{aligned} \tag{5.106}$$

Selected first ports according to the TPK order, the rectangular difference

$$\delta(w)_{ij} := w_{ij} - w_{ij_0} - w_{i_0 j} + w_{i_0 j_0} \tag{5.107}$$

download the split sequence

$$0 \longrightarrow A_N \xrightarrow{\Delta} A_N^{I_k} \oplus A_N^{J_k} \xrightarrow{\kappa_{k,N}} A_N^{I_k \times J_k} \xrightarrow{\delta} A_N^{(|I_k|-1)(|J_k|-1)} \longrightarrow 0. \tag{5.108}$$

This is an identity of the same APP fibre: it adds no cell foreign to the generator $\mathfrak{e}_\alpha$.

The local cellular action uses the two integer coordinates accumulated by that same ledger. For $\widehat{x} = \widehat{x}_k(\gamma)$ and $\widehat{y} = \alpha_* \widehat{x} = \widehat{x}_{k+1}(\gamma\alpha)$, we set

$$\begin{aligned} c_{\widehat{x}} &:= \kappa(\gamma), & c_\alpha &:= c_{\widehat{y}} := \kappa(\gamma\alpha), \\ v_{\widehat{x}} &:= \sum_{\epsilon \text{ en } \gamma} \mathrm{or}(\epsilon), & v_{\widehat{y}} &:= \sum_{\epsilon \text{ en } \gamma\alpha} \mathrm{or}(\epsilon), \\ v_\alpha &:= v_{\widehat{y}} - v_{\widehat{x}} = \mathrm{or}(\alpha). \end{aligned} \tag{5.109}$$

On the generators f, r, e, b, g is defined

$$\partial f = 3c_\alpha e + b, \qquad \partial r = 0, \qquad \partial e = g, \qquad \partial b = -3c_\alpha g, \qquad \partial g = 0. \tag{5.110}$$

The cancellation

$$\partial^2 f = 3c_\alpha g - 3c_\alpha g = 0 \tag{5.111}$$

is literal and uses the same carry with the two signs imposed by the orientation.

The incidence seed is obtained from the free module of the two leaves,

$$V_{\mathrm{TPK}} := \mathbf{F}_3 e_\Sigma \oplus \mathbf{F}_3 e_\Pi, \qquad \mathscr{I} := \mathbf{P}^1(V_{\mathrm{TPK}}), \qquad |\mathscr{I}| = 4, \tag{5.112}$$

and of its unordered pairs

$$\mathscr{E} := \binom{\mathscr{I}}{2}, \qquad |\mathscr{E}| = 6, \qquad \mathscr{B} := \mathscr{I} \times \{+,-\}, \qquad |\mathscr{B}| = 8. \tag{5.113}$$

The incidence application is determined on the base by

$$B[e_L] = \sum_{L' \neq L} e_{\{L,L'\}}, \qquad L \in \mathscr{F}, \tag{5.114}$$

and, by linearity,

$$(Ba)_{\{L,L'\}} = a_L + a_{L'}. \tag{5.115}$$

If $s(q) = \sum_{E \in \mathscr{E}} q_E$, each L appears three times and

$$s(Ba) = 0. \tag{5.116}$$

Therefore the function

$$W_c(q) := \mathbf{1}_{\{s(q)=0\}} - \frac{1}{3} \tag{5.117}$$

satisfies $W_c(q + Ba) = W_c(q)$. The identities (5.112)–(5.117) are internal and exact. The material lift of q from the cells and common carries is treated in the assembly layer; this incidence identity is not conflated with the construction of that lift.

5.2.3 Unitary transport, polarization, and balance on the common fiber

The non-emptiness of (5.100) allows one to fix, without selecting a prolongation,

$$p_k(\alpha, \widehat{y} \mid \widehat{x}) := \frac{1}{d_k(\widehat{x})}. \tag{5.118}$$

Let the space of the two leaves of the same state be

$$\mathscr{H}_k := \bigoplus_{\widehat{x} \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}} \left(\mathsf{H}_{\widehat{x}}^{\Sigma} \oplus \mathsf{H}_{\widehat{x}}^{\Pi}\right), \tag{5.119}$$

and let $\iota_{\widehat{x}}$ be the inclusion of the indicated fiber. The TPK transport of (5.26) gives the exact action

$$U_k \iota_{\widehat{x}} v := \sum_{(\alpha,\widehat{y}) \in \mathrm{Ch}_k(\widehat{x})} p_k(\alpha, \widehat{y} \mid \widehat{x})^{1/2} \iota_{\widehat{y}} U_\alpha v. \tag{5.120}$$

The children of two distinct parents are disjoint because truncation is a function. Moreover, two distinct witnesses α do not collapse into the same direct summand: the complete route γ, including its last step, is a coordinate of $\widehat{y}$. Consequently, the Gram identity is

$$U_k^* U_k\big|_{\mathsf{H}_{\widehat{x}}^{\Sigma} \oplus \mathsf{H}_{\widehat{x}}^{\Pi}} = \sum_{(\alpha,\widehat{y}) \in \mathrm{Ch}_k(\widehat{x})} p_k(\alpha, \widehat{y} \mid \widehat{x})\, U_\alpha^* U_\alpha. \tag{5.121}$$

Therefore $U_k^* U_k = I$ exactly when, in each initial fibre,

$$\sum_{(\alpha,\widehat{y}) \in \mathrm{Ch}_k(\widehat{x})} p_k(\alpha, \widehat{y} \mid \widehat{x})\, U_\alpha^* U_\alpha = I. \tag{5.122}$$

The isometry of every sheet transport U_α is sufficient for this equality, together with normalization of the weights; the necessary and sufficient condition is normalization of the average Gram matrix displayed in (5.122). For $\ell > k$, the complete history is preserved through

$$U_{\ell,k} := U_{\ell-1} \cdots U_k, \qquad U_{k,k} := I. \tag{5.123}$$

The grading acts on the two coordinates already present in each fiber of (5.119):

$$\sigma_k \iota_{\widehat{x}}(v_\Sigma, v_\Pi) := \iota_{\widehat{x}}(v_\Sigma, -v_\Pi), \qquad P_k := \frac{I + \sigma_k}{2}, \quad Q_k := \frac{I - \sigma_k}{2}. \tag{5.124}$$

The TRIT threshold belongs to the orientation and to the carry of $\widehat{x}$; it erases neither of the two APP sheets and does not require a third case in (5.124).

The leaf-preserving part and the leaf-changing part are two components of the same U_k:

$$A_k := P_{k+1}U_kP_k + Q_{k+1}U_kQ_k, \tag{5.125}$$

$$\eta_k := Q_{k+1}U_kP_k + P_{k+1}U_kQ_k. \tag{5.126}$$

By orthogonality of P_{k+1} and Q_{k+1},

$$\begin{aligned} U_k &= A_k + \eta_k, \\ A_k^*A_k + \eta_k^*\eta_k &= P_kU_k^*U_kP_k + Q_kU_k^*U_kQ_k. \end{aligned} \tag{5.127}$$

Proof of the sheetwise Gram balance. Expanding the products, orthogonality of the target projectors gives

$$\begin{aligned} A_k^*A_k &= P_kU_k^*P_{k+1}U_kP_k + Q_kU_k^*Q_{k+1}U_kQ_k, \\ \eta_k^*\eta_k &= P_kU_k^*Q_{k+1}U_kP_k + Q_kU_k^*P_{k+1}U_kQ_k. \end{aligned}$$

Their sum and $P_{k+1} + Q_{k+1} = I$ prove (5.127). The difference between $U_k^*U_k$ and that balance is $P_kU_k^*U_kQ_k + Q_kU_k^*U_kP_k$; it vanishes exactly when both cross blocks vanish. In particular, condition (5.122) yields $U_k^*U_k = I$ and reduces the balance to I. □

Proposition 6.24 develops this same general identity in the subsequent realization on complete histories, whose isometry is proved by retaining the label of each prolongation. This identity and the increment (5.103) are not two transports: A_k, η_k act on the history basis and b_α reads the edge of that same basis.

5.2.3.1 Signed polarization, non-autonomous telescoping, and return without reinitialization

No independent spectral branch is introduced here. The notations are restricted to the same space $\mathscr{H}_k$ and the same already constructed transport U_k

$$\mathcal{H}_k^{\mathrm{sp}} := \mathscr{H}_k, \qquad \Lambda(\gamma_{\widehat{x}}) := \big(\mathrm{or}, \mathrm{Carr}, \mathrm{Mem}, \partial, \gamma\big)(\widehat{x}),$$

and $\Sigma_{\mathrm{reg}}\Lambda(\gamma_{\widehat{x}})$ denotes its family of compatible truncations. Thus, the following signed reader, defect, and terminal are actions of the common correlative constructor, not a retrospective selection of histories.

5.2.3.2 Signed reader with genealogical register

For $v \in \mathcal{H}_k^{\mathrm{sp}}$, the signed polarization is

$$\mathrm{pol}_k(v) = \langle v, \sigma_k v\rangle = \|P_kv\|^2 - \|Q_kv\|^2. \tag{5.128}$$

The specialized reader furthermore preserves the source:

$$\mathcal{L}_{\mathrm{sp},k}^{\mathrm{sgn}}(x_k; v) = \big(\Lambda(\gamma_{x_k}), \Sigma_{\mathrm{reg}}(\Lambda(\gamma_{x_k})), \|P_kv\|^2, \|Q_kv\|^2, \mathrm{pol}_k(v)\big). \tag{5.129}$$

The TRIT orientation is preserved in $\Lambda(\gamma_{x_k})$; it is not identified with the sheet sign. At horizon N, the record keeps the family of readers for all levels $k \le N$. Truncating means removing only subsequent entries.

5.2.3.3 Non-autonomous and terminal product

We define

$$F_{0,0} = I_{\mathcal{H}_0^{\mathrm{sp}}}, \qquad F_{0,k} = A_{k-1}\cdots A_1A_0 \quad (k \ge 1). \tag{5.130}$$

Therefore,

$$F_{0,k+1} = A_kF_{0,k}. \tag{5.131}$$

The term published upon leaving the channel at step k and the terminal at horizon N are

$$\mathcal{D}_k = F_{0,k}^* \eta_k^* \eta_k F_{0,k}, \qquad \mathcal{T}_N = F_{0,N}^* F_{0,N}. \tag{5.132}$$

Theorem 5.32 (Spectral telescope–non-autonomous polar)**.** *For every finite horizon N,*

$$\boxed{I = \sum_{k=0}^{N-1} F_{0,k}^* \eta_k^* \eta_k F_{0,k} + F_{0,N}^* F_{0,N}.} \tag{5.133}$$

Moreover,

$$0 \preceq \mathcal{T}_{N+1} \preceq \mathcal{T}_N \preceq I,$$

so that the strong positive limit exists

$$\mathcal{T}_\infty = \text{s-lim}_{N\to\infty} \mathcal{T}_N$$

and

$$I = \sum_{k=0}^{\infty} F_{0,k}^* \eta_k^* \eta_k F_{0,k} + \mathcal{T}_\infty \tag{5.134}$$

in the strong topology. The theorem does not assert that $\mathcal{T}_\infty$ is zero.

Proof. Multiplying (5.127) by $F_{0,k}^*$ and $F_{0,k}$, and using (5.131), one obtains

$$F_{0,k}^* F_{0,k} = F_{0,k+1}^* F_{0,k+1} + F_{0,k}^* \eta_k^* \eta_k F_{0,k}.$$

The sum from $k = 0$ to $N - 1$ cancels all intermediate terms and leaves precisely (5.133). Since $A_k^* A_k \preceq I$,

$$\mathcal{T}_{N+1} = F_{0,N}^* A_N^* A_N F_{0,N} \preceq F_{0,N}^* F_{0,N} = \mathcal{T}_N.$$

Monotonicity and the positive bound provide the strong limit. Passing to the limit in the finite identity gives (5.134). □

5.2.3.4 Phase return and non-reinitialized evolution of the common state

The branch explicitly preserves

$$g(k + 9) = g(k), \qquad x_{k+9} \neq x_k \quad \text{in general.} \tag{5.135}$$

The second member records the increase in memory and possible changes of sheet, carry, cylinder and boundary. Neither σ_k, nor the projectors, nor the signed reader contract this difference.

The conditional expectation associated with the same weight is

$$(E_k F)(\widehat{x}) := \sum_{(\alpha,\widehat{y})\in \mathrm{Ch}_k(\widehat{x})} p_k(\alpha, \widehat{y} \mid \widehat{x}) F(\alpha, \widehat{y}). \tag{5.136}$$

For the fine increment b_f, set

$$b_c := E_k b_f, \qquad \kappa_k^{\mathrm{can}} := \frac{E_k|b_f| - |b_c|}{2} \geq 0. \tag{5.137}$$

Then

$$E_k b_f^+ = b_c^+ + \kappa_k^{\mathrm{can}}, \qquad E_k b_f^- = b_c^- + \kappa_k^{\mathrm{can}}. \tag{5.138}$$

The superscript can distinguishes this cancellation carry from the integer carry κ_α; both arise from the same transport, but have distinct types.

Signed memories require no external initial condition: for $\gamma = (\epsilon_1, \dots, \epsilon_k)$ they are defined by summing the ledger itself,

$$\begin{aligned} M_0^{\pm} &:= 0, \\ M_k^{\pm}(\gamma) &:= \sum_{j=1}^{k} b_{\epsilon_j}^{\pm}, \\ M_{k+1}^{\pm}(\gamma\alpha) &:= M_k^{\pm}(\gamma) + b_\alpha^{\pm}, \\ D_k^0 &:= M_k^+ - M_k^-, \qquad H_k^0 := M_k^+ + M_k^-. \end{aligned} \tag{5.139}$$

Thus, the signed balance, the total memory, and the polarization $\langle v, \sigma_k v\rangle$ are three coordinated readings of the same prefix, not three states reconstructed separately.

5.2.3.5 Nonadic Refinement, Orthogonal Losses and Terminal Memory

The index j in the following development is the level of the same tree of prolongations, and its thirteen-coordinate record is the restriction of the common record of (5.101). Accordingly, $D_{\mathrm{sol},j} := D_j^{(13)}$ is fixed and no additional domain is postulated.

5.2.3.6 Common nonadic refinement: inclusion, balance expectation and memory

Let $Y_j(x)$ be the finite set of cylinders compatible with the prefix $x_{\le j}$, endowed with the projective measure μ_j. The truncation

$$\tau_{j+1,j} : Y_{j+1}(x) \longrightarrow Y_j(x)$$

has nine admissible extensions over each cylinder. Finite spaces are considered.

$$\mathscr{H}_j(x) := \ell^2\big(Y_j(x), \mu_j\big).$$

The inclusion and the nonadic expectation are

$$J_{9,j} : \mathscr{H}_j \longrightarrow \mathscr{H}_{j+1}, \qquad (J_{9,j} f)(y) = f(\tau_{j+1,j} y), \tag{5.140}$$

$$E_{9,j} : \mathscr{H}_{j+1} \longrightarrow \mathscr{H}_j, \qquad (E_{9,j} g)(z) = \frac{1}{9} \sum_{\tau_{j+1,j} y = z} g(y). \tag{5.141}$$

The projective compatibility of μ_{j+1} and μ_j gives

$$E_{9,j} J_{9,j} = I_{\mathscr{H}_j}, \qquad J_{9,j}^* = E_{9,j}, \qquad P_{9,j} := J_{9,j} E_{9,j} = P_{9,j}^* = P_{9,j}^2. \tag{5.142}$$

The complementary microscopic projector is

$$Q_{9,j} := I - P_{9,j}. \tag{5.143}$$

If b_f is the increment on the fine fiber and

$$b_c := E_{9,j} b_f, \tag{5.144}$$

the elementary convexity of $|\cdot|$ constructs, rather than postulates, the carry of cancellation

$$\kappa_j := \frac{E_{9,j}|b_f| - |b_c|}{2} \ge 0. \tag{5.145}$$

Indeed, using $t^{\pm} = (|t| \pm t)/2$, one obtains

$$E_{9,j} b_f^+ = \frac{E_{9,j}|b_f| + E_{9,j} b_f}{2} = b_c^+ + \kappa_j, \tag{5.146}$$

$$E_{9,j} b_f^- = \frac{E_{9,j}|b_f| - E_{9,j} b_f}{2} = b_c^- + \kappa_j. \tag{5.147}$$

Both sheets lose the same amount when compressed; therefore, the signed difference is preserved while total memory records the cancellation:

$$E_{9,j}(b_f^+ - b_f^-) = b_c, \qquad E_{9,j}(b_f^+ + b_f^-) = |b_c| + 2\kappa_j. \tag{5.148}$$

5.2.3.7 Orthogonal factorization of the degrees of depth and of the resolution layers in $\mathscr{H}_j^{\text{depth}} \widehat{\otimes} \mathscr{H}_j^{\text{res}}$

To prevent the same loss from being counted both as depth and as resolution, the space at each level is typed as

$$\mathscr{H}_j = \mathscr{H}_j^{\text{depth}} \widehat{\otimes} \mathscr{H}_j^{\text{res}}. \tag{5.149}$$

For $j \geq 1$, the first factor carries

$$P_j^{\text{depth}} := J_{9,j-1} E_{9,j-1} \quad \text{on } \mathscr{H}_j^{\text{depth}},$$

and $P_0^{\text{depth}} = I$ is fixed. The second factor carries the finite shell partition inherited from the cylinder boundary. If $\sigma_j : Y_j^{\text{res}} \to S_j$ is that partition, its operators are

$$J_j^{\text{res}} f = f \circ \sigma_j, \qquad E_j^{\text{res}} g(s) = \frac{1}{\#\sigma_j^{-1}(s)} \sum_{\sigma_j(y)=s} g(y), \tag{5.150}$$

$$P_j^{\text{res}} := J_j^{\text{res}} E_j^{\text{res}}. \tag{5.151}$$

The three mutually orthogonal projectors are defined.

$$P_j^{\text{term}} := P_j^{\text{depth}} \otimes P_j^{\text{res}}, \tag{5.152}$$

$$Q_j^{\text{micro}} := (I - P_j^{\text{depth}}) \otimes I, \tag{5.153}$$

$$Q_j^{\text{shell}} := P_j^{\text{depth}} \otimes (I - P_j^{\text{res}}). \tag{5.154}$$

Then

$$Q_j^{\text{micro}} Q_j^{\text{shell}} = 0, \qquad I = P_j^{\text{term}} + Q_j^{\text{micro}} + Q_j^{\text{shell}}, \tag{5.155}$$

and, for all $\xi \in \mathscr{H}_j$,

$$\|\xi\|^2 = \|P_j^{\text{term}} \xi\|^2 + \|Q_j^{\text{micro}} \xi\|^2 + \|Q_j^{\text{shell}} \xi\|^2. \tag{5.156}$$

The term $(I - P_j^{\text{depth}}) \otimes (I - P_j^{\text{res}})$ does not appear a second time: it is already contained exactly once in Q_j^{micro}.

5.2.3.8 Cylinder extensions and full row of losses

An extension of cylinders from level j to level $j+1$ induces the map

$$\Gamma_j : \mathscr{H}_j \longrightarrow \mathscr{H}_{j+1}, \qquad \Gamma_j f = f \circ \tau_{j+1,j}, \tag{5.157}$$

with all leaf, orientation, carry, memory, and path labels transported in the cylinder basis. For $n > j$, we write

$$\Gamma_{j:n} := \Gamma_{n-1} \cdots \Gamma_j, \qquad \Gamma_{j:j} := I. \tag{5.158}$$

On $\mathscr{H}_j$, the nonnegative increments define multiplication operators

$$B_j^+ := M_{\sqrt{b_j^+}}, \qquad B_j^- := M_{\sqrt{b_j^-}}, \qquad K_j := M_{\sqrt{2\kappa_j}}. \tag{5.159}$$

Each root is taken pointwise over the finite set of cylinders; if a coordinate is zero, its operator is zero. The space of losses is the external orthogonal sum

$$\mathscr{E}_j := \mathscr{H}_j^{(+)} \oplus \mathscr{H}_j^{(-)} \oplus \mathscr{H}_j^{(\kappa)} \oplus \mathscr{H}_j^{(\mathrm{micro})} \oplus \mathscr{H}_j^{(\mathrm{shell})},$$

and the complete row is

$$L_j : \mathscr{H}_j \longrightarrow \mathscr{E}_j, \qquad L_j\xi = \big(B_j^+\xi, B_j^-\xi, K_j\xi, Q_j^{\mathrm{micro}}\xi, Q_j^{\mathrm{shell}}\xi\big). \tag{5.160}$$

Therefore,

$$\|L_j\xi\|^2 = \|B_j^+\xi\|^2 + \|B_j^-\xi\|^2 + \|K_j\xi\|^2 + \|Q_j^{\mathrm{micro}}\xi\|^2 + \|Q_j^{\mathrm{shell}}\xi\|^2. \tag{5.161}$$

The positive part, negative part, cancellation carry, microstructure, and shell each appear once. They are neither merged into an anonymous constant nor repeated in two summands.

5.2.3.9 Complete history terminal

Let $\mathrm{Hist}_J^{\mathrm{sol}}$ be the set of histories surviving to the horizon J, each with its package of thirteen coordinates. The terminal space is defined as the free space on these complete records:

$$\mathscr{T}_J^{\mathrm{sol}} := \ell^2\Big(\big\{(h, D_{\mathrm{sol},J}(h)) : h \in \mathrm{Hist}_J^{\mathrm{sol}}\big\}\Big). \tag{5.162}$$

The terminal evaluation

$$E_J^{\mathrm{term}} : \mathscr{H}_J \longrightarrow \mathscr{T}_J^{\mathrm{sol}} \tag{5.163}$$

sends each basic cylinder vector to the complete record of the history that generates it and extends linearly. In particular, the terminal retains fiber, relations, numbers, orientation, carry, memory, boundary, route, multisection, survival, and reader. It is not replaced by the last visible value of the route.

5.2.3.10 Observation column, Gram operator, and telescoping

For $0 \le j \le J$, the complete future column is

$$\begin{aligned} G_{j;J} &: \mathscr{H}_j \longrightarrow \mathscr{T}_J^{\mathrm{sol}} \oplus \bigoplus_{n=j}^{J-1} \mathscr{E}_n, \\ G_{j;J}\xi &:= E_J^{\mathrm{term}}\Gamma_{j:J}\xi \ \oplus \ \bigoplus_{n=j}^{J-1} L_n\Gamma_{j:n}\xi. \end{aligned} \tag{5.164}$$

For $j = J$, the sum of perdidas is empty and $G_{J;J} = E_J^{\mathrm{term}}$. The Gram terminal is

$$U_{j;J} := G_{j;J}^* G_{j;J} \succeq 0. \tag{5.165}$$

Rearranging the orthogonal sum of the codomain yields the literal identity.

$$G_{j;J}\xi \simeq \big(L_j\xi,\ G_{j+1;J}\Gamma_j\xi\big). \tag{5.166}$$

Consequently,

$$\boxed{U_{j;J} = L_j^* L_j + \Gamma_j^* U_{j+1;J}\Gamma_j} \tag{5.167}$$

and

$$U_{j;J} - \Gamma_j^* U_{j+1;J}\Gamma_j = L_j^* L_j \succeq 0. \tag{5.168}$$

There is no sign mutation: the loss term is on the positive side of the identity because it arises from a sum of squares.

Iterating (5.167) yields the exact telescoping identity

$$U_{j;J} = \Gamma_{j:J}^{*}(E_J^{\mathrm{term}})^{*}E_J^{\mathrm{term}}\Gamma_{j:J} + \sum_{n=j}^{J-1}\Gamma_{j:n}^{*}L_n^{*}L_n\Gamma_{j:n}, \tag{5.169}$$

o, in quadratic form,

$$\langle U_{j;J}\xi,\xi\rangle = \|E_J^{\mathrm{term}}\Gamma_{j:J}\xi\|^2 + \sum_{n=j}^{J-1}\|L_n\Gamma_{j:n}\xi\|^2. \tag{5.170}$$

The first term preserves the complete terminal future; the sum preserves, level by level, all the losses and all the carries that led to it.

5.2.4 Orientation, carry, and simultaneous composition of paths

Path inversion acts only once on $\mathfrak{e}_\alpha$. Let $\mathsf{J}(v_\Sigma, v_\Pi) := (v_\Pi, v_\Sigma)$ be the leaf exchange, and let P_{tr} be the transposition of port matrices. Its five local expressions are

$$\begin{gathered}\mathsf{J}\sigma_k = -\sigma_k\mathsf{J}, \qquad b_{\bar\alpha} = -b_\alpha, \qquad (b^+_{\bar\alpha}, b^-_{\bar\alpha}) = (b^-_\alpha, b^+_\alpha),\\ \vartheta_L(K,\epsilon) := \begin{cases}(L,-\epsilon), & K = L,\\ (K,\epsilon), & K \neq L,\end{cases} \qquad \kappa_{J,I}(v,u) = -P_{\mathrm{tr}}\kappa_{I,J}(u,v),\\ \kappa(\bar\alpha) = -\mathsf{C}_\alpha^{-1}\kappa(\alpha), \qquad v_{\bar\alpha} = -v_\alpha.\end{gathered} \tag{5.171}$$

Here J exchanges the two sheets, P_{tr} transposes the incidence matrix, and ϑ_L exchanges exactly the two faces in the direction L, fixing the other six. In the free basis of $\mathscr{B} = \mathscr{I}\times\{+,-\}$, the eight vectors are distinct, $\vartheta_L^2 = I$ and $\vartheta_L \neq \vartheta_{L'}$ for $L \neq L'$. The same orientation explains all signs in (5.171).

For composable extensions $\alpha : x \to y$ and $\beta : y \to z$, the native carry satisfies

$$\kappa(\beta\alpha) = \kappa(\beta) + \mathsf{C}(\beta)\kappa(\alpha). \tag{5.172}$$

The matrix lift is not left as a name. In the ordered basis (f, r, e, b, g), let $\widetilde{L}_N(\alpha) \in \mathrm{Mat}_5(\mathbb{Z})$ be the centered integral representative of the matrix of Ψ_α of (5.176) modulo 3^N, and define

$$c_N(\beta,\alpha) := \frac{\widetilde{L}_N(\beta)\widetilde{L}_N(\alpha) - \widetilde{L}_N(\beta\alpha)}{3^N} \in \mathrm{Mat}_5(\mathbb{Z}). \tag{5.173}$$

Divisibility follows from equality of the two compositions modulo 3^N. Writing $L_N = [\widetilde{L}_N]_{3^N}$, the integer lifts satisfy

$$\widetilde{L}_N(\beta)\widetilde{L}_N(\alpha) = \widetilde{L}_N(\beta\alpha) + 3^N c_N(\beta,\alpha) \tag{5.174}$$

and associativity produces the cocycle

$$c_N(\delta,\beta\alpha) + \widetilde{L}_N(\delta)c_N(\beta,\alpha) = c_N(\delta\beta,\alpha) + c_N(\delta,\beta)\widetilde{L}_N(\alpha). \tag{5.175}$$

The same carry increment acts upon the local complex through

$$\begin{gathered}\Psi_\alpha(r_x) = r_y, \quad \Psi_\alpha(e_x) = e_y, \quad \Psi_\alpha(g_x) = g_y, \quad \Psi_\alpha(f_x) = f_y,\\ \Psi_\alpha(b_x) = b_y + 3(c_y - c_x)e_y.\end{gathered} \tag{5.176}$$

The oriented boundary change remains in

$$K_\alpha := (v_y - v_x) f_y, \qquad K_{\beta\alpha} = K_\beta + \Psi_\beta K_\alpha. \tag{5.177}$$

The equations (5.172), (5.175), and (5.177) are three degrees of the same ledger of composition. None authorizes erasing the other two.

5.2.4.1 Nerve of extensions and Alexander–Whitney diagonal

For a history of the common ledger, write $A_n := \mathbf{Z}/3^n\mathbf{Z}$ and $\mathsf{T}_m(x)$ for the finite category of *all* its TPK prefixes of depth m, with the extension morphisms already constructed. The following diagonal and counit are applied to that same nerve; they do not define a fifth autonomous branch.

5.2.4.2 Nerve of routes, Alexander–Whitney diagonal and counit

The normalized complex is defined

$$G_{m,n}(x) := N_*^{\mathrm{norm}}(N\mathsf{T}_m(x); A_n)\,. \tag{5.178}$$

For a nondegenerate simplex $\sigma = [y_0 \to y_1 \to \cdots \to y_q]$, the diagonal is

$$\Delta_{\mathrm{AW}}(\sigma) = \sum_{j=0}^{q} [y_0 \to \cdots \to y_j] \otimes [y_j \to \cdots \to y_q]. \tag{5.179}$$

The counit is given by

$$\epsilon_G([y]) = 1, \qquad \epsilon_G(\sigma) = 0 \quad (q > 0). \tag{5.180}$$

In particular,

$$\Delta_{\mathrm{AW}}[y] = [y] \otimes [y], \qquad \epsilon_G([y]) = 1. \tag{5.181}$$

If $m' \geq m$ and $n' \geq n$, truncation and coefficient reduction induce

$$R^{n',n}_{m',m} : G_{m',n'}(x) \longrightarrow G_{m,n}(x), \tag{5.182}$$

and they are verified

$$R\partial = \partial R, \qquad (R \otimes R)\Delta_{\mathrm{AW}} = \Delta_{\mathrm{AW}} R, \qquad \epsilon_G R = \rho_{n',n}\epsilon_G. \tag{5.183}$$

The path is not reduced to its endpoints: the entire simplex remains in $G_{m,n}(x)$.

5.2.5 Cellular incidence and correlative filling of the same trajectory

The sequence (5.108) assigns to each prefix the two-term complex

$$C_{k,N}(\widehat{x}) := \left[A_N^{I_k} \oplus A_N^{J_k} \xrightarrow{\kappa_{k,N}} A_N^{I_k \times J_k} \right]. \tag{5.184}$$

A refinement acts on ports by truncating the extension and on coefficients by $A_{N'} \twoheadrightarrow A_N$. When $\alpha_u : I_{k'} \to I_k$ and $\beta_u : J_{k'} \to J_k$ are those maps, their action on generators is

$$(p, q) \longmapsto (p \circ \alpha_u, q \circ \beta_u), \qquad w \longmapsto w \circ (\alpha_u \times \beta_u), \tag{5.185}$$

and satisfies

$$\kappa_{k',N}\Gamma(u)_1 = \Gamma(u)_0 \kappa_{k,N}. \tag{5.186}$$

The incidence is not fabricated by labeling four copies of a neutral emission. It is generated by the free cellular completion of the module of the two sheets that the same state already bears. For

$$V_{\widehat{x}} := \mathbf{F}_3 e_{\Sigma,\widehat{x}} \oplus \mathbf{F}_3 e_{\Pi,\widehat{x}},$$

the four internal lines are

$$\mathscr{I}_{\widehat{x}} := \{L_0, L_\infty, L_+, L_-\} = \mathbf{P}^1(V_{\widehat{x}}), \qquad \begin{aligned} L_0 &= \langle e_\Sigma \rangle, & L_\infty &= \langle e_\Pi \rangle, \\ L_+ &= \langle e_\Sigma + e_\Pi \rangle, & L_- &= \langle e_\Sigma - e_\Pi \rangle. \end{aligned} \tag{5.187}$$

If v_L is, respectively, $(1,0)^t, (0,1)^t, (1,1)^t, (1,-1)^t$, the action of the direction L on the generators of sheet is the proyector

$$P_L := v_L (v_L^t v_L)^{-1} v_L^t, \tag{5.188}$$

that is, over $\mathbf{F}_3$,

$$P_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad P_\infty = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad P_+ = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix}, \quad P_- = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.$$

Direct calculation gives

$$P_L^2 = P_L, \qquad \operatorname{rk} P_L = 1, \qquad \operatorname{Im} P_L = L, \qquad P_L = P_{L'} \Longrightarrow L = L'. \tag{5.189}$$

Therefore, the four directions are distinct outputs of the module $V_{\widehat{x}}$; they are not four names placed upon the same action.

Definition 5.33 (Cell-free leaf TPK completion)**.** Let $\mathrm{Cell}_{\mathrm{TPK}}(\widehat{x})$ be the free complex

$$C_2(\widehat{x}) \xrightarrow{\partial_2} C_1(\widehat{x}) \xrightarrow{\partial_1} C_0(\widehat{x})$$

with

$$\begin{aligned} C_0(\widehat{x}) &:= \mathbf{F}_3[v_\star] \oplus \bigoplus_{L \in \mathscr{I}} \mathbf{F}_3[v_L] \oplus \bigoplus_{(L,\epsilon) \in \mathscr{B}} \mathbf{F}_3[v_{L,\epsilon}] \oplus \bigoplus_{E \in \mathscr{E}} \mathbf{F}_3[v_E], \\ C_1(\widehat{x}) &:= \bigoplus_{L \in \mathscr{I}} \mathbf{F}_3[u_L] \oplus \bigoplus_{(L,\epsilon) \in \mathscr{B}} \mathbf{F}_3[u_{L,\epsilon}] \oplus \bigoplus_{E = \{L,L'\} \in \mathscr{E}} \big(\mathbf{F}_3[u_{L'|L}] \oplus \mathbf{F}_3[u_{L|L'}]\big), \\ C_2(\widehat{x}) &:= \bigoplus_{E \in \mathscr{E}} \mathbf{F}_3[\omega_E]. \end{aligned}$$

Its action on generators is

$$\partial u_L = v_L - v_\star, \qquad \partial u_{L'|L} = v_E - v_L, \tag{5.190}$$

$$\partial u_{L,\epsilon} = v_{L,\epsilon} - v_L, \qquad \partial \omega_{\{L,L'\}} = u_L + u_{L'|L} - u_{L'} - u_{L|L'}. \tag{5.191}$$

The eight generators $v_{L,\epsilon}$ materially realize the screen $\mathscr{B}$. The preceding involution extends to the complex by

$$\vartheta_L v_{K,\epsilon} := v_{\vartheta_L(K,\epsilon)}, \qquad \vartheta_L u_{K,\epsilon} := u_{\vartheta_L(K,\epsilon)}, \tag{5.192}$$

and fixes the other generators. Since the basis is free,

$$|\{v_{L,\epsilon} : (L,\epsilon) \in \mathscr{B}\}| = 8, \qquad \vartheta_L^2 = I, \qquad \vartheta_L \vartheta_{L'} = \vartheta_{L'} \vartheta_L. \tag{5.193}$$

Moreover, $\partial \vartheta_L = \vartheta_L \partial$, because both paths send $u_{L,\epsilon}$ to $v_{L,-\epsilon} - v_L$ and fix the remaining boundaries.

The two words

$$p_{L,L'} := u_{L'|L} u_L, \qquad p_{L',L} := u_{L|L'} u_{L'}$$

are different paths in the free complex. Their difference is the boundary of $\omega_{\{L,L'\}}$, and

$$\partial^2 \omega_E = (v_L - v_\star) + (v_E - v_L) - (v_{L'} - v_\star) - (v_E - v_{L'}) = 0. \tag{5.194}$$

The representation of TPK on the leaves is fixed by

$$\varrho(u_L) = P_L, \qquad \varrho(u_{L'|L}) = P_{L'}, \qquad \varrho(p_{L,L'}) = P_{L'}P_L.$$

Even if two published matrices coincided in a specialization, the two paths do not collapse: they remain distinct free generators of $C_1(\widehat{x})$, joined by an explicit 2–cell.

The complete incidence coordinate is the group of 2–cochains.

$$Q_{\mathrm{inc}}(\widehat{x}) := C^2(\mathrm{Cell}_{\mathrm{TPK}}(\widehat{x}); \mathbf{F}_3) = \bigoplus_{E \in \mathscr{E}} \mathbf{F}_3 \omega_E^* \simeq \mathbf{F}_3^6. \tag{5.195}$$

The internal operation returns all of $Q_{\mathrm{inc}}(\widehat{x})$, not a selected element. Each q has a unique expansion $q = \sum_E q_E \omega_E^*$. For $a \in \mathbf{F}_3^{\mathscr{I}}$, its change of potential is

$$q \longmapsto q + Ba, \qquad (Ba)_{\{L,L'\}} = a_L + a_{L'}. \tag{5.196}$$

As each line belongs to three pairs,

$$s(Ba) = 3 \sum_{L \in \mathscr{I}} a_L = 0,$$

and therefore

$$W_c(q + Ba) = W_c(q) \qquad (q \in Q_{\mathrm{inc}}(\widehat{x})). \tag{5.197}$$

The unit of the completion only anchors the complex in the state:

$$\eta^{\mathrm{cell}}_{\widehat{x}} : V_{\widehat{x}} \longrightarrow V_{\widehat{x}} \otimes C_0(\mathrm{Cell}_{\mathrm{TPK}}(\widehat{x})), \qquad e_{\diamond,\widehat{x}} \longmapsto e_{\diamond,\widehat{x}} \otimes v_\star, \tag{5.198}$$

and marks the origin $q = 0$; it does not assert that the orbit of that origin is all of Q_{inc}.

The construction is functorial under common truncation. If $\tau_{\ell,k}\widehat{x}_\ell = \widehat{x}_k$, we define

$$\begin{aligned}
&\tau_V : V_{\widehat{x}_\ell} \longrightarrow V_{\widehat{x}_k}, && \tau_V e_{\diamond,\widehat{x}_\ell} = e_{\diamond,\widehat{x}_k},\\
&\tau_a : \mathbf{F}_3^{\mathscr{I}_{\widehat{x}_\ell}} \longrightarrow \mathbf{F}_3^{\mathscr{I}_{\widehat{x}_k}}, && (\tau_a a)_{\tau_{\mathscr{I}} L} = a_L,\\
&\tau_Q : Q_{\mathrm{inc}}(\widehat{x}_\ell) \longrightarrow Q_{\mathrm{inc}}(\widehat{x}_k), && (\tau_Q q)_{\tau_{\mathscr{E}} E} = q_E,
\end{aligned}$$

where $\tau_{\mathscr{I}}[v] = [\tau_V v]$ and $\tau_{\mathscr{E}}\{L, L'\} = \{\tau_{\mathscr{I}} L, \tau_{\mathscr{I}} L'\}$. The map of cadenas $\mathrm{Cell}(\tau) : C_\bullet(\widehat{x}_\ell) \to C_\bullet(\widehat{x}_k)$ acts in generators by

$$v_\bullet(\widehat{x}_\ell) \mapsto v_\bullet(\widehat{x}_k), \quad u_\bullet(\widehat{x}_\ell) \mapsto u_\bullet(\widehat{x}_k), \quad \omega_E(\widehat{x}_\ell) \mapsto \omega_E(\widehat{x}_k). \tag{5.199}$$

From (5.190)– (5.191) one obtains

$$\begin{aligned}
\mathrm{Cell}(\tau)\partial &= \partial\, \mathrm{Cell}(\tau),\\
\tau_V P_L &= P_{\tau_{\mathscr{I}} L} \tau_V, \qquad \tau_Q B = B \tau_a, \qquad W_c \circ \tau_Q = W_c,\\
\mathrm{Cell}(\tau)\vartheta_L &= \vartheta_{\tau_{\mathscr{I}} L}\, \mathrm{Cell}(\tau),\\
(\tau_V \otimes \mathrm{Cell}_0(\tau))\eta^{\mathrm{cell}}_{\widehat{x}_\ell} &= \eta^{\mathrm{cell}}_{\widehat{x}_k} \tau_V.
\end{aligned} \tag{5.200}$$

Identity and composition are verified on each generator. Thus $\mathrm{Cell}_{\mathrm{TPK}}$ is the functorial cellular completion of the same APP–TRIT–TPK fiber, not a carrier added from a subsequent publication.

5.2.5.1 Incidence measure, carry curvature, and adjoint naturality

In the following development, they are identified exclusively as abbreviations of the common completion,

$$I_{\mathrm{gau}} := \mathscr{I}_{\widehat{x}}, \qquad \mathscr{B}_{\mathrm{gau}} := \mathscr{B}_{\widehat{x}}, \qquad Q_{\mathrm{gau}} := Q_{\mathrm{inc}}(\widehat{x}).$$

With the uniform counting average on Q_{gau}, the function W_c of (5.117) satisfies

$$\mathbb{E}_Q W_c = 0, \qquad \mathbb{E}_Q W_c^2 = \frac{2}{9}, \qquad \mathbb{E}_Q W_c^3 = \frac{2}{27}. \tag{5.201}$$

These identities are properties of the same cell and the same carry, not data from an external theory.

5.2.5.2 Incidence, carry curvature, and common domain of naturalness

For $x \in C_{\mathrm{cont}}^{\mathrm{disc}}$, let us denote by $Y_m(x)$ the finite set of gauge prefixes of depth m that simultaneously conserve

fiber, extension relations, numbers, orientation, carry, memory,

boundary, route, multisection, survival, terminal and reader.

There exists a collar neighborhood application.

$$q_m : Y_m(x) \longrightarrow Q_{\mathrm{gau}} \tag{5.202}$$

which records the six incidences without erasing the history that produces them. For $\ell \geq m$, the truncation is written

$$\tau_{\ell,m} : Y_\ell(x) \longrightarrow Y_m(x).$$

For $y, z \in Y_m(x)$, let

$$\mathrm{Ext}_m^{\mathrm{adm}}(y, z) \tag{5.203}$$

the set of *all* admissible TPK extensions from y to z. An extension belongs to this set only if it transports the entire fiber, the relations Ext_Γ, the native and operatorial carry, the orientation, the accumulated memory, the boundary, the route, and the survival condition. We define

$$a_m(y, z) := \#\,\mathrm{Ext}_m^{\mathrm{adm}}(y, z), \qquad d_m(y) := \sum_{z \in Y_m(x)} a_m(y, z), \tag{5.204}$$

and, when $d_m(y) > 0$,

$$k_m(y, z) := \frac{a_m(y, z)}{d_m(y)}. \tag{5.205}$$

Thus, k_m is a normalized count of complete extensions, not a function introduced after projecting the state.

The restriction $C_{\mathrm{cont}}^{\mathrm{gau}}$ is formed by the surviving histories x for which the following conditions hold at every depth.

1. The sets $Y_m(x)$ are nonempty, $d_m(y) > 0$, and the truncations $\tau_{\ell,m}$ are surjective.
2. There exists a nonempty multisection of strictly positive rational weights $\mu_m : Y_m(x) \to \mathbf{Q}_{>0}$ such that
$$\sum_{y \in Y_m} \mu_m(y) = 1, \qquad \mu_m(y) = \sum_{\tau_{\ell,m}\widetilde{y} = y} \mu_\ell(\widetilde{y}). \tag{5.206}$$
3. Each μ_m is stationary:
$$\sum_{y \in Y_m} \mu_m(y) k_m(y, z) = \mu_m(z). \tag{5.207}$$

4. The marginal of $(q_m)_*\mu_m$ is the uniform counting measure on Q_{gau}. This condition makes the calculations of (5.201) literally applicable to the lift $W_c \circ q_m$.

5. Direct lumpability holds
$$\sum_{\tau_{\ell,m}\widetilde{z}=z} k_\ell(\widetilde{y},\widetilde{z}) = k_m(\tau_{\ell,m}\widetilde{y}, z) \tag{5.208}$$
for every $\widetilde{y} \in Y_\ell$ and $z \in Y_m$.

6. For the adjoint kernel
$$k_m^*(z,y) := \frac{\mu_m(y)k_m(y,z)}{\mu_m(z)}, \tag{5.209}$$
the adjoint lumpability condition is satisfied
$$\sum_{\tau_{\ell,m}\widetilde{y}=y} k_\ell^*(\widetilde{z},\widetilde{y}) = k_m^*(\tau_{\ell,m}\widetilde{z}, y). \tag{5.210}$$

7. The categories of prefixes possess the TPK root as an initial object, so that their nerve has the explicit terminal contraction of (5.228) below.

These conditions define the typed domain; outside it, a measure or natural operator is not published by mere declaration.

5.2.5.3 Projective measure, kernel, and direct and adjoint naturality

Having fixed a branch of the multisection $\{\mu_m\}_m$, let
$$H_m := \mathrm{Fun}(Y_m, \mathbf{Q}), \qquad \langle f, g\rangle_m := \sum_{y\in Y_m} \mu_m(y)f(y)g(y). \tag{5.211}$$

The operator generated by all extensions is
$$(K_m f)(y) := \sum_{z\in Y_m} k_m(y,z)f(z). \tag{5.212}$$

The Markov equations and stationarity give
$$K_m\mathbf{1} = \mathbf{1}, \qquad K_m^*\mathbf{1} = \mathbf{1}, \qquad \|K_m f\|_m \le \|f\|_m. \tag{5.213}$$

The lift and the truncated expectation are
$$J_{\ell,m}f := f \circ \tau_{\ell,m}, \qquad E_{m,\ell} := J_{\ell,m}^*. \tag{5.214}$$

The projectivity of μ implies
$$E_{m,\ell}J_{\ell,m} = I_{H_m}. \tag{5.215}$$

The two lumpability conditions discharge, respectively,
$$K_\ell J_{\ell,m} = J_{\ell,m}K_m, \qquad K_\ell^* J_{\ell,m} = J_{\ell,m}K_m^*. \tag{5.216}$$

The second equality is not inferred from the first without the attached condition: both remain registered in the domain.

The positive internal operator is defined
$$T_m := K_m^* K_m. \tag{5.217}$$

Then

$$\langle f, T_m f\rangle_m = \|K_m f\|_m^2 \geq 0, \qquad T_\ell J_{\ell,m} = J_{\ell,m} T_m. \tag{5.218}$$

5.2.5.4 Common law of 8 *faces and* 4 *Fubini squares*

On $Y_m^{\mathscr{B}_{\mathrm{gau}}}$, we define the rational mass

$$\Omega_m^{(8)}(\mathbf{y}) := \sum_{z\in Y_m} \mu_m(z) \prod_{(L,\varepsilon)\in\mathscr{B}_{\mathrm{gau}}} k_m(z, y_{L,\varepsilon}). \tag{5.219}$$

It is a probability because each factor is Markov. All faces arise from the same latent state z and the same kernel; they are not eight independently added measures.

For functions $f_{L,+}, f_{L,-} \in H_m$, finite Fubini gives

$$\begin{aligned}\sum_{\mathbf{y}} \Omega_m^{(8)}(\mathbf{y}) \prod_{L\in I_{\mathrm{gau}}} f_{L,+}(y_{L,+}) f_{L,-}(y_{L,-}) \\ = \sum_{z\in Y_m} \mu_m(z) \prod_{L\in I_{\mathrm{gau}}} (K_m f_{L,+})(z)(K_m f_{L,-})(z).\end{aligned} \tag{5.220}$$

Upon taking $f_{L,+} = f_{L,-} = f_L$, the four squares appear simultaneously

$$\sum_{z\in Y_m} \mu_m(z) \prod_{L\in I_{\mathrm{gau}}} (K_m f_L(z))^2. \tag{5.221}$$

The marginal of any opposite pair satisfies

$$\sum_{y_+,y_-} \Omega_{m,L}^{(2)}(y_+, y_-) f(y_+) g(y_-) = \langle K_m f, K_m g\rangle_m = \langle f, T_m g\rangle_m. \tag{5.222}$$

The commutativity of the product in (5.219) proves

$$(\vartheta_L)_* \Omega_m^{(8)} = \Omega_m^{(8)} \qquad (L \in I_{\mathrm{gau}}). \tag{5.223}$$

5.2.5.5 Exact internal operator and self-test witness

The projection onto the constant sector and its complement are

$$P_{\Omega,m} f := \langle \mathbf{1}, f\rangle_m \mathbf{1}, \qquad Q_m := I - P_{\Omega,m}. \tag{5.224}$$

The internal cell operator is defined by

$$D_m^{\mathrm{HMT}} := 3 Q_m. \tag{5.225}$$

The coefficient 3 is the cardinality of the residue field used in (5.188); it does not represent an added scale. For the lift

$$W_{c,m} := W_c \circ q_m$$

one has, by (5.201),

$$P_{\Omega,m} W_{c,m} = 0, \qquad D_m^{\mathrm{HMT}} W_{c,m} = 3 W_{c,m}, \qquad \|W_{c,m}\|_m^2 = \frac{2}{9}. \tag{5.226}$$

Thus, the complementary sector possesses a nonzero witness constructed by the incidence of the six edges.

5.2.5.6 Cellular terminal and strong retractor

Let $C_*(N\mathsf{Y}_m; A_n)$ be the normalized chain complex of the nerve of the prefix category, and let y_* be its initial root. The inclusion and the augmentation are

$$\iota_m : A_n[0] \longrightarrow C_*(N\mathsf{Y}_m; A_n), \quad \iota_m(1) = [y_*], \qquad \epsilon_m : C_*(N\mathsf{Y}_m; A_n) \longrightarrow A_n[0].$$

The initial object provides the extra degeneracy

$$H_m[y_0 \to \cdots \to y_q] := [y_* \to y_0 \to \cdots \to y_q], \tag{5.227}$$

with the normalized convention when a degeneration appears. It is verified

$$\epsilon_m \iota_m = I, \qquad \partial H_m + H_m \partial = I - \iota_m \epsilon_m, \qquad H_m^2 = H_m \iota_m = \epsilon_m H_m = 0. \tag{5.228}$$

This cellular terminal is distinct from the constant projection $P_{\Omega,m}$: the former contracts the nerve, while the latter separates the sectors of the function space. Both are preserved.

The same rule defines its action on an elementary emission $\alpha : x \to y$. Since U_α transports the ordered pair of sheets, its label map is $\overline{U}_\alpha e_{\Sigma,x} = e_{\Sigma,y}$ and $\overline{U}_\alpha e_{\Pi,x} = e_{\Pi,y}$. Its projectivization $\alpha_\mathscr{f}[v] := [\overline{U}_\alpha v]$ acts in $\mathbf{P}^1(V_x)$ and, therefore,

$$\begin{gathered}
\mathrm{Cell}_{\mathrm{TPK}}(\alpha) v_\star(x) = v_\star(y), \qquad \mathrm{Cell}_{\mathrm{TPK}}(\alpha) v_L(x) = v_{\alpha_\mathscr{f} L}(y), \\
\mathrm{Cell}_{\mathrm{TPK}}(\alpha) v_{\{L,L'\}}(x) = v_{\{\alpha_\mathscr{f} L, \alpha_\mathscr{f} L'\}}(y), \qquad \mathrm{Cell}_{\mathrm{TPK}}(\alpha) v_{L,\epsilon}(x) = v_{\alpha_\mathscr{f} L,\epsilon}(y), \\
\mathrm{Cell}_{\mathrm{TPK}}(\alpha) u_L(x) = u_{\alpha_\mathscr{f} L}(y), \qquad \mathrm{Cell}_{\mathrm{TPK}}(\alpha) u_{L,\epsilon}(x) = u_{\alpha_\mathscr{f} L,\epsilon}(y), \\
\mathrm{Cell}_{\mathrm{TPK}}(\alpha) u_{L'|L}(x) = u_{\alpha_\mathscr{f} L'|\alpha_\mathscr{f} L}(y), \qquad \mathrm{Cell}_{\mathrm{TPK}}(\alpha) \omega_{\{L,L'\}}(x) = \omega_{\{\alpha_\mathscr{f} L, \alpha_\mathscr{f} L'\}}(y).
\end{gathered} \tag{5.229}$$

In the leaf fiber and on its screen, one also has

$$\overline{U}_\alpha P_L = P_{\alpha_\mathscr{f} L} \overline{U}_\alpha, \qquad \mathrm{Cell}_{\mathrm{TPK}}(\alpha) \vartheta_L = \vartheta_{\alpha_\mathscr{f} L} \mathrm{Cell}_{\mathrm{TPK}}(\alpha). \tag{5.230}$$

Boundary formulas give

$$\partial \, \mathrm{Cell}_{\mathrm{TPK}}(\alpha) = \mathrm{Cell}_{\mathrm{TPK}}(\alpha) \partial, \qquad \mathrm{Cell}_{\mathrm{TPK}}(\beta\alpha) = \mathrm{Cell}_{\mathrm{TPK}}(\beta) \, \mathrm{Cell}_{\mathrm{TPK}}(\alpha). \tag{5.231}$$

Thus the map of complexes used in the terminal register is the free action induced by the same emission, not an added symbol.

5.2.5.7 Module of paths, totalization and nonadic return cone

Let $J_d(x)$ be the full category of depth-d prefixes of the common tree, $\mathrm{Term}_d(x)$ its terminal set, and $\Gamma_{d,N}(\nu) := C_{d,N}(\nu)$ the cellular complex of (5.184). The module, totalization, and cone that follow simultaneously preserve all continuations; they do not select a history or separate a cohomological construction from the common continuum.

5.2.5.8 Module of paths, cellular totalization and nonadic terminal

Let $\mathrm{Term}_d(x)$ be the conjunto of terminal of memory of the prefix. For $\nu \in J_d(x)$, definase

$$W_{d,N}(\nu) := A_N \big[\mathrm{Path}_{J_d(x)}(\nu, \mathrm{Term}_d(x)) \big]. \tag{5.232}$$

It is the free module on all terminal routes; it selects none. If $u : \nu \to \nu'$, the contravariant action is

$$W_{d,N}(u) : W_{d,N}(\nu') \longrightarrow W_{d,N}(\nu), \qquad [\lambda] \longmapsto [\lambda \circ u]. \tag{5.233}$$

Each generator preserves orientation, carry, boundary, route, and memory.

5.2.5.9 Bilateral bar complex and totalization of the bicolumn

For $q \geq 0$ and $r \in \{0, 1\}$, let

$$B^{d,N}_{q,r}(x) := \bigoplus_{\nu_0 \xrightarrow{u_1} \cdots \xrightarrow{u_q} \nu_q} W_{d,N}(\nu_q) \otimes_{A_N} \Gamma_{d,N}(\nu_0)_r. \tag{5.234}$$

The bar differential is defined without abbreviation by

$$\begin{aligned} d_{\mathrm{bar}}(w; u_1, \ldots, u_q; c) := {} & (w; u_2, \ldots, u_q; \Gamma(u_1)c) \\ & + \sum_{i=1}^{q-1} (-1)^i (w; u_1, \ldots, u_{i+1}u_i, \ldots, u_q; c) \\ & + (-1)^q (W(u_q)w; u_1, \ldots, u_{q-1}; c). \end{aligned} \tag{5.235}$$

For $q = 1$, this is exactly the relation

$$d_{\mathrm{bar}}(w; u; c) = w \otimes \Gamma(u)c - W(u)w \otimes c. \tag{5.236}$$

A transported incidence is thereby identified with the same incidence written in the refined chart; the relation is not concealed beneath the name of the totalizer.

The total complex is

$$K_{d,N}(x) := \mathrm{Tot}\, B^{d,N}_{\bullet,\bullet}(x), \qquad D_{\mathrm{tot}} := d_{\mathrm{bar}} + (-1)^q \partial_\Gamma \quad \text{on } B^{d,N}_{q,r}. \tag{5.237}$$

The functoriality of W and Γ, together with $\partial_\Gamma^2 = 0$, gives

$$D^2_{\mathrm{tot}} = 0. \tag{5.238}$$

In compact notation, but now already discharged by (5.234)– (5.235),

$$K_{d,N}(x) \simeq W_{d,N} \otimes^{\mathbf{L}}_{A_N[J_d(x)]} \Gamma_{d,N}. \tag{5.239}$$

5.2.5.10 Depth and terminal nonadic colimit

The prefixes form the colimit.

$$K_{\infty,N}(x) := \varinjlim_{d} K_{d,N}(x). \tag{5.240}$$

The nine-phase extension carries depth d to depth $d + 9$. Only after forming (5.240) does it induce a well-typed endomorphism

$$U_{\Gamma_9,N} : K_{\infty,N}(x) \longrightarrow K_{\infty,N}(x). \tag{5.241}$$

The terminal is

$$\mathcal{T}_{\mathrm{coh},N}(x) := \mathrm{Cone}\big(I - U_{\Gamma_9,N}\big). \tag{5.242}$$

With the homological convention

$$\mathrm{Cone}(f)_q = K_{\infty,N,q-1} \oplus K_{\infty,N,q},$$

its differential is

$$\partial_{\mathrm{Cone}}(a, b) = \big(-\partial_K a, \partial_K b + f(a)\big). \tag{5.243}$$

Although the visible phase of h and $\Gamma_9 h$ coincides, the generators $[h]$ and $[\Gamma_9 h]$ are different because their ledgers and depths are different. The terminal object preserves

$$(I - U_{\Gamma_9,N})[h] = [h] - [\Gamma_9 h]. \tag{5.244}$$

Precision reductions commute with the terminal:

$$r_{N+1,N} U_{\Gamma_9,N+1} = U_{\Gamma_9,N} r_{N+1,N}. \tag{5.245}$$

5.2.5.11 Terminal cohomological reader: incidence cycle and class in $H_0(\mathrm{Cone}(I - U_{\Gamma_9,N}))$

Each cell of $x_{\le d}$ carries a vector of incidence

$$\omega_{\nu,N}(x) \in A_N^{I_\nu \times J_\nu} = C_{\nu,N,0}$$

and the complete terminal route $\lambda_{\nu,x}$. The raw cycle is

$$z_{d,N}(x) := \sum_{\nu \in \mathrm{Cell}_d(x)} \epsilon_\nu [\lambda_{\nu,x}] \otimes \omega_{\nu,N}(x) \in B_{0,0}^{d,N}(x). \tag{5.246}$$

As the total complex is homologically non-negative,

$$D_{\mathrm{tot}} z_{d,N}(x) = 0. \tag{5.247}$$

Both the cycle and its class are preserved.

$$[z_{d,N}(x)] \in H_0(K_{d,N}(x)).$$

After including it in $K_{\infty,N}$, its terminal class is

$$[(0, z_{d,N}(x))] \in H_0(\mathcal{T}_{\mathrm{coh},N}(x)).$$

The complete reader is

$$\mathcal{L}_{\mathrm{coh},d,N}(x) := \big(z_{d,N}(x), [z_{d,N}(x)], U_{\Gamma_9,N} z_{d,N}(x), [(0, z_{d,N}(x))]\big). \tag{5.248}$$

The publication is not merely a quotient class: the representative, the route that produced it, its continuation and the terminal remain.

5.2.5.12 Surviving fibres and corrections without a selector

Let $\mathcal{S}_\lambda^{\mathrm{coh}}$ be the free A_N-module generated by the admissible finite histories at level $\lambda = (d, N)$. The reader extends linearly to

$$e_\lambda : \mathcal{S}_\lambda^{\mathrm{coh}} \longrightarrow \mathcal{O}_\lambda^{\mathrm{coh}}, \qquad \mathcal{O}_\lambda^{\mathrm{coh}} := H_0(K_{d,N}) \oplus H_0(\mathcal{T}_{\mathrm{coh},N}). \tag{5.249}$$

The surviving codomain is

$$\mathcal{O}_\infty^{\mathrm{surv}} := \mathrm{Im}\left(e_\infty : C_{\mathrm{cont}}^{\mathrm{coh}} \longrightarrow \varprojlim_\lambda \mathcal{O}_\lambda^{\mathrm{coh}} \right). \tag{5.250}$$

For $a = (a_\lambda)_\lambda \in \mathcal{O}_\infty^{\mathrm{surv}}$, define

$$\mathcal{F}_\lambda(a) := \left\{ s_\lambda \in \mathcal{S}_\lambda^{\mathrm{coh}} : \begin{array}{l} e_\lambda(s_\lambda) = a_\lambda, \\ \exists y \in C_{\mathrm{cont}}^{\mathrm{coh}} \text{ with } y|_\lambda = s_\lambda \text{ and } e_\infty(y) = a \end{array} \right\}. \tag{5.251}$$

These fibers are nonempty by the definition of the surviving codomain. If $\lambda' \ge \lambda$, the restriction is surjective:

$$\rho_{\lambda',\lambda} : \mathcal{F}_{\lambda'}(a) \twoheadrightarrow \mathcal{F}_\lambda(a). \tag{5.252}$$

Indeed, a complete history that witnesses $s_\lambda \in \mathscr{F}_\lambda(a)$ provides by truncation an antecedent at any later level. That antecedent is not chosen as part of the object.

The complete multisect is

$$\Sigma^{\mathrm{coh}}_{\lambda',\lambda}(s_\lambda; a) := \{s_{\lambda'} \in \mathscr{F}_{\lambda'}(a) : \rho_{\lambda',\lambda} s_{\lambda'} = s_\lambda\}. \tag{5.253}$$

For a provisional prolongation $\widetilde{s}_{\lambda'}$, let

$$\delta_{\lambda'} := a_{\lambda'} - e_{\lambda'}(\widetilde{s}_{\lambda'}). \tag{5.254}$$

The relation of all corrections is

$$\mathrm{Corr}_{\lambda',\lambda}(\widetilde{s}_{\lambda'}, \delta_{\lambda'}) := \left\{ \eta \in \mathcal{S}^{\mathrm{coh}}_{\lambda'} : \begin{array}{l} \rho_{\lambda',\lambda}\eta = 0, \\ e_{\lambda'}(\eta) = \delta_{\lambda'}, \\ \eta \text{ is supported on new cells}, \\ \eta \text{ preserves orientation, carry, memory and terminal} \end{array} \right\}. \tag{5.255}$$

If two lifts are comparable, their difference $\eta = s_{\lambda'} - \widetilde{s}_{\lambda'}$ belongs to this relation exactly when it satisfies the four preceding conditions. It is not asserted that (5.255) is nonempty for an arbitrary discrepancy: the governing non-emptiness is that of (5.253) on the surviving domain.

The local complex (5.110) and the vertex y_α, endpoint of that same extension in the nerve, form the augmented pullback. In it are defined

$$\mathbf{1}_\alpha = (r, [y_\alpha]), \qquad z_-(\alpha) = (r, [y_\alpha]), \tag{5.256}$$

$$z_+(\alpha) = (r + 3c_\alpha v_\alpha e + v_\alpha b, [y_\alpha]), \qquad h_*(\alpha) = (-v_\alpha f, 0). \tag{5.257}$$

The action on generators gives, without an additional abstract existence,

$$\partial z_- = \partial z_+ = 0, \qquad \partial h_* = z_- - z_+. \tag{5.258}$$

The correlative filling, the cell, and the collar preserve the same $(\alpha, \mathrm{or}(\alpha), \kappa(\alpha), \partial\alpha, \gamma\alpha, m(\gamma\alpha; m_0))$; they merely apply different internal readers to the common record.

For the same finite based complex, the total determinant line is defined, without requiring balance or acyclicity.

$$\mathrm{Det}(C_{k,N}) := \bigotimes_q \left(\bigwedge^{\mathrm{top}} C_{k,N,q} \right)^{(-1)^q}. \tag{5.259}$$

Refinement induces the determinantal morphism of the map of complexes and simultaneously transports homology modules, Smith normal forms, and Bockstein pages as fields of the register. Neither the existence of (5.259) nor its transport requires homology to vanish. If the cone of refinement is contractible and oriented, the morphism is canonically trivialized; in the general case the cone is preserved and not replaced by a fictitious isomorphism.

5.2.5.13 Smith Normal Form of the Terminal Operator and Primary Decomposition of Its Cokernel

For each prefix y, the unoriented carry and the oriented coefficient of boundary of the common register admit the lifts

$$\widetilde{c}_y, \widetilde{v}_y \in \mathbf{Z}, \qquad c_{y,n} := \widetilde{c}_y \bmod 3^n, \qquad v_{y,n} := \widetilde{v}_y \bmod 3^n. \tag{5.260}$$

The determinantal output is neither an input nor a separate branch: it is the sector produced by the same terminal reduction when the typed conditions are verified

$$
\begin{aligned}
C_{\mathrm{cont}}^{\mathrm{det}} := \big\{ & x \in C_{\mathrm{cont}}^{\mathrm{disc}} : x \text{ survives at every depth;} \\
& \widehat{P}_x^{\mathrm{red}} \text{ is finite and based;} \\
& \chi(\widehat{P}_x^{\mathrm{red}}) = 0; \\
& H_*(\widehat{P}_x^{\mathrm{red}} \otimes_{\mathbf{Z}_3} K_3) = 0; \\
& \text{the reduction produces a square block stable under refinement} \big\}.
\end{aligned}
\tag{5.261}
$$

5.2.5.14 Lifting of the cokernel through the Bockstein tower and preservation of carry

Only the common root is eliminated:

$$
\overline{P}_{y;m,n} := P_{y;m,n}^{\mathrm{gen}} / A_n \mathbf{1}_y, \qquad \widehat{P}_{y;m}^{\mathrm{red}} := \varprojlim_n \overline{P}_{y;m,n}. \tag{5.262}
$$

The base is first ordered by the TPK order of routes and then by

$$
f \prec e \prec b \prec g. \tag{5.263}
$$

The following internal algorithm is executed.

1. Find the coefficients that are units of $\mathbf{Z}_3$.
2. Choose the first according to (5.263) and the order of paths.
3. Cancel the corresponding pair and record the elementary operations, their sign, and their contribution to the orientation.
4. Repeat until no cancellable unit pivot remains.

The survival condition of (5.261) requires that, cofinally in m, the result be a two-term block

$$
\mathbf{Z}_3^{r_x} \xrightarrow{S_x} \mathbf{Z}_3^{r_x}, \qquad \det S_x \neq 0 \text{ in } K_3, \tag{5.264}
$$

and that a refinement only add unit contractible blocks and recorded changes of basis. If these conditions fail, the history does not belong to $C_{\mathrm{cont}}^{\mathrm{det}}$; a nonexistent terminal is not forced.

The identity route provides an elementary witness. After removing the root, the local complex is

$$
A_n f \xrightarrow{\binom{3c}{1}} A_n e \oplus A_n b \xrightarrow{(1,-3c)} A_n g. \tag{5.265}
$$

Is contractible via

$$
s(g) = e, \qquad s(ae + \beta b) = \beta f, \qquad s(f) = 0. \tag{5.266}
$$

Thus, the terminal conditions admit at least the internal identity witness and do not describe a formally empty subdomain.

5.2.5.15 Smith, 3-adic order and initial unit

In oriented bases, a valuation diagonalization has the form

$$
U_x S_x V_x = \mathrm{diag}(3^{a_1} u_1, \dots, 3^{a_r} u_r), \qquad a_i \in \mathbf{N}, quad u_i \in \mathbf{Z}_3^{\times}. \tag{5.267}
$$

We define

$$
d_x := v_3(\det S_x) = \sum_{i=1}^{r} a_i \tag{5.268}
$$

and the initial unit

$$
\lambda_x := 3^{-d_x} \det S_x \in \mathbf{Z}_3^{\times}. \tag{5.269}
$$

The orientation coordinate trivializes the determinant line. If a transition produces

$$S_x \oplus I_q = U S_{x'} V, \tag{5.270}$$

the orientation is transported by the inverse factor of $\det U \det V$. The oriented unit λ_x^{or} is then natural and does not change when contractible blocks are added.

At finite precision,

$$S_{x,n} = S_x \bmod 3^n, \qquad a_i^{(n)} = \min(a_i, n). \tag{5.271}$$

The terminal is, therefore, the compatible family of all precisions and not an isolated integer.

5.2.5.16 Bockstein Tower and Higher Order Carry

Let

$$C_x^1 \xrightarrow{S_x} C_x^0$$

the terminal block. If a class $[\bar{y}]$ admits a lift $y \in C_x^1$ with $S_x y \in 3^q C_x^0$, we define

$$\beta_q[\bar{y}] := [3^{-q} S_x y \bmod 3]\,. \tag{5.272}$$

Changing the lift alters the representative by a boundary of the corresponding page, so β_q is well defined. The higher carry is

$$\mathrm{Carr}_q(y) := 3^{-q} S_x y. \tag{5.273}$$

It does not replace the TPK carry of (5.260); it records its prolongation in the coefficient tower.

For a block $3^{a_i} u_i$, the class persists until page a_i, and on that page the nonzero differential is multiplication by $\bar{u}_i \in \mathbf{F}_3^\times$. Consequently,

$$\{\text{survival lengths}\} = \{a_1, \dots, a_r\}, \qquad d_x = \sum_i a_i. \tag{5.274}$$

The oriented product of the page trivializations satisfies

$$\Theta_{\mathrm{Bock}}(x) = \overline{\lambda_x^{\mathrm{or}}} \in \mathbf{F}_3^\times. \tag{5.275}$$

The proof is carried out in each diagonal block and transported by the recorded unimodular changes. Smith, Bockstein and the initial unit are thus three readings of the same terminal.

5.2.6 Naturalness of the ensemble and compatibility under refinement

Before forming the horizon record, we make explicit the total action of the five operations developed here on *the same* edge $\mathfrak{e}_\alpha$. If P_x, Q_x denote the restrictions of (5.124) to the fiber of $x = s(\alpha)$, and analogously in $y = t(\alpha)$, we first set

$$A_\alpha := P_y U_\alpha P_x + Q_y U_\alpha Q_x, \qquad \eta_\alpha := Q_y U_\alpha P_x + P_y U_\alpha Q_x. \tag{5.276}$$

The five readings are dependent families indexed by the $\mathfrak{e}_\alpha$ itself. The index fixes source, target, route, and ledger, but is not copied again within the value. Their types are the dependent records $\mathrm{LedgerEntry} := \mathrm{cod}(\lambda)$ and

$$\begin{aligned}
\mathsf{Y}_{\mathrm{sp}}[\alpha] &:= \mathrm{Rec}[U : \mathsf{H}_x \to \mathsf{H}_y; \sigma_x \in \mathrm{End}\,\mathsf{H}_x; \sigma_y \in \mathrm{End}\,\mathsf{H}_y; A, \eta : \mathsf{H}_x \to \mathsf{H}_y],\\
\mathsf{Y}_{\mathrm{sol}}[\alpha] &:= \mathrm{Rec}[b, b^+, b^- \in \mathrm{LedgerEntry}; \mathrm{upd} : \mathsf{Mem}_x \to \mathsf{Mem}_y],\\
\mathsf{Y}_{\mathrm{gau}}[\alpha] &:= \mathcal{P}_{\mathrm{fin}}\,\mathrm{Rec}[\mathrm{Cell}(\alpha); q \in Q_{\mathrm{inc}}(y); B; W_c(q)],\\
\mathsf{Y}_{\mathrm{coh}}[\alpha] &:= \mathrm{Rec}[I_y, J_y, \kappa_{y,N}, \delta_y, C_{y,N}; F_\alpha : C_{y,N} \to C_{x,N}],\\
\mathsf{Y}_{\mathrm{det}}[\alpha] &:= \mathrm{Rec}[\Psi_\alpha, K_\alpha, \mathbf{1}_\alpha, z_\pm, h_*; \mathrm{Det}, H_*, \mathrm{Smith}, \mathrm{Boc}].
\end{aligned}$$

Therefore, the common judgment is

$$\mathfrak{e}_\alpha : \mathrm{Ext}_k \ \vdash\ O_\bullet(\mathfrak{e}_\alpha) \in \mathsf{Y}_\bullet[\alpha], \qquad \bullet \in \{\mathrm{sp}, \mathrm{sol}, \mathrm{gau}, \mathrm{coh}, \mathrm{det}\}.$$

$$O_{\mathrm{sp}}(\mathfrak{e}_\alpha) := \big(U_\alpha, \sigma_x, \sigma_y, A_\alpha, \eta_\alpha\big), \tag{5.277}$$

$$O_{\mathrm{sol}}(\mathfrak{e}_\alpha) := \big(b_\alpha, b_\alpha^+, b_\alpha^-;\ (M^+, M^-, D, H) \mapsto (M^+ + b_\alpha^+, M^- + b_\alpha^-, D + b_\alpha, H + |b_\alpha|)\big), \tag{5.278}$$

$$O_{\mathrm{gau}}(\mathfrak{e}_\alpha) := \big\{\big(\mathrm{Cell}_{\mathrm{TPK}}(\alpha), q, B, W_c(q)\big) : q \in Q_{\mathrm{inc}}(y)\big\}, \tag{5.279}$$

$$O_{\mathrm{coh}}(\mathfrak{e}_\alpha) := \big(I_y, J_y, \kappa_{y,N}, \delta_y, C_{y,N}, F_\alpha : C_{y,N} \longrightarrow C_{x,N}\big), \tag{5.280}$$

$$O_{\mathrm{det}}(\mathfrak{e}_\alpha) := \big(\Psi_\alpha, K_\alpha, \mathbf{1}_\alpha, z_\pm(\alpha), h_*(\alpha), \mathrm{Det}(C_{y,N}), H_*(C_{y,N}), \mathrm{Smith}(C_{y,N}), \mathrm{Boc}(C_{y,N})\big). \tag{5.281}$$

The internal Archimedean reading is the first component of this simultaneous action; it does not yet introduce any classical form:

$$\mathcal{L}^{\mathrm{int}}_{\mathrm{arq}}(\mathfrak{e}_\alpha) := O_{\mathrm{sp}}(\mathfrak{e}_\alpha). \tag{5.282}$$

For every value in those families, including each element of the multisection O_{gau}, its support is the dependent index

$$\begin{aligned} \mathsf{B}_\alpha &:= \{(s(\alpha), t(\alpha), \gamma\alpha, \mathrm{Led}(\gamma\alpha))\},\\ \mathrm{supp}_\alpha : \mathsf{Y}_\bullet[\alpha] &\longrightarrow \mathsf{B}_\alpha, \qquad o \longmapsto (s(\alpha), t(\alpha), \gamma\alpha, \mathrm{Led}(\gamma\alpha)). \end{aligned} \tag{5.283}$$

Therefore, they remain typed, without a projection that recovers the edge,

$$\begin{aligned} s_\alpha(O_\bullet) &:= s(\alpha), \qquad t_\alpha(O_\bullet) := t(\alpha),\\ \gamma_\alpha(O_\bullet) &:= \gamma\alpha, \qquad \mathrm{Led}_\alpha(O_\bullet) := \mathrm{Led}(\gamma\alpha). \end{aligned} \tag{5.284}$$

Here $\mathrm{Cell}_{\mathrm{TPK}}(\alpha)$ is the map of complexes (5.229) induced by transport of the same sheet fiber, and F_α is (5.185) for that extension. In particular, O_{gau} preserves the complete multisection of q's; it does not choose the origin or an orbit.

The five formulas above constitute a single dependent action.

$$O(\mathfrak{e}_\alpha) := \big\langle O_{\mathrm{sp}}, O_{\mathrm{sol}}, O_{\mathrm{gau}}, O_{\mathrm{coh}}, O_{\mathrm{det}}; \mathrm{Cpl}_\alpha \big\rangle, \tag{5.285}$$

where Cpl_α is the certificate formed by the identities

$$\begin{gathered} \mathrm{supp}_\alpha(O_{\mathrm{sp}}) = \mathrm{supp}_\alpha(O_{\mathrm{sol}}) = \mathrm{supp}_\alpha(O_{\mathrm{gau}}) = \mathrm{supp}_\alpha(O_{\mathrm{coh}}) = \mathrm{supp}_\alpha(O_{\mathrm{det}}),\\ \mathsf{Q}(t(\alpha)) = \sigma_9 \mathsf{Q}(s(\alpha)), \quad g(t(\alpha)) = g(s(\alpha)) + [1]_9, \quad q^{(9)}(t(\alpha)) = q^{(9)}(s(\alpha)) + \chi_9(g(s(\alpha))),\\ A_\alpha^* A_\alpha + \eta_\alpha^* \eta_\alpha = P_x U_\alpha^* U_\alpha P_x + Q_x U_\alpha^* U_\alpha Q_x,\\ (M^+, M^-, D, H)' = (M^+ + b_\alpha^+, M^- + b_\alpha^-, D + b_\alpha, H + |b_\alpha|),\\ Q_{\mathrm{inc}} = C^2(\mathrm{Cell}_{\mathrm{TPK}}; \mathbf{F}_3), \qquad sB = 0, \qquad W_c(q + Ba) = W_c(q),\\ C_{y,N} \text{ is the same complex in } O_{\mathrm{coh}} \text{ and } O_{\mathrm{det}}, \qquad \partial h_* = z_- - z_+, \qquad K_{\beta\alpha} = K_\beta + \Psi_\beta K_\alpha. \end{gathered} \tag{5.286}$$

The symbol $\bullet$ ranges over the five readings of (5.285); all preserve the same source, destination, route, and ledger.

We collect, without separating the state, the operations constructed up to here:

$$\begin{aligned}\mathfrak{D}_{k,N}(\widehat{x}) := \big(&\{\mathfrak{e}_\alpha\}_\alpha;\\ &U_k, \sigma_k, P_k, Q_k, A_k, \eta_k;\\ &b_\alpha, b^{\pm}_\alpha, M^{\pm}_k, D^0_k, H^0_k, \kappa^{\mathrm{can}}_k;\\ &V_{\mathrm{TPK}}, \mathscr{I}, \mathscr{E}, \mathscr{B}, B;\\ &\mathrm{Cell}_{\mathrm{TPK}}(\widehat{x}), Q_{\mathrm{inc}}(\widehat{x}), W_c;\\ &I_k, J_k, \kappa_{k,N}, \delta, C_{k,N};\\ &c_\alpha, v_\alpha, \Psi_\alpha, K_\alpha, \mathbf{1}_\alpha, z_\pm(\alpha), h_*(\alpha);\\ &\mathrm{Det}(C_{k,N}), H_*(C_{k,N}), \mathrm{Smith}(C_{k,N}), \mathrm{Boc}(C_{k,N});\\ &\{O(\mathfrak{e}_\alpha)\}_\alpha\big).\end{aligned} \tag{5.287}$$

The semicolon merely separates levels of interpretation of the same dependent tuple; it does not define independent structures. The input state is neither retained as the first coordinate nor recovered through a projection. Each operation is proved through its action on the generators $\mathfrak{e}_\alpha$, which preserve the same support, the same route, and the same ledger.

For $\ell \geq k$ and $N' \geq N$, transport is defined component by component through truncation of histories, reduction of coefficients, and precomposition of ports. The naturality assertion that must be proved is a single one:

$$u_{(\ell,N'),(k,N)}\mathfrak{D}_{\ell,N'}(\widehat{x}_\ell) = \mathfrak{D}_{k,N}(\tau_{\ell,k}\widehat{x}_\ell). \tag{5.288}$$

Naturality is formulated over the generated history, not by pretending that an isolated fine edge must remain an edge after truncating its two endpoints. For $\gamma = (\varepsilon_1, \dots, \varepsilon_\ell)$, we define

$$\mathsf{E}_{\leq\ell}(\gamma) := (\mathfrak{e}_{\varepsilon_i})_{1\leq i\leq \ell}, \qquad O_{\leq\ell}(\gamma) := (O(\mathfrak{e}_{\varepsilon_i}))_{1\leq i\leq\ell}.$$

The two transports are the explicit prefix maps.

$$u^{\mathfrak{e}}_{\ell,k} : \mathsf{E}_{\leq\ell}(\gamma) \longrightarrow \mathsf{E}_{\leq k}(\gamma), \qquad (\mathfrak{e}_{\varepsilon_i})_{i\leq\ell} \longmapsto (\mathfrak{e}_{\varepsilon_i})_{i\leq k}, \tag{5.289}$$

$$u^{O}_{\ell,k} : O_{\leq\ell}(\gamma) \longrightarrow O_{\leq k}(\gamma), \qquad (O(\mathfrak{e}_{\varepsilon_i}))_{i\leq\ell} \longmapsto (O(\mathfrak{e}_{\varepsilon_i}))_{i\leq k}. \tag{5.290}$$

In each retained entry, the component sp intertwines U, σ, P, Q, A, η; the component sol applies the conditional expectation to $b, b^{\pm}, \kappa$; the component gau applies $\mathrm{Cell}(\tau) \oplus \tau_Q$; the component coh precomposes the ports with F; and the component det applies $\Psi, K, H_*, \mathrm{Smith}, \mathrm{Boc}$ to the same map of complexes. The prefix acts simultaneously on those five components. Its components already discharged are

$$\begin{gathered}U_{m,k} = U_{m,\ell}U_{\ell,k} \quad (m \geq \ell \geq k), \qquad E_k b^{\pm}_f = b^{\pm}_c + \kappa^{\mathrm{can}}_k,\\ r_{N',N}\kappa_{k,N'} = \kappa_{k,N}(r_{N',N} \oplus r_{N',N}),\\ \Psi_\beta\Psi_\alpha = \Psi_{\beta\alpha}, \qquad K_{\beta\alpha} = K_\beta + \Psi_\beta K_\alpha,\\ u^{O}_{\ell,k}O_{\leq\ell}(\gamma) = O_{\leq k}(\gamma) = \mathrm{map}(O)\big(u^{\mathfrak{e}}_{\ell,k}\mathsf{E}_{\leq\ell}(\gamma)\big).\end{gathered} \tag{5.291}$$

The first equality uses multiplication of the conditional weights over the same system of common cylinders; the remaining ones are the preceding explicit formulas. No visible projection can be used to reconstruct or select $\widehat{x}$.

To complete the last component, let us denote by $F_{(\ell,N'),(k,N)} : C_{\ell,N'} \to C_{k,N}$ the map of complexes of (5.185). Its cone is preserved as part of the transition. Functoriality of homology and of the Bockstein sequence gives

$$H_*(F_{m,k}) = H_*(F_{\ell,k})H_*(F_{m,\ell}), \qquad \mathrm{Boc}(F_{m,k}) = \mathrm{Boc}(F_{\ell,k})\,\mathrm{Boc}(F_{m,\ell}). \tag{5.292}$$

The determinant line is transported by the identity of the exact triangle.

$$\mathrm{Det}(C_{k,N}) \simeq \mathrm{Det}(C_{\ell,N'}) \otimes \mathrm{Det}\big(\mathrm{Cone}\, F_{(\ell,N'),(k,N)}\big)\,. \tag{5.293}$$

This formula also records the refinements that add homology. The Smith reading is conserved without feigning invariance: each transition is assigned the total certificate

$$\mathcal{S}(F) := \big(\mathrm{Smith}(C_{\ell,N'}), \mathrm{Smith}(C_{k,N}), \mathrm{Smith}(\mathrm{Cone}\, F)\big), \tag{5.294}$$

which literally determines which summands are conserved, born, or die.

The action of a coherent symmetry g on the common tree induces permutation isometries $\widetilde{g}_k$ on $\mathscr{H}_k$. The bijection of children and preservation of the weights of (5.96) prove, on the basis vectors,

$$\widetilde{g}_{k+1}U_k = U_k\widetilde{g}_k, \qquad \widetilde{g}_k\sigma_k = \sigma_k\widetilde{g}_k, \qquad \widetilde{g}_kP_k = P_k\widetilde{g}_k, \qquad \widetilde{g}_kQ_k = Q_k\widetilde{g}_k. \tag{5.295}$$

Theorem 5.34 (Totality and naturality of the correlative constructor)**.** *For every total state of* (5.56)*, every finite horizon, and every coefficient level, the expression* (5.287) *is defined. Its five characteristics are simultaneous operations on the same extension ledger and satisfy the single identity* (5.288)*. The collar, the complex, and the determinant line remain nonempty even when their subsequent readers are neither acyclic nor invertible.*

Proof. Nonemptiness of the tree and its ports is proposition 5.15; the measure and the expectation are total by theorem 5.28. The formulas (5.120)–(5.139) define transport, polarity, balance, and memory for all generators. The four directions of (5.187) are distinct by (5.189); the cellular completion definition 5.33 contains its two path orders and six cells, while (5.200) proves its naturality. The cellular sequence is exact by (5.108), the local complex satisfies $\partial^2 = 0$, and the correlated filling is explicit by (5.258). Every finite based construction possesses the line (5.259); homology, Bockstein, and the Smith certificate are transported by (5.292)– (5.294). Finally, the identities are verified on each generator $\mathfrak{e}_\alpha$ through (5.291), (5.200), and (5.295); by linearity and by the functorial composition of routes, (5.288) is obtained for the integral record. □

5.2.7 Causal separation of the identities, deductions, and realizations of the correlator constructor

No vacuity and exact identities of the correlator constructor The nonemptiness imported from (5.64) and the identities (5.104), (5.108), (5.116), (5.121), (5.127), (5.138), (5.111), (5.175), and (5.258) follow from the definitions and the exhibited APP–TRIT–TPK relations. Their status is `EXACT_INTERNAL`.

Starting hypotheses for the isometry of U_k, the cellular sequence, and the composition Ψ/K The construction of U_k takes as its starting structure the finiteness of the fibres, survival at every horizon, functional truncation, and the transports of both sheets already produced by TPK. Equality $U_k^*U_k = I$ is equivalent to verifying the normalized average Gram matrix of (5.122); in particular, it suffices to check $U_\alpha^*U_\alpha = I$ for each emission. General identity (5.121) is retained for all declared sheet transports. The cellular sequence uses both ordered APP ports. Composition Ψ/K uses integer carry, orientation, and boundary. Under these enumerated premises, the stated conclusions are affirmative.

Additional data for isometric realizations, balanced retracts, and trivialization of the determinant line The internal constructor is completed by the positive Gram form of (5.121), the total space Q_{inc}, the cellular sequence, and the determinant line with its transition cone. A specialized publication may require additional data: the isometry of each U_α, a concrete numerical identification of the APP defect,

a balanced acyclic retraction, or trivialization of a determinant line. Those data are intertwiners of the published codomain; they do not form part of the domain or of the existence of $\mathfrak{D}_{k,N}$. Their absence precludes exclusively the promotion that mentions them.

Comparison Criterion 5.35 (Falsifiers of the intrinsic correlation)**.** The joint construction fails at the first level at which any of the following facts occurs:

1. an operation uses an extension, orientation, carry, memory, boundary or route different from that recorded in $\mathfrak{e}_\alpha$;
2. a child of $\mathrm{Ch}_k(\widehat{x}_k)$ is chosen and the remaining ones are eliminated;
3. the weights of (5.118) do not sum to one, (5.121) fails, or $U_k^* U_k = I$ is declared without verifying the normalized average Gram matrix of (5.122), for example through the isometry of each emission transport;
4. κ_k^{can} is identified with the integer carry κ_α;
5. $sB = 0$ fails, $Q_{\mathrm{inc}}(\widehat{x})$ is contracted to its origin, the action $q \mapsto q + Ba$ is altered, or the two path orders are identified before applying the reader;
6. a refinement breaks (5.186) or the cocycle (5.175);
7. fails $\partial^2 = 0$, $z_\pm$ are not ciclos or $\partial h_* \neq z_- - z_+$;
8. a nonzero determinantal scalar is asserted without the retract, the balance, and the acyclicity required by that publication;
9. any of the five operations is presented as an object separate from the constructor $\mathfrak{D}_{k,N}$.

In all those cases the diagnosis is: *common object substituted; conclusion not transferable*.

5.2.8 Joint emergence of the five constructions

For $0 \le k \le N$, let

$$\rho_{N,k} := \rho_k \circ \rho_{k+1} \circ \cdots \circ \rho_{N-1}, \qquad \rho_{k,k} := \mathrm{id}_{H_k},$$

and, for a surviving history $\zeta \in H_k$, define

$$\mathrm{Desc}_{k,N}(\zeta) := \{x \in H_N : \rho_{N,k}(x) = \zeta\}.$$

The finite tree $\mathscr{T}_{k,N}(\zeta)$ has vertices

$$\coprod_{j=k}^{N} \{y \in H_j : \rho_{j,k}(y) = \zeta\}$$

and has as edges only the TPK prolongations $a : y \to z$ with $z \in \rho_j^{-1}(y)$. Thus neither its vertices nor its prolongations come from an auxiliary tree.

For $x \in \mathrm{Desc}_{k,N}(\zeta)$, the marked branch $\lambda_{\zeta,x}$ is the sequence

$$\zeta = x_k \longrightarrow x_{k+1} \longrightarrow \cdots \longrightarrow x_N = x$$

determined by the truncations of x. The common base register is

$$\begin{aligned}\mathscr{R}_{k,N}(\zeta;x) := \big(&\mathscr{T}_{k,N}(\zeta), \lambda_{\zeta,x};\\ &\big(\varepsilon_a, s_a, o_a, (\delta_{\diamond,a}, r_{\diamond,a}, q_{\diamond,a})_{\diamond\in\{\Sigma,\Pi\}}, \mathrm{Carr}_a, C_a, t_a, \mathrm{Fr}_a, \mathrm{Ruta}_a, \mathrm{Mem}_a, \mathrm{Surv}_a\big)_a;\\ &\mathrm{src}, \mathrm{tgt}, \circ, (\rho_j)_{k\le j<N}\big),\end{aligned} \tag{C1}$$

where

$$U_a(m_0) = C_a m_0 + t_a, \qquad \delta_{\diamond,a} = r_{\diamond,a} + 9q_{\diamond,a}.$$

The symbol m_0 in this formula is a memory coordinate; it is not the modular depth m used below. The true base space is

$$\mathfrak{R}_{k,N}(\zeta) := \{\mathscr{R}_{k,N}(\zeta;x) : x \in \mathrm{Desc}_{k,N}(\zeta)\}.$$

The marked branch is not an added input: it is the sequence of actually produced edges ending at x. The rest of the register simultaneously preserves the lateral fibres of the tree; thus the mark does not replace branching with an isolated path.

Set $R_m := \mathbb{Z}/3^m\mathbb{Z}$, and let $V_j(\zeta) := \mathrm{Desc}_{k,j}(\zeta)$. Transport, the sheet projectors and the terminal residue restrict to the subtree through

$$\mathcal{U}_j^\zeta := \mathcal{U}_j \restriction_{\ell^2(V_j(\zeta),\mu_j)}, \qquad P_j^\zeta := P_j \restriction_{V_j(\zeta)}, \qquad Q_j^\zeta := I - P_j^\zeta,$$

$$A_j^\zeta := P_{j+1}^\zeta \mathcal{U}_j^\zeta P_j^\zeta + Q_{j+1}^\zeta \mathcal{U}_j^\zeta Q_j^\zeta, \qquad \eta_j^\zeta := Q_{j+1}^\zeta \mathcal{U}_j^\zeta P_j^\zeta + P_{j+1}^\zeta \mathcal{U}_j^\zeta Q_j^\zeta.$$

For $k \le n \le N$, let

$$F_{k,k}^\zeta := I, \qquad F_{k,n}^\zeta := A_{n-1}^\zeta \cdots A_k^\zeta, \qquad T_{k,n}^\zeta := (F_{k,n}^\zeta)^* F_{k,n}^\zeta.$$

The ports belonging to the same subtree are

$$\mathscr{P}_j^\Sigma(\zeta) := \{(y,\Sigma) : y \in V_j(\zeta)\}, \qquad \mathscr{P}_j^\Pi(\zeta) := \{(y,\Pi) : y \in V_j(\zeta)\};$$

we denote by $B_j^\zeta, \kappa_j^\zeta, \delta_j^\zeta$ the restrictions of the incidence and the rectangular complex to those ports, and by L_j^ζ the precomposition induced by removing prefixes.

To define the path reader without abbreviations, let

$$W_\ell^\zeta(y) := R_m[\mathrm{Path}_{\mathscr{T}_{k,\ell}(\zeta)}(y, \mathrm{Term}_\ell)]$$

and set

$$\mathscr{D}^{(m)}_{q,r;k,\ell}[\mathscr{R}] := \bigoplus_{y_0 \to \cdots \to y_q \text{ in } \mathscr{T}_{k,\ell}(\zeta)} W_\ell^\zeta(y_q) \otimes_{R_m} \big(\Gamma_r(y_0) \otimes_{\mathbb{Z}} R_m\big), \qquad \mathrm{Tot}_d\,\mathscr{D} := \bigoplus_{q+r=d} \mathscr{D}^{(m)}_{q,r;k,\ell}[\mathscr{R}].$$

The formulas already proved produce, on each $\mathscr{R} \in \mathfrak{R}_{k,N}(\zeta)$, the five objects

$$\begin{aligned}
\mathcal{F}_{\mathrm{sp}}[\mathscr{R}] &:= (\ell^2(V_j(\zeta),\mu_j), \mathcal{U}_j^\zeta, A_j^\zeta, \eta_j^\zeta, T_{k,j}^\zeta)_{k\le j\le N},\\
\mathcal{F}_{\mathrm{sol}}[\mathscr{R}] &:= (b, \kappa_{\mathrm{can}}, C_\alpha, \kappa_\alpha)_{\alpha\subset\mathscr{T}_{k,N}(\zeta)},\\
\mathcal{F}^{(m)}_{\mathrm{gau}}[\mathscr{R}] &:= (\mathscr{P}_j^\Sigma(\zeta), \mathscr{P}_j^\Pi(\zeta), B_j^\zeta, \kappa_j^\zeta, \delta_j^\zeta; R_m)_{k\le j\le N},\\
\mathcal{F}^{(m)}_{\mathrm{coh}}[\mathscr{R}] &:= (\Gamma_y \otimes R_m, \partial, \Psi_\alpha, H_\bullet)_{y,\alpha\subset\mathscr{T}_{k,N}(\zeta)},\\
\mathcal{F}^{(m)}_{\mathrm{det}}[\mathscr{R}] &:= (\mathrm{Det}(\mathrm{Tot}\,\mathscr{D}^{(m)}_{\bullet,\bullet;k,\ell}[\mathscr{R}]))_{k\le\ell\le N}.
\end{aligned} \tag{C2}$$

Here $\mathscr{D}^{(m)}_{\bullet,\bullet;k,\ell}[\mathscr{R}]$ is the normalized bicomplex of paths and memory from the preceding sections, restricted to the subtree of horizon ℓ and reduced over R_m. The final reader preserves the ordered family of determinantal lines up to horizon N; in this way, its truncation is a canonical projection and does not assume a nonexistent determinantal factorization. The law μ is the canonical law of the census, and the ports are fixed through the lexicographically minimal branch of the APP order. Thus none of the five readers receives an external weighting or port.

For $T \in \mathfrak{T} := \{\mathrm{sp}, \mathrm{sol}, \mathrm{gau}, \mathrm{coh}, \mathrm{det}\}$, define the typed total space

$$\widetilde{\mathcal{F}}^{(m)}_{T;k,N}(\zeta) := \coprod_{\mathscr{R}\in\mathfrak{R}_{k,N}(\zeta)} \{\mathcal{F}^{(m)}_{T}[\mathscr{R}]\}_{\mathscr{R}}, \qquad p_T : \widetilde{\mathcal{F}}^{(m)}_{T;k,N}(\zeta) \longrightarrow \mathfrak{R}_{k,N}(\zeta),$$

where $\mathcal{F}^{(m)}_{\mathrm{sp}} := \mathcal{F}_{\mathrm{sp}}$ and $\mathcal{F}^{(m)}_{\mathrm{sol}} := \mathcal{F}_{\mathrm{sol}}$; that is, the superscript m is inert for those two readers. The projection p_T forgets only the reader structure and preserves its source register. The correct fibre product is

$$\begin{aligned}\mathcal{J}^{(m)}_{k,N}(\zeta) := \widetilde{\mathcal{F}}^{(m)}_{\mathrm{sp;k,N}}(\zeta) \underset{\mathfrak{R}_{k,N}(\zeta)}{\times} \widetilde{\mathcal{F}}^{(m)}_{\mathrm{sol;k,N}}(\zeta) \underset{\mathfrak{R}_{k,N}(\zeta)}{\times} \widetilde{\mathcal{F}}^{(m)}_{\mathrm{gau;k,N}}(\zeta)\\ \underset{\mathfrak{R}_{k,N}(\zeta)}{\times} \widetilde{\mathcal{F}}^{(m)}_{\mathrm{coh;k,N}}(\zeta) \underset{\mathfrak{R}_{k,N}(\zeta)}{\times} \widetilde{\mathcal{F}}^{(m)}_{\mathrm{det;k,N}}(\zeta).\end{aligned} \tag{C3}$$

Equality of the five projections requires preserving the same tree, the same edges, the same produced branch and the same register. For each $\mathscr{R}$, the five constructions determine the element

$$s^{(m)}_{k,N}(\mathscr{R}) := (\mathcal{F}^{(m)}_{T}[\mathscr{R}])_{T\in\mathfrak{T}} \in \mathcal{J}^{(m)}_{k,N}(\zeta).$$

Existence of this element follows from the operations of (C2), not from the fibre-product notation.

Removal of the last layer induces

$$\mathrm{res}^{\mathfrak{R}}_{N+1,N}\big(\mathscr{R}_{k,N+1}(\zeta;x)\big) := \mathscr{R}_{k,N}(\zeta;\rho_N(x)).$$

Restriction of each operator to the retained generators defines

$$r^{m}_{N+1,N} : \mathcal{J}^{(m)}_{k,N+1}(\zeta) \longrightarrow \mathcal{J}^{(m)}_{k,N}(\zeta).$$

In the determinantal reader, $r^{m}_{N+1,N}$ removes only the last coordinate of the family of lines of (C2). The reduction $R_{m+1} \twoheadrightarrow R_m$ defines, by base change,

$$q^{N}_{m+1,m} : \mathcal{J}^{(m+1)}_{k,N}(\zeta) \longrightarrow \mathcal{J}^{(m)}_{k,N}(\zeta).$$

On each generator, we have

$$\begin{gathered} r^{m}_{N+1,N} q^{N+1}_{m+1,m} = q^{N}_{m+1,m} r^{m+1}_{N+1,N},\\ \partial\Psi_\alpha = \Psi_\alpha\partial, \qquad L^\zeta_j \kappa^\zeta_j = \kappa^\zeta_{j+1} L^\zeta_j, \qquad L^\zeta_j \delta^\zeta_j = \delta^\zeta_{j+1} L^\zeta_j,\end{gathered} \tag{C4}$$

and compositions of the maps r and q satisfy the functorial identities. The first equality holds because deleting the last layer and reducing the coefficients act on distinct coordinates. The other three are the naturality identities proved earlier. A unique pro-system in (N, m) is obtained, not five juxtaposed limits.

At the root, define

$$\mathfrak{J}^{(m)}_{N,\bullet} := \mathcal{J}^{(m)}_{0,N}(*). \tag{C5}$$

The joint discrete structure of the continuum is the limit of those correlative objects:

$$\boxed{C^{\mathrm{disc}}_{\mathrm{cont}} := \varprojlim_{\substack{N\geq 1\\ m\geq 1}} \big(\mathfrak{J}^{(m)}_{N,\bullet}, r^{m}_{N+1,N}, q^{N}_{m+1,m}\big).} \tag{C6}$$

This is a definition through the pro-system generated by the complete tree; it is not the image or graph of a map retaining the input state as its first coordinate.

The registers have a produced terminal mark. Their compatible projections induce

$$\Pi : C^{\mathrm{disc}}_{\mathrm{cont}} \longrightarrow H^{\mathrm{enr}}_{\infty}.$$

Conversely, a complete history determines, through its already emitted prefixes, the compatible sections $s^{(m)}_{0,N}$. Thus, after having defined the continuum, one obtains

$$\mathrm{Gen}_{\mathrm{cont}} : H^{\mathrm{enr}}_{\infty} \longrightarrow C^{\mathrm{disc}}_{\mathrm{cont}}, \qquad \Pi \circ \mathrm{Gen}_{\mathrm{cont}} = \mathrm{id}_{H^{\mathrm{enr}}_{\infty}} . \tag{C7}$$

This section proves recoverability; it is not used to define $C^{\mathrm{disc}}_{\mathrm{cont}}$.

Theorem 5.36 (Correlative emergence of the five constructions)**.** *For every surviving history $\zeta \in H_k$, every $N > k$, every $m \geq 1$ and every $\mathscr{R} \in \mathfrak{R}_{k,N}(\zeta)$, the five constructions of* (C2) *are defined on the same register, and* (C3) *contains $s^{(m)}_{k,N}(\mathscr{R})$. Their truncations, modular reductions and transports satisfy* (C4)*. Furthermore, $C^{\mathrm{disc}}_{\mathrm{cont}} \neq \varnothing$, the map Π is surjective and is split by* $\mathrm{Gen}_{\mathrm{cont}}$*. The five components are inseparable aspects of the same continuum, not five domains or five independent maps.*

Proof. The survival defining H_k and the TPK prolongation law give $\rho_k^{-1}(\zeta) \neq \varnothing$ for each vertex. Since the fibres are finite, Kőnig's lemma produces $H^{\mathrm{enr}}_{\infty} \neq \varnothing$.

Given a register $\mathscr{R}$, the transport of histories and sheets produces $\mathcal{F}_{\mathrm{sp}}[\mathscr{R}]$; affine composition and the exact cancellation defect produce $\mathcal{F}_{\mathrm{sol}}[\mathscr{R}]$; incidences and the rectangular sequence produce $\mathcal{F}^{(m)}_{\mathrm{gau}}[\mathscr{R}]$; the memory complex and its transport produce $\mathcal{F}^{(m)}_{\mathrm{coh}}[\mathscr{R}]$; and the lines of the normalized path assembly produce $\mathcal{F}^{(m)}_{\mathrm{det}}[\mathscr{R}]$. Each construction acts on the same generated edges, not on an assumed subdomain or on the abstract ambient space of 729 words.

Affine, transport, incidence and memory compatibilities prove (C4). Truncating the determinantal family of (C2) commutes by definition with r; its base change commutes with q. The sections $s^{(m)}_{0,N}$ are compatible, so they produce $\mathrm{Gen}_{\mathrm{cont}}$. The identity (C7) proves simultaneously nonemptiness of the limit, surjectivity of Π and recoverability of each history without introducing it as a defining coordinate.

The fibre, relation, number, orientation, carry, memory, boundary and route remain in the common register; the multisection, terminals, and linear and probabilistic readers remain in the five correlative constructions. Passing to the limit therefore preserves dependency closure and does not separate the continuum. □

Subsequent recognition of the uniquely constructed continuum through spectral, solenoidal, gauge, cohomological or determinantal language belongs to the later conventional comparison. It does not select its states or enter its APP–TRIT–TPK generation.

Chapter 6

Existence of the discrete continuum: nonemptiness, preservation, terminality, naturality, refinement, and compatible limit

6.1 Multivalued terminal, unique naturality and passage to the limit

Tesis rectora

The discrete continuum produces a single system of histories, extensions, memories, and terminals. The internal discriminants $\mathrm{sp}, \mathrm{sol}, \mathrm{gau}, \mathrm{coh}, \mathrm{det}$ name five characteristics that are simultaneous within that same system: they neither fix distinct inputs nor authorize the selection of different histories. In this chapter, the terminal preserves all continuations, the connection remains a nonadic correspondence, and naturality is expressed by a single identity.

6.1.1 Surviving histories with extension witnesses

Let $\widehat{x}_k \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$ be the total state of (5.57). For $N \geq k$, we define without any other predicate of membership

$$\mathscr{H}_{k,N}(\widehat{x}_k) := \mathrm{Term}_{k,N}(\widehat{x}_k). \tag{6.1}$$

Each $h = (\varepsilon_{k+1}, \ldots, \varepsilon_N)$ on the right contains through (5.65) its intermediate states, the witnesses of Ext, the carries, boundaries, routes, and ledger. Each edge satisfies the phase action (5.17); hence every nine-step subpath determines, with its nine emissions and not merely with its length, an element of $\mathsf{Z}_{9,j}^{\Gamma}$ and a witness of $\Gamma_{9,j}$ through (5.71)– (5.73). Therefore, Ext and nonadic holonomy arise from the same phase-compatible word. To (6.1) there is adjoined neither a survival filter nor a second condition Γ_9.

For $k \leq \ell \leq N$, let

$$\mathscr{P}_{\ell|k}(\widehat{x}_k) := \{h_{[k,\ell]} : h \in \mathscr{H}_{k,N}(\widehat{x}_k) \text{ for some } N \geq \ell\}. \tag{6.2}$$

For $p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)$, we use the abbreviation

$$\mathscr{H}_{\ell,N}(p) := \{q : p \star q \in \mathscr{H}_{k,N}(\widehat{x}_k)\}. \tag{6.3}$$

The prolongation neutral of (5.59) extends each prefix to cualquier horizon. Consequently,

$$\mathscr{H}_{k,N}(\widehat{x}_k) \neq \varnothing, \qquad \mathscr{P}_{\ell|k}(\widehat{x}_k) \neq \varnothing, \tag{6.4}$$

by proposition 5.15.

The truncation

$$\pi^{\mathscr{H}}_{N+1,N} : \mathscr{H}_{k,N+1}(\widehat{x}_k) \longrightarrow \mathscr{H}_{k,N}(\widehat{x}_k) \tag{6.5}$$

is exactly (5.68) and is surjective by lemma 5.16. Survival is, by (5.83), a demonstrated output of the total domain and not a prior selection.

6.1.2 Generated terminal record and its 13 coordinates

Let us fix a history

$$h = (\varepsilon_{j+1} : x_j \longrightarrow x_{j+1})_{j=k}^{N-1}, \qquad \gamma_{k,k} := I_{x_k}, \qquad \gamma_{k,j+1} := \gamma_{k,j} \star \varepsilon_{j+1},$$

The operator notation $U_{\gamma_{k,j+1}} = U_{\varepsilon_{j+1}} U_{\gamma_{k,j}}$ preserves the order of application, whereas $\star$ preserves the chronological order of the word. We further fix a coefficient level $r \geq 1$. For brevity, we write

$$C_{x_j,r} := C_{j,r}(x_j), \qquad F_{\varepsilon_{j+1}} : C_{x_{j+1},r} \longrightarrow C_{x_j,r}$$

for the complex and the map of complexes of (5.184) and (5.185). The type of the level record j, denoted $\mathfrak{R}_{j,r}$, is a dependent record with the following thirteen fields. In each field we indicate the type, the seed and the action of an edge $\varepsilon := \varepsilon_{j+1}$.

The state x_k already contains the complete word $\gamma_{0,k} = \varepsilon_1 \star \cdots \star \varepsilon_k$. Therefore a "seed in k" never restarts the genealogy: it is the fold of the same updates from the root to k. We denote

$$\begin{gathered} M_k^{\pm} := \sum_{i=1}^{k} b_{\varepsilon_i}^{\pm}, qquadD_k := \sum_{i=1}^{k} b_{\varepsilon_i}, qquadH_k := \sum_{i=1}^{k} |b_{\varepsilon_i}|, \\ \mathbf{c}_{\le k} := \big(c_r(\varepsilon_i, \gamma_{0,i-1})\big)_{1\le i\le k}, \qquad \mathbf{k}_{\le k} := \big(\kappa_{i-1}^{\mathrm{can}}\big)_{1\le i\le k}, \\ \mathbf{F}_{\le k} := \big(F_{\varepsilon_i} : C_{x_i,r} \to C_{x_{i-1},r}\big)_{1\le i\le k}. \end{gathered} \tag{6.6}$$

All empty lists appearing below are understood literally only in $k = 0$; for $k > 0$ they are replaced by prefixes inherited from (6.6) and from the ledger of $\gamma_{0,k}$. Thus the record does not preserve an opaque copy of x_k, but neither does it lose its APP–TRIT–TPK past.

Fiber F: local domain and conservation under prolongation The elementary fiber is

$$\mathrm{Fib}_r(x) := \big(\mathsf{H}_x^{\Sigma} \oplus \mathsf{H}_x^{\Pi},\ \mathsf{M}_x,\ \mathrm{Cell}_{\mathrm{TPK}}(x),\ C_{x,r}\big). \tag{6.7}$$

The field $\mathsf{F}_{k,j}$ is a word in the category of these fibers. Its seed and update are

$$\mathsf{F}_{k,k} := \big(\mathrm{Fib}_r(x_0), I\big) \star \overset{k}{\underset{i=1}{\star}} \big(\mathrm{Fib}_r(x_i), U_{\varepsilon_i}, \mathsf{C}_{\varepsilon_i}, \mathrm{Cell}_{\mathrm{TPK}}(\varepsilon_i), F_{\varepsilon_i}\big), \tag{6.8}$$

$$\mathrm{Upd}_{\varepsilon}^{\mathsf{F}}\, \mathsf{F}_{k,j} := \mathsf{F}_{k,j} \star \big(\mathrm{Fib}_r(x_{j+1}), U_{\varepsilon}, \mathsf{C}_{\varepsilon}, \mathrm{Cell}_{\mathrm{TPK}}(\varepsilon), F_{\varepsilon}\big). \tag{6.9}$$

It is nonempty because the two sheets, the memory, the cellular unit (5.198), and the port complex have already been constructed. The composition of its five maps proves naturality.

Extensions E: morphisms of compatible prolongation of the state The codomain is the category of typed relation words. We set

$$\mathsf{E}_{k,k} := (I_{x_0}, \mathrm{Ext}_{I_{x_0}}) \star \overset{k}{\underset{i=1}{\star}} \big(\varepsilon_i, \mathrm{Ext}_{\varepsilon_i}, \mathrm{Ext}_{\varepsilon_i} \circ \mathrm{Ext}_{\gamma_{0,i-1}} \subseteq \mathrm{Ext}_{\gamma_{0,i}}\big), \tag{6.10}$$

$$\mathrm{Upd}_{\varepsilon}^{\mathsf{E}}\, \mathsf{E}_{k,j} := \mathsf{E}_{k,j} \star \big(\varepsilon, \mathrm{Ext}_{\varepsilon}, \mathrm{Ext}_{\varepsilon} \circ \mathrm{Ext}_{\gamma_{0,j}} \subseteq \mathrm{Ext}_{\gamma_{0,j+1}}\big). \tag{6.11}$$

Identity and neutral emission prove nonemptiness; associativity of the composition relational proof naturality.

Relations R: incidence, orientation, and compatibility of composition Let $\mathrm{RelBlock}_{j,r}$ be the type of blocks of equations labeled by the edge and the prefix over which they are verified, and let $\mathrm{Pres}_{j,r} := \mathrm{List}(\mathrm{RelBlock}_{j,r})$. The unit block and the seed are

$$\mathsf{B}_I := (I_{x_0}; U_I = I,\ \mathsf{U}_I = I,\ \kappa(I) = 0,\ \partial I = 0), \qquad \mathsf{R}_{k,k} := (\mathsf{B}_I) \star \overset{k}{\underset{i=1}{\star}} \mathsf{B}_R(\varepsilon_i; \gamma_{0,i-1}). \tag{6.12}$$

For an edge $\varepsilon : x_j \to x_{j+1}$, the new block is the labeled tuple

$$\begin{aligned}\mathsf{B}_R(\varepsilon;\gamma_{0,j}) := \big(&\varepsilon,\gamma_{0,j};\ \delta^{\diamond}(\varepsilon)=\mathrm{res}^{\diamond}(\varepsilon)+9\,\mathrm{quo}^{\diamond}(\varepsilon),\\ &\Delta(\varepsilon)=\mathrm{or}(\varepsilon)+3\kappa(\varepsilon),\quad U_{\gamma_{0,j+1}}=U_\varepsilon U_{\gamma_{0,j}},\\ &\mathsf{U}_{\gamma_{0,j+1}}=\mathsf{U}_\varepsilon\mathsf{U}_{\gamma_{0,j}},\quad \kappa(\gamma_{0,j+1})=\kappa(\varepsilon)+\mathsf{C}_\varepsilon\kappa(\gamma_{0,j}),\\ &\partial\gamma_{0,j+1}=\partial\varepsilon+\partial\gamma_{0,j},\quad \mathrm{Cpl}_\varepsilon\ \text{of (5.286)}\big).\end{aligned} \tag{6.13}$$

The update concatenates the block without losing date or multiplicity:

$$\mathrm{Upd}^{\mathsf{R}}_{\varepsilon}\,\mathsf{R}_{k,j} := \mathsf{R}_{k,j}\star\mathsf{B}_R(\varepsilon;\gamma_{0,j}). \tag{6.14}$$

The truncation $\mathrm{tr}^{\mathsf{R}}_{j+1,j}$ removes the final labeled block. Moreover, $a_*\mathsf{B}_R(\varepsilon;\gamma)=\mathsf{B}_R(a\varepsilon;a\gamma)$, because each equation is natural over the same edge and the same prefix.

Numbers N: publication of value with conservation of genealogy For an edge $\varepsilon: x_j\to x_{j+1}$, we define the numerical datum

$$\nu(\varepsilon) := \big(j+1,\mathsf{Q}_{j+1},g_{j+1},q^{(9)}_{j+1},\beta_{j+1},\mathrm{res}^{\Sigma},\mathrm{quo}^{\Sigma},\mathrm{res}^{\Pi},\mathrm{quo}^{\Pi},\mathrm{or},\kappa,\Delta\big)(\varepsilon). \tag{6.15}$$

Its type is

$$\mathbb{N}\times\widetilde{O}_9\times C_9\times\mathbb{N}\times\mathbb{Z}/12\mathbb{Z}\times\{0,\dots,8\}^2\times\mathbb{Z}^5.$$

The seed contains the complete numerical list of the prefix $0\to k$; the update adds exactly the datum of the next edge:

$$\mathsf{N}_{k,k} := ((0,\mathsf{Q}_0,g_0,q^{(9)}_0,\beta_0;0,\dots,0))\star\overset{k}{\underset{i=1}{\star}}\nu(\varepsilon_i),\qquad \mathrm{Upd}^{\mathsf{N}}_{\varepsilon}\,\mathsf{N}_{k,j} := \mathsf{N}_{k,j}\star\nu(\varepsilon). \tag{6.16}$$

Totality proceeds from the divisions APP, the division TRIT, and the odometer TPK.

Orientation O: sign transport and leaf selection The type of an orientation state is

$$\mathbb{Z}\times(\mathsf{H}^{\Sigma}_x\oplus\mathsf{H}^{\Pi}_x)\times\mathbb{Z}[\mathsf{A}],$$

with seed and update

$$\mathsf{O}_{k,k} := \left(\sum_{i=1}^{k}\mathrm{or}(\varepsilon_i),\mathrm{Sh}(x_k),\partial\gamma_{0,k}\right), \tag{6.17}$$

$$\mathrm{Upd}^{\mathsf{O}}_{\varepsilon}(\mathfrak{o},\mathrm{Sh},\mathfrak{b}) := \big(\mathfrak{o}+\mathrm{or}(\varepsilon),U_\varepsilon\,\mathrm{Sh},\mathfrak{b}+\partial\varepsilon\big). \tag{6.18}$$

The APP leaves prove nonemptiness. Functoriality of U, additivity of or, and telescoping of the boundary prove naturality.

Carry K: update of the quotient and residual memory We use the typed integer lifts in (5.173). The field has type

$$\mathsf{M}_{x_j}\times\mathrm{Hom}(\mathsf{M}_{x_0},\mathsf{M}_{x_j})\times\mathrm{Mat}_5(\mathbb{Z})\times\mathrm{List}(\mathrm{Mat}_5(\mathbb{Z}))\times\mathrm{List}(\mathbb{Q}_{\ge0}).$$

For $\gamma_{k,j}=\varepsilon_j\cdots\varepsilon_{k+1}$, we explicitly fix

$$\widetilde{L}_{\gamma_{k,k}} := I_5,\qquad \widetilde{L}_{\gamma_{k,j}} := \widetilde{L}_r(\varepsilon_j)\cdots\widetilde{L}_r(\varepsilon_{k+1}). \tag{6.19}$$

For the inherited prefix we also fix

$$\widetilde{L}_{\gamma_{0,k}} := \widetilde{L}_r(\varepsilon_k)\cdots\widetilde{L}_r(\varepsilon_1).$$

The seed and update are

$$\mathsf{K}_{k,k} := \big(\kappa(\gamma_{0,k}), \mathsf{C}_{\gamma_{0,k}}, \widetilde{L}_{\gamma_{0,k}}, \mathbf{c}_{\le k}, \mathbf{k}_{\le k}\big), \tag{6.20}$$

$$\mathrm{Upd}^{\mathsf{K}}_{\varepsilon}(\kappa_\gamma, \mathsf{C}_\gamma, \widetilde{L}_\gamma, \mathbf{c}, \mathbf{k}) := \big(\kappa(\varepsilon) + \mathsf{C}_\varepsilon\kappa_\gamma,\ \mathsf{C}_\varepsilon\mathsf{C}_\gamma,\ \widetilde{L}_r(\varepsilon)\widetilde{L}_\gamma,\ \mathbf{c}\star c_r(\varepsilon,\gamma),\ \mathbf{k}\star\kappa_j^{\mathrm{can}}\big). \tag{6.21}$$

The identity provides the seed; the two cocycles (5.10) and (5.175) prove independence of parenthesization and naturality.

Memory M: record of the traversal and compatibility under truncation Its type at the same time preserves affine memory, ledger, and signed memories:

$$\mathrm{LedgerEntry} := \{\lambda(\varepsilon) : \varepsilon \text{ typed elementary emission}\}. \tag{6.22}$$

$$\mathsf{M}_x \times \mathrm{List}(\mathrm{LedgerEntry}) \times \mathbb{N}^2 \times \mathbb{Z} \times \mathbb{N}.$$

We set

$$\mathsf{M}_{k,k} := \big(m_k, \mathrm{Led}(\gamma_{0,k}), M_k^+, M_k^-, D_k, H_k\big), \tag{6.23}$$

$$\mathrm{Upd}^{\mathsf{M}}_{\varepsilon}(m, \mathbf{Led}, M^+, M^-, D, H) := \big(\mathsf{C}_\varepsilon m + \kappa(\varepsilon),\ \mathbf{Led}\star\lambda(\varepsilon),\ M^+ + b_\varepsilon^+,\ M^- + b_\varepsilon^-,\ D + b_\varepsilon,\ H + |b_\varepsilon|\big). \tag{6.24}$$

The affine action and (5.139) prove totality and naturality; the past is not recomputed from the last value.

Boundary B: gluing data and survival of the extension The type is a boundary chain accompanied by a word of complejos based and chain maps. Its seed and update are

$$\mathsf{B}_{k,j} \in \mathrm{Rec}[\mathfrak{b} \in \mathbb{Z}[\mathsf{A}_j]; C_{x_j,r} \in \mathrm{Ch}_{\mathrm{bas}}; \mathbf{F} \in \mathrm{Path}_{\mathrm{Ch}_{\mathrm{bas}}}(C_{x_j,r}, C_{x_0,r})].$$

$$\mathsf{B}_{k,k} := \big(\partial\gamma_{0,k}, C_{x_k,r}, \mathbf{F}_{\le k}\big), \tag{6.25}$$

$$\mathrm{Upd}^{\mathsf{B}}_{\varepsilon}(\mathfrak{b}, C_{x_j,r}, \mathbf{F}) := \big(\mathfrak{b} + \partial\varepsilon,\ C_{x_{j+1},r},\ \mathbf{F}\star F_\varepsilon\big). \tag{6.26}$$

Non-emptiness proceeds from the common ports; $\partial^2 = 0$, $F_{\beta\varepsilon} = F_\varepsilon F_\beta$, and (5.35) prove compatibility.

Route G: observable history of the surviving extension The field is the list of prefixes in the path category:

$$\mathsf{G}_{k,k} := (\gamma_{0,i})_{0\le i\le k}, \qquad \mathrm{Upd}^{\mathsf{G}}_{\varepsilon}\,\mathsf{G}_{k,j} := \mathsf{G}_{k,j}\star\gamma_{0,j+1}. \tag{6.27}$$

Identity, associative concatenation, and $a(\varepsilon\gamma) = a(\varepsilon)a(\gamma)$ prove the three required properties.

Multisection X: stable finite fiber and obstruction to pointwise selection For $M \ge j$, we define by action

$$\mathsf{X}_{k,j}(M) := \{\gamma_{k,j}\star q : q \in \mathrm{Term}_{j,M}(x_j)\}. \tag{6.28}$$

Thus

$$\mathsf{X}_{k,k}(M) = \mathrm{Term}_{k,M}(x_k),$$

and

$$\mathrm{Upd}^{\mathsf{X}}_{\varepsilon}\,\mathsf{X}_{k,j}(M) := \{\gamma_{k,j}\star\varepsilon\star q : q \in \mathrm{Term}_{j+1,M}(x_{j+1})\}. \tag{6.29}$$

The neutral prolongation proves nonemptiness. Deleting the final step and acting by a symmetry commute literally with concatenation.

Survival S: persistence under refinement and passage to the limit Here, a proposition is not stored, but witnesses. Let

$$s_{j,j} := I_{x_j}, \qquad s_{j,M+1} := s_{j,M} \star \varepsilon^0_M(t(s_{j,M})). \tag{6.30}$$

The seed is $\mathsf{S}_{k,k} := (s_{k,M})_{M\geq k}$, and

$$\mathrm{Upd}^{\mathsf{S}}_{\varepsilon}\, \mathsf{S}_{k,j} := (\gamma_{k,j} \star \varepsilon \star s_{j+1,M})_{M\geq j+1}. \tag{6.31}$$

By construction $\pi_{M+1,M} s_{j,M+1} = s_{j,M}$; the naturality of neutral emission proves equivariance.

Terminal T: universality of the limit object and factorization of readers The terminal is the inverse system, not a selected queue:

$$\mathsf{T}(x_j) := \big((\mathrm{Term}_{j,M}(x_j))_{M\geq j}, (\pi_{M+1,M})_{M\geq j}\big). \tag{6.32}$$

For each $M \geq j$, the map of prefix tipado is

$$\mathrm{pref}_{\gamma_{k,j},M} : \mathrm{Term}_{j,M}(x_j) \longrightarrow \mathrm{Term}_{k,M}(x_k), \qquad q \longmapsto \gamma_{k,j} \star q. \tag{6.33}$$

We define the field state and its update by

$$\mathsf{T}_{k,j} := \Big(\mathsf{T}(x_j), (\mathrm{pref}_{\gamma_{k,j},M})_{M\geq j}\Big), \tag{6.34}$$

$$\mathrm{Upd}^{\mathsf{T}}_{\varepsilon}\, \mathsf{T}_{k,j} := \Big(\mathsf{T}(x_{j+1}), (\mathrm{pref}_{\gamma_{k,j+1},M})_{M\geq j+1}\Big), \qquad \gamma_{k,j+1} := \gamma_{k,j} \star \varepsilon. \tag{6.35}$$

In particular, $\mathsf{T}_{k,k}$ uses $\gamma_{k,k} = I_{x_k}$. The witnesses (6.30) and the surjectivity of π prove that the system is nonempty; level by level,

$$\pi^{\mathscr{H}}_{M+1,M}\, \mathrm{pref}_{\gamma_{k,j},M+1} = \mathrm{pref}_{\gamma_{k,j},M}\, \pi^{\mathscr{H}}_{M+1,M}, \tag{6.36}$$

because both traversals only remove the last emission of q.

13. Terminal reader L: evaluation of the compatible extension and conservation of genealogy The reader contains no classical object. Its type is the category of paths of the unique dependent constructor $\mathfrak{D}_{j,r}$ of (5.287). We set

$$u^{\mathfrak{D}}_{j+1,j} := u_{(j+1,r),(j,r)} : \mathfrak{D}_{j+1,r}(x_{j+1}) \longrightarrow \mathfrak{D}_{j,r}(x_j), \tag{6.37}$$

the component of the common transport (5.288) that truncates the last emission, reduces the coefficients and precomposes the ports. By composition,

$$u^{\mathfrak{D}}_{m,k} = u^{\mathfrak{D}}_{\ell,k} u^{\mathfrak{D}}_{m,\ell} \qquad (m \geq \ell \geq k). \tag{6.38}$$

$$\mathsf{L}_{k,k} := (\mathfrak{D}_{0,r}(x_0)) \star \overset{k}{\underset{i=1}{\star}} \big(\mathfrak{D}_{i,r}(x_i), u^{\mathfrak{D}}_{i,i-1}, O(\mathfrak{e}_{\varepsilon_i})\big), \tag{6.39}$$

$$\mathrm{Upd}^{\mathsf{L}}_{\varepsilon}\, \mathsf{L}_{k,j} := \mathsf{L}_{k,j} \star \big(\mathfrak{D}_{j+1,r}(x_{j+1}), u^{\mathfrak{D}}_{j+1,j}, O(\mathfrak{e}_{\varepsilon})\big). \tag{6.40}$$

The totality of $\mathfrak{D}$ and (6.38) proves non-emptiness and naturality.

The thirteen preceding seeds form a single element.

$$\mathfrak{r}^{0}_{k,r} := \langle \mathsf{F}_{k,k}; \mathsf{E}_{k,k}; \mathsf{R}_{k,k}; \mathsf{N}_{k,k}; \mathsf{O}_{k,k}; \mathsf{K}_{k,k}; \mathsf{M}_{k,k}; \mathsf{B}_{k,k}; \mathsf{G}_{k,k}; \mathsf{X}_{k,k}; \mathsf{S}_{k,k}; \mathsf{T}_{k,k}; \mathsf{L}_{k,k} \rangle \in \mathfrak{R}_{k,r}. \tag{6.41}$$

The action of an edge is the total application.

$$\mathrm{Upd}_{\varepsilon} : \mathfrak{R}_{j,r}(\gamma_{0,j}) \longrightarrow \mathfrak{R}_{j+1,r}(\gamma_{0,j+1}), \qquad \mathrm{Upd}_{\varepsilon} := \langle \mathrm{Upd}^{\mathsf{F}}_{\varepsilon}, \dots, \mathrm{Upd}^{\mathsf{L}}_{\varepsilon} \rangle, \tag{6.42}$$

with the thirteen actions (6.9)– (6.40). Finally, the terminal register is *generated* by the fold

$$\boxed{\mathfrak{r}_{k,N}(h) := \mathrm{Upd}_{\varepsilon_N} \circ \cdots \circ \mathrm{Upd}_{\varepsilon_{k+1}}(\mathfrak{r}^{0}_{k,r}).} \tag{6.43}$$

It is not the unpacking of an intact copy of the state. On the image of this fold, the truncation is defined componentwise

$$\mathrm{tr}_{13;j+1,j}\, \mathfrak{r}_{k,j+1}(h \star \varepsilon) := \mathfrak{r}_{k,j}(h). \tag{6.44}$$

It is well defined: the fields E and G preserve the ordered list of emissions and prefixes, so that equality of two records entails equality of their labeled histories. In $\mathsf{F}, \mathsf{E}, \mathsf{R}, \mathsf{N}, \mathsf{G}, \mathsf{T}, \mathsf{L}$, the last entry or block is deleted; in $\mathsf{O}, \mathsf{K}, \mathsf{M}, \mathsf{B}$, the cumulative formula is applied to the recovered prefix; and in X, S, the cone of tails is restricted. Neither an idempotent union is inverted nor a continuation selected.

Proposition 6.1 (Totality and naturalness of the thirteen updates)**.** *All the seeds of* (6.41) *exist, each* $\mathrm{Upd}_{\varepsilon}$ *is total, and, for every coherent symmetry a and every horizon truncation,*

$$a_{*}\, \mathrm{Upd}_{\varepsilon} = \mathrm{Upd}_{a\varepsilon}\, a_{*}, \qquad \mathrm{tr}_{13;j+1,j}\, \mathrm{Upd}_{\varepsilon}\, \mathfrak{r}_{k,j}(h) = \mathfrak{r}_{k,j}(h). \tag{6.45}$$

Proof. The existence of each seed was exhibited in the thirteen paragraphs. In $\mathsf{F}, \mathsf{E}, \mathsf{G}, \mathsf{X}, \mathsf{S}, \mathsf{T}, \mathsf{L}$, the formula is concatenation with an already typed map. In $\mathsf{R}, \mathsf{N}, \mathsf{O}, \mathsf{K}, \mathsf{M}, \mathsf{B}$, the formula is, respectively, concatenation of a labeled block of equations, adjunction of a numerical datum, transport of sheets, composition of cocycles, affine action, and chain map. The naturality identities cited after each formula prove the first equality of (6.45) componentwise. The second is exactly (6.44); its sound definition uses the ordered history preserved by E and G. □

Proposition 6.2 (Joint Certificate of the Five Internal Developments)**.** *The updates of the thirteen coordinates jointly transport: the spectral–polar telescoping and return without reinitialization of theorem 5.32 y equation* (5.135)*; the orthogonal balance, the remark column, and the Stein identity of equations* (5.155) *y* (5.167)*; direct and adjoint naturality and the cellular retraction of equations* (5.216) *y* (5.228)*; totalization, the cone of the nonadic return, and the complete fibers of equations* (5.238), (5.242) *y* (5.253)*; and the Alexander–Whitney diagonal, Smith reduction, and the Bockstein tower of equations* (5.183), (5.267) *y* (5.275)*. All these actions have as their domain the same register generated by* (6.43)*; none introduces an initial subdomain, a privileged history, or a selection motivated by a subsequent application.*

Proof. Each cited identity acts on a coordinate of the common register, and its truncation maps are restrictions of (6.44). The componentwise naturality proved in (6.45) permits their assembly into a single update. Equality of domain and preservation of the ordered history preclude replacing correlative generation with five retrospective projections. □

6.1.3 Multivalued terminal without selector

The finite terminal generated by $\widehat{x}_k$ is the multisection

$$\mathfrak{T}_{k,N}(\widehat{x}_k) := \left\{ \mathfrak{r}_{k,N}(h) : h \in \mathscr{H}_{k,N}(\widehat{x}_k) \right\}. \tag{6.46}$$

The expression of the right returns the set whole. No contains a rule that distinguishes a history privileged.

The terminal level environment is obtained by gathering those multisects without identifying records:

$$\mathfrak{T}_{k,N} := \bigcup_{\widehat{x}_k \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}} \mathfrak{T}_{k,N}(\widehat{x}_k). \tag{6.47}$$

The linear version, when contributions must be added, is defined on the free module by

$$\begin{aligned} \mathsf{E}^{\mathrm{all}}_{k,N} : \mathbb{Z}[\widehat{\mathcal{X}}_k^{\mathrm{tot}}] &\longrightarrow \mathbb{Z}[\mathfrak{T}_{k,N}], \\ [\widehat{x}_k] &\longmapsto \sum_{h \in \mathscr{H}_{k,N}(\widehat{x}_k)} [\mathfrak{r}_{k,N}(h)]. \end{aligned} \tag{6.48}$$

Each witness appears with its multiplicity. If exists a measure projective positive μ, the version isometric uses all the probabilities conditional:

$$\widehat{\mathsf{E}}^{\mu}_{k,N} e_{\widehat{x}_k} := \sum_{h \in \mathscr{H}_{k,N}(\widehat{x}_k)} \mu_{\widehat{x}_k,N}(h)^{1/2} e_{\mathfrak{r}_{k,N}(h)}. \tag{6.49}$$

The projectivity gives

$$\left\| \widehat{\mathsf{E}}^{\mu}_{k,N} e_{\widehat{x}_k} \right\|^2 = \sum_{h \in \mathscr{H}_{k,N}(\widehat{x}_k)} \mu_{\widehat{x}_k,N}(h) = 1. \tag{6.50}$$

The sum is not substituted by “the history that generates the cylinder”.

6.1.4 The nonadic connection as correspondence

The nonadic holonomy was generated by the odometer and the TPK connection, without a membership hypothesis, in – . In this chapter(5.71) we use (5.73)

$$\mathsf{Z}_{9,k} := \mathsf{Z}^{\Gamma}_{9,k}. \tag{6.51}$$

The maps

$$\widehat{\mathcal{X}}_k^{\mathrm{tot}} \xleftarrow{s_{9,k}} \mathsf{Z}^{\Gamma}_{9,k} \xrightarrow{t_{9,k}} \widehat{\mathcal{X}}_{k+9}^{\mathrm{tot}} \tag{6.52}$$

are those of (5.72); its source map is surjective by proposition 5.20. Every point of the apex preserves the nine phase-compatible emissions. It is not replaced by the pair of its endpoints.

For $N \geq k + 9$, define the apex of horizon before of linearizing:

$$\mathsf{Z}^{\Gamma}_{9;k,N} := \coprod_{z=(\widehat{x}_k,\boldsymbol{\omega}) \in \mathsf{Z}^{\Gamma}_{9,k}} \mathrm{Term}_{k+9,N}(t_{9,k} z). \tag{6.53}$$

An element is written (z, q), where $\boldsymbol{\omega}$ is the nonadic word of nine emissions and q its tail up to N. The maps on histories use the labeled codomain

$$\mathscr{D}^{\Gamma}_{9;k,N} := \coprod_{z \in \mathsf{Z}^{\Gamma}_{9,k}} \mathrm{Term}_{k+9,N}(t_{9,k} z). \tag{6.54}$$

Thus the maps are

$$S_{k,N}(z,q) := \omega \star q, \tag{6.55}$$

$$T_{k,N}(z,q) := (z,q) \in \mathscr{D}^{\Gamma}_{9;k,N}. \tag{6.56}$$

The first lands in $\coprod_x \mathscr{H}_{k,N}(x)$; the second expressly preserves the labelled summand by z.

The link map of the apex is the explicit action

$$\pi^{Z}_{N+1,N}(z, q \star \varepsilon) := (z,q). \tag{6.57}$$

It is surjective: if (z,q) is given, one adds to the tail the emission neutral at the endpoint of q. The codomain of tails has link

$$\pi^{\mathscr{D}}_{N+1,N}(z, q \star \varepsilon) := (z,q). \tag{6.58}$$

We denote by $\pi^{\mathscr{H},j}_{N+1,N}$ the map (6.5) with initial level j. Then

$$\pi^{\mathscr{H},k}_{N+1,N} S_{k,N+1} = S_{k,N} \pi^{Z}_{N+1,N}, \tag{6.59}$$

$$\pi^{\mathscr{D}}_{N+1,N} T_{k,N+1} = T_{k,N} \pi^{Z}_{N+1,N}. \tag{6.60}$$

In the first square, both paths send $\omega \star q \star \varepsilon$ to $\omega \star q$; in the second, they send $(z, q \star \varepsilon)$ to (z,q). By unique decomposition of a word into its first nine emissions and its tail, $S_{k,N}$ is bijective. The second square is Cartesian by the coproduct–fibered definition of (6.53). These are the Beck–Chevalley squares preserving witnesses and multiplicities.

The corresponding apex of registers, now generated by the thirteen updates, is

$$\begin{aligned} \mathsf{Z}^{\mathfrak{T}}_{9;k,N} := \big\{ & (z, q; \mathfrak{r}_{k,N}(\omega \star q), \mathfrak{r}_{k+9,N}(q)) : \\ & z = (\widehat{x}_k, \omega) \in \mathsf{Z}^{\Gamma}_{9,k}, \quad q \in \mathrm{Term}_{k+9,N}(t_{9,k} z) \big\}. \end{aligned} \tag{6.61}$$

Its source and target maps read, respectively, the primer or the second record, but never remove from their domain the witness (z,q):

$$\mathfrak{T}_{k,N} \xleftarrow{\ s^{\mathfrak{T}}_{9;k,N}\ } \mathsf{Z}^{\mathfrak{T}}_{9;k,N} \xrightarrow{\ t^{\mathfrak{T}}_{9;k,N}\ } \mathfrak{T}_{k+9,N}. \tag{6.62}$$

If $\zeta = (z, q; r_s, r_t)$, its action is

$$s^{\mathfrak{T}}_{9;k,N}(\zeta) := r_s, \qquad t^{\mathfrak{T}}_{9;k,N}(\zeta) := r_t. \tag{6.63}$$

Its link is defined by

$$\begin{aligned} & \pi^{Z,\mathfrak{T}}_{N+1,N}\big(z, q \star \varepsilon; \mathfrak{r}_{k,N+1}(\omega \star q \star \varepsilon), \mathfrak{r}_{k+9,N+1}(q \star \varepsilon)\big) \\ & \qquad := (z, q; \mathfrak{r}_{k,N}(\omega \star q), \mathfrak{r}_{k+9,N}(q)). \end{aligned} \tag{6.64}$$

The pair (z,q) is a coordinate of the apex, not a representation chosen of a triad; therefore the link is well defined even if two registros terminals coincide. The compatibility of Upd with the deletion of the ultima edge proof that (6.64) commutes with both maps of (6.62).

If an action on free modules is desired, this correspondence is linearized by summing all witnesses:

$$[\Gamma_9]_{k,N}[r] := \sum_{\zeta \in (s^{\mathfrak{T}}_{9;k,N})^{-1}(r)} [t^{\mathfrak{T}}_{9;k,N}(\zeta)]. \tag{6.65}$$

The formula preserves multiplicities. Equality of phases after nine steps does not contract the states, the witnesses, or their ledgers.

6.1.5 Uniqueness of the prefix decomposition and naturality of the truncation system

For $k \le \ell \le N$, every history of $\mathscr{H}_{k,N}(\widehat{x}_k)$ has a unique prefix $p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)$. Therefore there is a disjoint decomposition by prefixes, expressed without choosing any of them:

$$\mathscr{H}_{k,N}(\widehat{x}_k) = \bigsqcup_{p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)} \left\{ p \star q : q \in \mathscr{H}_{\ell,N}(p) \right\}. \tag{6.66}$$

Let Conc_p be the operation that prepends the record of the prefix p and successively applies (6.42). We define the transition in common over a complete family of terminals by

$$\mathfrak{u}_{\ell,k}\left(\left(\mathfrak{T}_{\ell,N}(p) \right)_{p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)} \right) := \bigcup_{p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)} \mathrm{Conc}_p\, \mathfrak{T}_{\ell,N}(p). \tag{6.67}$$

Writing $\mathbf{G}_{k,N}(\widehat{x}_k) := \mathfrak{T}_{k,N}(\widehat{x}_k)$, all naturality is concentrated in the single identity

$$\boxed{\mathfrak{u}_{\ell,k}\left(\left(\mathbf{G}_{\ell,N}(p) \right)_{p \in \mathscr{P}_{\ell|k}(\widehat{x}_k)} \right) = \mathbf{G}_{k,N}(\widehat{x}_k).} \tag{6.68}$$

There is no distinct law for each internal discriminant. The five characteristics obey (6.68) because each is updated by means of the same prefix, the same extension, and the same ledger.

The nonadic correspondence is compatible with this identity through the maps already constructed, not through a condition that is implicit. For every horizon, (6.59) and (6.60) preserve the nonadic witness with its multiplicity, and (6.64) does the same in the thirteen coordinates. If a is a coherent symmetry of the common state, its action

$$a^{\mathcal{Z}}(z, q) := (a^{\mathcal{Z}} z, aq)$$

satisfies

$$Sa^{\mathcal{Z}} = aS, \qquad Ta^{\mathcal{Z}} = aT, \qquad \pi^{\mathcal{Z}} a^{\mathcal{Z}} = a^{\mathcal{Z}} \pi^{\mathcal{Z}}, \qquad s^{\mathfrak{T}} a^{\mathcal{Z}} = a s^{\mathfrak{T}}, \qquad t^{\mathfrak{T}} a^{\mathcal{Z}} = a t^{\mathfrak{T}}. \tag{6.69}$$

These equalities are verified entry by entry using (5.81) and the naturality of the thirteen updates. They are the material condition that permits the use of (6.65); a mere equality of visible values does not replace it.

6.1.6 Passage to the limit without interchanging image and limit

Truncating a history and each of the thirteen fields defines

$$\pi^{\mathfrak{T}}_{N+1,N} : \mathfrak{T}_{k,N+1}(\widehat{x}_k) \longrightarrow \mathfrak{T}_{k,N}(\widehat{x}_k), \qquad \pi^{\mathfrak{T}}_{N+1,N} \mathfrak{r}_{k,N+1}(h) = \mathfrak{r}_{k,N}(h_{\le N}). \tag{6.70}$$

It is surjective by (6.5). The complete terminal is therefore

$$\mathfrak{T}_{k,\infty}(\widehat{x}_k) := \left\{ (r_N)_{N \ge k} : r_N \in \mathfrak{T}_{k,N}(\widehat{x}_k), \quad \pi^{\mathfrak{T}}_{N+1,N} r_{N+1} = r_N \right\}. \tag{6.71}$$

The finite sets of (6.46) are nonempty and their transition maps are surjective; therefore,

$$\mathfrak{T}_{k,\infty}(\widehat{x}_k) \neq \varnothing. \tag{6.72}$$

Corollary 6.3 (Simultaneous persistence of the five developments)**.** *In each element of $\mathfrak{T}_{k,\infty}(\widehat{x}_k)$ there simultaneously persist the strong limit $\mathcal{T}_\infty$ of the polar telescopy, the Gram family and losses, the incidence measure with its two naturalities, the cone* $\mathrm{Cone}(I - U_{\Gamma_9,N})$*, and the compatible family of Smith forms and Bockstein pages. None of these data is obtained by reconstructing only the visible terminal value.*

Proof. Surjectivity of the truncations preserves the complete witnesses. The telescoping, naturality, and reduction equations of proposition 6.2 commute with those truncations; by universality of the inverse limit, they define a unique compatible family on each surviving history. □

The apex nonadico in the limit is defined, not inferred from an image:

$$\mathsf{Z}^{\Gamma}_{9;k,\infty} := \varprojlim_{N\geq k+9} \big(\mathsf{Z}^{\Gamma}_{9;k,N}, \pi^{Z}_{N+1,N}\big). \tag{6.73}$$

Since the links do not modify the finite witness z and only truncate its tail, there exists the explicit isomorphism

$$\mathsf{Z}^{\Gamma}_{9;k,\infty} \xrightarrow{\cong} \coprod_{z\in \mathsf{Z}^{\Gamma}_{9,k}} \mathrm{Msect}(t_{9,k}z), \qquad ((z,q_N))_N \longmapsto (z,(q_N)_N). \tag{6.74}$$

The inverse takes a witness z and a compatible tail $(q_N)_N$, and forms $((z,q_N))_N$. Both compositions are identities coordinate by coordinate. The limit maps are

$$S_{k,\infty}((z_N)_N) := (S_{k,N}z_N)_N, \qquad T_{k,\infty}((z_N)_N) := (T_{k,N}z_N)_N; \tag{6.75}$$

are well defined precisely by (6.59) and (6.60).

The apex of registers is defined in the same way

$$\mathsf{Z}^{\mathfrak{T}}_{9;k,\infty} := \varprojlim_{N\geq k+9} \big(\mathsf{Z}^{\mathfrak{T}}_{9;k,N}, \pi^{Z,\mathfrak{T}}_{N+1,N}\big). \tag{6.76}$$

The correspondences (6.62) then form, component by component, the span

$$\mathfrak{T}_{k,\infty} \xleftarrow{s^{\mathfrak{T}}_{9;k,\infty}} \mathsf{Z}^{\mathfrak{T}}_{9;k,\infty} \xrightarrow{t^{\mathfrak{T}}_{9;k,\infty}} \mathfrak{T}_{k+9,\infty}. \tag{6.77}$$

The image of a limit has not been identified with the limit of certain images: (6.71), (6.73) and (6.76) construct directly the three compatible families and their maps.

6.1.7 Internal reconstruction of the enriched state from its 13 genealogical coordinates

Recovering does not unpack names: it repeats the fold that generated the record. For $h = (\varepsilon_{k+1},\dots,\varepsilon_N)$, we define

$$\boxed{\mathrm{Rec}_{13;k,N}(h) := \mathrm{Upd}_{\varepsilon_N} \circ \cdots \circ \mathrm{Upd}_{\varepsilon_{k+1}}(\mathfrak{r}^0_{k,r}).} \tag{6.78}$$

By (6.43), $\mathrm{Rec}_{13;k,N}(h) = \mathfrak{r}_{k,N}(h)$, but the equality is now an identity between two compositions of actions, not the projection of a preserved input. If pr_{A} denotes the projector from the register to field $\mathsf{A} \in \{\mathsf{F},\mathsf{E},\mathsf{R},\mathsf{N},\mathsf{O},\mathsf{K},\mathsf{M},\mathsf{B},\mathsf{G},\mathsf{X},\mathsf{S},\mathsf{T},\mathsf{L}\}$, then

$$\mathrm{pr}_{\mathsf{A}}\,\mathrm{Rec}_{13;k,N}(h) = \mathrm{Upd}^{\mathsf{A}}_{\varepsilon_N} \circ \cdots \circ \mathrm{Upd}^{\mathsf{A}}_{\varepsilon_{k+1}}(\mathsf{A}_{k,k}). \tag{6.79}$$

The proof is induction on $N-k$: for $N=k$ both sides are the seed; the inductive step applies the component A of $\mathrm{Upd}_{\varepsilon_N}$.

Además,

$$\mathrm{Rec}_{13;k,N}(h_{\leq N}) = \mathrm{tr}_{13,N+1,N}\big(\mathrm{Rec}_{13;k,N+1}(h)\big), \tag{6.80}$$

where $\mathrm{tr}_{13,N+1,N}$ removes only the last update and restricts its cone of tails. Consequently, an element of $\mathfrak{T}_{k,\infty}(\widehat{x}_k)$ determines a compatible family of the thirteen coordinates at every depth.

6.1.8 Multivalued terminality, naturality, and compatible limit of the continuum

Theorem 6.4 (Multivalued terminal, naturality, and limit of the continuum)**.** *For every $\widehat{x}_k \in \widehat{\mathcal{X}}_k^{\mathrm{tot}}$, the rules* (6.1)– (6.80) *construct, from the unique discrete continuum:*

1. *a multisection terminal finite not empty at each horizon;*
2. *an evaluation that conserves all histories and multiplicities;*
3. *the connection nonadic as a correspondence with witnesses;*
4. *the unique identity of naturality* (6.68)*;*
5. *a nonempty inverse terminal and a nonadic correspondence in the limit;*
6. *the compatible recovering of the fiber, extensions, relations, numbers, orientation, carry, memory, boundary, route, multisection, survival, terminal, and reader.*

The five intrinsic characteristics remain correlated within each record and each extension witness.

Proof. The non-emptiness of $\mathscr{H}_{k,N}(\widehat{x}_k)$ is nonempty by proposition 5.15, and its truncation is surjective by lemma 5.16. The rule (6.42) applies the APP, TRIT, and TPK identities to each witness ε_j; by induction on $N-k$, it produces all the fields of (6.43) and conserves their relations.

Taking the complete set in (6.46), or the complete sum in (6.48), proves that the terminal does not contain a selector. The weighted version is isometric by the projective equality (6.50).

The witness $z = (\widehat{x}_k, \boldsymbol{\omega})$ carries the phase action of each of its nine emissions; by proposition 5.18 it defines the two maps in (6.52) without converting the relation into a function or identifying phase with state. Equations (6.55)–(6.64) prove the two horizon squares and the same construction over registers. Summing the source space of each witness yields (6.65) without erasing multiplicities.

The partition (6.66) is disjoint because every history has a determined prefix of length ℓ. Concatenating each prefix with all its continuations reconstructs once and only once each history of $\mathscr{H}_{k,N}(\widehat{x}_k)$. This directly proves (6.68) for the whole register; five disconnected proofs are not needed.

Surjectivity of (6.70) and finiteness of each level imply nonemptiness of (6.71). The explicit links (6.57) and (6.64), together with their squares, construct the limits (6.73) and (6.76); from them follows (6.77). Finally, (6.78) reruns the successive updates, and (6.80) proves that those readings pass jointly to the limit. □

6.1.9 Obstructions to the terminality of the enriched state: loss of fiber, orientation, memory, or reader

Proposition 6.5 (Falsifiers of the terminal set)**.** *Any of the following operations replaces the constructed object and blocks the conclusion of theorem 6.4:*

1. *send to cylinder to to single history when it admits several;*
2. *choosing a tail of the terminal field* T *and eliminating the remaining ones;*
3. *replace* Γ_9 *by a function without proving uniqueness of each target and of its witness;*
4. *linearize to correspondence while ignoring multiplicities;*
5. *identifying phase return with state return;*
6. *preserve the input intact as the first coordinate and use its recoverability as purported generation;*
7. *omit any of the thirteen fields of* (6.43)*;*
8. *allowing two intrinsic characteristics to use different histories, carries, boundaries, or terminals;*
9. *replace* (6.68) *by five independent assertions;*

10. *assert operatorial compatibility of* Γ_9 *without preserving the space of witnesses and its multiplicities;*
11. *interchanging, without proof, formation of images and passage to the limit;*
12. *present a list of thirteen names without the actions* (6.42) *that produce them.*
13. *omit the polar telescoping, the loss row, the naturality adjoint, the module of all continuations or the reduction Smith–Bockstein certified in proposition 6.2;*
14. *turning any of those five developments into an autonomous branch or using a later classical application to select its domain.*

Proof. The first five operations contract the multisection or the correspondence. The next four break their common support and naturality. The final three eliminate the generative proof or alter passage to the limit. In each case, the resulting object ceases to satisfy at least one of (6.46), (6.62), (6.68), or (6.80); therefore, the conclusion does not carry over. □

Hypothesis, domain, and conclusion

The organization of the complete terminal object, unique naturality, and passage to the limit are established jointly. The surviving multisection, the carries, the register, the boundary, the route, and the nonadic connection are its structural antecedents. The linearization over free modules is proved by (6.65) and its Beck–Chevalley squares. A subsequent promotion to a bounded operator on an analytic completion additionally requires that norm to be declared and the bound proved; the correspondence (6.77) does not depend on that interface.

6.2 Joint nonadic connection Γ_9 as a compatible correspondence of the inverse system

6.2.1 Terminal Assembly Theorem of the Correlative Constructions Generated by the Common State

Each depth k possesses an enriched state $\mathcal{E}_k$ with all its surviving emissions and a single correlative constructor

$$O_k : \mathcal{E}_k \longrightarrow \mathcal{Z}_k, \qquad \widehat{x}_k \longmapsto O\big(\{\mathfrak{e}_\alpha : \alpha \in \mathrm{Ch}_k(\widehat{x}_k)\}\big). \tag{6.81}$$

The value of O_k simultaneously preserves the spectral, solenoidal, gauge, coherent, and determinantal coordinates,

$$(\mathrm{sp}, \mathrm{sol}, \mathrm{gau}, \mathrm{coh}, \mathrm{det}), \tag{6.82}$$

as five characteristics of the same state and of the same genealogical register. The truncations

$$u^{\mathfrak{e}}_{\ell,k} : \mathcal{E}_\ell \to \mathcal{E}_k, \qquad u^{O}_{\ell,k} : \mathcal{Z}_\ell \to \mathcal{Z}_k$$

satisfy the unique naturality

$$u^{O}_{\ell,k} \circ O_\ell = O_k \circ u^{\mathfrak{e}}_{\ell,k}, \qquad \ell \geq k. \tag{6.83}$$

Therefore, the corresponding action passes to the limit as

$$O_\infty : C^{\mathrm{disc}}_{\mathrm{cont}} := \varprojlim_k \mathcal{E}_k \longrightarrow \mathcal{Z}_\infty := \varprojlim_k \mathcal{Z}_k. \tag{6.84}$$

The five terminal applications are seen as intrinsic manifestations of that single value:

$$\boxed{\mathfrak{G}^{\mathrm{int}}_T := \mathrm{View}_T\Big(O_\infty(C^{\mathrm{disc}}_{\mathrm{cont}})\Big), \quad T \in \{\mathrm{sp}, \mathrm{sol}, \mathrm{gau}, \mathrm{coh}, \mathrm{det}\}.} \tag{6.85}$$

Simultaneity precedes the specialized resolutions: each view exposes the required coordinate and the complete state conserves the other four.

6.2.2 Survival and inverse limit

Let $\mathrm{Surv}_N^{(\chi)}$ be the set of histories of depth N that simultaneously satisfy the active laws of channel χ and admit prolongation. We define the compatible truncations

$$\tau_{N+1,N} : \mathrm{Surv}_{N+1}^{(\chi)} \longrightarrow \mathrm{Surv}_N^{(\chi)}$$

These preserve the enriched prefix. The genealogical continuum is the limit.

$$X_\chi = \varprojlim_N \big(\mathrm{Surv}_N^{(\chi)}, \tau_{N+1,N}\big), \qquad \tau_{N+1,N}(x_{N+1}) = x_N. \tag{6.86}$$

The global space of surviving sections and one of its enriched sections are denoted, respectively, by

$$X_\infty := \bigsqcup_\chi X_\chi, \qquad \widehat{\Omega}_\infty \in X_\infty. \tag{6.87}$$

The global Archimedean reader is

$$P_{\mathrm{arq}} := \mathrm{ev}_{\mathbb{R}} : X_\infty \longrightarrow \mathbb{R}; \tag{6.88}$$

its restriction to each channel evaluates the unitary intersection of the compatible cylinders of the corresponding section. When the exceptional reader intervenes, $X_\infty^{\mathrm{cal}} \subseteq X_\infty$ denotes the subspace in which the calibration type of (6.103) has been fixed. Survival determines the section by internal compatibility: every history must be prolongable in the complete system. The numerical reader intervenes afterward to certify and publish the intersection of the already compatible descendant.

6.2.3 Joint nonadic connection, holonomy, and vertical memory

At depth K, the holonomy of the nonadic return is initially the typed correspondence

$$\Gamma_{9,K} = \mathrm{Hol}_{C_9}(\nabla_{\mathrm{TPK}}) : \widehat{\mathcal{X}}_K \rightrightarrows \widehat{\mathcal{X}}_{K+9}. \tag{6.89}$$

Its iterates are relational compositions. Only when each state has a unique compatible prolongation is it restricted to a map, and only when that map is invertible does it constitute a monodromy. This distinction conserves all surviving extensions before selecting a section. After nine phases the local phase returns, while the complete state advances:

$$g(K+9) = g(K), \qquad q_{\mathrm{mem},K+9} = q_{\mathrm{mem},K} + 1, \qquad \widehat{x}_{K+9} \neq \widehat{x}_K \text{ in general.}$$

Block, cylinder, prefix, carry, and memory continue to evolve. This is the difference between visible periodicity and return with biography.

The transported state at level (K) can be exhibited as

$$\widehat{x}_K = (B_K, C_K, p_K, c_K, \Sigma_K, W_K, g(K), q_{\mathrm{mem},K}, s_K), \tag{6.90}$$

where each coordinate has its own transport law. The phase return is represented on the catalog.

$$\mathcal{U}_6^{\mathrm{cat}} \cong \mathfrak{S}_+ \times \mathfrak{S}_\times, \qquad |\mathfrak{S}_+| = 18, \qquad |\mathfrak{S}_\times| = 26.$$

Conditional averages

$$(E_+ f)(s,e) = \frac{1}{18} \sum_{s' \in \mathfrak{S}_+} f(s',e), \qquad (E_\times f)(s,e) = \frac{1}{26} \sum_{e' \in \mathfrak{S}_\times} f(s,e')$$

commute. The phase word $\tau = (+1, -1, 0, +1, -1, 0, +1, -1, 0)$ applies $E_+, E_\times, I$ in that order, and one revolution closes through

$$\mathcal{K}_{\mathrm{ph}}^{9} = (E_+E_\times) \otimes I_{\ell^2(C_9)}, \qquad \left\langle \delta_u, E_+E_\times \delta_v \right\rangle = \frac{1}{468} \quad (u, v \in \mathcal{U}_6^{\mathrm{cat}}). \tag{6.91}$$

The sum and product sheets do not act as independent filters: they are two components of a single holonomy that closes only after traversing the complete cycle.

The compression–expression colligation separates what returns from what remains as memory. If (J) embeds the history space into the phase space, (T) is the surviving compression and η the defect channel, then

$$\boxed{U_{\Gamma_9} J = JT + \eta, \qquad J^*\eta = 0, \qquad I - T^*T = \eta^*\eta.} \tag{6.92}$$

The first equality decomposes transport into compressed return and memory expression; the second proves their orthogonality; the third measures exactly the information that cannot fit within the periodic shadow. The central statement is thereby formalized: the phase returns, not the complete state.

The vertical memory is organized through the cyclic extension oriented

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0, \qquad c(r, r') = \left[\left[\frac{r + r'}{9} \right]\right]_{12}. \tag{6.93}$$

Here $\iota([b]_{12}) = [9b]_{108}$ and $p([\theta]_{108}) = [\theta]_9$. The extension does not split: C_{108} has exponent 108, whereas $C_{12} \times C_9$ has exponent 36. The cocycle records the carry from each turn of the base C_9 in the dodecaphase memory C_{12}. C_{108} is therefore an oriented phase–memory calendar. Only after the dimensional chart is that extension realized as a finite 108-step quantum clock.

The local MD lift carrying the TRIT signature is the topological–temporal unit of that genealogical crystal. On $\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^{108}$, with basis $\{|j\rangle : j \in \mathbb{Z}/108\mathbb{Z}\}$, let

$$\zeta = e^{2\pi \mathrm{i}/108}, \qquad |\widetilde{k}\rangle = \frac{1}{\sqrt{108}} \sum_{j=0}^{107} \zeta^{jk} |j\rangle, \qquad U_{\mathrm{clk}}|j\rangle = |j+1\rangle.$$

With $\omega_0 = 2\pi/(108 t_0)$, the Hamiltonian

$$H_{\mathrm{clk}} = \hbar_{\mathrm{int}} \omega_0 \sum_{k=0}^{107} k \, |\widetilde{k}\rangle\langle\widetilde{k}| \tag{6.94}$$

generates exactly

$$U_{\mathrm{step}} = \exp\!\left(-\frac{\mathrm{i} H_{\mathrm{clk}} t_0}{\hbar_{\mathrm{int}}} \right) = U_{\mathrm{clk}}, \qquad U_{\mathrm{step}}^{108} = I, \tag{6.95}$$

If $Z_{\mathrm{clk}}|j\rangle = \zeta^j |j\rangle$, then

$$\langle j_0 | U_{\mathrm{step}}^{-n} Z_{\mathrm{clk}} U_{\mathrm{step}}^{n} | j_0 \rangle = \zeta^{j_0 + n}, \tag{6.96}$$

whose orbit has primitive period 108. In HMT terminology, this is the internal genealogical time crystal: the observable calendar closes, C_{12} records the circuit, and the enriched TPK state need not return. Its subsequent realization as a macroscopic physical phase also requires a Floquet protocol, primitive subharmonic response, robustness, persistence, and a protection mechanism; that chart does not alter the finite theorem of unitary periodicity.

6.2.4 Archimedean publication, genealogical number and measurement

The Archimedean publication uses semi-open ternary cylinders.

$$I_{N,L} = \left[\frac{N}{3^L}, \frac{N+1}{3^L}\right), \qquad \operatorname{diam} I_{N,L} = 3^{-L} \longrightarrow 0. \tag{6.97}$$

A compatible section determines nested cylinders and, by completeness, a unique real point. The HMT number is the section itself,

$$x = (x_N)_N \in X_\chi = \varprojlim_N \mathrm{Surv}_N^{(\chi)}, \tag{6.98}$$

not the tuple formed by it and its evaluations. The value appears when a reader forgets part of the genealogy. Therefore, precision is depth: measuring means descending to a finer cylinder while the causal prefix remains in the antecedent. The real line is reconstructed as the Archimedean quotient of a space of much richer histories.

6.2.5 Dimensional realization of the HMT state: screen map, observable magnitude, and spectral chart

Dimensional Mechanics begins where the genealogical state couples to a realization boundary. With a field K_n fixed, let $M_n(x)$ be the module generated by the prolongation channels of a state x, let $\mathcal{R}_n(x)$ be the submodule of its relations, and let $\beta_n(x)$ be the conserved boundary datum. The dimensional screen is

$$\Sigma_n(x) = \big(K_n, M_n(x), \beta_n(x), \mathcal{R}_n(x)\big), \qquad d_{\Sigma_n}(x) = \dim_{K_n} \frac{M_n(x)}{\mathcal{R}_n(x)}. \tag{6.99}$$

If $M_n(x) \simeq K_n^{g_n}$ and the columns of $R_n(x)$ generate the relations, then

$$\boxed{d_{\Sigma_n}(x) = g_n - \operatorname{rank}_{K_n} R_n(x).} \tag{6.100}$$

Dimension is not attached as a label: it is the number of independent channels that survive after imposing the boundary relations.

A physical quantity is a section of a dimensional line L_D; a unit is a chart $\chi_u : L_D \to \mathbb{R}$ that publishes its coordinate. Hence

$$\text{TPK state} \longrightarrow \Sigma_n(x) \longrightarrow s_D \in \Gamma(L_D) \xrightarrow{\chi_u} [s_D]_u \in \mathbb{R} \tag{6.101}$$

separates structure, dimensional type, and measured number exactly. Measuring consists in coupling a section to a reversible apparatus, imposing edge compatibility, and applying the reader; changing units changes χ_u, not the section or its genealogy.

6.2.6 Double projection mathematical and dimensional realization

The exceptional branch preserves gauge data that the real publication does not need. Let $\mathscr{C}_{\mathrm{exc}}$ be the space of gauges, and let

$$\mathfrak{E} : X_\infty^{\mathrm{cal}} \times \mathscr{C}_{\mathrm{exc}} \longrightarrow \mathbf{Exc} \tag{6.102}$$

the incidence reader. We fix once

$$\begin{aligned}\chi_{\mathrm{exc}} = \big(&\text{projective order},\ \text{Paley gauge},\ \text{dodecad},\\ &\text{incidence alignment},\ \text{lattice chamber}\big) \in \mathscr{C}_{\mathrm{exc}}\end{aligned} \tag{6.103}$$

and abreviamos $\mathfrak{E}_{\chi_{\mathrm{exc}}}(x) := \mathfrak{E}(x, \chi_{\mathrm{exc}})$. The gauge initial it transports by the history; not vuelve to elegirse in each depth.

The same calibrated limit then admits two readers with distinct codomains:

$$\mathbb{R} \xleftarrow{\mathrm{ev}_{\mathbb{R}}} X_{\infty}^{\mathrm{cal}} \xrightarrow{\mathfrak{E}_{\chi_{\mathrm{exc}}}} \mathbf{Exc}. \tag{6.104}$$

The first branch contracts cylinders to a continuous value. The second preserves incidences, orientations, gauge, and boundary. Both descend in parallel from the same source state. This bifurcation jointly explains metric continuity and the emergence of exceptional symmetries. The second branch is a calibrated reconstruction: it is exact once χ_{exc} has been fixed, but the bare state does not retrospectively select the five data composing that gauge.

The non-serializing dimensional realization does not serialize those two branches. It is a third reader of the same antecedent:

$$P_{\mathrm{dim}} : X_{\infty} \longrightarrow \mathcal{R}_{\mathrm{MD}}, \qquad \mathcal{R}_{\mathrm{MD}} = \{\text{action, mass, field, geometry, information}\}. \tag{6.105}$$

In this manner, a number, a symmetry, and a physical magnitude may share a genealogy without being confused with or reduced to one another.

The thesis of the continuum is thus formulated precisely: Archimedean reality is the zero-radius shadow of infinitely refinable discrete histories; what the shadow omits reappears as memory, incidence, geometry, and physical structure.

6.3 Surviving extensions, monodromy, and dynamics of the quotient

The language of paths requires a decisive precision. An APP path, a visible emission, an enriched TPK history, and a global section are not four names for the same object. They constitute four consecutive levels of a single construction. The path preserves positional order; the emission preserves a finite reading; the history adds signature, carry, orientation, boundary, and memory; the global section requires all of its prefixes to survive simultaneously at every depth.

This hierarchy makes it possible to separate two questions that had remained intermingled. The first is logical: under what hypotheses a finite prefix truly belongs to a compatible infinite extension. The second is dynamical: what it means to transport a single history and what it means to transfer all its compatible continuations simultaneously. The distinction is essential in APP. A given trajectory carries one state to another; a path transfer carries a distribution of extensions to another distribution.

This section resolves the finite problem at depth six. The published deterministic chronology has visible-phase return and cannot select a unique probability. By contrast, transport biased by the nonadic phase, when each active channel is interpreted as the normalized renewal of its entire fibre of compatible continuations, has a uniform nine-step return over the (468) emissions. The weights (1/3) then cease to be an external choice: they follow from the three occurrences of each signature (+1,-1,0) in the oriented nonadic cycle. Normalization within each fibre remains a precise mathematical premise —the uniform count of all compatible paths— and must not be conflated with the successor of a single trajectory. Passage to the inverse limit over all depths preserves a distinct statement, formulated at the end of the section.

6.3.1 5 levels of the notion of path

Let Γ_{APP} be the category of cardinal paths of the APP torus. For each depth m, let $\mathcal{H}_m$ be the finite set of admissible enriched histories

$$h_m = (v_0, e_1, v_1, \ldots, e_m, v_m),$$

where each arrow e_j transports all fields declared by TPK. If $n \geq m$, the application

$$p_{n,m} : \mathcal{H}_n \longrightarrow \mathcal{H}_m$$

removes the tail beyond depth m. The positional shadow

$$\mathrm{sh}_m : \mathcal{H}_m \longrightarrow \Gamma_{\mathrm{APP}}$$

forgets the memory fiber and preserves the underlying APP path.

Definition 6.6 (Hierarchy of extensions)**.** We distinguish the following objects.

1. An *APP path* is a morphism of Γ_{APP}.
2. An *observable route* is a reading of that morphism that jointly conserves the sum and product leaves.
3. A *TPK extension* is a lift of the observable route to a history $h_m \in \mathcal{H}_m$, with its residue, quotient, signature, orientation, boundary, carry, and record data.
4. A *surviving extension* is a finite history that admits compatible prolongations to every horizon.
5. A *global section* is a compatible family $x = (h_m)_{m\geq 0}$ of surviving extensions.

In particular, the route is the shadow of the extension; it is not an external object that the extension subsequently chooses.

For $h \in \mathcal{H}_m$, its cylinder of prolongations is

$$Z_m(h) = \{x = (h_n)_n \in \varprojlim_n \mathcal{H}_n : x_m = h\}.$$

In particular, every family of $Z_m(h)$ also satisfies $p_{n,\ell}(h_n) = h_\ell$ for $n \geq \ell$; collections of incompatible truncations are not admitted. Let us also define

$$\mathcal{S}_m^{(N)} = p_{N,m}(\mathcal{H}_N), \qquad \mathcal{S}_m^{\infty} = \bigcap_{N\geq m} \mathcal{S}_m^{(N)}.$$

Theorem 6.7 (Conditional extension survivor criterion)**.** *Let us fix $h \in \mathcal{H}_m$ and, for $N \geq m$, write*

$$\mathcal{P}_N(h) = \{g \in \mathcal{H}_N : p_{N,m}(g) = h\}.$$

Suppose that the truncations are coherent and that each $\mathcal{P}_N(h)$ is finite. The following are equivalent:

1. *$\mathcal{P}_N(h) \neq \varnothing$ for every $N \geq m$, that is, $h \in \mathcal{S}_m^{\infty}$;*
2. *the tree of finite extensions of h is finitely branching and has a nonempty level at every depth;*
3. *$Z_m(h) \neq \varnothing$.*

Consequently, whenever the surviving finite truncations are nonempty, the set

$$\Omega_{\mathrm{H}}^{\mathrm{surv}} = \varprojlim_m \mathcal{S}_m^{\infty}$$

is exactly the space of surviving global sections. The theorem does not assert that these truncations are nonempty for every APP input: that property must be proved by means of the survival protocol.

Proof. The implication from the third condition to the first two is obtained by truncation. Now assume the first condition and order the elements of $\bigsqcup_{N\geq m} \mathcal{P}_N(h)$ by the prefix relation. Each level is finite and nonempty, and coherence of the truncations makes this union a finitely branching tree with nodes at every depth; this yields the second condition. Conversely, from the second condition König's lemma provides an infinite branch. Its truncations form a compatible family belonging to $Z_m(h)$, which is the third condition. The same construction identifies the indicated inverse limit wherever its finite truncations are nonempty. □

The theorem resolves the possible discrepancy between "extendable to each horizon separately" and "possessing a global prolongation": finiteness of the branches is the hypothesis that permits the choice

of a single compatible chain. It does not claim that all APP paths belong to $\mathrm{sh}(\Omega_{\mathrm{H}}^{\mathrm{surv}})$. That coverage requires proving that the enriched closures do not empty the corresponding fibers.

6.3.2 Phase return and monodromy relation

The return of the phase–length quotient is formalized separately in definition 1.163 y theorem 1.165:

$$(b,r) \xrightarrow{9} (b+1,r), \qquad (b,r) \xrightarrow{108} (b,r).$$

These equalities belong to the odometer 9×12. They do not constitute the proof of $F_{\mathrm{obs}}^{108} = I$, which uses the observable state and appears below.

Let ϕ be the phase coordinate with values in $\mathbb{Z}/9\mathbb{Z}$. A visible-phase return satisfies

$$\phi(h_{k+9}) = \phi(h_k).$$

The complete record may, however, satisfy

$$B(h_{k+9}) \neq B(h_k).$$

This inequality is not a failure of periodicity: it is the memory of the circuit. An ordinary action of C_9 on the complete state would require the ninth power to be the identity and would erase precisely that information.

To type the return, let H be a hexad and $P_2(H)$ its set of fifteen pairs. Let $\mathcal{B}_k$ be the record states that survive at phase k, let $\mathcal{T}_k \subseteq \mathcal{B}_k \times \mathcal{B}_{k+1}$ be the published transport relation, and suppose a fiber encoder is given

$$c_k : \mathcal{B}_k \longrightarrow P_2(H).$$

Only after declaring those encoders is the observable relation defined.

$$R_k = (c_k \times c_{k+1})(\mathcal{T}_k) \subseteq P_2(H) \times P_2(H).$$

The relational monodromy of a loop is

$$\mathcal{M}_k = R_{k+8} \circ R_{k+7} \circ \cdots \circ R_k.$$

Proposition 6.8 (Classification of the nonadic return given the encoder)**.** *Three logically distinct levels are given.*

1. *Without a proof of functionality, the return is the relation $\mathcal{M}_k$.*
2. *If each R_k is the graph of a map $\mu_k : P_2(H) \to P_2(H)$, the transport is the skew product*

$$T(k,p) = (k+1, \mu_k(p)),$$

and

$$T^9(k,p) = (k, M_k(p)), \qquad M_k = \mu_{k+8} \circ \cdots \circ \mu_k.$$

3. *If the μ_k are bijective, M_k is an automorphic holonomy. The transport descends to an ordinary action of C_9 on the complete state if and only if $M_k = I$ in all fibers.*

Proof. The first claim is the definition of image and relational composition once $(c_k)_k$ have been fixed. Under functionality, nine consecutive applications keep the first coordinate fixed and compose their actions on the second. The composition of bijections is a bijection. Finally, $T^9 = I$ is exactly equivalent to $M_k = I$ for each phase and each point of the fiber. □

Corollary 6.9 (No return under cumulative transport)**.** *Let $q : X \to V$, $T : X \to X$, and $x \in X$ be given. If*

$$q(T^9 x) = q(x), \qquad T^9 x = \mathcal{M}_x\, x, \qquad \mathcal{M}_x\, x \neq x,$$

then the projection returns and the state does not:

$$q(T^9 x) = q(x), \qquad T^9 x \neq x.$$

The pointwise hypothesis $\mathcal{M}_x\, x \neq x$ is indispensable; the global inequality $\mathcal{M}_x \neq I$ does not exclude x from being a fixed point.

Proof. The first equality is a hypothesis. The second and the pointwise separation give $T^9 x = \mathcal{M}_x\, x \neq x$. The statement would be refuted by a case that satisfies the three premises and had $T^9 x = x$; it does not authorize replacing the third premise by $\mathcal{M}_x \neq I$. □

Theorem 6.10 (Functional sufficiency of the enriched tuple)**.** *Let*

$$E : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathcal{S}_E$$

the tuple that conserves the visible block, new blocks and carry, lifting state, cylinders, boundary signature, orientation, observable, phase, and dodecaphasic register. Let

$$T : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \to \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}, \qquad O : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \to Y.$$

When maps exist

$$\widehat{T} : \mathcal{S}_E \to \mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}, \qquad \widehat{O} : \mathcal{S}_E \to Y$$

such that

$$T = \widehat{T} \circ E, \qquad O = \widehat{O} \circ E,$$

the equality $E(x) = E(y)$ implies $T(x) = T(y)$, $O(x) = O(y)$ and, by determinism, the same continuations and subsequent outputs.

Proof. By factorization,

$$T(x) = \widehat{T}(E(x)) = \widehat{T}(E(y)) = T(y), \qquad O(x) = \widehat{O}(E(x)) = \widehat{O}(E(y)) = O(y).$$

The first equality permits iteration of the argument. This is a sufficient condition, not an unproved equivalence. Two states with the same tuple and different transitions or outputs, access to an absent coordinate, or querying a target value are falsifiers. The visible five-element microfiber of proposition 8.36 controls only the nonfaithfulness of the word w_6; it does not prove this positive factorization. □

The published finite window contains nine phase returns with change of the enriched state and a local selection from three continuations to one upon increasing two horizons. This proves return with memory and refutes the identification of the register with a memoryless cycle. Global extraction of the nine encoders c_k and, through them, of the relations R_k, from all surviving histories is a distinct operation. The preceding proposition classifies the return once the register–pairs map is given; it does not derive that map from the enriched TPK state.

The concrete episode of the ninth phase, with its three continuations, the block B_{11}, the boundary $(502, 662, 638)$, and the integer inequalities of cylinders, is proved only once in the theorem 8.39. In this residence only its typed consequence is used:

$$\#\,\mathrm{Surv}_1(B_9) = 3, \qquad \#\,\mathrm{Surv}_2(B_9) = 1.$$

The other two words can precede the same ternary tail only by changing the deep Hensel extension. They share part of the visible residue, but not the genealogy of the state.

6.3.3 The catalog of 468 emissions as a product of channels

The finite catalogue starts from the set Ω_{seed} of 104 976 microscopic presentations. Let $\mathcal{U}_6$ be the set of distinct sextuple emissions and let

$$F : \Omega_{\mathrm{seed}} \twoheadrightarrow \mathcal{U}_6.$$

The exact census is

$$|\mathcal{U}_6| = 468, \qquad \#\{U : |F^{-1}(U)| = 144, 432, 1944\} = 432, 18, 18.$$

These counts belong to F. Comparing them with depth-six TPK histories would require an explicit map from the history domain to Ω_{seed}; no result in this section presupposes that map or identifies catalogue presentations with enriched states. The finite catalogue supplies, for every emission, an additive signature s and a multiplicative signature e. The joint map is a bijection

$$\mathcal{U}_6 \xrightarrow{\sim} \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\mathcal{S}_+| = 18, \quad |\mathcal{S}_\times| = 26.$$

Thus,

$$\boxed{468 = 18 \cdot 26}$$

is a factorization of the object and not merely of its cardinality. The first coordinate preserves how the emission sums; the second, how the product accumulates. This separation is the explicit finite form of sum–product incompatibility: both readings coexist in the state, but each projection forgets the complementary signature.

The first coordinate admits an additional parametrization that will be useful when comparing it with the nonadic boundary. If an additive seed has coordinates $(i, j) \in (\mathbb{Z}/9\mathbb{Z})^2$ and orientation $\varepsilon = +1$ for the east–south directions and -1 for north–west, its complete signature is determined bijectively by

$$\big(i + j \bmod 9, \varepsilon\big) \in (\mathbb{Z}/9\mathbb{Z}) \times \{\pm 1\}.$$

Therefore,

$$\boxed{\mathcal{S}_+ \simeq (\mathbb{Z}/9\mathbb{Z}) \times \{\pm 1\}.}$$

The product coordinate has no analogous uniformity: its 26 signatures have fibers of seeds of sizes 8, 24, and 108, with histogram $24 \times 8 + 1 \times 24 + 1 \times 108 = 324$. This asymmetry is structural. The factor 18 already contains phase and orientation; any subsequent descent of the product factor to a class of pairs must preserve additional memory or accept nonuniform fibers.

On $\ell^2(\mathcal{S}_+ \times \mathcal{S}_\times)$, let us define the conditional expectations

$$(E_+ f)(s, e) = \frac{1}{18} \sum_{s' \in \mathcal{S}_+} f(s', e),$$
$$(E_\times f)(s, e) = \frac{1}{26} \sum_{e' \in \mathcal{S}_\times} f(s, e').$$

The first operator renews the additive signature and preserves the multiplicative one; the second performs the dual operation. The third channel retains both.

6.3.4 The unique path and path transfer

Unlike the return of the odometer defined in definition 1.163 y theorem 1.165, the following proposition proves the return of the observable operator F_{obs}.

The published observable law updates a single cursor at each step. In the phases +1, the additive cursor advances; in the phases −1, the multiplicative cursor advances; in the phases 0, both remain stationary. After the steps $27, 54, 81, 108$, the two orientations are inverted. Denote this deterministic evolution by F_{obs}.

Proposition 6.11 (Return of the Observable Chronology)**.** *For every choice of the two initial positions and orientations, the positions and orientations are restored after* 54 *steps. Upon also restoring the phase, one obtains*

$$F_{\mathrm{obs}}^{108} = I.$$

Therefore, the Poincaré return of 108 *steps induces the identity on* $\mathcal{U}_6$ *and does not select a unique stationary measure.*

Proof. In every block of 27 steps, each cursor makes exactly nine advances in a fixed orientation. Since the position space is $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$, its displacement is $9d = 0$. At the end of the block, d is inverted. Two blocks restore position and orientation; four also restore the index in Θ_{108}. The induced return is consequently the identity. Every probability is stationary for the identity, so none is selected by that chronology. □

The problem arises even before the return if one attempts to forget the route memory. The product signature

$$e_0 = (5, 5, 5, 5, 5, 5)$$

has twenty-four representatives. After an advance in its own orientation, those representatives separate, eight by eight, among

$$(5, 5, 5, 7, 1, 7), \qquad (5, 5, 5, 7, 7, 1), \qquad (5, 5, 5, 1, 7, 7).$$

Thus, the product advance does not descend to a map of the twenty-six signatures: the representative that had been forgotten becomes relevant again. This witness explains why an individual route cannot be turned, by mere projection, into the refreshment of a complete fiber.

The APP reading is different. Instead of choosing a representative, it preserves all compatible continuations. To formalize it in the finite catalogue, consider the subalgebras of functions that depend only on one of the two signatures. With respect to uniform counting, E_+ and $E_\times$ are the conditional expectations that forget exactly the active coordinate. They are the only Markov projectors that simultaneously satisfy:

1. preservation of the coordinate inactive;
2. complete forgetting of the active coordinate;
3. preservation of the uniform counting state.

Indeed, a row that has forgotten the source coordinate must be constant on the 18, respectively 26, compatible destinations; the normalization forces the values $1/18$ and $1/26$. This is the relative canonicity of the renewal: no preference is postulated between branches that APP declares equally possible.

Let $C_9 = \mathbb{Z}/9\mathbb{Z}$, with the phase word

$$\tau = (+1, -1, 0, +1, -1, 0, +1, -1, 0).$$

Write

$$P_{+1} = E_+, \qquad P_{-1} = E_\times, \qquad P_0 = I.$$

Definition 6.12 (Phase-biased TPK transfer)**.** On $\mathcal{U}_6 \times C_9$ we define

$$\mathcal{K}_{\mathrm{ph}}\big((u,r),(v,r+1)\big) = P_{\tau(r)}(u,v),$$

and set the remaining entries to zero. This definition is relative to the reader of all compatible paths: an active phase uniformly renews the fiber read by that phase, and the neutral phase retains the emission.

Theorem 6.13 (Uniform nonadic return)**.** *The kernel $\mathcal{K}_{\mathrm{ph}}$ is doubly stochastic and irreducible, has period exactly nine, and possesses a unique stationary state,*

$$\pi_{\mathrm{ph}}(u,r) = \frac{1}{9 \cdot 468}.$$

In each phase fiber, its return of nine steps is

$$\mathcal{K}_{\mathrm{ph}}^{9}\big|_r = E_+E_\times, \qquad (E_+E_\times)(u,v) = \frac{1}{468}.$$

If the initial phase is uniformly distributed, the shadow of a step over the emissions is

$$\overline{K}_{\mathrm{ph}} = \frac{1}{3}(I + E_+ + E_\times).$$

Proof. Each $P_{\tau(r)}$ is doubly stochastic and the shift $r \mapsto r+1$ is a permutation; their skew product conserves both sums. The three operators are idempotent and commute. Since each appears three times in the nonadic word,

$$\prod_{r \in C_9} P_{\tau(r)} = E_+^3 E_\times^3 I^3 = E_+E_\times.$$

The first expectation forgets the additive signature and the second the multiplicative signature, so their composition assigns to each of the $18 \cdot 26 = 468$ destinations the probability $1/468$. Hence, in nine steps any two states of the same phase communicate; the remaining steps communicate the phases, and the kernel is irreducible. Every return must have length divisible by nine, whereas the diagonal of $\mathcal{K}_{\mathrm{ph}}^{9}$ is positive; the period is nine. Double stochasticity and irreducibility yield the unique uniform state. Finally, averaging the nine phases counts three copies of each channel and produces the final formula. □

Forgetting the phase is not a strong Markov quotient: from the same emission, two distinct phases apply I, E_+, or $E_\times$, which have distinct rows. The operator $\overline{K}_{\mathrm{ph}}$ is an averaged shadow in the stationary phase, not the chronological successor of a phaseless emission. This distinction preserves both the dynamics and the meaning of the measure.

Definition 6.14 (Averaged kernel induced by transferrence)**.** We call the phase shadow the averaged kernel of the catalog

$$\boxed{K_{\mathrm{cat}} = \frac{1}{3}(I + E_+ + E_\times).}$$

The weights are induced by the TPK calendar, which contains three occurrences of each sign. The renewal operators are induced relative to the uniform normalization of all compatible continuations of the active fiber. Neither statement identifies K_{cat} with F_{obs}.

Proposition 6.15 (Convex family of stochastic kernels with a common uniform measure)**.** *For $a, b, c \geq 0$, $a + b + c = 1$, the family*

$$K_{a,b,c} = aI + bE_+ + cE_\times$$

consists of symmetric, doubly stochastic kernels. If $b, c > 0$, they are irreducible and, because they have positive diagonal, aperiodic. Their spectrum is

$$\operatorname{Spec}(K_{a,b,c}) = \{1^{[1]}, (a+c)^{[17]}, (a+b)^{[25]}, a^{[425]}\}.$$

In particular, there exists a continuum of dynamics with the same factorization and the same uniform measure. The choice $K_{\mathrm{cat}} = K_{1/3,1/3,1/3}$ is not characterized by the census alone. It is selected jointly by the TPK phase word and the normalized transfer of the definition 6.12.

Proof. The three summands are symmetric stochastic kernels; by convexity, the same is true of $K_{a,b,c}$, and symmetry converts row stochasticity into column stochasticity. If $b, c > 0$, two steps make it possible to renew both coordinates successively and connect any pair of states. Moreover,

$$K_{a,b,c}((s,e),(s,e)) = a + \frac{b}{18} + \frac{c}{26} > 0,$$

so that the kernel is aperiodic. In the orthogonal decomposition

$$\mathbf{1} \oplus \ell_0^2(\mathcal{S}_+) \oplus \ell_0^2(\mathcal{S}_\times) \oplus \big(\ell_0^2(\mathcal{S}_+) \otimes \ell_0^2(\mathcal{S}_\times)\big),$$

the pairs $(E_+, E_\times)$ act, respectively, as $(1,1), (0,1), (1,0), (0,0)$. The four eigenvalues and the multiplicities $1, 17, 25, 425$ are thereby obtained. For $b, c > 0$, irreducibility makes the uniform stationary measure unique, which exhibits non-uniqueness even under that requirement. □

Theorem 6.16 (Exact spectrum of the balanced refreshment)**.** *The kernel K_{cat} is symmetric, doubly stochastic, irreducible and aperiodic. Its spectrum, with multiplicities, is*

$$\boxed{\operatorname{Spec}(K_{\mathrm{cat}}) = \left\{1^{[1]}, \left(\frac{2}{3}\right)^{[42]}, \left(\frac{1}{3}\right)^{[425]}\right\}.}$$

Consequently, its spectral gap is (1/3) and its only stationary state is

$$\boxed{\tau_{468}(f) = \frac{1}{468} \sum_{U \in \mathcal{U}_6} f(U).}$$

Proof. The operators E_+ and $E_\times$ are commuting orthogonal averaging projectors. The rows and columns of each sum to one; the same is true of their average. From (s,e), (s',e') is reached in two renewals, and the contribution of I provides a self-edge. This proves irreducibility and aperiodicity.

The space decomposes orthogonally into four sectors:

$$\mathbf{1}, \qquad \ell_0^2(\mathcal{S}_+), \qquad \ell_0^2(\mathcal{S}_\times), \qquad \ell_0^2(\mathcal{S}_+) \otimes \ell_0^2(\mathcal{S}_\times).$$

Their dimensions are $1, 17, 25, 17 \cdot 25$. In the constant sector the three summands act as the identity; in each one-coordinate sector they act as (I+I+0); in the interaction sector, as (I+0+0). Dividing by three gives the announced eigenvalues and multiplicities. A finite irreducible and aperiodic kernel has a unique stationary state; since it is doubly stochastic, that state is uniform. □

The theorem is exact relative to the factorization $\mathcal{U}_6 \simeq \mathcal{S}_+ \times \mathcal{S}_\times$, the TPK calendar, and the uniform count of the compatible continuations of each fiber. The family $K_{a,b,c}$ proves that the dynamics do not follow from the census alone. The proposition 6.11 distinguishes the transfer of all paths from the chronology of one of them.

6.3.5 Compensated elevation constructed from the quotient

Let us write $m(U) = |F^{-1}(U)|$. From the kernel already chosen in the quotient we define the kernel of presentations by

$$\boxed{K_{\mathrm{seed}}(x,y) = \frac{K_{\mathrm{cat}}(F(x),F(y))}{m(F(y))}}$$

This kernel is stochastic. Summing over a target fiber yields

$$\sum_{F(y)=V} K_{\mathrm{seed}}(x,y) = K_{\mathrm{cat}}(F(x),V),$$

independently of the representative x. This identity shows that the constructed lift projects exactly onto K_{cat}. It does not prove that a preexisting microscopic dynamics of the enriched TPK state descends to the catalog.

Theorem 6.17 (Reversible elevation constructed from the quotient)**.** *The probability*

$$\widetilde{\tau}(x) = \frac{1}{468\, m(F(x))}$$

is estacionaria and reversible for K_{seed}, and $F_{\#}\widetilde{\tau} = \tau_{468}$. If

$$J_F \delta_U = m(U)^{-1/2} \sum_{F(x)=U} \delta_x, \qquad D = \mathrm{diag}(m(U)),$$

then

$$K_{\mathrm{seed}} J_F = J_F \big(D^{1/2} K_{\mathrm{cat}} D^{-1/2}\big).$$

In particular, Hilbert-space intertwining without conjugation by D occurs if and only if K_{cat} commutes with the fiber multiplicities.

Proof. Normalization follows because each of the 468 fibres receives total mass (1/468). Using the symmetry of K_{cat}, for $F(x) = U$ and $F(y) = V$ we have

$$\widetilde{\tau}(x) K_{\mathrm{seed}}(x,y) = \frac{K_{\mathrm{cat}}(U,V)}{468 m(U) m(V)} = \widetilde{\tau}(y) K_{\mathrm{seed}}(y,x).$$

This proves detailed balance, stationarity, and the identity of the image measure. Applying both sides of the last identity to a basis vector δ_V gives, on the fiber U, the coefficient $K_{\mathrm{cat}}(U,V)/\sqrt{m(V)}$; that is exactly the coefficient of the conjugate operator shown. □

Theorem 6.18 (Phase Lift Faithful to Quiescence)**.** *Let $X = \Omega_{\mathrm{seed}}$, $m(u) = |F^{-1}(u)|$, and let us define*

$$\begin{aligned} L_0(x,y) &= \mathbf{1}_{\{x=y\}}, \\ L_+(x,y) &= \frac{E_+(F(x),F(y))}{m(F(y))}, \\ L_\times(x,y) &= \frac{E_\times(F(x),F(y))}{m(F(y))}. \end{aligned}$$

On $X \times C_9$, let

$$\widehat{\mathcal{K}}_{\mathrm{ph}}\big((x,r),(y,r+1)\big) = L_{\tau(r)}(x,y).$$

Then (F, id_{C_9}) satisfies the property of strong aggregability *(*strong lumpability*) from $\widehat{\mathcal{K}}_{\mathrm{ph}}$ to $\mathcal{K}_{\mathrm{ph}}$. The microscopic kernel is irreducible, has period nine, and its unique stationary state is*

$$\widetilde{\pi}_{\mathrm{ph}}(x,r) = \frac{1}{9 \cdot 468\, m(F(x))}.$$

Its nonadic return satisfies

$$\widehat{\mathcal{K}}^{9}_{\mathrm{ph}}\big((x,r),(y,r)\big) = \frac{1}{468\, m(F(y))}.$$

Proof. The sum of L_+, respectively $L_\times$, over a target fiber is E_+, respectively $E_\times$, and L_0 projects to the identity. This proves aggregability in each phase. The factors $m(F(y))$ cancel under composition: first the active signature is selected uniformly and then a representative of the obtained emission. Thus, L_+ and $L_\times$ are commuting projectors and

$$L_+ L_\times(x,y) = \frac{1}{468\, m(F(y))}.$$

The positivity of this entry connects all representatives in nine steps. The phase forces the return lengths to be multiples of nine, and the diagonal entry of the return is positive. The stationary formula is verified by first summing the $m(u)$ representatives of each emission; each of the $9 \cdot 468$ phase–emission classes receives the same mass. □

This lift improves the reading of the averaged kernel K_{seed}: in the neutral phase it preserves the microscopic representative, instead of silently remixing its fiber. Upon averaging and forgetting the phase, both constructions have the same shadow K_{cat}, but not the same hidden dynamics. The distinction is necessary in order to respect that the zero of TRIT is memory of quiescence.

6.3.6 Minimal congruences stable under advance, half-turn and 4th of a turn: 28 and 162 memory classes

The witness $e_0 = (5,5,5,5,5,5)$ shows that the product signature is too coarse to transport a route. The exact missing minimal memory can be computed. Let

$$\mathcal{X}_\times = X_9 \times \mathscr{D}_{\mathrm{card}}$$

the space of 324 product seeds. Let P denote the advance by one cell in the stored orientation, H the half-turn of that orientation, and Q the quarter-turn

$$N \longmapsto E \longmapsto S \longmapsto O \longmapsto N.$$

Theorem 6.19 (Forward and spin congruences)**.** *The minimal congruence that refines the twenty-six product signatures and is stable under P and H has 28 classes: twenty-seven have size eight, and one has size 108. The only new splitting is*

$$(5,5,5,5,5,5) \longrightarrow \mathcal{L}_0 \sqcup \mathcal{L}_1 \sqcup \mathcal{L}_2, \qquad |\mathcal{L}_j| = 8.$$

Its orbits under P, H have sizes

$$9, \quad 9, \quad 9, \quad 1.$$

By combining this refinement with the eighteen additive signatures one obtains

$$18 \cdot 28 = 504 = 468 + 36.$$

The minimal congruence stable under P and Q has 162 classes of two seeds. Each class is an orbit of the involution

$$J(i,j,d) = \big(7-i,\, 7-j,\, \overline{d}\big) \pmod 9.$$

The operators induced by P, Q act transitively on the 162 classes.

Proof. One begins with the partition by the twenty-six signatures and iteratively refines a class whenever two of its elements have images in distinct classes under any of the generators. The process terminates because $\mathcal{X}_\times$ is finite. For (P, H), the exhaustive census produces the histogram $27 \times 8 + 1 \times 108 = 324$, the four indicated orbits, and three classes over the exceptional fiber of size twenty-four. For (P, Q), it produces $162 \times 2 = 324$. Direct verification proves that J preserves every signature, commutes with both generators, and pairs exactly the two elements of each class; the graph of classes generated by P, Q is connected. □

The excess 36 and the object R_{36} have distinct types. The boundary at depth thirty-six is

$$R_{36} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix},$$

that is, three ordered blocks of six trits, one per channel. It is not a set of thirty-six states. The term $504 - 468 = 36$, for its part, counts additional sheet memory: the half-turn that makes product transport functional adds exactly two new sheets to a single signature and, when repeated over the eighteen additive signatures, produces $18(3 - 1) = 36$. The coincidence of the integer (36) expresses two gradings of transport, boundary depth and sheet multiplicity, but does not authorize identification of their objects.

The quarter-turn Q was not hidden in F_{obs} either. The published chronology contains programmed advances and half-turns; incorporating Q is an explicit enlargement of the route alphabet. Once it is incorporated, a lazy symmetric random walk on $P^{\pm 1}, Q^{\pm 1}$ is irreducible and aperiodic on the 162 classes, and its uniform measure is unique. This is the exact mathematical form of "counting the turns": the turn is a transport coordinate and not a subsequent decimal correction.

6.3.7 Mode and Orientation Cocycles

The same rule makes it possible to define the operational counters without introducing Dimensional Mechanics. Add to the state the last active mode $m \in \{\Sigma, \Pi\}$. A signature $+1$ fixes $m = \Sigma$, a signature -1 fixes $m = \Pi$, and a signature 0 preserves the previous mode. For an arrow a, define the signed cocycle

$$\omega_{\mathrm{sw}}(a) = \begin{cases} +1, & \Pi \longrightarrow \Sigma, \\ -1, & \Sigma \longrightarrow \Pi, \\ 0, & \text{the mode is preserved.} \end{cases}$$

Its positive variation is $s(a) = |\omega_{\mathrm{sw}}(a)|$. We further define $g(a) = 1$ when the ordered pair of cardinal orientations changes and $g(a) = 0$ when it is preserved. Keeping the mode and the terminal orientation fixed at the endpoints, the sums

$$\Omega_{\mathrm{sw}}(\gamma) = \sum_{a \subset \gamma} \omega_{\mathrm{sw}}(a), \qquad S(\gamma) = \sum_{a \subset \gamma} s(a), \qquad G(\gamma) = \sum_{a \subset \gamma} g(a)$$

are additive under concatenation.

In a nonadic closed loop, the sequence of modes is

$$(\Sigma, \Pi, \Pi, \Sigma, \Pi, \Pi, \Sigma, \Pi, \Pi).$$

Therefore,

$$\Omega_{\mathrm{sw}}(C_9) = 0, \qquad S(C_9) = 6 :$$

there are three changes $\Pi \to \Sigma$, three changes $\Sigma \to \Pi$, and three retentions. In the cycle of 108 steps,

$$\#(+1) = \#(-1) = \#(0) = 36, \qquad \Omega_{\mathrm{sw}} = 0, \qquad S = 72, \qquad G = 4.$$

The final number counts the four simultaneous inversions programmed in 27, 54, 81, 108. These cocycles proceed directly from the TPK calendar.

6.3.7.1 Quotient of modes and areal-volumetric correspondence

The calendar sign, mode label, and geometric sheet are three typed objects. In particular, the phase sign is not identified with the angular observable on digits. For the geometric correspondence, we fix the typed HMT reader

$$\mathfrak{g}_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \mathfrak{g}_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

The first assignment expresses the additive or boundary reading; the second, the multiplicative or interior reading. The map $\mathfrak{g}_{\mathrm{av}}$ is part of the sheet typing. The following result proves that, once that typing is fixed, TPK dynamics forces the incidence between them.

Theorem 6.20 (Necessary descent of leaf incidence)**.** *Let m_r be the mode obtained after applying phase r of the primitive block $(+1, -1, 0)$, with the rule*

$$+1 : \ m \mapsto \Sigma, \qquad -1 : \ m \mapsto \Pi, \qquad 0 : \ m \mapsto m.$$

The cyclic orbit of modes is (Σ, Π, Π). If

$$N_3(i, j) := \#\{r \in \mathbb{Z}/3\mathbb{Z} : (m_r, m_{r+1}) = (i, j)\},$$

then, in the order (Σ, Π),

$$\boxed{N_3 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.}$$

By repetition of the calendar,

$$N_9 = 3N_3, \qquad N_{27} = 9N_3, \qquad N_{108} = 36N_3.$$

After applying $\mathfrak{g}_{\mathrm{av}}$, the primitive incidence matrix is, in the order $(\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}})$,

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.}$$

Thus, the two cross transitions, the unique volumetric self-retention, the absence of areal self-retention and the unit primitive multiplicities are consequences of the TPK mode quotient; they are not four added postulates.

Proof. The three consecutive pairs, with cyclic closure, are

$$\Sigma \longrightarrow \Pi, \qquad \Pi \longrightarrow \Pi, \qquad \Pi \longrightarrow \Sigma.$$

Each appears once, and the pair $\Sigma \to \Sigma$ does not appear. This determines the four entries of N_3. The calendars of lengths 9, 27, 108 respectively contain 3, 9, 36 copies of the primitive block, so their incidence matrices are the indicated multiples. The greatest common divisor of the nonzero entries of each long matrix removes only that global repetition and returns N_3. Finally, $\mathfrak{g}_{\mathrm{av}}$ transports Σ, Π to the areal and volumetric sheets without altering the incidence. □

The real hyperbolic realization that uses this matrix and proves its Lorentz invariance is formulated in section 3.5.6; there F_{av} is used as an antecedent, without repeating its derivation.

This theorem must be distinguished from a stronger Markov assertion. Forgetting the phase is not a strong Markov quotient of $\mathcal{K}_{\mathrm{ph}}$: the visible mode does not determine which of the three operators

$I, E_+, E_\times$ acts at the next elementary iteration. What descends without an additional hypothesis is the edge multigraph of a TPK block.

There is, however, a memory-one completion uniquely determined by that descent. Let X_{av} be the smallest subshift of finite type over $\{\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}}\}$ that contains all the words obtained by forgetting the phase and retains only consecutive pairs. Every one-step subshift with that property must admit exactly the three observed pairs; the smallest such subshift excludes the sole unobserved pair. Its adjacency matrix is therefore F_{av}.

Corollary 6.21 (Parry Measure of the One-Memory Wrapper)**.** *The subshift X_{av} is primitive, has topological entropy* $\log\varphi$*, and possesses a unique measure of maximal entropy. Its stationary vertex weights satisfy*

$$\boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.}$$

Proof. The Perron root of F_{av} is φ, and a positive Perron vector is $(1, \varphi)$. Since the matrix is symmetric, the Parry vertex weights are proportional to the product of the left and right vectors, that is, to $(1, \varphi^2)$. □

The Parry measure belongs to the memory-one path envelope. It is not the image of τ_{468}, nor the temporal frequency of the periodic orbit of modes. The latter is

$$\nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{ar}}) = \frac{1}{3}, \qquad \nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{vol}}) = \frac{2}{3},$$

whereas τ_{468} is uniform over emissions, and the Parry measure weights renewal histories of arbitrary length. The three measures answer distinct questions. The irrational ratio φ^{-2} is thus derived canonically from the path envelope, without attributing it to a quotient of finite cardinalities.

From chronological counting to the return marked by π The two formulas

$$\left(\frac{1}{3}, \frac{2}{3}\right) \qquad \text{and} \qquad \frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}$$

are not approximations of one another. The first counts the three instants of the primitive calendar (Σ, Π, Π); the second weights all the admissible histories of the memory-one envelope. Hence the chronological frequency is rational, and the Parry ratio is irrational. In what follows, we write

$$\frac{\pi_{\mathrm{HMT}}}{\varphi^2} = \pi_{\mathrm{HMT}}\varphi^{-2};$$

this is not division by φ^{-2}.

The appearance of φ^{-2} can be seen directly in the linear dynamics. If F_n denotes the n-th Fibonacci number,

$$F_{\mathrm{av}}^{\,n} = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix} \qquad (n \geq 1).$$

The eigenvalues of F_{av} are φ and $-\varphi^{-1}$. The contracted branch reverses orientation in one iteration. Upon passing to the quadratic memory, namely $\mathrm{Sym}^2(\mathbb{R}^2)$, that reversal is recorded before the sign disappears. In the basis $(x^2, 2xy, y^2)$, with the images of the basis vectors represented by rows, the induced operator is

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}, \qquad \chi(t) = (t+1)(t^2 - 3t + 1).$$

Its three eigenvalues are

$$\varphi^2, \qquad -1, \qquad \varphi^{-2}.$$

Thus, φ^{-2} is the positive stable mode of second-order memory. This step explains why the golden ratio appears here as a return law and not as an added statistical mean.

The closure π belongs to another level of the same HMT state: it is the coinductive output of the regional reader already constructed, not a new eigenvalue of F_{av}. Let

$$P_{\mathrm{ar}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad P_{\mathrm{vol}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

Among the positive operators that preserve both sheets, there is exactly one whose volumetric normalization is one and whose areal mark is the generated closure π_{HMT}:

$$D_\pi = \pi_{\mathrm{HMT}} P_{\mathrm{ar}} + P_{\mathrm{vol}}.$$

Uniqueness is relative to these three explicit clauses: positivity, diagonality with respect to the leaves, and the two normalizations. With $e_{\mathrm{ar}} = (1,0)^T$ and $e_{\mathrm{vol}} = (0,1)^T$, the marked return of length n is

$$\Theta_n := \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}} \rangle} = \pi_{\mathrm{HMT}} \frac{F_{n-1}}{F_{n+1}}.$$

Therefore,

$$\boxed{\lim_{n\to\infty} \Theta_n = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.}$$

The mark π_{HMT} is applied only once, at the boundary return; it is not reinjected at every transition. Finite combinatorics produces the stable mode φ^{-2}, the coinductive reader produces the closure π_{HMT}, and D_π composes both data without reversing their causal order.

The native length 108 provides an exact witness to that convergence:

$$(F_{\mathrm{av}}^{108})_{\mathrm{ar,ar}} = F_{107} = 10284720757613717413913,$$

$$(F_{\mathrm{av}}^{108})_{\mathrm{vol,vol}} = F_{109} = 26925748508234281076009.$$

Consequently,

$$\left| \frac{F_{107}}{F_{109}} - \varphi^{-2} \right| = 6.1684979916614407936\ldots \times 10^{-46},$$

and, after the only closing marker,

$$\left| \pi_{\mathrm{HMT}} \frac{F_{107}}{F_{109}} - \frac{\pi_{\mathrm{HMT}}}{\varphi^2} \right| = 1.9378907974286976068\ldots \times 10^{-45}.$$

These errors measure the finite approximation of the return; they are not adjustments of π or of φ.

Cylindrical reader of the ratio. Let $I_n^\pi = [\underline{\pi}_n, \overline{\pi}_n]$ and $I_n^\varphi = [\underline{\varphi}_n, \overline{\varphi}_n]$ be the positive, nested cylinders produced by the two HMT readers. The interval operation

$$Q(I,J) := \left[\frac{\inf I}{(\sup J)^2}, \frac{\sup I}{(\inf J)^2} \right]$$

is the smallest interval containing x/y^2 for every $(x,y) \in I \times J$. It preserves nesting: if the input cylinders are refined, then $Q(I_n^\pi, I_n^\varphi)$ is also refined. Since their diameters tend to zero and the limit of I_n^φ is positive,

$$\bigcap_n Q(I_n^{\pi}, I_n^{\varphi}) = \left\{ \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} \right\}.$$

With the twelve already published base-thousand blocks, the quotient interval forces thirty-five decimal digits:

$$\frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} = 1.19998161486432666111577775331680692\ldots.$$

This construction preserves the provenance of each digit: the numerator comes from the closure cylinder and the denominator from the autoscale.

Algebraic separation between areal reading, volumetric reading and their respective codomains The complete ratio cannot arise from the rational algebra of F_{av} alone. Indeed, its rational spectral functions belong to $\mathbb{Q}(\sqrt{5})$; φ^{-2} is found there, but not the transcendental number π. Consequently, any derivation purporting to obtain π/φ^2 solely from the matrix 2×2 would be ill typed. The transcendental datum must derive from the coinductive closure reader, or from an equivalent boundary cocycle proved independently. This negative control fixes the division of labor between the finite correspondence and the number reader.

Exchange involution of the quotient The correspondence admits two exact orientations of the same law. If

$$\mathscr{R}(x, y) = \frac{x}{y^2}, \qquad \mathsf{J}(x, y) = (y, x),$$

then $\mathsf{J}^2 = I$ and

$$\mathscr{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \qquad (\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \frac{\varphi}{\pi^2}.$$

The identities are also verified.

$$\mathscr{R}(\pi, \varphi)\mathscr{R}(\varphi, \pi) = \frac{1}{\pi\varphi}, \qquad \frac{\mathscr{R}(\pi, \varphi)}{\mathscr{R}(\varphi, \pi)} = \left(\frac{\pi}{\varphi}\right)^3.$$

Writing $\mathcal{B}_{\mathrm{av}}^{(\pi)} = \mathscr{R}(\pi, \varphi)$ also yields the exact reparametrization

$$\frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 \left(\mathcal{B}_{\mathrm{av}}^{(\pi)}\right)^2}, \qquad e^{\varphi/\pi^2} = \exp\left[\frac{1}{\varphi^3 \left(\mathcal{B}_{\mathrm{av}}^{(\pi)}\right)^2}\right].$$

Thus, the change of orientation between closure and growth transports the boundary ratio to its exchanged reading:

$$\frac{\pi}{\varphi^2} \overset{\mathsf{J}}{\longleftrightarrow} \frac{\varphi}{\pi^2}.$$

The first orientation reads the marked areal closure over quadratic volumetric memory; the second reads interior growth over quadratic closure. This correspondence is a theorem of the HMT reader. Dimensional Mechanics subsequently applies the second orientation within the electronic construction, without converting the electron into an antecedent of π, φ, or of the correspondence.

Ambivalence Principle of the areal and volumetric readers The Ambivalence Principle asserts that the areal reading and the volumetric reading are two coordinated, but not interchangeable, functionals of one and the same state with memory. Their coincidence on the diagonal is

$$\mathcal{L}_{\mathrm{ar}}^{\mathrm{diag}}(x) = \mathcal{L}_{\mathrm{vol}}^{\mathrm{diag}}(x).$$

The diagonal equality does not erase the ambivalence outside of it.

On the areal–volumetric boundary, both readers factor through the same positive memory amplitude $\mathcal{M}(x)$:

$$\mathcal{L}_{\mathrm{vol}}(x) = \mu_{\mathrm{vol}}\mathcal{M}(x), \qquad \mathcal{L}_{\mathrm{ar}}(x) = \pi_{\mathrm{HMT}}\mu_{\mathrm{ar}}\mathcal{M}(x).$$

Then the Parry theorem and the return mark give

$$\boxed{\frac{\mathcal{L}_{\mathrm{ar}}(x)}{\mathcal{L}_{\mathrm{vol}}(x)} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.}$$

With volumetric normalization, the relative difference of readers is

$$\frac{\mathcal{L}_{\mathrm{ar}} - \mathcal{L}_{\mathrm{vol}}}{\mathcal{L}_{\mathrm{vol}}} = \frac{\pi_{\mathrm{HMT}}}{\varphi^2} - 1 = 0.1999816148643266611\ldots.$$

The physical reading of this correspondence is undertaken later, in the Cartan–Holst chapter, after constructing holonomy, co-tetrad, connection, torsion, and curvature. Here the result is entirely HMT: an exact ratio between two readers of the same sheet memory.

They should be distinguished from the enriched extractor subsequently used in Dimensional Mechanics. There a complete history preserves the action count n_A, the twelve oriented events $e_0, \ldots, e_{11}$ and the torsional cochain at step level; these yield

$$s_C = \sum_{i=0}^{5}(e_i + e_{i+6}), \qquad W_{\pm} = 6n_A \pm s_C.$$

The channels already generated by HMT then satisfy the exact identity

$$\exp\!\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6}C^*_{\mathrm{rad}}\right) = \left(q_+^{-W_+}q_-^{-W_-}\right)^{1/12}.$$

Therefore, the route–angular-character passage is not absent: it is realized on the enriched dodecaphase record. What this phase calculation proves by itself are $\Omega_{\mathrm{sw}}, S, G$; it neither replaces them nor permits reconstruction of the complete record after it has been projected.

The uniform measure on the 104 976 presentations descends to atoms of masses $1/729$, $1/243$ and $1/54$, but not to $1/468$. In the fivefold microfiber of π, the two probabilities are

$$\tau_{468}(\mathscr{R}_\pi) = \frac{5}{468}, \qquad F_{\#}\mu_{\mathrm{seed}}(\mathscr{R}_\pi) = \frac{7}{729}.$$

Both the averaged lift and the phase lift realize the first: they do not push forward the uniform measure on seeds, but assign the same total mass to each observable class. The phase lift also preserves microscopic stillness at neutral steps.

To relate phase elevation to the enriched histories of depth six, a kernel $\mathcal{K}_6$ on $\mathcal{H}_6^{\mathrm{cat}} \times C_9$ is required. It descends to $\widehat{\mathcal{K}}_{\mathrm{ph}}$ through $\rho_6 \times \mathrm{id}_{C_9}$ if and only if it satisfies, at each phase, the strong lumpability condition

$$\sum_{\rho_6(g)=y} \mathcal{K}_6((h,r),(g,r+1)) = L_{\tau(r)}(\rho_6(h), y),$$

independently of h within each fiber of ρ_6. In that case, composition with F projects to $\mathcal{K}_{\mathrm{ph}}$. Constructing a family $(\mathcal{K}_m)_{m\geq 6}$ that satisfies this identity and commutes with all truncations is the remaining step toward a transfer of the inverse limit.

6.3.8 Scale cocycle and cylindrical conservation

Let $r = (1, \varphi)$ be a Perron–Frobenius vector of F_{av}. The Parry transition matrix is

$$P_{ij} = \frac{(F_{\mathrm{av}})_{ij} r_j}{\varphi r_i} = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}.$$

For an admissible route $\gamma : i \to j$ of length n,

$$\mathbb{P}(\gamma \mid i) = \frac{r_j}{\varphi^n r_i}, \qquad \boxed{\chi_P(\gamma) = \varphi^n \frac{r_i}{r_j}.}$$

The telescope proves

$$\chi_P(\gamma_2 \circ \gamma_1) = \chi_P(\gamma_2)\chi_P(\gamma_1).$$

On a closed route, $\chi_P = \varphi^n$; its square and its inverse generate the combinations

$$C_n = \frac{\chi_P^2 + \chi_P^{-2}}{2}, \qquad S_n = \frac{\chi_P^2 - \chi_P^{-2}}{2},$$

which satisfy

$$x_{n+1} = 3x_n - x_{n-1}.$$

Since F_{av} is symmetric, let

$$\ell = \frac{r}{1 + \varphi^2}, \qquad \ell^{\mathsf{T}} r = 1.$$

The measure of a cylinder is

$$\mu[x_0 \cdots x_n] = \ell_{x_0} r_{x_n} \varphi^{-n}.$$

Therefore,

$$\boxed{V_n(x) = \frac{\mu[x_0]}{\mu[x_0 \cdots x_n]} = \varphi^n \frac{r_{x_0}}{r_{x_n}} = \chi_P(x_0 \cdots x_n).}$$

For a typed dimension scale $D > 0$,

$$a_n^{(D)}(x) = V_n(x)^{1/D}$$

satisfies the cylindrical conservation law

$$\boxed{\left(a_n^{(D)}(x)\right)^D \mu[x_0 \cdots x_n] = \mu[x_0].}$$

In spatial rank three and on closed returns, we write $a_n := a_n^{(3)}$ and obtain

$$\boxed{\frac{a_9}{a_0} = \varphi^3, \qquad \frac{a_{27}}{a_0} = \varphi^9, \qquad \frac{a_{108}}{a_0} = \varphi^{36}.}$$

If $A_k := a_{9k}$ for $k \geq 1$, then, for $k \geq 2$,

$$A_{k+1} - 2A_k + A_{k-1} = A_{k-1}(\varphi^3 - 1)^2 > 0.$$

The inequality proves convexity in return depth; a physical acceleration further requires a duration chart.

The primary computation of $\mathrm{Sym}^2(F_{\mathrm{av}})$ in section 6.3.7.1 shows that its spectrum is $\{\varphi^2, -1, \varphi^{-2}\}$. Here we conserve only the corollary for the scale cocycle: on a closed route with $V_n = \varphi^n$, the stable mode obeys

$$\boxed{M_n = \varphi^{-2n} = V_n^{-2}.}$$

Identification of these three eigenspaces with the three TRIT sheets requires an intertwiner; coincidence of cardinality does not replace it. The corollary would be refuted if the closed route failed to satisfy $V_n = \varphi^n$ or if the stable mode did not have eigenvalue φ^{-2}.

6.3.9 Dynamic prolongation theorem: global hypotheses and certified domain

The following objects have been explicitly constructed and separated from the finite problem:

$$F, \qquad F_{\mathrm{obs}}, \qquad \mathcal{K}_{\mathrm{ph}}, \qquad \widehat{\mathcal{K}}_{\mathrm{ph}}, \qquad K_{\mathrm{cat}}, \qquad \tau_{468}, \qquad F_{\mathrm{av}}, \qquad \mathrm{Sym}^2(F_{\mathrm{av}}), \qquad D_\pi, \qquad Q.$$

For F_{obs}, deterministic return has been proved and an explicit witness of failure to descend as a product has been exhibited. For $\mathcal{K}_{\mathrm{ph}}$, double stochasticity, irreducibility, period nine, uniform nonadic return, and uniqueness of π_{ph} have been proved. For $\widehat{\mathcal{K}}_{\mathrm{ph}}$, strong lumpability, microscopic conservation of rest, and the compensated stationary measure have been proved. K_{cat} is no longer an average without provenance: it is the shadow of one step after the uniform phase is averaged. The TPK mode quotient induces F_{av}; its quadratic lift separates the modes $\varphi^2, -1, \varphi^{-2}$. The operator D_π marks the boundary return exactly once with the generated closure, and the interval reader Q preserves the nesting of the cylinders of π and φ. These four objects construct $\pi_{\mathrm{HMT}}/\varphi^2_{\mathrm{HMT}}$ without conflating temporal frequency, the uniform measure, and the Parry measure.

The force of this induction is relative and concrete. The TPK word forces the weights $1/3$. The APP interpretation of all compatible continuations, together with uniform counting, forces E_+ and $E_\times$. The deterministic trajectory F_{obs} does not force those operators and, indeed, does not produce them. This is not a defect of the result, but the mathematical difference between evolution along a path and transfer over a space of paths.

The finite conclusion is complete in its domain: the uniform return, the stationary measure, the lumpability at depth six, and the separation between evolution of a route and transfer of the route space remain proved by the constructed objects. In particular, $\widehat{\mathcal{K}}_{\mathrm{ph}}$ is not identified with the chronology of F_{obs}, as proposition 6.11 shows.

6.4 Correlative construction of the continuum: histories, transport, incidence and terminal

The arithmetic published by a normal form preserves a precise reading of the state that produces it. To situate that reading within HMT, the histories, sheets and operations acting on them must also be retained. This chapter brings together that common substrate. Its various constructions are obtained from the same APP–TRIT–TPK execution tree; the divisions of the exposition allow their properties to be studied without turning them into independent domains chosen by a subsequent application.

The starting point is the formal kernel presented above. An admissible emission contains the APP operation, the TRIT orientation, the sheet change, the residue and quotient, together with the effective TPK memory update. When only a residue is published, the execution history still belongs to the starting object. Two executions with identical final readings are not identified for that reason alone.

6.4.1 Admissible histories and memory by composition

Let X_k be the set of admissible histories of length k. Its elements are constructed by successive emissions from the kernel's initial domain. We write $h\varepsilon$ for the prolongation of h by an admissible emission ε, and $\rho_k(h\varepsilon) = h$ for removal of the last emission. The emission label is preserved, even when different labels produce the same published state.

On the two arithmetic sheets, the local data satisfy the exact divisions

$$\delta_\diamond = r_\diamond + 9q_\diamond, \qquad 0 \le r_\diamond < 9, \qquad \diamond \in \{\Sigma, \Pi\}.$$

The oriented TRIT coordinate likewise admits an expression $\Delta = o_r + 3\kappa$, with the oriented representative declared by the kernel. Preservation of the quotient allows these publications to be composed without replacing an emission by its isolated residue.

In a memory chart, the update of an emission is written

$$U_\varepsilon(m) = C_\varepsilon m + \kappa_\varepsilon.$$

For a trajectory $\alpha = (\varepsilon_1, \dots, \varepsilon_k)$, the effective operation is the ordered composition of these updates. Its linear part and its translation are

$$C_\alpha = C_{\varepsilon_k} \cdots C_{\varepsilon_1}, \qquad \kappa_\alpha = \sum_{j=1}^{k} C_{\varepsilon_k} \cdots C_{\varepsilon_{j+1}} \kappa_{\varepsilon_j}.$$

The empty product in the last sum is the identity.

Proposition 6.22 (Affine compatibility of concatenation)**.** *If α precedes β, then*

$$C_{\beta\alpha} = C_\beta C_\alpha, \qquad \kappa_{\beta\alpha} = C_\beta \kappa_\alpha + \kappa_\beta, \qquad U_{\beta\alpha} = U_\beta U_\alpha.$$

Proof. Substituting $U_\alpha(m)$ into U_β produces $C_\beta C_\alpha m + C_\beta \kappa_\alpha + \kappa_\beta$. Decomposition into linear part and translation gives the three identities. Associativity of composition proves that the result does not depend on an auxiliary subdivision of the trajectory. □

This cocycle identity is the precise content of accumulated memory. The quantity transported by a second trajectory depends on the chart update it performs; in general, it is not the sum of two registers without transport.

The nonadic return preserves a second distinction. In phase and turn coordinates, with $\bar{r} \in \{0, \dots, 8\}$, its publication is

$$\sigma_9(w, r) = \left(w + \left\lfloor \frac{\bar{r} + 1}{9} \right\rfloor, r + 1 \pmod 9 \right), \qquad \sigma_9^9(w, r) = (w + 1, r).$$

During nine steps, exactly one crossing from 8 to 0 occurs. The phase returns and the turn coordinate increases. The enriched holonomy also retains the memory updates accompanying that path.

6.4.2 Tree refinement and measure of histories

The finite nonempty initial set of admissible seeds is fixed, with strictly positive initial mass summing to 1. In this section each history has a finite positive number of prolongations. Removal of emissions defines the refinement maps. Kernel admissibility provides the prolongations; when a residence uses a neutral emission, this explicitly gives a section of ρ_k. Existence of that section refers to the tree including that emission, not to any arbitrary restriction of routes.

Let $d(h) \geq 1$ be the number of admissible emissions at h. Equiprobable choice among its children defines

$$\mu(h\varepsilon) = \frac{\mu(h)}{d(h)}.$$

More generally, a positive local distribution $p(\varepsilon \mid h)$, whose sum is 1, defines $\mu(h\varepsilon) = \mu(h)p(\varepsilon \mid h)$. This second formulation preserves the reader's weights when the numbers of prolongations are not uniform.

Proposition 6.23 (Cylindrical compatibility and conditional expectation)**.** *At each level we have*

$$\sum_{\rho_k(y)=x} \mu(y) = \mu(x).$$

In the spaces $L^2(X_k, \mu_k)$, the maps

$$(J_k f)(y) = f(\rho_k(y)), \qquad (E_k g)(x) = \sum_{\rho_k(y)=x} \frac{\mu(y)}{\mu(x)} g(y)$$

satisfy $E_k = J_k^*$, $E_k J_k = I$ and $\|J_k f\| = \|f\|$.

Proof. The first identity is normalization of the local probabilities. Applying it to $|f(x)|^2$ yields isometry. Grouping by parents the sum defining $\langle J_k f, g\rangle$ gives the formula for E_k; on a function constant on each fiber, that formula returns its value. □

The compatible masses define a probability measure on the space of infinite histories: the cylinder of a finite history receives its mass $\mu(h)$. The measure extends from the cylinder algebra, and its uniqueness follows because these generate the sigma-algebra. If the tree is finitely branching and each history has a prolongation, the inverse limit of its levels under emission removal is nonempty. In the cylindrical topology, each nonempty cylinder has positive measure.

This measure distinguishes histories converging to the same publication. The uniform measure on terminal values would be a different reading, since it would eliminate the multiplicities that the construction has just preserved.

6.4.3 Transport by sheets and exact accounting of outputs

First consider the space with orthonormal basis consisting of the histories of level k. The transport preserving the label of each prolongation is

$$\mathcal{U}_k e_h = \sum_{\varepsilon \text{ admisible en } h} \sqrt{p(\varepsilon \mid h)}\, e_{h\varepsilon}.$$

The sets of children of distinct parents are disjoint. Normalization of p therefore proves $\mathcal{U}_k^* \mathcal{U}_k = I$. The representation through history masses is related to this one by the diagonal change of basis incorporating $\sqrt{\mu(h)}$.

The sheet label is part of the complete register of a history. We write

$$\widehat{h} = ((h_0, s_0), \ldots, (h_k, s_k)), \qquad s_j \in \{\Sigma, \Pi\},$$

where s_j is the active sheet at step j. Prolongation adds the emission and the sheet s_{k+1} determined by the operational TPK selector, preserving the entire prefix, including the initial sheet. In the basis of these lifted histories,

$$\mathcal{U}_k e_{\widehat{h}} = \sum_{\varepsilon \text{ admisible en } \widehat{h}} \sqrt{p(\varepsilon \mid \widehat{h})}\, e_{\widehat{h}\varepsilon}, \qquad P_k e_{\widehat{h}} = \mathbf{1}_{s_k=\Sigma} e_{\widehat{h}}, \quad Q_k = I - P_k.$$

Thus, P_k reads the current sheet, while histories remain distinguished by their complete prefix. Two initial histories reaching the same active sheet still have distinct children. The isometry proof by disjoint families of prolongations applies literally to this basis. Tritic orientation is another register coordinate: the value 0 preserves the threshold reading on each sheet and does not add a third sheet to this decomposition. We now separate sheet preservation and sheet exchange:

$$A_k = P_{k+1} \mathcal{U}_k P_k + Q_{k+1} \mathcal{U}_k Q_k, \qquad \eta_k = Q_{k+1} \mathcal{U}_k P_k + P_{k+1} \mathcal{U}_k Q_k.$$

Proposition 6.24 (Gram identity by sheets)**.** *For a linear transport U, whether isometric or not, the preceding decomposition satisfies*

$$A^*A + \eta^*\eta = PU^*UP + QU^*UQ.$$

In particular, for $U = \mathcal{U}_k$,

$$A_k^*A_k + \eta_k^*\eta_k = I.$$

Proof. In A^*A and $\eta^*\eta$, mixed terms containing $P_{k+1}Q_{k+1}$ vanish. Summing the remaining terms yields $P_kU^*(P_{k+1} + Q_{k+1})UP_k$, and its analogue with Q_k. The first identity follows from complementarity of the projectors; the second also uses $U^*U = I$. □

The first identity is the general formula. Replacing its right-hand side by U^*U requires the cross blocks of that Gram matrix to vanish. Isometric preservation of history transport provides that condition here; it should not automatically be attributed to a subsequent compression.

Write $F_{0,0} = I$, $F_{0,n} = A_{n-1} \cdots A_0$ and $T_N = F_{0,N}^* F_{0,N}$.

Theorem 6.25 (Finite decomposition with terminal residual)**.** *For each horizon N,*

$$I = \sum_{n=0}^{N-1} F_{0,n}^* \eta_n^* \eta_n F_{0,n} + T_N.$$

The sequence T_N is positive and decreasing, and has a positive strong limit T_∞. The sum of outputs converges strongly to $I - T_\infty$.

Proof. Proposition 6.24 gives $T_n - T_{n+1} = F_{0,n}^* \eta_n^* \eta_n F_{0,n}$. The telescoping sum proves the finite equality and monotonicity. For each vector, the quadratic forms decrease to a limit; polarization defines a bounded positive form and, by the representation theorem for bounded forms, an operator T_∞. Convergence is strong because, for a positive operator $S \le I$, $\|Sv\|^2 \le \langle v, Sv\rangle$; this is applied to $S = T_N - T_\infty$. □

The terminal residue is retained until its extinction in the domain under consideration is proved. This distinction prevents a phase return, by itself, from becoming an assumption of exhaustion of all histories.

6.4.4 Oriented balance and cancellation under refinement

A history carries its accumulated orientation $o(h)$ and counts of its visits to the two sheets. The corresponding local balance is

$$b(h) = o(h)\big(N_\Sigma(h) - N_\Pi(h)\big), \qquad b^+ = \frac{|b| + b}{2}, \quad b^- = \frac{|b| - b}{2}.$$

When a reader publishes the mean over prolongations, $b_c = Eb_f$ is defined. Orientation remains in the argument of b_f; it is not removed before averaging.

Proposition 6.26 (Exact cancellation defect)**.** *The quantity*

$$\kappa_{\mathrm{can}} = \frac{E|b_f| - |Eb_f|}{2}$$

is nonnegative and satisfies

$$E(b_f^+) = (b_c)^+ + \kappa_{\mathrm{can}}, \qquad E(b_f^-) = (b_c)^- + \kappa_{\mathrm{can}}.$$

Proof. The weighted triangle inequality gives $|Eb_f| \le E|b_f|$. Writing the positive and negative parts through $(|b| \pm b)/2$ yields both equalities. □

The information omitted by publishing only the balance is the common cancellation of opposite contributions. This quantity is determined from the same prolongations used by the preceding transport. The factor $1/9$ appears only when the fiber contains nine children with equal weights; conditional expectation is the rule that remains valid for general branching and weights.

6.4.5 Ternary incidence of the sheets and rectangular complex

The two sheets determine the module $V = \mathbb{F}_3 e_\Sigma \oplus \mathbb{F}_3 e_\Pi$. Its four projective directions are the lines generated by $e_\Sigma, e_\Pi, e_\Sigma + e_\Pi, e_\Sigma - e_\Pi$. They give rise to six unordered pairs. The eight nonzero vectors are their oriented representatives. Thus, the counts $4, 6, 8$ belong to distinct operations on the same sheet module.

On the six pair positions, we define

$$(Ba)_{\{L,L'\}} = a_L + a_{L'}, \qquad s(q) = \sum_{\{L,L'\}} q_{\{L,L'\}}.$$

Each direction occurs in three pairs; hence $sB = 0$ in $\mathbb{F}_3$. The reader $W(q) = \mathbf{1}_{s(q)=0} - 1/3$ is invariant under $q \mapsto q + Ba$. On the uniform ambient space $\mathbb{F}_3^6$, its moments are

$$\mathbb{E}W = 0, \qquad \mathbb{E}W^2 = \frac{2}{9}, \qquad \mathbb{E}W^3 = \frac{2}{27}.$$

Indeed, s is surjective and each fiber contains 3^5 elements. The reader equals $2/3$ with probability $1/3$ and $-1/3$ with probability $2/3$. These means describe the uniform ambient space; the distribution induced by a subset of histories must be calculated with its own multiplicities, already preserved in X_k.

To fix the ports without losing multiplicities, at depth k the labeled readings $\lambda_\Sigma(h) = (h, \Sigma)$ and $\lambda_\Pi(h) = (h, \Pi)$ are retained. Their sets are

$$I_k = \{\lambda_\Sigma(h) : h \in X_k\}, \qquad J_k = \{\lambda_\Pi(h) : h \in X_k\}.$$

They are finite and nonempty because X_k is. Values, quotients and residues are published on these ports; equality of values does not identify their labels. The product $I_k \times J_k$ is the domain of the rectangular reading, within which the support of admissible incidences is recorded.

With this level fixed, write $I = I_k$, $J = J_k$ and $A_N = \mathbb{Z}/3^N\mathbb{Z}$. Choose reference ports i_0, j_0. This choice only provides coordinates for the reconstruction formulas. The maps

$$\kappa(u, v)_{ij} = u_i - v_j, \qquad (\delta w)_{ij} = w_{ij} - w_{ij_0} - w_{i_0 j} + w_{i_0 j_0}$$

define the following sequence, valid over the finite ring A_N:

$$0 \longrightarrow A_N \longrightarrow A_N^I \oplus A_N^J \xrightarrow{\kappa} A_N^{I \times J} \xrightarrow{\delta} A_N^{(I\setminus\{i_0\})\times(J\setminus\{j_0\})} \longrightarrow 0.$$

Proposition 6.27 (Exactness of rectangular incidence)**.** *The preceding sequence is exact, with first arrow given by the constant diagonal.*

Proof. The equality $u_i - v_j = 0$ for each pair forces all coordinates of u and v to be the same constant. Direct substitution gives $\delta\kappa = 0$. If $\delta w = 0$, take $u_i = w_{ij_0}$ and $v_j = w_{i_0 j_0} - w_{i_0 j}$. Then $u_i - v_j = w_{ij}$. Finally, any matrix of the last term is extended with zero reference row and column; its image under δ is the initial matrix. The proof uses only addition and subtraction, so it does not require division by a unit of the ring. □

Reducing from A_{N+1} to A_N, keeping k, I_k, J_k, i_0, j_0 fixed, commutes with both maps. The reconstruction formulas are the same at each modular depth. This is the arithmetic compatibility proved in this

section. Prolongation of histories $k \to k+1$ preserves prefix labels; its maps between sets of ports are data distinct from the change of ring $N \to N+1$.

These maps are obtained from emission removal:

$$\rho_k^{\Sigma}(h\varepsilon, \Sigma) = (h, \Sigma), \qquad \rho_k^{\Pi}(h\varepsilon, \Pi) = (h, \Pi).$$

A reference history with compatible prolongations is fixed, whose existence was proved for the tree without terminal leaves. Its two labels define compatible reference ports at all levels. Coordinate transport is precomposition:

$$(L_k u)_{i'} = u_{\rho_k^{\Sigma}(i')}, \quad (L_k v)_{j'} = v_{\rho_k^{\Pi}(j')}, \quad (L_k w)_{i'j'} = w_{\rho_k^{\Sigma}(i'),\rho_k^{\Pi}(j')}.$$

For the last module of the sequence, the matrix is first extended by zero in the reference row and column, this same formula is applied and the result is restricted to the new complement of the reference ports. This rule defines L_k even when a new port has the marked port as its parent.

Proposition 6.28 (Naturality of the rectangular complex under prolongation)**.** *The preceding maps satisfy $L_k\kappa_k = \kappa_{k+1}L_k$ and $L_k\delta_k = \delta_{k+1}L_k$. They also commute with coefficient reduction $A_{N+1} \to A_N$ and compose according to prefix removal.*

Proof. The first identity follows from $u_{\rho_k^{\Sigma}(i')} - v_{\rho_k^{\Pi}(j')}$. In the second, each of the four terms defining δ is transported by the same precomposition. Compatibility of the marked ports identifies their rows and columns; when a parent is the marked port, the four terms cancel and agree with extension by zero. All formulas are sums and differences with integer coefficients, so they commute with modular reduction. Composition of precompositions is precomposition with the composite prefix, proving the last assertion. □

6.4.6 Memory complex and compatibility of incidences

The same accumulated memory coordinate $c_y \in \mathbb{Z}$, at a residence y, defines a free integer complex. Its reduction to A_N uses the same integer register before reduction; successive depths are therefore compatible. Its generators are f_y in degree 2, e_y, b_y, r_y in degree 1, and g_y in degree 0:

$$\partial f_y = 3c_y e_y + b_y, \qquad \partial e_y = g_y, \qquad \partial b_y = -3c_y g_y, \qquad \partial r_y = 0.$$

The identity $\partial^2 = 0$ is verified on f_y through $3c_y g_y - 3c_y g_y = 0$, and is immediate on the other generators.

If a trajectory $\alpha : y \to y'$ updates memory, its transport in the complex sends the correspondingly named generators to their new representatives, except

$$\Psi_\alpha(b_y) = b_{y'} + 3(c_{y'} - c_y)e_{y'}.$$

Proposition 6.29 (Naturality of the memory complex)**.** *We have $\partial\Psi_\alpha = \Psi_\alpha\partial$ and $\Psi_{\beta\alpha} = \Psi_\beta\Psi_\alpha$. The maps extend linearly over the chosen coefficient ring.*

Proof. On f_y, the image of its boundary is $3c_y e_{y'} + b_{y'} + 3(c_{y'} - c_y)e_{y'} = 3c_{y'}e_{y'} + b_{y'}$. On b_y, the boundary of its image is $-3c_{y'}g_{y'} + 3(c_{y'} - c_y)g_{y'} = -3c_y g_{y'}$. The other two cases are immediate. In a concatenation, memory differences sum telescopically, proving the second identity. □

The relation between two representatives of the same residence can also be written as an explicit boundary. For an integer coordinate v, reduced in the same ring where appropriate, let

$$z^- = r_y, \qquad z^+ = r_y + 3c_y v e_y + v b_y, \qquad h_* = -v f_y.$$

Then $\partial h_* = z^- - z^+$. Under a transport that also updates v, the correction $K_\alpha = (v_{y'} - v_y) f_{y'}$ satisfies $K_{\beta\alpha} = K_\beta + \Psi_\beta K_\alpha$. The symbols K_α of this local homotopy do not denote the dodecaphasic seal K: they belong to another domain and their function is specified by the preceding identity. Their function can also be checked in the equality

$$z^+_{y'} - \Psi_\alpha z^+_y = \partial K_\alpha.$$

Both sides equal $(v_{y'} - v_y)(3c_{y'} e_{y'} + b_{y'})$.

Proposition 6.30 (Homology and memory of the local complex)**.** *Over $\mathbb{Z}$, or after reduction to A_N, we have*

$$H_0(\Gamma) = H_2(\Gamma) = 0, \qquad H_1(\Gamma) \cong A_N[r_y]$$

in the modular realization, and $H_1(\Gamma) \cong \mathbb{Z}[r_y]$ in the integer realization.

Proof. Define the homotopy of degree 1 by $h(g_y) = e_y$, $h(b_y) = f_y$, and zero on the other generators. Let p be the projection onto the summand generated by r_y and ι its inclusion. Checking on each generator gives

$$\partial h + h\partial = I - \iota p.$$

In particular, on b_y the terms $3c_y e_y$ and $-3c_y e_y$ cancel. The complex deformation retracts onto the module generated by r_y, concentrated in degree 1, which proves the assertion. □

The transport Ψ_α is a shear of determinant 1. Thus, this complex explicitly preserves how c_y changes at the chain level, but its local homology does not distinguish the values of that coordinate. The full memory remains in the labels and transports of the source state; it is not recovered from H_1 alone. A memory-dependent numerical torsion requires the specified assembly and determinantal reading, in addition to this local complex.

6.4.7 Assembly with terminal paths

For a finite horizon, the residences and their prolongations form a path category. Each residence ν is assigned the free module $W(\nu) = A_N[\mathrm{Path}(\nu, \mathrm{Term})]$, which preserves each terminal continuation as a generator. An initial path acts on W by precomposition. The complex $\Gamma(\nu)$ of the preceding section acts covariantly through Ψ.

The assembly uses both transports in the same bigraded module:

$$\mathcal{B}_{q,r} = \bigoplus_{\nu_0 \to \cdots \to \nu_q} W(\nu_q) \otimes_{A_N} \Gamma_r(\nu_0).$$

The normalized path complex is used: degenerate chains containing identities are omitted. The finite horizon then bounds the number of strict prolongations and the horizontal degree. The horizontal boundary removes an intermediate residence by composing the adjacent arrows. At the first endpoint it transports Γ; at the last it precomposes W. The alternating signs yield the path boundary d_{bar}. The total differential is

$$D = d_{\mathrm{bar}} + (-1)^q \partial_\Gamma.$$

The face identities cancel the terms of d^2_{bar} in pairs. The naturality of Proposition 6.29 implies that d_{bar} commutes with ∂_Γ; the factor $(-1)^q$ cancels the cross terms of the square. Therefore, $D^2 = 0$. Compatibility is proved on path generators and is not introduced by a label of membership in a complex.

Terminal evaluation likewise does not require choosing a particular history. For each continuation h, the effective composition of its updates is applied. The result preserves the pair formed by h and its reading, with its multiplicity. If $k < \ell < N$, the continuations decompose as a disjoint union of prefixes up to ℓ and their continuations up to N. Proposition 6.22 proves that evaluating directly or evaluating these two parts produces the same reading. This yields the naturality square of the terminal.

The path modules, incidences, memory transport and their differentials arise from the same prolongations. Their assembly does not consist in adding to a state five coordinates that would be preserved by definition: their relations are constructed through sums, boundaries and effective compositions, and are verified on their generators.

6.4.8 Determinants, limit and arithmetic reading

At each residence, the free local complex Γ admits its graded determinant line

$$\operatorname{Det}\Gamma = \bigotimes_{r} \left(\bigwedge^{\operatorname{rk}\Gamma_r} \Gamma_r \right)^{(-1)^r}.$$

The total assembly of the preceding section, in turn, has the modules $\operatorname{Tot}_d \mathcal{B} = \bigoplus_{q+r=d} \mathcal{B}_{q,r}$. At a finite horizon and over the same ring, they are free of finite rank and only finitely many of them are nonzero. Its line is

$$\operatorname{Det}(\operatorname{Tot}\mathcal{B}) = \bigotimes_{q,r} \left(\bigwedge^{\operatorname{rk}\mathcal{B}_{q,r}} \mathcal{B}_{q,r} \right)^{(-1)^{q+r}}.$$

This formula follows from decomposition as a direct sum in each degree. It distinguishes the line of the local complex from that of the assembly with all paths; their bases are ordered through the preserved labels. Modular reduction commutes with these exterior powers because the modules and their bases come from the same free integer modules at a fixed horizon. The line is defined by the modules and their degrees, both over $\mathbb{Z}$ and after reduction to A_N; the negative exponent denotes the dual module. A nonzero numerical torsion additionally requires specifying the complex over a field, the bases and the relevant homology identifications. To calculate Smith factors, the integer matrix produced before reduction is used, not an arbitrary lift of a modular matrix. A square integer block with nonzero determinant is invertible over $\mathbb{Q}$; its reduction is invertible over A_N only when that determinant is a unit, that is, when it is not divisible by 3. Refinement of memories and incidences allows the stability of the relevant invariant factors to be formulated and checked; these conditions do not follow from the existence of the determinant line.

Passage to the limit preserves the compatible projective systems of residues, the histories and their multiplicities. The squares proved in the preceding sections remain commutative because their maps are given by the same formulas at each level. For an Archimedean coordinate, the additional step consists in publishing nonempty cylindrical intervals, compatible by inclusion and with diameter tending to zero. Their nested compact closures have a single-point intersection: existence follows from compactness and uniqueness from the diameter bound. This is the value of the limit reading. If the intervals are half-open, the point may belong only to their closures; the boundary representation rule then determines its positional notation. The value does not replace the history that produced it. The other publication preserves the incidences of the same state. The two destinations share their origin without thereby receiving the same information.

In the following chapters, the coinductive regions, dodecaphasic register and exceptional incidence are published from that substrate with their respective maps. The Hilbert realization then preserves the phase labels and specifies its own unital inclusion; duality and screens act on the codomains constructed there. The joint operations assembled here transmit histories, sheets, orientation and memory to those publications. Identifying a specific functional with an external analytic form requires, in turn, writing its

action on the generators and verifying its inner products: the conservation identities of this chapter do not replace that composition.

6.4.9 Provenance, verification and scope

The five operations are recognized by their action on the same histories and by the relations proved in the preceding sections. The affine transport U_α of memory and the linear transport $\mathcal{U}_k$ of histories have the respective domains of Sections 6.4.1 and 6.4.3. The sheet grading is $\sigma_k = P_k - Q_k$. For a history $h_j = (\varepsilon_1, \dots, \varepsilon_j)$, accumulation of the balance is made explicit through

$$M_0^{\pm} = 0, \qquad M_k^{\pm}(h_k) = \sum_{j=1}^{k} b^{\pm}(h_j), \qquad M_{k+1}^{\pm}(h_k\varepsilon) = M_k^{\pm}(h_k) + b^{\pm}(h_k\varepsilon).$$

Each summand is the signed reading of the corresponding prefix, defined in Section 6.4.4. Separating the last summand proves the update; the identities $M_k^+ - M_k^- = \sum_{j=1}^k b(h_j)$ and $M_k^+ + M_k^- = \sum_{j=1}^k |b(h_j)|$ follow from the definitions of the positive and negative parts. Accumulation and conditional cancellation are thus distinct operations on the same contributions.

Joint operation	Objects and effective action	Development and proof
Transport and grading of sheets	$\mathcal{U}_k : \ell^2(\widehat{X}_k) \to \ell^2(\widehat{X}_{k+1})$, with $\widehat{X}_k$ formed by the lifted histories; $\sigma_k = P_k - Q_k$, A_k and η_k preserve or exchange the current sheet.	Section 6.4.3; Proposition 6.24 and Theorem 6.25.
Balance, cancellation and memory	$b : X_k \to \mathbb{Z}$, $b^{\pm} : X_k \to \mathbb{N}_0$; accumulation $M_k^{\pm}$ over prefixes and cancellation $\kappa_{\mathrm{can}} = (E\lvert b_f\rvert - \lvert Eb_f\rvert)/2$ when publishing the conditional mean.	Section 6.4.4; Proposition 6.26.
Ternary incidence of the sheets	$B : \mathbb{F}_3^4 \to \mathbb{F}_3^6$, $(Ba)_{\{L,L'\}} = a_L + a_{L'}$; the complete ambient space of q is preserved, with $sB = 0$ and $W(q + Ba) = W(q)$.	First part of Section 6.4.5.
Ports and rectangular complex	$\kappa : A_N^{I_k} \oplus A_N^{J_k} \to A_N^{I_k \times J_k}$, $\kappa(u,v)_{ij} = u_i - v_j$; the difference δ and precomposition L_k preserve labels and their multiplicities.	Propositions 6.27 and 6.28.
Cellular memory, filling and determinant line	$\Psi_\alpha : \Gamma_y \to \Gamma_{y'}$, $K_\alpha \in \Gamma_{y',2}$, $\partial h_* = z^- - z^+$; the lines $\mathrm{Det}\,\Gamma$ and $\mathrm{Det}(\mathrm{Tot}\,\mathcal{B})$ are formed on the corresponding based complexes.	Sections 6.4.6–6.4.8; Propositions 6.29 and 6.30.

The table identifies five actions of the same construction: each prefix preserves its sheets, orientation, residues, quotients, memory and terminal prolongations. Port precomposition takes coordinates from one level to the refined level; coefficient reduction takes A_{N+1} to A_N. Their directions and domains are distinct and their commutative squares are made explicit in Proposition 6.28. The assembly in Section 6.4.7 simultaneously uses terminal continuations and transport of the memory complex; its composition formulas combine the table's actions on the same system of histories. Reading a determinant line as a scalar retains the basis, homology and nonsingularity conditions of Section 6.4.8.

This development brings together the constructions of state, tree and common measure; the correlative intrinsic operations; and the terminal assembly with naturality and limit proved in this section. Their balance, incidence and memory identities are incorporated, with proofs within this chapter. The five constructions of the continuum are retained as operations on the same tree. The exposition expands their local proofs and makes explicit the conditions of each specialization: isometric transport, uniform weights, extinction of the terminal and nonsingularity of a determinantal block.

The attached checker tests exact instances of the cocycles, weighted cancellation, rectangular sequence and memory complex. These checks accompany the general proofs in the text and verify the operators defined here in their respective domains. The subsequent step toward exceptional representations and the Hilbert realization preserves their actions on generators: Section 23.5 specifies the phase fiber, Weyl

operators and inclusions determining their closures. Documentary preservation and finite checks retain their function of traceability and comparison of these proofs.

6.5 Correlative construction of the continuum: histories, transport, incidence and terminal

The arithmetic published by a normal form preserves a precise reading of the state that produces it. To situate that reading within HMT, the histories, sheets and operations acting on them must also be retained. This chapter brings together that common substrate. Its various constructions are obtained from the same APP–TRIT–TPK execution tree; the divisions of the exposition allow their properties to be studied without turning them into independent domains chosen by a subsequent application.

The starting point is the formal kernel presented above. An admissible emission contains the APP operation, the TRIT orientation, the sheet change, the residue and quotient, together with the effective TPK memory update. When only a residue is published, the execution history still belongs to the starting object. Two executions with identical final readings are not identified for that reason alone.

6.5.1 Admissible histories and memory by composition

Let X_k be the set of admissible histories of length k. Its elements are constructed by successive emissions from the initial domain of the kernel. We write $h\varepsilon$ for the prolongation of h by an admissible emission ε, and $\rho_k(h\varepsilon) = h$ for deletion of the last emission. The emission label is retained, even when different labels produce the same published state.

On the two arithmetic sheets, the local data satisfy the exact divisions

$$\delta_\diamond = r_\diamond + 9q_\diamond, \qquad 0 \le r_\diamond < 9, \qquad \diamond \in \{\Sigma, \Pi\}.$$

The oriented TRIT coordinate likewise admits an expression $\Delta = o_r + 3\kappa$, with the oriented representative declared by the kernel. Preservation of the quotient allows these publications to be composed without replacing an emission by its isolated residue.

In a memory chart, the update of an emission is written

$$U_\varepsilon(m) = C_\varepsilon m + \kappa_\varepsilon.$$

For a trajectory $\alpha = (\varepsilon_1, \dots, \varepsilon_k)$, the effective operation is the ordered composition of these updates. Its linear part and its translation are

$$C_\alpha = C_{\varepsilon_k} \cdots C_{\varepsilon_1}, \qquad \kappa_\alpha = \sum_{j=1}^{k} C_{\varepsilon_k} \cdots C_{\varepsilon_{j+1}} \kappa_{\varepsilon_j}.$$

The empty product in the last sum is the identity.

Proposition 6.31. Affine compatibility of concatenation

If α precedes β, then

$$C_{\beta\alpha} = C_\beta C_\alpha, \qquad \kappa_{\beta\alpha} = C_\beta \kappa_\alpha + \kappa_\beta, \qquad U_{\beta\alpha} = U_\beta U_\alpha.$$

Proof. Substituting $U_\alpha(m)$ into U_β produces $C_\beta C_\alpha m + C_\beta \kappa_\alpha + \kappa_\beta$. Decomposition into linear part and translation gives the three identities. Associativity of composition proves that the result does not depend on an auxiliary subdivision of the trajectory. □

This cocycle identity is the precise content of accumulated memory. The quantity transported by a second trajectory depends on the chart update it performs; in general, it is not the sum of two registers without transport.

The nonadic return preserves a second distinction. In phase and turn coordinates, with $\bar{r} \in \{0, \dots, 8\}$, its publication is

$$\sigma_9(w, r) = \left(w + \left\lfloor \frac{\bar{r} + 1}{9} \right\rfloor, r + 1 \pmod 9 \right), \qquad \sigma_9^9(w, r) = (w + 1, r).$$

During nine steps, exactly one crossing from 8 to 0 occurs. The phase returns and the turn coordinate increases. The enriched holonomy also retains the memory updates accompanying that path.

6.5.2 Tree refinement and measure of histories

Fix the nonempty finite initial set of admissible seeds, with strictly positive initial mass summing to 1. In this section, each history has a positive finite number of prolongations. Deletion of emissions defines the refinement maps. Admissibility of the kernel supplies the prolongations; when a residence uses a neutral emission, this explicitly gives a section of ρ_k. The existence of that section concerns the tree including that emission, not an arbitrary restriction of routes.

Let $d(h) \geq 1$ be the number of admissible emissions at h. Equiprobable choice among its children defines

$$\mu(h\varepsilon) = \frac{\mu(h)}{d(h)}.$$

More generally, a positive local distribution $p(\varepsilon \mid h)$, whose sum is 1, defines $\mu(h\varepsilon) = \mu(h)p(\varepsilon \mid h)$. This second formulation preserves the reader's weights when the numbers of prolongations are not uniform.

Proposition 6.32. Cylindrical compatibility and conditional expectation

At each level, we have

$$\sum_{\rho_k(y)=x} \mu(y) = \mu(x).$$

In the spaces $L^2(X_k, \mu_k)$, the maps

$$(J_k f)(y) = f(\rho_k(y)), \qquad (E_k g)(x) = \sum_{\rho_k(y)=x} \frac{\mu(y)}{\mu(x)} g(y)$$

satisfy $E_k = J_k^*$, $E_k J_k = I$ and $\|J_k f\| = \|f\|$.

Proof. The first identity is the normalization of the local probabilities. Applying it to $|f(x)|^2$ gives the isometry. Grouping the sum defining $\langle J_k f, g \rangle$ by parents gives the formula for E_k; on a function constant on each fiber, that formula returns its value. □

The compatible masses define a probability measure on the space of infinite histories: the cylinder of a finite history receives its mass $\mu(h)$. The measure extends from the cylinder algebra, and its uniqueness follows from the fact that cylinders generate the sigma-algebra. If the tree is finitely branching and every history has a prolongation, the inverse limit of its levels under deletion of emissions is nonempty. In the cylindrical topology, every nonempty cylinder has positive measure.

This measure distinguishes histories converging to the same publication. The uniform measure on terminal values would be a different reading, since it would eliminate the multiplicities that the construction has just preserved.

6.5.3 Transport by sheets and exact accounting of outputs

First consider the space with an orthonormal basis formed by the histories at level k. The transport preserving the label of each prolongation is

$$\mathcal{U}_k e_h = \sum_{\varepsilon \text{ admissible en } h} \sqrt{p(\varepsilon \mid h)}\, e_{h\varepsilon}.$$

The sets of children of distinct parents are disjoint. Normalization of p therefore proves $\mathcal{U}_k^* \mathcal{U}_k = I$. The representation through history masses is related to this one by the diagonal change of basis incorporating $\sqrt{\mu(h)}$.

Let P_k, Q_k be the complementary projectors onto the two sheets. We separate sheet preservation and sheet exchange:

$$A_k = P_{k+1}\mathcal{U}_k P_k + Q_{k+1}\mathcal{U}_k Q_k, \qquad \eta_k = Q_{k+1}\mathcal{U}_k P_k + P_{k+1}\mathcal{U}_k Q_k.$$

Proposition 6.33. Gram identity by sheets

For a linear transport U, whether isometric or not, the preceding decomposition satisfies

$$A^*A + \eta^*\eta = PU^*UP + QU^*UQ.$$

In particular, for $U = \mathcal{U}_k$,

$$A_k^* A_k + \eta_k^* \eta_k = I.$$

Proof. In A^*A and $\eta^*\eta$, the mixed terms containing $P_{k+1}Q_{k+1}$ vanish. Adding the remaining terms gives $P_k U^*(P_{k+1} + Q_{k+1})UP_k$, and its analogue with Q_k. The first identity follows from complementarity of the projectors; the second also uses $U^*U = I$. □

The first identity is the general formula. Replacing its right-hand side by U^*U requires the cross blocks of that Gram matrix to vanish. Isometric preservation of history transport provides that condition here; it should not automatically be attributed to a subsequent compression.

Write $F_{0,0} = I$, $F_{0,n} = A_{n-1} \cdots A_0$ and $T_N = F_{0,N}^* F_{0,N}$.

Theorem 6.34. Finite decomposition with terminal residue

For each horizon N,

$$I = \sum_{n=0}^{N-1} F_{0,n}^* \eta_n^* \eta_n F_{0,n} + T_N.$$

The sequence T_N is positive and decreasing, and has a positive strong limit T_∞. The sum of outputs converges strongly to $I - T_\infty$.

Proof. Proposition 6.33 gives $T_n - T_{n+1} = F_{0,n}^* \eta_n^* \eta_n F_{0,n}$. The telescoping sum proves the finite equality and monotonicity. For each vector, the quadratic forms decrease to a limit; polarization defines a bounded positive form and, by the representation theorem for bounded forms, an operator T_∞. Convergence is strong because, for a positive operator $S \le I$, $\|Sv\|^2 \le \langle v, Sv\rangle$; this is applied to $S = T_N - T_\infty$. □

The terminal residue is retained until its extinction in the domain under consideration is proved. This distinction prevents a phase return, by itself, from becoming an assumption of exhaustion of all histories.

6.5.4 Oriented balance and cancellation under refinement

A history carries its accumulated orientation $o(h)$ and the counts of its visits to the two sheets. The corresponding local balance is

$$b(h) = o(h)\big(N_\Sigma(h) - N_\Pi(h)\big), \qquad b^+ = \frac{|b| + b}{2}, \quad b^- = \frac{|b| - b}{2}.$$

When a reader publishes the mean over prolongations, $b_c = Eb_f$ is defined. Orientation remains in the argument of b_f; it is not removed before averaging.

Proposition 6.35. Exact cancellation defect

The quantity

$$\kappa_{\mathrm{can}} = \frac{E|b_f| - |Eb_f|}{2}$$

is nonnegative and satisfies

$$E(b_f^+) = (b_c)^+ + \kappa_{\mathrm{can}}, \qquad E(b_f^-) = (b_c)^- + \kappa_{\mathrm{can}}.$$

Proof. The weighted triangle inequality gives $|Eb_f| \le E|b_f|$. Expressing the positive and negative parts through $(|b| \pm b)/2$ yields both equalities. □

The information omitted by publishing only the balance is the common cancellation of opposite contributions. This quantity is determined from the same prolongations used by the preceding transport. The factor $1/9$ appears only when the fiber contains nine children with equal weights; conditional expectation is the rule that remains valid for general branching and weights.

6.5.5 Ternary incidence of the sheets and rectangular complex

The two sheets determine the module $V = \mathbb{F}_3 e_\Sigma \oplus \mathbb{F}_3 e_\Pi$. Its four projective directions are the lines generated by $e_\Sigma, e_\Pi, e_\Sigma + e_\Pi, e_\Sigma - e_\Pi$. They give rise to six unordered pairs. The eight nonzero vectors are their oriented representatives. Thus, the counts $4, 6, 8$ belong to distinct operations on the same sheet module.

On the six pair positions, we define

$$(Ba)_{\{L,L'\}} = a_L + a_{L'}, \qquad s(q) = \sum_{\{L,L'\}} q_{\{L,L'\}}.$$

Each direction occurs in three pairs; hence $sB = 0$ in $\mathbb{F}_3$. The reader $W(q) = \mathbf{1}_{s(q)=0} - 1/3$ is invariant under $q \mapsto q + Ba$. On the uniform ambient space $\mathbb{F}_3^6$, its moments are

$$\mathbb{E}W = 0, \qquad \mathbb{E}W^2 = \frac{2}{9}, \qquad \mathbb{E}W^3 = \frac{2}{27}.$$

Indeed, s is surjective and each fiber contains 3^5 elements. The reader equals $2/3$ with probability $1/3$ and $-1/3$ with probability $2/3$. These means describe the uniform ambient space; the distribution induced by a subset of histories must be calculated with its own multiplicities, already preserved in X_k.

For the effective ports of a level, let I and J be the nonempty sets of ports of its two sheets and $A_N = \mathbb{Z}/3^N\mathbb{Z}$. Fix reference ports i_0, j_0. The maps

$$\kappa(u, v)_{ij} = u_i - v_j, \qquad (\delta w)_{ij} = w_{ij} - w_{ij_0} - w_{i_0 j} + w_{i_0 j_0}$$

define the following sequence, valid over the finite ring A_N:

$$0 \longrightarrow A_N \longrightarrow A_N^I \oplus A_N^J \xrightarrow{\kappa} A_N^{I\times J} \xrightarrow{\delta} A_N^{(I\setminus\{i_0\})\times(J\setminus\{j_0\})} \longrightarrow 0.$$

Proposition 6.36. Exactness of rectangular incidence

The preceding sequence is exact, with first arrow given by the constant diagonal.

Proof. The equality $u_i - v_j = 0$ for each pair forces all coordinates of u and v to be the same constant. Direct substitution gives $\delta\kappa = 0$. If $\delta w = 0$, take $u_i = w_{ij_0}$ and $v_j = w_{i_0j_0} - w_{i_0j}$. Then $u_i - v_j = w_{ij}$. Finally, any matrix in the last term extends with zero reference row and column; its image under δ is the initial matrix. The proof uses only addition and subtraction, so it does not require division by a unit of the ring. □

Reduction from A_{N+1} to A_N commutes with the two maps. The reconstruction formulas are the same at every depth. Incidence and its exactness are thus compatible with arithmetic refinement of the starting state.

6.5.6 Memory complex and compatibility of incidences

The same accumulated memory coordinate $c_y \in \mathbb{Z}$, in a residence y, defines a free integer complex. Its reduction to A_N uses the same integer register before reducing it; successive depths are therefore compatible. Its generators are f_y in degree 2, e_y, b_y, r_y in degree 1, and g_y in degree 0:

$$\partial f_y = 3c_y e_y + b_y, \qquad \partial e_y = g_y, \qquad \partial b_y = -3c_y g_y, \qquad \partial r_y = 0.$$

The identity $\partial^2 = 0$ is verified on f_y through $3c_y g_y - 3c_y g_y = 0$, and is immediate on the other generators.

If a trajectory $\alpha : y \to y'$ updates memory, its transport in the complex sends the correspondingly named generators to their new representatives, except

$$\Psi_\alpha(b_y) = b_{y'} + 3(c_{y'} - c_y)e_{y'}.$$

Proposition 6.37. Naturality of the memory complex

We have $\partial\Psi_\alpha = \Psi_\alpha\partial$ and $\Psi_{\beta\alpha} = \Psi_\beta\Psi_\alpha$. The maps extend linearly over the chosen coefficient ring.

Proof. On f_y, the image of its boundary is $3c_y e_{y'} + b_{y'} + 3(c_{y'} - c_y)e_{y'} = 3c_{y'}e_{y'} + b_{y'}$. On b_y, the boundary of its image is $-3c_{y'}g_{y'} + 3(c_{y'} - c_y)g_{y'} = -3c_y g_{y'}$. The other two cases are immediate. In a concatenation, memory differences add telescopically, proving the second identity. □

The relation between two representatives of the same residence can also be written as an explicit boundary. For an integer coordinate v, reduced in the same ring where appropriate, let

$$z^- = r_y, \qquad z^+ = r_y + 3c_y v e_y + v b_y, \qquad h_* = -v f_y.$$

Then $\partial h_* = z^- - z^+$. Under a transport that also updates v, the correction $K_\alpha = (v_{y'} - v_y)f_{y'}$ satisfies $K_{\beta\alpha} = K_\beta + \Psi_\beta K_\alpha$. The symbols K_α of this local homotopy do not denote the dodecaphasic seal K: they belong to another domain and their function is specified by the preceding identity. Their function can also be checked in the equality

$$z^+_{y'} - \Psi_\alpha z^+_y = \partial K_\alpha.$$

Both sides equal $(v_{y'} - v_y)(3c_{y'}e_{y'} + b_{y'})$.

Proposition 6.38. Homology and memory of the local complex

Over $\mathbb{Z}$, or after reduction to A_N, we have

$$H_0(\Gamma) = H_2(\Gamma) = 0, \qquad H_1(\Gamma) \cong A_N[r_y]$$

in the modular realization, and $H_1(\Gamma) \cong \mathbb{Z}[r_y]$ in the integer realization.

Proof. Define the degree-1 homotopy by $h(g_y) = e_y$, $h(b_y) = f_y$, and zero on the other generators. Let p be the projection onto the summand generated by r_y and ι its inclusion. Checking on each generator gives

$$\partial h + h\partial = I - \iota p.$$

In particular, on b_y the terms $3c_y e_y$ and $-3c_y e_y$ cancel. The complex deformation retracts onto the module generated by r_y, concentrated in degree 1, which proves the assertion. □

The transport Ψ_α is a shear of determinant 1. Thus, this complex explicitly preserves how c_y changes at the chain level, but its local homology does not distinguish the values of that coordinate. The full memory remains in the labels and transports of the source state; it is not recovered from H_1 alone. A memory-dependent numerical torsion requires the specified assembly and determinantal reading, in addition to this local complex.

6.5.7 Assembly with terminal paths

For a finite horizon, the residences and their prolongations form a path category. Each residence ν is assigned the free module $W(\nu) = A_N[\mathrm{Path}(\nu, \mathrm{Term})]$, which preserves each terminal continuation as a generator. An initial path acts on W by precomposition. The complex $\Gamma(\nu)$ of the preceding section acts covariantly through Ψ.

The assembly uses both transports in the same bigraded module:

$$\mathcal{B}_{q,r} = \bigoplus_{\nu_0 \to \cdots \to \nu_q} W(\nu_q) \otimes_{A_N} \Gamma_r(\nu_0).$$

The normalized path complex is used: degenerate chains containing identities are omitted. The finite horizon then bounds the number of strict prolongations and the horizontal degree. The horizontal boundary removes an intermediate residence by composing the adjacent arrows. At the first endpoint it transports Γ; at the last it precomposes W. The alternating signs yield the path boundary d_{bar}. The total differential is

$$D = d_{\mathrm{bar}} + (-1)^q \partial_\Gamma.$$

The face identities cancel the terms of d_{bar}^2 in pairs. The naturality of Proposition 6.37 implies that d_{bar} commutes with ∂_Γ; the factor $(-1)^q$ cancels the cross terms of the square. Therefore, $D^2 = 0$. Compatibility is proved on path generators and is not introduced by a label of membership in a complex.

Terminal evaluation likewise does not require choosing a particular history. For each continuation h, the effective composition of its updates is applied. The result preserves the pair formed by h and its reading, with its multiplicity. If $k < \ell < N$, the continuations decompose as a disjoint union of prefixes up to ℓ and their continuations up to N. Proposition 6.31 proves that evaluating directly or evaluating these two parts produces the same reading. This yields the naturality square of the terminal.

The path modules, incidences, memory transport and their differentials arise from the same prolongations. Their assembly does not consist in adding to a state five coordinates that would be preserved by definition: their relations are constructed through sums, boundaries and effective compositions, and are verified on their generators.

6.5.8 Determinants, limit and arithmetic reading

At each finite truncation, the free complex admits its graded determinant line

$$\operatorname{Det}\Gamma = \bigotimes_r \left(\bigwedge^{\operatorname{rk}\Gamma_r} \Gamma_r \right)^{(-1)^r}.$$

The line is defined by the modules and their degrees, both over $\mathbb{Z}$ and after reduction to A_N; the negative exponent denotes the dual module. A nonzero numerical torsion additionally requires specifying the complex over a field, the bases and the relevant homology identifications. To calculate Smith factors, the integer matrix produced before reduction is used, not an arbitrary lift of a modular matrix. A square integer block with nonzero determinant is invertible over $\mathbb{Q}$; its reduction is invertible over A_N only when that determinant is a unit, that is, when it is not divisible by 3. The refinement of memories and incidences allows the stability of the relevant invariant factors to be formulated and checked; these conditions do not follow from the existence of the determinant line.

Passage to the limit preserves the compatible projective systems of residues, the histories and their multiplicities. The squares proved in the preceding sections remain commutative because their maps are given by the same formulas at each level. For an Archimedean coordinate, the additional step consists in publishing nonempty cylindrical intervals, compatible by inclusion and with diameter tending to zero. Their nested compact closures have a single-point intersection: existence follows from compactness and uniqueness from the diameter bound. This is the value of the limit reading. If the intervals are half-open, the point may belong only to their closures; the boundary representation rule then determines its positional notation. The value does not replace the history that produced it. The other publication preserves the incidences of the same state. The two destinations share their origin without thereby receiving the same information.

The sector of normal forms studied in the arithmetic chapter is obtained through the normalized publication of TPK prefixes. Its integer evaluation and operations are subsequent readers on the substrate constructed here. Spectral functionals, finite parts and irreducible clocks are applied to these published modes. Identifying a specific functional with an external analytic form requires, in turn, writing its action on the generators and verifying its inner products: the conservation identities of this chapter do not replace that composition.

6.5.9 Provenance, verification and scope

This development brings together the author's architecture from owners 04b1, 04b2 and 04b3 of the discrete structure, and the balance, incidence and memory identities from developments 05. It jointly preserves the five constructions of the continuum as operations on a single tree. The exposition expands their local proofs and makes explicit the conditions of each specialization: isometric transport, uniform weights, extinction of the terminal and nonsingularity of a determinantal block.

The attached checker tests exact instances of the cocycles, weighted cancellation, rectangular sequence and memory complex. These checks accompany the general proofs in the text. Their scope is local: neither a finite enumeration nor the preservation of provenance files is presented as a proof of Weil positivity or as an identification of the spectral operator that has not yet been composed.

Chapter 7

Projective measure of the genealogical continuum: evolutionary conservation of unity, disintegration by values, and conditioning of futures

7.1 Projective measure and evolutionary conservation of the unit

Cylinder topology provides a notion of proximity; a theory of paths also requires weights. The evolutionary conservation of the unit here takes an exact probabilistic form: every cylinder distributes its weight among its extensions, and the total sum remains equal to one. The unit is not fixed in a cell; it is transported through refinement.

7.1.1 Consistent weights on finite levels

Let μ_n be a probability on the finite set $\mathcal{S}_n$. The family is *projectively consistent* when

$$\mu_n(a) = \sum_{\substack{b \in \mathcal{S}_{n+1} \\ \rho_{n+1,n}(b)=a}} \mu_{n+1}(b) \qquad (a \in \mathcal{S}_n). \tag{7.1}$$

This equality expresses the local preservation of the unit: the weight of a truncated history is the sum of the weights of all its children.

Theorem 7.1 (Genealogical measure on cylinders)**.** *Every family of finite probabilities that satisfies* (7.1) *determines a unique Borel probability μ_∞ on Ω_∞ such that*

$$\mu_\infty([a]_n) = \mu_n(a). \tag{7.2}$$

Proof.

$$\mathscr{A} := \{\text{finite unions of cylinders}\}$$

is an algebra: the intersection of two cylinders is either empty or a cylinder of the deeper level. Every element of $\mathscr{A}$ can be refined into a disjoint union of cylinders of a common level. If $A = \bigsqcup_{a \in I} [a]_n$, we set

$$\mu_0(A) = \sum_{a \in I} \mu_n(a).$$

Iterating (7.1) proves that the value does not depend on the chosen common level.

If a cylinder $[a]_n$ is empty, finite branching and Koenig's lemma [73] imply that there is a depth with no descendants of a. Iterated consistency then gives $\mu_n(a) = 0$. Hence μ_0 is well defined even for representations containing empty cylinders and is finitely additive.

The cylinders are both open and closed. If a decreasing sequence of elements of $\mathscr{A}$ had empty intersection, compactness would imply that one of them was already empty; hence μ_0 is continuous at the empty set and constitutes a countably additive premeasure. The Caratheodory extension theorem —equivalently, the Kolmogorov extension for this finite projective system— extends it to the σ-algebra generated by the cylinders [22, 75]. This is the Borel algebra of Ω_∞, and finiteness of the measure ensures uniqueness. □

The measure may follow from local transitions. If $P_n(b \mid a) \geq 0$ satisfies

$$\sum_{\rho_{n+1,n}(b)=a} P_n(b \mid a) = 1,$$

then $\mu_{n+1}(b) = \mu_n(a)P_n(b \mid a)$ is consistent. Uniformity is a possible choice, not an obligation. The weights may depend on the sheet, carry, orientation, a nonnegative action cost, or a record, provided they preserve the sum. For example,

$$P_n(b \mid a) = \frac{e^{-\beta a_n(b|a)}}{\sum_{b' \mapsto a} e^{-\beta a_n(b'|a)}}, \qquad a_n \geq 0,$$

defines normalized positive weights. The orthogonal action phase belongs to the kernel of section 65.4; it is not inserted into these positive probabilities.

7.1.2 Decomposition of the genealogical measure on fibers of equal Archimedean value

The Archimedean evaluation transports the measure to K:

$$\nu := \mathrm{Val}_* \, \mu_\infty, \qquad \nu(B) = \mu_\infty(\mathrm{Val}^{-1}(B)). \tag{7.3}$$

The visible probability of a region sums the weight of all the genealogies that publish it. When two sections possess the same value, their contributions are aggregated in ν, although they remain separate in μ_∞.

Proposition 7.2 (Value Decomposition)**.** *If K is a standard Borel space, there exists a family of conditional measures $\{\mu_y\}_{y \in K}$, defined for ν-almost every y, such that μ_y is supported on $\mathfrak{G}_y = \mathrm{Val}^{-1}(y)$ and*

$$\int_{\Omega_\infty} F \, \mathrm{d}\mu_\infty = \int_K \left(\int_{\mathfrak{G}_y} F \, \mathrm{d}\mu_y \right) \mathrm{d}\nu(y)$$

for every integrable function F.

This formula separates value and genealogy at the level of the measure. Physics that depends only on the value first integrates the entire fibre; a memory observable can distinguish different distributions μ_y over the same real coordinate.

7.1.3 Conditioning of the measure through restriction of the future extension tree

Let $A \subseteq \Omega_\infty$ be an observable event with $\mu_\infty(A) > 0$. The conditional measure is

$$\mu_\infty(B \mid A) = \frac{\mu_\infty(B \cap A)}{\mu_\infty(A)}. \tag{7.4}$$

When A is the reading of a register, its intersection with each cylinder eliminates the incompatible extensions. Normalization does not create new branches: it redistributes the unit among those that have survived.

Proposition 7.3 (Compatible update)**.** *If A is a union of cylinders at level m, then for every $n \geq m$ the conditional distribution on $\mathcal{S}_n$ is obtained by removing the states whose truncations do not belong to A and renormalizing the remaining weights. The conditional distributions continue to satisfy* (7.1)*.*

Proof. The identity is Bayes' rule on finite sets. The sum of the weights of the conditioned children coincides with the conditioned weight of the parent, because intersection and disjoint union commute. □

7.1.4 Combinatorial conservation and dimensional completion

The same law appears in the binomial completion:

$$1 = \sum_{r=0}^{d} \binom{d}{r} \left(\frac{9}{10}\right)^{d-r} \left(\frac{1}{10}\right)^{r}.$$

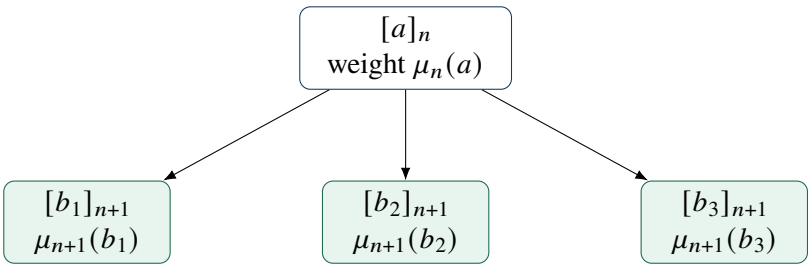
In three dimensions,

$$1000 = 729 + 243 + 27 + 1,$$

so that the interior, new faces, extreme edges, and final vertex form a partition of decimal unity. The passage $729 + 270 = 999 \to 729 + 271 = 1000$ distinguishes the state prior to closure of the completed unity. In the path system, the analogous identity is

$$\mu([a]_n) = \sum_{b \mapsto a} \mu([b]_{n+1}).$$

The unit evolves as it is distributed among the strata and is recovered by summing the complete genealogy.



$\mu_n(a) = \mu_{n+1}(b_1) + \mu_{n+1}(b_2) + \mu_{n+1}(b_3)$:
the unit is preserved when the genealogy is refined.

Figure 7.1: Projective weight conservation on cylinders.

Hypothesis, domain, and conclusion

The projective measure is constructed on the HMT inverse system. The extension theorem is classical mathematics; the identification of its cylinders with TPK states is exact once the transition weights have been fixed. The selection of a specific physical measure belongs to the dynamical model and does not follow solely from the census of branches.

The projective measure is characterized by positivity, conservation of weight between parents and children, and conditioning within the observed event. A complete experimental realization adds preparation and the sampling protocol; with those data, the same measure produces reading probabilities comparable with frequencies.

7.2 Discrete calculation of the measure on the inverse limit: differences, carry cocycle, ultrametric, reconstruction of $\mathbb{R}$, and genealogical disintegration

The distinction between counting and measuring admits an operator formulation. Counting assigns a cardinality to a collection of marks. Measuring evaluates relations among marks by means of a local rule, integrates them along a path, and preserves the chart in which the result is published. The minimal unit of that process is a difference; its composition produces length, circulation, and, when a modular reduction intervenes, carry. This architecture places the measure prior to its real coordinate: the published scalar is the contraction of a calculation possessing a domain, orientation, and memory.

7.2.1 Marks and difference operator

Let P_n be the path with ordered vertices $V(P_n) = \{v_0, \dots, v_{n-1}\}$ and oriented edges $e_j = (v_{j-1}, v_j)$, $1 \le j \le n-1$. For a commutative ring A, we define

$$C^0(P_n; A) = A^{V(P_n)}, \qquad C^1(P_n; A) = A^{E(P_n)},$$

and the difference operator

$$d : C^0(P_n; A) \longrightarrow C^1(P_n; A), \qquad (df)(e_j) = f(v_j) - f(v_{j-1}). \tag{7.5}$$

Theorem 7.4 (Range of the difference operator on a path)**.** *If A is a field, then*

$$\ker d = A\mathbf{1}, \qquad \operatorname{rank} d = n - 1.$$

Consequently, n connected marks determine $n-1$ independent differences and a unique constant mode.

Proof. The equality $df = 0$ successively implies $f(v_0) = f(v_1) = \cdots = f(v_{n-1})$, so that the kernel is formed by the constant functions and has dimension one. The rank–nullity theorem gives $\operatorname{rank} d = n - 1$. Equivalently, every assignment $(a_1, \dots, a_{n-1})$ to the edges is integrated uniquely once $f(v_0)$ has been fixed:

$$f(v_k) = f(v_0) + \sum_{j=1}^{k} a_j.$$

□

The constant mode expresses freedom of choosing the origin. Differences contain relational information; the initial mark supplies the section reconstructing positions. In the inaugural HMT cell, nine ordered marks produce eight interior differences. Periodic closure adds the ninth edge and transforms the path into a cycle; the two-dimensional completion of those intervals will be realized exactly in the APP construction.

7.2.2 Positive length and oriented integral

Two evaluations of a route must remain separate. A discrete metric is a positive cochain.

$$\ell : E(P_n) \longrightarrow \mathbb{R}_{>0}.$$

For an unoriented path $|\gamma|$, its length is

$$L_\ell(\gamma) = \sum_{e \in |\gamma|} m_\gamma(e)\, \ell(e), \tag{7.6}$$

where $m_\gamma(e)$ counts the traversals of the edge. An oriented cochain $\omega \in C^1(P_n; A)$, by contrast, is integrated with sign:

$$\int_\gamma \omega := \sum_{k=1}^{r} \varepsilon_k \omega(e_{i_k}), \qquad \varepsilon_k \in \{-1, +1\}. \tag{7.7}$$

Length sums geometric cost; the oriented integral sums transport. The first is invariant under route inversion, and the second changes sign.

Proposition 7.5 (Discrete Fundamental Theorem)**.** *For $f \in C^0(P_n; A)$ and every path orientada $\gamma : a \to b$,*

$$\int_\gamma df = f(b) - f(a).$$

In particular, the integral of an exact cocycle over a cycle is zero.

Proof. The sum of the consecutive differences telescopes. Each interior vertex appears once with positive sign and once with negative sign; only the endpoints remain. □

The proposition distinguishes two levels of closure. The group $H_1(C_n; \mathbb{Z}) \cong \mathbb{Z}$ provides the topological carrier of the turn; a holonomy further requires a transport. If $T : \mathrm{Path}(C_n) \to C$ is a functor toward a category of automorphisms, the holonomy of a cycle γ is

$$\mathrm{Hol}_T(\gamma) = T(e_r) \cdots T(e_1). \tag{7.8}$$

The cycle contributes the traversal class; T contributes the discrete connection that turns that class into an endomorphism. This distinction will be essential when the visible-phase return recovers the phase and the transport conserves a different boundary state.

7.2.3 Carry as a composition cocycle

Modular reduction publishes a class, and a section chooses representatives. Let $Q = \mathbb{Z}/9\mathbb{Z}$, and let $s_0 : Q \to \{0, \ldots, 8\} \subset \mathbb{Z}$ be the ordinary residue section. We define

$$\kappa_9(a, b) := \frac{s_0(a) + s_0(b) - s_0(a + b)}{9} \in \mathbb{Z}. \tag{7.9}$$

Then

$$s_0(a) + s_0(b) = s_0(a + b) + 9\kappa_9(a, b).$$

Proposition 7.6 (Cocycle Identity of the Carry)**.** *The map $\kappa_9 : Q \times Q \to \mathbb{Z}$ satisfies*

$$\kappa_9(a, b) + \kappa_9(a + b, c) = \kappa_9(b, c) + \kappa_9(a, b + c). \tag{7.10}$$

It is, therefore, a normalized 2-cocycle associated with the chosen section.

Proof. Both sides are expanded using (7.9). After multiplication by nine, both are equal to

$$s_0(a) + s_0(b) + s_0(c) - s_0(a + b + c).$$

Normalization is obtained from $s_0(0) = 0$. □

The cocyclic identity expresses the associativity of lifting: grouping first $(a + b) + c$ or $a + (b + c)$ produces the same visible class and the same total carry. In a category of routes, the same structure takes the form

$$\widetilde{g}\,\widetilde{h} = \kappa(g, h)\,\widetilde{gh},$$

where $\widetilde{g}, \widetilde{h}$ are enriched transports lifting visible morphisms. The carry is thus a perfectly controlled composition defect before receiving any geometric interpretation as curvature or torsion.

7.2.4 Compatibility of the nonadic, ternary, and decimal-completion charts in base 10^3

The residual readers that intervene in TPK are not distinct names of a single operation. Let

$$R_9 := \mathbb{Z}/9\mathbb{Z}, \qquad r_9 : \mathbb{Z} \longrightarrow R_9, \qquad r_3 : \mathbb{Z} \longrightarrow \mathbb{F}_3$$

the canonical reductions, and let

$$\pi_3 : R_9 \longrightarrow \mathbb{F}_3, \qquad \pi_3(\overline{n}) = n \bmod 3.$$

The square of reductions commutes:

$$\begin{array}{ccc} \mathbb{Z} & \xrightarrow{\ r_9\ } & R_9 \\ {\scriptstyle r_3}\downarrow & & \downarrow{\scriptstyle \pi_3} \\ \mathbb{F}_3 & = & \mathbb{F}_3. \end{array} \qquad r_3 = \pi_3 \circ r_9. \tag{7.11}$$

The positive section

$$s_+ : R_9 \longrightarrow \{1, \dots, 9\}, \qquad s_+(\overline{0}) = 9, \qquad s_+(\overline{k}) = k \quad (1 \le k \le 8),$$

produce, for $n > 0$, the root digital positive

$$\mathrm{dr}_9^+(n) = s_+(r_9(n)).$$

This section is not a homomorphism: it publishes the null class by means of 9 and forgets the quotient. The residual section $s_0(\overline{0}) = 0$ publishes that same class by means of 0. Therefore, the visible change $9 \mapsto 0$ is a change of section, and the equality

$$9 = s_0(\overline{0}) + 9 \cdot 1$$

preserves the carry 1 as quotient. The topological successor of the positive cycle is, by contrast, $9 \mapsto 1$, with

$$10 = s_+(\overline{1}) + 9 \cdot 1.$$

Thus the closure $P_9 \to C_9$, the change of chart and the increment of memory are separated; none of the three is replaced by the other two.

The coordinate of the radical belongs to another diagram. For $\mathfrak{m} = (3) \subset R_9$, the application

$$\iota_{\mathfrak{m}} : \mathbb{F}_3 \longrightarrow \mathfrak{m}, \qquad \overline{a} \longmapsto 3a,$$

is an isomorphism of vector spaces over $\mathbb{F}_3$, with inverse

$$\eta_{\mathfrak{m}} : \mathfrak{m} \longrightarrow \mathbb{F}_3, \qquad \eta_{\mathfrak{m}}(3a) = a \bmod 3. \tag{7.12}$$

It is not a ring isomorphism. Nor does it coincide with direct reduction: for $3a \in \mathfrak{m}$, one has $\pi_3(3a) = 0$, whereas $\eta_{\mathfrak{m}}(3a) = a \bmod 3$. The first reading publishes the residue class; the second publishes the internal coordinate of the radical.

Finally, let $u_j \in \{0, \dots, 999\}$ and

$$D_N = 1000 D_{N-1} + u_N, \qquad D_0 = 0,$$

the concatenation of blocks in base 10^3. Since $10^3 \equiv 1 \pmod 9$,

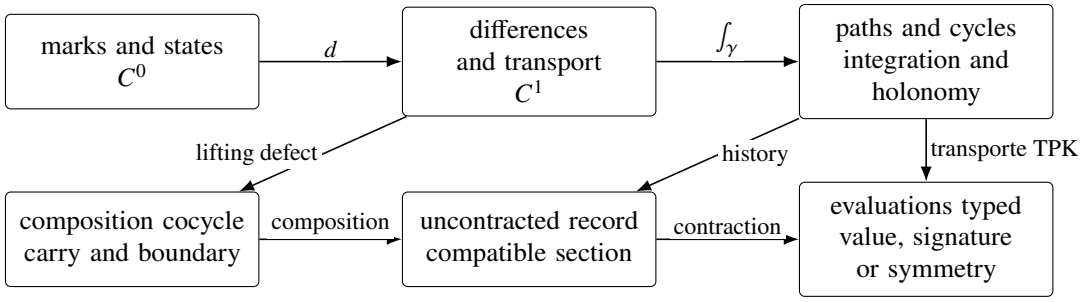


Figure 7.2: Architecture of the discrete measure complex. The difference operator, path integral, and composition cocycle occupy distinct domains; TPK assembles them into a compatible section before a reader publishes a value or a symmetry.

$$r_9(D_N) = r_9\left(\sum_{j=1}^{N} u_j\right), \qquad r_3(D_N) = r_3\left(\sum_{j=1}^{N} u_j\right). \tag{7.13}$$

The basis 10^3 preserves the order of the blocks; the reductions preserve only their accumulated class. The digital root adds a positive section; the radical coordinate recovers an internal direction of (3). This hierarchy fixes what information each reader publishes and what quotient, order, or chart TPK memory must retain in order to reconstruct the antecedent.

7.2.5 Graded system of measurement and non-contracted recording

The three previous levels are organized in a graded system:

degree 0	:	values or states on marks,
degree 1	:	differences and transports along edges,
degree 2	:	composition and carry cocycles.

Degrees zero and one form the cellular complex $C^0 \xrightarrow{d} C^1$; degree two lies in the nerve complex of the path category. Their union constitutes the *discrete measure complex*: an organizing structure that preserves the distinction between cellular geometry and categorical memory.

For an enriched route $\Gamma = (x_0 \xrightarrow{e_1} x_1 \to \cdots \xrightarrow{e_r} x_r)$, the register is the uncontracted integral

$$\Lambda(\Gamma) = \big((x_{k-1}, e_k, x_k), \omega_k, \kappa_k, \sigma_k, b_k, m_k\big)_{k=1}^{r}, \tag{7.14}$$

where ω_k is the local reading, κ_k the carry, σ_k the orientation or partial signature, b_k the boundary datum, and m_k the preserved memory. An observable is a typed map

$$O = F_O \circ \Lambda.$$

Evaluation may publish a sum, a residual class, a signature, or a scalar without converting those outputs into complete states. Concatenation of routes concatenates registers and adds the cocycle at the common boundary; the uncontracted register therefore preserves exactly the information required to recompose the history that an isolated coordinate contracts.

7.2.6 Reconstruction of the continuum from the inverse system of compatible cylinders

Prolongation to arbitrary depth is formulated by means of an inverse system. Let S_n be nonempty finite sets of enriched prefixes and $r_{n+1,n} : S_{n+1} \to S_n$ surjective restriction maps. Their space of compatible sections is

$$\Omega_\infty = \varprojlim_n S_n = \{(x_n)_n : r_{n+1,n}(x_{n+1}) = x_n\}.$$

Each S_n is endowed with the discrete topology and Ω_∞ with the subspace topology of the product.

7.2.7 Cylinders, ultrametric and Archimedean return with memory conservation

For $a \in S_n$, the prefix cylinder a is

$$[a]_n := \{x \in \Omega_\infty : x_n = a\}. \tag{7.15}$$

Two cylinders at the same level are disjoint, and every cylinder at level $n+1$ is contained in the cylinder of its restriction. This clopen basis publishes the depth shared by two sections without contracting their memory to a real coordinate.

For $x \neq y$, let

$$N(x, y) := \min\{n \geq 0 : x_n \neq y_n\}.$$

Fijado $0 < \vartheta < 1$, definimos

$$d_\vartheta(x, y) := \vartheta^{N(x,y)}, \qquad d_\vartheta(x, x) := 0. \tag{7.16}$$

Proposition 7.7 (First Divergence Ultrametric)**.** *The function d_ϑ is an ultrametric, and its balls are precisely the cylinders, with the index adjustment corresponding to the initial level:*

$$d_\vartheta(x, z) \leq \max\{d_\vartheta(x, y), d_\vartheta(y, z)\}.$$

Therefore, two sections that publish the same value can remain at positive distance when their sheet, carry, boundary or history of prolongation diverges.

Proof. If x and y agree through level n, and y and z do as well, then x and z agree through that level. The first divergence of the first and third states therefore occurs no earlier than the minimum of the other two. Since $0 < \vartheta < 1$, raising ϑ to those exponents yields the strong inequality. The description of the balls follows directly from fixing a common prefix. □

Theorem 7.8 (Compactness and completeness of the genealogical space)**.** *If each S_n is finite and the bonding maps are surjective, then Ω_∞, with d_ϑ, is nonempty, compact, and complete. If, in addition,*

$$\forall x \in \Omega_\infty \; \forall n \; \exists y \neq x : y_n = x_n, \tag{7.17}$$

has no isolated points. In that regime it is a compact metrizable, zero-dimensional, and perfect space; by the classical characterization, it is homeomorphic to Cantor space.

Proof. Surjectivity and finite branching provide a section by König's lemma. The product of the finite discrete sets is compact, and the equations $r_{n+1,n}(x_{n+1}) = x_n$ define a closed subspace. The induced topology coincides with the cylinder topology and, by proposition 7.7, with that of d_ϑ. Every compact metric space is complete. The condition (7.17) guarantees that every cylinder contains a section distinct from its center, so no singleton is open. □

Visible periodicity and state return belong to distinct maps. Let $p : E \twoheadrightarrow B$ be a projection, $T : E \to E$ an enriched transport, and $f : B \to B$ the published evolution, with $p \circ T = f \circ p$. If $f^9 = I_B$, then

$$p \circ T^9 = p, \tag{7.18}$$

so that T^9 preserves each fiber of p, but need not be the identity on it. In the nonadic coordinate

$$(q, r) \longmapsto \begin{cases} (q, r+1), & r < 9, \\ (q+1, 1), & r = 9, \end{cases}$$

one revolution recovers the position and increases the height. Under CT108 periodicity, nine iterations advance one dodecaphase phase, and one hundred eight recover position and phase; the enriched state may still preserve different sheet, boundary, orientation, and genealogy. This is the formal distinction between phase return and state return.

Theorem 7.9 (Reconstruction by Compatible Sections)**.** *The space Ω_∞ is nonempty and compact. Suppose that to each prefix $x_n \in S_n$ there is assigned a compact interval $I_n(x_n) \subset \mathbb{R}$ such that, for every section $x = (x_n)_n$,*

$$I_{n+1}(x_{n+1}) \subseteq I_n(x_n), \qquad \operatorname{diam} I_n(x_n) \longrightarrow 0.$$

Then there exists a unique value

$$\mathrm{ev}_{\mathbb{R}}(x) \in \bigcap_{n \geq 0} I_n(x_n). \tag{7.19}$$

If the interval assignments are locally constant at each level, the evaluation $\mathrm{ev}_{\mathbb{R}} : \Omega_\infty \to \mathbb{R}$ is continuous.

Proof. Surjectivity permits compatible prefixes to be constructed inductively; compactness of the finite sets and the finite-intersection property yield a global section. The product $\prod_n S_n$ is compact, and Ω_∞ is closed, since every compatibility equation defines a closed set. For a fixed section, the intervals are compact, nested, and of diameter tending to zero; the nested-interval theorem yields a unique common point. Given $\varepsilon > 0$, one chooses a level whose interval has diameter less than ε. Sections sharing that prefix have evaluations within the same interval, which proves continuity. □

The real line thus appears as the codomain of a contraction. Two sections may share a value while preserving different records; the relation

$$x \sim_{\mathbb{R}} y \quad \Longleftrightarrow \quad \mathrm{ev}_{\mathbb{R}}(x) = \mathrm{ev}_{\mathbb{R}}(y)$$

forms the Archimedean quotient. The genealogy remains in Ω_∞, whereas the coordinate resides in its real image. The continuum problem therefore receives a constructive answer within the domain covered by the declared prefix systems: continuity of evaluation and memory of the section are coordinated properties, not competing descriptions.

7.2.8 Coherent coverage and reconstruction of the Archimedean quotient

The preceding evaluation assigns a value to each section. To prove that the visible space is completely reconstructed, it is also necessary that refinement lose no points. Let $K \subset \mathbb{R}$ be compact, and suppose that the intervals of the preceding theorem satisfy

$$K = \bigcup_{a \in S_0} I_0(a), \tag{7.20}$$

$$I_n(a) = \bigcup_{\substack{b \in S_{n+1} \\ r_{n+1,n}(b) = a}} I_{n+1}(b) \qquad (a \in S_n). \tag{7.21}$$

These identities define a *coherent covering*: every visible compact decomposes exactly into the compacts of its prolongations.

Theorem 7.10 (Genealogical Reconstruction of a Compact Set)**.** *Suppose that:*

1. *the sets S_n are finite and nonempty, and the bonding maps $r_{n+1,n}$ are surjective;*
2. *the intervals are compact, nonempty, nested, and uniformly contractive;*
3. (7.20) *and* (7.21) *hold.*

Then $\mathrm{ev}_{\mathbb{R}}(\Omega_\infty) = K$*, and the map induced*

$$\overline{\mathrm{ev}}_{\mathbb{R}} : \Omega_\infty/\!\sim_{\mathbb{R}} \xrightarrow{\cong} K \tag{7.22}$$

is a homeomorphism. The fiber over $y \in K$ is the complete set of compatible sections that publish that same value.

Proof. Compactness and continuity follow from theorem 7.9. With $y \in K$ fixed, let

$$T_n(y) := \{a \in S_n : y \in I_n(a)\}.$$

Coherent coverage makes every $T_n(y)$ nonempty and connects each state to a prolongation. The resulting tree is finitely branching and has vertices at every depth; by the infinite-branch lemma it admits a compatible chain $(x_n)_n$. The point y belongs to every $I_n(x_n)$, and contraction forces $\mathrm{ev}_{\mathbb{R}}(x) = y$. Therefore, the evaluation is surjective. The quotient map is continuous and bijective; since its domain is compact and K is Hausdorff, it is a homeomorphism. □

The theorem distinguishes two assertions. The contraction produces a unique value for each genealogy; the coherent covering proves that all values of the compact set appear. A check at finite depth certifies the examined levels, but it does not replace any of these infinite hypotheses.

Proposition 7.11 (Genealogical Atlas of the Real Line)**.** *For each $m \geq 1$, let $K_m = [-m, m]$, and suppose that a system is given that satisfies theorem 7.10, together with closed inclusions*

$$J_m : \Omega_\infty^{(m)} \hookrightarrow \Omega_\infty^{(m+1)}$$

that intertwine the evaluations and the inclusion $K_m \hookrightarrow K_{m+1}$. Then the Archimedean quotient of the strict colimit of the sections is

$$\varinjlim_m K_m = \bigcup_{m \geq 1} [-m, m] = \mathbb{R},$$

with its usual topology, while the fibers of the colimit preserve the genealogies of each value.

Proof. Each piece has quotient K_m by (7.22). The declared inclusions make these quotients compatible. The final topology of the exhaustion by compact intervals coincides with the usual topology of $\mathbb{R}$: a set is open exactly when its intersection with each K_m is open in K_m. □

7.2.9 Algebraic descent of operations

Reconstructing the visible space does not suffice to reconstruct its algebra. Let $\star$ be a continuous partial operation on Ω_∞, with domain $D_\star$ saturated by the fibers of $\mathrm{ev}_{\mathbb{R}} \times \mathrm{ev}_{\mathbb{R}}$.

Theorem 7.12 (Fiberwise Descent Criterion)**.** *There exists a visible operation $\overline{\star}$ that satisfies*

$$\mathrm{ev}_{\mathbb{R}}(x \star y) = \mathrm{ev}_{\mathbb{R}}(x) \,\overline{\star}\, \mathrm{ev}_{\mathbb{R}}(y)$$

if and only if the value of the left-hand side is constant upon replacing x or y by any other representative of its respective fiber. If two descended continuous operations coincide with addition and multiplication on dense subsets of their visible domains, they coincide with them throughout the domain.

Proof. Constancy on fibers is precisely the universal property of the quotient: it permits $\overline{\star}$ to be defined independently of the representative and is necessary for that definition to be meaningful. The final assertion follows from continuity and density. □

APP conserves the datum required to address this descent: the sum and product leaves act on the same support, but maintain different quotients, carries, and fibers. The visible operation can descend even though the memory of its representatives remains distinct.

7.2.10 Projective measure and conservation of the unit

Cylinder topology organizes proximity and truncation; a path theory also requires weights. Let μ_n be a probability measure on S_n. The family is projectively consistent when

$$\mu_n(a) = \sum_{\substack{b \in S_{n+1} \\ r_{n+1,n}(b)=a}} \mu_{n+1}(b). \tag{7.23}$$

The equality expresses the local conservation of the unit: the weight of a truncated history is the sum of the weights of all its prolongations.

Theorem 7.13 (Genealogical Measure on the Inverse Limit)**.** *Every family of finite probabilities satisfying* (7.23) *determines a unique Borel probability μ_∞ on Ω_∞ such that*

$$\mu_\infty([a]_n) = \mu_n(a) \tag{7.24}$$

for every prefix cylinder $a \in S_n$.

Proof. Finite unions of cylinders form an algebra. Any one of them can be refined into a disjoint union at a common level, and (7.23) proves that the sum of their weights does not depend on the chosen level. A premeasure is thereby obtained. Since the cylinders are both open and closed and Ω_∞ is compact, a decreasing sequence of elements of the algebra with empty intersection already reaches the empty set at some level. The premeasure is therefore continuous at the empty set and extends uniquely to the σ-algebra of Borel sets. □

The evaluation transports that measure to the visible compact,

$$\nu = (\mathrm{ev}_{\mathbb{R}})_* \mu_\infty, \qquad \nu(B) = \mu_\infty\big(\mathrm{ev}_{\mathbb{R}}^{-1}(B)\big). \tag{7.25}$$

The visible probability adds the genealogies of a single fiber without erasing them from the total space.

Proposition 7.14 (Value Decomposition and Genealogical Multiplicity)**.** *If K is a standard Borel space, then for ν-almost every $y \in K$ there exists a conditional probability μ_y supported on*

$$\mathfrak{G}_y := \mathrm{ev}_{\mathbb{R}}^{-1}(y)$$

such that, for every integrable function F,

$$\int_{\Omega_\infty} F \, \mathrm{d}\mu_\infty = \int_K \left(\int_{\mathfrak{G}_y} F \, \mathrm{d}\mu_y \right) \mathrm{d}\nu(y). \tag{7.26}$$

Thus, the visible coordinate and the distribution of histories that realize it are distinct typed data: an observable that factors through $\mathrm{ev}_{\mathbb{R}}$ *reads only ν, whereas a memory reader can distinguish the measures μ_y within a single fibre.*

Proposition 7.15 (Compatible cylinder conditioning)**.** *Let $A \subseteq \Omega_\infty$ be a union of cylinders of level m, with $\mu_\infty(A) > 0$. For every $n \geq m$, the conditioned distribution on S_n is obtained by suppressing the states whose truncation does not belong to A and renormalizing the remaining weights. The resulting distributions continue to satisfy projective consistency* (7.23)*.*

Proof. This is Bayes' rule on the finite sets at level n. The sum of the conditional weights of the prolongations equals the conditional weight of the parent because intersection with A distributes over the disjoint union of its prolongations. Conditioning eliminates incompatible futures and redistributes the unit among the survivors; it neither creates new histories nor removes from the total space those lying outside the event being read. □

This separation provides the exact basis for distinguishing preparation, reading, conditioning, and history in the quantum realization.

Mathematical force and architectural function

The rank $n - 1$, the discrete fundamental theorem, the carry cocycle identity, the reconstruction theorems, and the projective measure are exact results in the declared domains. Their HMT application uses as its starting structure the states, restrictions, intervals, and transports constructed by APP–TRIT–TPK. The discrete measure complex is an organizing formalization: it does not identify the degree-two categorical cocycle with a geometric cell until the corresponding map is provided. This separation allows the common language subsequently to govern holonomy, the sum over paths, and the transition from number to particle without anticipating their physical realizations.

Chapter 8

nonadic holonomy Γ_9 of the Topological Phase Kernel: transport of the enriched state, coinductive prolongation and 9→1 return with memory advance

The connection is constructed from the complete orbital classification and from its first coinductive elevation. The following development fixes the three initial histories, the oriented boundaries and the chain $w_6 \to w_{30} \to R_{36}$ before introducing the nonadic holonomy.

8.1 Orbital classification, initial words and 1st boundary

The ternary reduction of the emitter realizes 243 words within the ambient fiber $\mathbb{F}_3^6$. This unit does not choose three words by decimal comparison. It first constructs the symmetry action of the catalogue, classifies its orbits by integer invariants, and only afterwards orients the three structural representatives.

8.1.1 Dihedral action on 6 coordinates

For $u = (u_1, u_2, u_3, u_4, u_5, u_6) \in \mathbb{F}_3^6$, define

$$r(u) = (u_3, u_1, u_2, u_5, u_6, u_4),$$
$$s(u) = (u_4, u_5, u_6, u_1, u_2, u_3).$$

We verify

$$r^3 = s^2 = 1, \qquad srs = r^{-1}.$$

Therefore, r, s generate an action of D_3.

The same permutation acts on the six blocks of each emission $U = (U_1, \ldots, U_6)$. The projection Ψ satisfies

$$\Psi(gU) = g\Psi(U), \qquad g \in D_3.$$

Theorem 8.1 (Orbital decomposition of the catalog)**.** *The 243 realized words decompose into 43 orbits:*

$$38 \textit{ orbits of cardinality } 6, \qquad 5 \textit{ orbits of cardinality } 3.$$

In particular,

$$38 \cdot 6 + 5 \cdot 3 = 243.$$

Proof. The set is applied to each word.

$$\{u, ru, r^2u, su, sru, sr^2u\}$$

and repetitions are removed. Exhaustive enumeration of the catalog produces the indicated histogram. The equivariance of Ψ ensures that no orbit leaves the realized image. □

8.1.2 Fiber Invariants

For a word realized w, let

$$\mathcal{F}_w := \{U \in \operatorname{im} T_{\min} : \Psi(U) = w\},$$
$$n(w) := |\mathcal{F}_w|, \qquad M(w) := \sum_{U \in \mathcal{F}_w} \operatorname{mult}(U),$$

and

$$c(w) = \big(\#\{j : w_j = 0\}, \#\{j : w_j = 1\}, \#\{j : w_j = 2\}\big).$$

The enriched catalogue further preserves, for each emission, a diagonal coordinate $\mathrm{diag}_c(U) \in \{0, \dots, 8\}$, a cardinal orientation $h_+(U)$, and the multiplicative signature $E_{\mathrm{sig}}(U)$. All of them are computed from the seed route; they are not read from a target constant. Their componentwise algorithm will be printed alongside the complete catalogue in the certification appendix and forms part of the input state of the following predicates.

Definition 8.2 (Closure orbit)**.** An orbit $\mathcal{O}$ is of closure if it has cardinality six and, for each $w \in \mathcal{O}$,

$$n(w) = 5, \qquad M(w) = 1008,$$

$$\{\mathrm{mult}(U) : U \in \mathcal{F}_w\} = \{432, 144, 144, 144, 144\},$$

and the common tritic census is $c(w) = (2, 3, 1)$.

Definition 8.3 (Radical Minimal Orbits)**.** An orbit $\mathcal{O}$ is minimally radical if it has cardinality six, each word possesses a unique emission of multiplicity 144, and

$$\{\mathrm{diag}_c(U) : \Psi(U) \in \mathcal{O}\} = \{0, 3, 6\}.$$

Among them, the orbit with census $(2, 3, 1)$ is called the propagation orbit, and the orbit with census $(2, 2, 2)$ is called the self-scaling orbit.

Theorem 8.4 (Uniqueness of the Three Structural Orbits)**.** *In the catalogue of 468 emissions there exists a unique closure orbit, a unique minimally radical orbit of propagation, and a unique minimally radical orbit of self-scale.*

Proof. The 43 orbits of theorem 8.1 are enumerated. For each one, $n(w)$, $M(w)$, the multiset of multiplicities, the census $c(w)$, and the diagonal support are computed. The predicates of definitions 8.2 y 8.3 leave exactly one orbit in each class. The proof is exhaustive over a finite set and does not use decimal digits of the analytic characters. □

The three orbits are

$$\begin{aligned} \mathcal{O}_{\mathrm{cl}} &= \{001112, 010211, 100121, 112001, 121100, 211010\}, \\ \mathcal{O}_{\mathrm{prop}} &= \{011120, 012110, 101201, 110012, 120011, 201101\}, \\ \mathcal{O}_{\mathrm{aut}} &= \{002112, 020211, 112002, 121200, 200121, 211020\}. \end{aligned}$$

8.1.3 Internal Orientation of Each Orbit

We fix the internal caliber.

$$\mathrm{diag}_c(U) = 6, \qquad h_+(U) = ES.$$

A word in an orbit is admissible in that gauge if some emission in its fiber satisfies both conditions.

Proposition 8.5 (Unique oriented representative)**.** *Each of the three structural orbits contains a unique word admissible in the gauge* $(6, ES)$*. They are*

$$\boxed{w_6^{\pi} = 010211, \qquad w_6^{e} = 201101, \qquad w_6^{\varphi} = 121200.}$$

Proof. The enumeration of the catalogue fibers counts the words containing an emission with $\mathrm{diag}_c = 6$ and $h_+ = ES$. In each of the three orbits, the number of coincidences is one. The superscripts π, e, φ henceforth name the structural functions of closure, propagation, and self-scaling; they did not participate in the selection. □

8.1.4 Closure microfiber

The fiber of the representative w_6^{π} consists of five emissions:

U_6	E_{sig}	mult	diag_c	stratum
501|614|498|169|272|272	555555	432	4	$\perp$
810|923|870|169|272|272	339555	144	6	++
810|983|810|169|272|272	393555	144	6	++
870|923|810|169|272|272	933555	144	6	++
870|923|810|418|674|521	933717	144	5	−−

Thus,

$$432 + 4 \cdot 144 = 1008, \qquad 5 = 1_{\perp} + 3_{++} + 1_{--}.$$

The unipolar emissions oriented of the other two channels are

$$U_e = 850|963|890|149|252|212,$$

$$U_{\varphi} = 830|943|830|109|252|252.$$

The mass 1008 of this microfiber is not the period of the calendar C_{108}; the two numbers belong to different domains.

8.1.5 Ternary lifting matrices

On row vectors of $\mathbb{F}_3^6$, the two unique transports reconstructed from the oriented register produced by the TPK transition are

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix}.$$

The simultaneous compatibility of the three biographies uniquely selects the lifting calendar (L_0, L_0, L_1, L_1) among the sixteen binary calendars of length four.

Definition 8.6 (Block recurrence and concatenation)**.** For each channel $\chi \in \{\pi, e, \varphi\}$, let $b_0^{\chi} = w_6^{\chi}$ and

$$b_{k+1}^{\chi} = b_k^{\chi} L_{\epsilon_k} \pmod 3, \qquad (\epsilon_0, \epsilon_1, \epsilon_2, \epsilon_3) = (0, 0, 1, 1).$$

The accumulated word is

$$w_{30}^{\chi} = b_0^{\chi} \| b_1^{\chi} \| b_2^{\chi} \| b_3^{\chi} \| b_4^{\chi}.$$

This formulation distinguishes the current block $b_k \in \mathbb{F}_3^6$ from the concatenated word $w_{6(k+1)}$. A word of length $6k$ is not multiplied by a matrix 6×6.

Theorem 8.7 (Ternary biographies of thirty positions)**.** *The recurrence of the definition 8.6 produce*

$$w_{30}^{\pi} = 010211|012222|010211|002111|110221,$$
$$w_{30}^{e} = 201101|121221|102011|012222|102011,$$
$$w_{30}^{\varphi} = 121200|112202|121020|010210|010200.$$

Proof. The five row vectors are successively multiplied by the indicated matrices, reducing each coordinate modulo three after each product. The concatenation of the five computed blocks gives the three expressions. Each equality can be verified component by component by means of 24 scalar products per channel. □

The environmental indices of the five blocks are

	b_0	b_1	b_2	b_3	b_4
π	103	161	103	67	349
e	523	457	301	161	301
φ	450	398	438	102	99

,

where each word of six trits is interpreted as an integer in base three.

8.1.6 1st common boundary

The boundary is obtained through a finite relation that preserves axis, aggregate, saturation, column occupancy, and dual neutrality. The incidence matrix used in this relation is

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3). \tag{8.1}$$

If u_4^{χ} is the fifth block of w_{30}^{χ}, the axis and the aggregate prior to separating the two lateral channels are

$$u_5^{\varphi} = u_4^{e} = 102011, \qquad u_5^{\pi} + u_5^{e} = 210112, \qquad u_4^{\varphi} A_W L_1^3 = 111101. \tag{8.2}$$

From them, they calculate

$$q = 012120, \qquad a = 111101, \qquad qA_W = 012000, \qquad aA_W = 120210. \tag{8.3}$$

Depth six imposes the saturation $c = 111111$; the minimal compatible occupancy is colw = 223232; and dual neutrality requires

$$(BA_W)\mathbf{1} = 000. \tag{8.4}$$

Proposition 8.8 (Enumeration of the first boundary)**.** *The conditions* (8.2)– (8.4) *leave exactly two matrices:*

$$B_- = \begin{pmatrix} 021222 \\ 222220 \\ 102011 \end{pmatrix}, \qquad B_+ = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}. \tag{8.5}$$

The mirror involution swaps its first two rows. Its internal cards are, respectively,

$$B_- \longmapsto (789, 048, 894), \qquad B_+ \longmapsto (793, 045, 894). \tag{8.6}$$

The orientation APP of the cylinder semiabierto selecciona B_+.

Proof. The axis fixes the third row and the aggregate fixes the sum of the first two. Saturation and occupation eliminate the distributions that do not fill the six columns. The enumeration of the solutions of the six linear equations of (8.4) leaves the two matrices of (8.5); the semi-open chart and the orientation distinguish the second without consulting a target decimal expansion. □

We therefore define,

$$R_{36} := B_+ = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}, \qquad \mathrm{ind}_3(R_{36}) = (726, 215, 301). \tag{8.7}$$

The object R_{36} contains three ordered blocks of six trits. It is not the predictive quotient C_{36}^{pred} of theorem 1.166 or the excess of 36 classes of the seed gauge.

8.1.7 Residue–quotient lifting

Let $A \in M_6(\mathbb{Z})$ be the integer lift of L_0:

$$A = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad \det A = 1.$$

For $x_k \in \mathbb{Z}^6$, define

$$y_k = x_k A, \qquad u_k = y_k \bmod 3 \in \{0,1,2\}^6, \qquad x_{k+1} = \frac{y_k - u_k}{3}.$$

Then

$$x_k A = u_k + 3x_{k+1}. \tag{8.8}$$

Theorem 8.9 (Reversibility of the lift)**.** *The pair (u_k, x_{k+1}) is uniquely determined by x_k, and*

$$x_k = (u_k + 3x_{k+1})A^{-1}.$$

Proof. Euclidean division by three in each coordinate of $x_k A$ determines residue and quotient. Since $\det A = 1$, the inverse A^{-1} has integer coefficients. Multiplying equation (8.8) by it recovers x_k. □

In channel e, the visible block 102011 reappears twice, but the prestates modulo 27 are

$$(25, 11, 7, 17, 8, 16) \neq (7, 8, 4, 23, 26, 7),$$

and the subsequent quotients are

$$(6, 13, 9, 2, 13, 1) \neq (15, 0, 3, 19, 23, 25).$$

It is thus explicitly verified that the visible-phase return of a word is not the return of the enriched state.

8.1.8 Obstructions to orbital selection and to the lifting $w_6 \to w_{30} \to R_{36}$: uniqueness, gauge, and Hensel reversibility

Comparison Criterion 8.10 (Orbital selection refutation criteria)**.** The unit is refuted if:

1. the action D_3 leaves the catalogue or changes multiplicities;
2. any one of the three structural predicates leaves more than one orbit;
3. the gauge $(6, ES)$ selects two words in an orbit;
4. a target digit is used to define the predicates;
5. the accumulated word w_{6k} is multiplied by L_0 or L_1 instead of the block b_k;

6. $\det A \neq 1$ or fails the inverse of the lift;
7. two equal visible residues are declared to be equal complete states.

The first joint boundary has already been constructed. The next unit will classify the nine phase components, prove the nonadic return without resetting, and construct the oriented mirror with its local resolution $3 \to 1$.

8.2 Joint Holonomy Γ_9: observable compression T, orthogonal component η and terminal memory conservation

The nine phases that appear after R_{36} are not nine independent proofs. They are the nine local components of a single connection on enriched states. Their composition around a turn defines a holonomy. The return of the phase label conserves the continuity of prefix, carry, boundary, Witt shadow, and memory.

8.2.1 Transport of the enriched state by the nonadic holonomy and memory update

At the level K, we write

$$\widehat{x}_K = (B_K, C_K, p_K, c_K, \Sigma_K, W_K, g(K), q_{\mathrm{mem},K}),$$

where:

1. $B_K = (u_K^{\pi}, u_K^{e}, u_K^{\varphi})$ is the visible block of three words of six trits;
2. C_K is the cylinder ternario compatible;
3. p_K is the complete prefix;
4. c_K is the accumulated carry;
5. Σ_K is the signature joint of boundary;
6. W_K is the Witt incidence shadow;
7. $g(K) = 1 + ((K-1) \bmod 9)$ is the public phase label;
8. $q_{\mathrm{mem},K} \in \mathbb{Z}_{\geq 0}$ is the memory vertical not acotada.

The dodecaphasic coordinate is derived:

$$\beta_K = [q_{\mathrm{mem},K}]_{12}.$$

q_{mem} is not replaced by β, since reduction modulo twelve would lose the number of circuits.

8.2.2 Local transition relations and construction of the nonadic holonomy Γ_9

For each K, let

$$\mathcal{R}_K \subseteq \widehat{X}_K \times \widehat{X}_{K+1}$$

the relation of compatible extension between complete states. The relational composition of a loop is

$$\Gamma_{9,K} := \mathcal{R}_{K+8} \circ \cdots \circ \mathcal{R}_{K+1} \circ \mathcal{R}_K : \widehat{X}_K \longrightarrow \widehat{X}_{K+9}. \tag{8.9}$$

Definition 8.11 (Nonadic holonomy)**.** The holonomy of one turn is

$$\Gamma_9 := \mathrm{Hol}_{C_9}(\nabla_{\mathrm{TPK}}),$$

whose realization at level K is $\Gamma_{9,K}$. The nine relations $\mathcal{R}_K, \ldots, \mathcal{R}_{K+8}$ are charts of this single connection.

Theorem 8.12 (Phase return without restart)**.** *If* $(\widehat{x}_K, \widehat{x}_{K+9}) \in \Gamma_{9,K}$*, then*

$$g(K+9) = g(K), \qquad q_{\mathrm{mem},K+9} = q_{\mathrm{mem},K} + 1,$$

and

$$\beta_{K+9} = \beta_K + 1 \pmod{12}.$$

In general, $\widehat{x}_{K+9} \neq \widehat{x}_K$.

Proof. The first identity follows from the definition of g. A complete turn increments the unbounded winding counter by definition. Reducing that identity modulo twelve yields the third. The remaining coordinates are transported by the composition equation (8.9); no law of the TPK resets them. Therefore, equality of phase does not imply equality of the complete state. □

8.2.3 Exhaustive classification of the 9 phases of the Topological Phase Kernel

The visible blocks and the local censuses of the first round are

K	N_π	N_e	N_φ	N_{loc}	N_{ext}	u^π	u^e	u^φ
1	378	422	349	3	2	012222	121221	112202
2	238	368	388	2	5	010211	102011	121020
3	184	284	173	5	4	002111	012222	010210
4	207	207	122	4	1	110221	102011	010200
5	39	151	151	1	1	222220	021222	102011
6	110	110	69	1	3	111201	201202	221021
7	81	29	81	3	3	212121	222210	200221
8	59	59	59	3	2	200121	212212	110110
9	43	43	43	2	1	100100	020112	010122

Theorem 8.13 (Functions of the nine components)**.** *In the preceding turn, the nine components perform the following functions:*

1. *local opening of three orientations and first resolution;*
2. *binary split with a local maximum of five extensions;*
3. *maximal local multiplicity of five states;*
4. *contraction of four local states to an extension;*
5. *first strong saturation, with a single continuation;*
6. *unique local present and triple opening of the future;*
7. *triple mirror fiber;*
8. *synchronization of the three censuses in* 59*;*
9. *oriented closure: two local input states and a relation that, after the additional horizon, conserves a prolongation.*

Proof. Each assertion is read from the censuses $N_{\mathrm{loc}}, N_{\mathrm{ext}}$, from the equality or inequality of N_π, N_e, N_φ, and from the explicit extension relation in the ninth, tenth, and eleventh phases to be proved in the following unit. The table enumerates the entire revolution; no subset of phases has been chosen. □

The fifth component coincides with the first common boundary.

$$R_{36} = (222220|021222|102011)^T.$$

The ninth component contains

$$B_9 = (100100|020112|010122).$$

The presence of two local states in the ninth phase and of three extensions from the oriented state belongs to different layers; they are not contradictory censuses.

Holonomy acts on the complete enriched state. Before its modal quotient is published, one therefore constructs the involution that exchanges the π and e fibres, the fixed φ axis, the ternary invariants, and the local $3 \to 1$ resolution determined by the second horizon.

8.3 Mirror involution and local selection $3 \to 1$ of the surviving extension

The ninth phase contains two local input states. Once the oriented state B_9 has been fixed, the boundary relation produces three extensions toward the first phase. The three share an axis of self-scale and a ternary aggregate; they differ in the ordered distribution of that aggregate between the branches of closure and propagation. A second horizon conserves exactly one.

8.3.1 Symmetric and axial coordinates

Let

$$\mathcal{B} := (\mathbb{F}_3^6)^3.$$

A visible block is

$$B = (u^\pi, u^e, u^\varphi) \in \mathcal{B}.$$

We define

$$q(B) := u^\pi + u^e + u^\varphi, \qquad a(B) := u^\pi + u^e - u^\varphi.$$

All operations are performed componentwise in $\mathbb{F}_3^6$.

Theorem 8.14 (Reconstruction of the axis and the aggregate)**.** *The coordinates q, a determine*

$$\boxed{u^\varphi = 2(q-a),} \qquad \boxed{u^\pi + u^e = q - u^\varphi.}$$

Proof. Subtracting the definitions gives $q - a = 2u^\varphi$. In $\mathbb{F}_3$, $2^{-1} = 2$; therefore, $u^\varphi = 2(q-a)$. Substitution into the definition of q recovers the remaining aggregate. □

The specular involution is

$$\mathfrak{c}(u^\pi, u^e, u^\varphi) = (u^e, u^\pi, u^\varphi).$$

Proposition 8.15 (Invariants of the Involution)**.** $\mathfrak{c}^2 = \mathrm{id}$*, y*

$$q(\mathfrak{c}B) = q(B), \qquad a(\mathfrak{c}B) = a(B).$$

In particular, u^φ and $u^\pi + u^e$ are invariantes.

Proof. Exchanging the first coordinates twice recovers B. Both q and a depend on them only through their sum, so that the exchange preserves them. The theorem 8.14 transfers that invariance to the axis and the aggregate. □

The involution asserts neither that $\pi = e$ nor that one is the quotient of the other. It asserts that the two branches occupy conjugate positions with respect to a fixed structure.

8.3.2 Oriented state in phase 9 and associated boundary data

The visible projection of the selected state is

$$B_9 = (100100 \mid 020112 \mid 010122).$$

The induced relation on visible blocks is denoted

$$\mathcal{M}_9^B \subseteq \mathcal{B} \times \mathcal{B}.$$

The two local input states of the phase table precede this relation. After selecting the complete state that projects to B_9, its output fiber has cardinal three.

Theorem 8.16 (The three extensions of the ninth phase)**.** *The relational image of B_9 contains exactly*

$$\begin{aligned} B_{10}^{(0)} &= (101222 \mid 112221 \mid 112002), \\ B_{10}^{(1)} &= (102221 \mid 111222 \mid 112002), \\ B_{10}^{(2)} &= (111221 \mid 102222 \mid 112002). \end{aligned}$$

The three satisfy

$$q_{10} = 022112, \qquad a_{10} = 101111,$$

and, consequently,

$$u_{10}^{\varphi} = 112002, \qquad u_{10}^{\pi} + u_{10}^{e} = 210110.$$

Proof. The extension relation on complete states is enumerated in the fiber of B_9 and produces the three indicated rows. Adding and subtracting their three components gives the same pair (q_{10}, a_{10}) in all three cases. The theorem 8.14 produces the common axis and aggregate. The first two components are distinct, so the three rows represent different distributions of the same aggregate. □

All their publications in base three are

$$(279, 352, 365), \qquad (280, 351, 365), \qquad (282, 350, 365).$$

8.3.3 Exact compatibility of cylinders

A ternary word of length L and index N determines the half-open cylinder

$$I_3(N, L) = \left[\frac{N}{3^L}, \frac{N+1}{3^L} \right).$$

A prefix of b decimal blocks, with associated integer D, determines

$$I_{1000}(D, b) = \left[\frac{D}{1000^b}, \frac{D+1}{1000^b} \right).$$

Lemma 8.17 (Integer intersection test)**.** *The cylinders $I_3(N, L)$ and $I_{1000}(D, b)$ intersect if and only if*

$$N 1000^b < (D+1) 3^L, \qquad (N+1) 1000^b > D 3^L.$$

Proof. Two half-open intervals $[a, b)$ and $[c, d)$ intersect if and only if $a < d$ and $c < b$. We substitute the four endpoints and multiply by the positive integer $3^L 1000^b$. □

The test uses only integer arithmetic. It does not depend on a floating-point tolerance.

8.3.4 2nd horizon and uniqueness

The following block is

$$B_{11} = (022212 \mid 110001 \mid 100021),$$

and the corresponding decimal boundary is

$$(502, 662, 638).$$

Theorem 8.18 (Local resolution $3 \to 1$)**.** *The three extensions of theorem 8.16 are compatible at depth one. When B_{11} and the boundary $(502, 662, 638)$ are imposed simultaneously, only $B_{10}^{(0)}$ prolongs as the same complete state. Therefore,*

$$\boxed{\#\,\mathrm{Surv}_1^{\mathrm{cal}}(B_9) = 3, \qquad \#\,\mathrm{Surv}_2^{\mathrm{cal}}(B_9) = 1.}$$

Proof. We apply lemma 8.17 to each of the three channels. At the first horizon, the six inequalities of every candidate are satisfied. After adjoining B_{11}, the inequalities of the three channels remain satisfied for $B_{10}^{(0)}$. In $B_{10}^{(1)}$ and $B_{10}^{(2)}$, compatibility of channel φ is preserved, but the conditions of branches π and e fail. Enumeration therefore leaves a unique state at depth two. □

This proof does not define the global connection from a local example. It is an explicit witness of how a multivalued relation at one horizon can become single-valued by preserving memory and requiring a longer prolongation.

8.3.5 Phase return with block change

The first phase of the initial loop is

$$B_1 = (012222 \mid 121221 \mid 112202),$$

while the first phase of the next turn is

$$B_{10} = (101222 \mid 112221 \mid 112002).$$

Thus,

$$g(1) = g(10) = 1, \qquad B_1 \neq B_{10}.$$

The phase returns, but the axis, the aggregate, the distribution, and the memory of quotient have evolved.

8.3.6 Diagram of the mirror involution π/e, the fixed axis φ, and the local selection $3 \to 1$ by prolongability

8.3.7 Residue–quotient memory during the mirror

The recurrence

$$x_k A = u_k + 3x_{k+1}$$

of the equation (8.8) is applied to each of the three channels. The part u_k publishes the visible block; x_{k+1} conserves the quotient. Since $A \in \mathrm{GL}_6(\mathbb{Z})$, the pair recovers the preceding state. The mirror can exchange the visible branches without eliminating their provenance quotients.

8.3.8 Obstructions to the mirror involution π/e and to the local selection $3 \to 1$: invariants, depth-2 horizon, and Hensel memory

Comparison Criterion 8.19 (Refutation Criteria for the Mirror)**.** The construction is refuted if:

1. the involution modifies u^{φ} or $u^{\pi} + u^{e}$;
2. the two local input states are conflated with the three outputs;

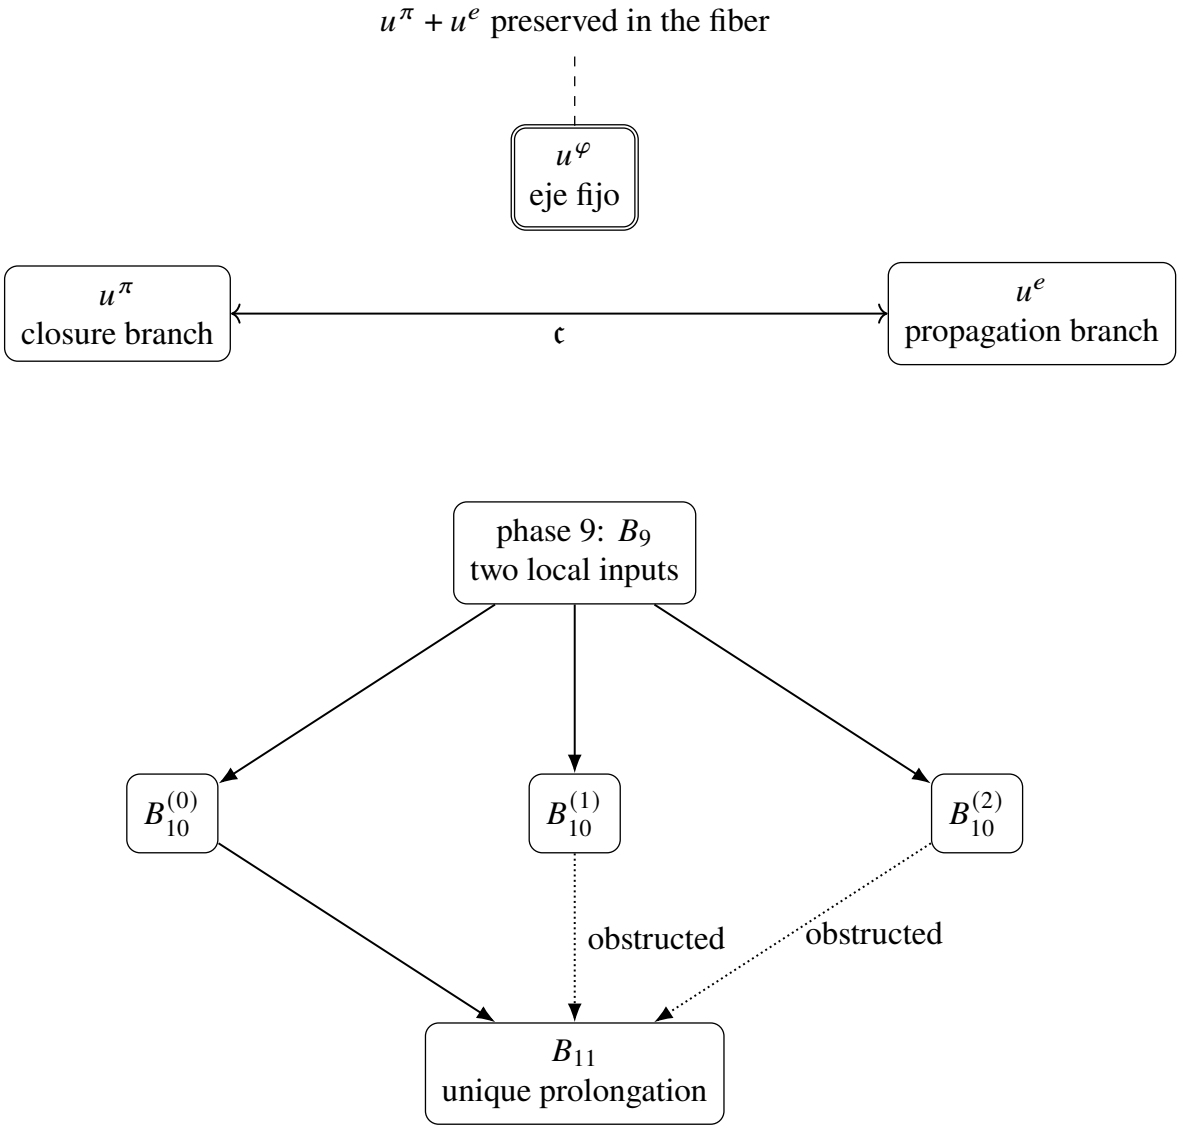

Figure 8.1: The mirror preserves the axis u^{φ} and the aggregate $u^{\pi} + u^{e}$. The return of the ninth phase opens three visible extensions; the memory of the second horizon preserves one. The circuit does not reset the state.

3. one of the three outputs has a different (q_{10}, a_{10});
4. the cylinder test uses a floating tolerance;
5. more than one output survives the declared second horizon;
6. phase return is interpreted as equality $B_1 = B_{10}$;
7. the visible exchange erases the Hensel quotients.

The mirror and the local selection have now been constructed. The following units will develop the Sturmian vacancies and then the three complete analytic biographies.

8.3.9 Joint transfer of the fiber of 468 emissions

The factorization of the catalog is

$$\mathcal{U}_6^{\mathrm{cat}} \cong \mathfrak{S}_+ \times \mathfrak{S}_\times, \qquad |\mathfrak{S}_+| = 18, \qquad |\mathfrak{S}_\times| = 26.$$

For a function f on the catalogue, let

$$(E_+ f)(s,e) = \frac{1}{18} \sum_{s' \in \mathfrak{S}_+} f(s', e),$$

and

$$(E_\times f)(s,e) = \frac{1}{26} \sum_{e' \in \mathfrak{S}_\times} f(s, e').$$

The projectors E_+ and $E_\times$ commute.

Let

$$\tau = (+1, -1, 0, +1, -1, 0, +1, -1, 0), \qquad P_{+1} = E_+, quadP_{-1} = E_\times, quadP_0 = I.$$

On $\mathcal{U}_6^{\mathrm{cat}} \times C_9$ we define phase transfer by

$$\mathcal{K}_{\mathrm{ph}}\big((u,r),(v,[r+1]_9)\big) := P_{\tau(r)}(u,v), \tag{8.10}$$

and we make it zero for the remaining pairs of phases. Thus, the cyclic permutation and the operator applied in each of the nine steps are determined.

Proposition 8.20 (Joint Renewal After a Turn)**.**

$$\mathcal{K}_{\mathrm{ph}}^9 = E_+ E_\times.$$

In particular, on a point mass,

$$(E_+ E_\times)(u,v) = \frac{1}{18 \cdot 26} = \frac{1}{468}.$$

Proof. The ordered product over a loop is

$$P_{\tau(8)} P_{\tau(7)} \cdots P_{\tau(0)} = I E_\times E_+ I E_\times E_+ I E_\times E_+ = E_+^3 E_\times^3 I^3 = E_+ E_\times.$$

The second equality uses commutativity and the final one idempotence. The second result is the uniform distribution on the product of the two signatures. □

This identity expresses a joint renewal, not nine independent filtrations.

8.3.10 Decomposition of the holonomy U_{Γ_9} into visible compression T and orthogonal component η: $I - T^*T = \eta^*\eta$

Let $\mathcal{H}_{\text{vis}}$ and $\mathcal{H}_{\text{full}}$ be Hilbert spaces for the visible and complete realizations. Let

$$J : \mathcal{H}_{\text{vis}} \longrightarrow \mathcal{H}_{\text{full}}$$

an isometric inclusion and U_{Γ_9} an isometric realization of the holonomy. We define

$$T := J^* U_{\Gamma_9} J, \qquad \eta := (I - JJ^*) U_{\Gamma_9} J.$$

Theorem 8.21 (Compression-decomposition expression)**.** *The following hold*

$$\boxed{U_{\Gamma_9} J = JT + \eta,}$$

$$J^*\eta = 0, \qquad \boxed{I - T^*T = \eta^*\eta.}$$

Proof. We decompose $U_{\Gamma_9} J$ by means of the orthogonal projections JJ^* and $I - JJ^*$:

$$U_{\Gamma_9} J = JJ^* U_{\Gamma_9} J + (I - JJ^*) U_{\Gamma_9} J = JT + \eta.$$

Orthogonality gives $J^*\eta = 0$. Since J and U_{Γ_9} are isometries,

$$I = J^* U_{\Gamma_9}^* U_{\Gamma_9} J = T^*T + \eta^*\eta.$$

Reorder the proof of the last identity. □

T is the visible compression; η is the complementary expression. Neither should be called a strict contraction. For that function a different operator is reserved.

8.3.11 Strict contraction and terminal telescoping

Let V_9 be an isometry and let q be a parameter with $0 < q < 1$. We define

$$M_9 = qV_9, \qquad D_9 = (I - M_9^* M_9)^{1/2}.$$

Then $\|M_9\| = q < 1$ and

$$I - M_9^* M_9 = D_9^* D_9.$$

Theorem 8.22 (Stein Identity with Terminal Term)**.** *For every $L \geq 1$,*

$$\boxed{I = \sum_{r=0}^{L-1} M_9^{*r} D_9^* D_9 M_9^r + M_9^{*L} M_9^L.}$$

More generally, if S_0 satisfies $S_0 - M_9^* S_0 M_9 = D_9^* D_9$, then

$$\boxed{S_0 = \sum_{r=0}^{L-1} M_9^{*r} D_9^* D_9 M_9^r + M_9^{*L} S_0 M_9^L.}$$

Proof. We multiply the defect identity on the left by M_9^{*r} and on the right by M_9^r. Upon summing over $r = 0, \ldots, L-1$, the interior terms telescope, leaving the initial and terminal terms. The same proof applies to the general Stein equation. □

The final term does not vanish at finite depth. Its disappearance in a limit requires a convergence proof; it is not part of the algebraic identity.

8.3.12 Carry Cocycle and Relational Powers

For composable arrows γ_1, γ_2, the carry satisfies

$$\mathrm{Carr}(\gamma_2\gamma_1) = \mathrm{Carr}(\gamma_2)H(\gamma_1) + Y(\gamma_2)\,\mathrm{Carr}(\gamma_1).$$

The formula preserves the contribution of the first stage after transporting it through the second.

The longer loops are written with displaced indices:

$$\begin{aligned}\Gamma_{27,K} &= \Gamma_{9,K+18} \circ \Gamma_{9,K+9} \circ \Gamma_{9,K},\\ \Gamma_{54,K} &= \Gamma_{9,K+45} \circ \cdots \circ \Gamma_{9,K},\\ \Gamma_{108,K} &= \Gamma_{9,K+99} \circ \cdots \circ \Gamma_{9,K}.\end{aligned}$$

Only after declaring a global operator on the graded union may this notation be abbreviated as $\Gamma_9^3, \Gamma_9^6, \Gamma_9^{12}$.

8.3.13 Complete nonadic state: phase, carry, boundary, route, and memory after the prolongation

The one-turn connection is recorded by the quintuple

$$\mathfrak{N}_9 = \big(\Gamma_9, T, \eta, \mathrm{Carr}, S_{\mathrm{term}}\big),$$

where $S_{\mathrm{term}} = M_9^{*L} S_0 M_9^L$ at a finite depth L. An application functor that uses the connection must declare its compatibility with all five fields. Commuting only with the visible phase does not constitute naturality with respect to the complete nonadic state.

8.3.14 Obstructions of the holonomy Γ_9: 9→1 return, composition indices and phase conservation, carry, boundary, path and memory

Comparison Criterion 8.23 (Refutation Criteria of the Connection)**.** The construction is refuted if:

1. the nine phases are presented as independent filters;
2. the return $9 \to 1$ resets q_{mem}, the prefix, or the carry;
3. T is called a strict contraction;
4. some identity of theorem 8.21 fails;
5. the terminal term is removed at finite depth;
6. $\Gamma_{27,K}$ is composed without shifting the indices;
7. an application functor ignores any of the five fields of $\mathfrak{N}_9$.

The complete developments that follow first reconstruct the finite emitter, its factorization and its microfibers; they then unfold the specular involution, the three extensions of B_9, uniqueness at two horizons and the Bockstein–Hensel inverse that preserves memory during phase return.

8.4 Finite arithmetic image and factorization $468 = 18 \cdot 26$

The image in base 1000 of the finite map that assigns the decimal blocks is a proper subset of the one thousand decimal blocks. The evolution law defined in the section 4.1 and the arithmetic of $\mathbb{Z}/9\mathbb{Z}$ determine an image of 42 triples, organized into six classes of seven. The same separation of the additive and multiplicative observables subsequently factors the 468 outputs into 18 additive signatures and 26 multiplicative signatures.

8.4.1 Primitives and recurrence of the finite sender

Definition 8.24 (Initial data of $T_{\min}$)**.** Let $D = \{N, E, S, O\}$ be given, with cardinal vectors

$$v(N) = (-1, 0), \quad v(E) = (0, 1), \quad v(S) = (1, 0), \quad v(O) = (0, -1) \qquad \text{in } (\mathbb{Z}/9\mathbb{Z})^2.$$

The temporal signature and the multiplicative index are fixed by

$$\operatorname{sgn}_9(t) = \begin{cases} +1, & t \bmod 9 \in \{1, 4, 7\}, \\ -1, & t \bmod 9 \in \{2, 5, 8\}, \\ 0, & t \bmod 9 \in \{0, 3, 6\}, \end{cases}$$

and

$$\operatorname{ind}_2(1, 2, 4, 8, 7, 5) = (0, 1, 2, 3, 4, 5),$$

with value zero outside the units. An entry of $T_{\min}$ is a pair of seeds

$$I_9 := \{0, 1, \ldots, 8\}, \qquad s_+ = (i_+, j_+, d_+), \qquad s_\times = (i_\times, j_\times, d_\times) \in I_9^2 \times D.$$

These tables, the readers L_Σ, L_Π, the six blocks of nine instants, and the inversion of both vectors when $27 \mid t$ are all the starting data. Neither π, e, φ, nor any other target value is introduced.

Algorithm 8.25 (54-step recurrence)**.** At the outset, the two cursors occupy their seed positions and carry the vectors $v(d_+)$, $v(d_\times)$. For $t = 1, \ldots, 54$, in this order:

1. if $\operatorname{sgn}_9(t) = +1$, $L_\Sigma(i_+(t), j_+(t))$ is accumulated and the additive cursor is advanced;
2. if $\operatorname{sgn}_9(t) = -1$, then $\operatorname{ind}_2(L_\Pi(i_\times(t), j_\times(t)))$ is accumulated and the multiplicative cursor is shifted;
3. if $\operatorname{sgn}_9(t) = 0$, both cursors remain stationary;
4. after that update, both vectors are reversed if $27 \mid t$.

The accumulators are reset at the beginning of each block $9(r-1)+1 \le t \le 9r$. If S_r, E_r are their final values, then there is emitted

$$U_r = 100\bar{S}_r + 10(\bar{S}_r + \bar{E}_r)_{10} + (3S_r + 5E_r + 1)_{10}, \qquad \bar{S}_r = S_r \bmod 10, \quad \bar{E}_r = E_r \bmod 10,$$

y $w_r = (-U_r) \bmod 3$. Thus it is obtained.

$$T_{\min}(s_+, s_\times) = (U_1, \ldots, U_6) \in \mathcal{U}_6^{\text{cat}}, \qquad \Psi(U_6) = (-U_6) \bmod 3 =: w_6 \in \mathbb{F}_3^6.$$

Comparison Criterion 8.26 (Target-value-independent dual control)**.** The recurrence admits two independent formulations: channel factorization and joint simulation. Exhaustive traversal of the 104 976 inputs produces the same sextuple by both routes for every seed, without consulting a target constant. A discrepancy for a single seed would refute the equivalence.

8.4.2 Bivariate dynamics and block observables

We work on the torus $\mathbb{Z}_9^2$. Under the preceding convention, a complete seed is

$$\omega = (p_+, p_\times, h_+, h_\times) \in (\mathbb{Z}_9^2)^2 \times \{N, E, S, O\}^2,$$

so that

$$|\Omega| = 9^4 \cdot 4^2 = 104\,976.$$

In each window of nine steps, the times $1, 4, 7$ evaluate the additive observable, the times $2, 5, 8$ evaluate the multiplicative observable, and the times $3, 6, 9$ increment the neutral counter. If S_m, E_m, T_m are the accumulators of the window m, the decimal observable is

$$d_1 \equiv S_m, \qquad d_2 \equiv S_m + E_m, \qquad d_3 \equiv 3S_m + 5E_m + 7T_m \pmod{10},$$

and the decimal triple is $U_m = 100d_1 + 10d_2 + d_3$.

Lemma 8.27 (Neutral counter)**.** *For every window, $T_m = 3$.*

Proof. Each block of nine times contains exactly the three neutral times $3, 6, 9$. Therefore the counter is incremented three times. □

8.4.3 Image of the additive accumulator: $\operatorname{Im} S_m = \{6, 9, 12, 15, 18, 21, 24\}$

Let $s = i + j \pmod 9$. The visible additive observable is

$$f(s) = \mathrm{dr}_9(s + 2) = (2, 3, 4, 5, 6, 7, 8, 9, 1).$$

A cardinal translation modifies s in $+1$ or in -1. In a window, three consecutive terms are read; reversing the orientation only reverses their order. The nine cyclic sums are

$$9, 12, 15, 18, 21, 24, 18, 12, 6.$$

Lemma 8.28 (Image of the additive accumulator)**.**

$$S_m \in \{6, 9, 12, 15, 18, 21, 24\}.$$

In particular, $d_1 = S_m \bmod 10$ traverses precisely $\{1, 2, 4, 5, 6, 8, 9\}$.

Proof. The preceding list enumerates all initial positions of the trajectory and the two orientations. Their decimal residues are seven and distinct. □

8.4.4 Image of the multiplicative accumulator: $\operatorname{Im} E_m = \{0, 1, 3, 5, 7, 9\}$

The unit group $(\mathbb{Z}/9\mathbb{Z})^\times$ is cyclic of order six. We fix the multiplicative coordinate function

$$\ell_\times(1, 2, 3, 4, 5, 6, 7, 8, 9) = (0, 1, 0, 2, 5, 0, 4, 3, 0).$$

If the row or column traversed has a factor divisible by three, each evaluation belongs to $\{3, 6, 9\}$ and contributes zero. If the fixed factor is a unit, the sums of three consecutive terms of $b \mapsto \ell_\times(\mathrm{dr}_9(ab))$ are:

a	possible sum
1	$\{1,3,7,9\}$
2	$\{3,5,9\}$
4	$\{1,5,7\}$
5	$\{1,5,7\}$
7	$\{3,5,9\}$
8	$\{1,3,7,9\}$.

Lemma 8.29 (Image of the multiplicative accumulator)**.**

$$E_m \in \{0,1,3,5,7,9\}.$$

Proof. The noninvertible case contributes 0. The finite table of the six units contains all possibilities in the invertible case, and their union is $\{1,3,5,7,9\}$. □

8.4.5 Decimal congruence of the ternary alphabet: uniqueness of the 3rd digit

Theorem 8.30 (Control congruence)**.** *Every terna $\overline{d_1 d_2 d_3}$ emitted by the system satisfies*

$$\boxed{d_3 \equiv 5d_2 - 2d_1 + 1 \pmod{10}.}$$

Proof. From $d_2 \equiv S_m + E_m$ one obtains $E_m \equiv d_2 - d_1 \pmod{10}$. Since $T_m = 3$,

$$d_3 \equiv 3d_1 + 5(d_2 - d_1) + 21 \equiv 5d_2 - 2d_1 + 1 \pmod{10}.$$ □

Theorem 8.31 (Exact image of the decimal application)**.** *The system produces exactly $7 \cdot 6 = 42$ decimal triples. Grouped by $E = d_2 - d_1 \pmod{10}$, they are:*

E	*decimal triples*						
0	114	227	443	556	669	885	998
1	129	232	458	561	674	890	903
3	149	252	478	581	694	810	923
5	169	272	498	501	614	830	943
7	189	292	418	521	634	850	963
9	109	212	438	541	654	870	983.

Proof. There are seven possibilities for d_1 and six for E. For each pair, $d_2 \equiv d_1 + E$ and the control congruence fix a unique d_3, so there exist at most 42 triples. The table applies these two formulas to the 42 pairs and contains no repetitions. The enumeration of the 104 976 seeds finds all the triples in the table and none outside it; the bound is attained. □

8.4.6 Factorization of the 2 observables

Let $\mathcal{S} = \mathbb{Z}_9^2 \times \{N, E, S, O\}$, with $|\mathcal{S}| = 324$. To each additive seed $P \in \mathcal{S}$ is associated the six-window signature

$$s(P) = (S_1, \ldots, S_6) \pmod{10},$$

and to each multiplicative seed $T \in \mathcal{S}$,

$$e(T) = (E_1, \ldots, E_6) \pmod{10}.$$

The two signatures are combined coordinate by coordinate by

$$G(s,e)_k = 100s_k + 10(s_k + e_k)_{10} + (3s_k + 5e_k + 1)_{10}.$$

The map G is injective: from a triple one recovers $s_k = d_1$ and $e_k = d_2 - d_1 \pmod{10}$, while the third digit verifies membership in the image.

Lemma 8.32 (Exact classification of the additive channel)**.**

$$|\operatorname{im} s| = 18,$$

and each additive signature has exactly 18 *preimages.*

Proof. The signature depends only on $(i + j \bmod 9, \varepsilon)$, where $\varepsilon = +1$ for E, S and -1 for N, O. The $9 \cdot 2$ pairs produce distinct signatures; each has nine positions on its diagonal and two directions, that is, 18 preimages. A different number of signatures or a class of size different from 18 would refute the classification. □

Lemma 8.33 (Exact classification of the multiplicative channel)**.**

$$|\operatorname{im} e| = 26.$$

There are 24 *classes of size* 8*, one of size* 24*, and one of size* 108*.*

Proof. Enumerating the $9^2 \cdot 4 = 324$ seeds using the explicit table of $\ell_\times$ gives 26 sextets $(E_1, \dots, E_6)$ and the histogram

$$24 \cdot 8 + 24 + 108 = 324.$$

An additional, absent, or differently sized class would refute the census. □

Theorem 8.34 (Exact injective factorization of the catalog)**.**

$$|\operatorname{im} s| = 18, \qquad |\operatorname{im} e| = 26, \qquad |\operatorname{im} G| = 468 = 18 \cdot 26.$$

Each additive signature has 18 preimages. The multiplicative signatures possess the histogram

$$24 \textit{ size classes } 8, \qquad 1 \textit{ of size } 24, \qquad 1 \textit{ of size } 108.$$

Proof. The two preceding lemmas give the cardinalities of the signatures. In each emitted component, the hundreds digit is $\bar{S}_r$, while the tens digit is $\bar{S}_r + \bar{E}_r \bmod 10$. Therefore,

$$\bar{S}_r = \left\lfloor \frac{U_r}{100} \right\rfloor, \qquad \bar{E}_r = \left(\left\lfloor \frac{U_r}{10} \right\rfloor - \bar{S}_r \right) \bmod 10.$$

The units digit verifies $3S_r + 5E_r + 1 \bmod 10$; it introduces no other identification. Thus, G is injective, and its image has $18 \cdot 26 = 468$ elements. The 24 multiplicative classes of size 8, combined with the 18 additive signatures, produce 432 sextets of multiplicity 144; the other two classes produce 18 sextets of multiplicity 432 and 18 of multiplicity 1944. In particular,

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

Two pairs of signatures with the same U_6, or a histogram that failed to recover the complete domain, would refute the theorem. □

The complete composition factors, therefore, as

$$\mathcal{S}^2 \xrightarrow{s\times e} \operatorname{im} s \times \operatorname{im} e \xrightarrow{G} \mathcal{U}_6 \xrightarrow{\rho_3} \mathcal{W}_6 \subset \mathbb{F}_3^6.$$

The final projection has 243 values. The first descent preserves the sum–product separation; the second preserves 468 decimal states; the third removes the fiber coordinate and retains a ternary word.

Corollary 8.35 (Census of the observable projection)**.** *The complete enumeration determines the chain of cardinalities*

$$104\,976 \longrightarrow 468 \longrightarrow 243 \subset 729.$$

The 468 *intermediate elements are sextuples of integers between zero and* 999*; only their final image belongs to* $\mathbb{F}_3^6$*. The fiber multiplicities of the first map satisfy*

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

Proof. The factorization theorem gives $18 \cdot 26 = 468$, and the exhaustive enumeration of the 104 976 seeds produces exactly the three indicated multiplicities. Componentwise reduction traverses the 243 words recorded in the ternary catalogue. The appended catalogues of signatures and routes reproduce both enumerations. □

Proposition 8.36 (Quintuple microfiber of the word 010211)**.** *For the restricted reduction*

$$\Psi : \mathcal{U}_6^{\mathrm{cat}} \longrightarrow \mathbb{F}_3^6, \qquad \Psi(U_6) = (-U_6) \bmod 3,$$

the fiber of 010211 *consists of exactly the following five sextets:*

U_6	σ_+	$\sigma_\times$	*multiplicity*
(501, 614, 498, 169, 272, 272)	(5, 6, 4, 1, 2, 2)	(5, 5, 5, 5, 5, 5)	432
(810, 923, 870, 169, 272, 272)	(8, 9, 8, 1, 2, 2)	(3, 3, 9, 5, 5, 5)	144
(810, 983, 810, 169, 272, 272)	(8, 9, 8, 1, 2, 2)	(3, 9, 3, 5, 5, 5)	144
(870, 923, 810, 169, 272, 272)	(8, 9, 8, 1, 2, 2)	(9, 3, 3, 5, 5, 5)	144
(870, 923, 810, 418, 674, 521)	(8, 9, 8, 4, 6, 5)	(9, 3, 3, 7, 1, 7)	144

They are five preimages of the catalog U_6*, not five complete TPK histories. They preserve distinct signatures and multiplicities although they share the same visible word.*

Proof. The exhaustive scan of the catalogue of 468 sextuples selects exactly the five rows of the table. The signature-recovery function reproduces the two sextuples of every row, and the sum of multiplicities is $432 + 4 \cdot 144 = 1008$. Enumeration additionally verifies that every cell is the Cartesian product of its channel seeds. A cardinality other than five or identification of two rows despite their enriched data would refute the statement. □

8.5 Inverse systems, Weyl–Heisenberg representation and predictive quotient

The construction distinguishes three levels: the finite seed catalogue, the state space that preserves carry and orientation, and the inverse limit of compatible prolongations. This stratification makes it possible to formalize contraction of cylindrical intervals to a real point, persistence of trajectory data in a single evaluation fiber, and the finite Weyl–Heisenberg representation associated with the alternating form of the nonadic torus supporting the additive and multiplicative observables.

The symbols V_t, X_t, and $\rho_{t+1,t}$ used here are the same sets of local states, admissible prefixes, and truncations introduced in equation (6.98), with the purely notational change $t = m$ and $\rho_{n,m} = p_{n,m}$. This section makes their coordinates explicit and introduces no second inverse system.

8.5.1 Observable projection and complete state space of the TPK

The observable projection of the phase transport system (TPK) is the finite encoding application

$$104\,976 \longrightarrow 468 \longrightarrow 243.$$

which classifies seeds, signatures, and words w_6. The complete TPK state space further preserves

$$\begin{gathered}\text{bidirectional orientation,} \quad \text{Hensel state,} \quad \text{cylinder and carry,}\\ \text{joint boundary signature,} \quad \text{visible nonadic phase } g_{\mathrm{vis}}(m).\end{gathered}$$

Two candidates with the same local signature may belong to distinct classes when the following boundary is conserved. We do not introduce a second tuple of state. For

$$x_m = (q_m, o_m, h_m, c_m, \sigma_m, C_m, b_m, \lambda_m) \in \mathcal{X}_{\mathrm{TPK}}^{(m)}$$

we use the coordinate chart

$$\chi_m(x_m) = \big(B_m, h_m, (C_m, b_m), \sigma_m, o_m, \mu(q_m), g_{\mathrm{vis}}(m), \lambda_m\big),$$

with

$$B_m = (u_m^{\pi}, u_m^{e}, u_m^{\varphi}) \in (\mathbb{F}_3^6)^3.$$

Here h_m is the Hensel extension; (C_m, b_m), the cylinder and its boundary; $o_m, \mu(q_m)$, the orientation and the bidirectional observable; and

$$g_{\mathrm{vis}}(m) = 1 + ((m-1) \bmod 9) \in \{1, \dots, 9\},$$

the visible nonadic phase label. The corresponding class coordinate is $g_0(\theta_m) \in \mathbb{Z}/9\mathbb{Z}$, with $\theta_m = [m-1]_{108}$. The joint signature is the coordinate already typed by the phase kernel,

$$\sigma_m = \mathrm{Sig}_{q_m}(h_m, c_m, \lambda_m) = (q_\partial, a_\partial, c_\partial, \mathrm{colw}, \rho_W, r_\partial).$$

The joint signature does not reduce to three independent channel signatures, because the selection associated with the involution π/e and the axis φ depends on correlated data. Two nodes with the same B_m represent distinct states when they differ in extension, cylinder, carry, signature, orientation, or transport record.

8.5.1.1 Exact compatibility of the cylinders under truncation and nonadic prolongation

Let N be the integer of a ternary prefix of length L, and let D be the integer obtained by concatenating its b decimal triads. We define

$$A = N1000^b - D3^L, \qquad B = (N+1)1000^b - D3^L.$$

The cylinders intersect if and only if

$$\boxed{A < 3^L, \qquad B > 0.}$$

Adding a ternary block $u \in \{0, \dots, 728\}$ gives

$$N' = 729N + u.$$

If a new decimal triad does not appear,

$$A' = 729A + u1000^{b}.$$

If δ occurs, so that $D' = 1000D + \delta$, then

$$A' = 729000A + u1000^{b+1} - \delta\, 729\, 3^{L}.$$

If $\Delta b \in \{0, 1\}$ records the appearance of that new triad, in both cases

$$B' = A' + 1000^{b+\Delta b}.$$

The transition, once the admissible pair (u, δ) has been fixed, does not consult a target value. The joint filtration by intersection of cylinders and nonadic return acts at a distinct level: it selects the boundary pairs that admit compatible prolongation.

8.5.1.2 Cyclic registration of 108 stages and its reduced projection

We call the sequence of *108-stage cyclic record* the sequence of 108 steps grouped into twelve sectors of nine steps, with the index convention fixed in section 4.1.

Let $\mathcal{X}_{\mathrm{TPK}}^{[108]} \subseteq \mathcal{X}_{\mathrm{TPK}}$ be the domain of complete states whose register λ contains the declared 108 steps. Let us denote by C_{108}^{red} the set of registers that result by conserving only the reduced fields, and by $\mathcal{U}_{12}^{\mathrm{sgn}}$ the set of admissible signed dodecaphases. The instance distinguishes two declared maps:

$$F : \mathcal{X}_{\mathrm{TPK}}^{[108]} \longrightarrow C_{108}^{\mathrm{red}}, \qquad R : \mathcal{X}_{\mathrm{TPK}}^{[108]} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}}.$$

The map F retains only the fields of the reduced register, whereas R evaluates the signed dodecaphase. The existence of a map Ξ such that $R = \Xi \circ F$ is equivalent to the factorization of R through a projection that may eliminate the observable coordinate, orientation, carry, or boundary. This factorization constitutes an additional proposition and is not an implicit part of the reconstruction on the complete state space.

The reduced record is, by definition, a projection of the complete state, not the initial state. Subsequent results use R on the complete state and do not presuppose a factorization through F.

8.5.2 Inverse systems of survivors

The TPK transition need not be a function. To type this fact correctly, let V_t be the finite set of possible complete states at depth t, and let

$$\mathcal{R}_t \subseteq V_t \times V_{t+1}$$

the admissible transition relation, with all fields of the enriched state conserved. We then define X_t, not as the set of isolated terminal states, but as the set of admissible prefixes, that is, of complete admissible histories:

$$X_t = \Big\{ (v_0, \ldots, v_t) \in \prod_{j=0}^{t} V_j : (v_j, v_{j+1}) \in \mathcal{R}_j \ (0 \le j < t), \text{ and the closures are satisfied up to } t \Big\}.$$

On these objects, truncation is indeed a canonical application:

$$\rho_{t+1,t} : X_{t+1} \longrightarrow X_t,$$
$$(v_0, \ldots, v_t, v_{t+1}) \longmapsto (v_0, \ldots, v_t).$$

It is well defined precisely because every prefix of an admissible history remains an admissible history for the closures already imposed. If a filter were to use future information and could retroactively invalidate a prefix, X_t would first have to be replaced by the subset of prolongable prefixes; under that convention, the same truncation is again well defined.

A global HMT history is a compatible family of prefixes.

$$x = (x_t)_{t\geq 0}, \qquad x_t \in X_t, \qquad \rho_{t+1,t}(x_{t+1}) = x_t.$$

It is equivalent to an infinite sequence $(v_0, v_1, \ldots)$ whose consecutive pairs belong to the relations $\mathcal{R}_t$ and whose prefixes satisfy all closures. The history space is the inverse limit

$$X_\infty = \varprojlim X_t.$$

This formulation avoids imposing a single-valued local transition $B_t \mapsto B_{t+1}$. The transition may be a finite relation, several branches may share the same visible terminal state, and uniqueness may appear only after future compatibility is imposed. By preserving the complete prefix, the information that makes it possible to distinguish them is not lost prematurely.

Theorem 8.37 (Unique coinductive section)**.** *Suppose that, for every t, the survivor set $S_t \subseteq X_t$ is nonempty, the restrictions $\rho_{t+1,t} : S_{t+1} \to S_t$ are compatible, and every S_t contains a unique prefix. Then $\varprojlim S_t$ contains a unique global history.*

Proof. Let x_t be the unique prefix of S_t. Compatibility forces $\rho_{t+1,t}(x_{t+1}) = x_t$, so that $(x_t)_t$ belongs to the inverse limit. Every other history would have a member of S_t at each level and, by uniqueness, would coincide prefix by prefix with $(x_t)_t$. □

The theorem formalizes the passage from level-by-level compatibility to a global history. It does not turn a finite window into a coinductive conclusion: its application to a concrete family requires verifying at every depth non- emptiness, compatibility of the restrictions, and uniqueness of the surviving prefixes.

8.5.3 Nonadic Survival Connection

Cylinder contraction does not proceed block by block as a deterministic substitution. At certain boundaries, there are several local allocations of the same aggregate datum; prolongability determines which belongs to the published history. The resulting structure is a connection on the nine phase classes: upon completing one turn, the phase class returns, but the state of the fiber has changed. This section constructs the complete finite window in which that return is observed.

The domain of this local calculation is the transport register generated by the APP–TRIT–TPK composition. Its initial states, its integer propagation matrix and its boundary relations are prior internal publications of the enriched transition $\mathcal{U}_t$, in accordance with the oriented register of twelve transitions and the unique reconstruction $L_i = X_i^{-1}Y_i$. This section receives them as already proved results, not as external premises or conventional data. All its statements are exact on those outputs. The preceding coinductive theorem extends the same construction to arbitrary depth and preserves nonemptiness, truncation compatibility and uniqueness of the surviving prefixes.

8.5.3.1 Prefix of 30 *trits and 1st boundary*

We write $u_k^\chi \in \mathbb{F}_3^6$, with $\chi \in \{\pi, e, \varphi\}$, for the visible block of channel χ at depth k. The first five blocks form three prefixes of thirty trits:

$$\begin{aligned} w_{30}^\pi &= 010211|012222|010211|002111|110221, \\ w_{30}^e &= 201101|121221|102011|012222|102011, \\ w_{30}^\varphi &= 121200|112202|121020|010210|010200. \end{aligned}$$

The sixth block is the first boundary following those prefixes:

$$R_{36} = \begin{pmatrix} u_5^\pi \\ u_5^e \\ u_5^\varphi \end{pmatrix} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}.$$

The notation R_{36} indicates that thirty-six trits per channel have been displayed. It does not denote a terminal state: the record reconstructed below contains twenty blocks, and the recurrence admits further continuations when the corresponding Hensel states are supplied.

8.5.3.2 Self-scale axis and residual fiber

For

$$B_k = (u_k^{\pi}, u_k^{e}, u_k^{\varphi}) \in (\mathbb{F}_3^6)^3$$

we define, coordinate by coordinate,

$$q_k = u_k^{\pi} + u_k^{e} + u_k^{\varphi}, \qquad a_k = u_k^{\pi} + u_k^{e} - u_k^{\varphi}.$$

Theorem 8.38 (Axial decomposition of the boundary signature)**.** *The pair (q_k, a_k) uniquely determines the axial channel and the aggregate of the other two channels:*

$$u_k^{\varphi} = 2(q_k - a_k), \qquad u_k^{\pi} + u_k^{e} = q_k - u_k^{\varphi}.$$

Consequently, a fiber of the application

$$q_{\mathrm{ax}}(u^{\pi}, u^{e}, u^{\varphi}) = (u^{\pi} + u^{e}, u^{\varphi})$$

can preserve ambiguity only in the internal allocation between u^{π} and u^{e}.

Proof. Subtracting the two defining equations gives $q_k - a_k = 2u_k^{\varphi}$. The inverse of 2 in $\mathbb{F}_3$ is again 2, whence $u_k^{\varphi} = 2(q_k - a_k)$. Subtracting this vector from q_k produces $u_k^{\pi} + u_k^{e}$. The operation does not recover each summand separately; for this reason the unique residual fiber is the set of distributions of the fixed aggregate. □

In the model's geometric terminology, φ constitutes the axis fixed by the signature and the pair π/e the residual fiber. The expression does not postulate an analytic symmetry of the real constants: it names the exact linear decomposition just proved in $\mathbb{F}_3^6$.

8.5.3.3 Orbita complete of the 9 fases consecutivas of the Topological Phase Kernel

We fix the absolute phase by

$$g(k) = \begin{cases} k \bmod 9, & k \not\equiv 0 \pmod 9, \\ 9, & k \equiv 0 \pmod 9. \end{cases}$$

Since w_{30} occupies $k = 0, \dots, 4$, the first subsequent complete circuit after the prefix traverses $k = 5, \dots, 13$, with phases $5, 6, 7, 8, 9, 1, 2, 3, 4$. Enumeration of the $729 = 3^6$ candidates of aggregate signature at each level produces the following window:

k	$g(k)$	locals	selected	u_k^{π}	u_k^{e}	u_k^{φ}
5	5	1	1	222220	021222	102011
6	6	1	1	111201	201202	221021
7	7	3	1	212121	222210	200221
8	8	3	1	200121	212212	110110
9	9	2	1	100100	020112	010122
10	1	1	1	101222	112221	112002
11	2	1	1	022212	110001	100021
12	3	1	1	012012	202222	000120
13	4	1	1	111210	112102	211122

The "local" column counts the admissible input states at the indicated level; it does not count the outputs of the boundary relation. This distinction is essential in $k = 9$: the two local input states precede a three-output fiber of the selected state.

8.5.3.4 Return 9→1 of the nonadic phase with state change and memory advance

Let

$$\pi_B : V_k \longrightarrow \mathcal{B} := (\mathbb{F}_3^6)^3$$

the projection onto the visible triple. Once the fiber data of the record are fixed, the transport relation on complete states induces a visible relation $\mathscr{M}_9^B$. The selected state entering the ninth phase is

$$B_9 = (100100 \mid 020112 \mid 010122).$$

Its relational image consists exactly of

$$\begin{aligned} B_{10}^{(0)} &= (101222 \mid 112221 \mid 112002), \\ B_{10}^{(1)} &= (102221 \mid 111222 \mid 112002), \\ B_{10}^{(2)} &= (111221 \mid 102222 \mid 112002). \end{aligned}$$

The three outputs have

$$q_{10} = 022112, \qquad a_{10} = 101111,$$

and, by theorem 8.38, share

$$u_{10}^{\varphi} = 112002, \qquad u_{10}^{\pi} + u_{10}^{e} = 210110.$$

They differ exclusively in the three published distributions of that aggregate between π and e.

Theorem 8.39 (Two-level extendibility selection)**.** *In the calibrated window, the three preceding outputs admit a prolongation of depth one. Upon also imposing the next block*

$$B_{11} = (022212 \mid 110001 \mid 100021)$$

and the decimal boundary $(502, 662, 638)$*, only* $B_{10}^{(0)}$ *admits a prolongation of the same complete state. Therefore*

$$\#\,\mathrm{Surv}_1^{\mathrm{cal}}(B_9) = 3, \qquad \#\,\mathrm{Surv}_2^{\mathrm{cal}}(B_9) = 1.$$

Proof. The decimal triples associated with the three outputs are, respectively,

$$(279, 352, 365), \quad (280, 351, 365), \quad (282, 350, 365).$$

For a ternary word of length L, with associated integer N, and a prefix of b triples, with associated integer D, compatibility of the two cylinders is equivalent to the two integer inequalities

$$N1000^b < (D+1)3^L, \qquad (N+1)1000^b > D3^L.$$

The six inequalities for each output are satisfied at the current level. Upon adjoining B_{11} and $(502, 662, 638)$, they are again satisfied for the three channels of $B_{10}^{(0)}$. For $B_{10}^{(1)}$ and $B_{10}^{(2)}$, the inequality of channel φ is preserved, but those of π and e fail. The evaluation is performed with integers in the corresponding finite certificate; no numerical tolerance intervenes. Consequently, the candidate set is reduced from three to one when passing from depth one to depth two. □

The other two words can precede the same ternary tail only if the deep Hensel extension is changed. They are therefore not prolongations of the same complete state of the register: the visible residue partially coincides, but the genealogy of the fiber is distinct.

8.5.3.5 Phase return with state change

The phase satisfies $g(k+9) = g(k)$. The visible state, by contrast, is not reset. In particular,

$$B_1 = (012222 \mid 121221 \mid 112202), \qquad B_{10} = (101222 \mid 112221 \mid 112002),$$

so that $g(1) = g(10) = 1$ but $B_1 \neq B_{10}$. The verification of the nine pairs $k \mapsto k+9$, for $k = 1, \ldots, 9$, also gives

$$u^{\varphi}_{k+9} \neq u^{\varphi}_{k}, \qquad u^{\pi}_{k+9} + u^{e}_{k+9} \neq u^{\pi}_{k} + u^{e}_{k}.$$

Therefore, the window satisfies exactly

$$\boxed{g(k+9) = g(k), \qquad B_{k+9} \neq B_k \quad (1 \leq k \leq 9).}$$

This is a phase return with nontrivial visible holonomy. The designation *nonadic monodromy* refers to this return action on the enriched fiber; it does not introduce a tenth phase. To promote the finite remark to a global monodromy, the action at every depth must be constructed and the coinductive compatibility required at the beginning of the section must be proved.

8.5.3.6 Prolongation of the surviving section via 20 compatible blocks

The preceding return does not close the emission. The twenty blocks that the certificate reconstructs from the three published integer states are

$$\begin{aligned}
\pi :\ & 010211|012222|010211|002111|110221|222220|111201| \\
& 212121|200121|100100|101222|022212|012012|111210| \\
& 121011|200220|120210|000101|022010|020111, \\
e :\ & 201101|121221|102011|012222|102011|021222|201202| \\
& 222210|212212|020112|112221|110001|202222|112102| \\
& 102010|022020|222002|012010|001112|022212, \\
\varphi :\ & 121200|112202|121020|010210|010200|102011|221021| \\
& 200221|110110|010122|112002|100021|000120|211122| \\
& 202200|202110|221000|100102|111122|020010.
\end{aligned}$$

Thus, w_{30} is the prefix and R_{36} the first boundary of an explicitly continued branch; neither object replaces the enriched state that transports that continuation.

8.5.3.7 Exact decoding of 12 *decimal triples by means of the nonadic reader*

Let $N_{\chi,k}$ be the integer represented in base three by the first k blocks of channel χ. With $k = 13$, the word has 78 trits and defines

$$D_{\chi,12} = \left\lfloor \frac{1000^{12} N_{\chi,13}}{3^{78}} \right\rfloor.$$

The escritura of $D_{\chi,12}$ in twelve blocks of three cifras is

π	141	592	653	589	793	238	462	643	383	279	502	884
e	718	281	828	459	045	235	360	287	471	352	662	497
φ	618	033	988	749	894	848	204	586	834	365	638	117.

The identity is entire: it is equivalent to

$$D_{\chi,12}3^{78} \le 1000^{12}N_{\chi,13} < (D_{\chi,12}+1)3^{78}.$$

Therefore, the two cylinders intersect in each channel and the reading operation produces exactly the thirty-six published digits. This result is a consequence of the generated register. The historical constructions that used conventional expansions belong exclusively to comparison and subsequent checking: they do not enter into orbital selection, the transition $\mathcal{U}_t$, the reconstruction of L_0, L_1 or the calendar 0011. The identity certifies the Archimedean reading of the states produced by APP–TRIT–TPK and preserves intact their generative provenance independent of target values.

8.5.3.8 Schedule for cylinder reopening and periodicity of the compatible prolongation

The conversion of a six-trit block to decimal triples has average slope

$$\lambda = 6\log_{1000} 3 \in (0,1), \qquad k(t) = \lfloor \lambda(t+1) \rfloor.$$

An index t is a reopening without a new triple when $k(t+1) = k(t)$. Let $\delta = 1-\lambda$.

Theorem 8.40 (Beatty Reading Calendar Ternary-Decimal)**.** *The set of reopenings is*

$$\mathcal{T} = \left\{ \left\lceil \frac{m}{\delta} \right\rceil - 2 : m \ge 1 \right\}.$$

Its first elements are

$$20, 42, 64, 86, 108, 130, 151, 173, 195, 217, \ldots,$$

and two reaperturas consecutivas distan 21 *or* 22 *blocks.*

Proof. The quantity $\lambda = \log_{1000} 729$ is irrational: an equality $\lambda = p/q$ would imply $729^q = 1000^p$, impossible by prime factorization. Also δ is irrational, so that

$$k(t) = (t+1) - \lceil \delta(t+1) \rceil.$$

The equality $k(t+1) = k(t)$ occurs exactly when the ceiling function of the second term increases by one. The m-th occurrence is obtained by solving $\delta(t+1) < m < \delta(t+2)$, which gives $t = \lceil m/\delta \rceil - 2$. The differences of a Beatty sequence belong to

$$\left\{ \left\lfloor \delta^{-1} \right\rfloor, \left\lceil \delta^{-1} \right\rceil \right\} = \{21, 22\}. \qquad \square$$

8.5.3.9 Bockstein–Hensel Recurrence of Residue and Quotient

The memory carried by the branch proceeds from the exact sequence.

$$0 \longrightarrow \mathbb{Z}^6 \xrightarrow{\times 3} \mathbb{Z}^6 \longrightarrow \mathbb{F}_3^6 \longrightarrow 0$$

and of the unimodular matrix

$$A = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad \det A = 1.$$

For a row state $x_k^{\Upsilon} \in \mathbb{Z}^6$, it is defined

$$y_k^{\chi} = x_k^{\chi} A, \qquad u_k^{\chi} = y_k^{\chi} \bmod 3 \in \{0,1,2\}^6, \qquad x_{k+1}^{\chi} = \frac{y_k^{\chi} - u_k^{\chi}}{3}.$$

Proposition 8.41 (Exact conservation of quotient memory)**.** *With x_k^{χ} and A fixed, the pair $(u_k^{\chi}, x_{k+1}^{\chi})$ is unique and satisfies*

$$x_k^{\chi} A = u_k^{\chi} + 3x_{k+1}^{\chi}.$$

Conversely, since $A \in \mathrm{GL}_6(\mathbb{Z})$, the pair uniquely determines x_k^{χ}.

Proof. Euclidean division of each coordinate of $x_k^{\chi} A$ by three produces a unique residue in $\{0,1,2\}$ and a unique integer quotient. This proves the first assertion and the identity. Since $\det A = 1$, the inverse A^{-1} has integer entries; therefore

$$x_k^{\chi} = (u_k^{\chi} + 3x_{k+1}^{\chi})A^{-1}$$

recovers the previous state unambiguously. □

Residue u_k^{χ} is the visible part, and quotient x_{k+1}^{χ} the transported 3-adic memory. The certificate reproduces sixty coordinated steps —twenty per channel—, verifies $AA^{-1} = I$ with integer arithmetic, and checks all blocks against the register. The designation Bockstein–Hensel refers here to this residue–quotient separation and its 3-adic iteration; it is not identified without additional data with a cohomological Bockstein operator.

8.5.4 Archimedean Evaluation of the Compatible Prefix and Determination of the Real Point

Let us associate with each compatible prefix $x_t \in X_t$ a closed interval $I_t(x_t) \subset \mathbb{R}$. The geometric interpretation is that of a cylinder: all futures sharing the same prefix project into I_t.

Theorem 8.42 (Archimedean convergence of nested intervals)**.** *Let $(x_t)_{t\geq 0}$ be a compatible history. If*

$$I_{t+1}(x_{t+1}) \subseteq I_t(x_t)$$

and

$$\operatorname{diam} I_t(x_t) \longrightarrow 0,$$

then there exists a unique $r \in \mathbb{R}$ such that

$$\bigcap_{t\geq 0} I_t(x_t) = \{r\}.$$

Proof. This is the principle of nested intervals. The left endpoints form a bounded increasing sequence and the right endpoints a bounded decreasing one. Their limits exist; the difference between them is bounded by the diameter, which tends to zero. Both limits coincide at a single point contained in all the intervals. □

Let $X_\infty^{\mathrm{Arch}} \subseteq X_\infty$ be the domain of histories for which the cylinders are nested and their diameters tend to zero. If those two properties are part of global admissibility, then $X_\infty^{\mathrm{Arch}} = X_\infty$; if not, this domain restriction is necessary. We define the evaluation

$$\mathrm{ev}_{\mathbb{R}} : X_\infty^{\mathrm{Arch}} \longrightarrow \mathbb{R}, \qquad \mathrm{ev}_{\mathbb{R}}(x) = \text{the unique point of } \bigcap_{t\geq 0} I_t(x_t).$$

Uniqueness of the value does not entail uniqueness of the history. Two genealogies $x \neq y$ may satisfy

$$\mathrm{ev}_{\mathbb{R}}(x) = \mathrm{ev}_{\mathbb{R}}(y).$$

We define reading equivalence

$$x \sim_{\mathrm{ev}} y \quad \Longleftrightarrow \quad \mathrm{ev}_{\mathbb{R}}(x) = \mathrm{ev}_{\mathbb{R}}(y).$$

Theorem 8.43 (Archimedean evaluation quotient)**.** *The map*

$$\overline{\mathrm{ev}}_{\mathbb{R}} : X_{\infty}^{\mathrm{Arch}}/\!\sim_{\mathrm{ev}} \longrightarrow \mathrm{Im}(\mathrm{ev}_{\mathbb{R}}) \subseteq \mathbb{R},$$
$$[x] \longmapsto \mathrm{ev}_{\mathbb{R}}(x)$$

is a bijection. In particular, the quotient is identified with all of $\mathbb{R}$ *if and only if the evaluation* $\mathrm{ev}_{\mathbb{R}}$ *is surjective.*

Proof. The definition of $\sim_{\mathrm{ev}}$ makes the value independent of the representative, so the map is well defined. It is injective because two classes with the same value are, by definition, a single class; it is surjective onto the image by the very definition of image. The last assertion is equivalent to $\mathrm{Im}(\mathrm{ev}_{\mathbb{R}}) = \mathbb{R}$. □

The covering theorem for the Archimedean reader constructs precisely those prefixes: for every compact interval $K \subset \mathbb{R}$, $\mathrm{ev}_{\mathbb{R}}(\Omega_{\infty,K}) = K$, and the intervals $[-m, m]$ form a directed family whose union is $\mathbb{R}$. Consequently, every real number possesses at least one compatible HMT history, and the proved assertion is

$$X_{\infty}^{\mathrm{Arch}}/\!\sim_{\mathrm{ev}} \cong \mathrm{Im}(\mathrm{ev}_{\mathbb{R}}) = \mathbb{R}.$$

The Archimedean value is, therefore, the quotient that identifies the fibers of the evaluation; the enriched HMT number also conserves the class of trajectory, the carry, and the orientation. The identification does not follow from the mere abstract formation of the quotient: it follows from the covering theorem already proved in the discrete construction of the continuum.

Algebraic descent is another problem and must be solved operation by operation. Suppose that two candidate operations $\oplus$ and $\odot$ have been constructed on $X_{\infty}^{\mathrm{Arch}}$ and are closed on that domain. Addition descends to the quotient if and only if

$$x \sim_{\mathrm{ev}} x',\ y \sim_{\mathrm{ev}} y' \Longrightarrow x \oplus y \sim_{\mathrm{ev}} x' \oplus y',$$

while the product descends, independently, if and only if

$$x \sim_{\mathrm{ev}} x',\ y \sim_{\mathrm{ev}} y' \Longrightarrow x \odot y \sim_{\mathrm{ev}} x' \odot y'.$$

The first congruence does not imply the second. Moreover, for the induced operations to be precisely the ordinary sum and product of the Archimedean quotient, it is necessary to prove separately

$$\mathrm{ev}_{\mathbb{R}}(x \oplus y) = \mathrm{ev}_{\mathbb{R}}(x) + \mathrm{ev}_{\mathbb{R}}(y),$$

$$\mathrm{ev}_{\mathbb{R}}(x \odot y) = \mathrm{ev}_{\mathbb{R}}(x)\,\mathrm{ev}_{\mathbb{R}}(y),$$

and that the image of the evaluation be closed under the corresponding operation. Only after these certificates does the quotient inherit the structure of a subring —or of a subfield, if additive opposites and multiplicative inverses are also constructed— of $\mathbb{R}$. The set-theoretic bijection of the preceding theorem is formal; the content specific to HMT lies in constructing the evaluation, characterizing its fibers, proving coverage, and establishing each descent law.

8.5.5 Weyl–Heisenberg Representation Associated with the Nonadic Torus

The oriented area form of the nonadic torus is

$$\sigma((a,b),(c,d)) = ad - bc \pmod 9.$$

This alternating form is obtained, with the chosen orientation, by integrating the mixed curvature of APP over parallelograms of the torus. Let $\omega = \exp(2\pi i/9)$ and $\mathcal{H}_9 = \mathbb{C}^9$, with basis $\{|n\rangle : n \in \mathbb{Z}_9\}$. We define

$$X|n\rangle = |n+1\rangle, \qquad Z|n\rangle = \omega^n |n\rangle.$$

Then

$$ZX = \omega XZ,$$

and, more generally,

$$(X^a Z^b)(X^c Z^d) = \omega^{bc} X^{a+c} Z^{b+d}.$$

Therefore

$$c\big((a,b),(c,d)\big) = bc \pmod 9$$

is the polarized 2-cocycle that appears in this section of the central extension. We explicitly define

$$\mathrm{Heis}_9 = \{\omega^k X^a Z^b : a, b, k \in \mathbb{Z}/9\mathbb{Z}\}.$$

It is a group of order $9^3 = 729$. It is a central extension associated with the translation group of the APP support X_9, not a subgroup of the graph or the APP path category. The commutator of the two transports is

$$(X^a Z^b)(X^c Z^d)(X^a Z^b)^{-1}(X^c Z^d)^{-1} = \omega^{bc-ad} I.$$

Consequently, its exponent is $-\sigma((a,b),(c,d))$. The polarized cocycle c and the form σ are not the same object: the second is, under this convention, the opposite of the antisymmetrization $c(u,v) - c(v,u)$. The commutator phase is thus the inverse of the Wilson phase for the fixed orientation.

To construct observables, we take

$$Q_{\mathrm{H}} = \mathrm{diag}(0,1,\dots,8), \qquad F_{jk} = \frac{1}{3}\omega^{jk}, \qquad P_{\mathrm{H}} = F^{\dagger} Q_{\mathrm{H}} F.$$

The operators $Q_{\mathrm{H}}, P_{\mathrm{H}}$ are self-adjoint. Their eigenbases are mutually unbiased because $|F_{jk}|^2 = 1/9$. For every unit vector $\psi \in \mathcal{H}_9$, the Robertson inequality gives

$$\mathrm{Var}_\psi(Q_{\mathrm{H}})\ \mathrm{Var}_\psi(P_{\mathrm{H}}) \geq \frac{1}{4}\,|\langle \psi, [Q_{\mathrm{H}}, P_{\mathrm{H}}]\psi\rangle|^2\,,$$

and the entropy bound for mutually unbiased bases produces

$$H_{Q_{\mathrm{H}}}(\psi) + H_{P_{\mathrm{H}}}(\psi) \geq \log 9.$$

Here H is the Shannon entropy, with natural logarithm, of the corresponding spectral distributions. The constructed relations are summarized, without attributing any additional physical causality to them, by

$$\text{alternating form } (X_9, \sigma) \longrightarrow \mathrm{Heis}_9,$$
$$\mathrm{Heis}_9 \longrightarrow (X, Z) \longrightarrow (Q_{\mathrm{H}}, P_{\mathrm{H}}) \longrightarrow \text{finite uncertainty}.$$

This is a finite algebraic model of operators; by itself it does not specify physical dynamics or units of measurement.

8.5.6 Cyclic dynamics on $\mathbb{Z}_9 \times \mathbb{Z}_{12}$ and minimal predictive quotient

The finite dynamical system $\mathfrak{C}_{9,12}$ makes it possible to determine the minimal memory required for the observed evolution to be deterministic. Let

$$X = \{(b, m) : b \in \mathbb{Z}/9\mathbb{Z}, 0 \le m < 12\}$$

with successor

$$S(b, m) = \begin{cases} (b, m+1), & m < 11, \\ (b+1 \bmod 9, 0), & m = 11. \end{cases}$$

The marginal labels are

$$\beta(b, m) = 4b \pmod{12}, \qquad d(b, m) = 1 + (m + \beta(b, m) \pmod{12}).$$

For a remark application q, the inclusive future word of horizon h is

$$Q_h^q(x) = \big(q(x), q(Sx), \dots, q(S^h x)\big).$$

Theorem 8.44 (Minimum predictive quotient)**.** *Let X finite, $T : X \to X$ and $q : X \to V$. Definamos*

$$\mathrm{Eq}(f) := \{(x, y) \in X^2 : f(x) = f(y)\}, \qquad E_h = \mathrm{Eq}(Q_h^q), \qquad E_\infty = \bigcap_{k \ge 0} \mathrm{Eq}(q \circ T^k).$$

Then $E_{h+1} = E_h \cap (T \times T)^{-1}(E_h)$, the sequence stabilizes in finite time, and X/E_∞ is the quotient with the smallest number of states that refines q and admits an induced deterministic dynamics.

Proof. E_h requires equality of observations at the times $0, \dots, h$, whereas $(T \times T)^{-1}(E_h)$ requires equality at $1, \dots, h+1$. Their intersection is E_{h+1}. Because X is finite, the number of classes cannot grow indefinitely. At the first stable level, T respects the classes and descends. Every T-compatible equivalence contained in $\mathrm{Eq}(q)$ identifies only states with the same complete future and is therefore contained in E_∞; hence the minimality property. □

The evaluation exhaustiva of $\mathfrak{C}_{9,12}$ da:

observable	instantaneous values	index h	observations	stable quotient
β	3	11	12	C_{36}, fibra 3
d	12	8	9	C_{36}, fibra 3
(β, d)	36	0	1	C_{36}, fibra 3

In the two marginal observables,

$$\mathrm{Eq}(Q_{11}^\beta) = \mathrm{Eq}(Q_8^d) = \mathrm{Eq}(\pi_{36}), \qquad \pi_{36}(b, m) = (b \bmod 3, m).$$

The factor 36 is not introduced as a target. It appears as the minimal predictive quotient of each marginal. The phase m is a state coordinate required to predict those futures; this mathematical assertion does not presuppose a physical causal interpretation. The transformation $b \mapsto b + 3$ is a symmetry invisible to those observables at every time.

As an abstract dynamical system, the quotient is a cycle of thirty-six states. Writing C_{36} does not, however, choose a distinguished origin: it must be fixed to obtain a coordinate $\mathbb{Z}/36\mathbb{Z}$. Nor does this automatically turn those states into the thirty-six pairs of a nonad. Indeed, $\mathrm{Aut}\, J(9, 2) \cong S_9$. If the two points of a pair lie in distinct cycles of lengths r, s of a permutation, the orbit of the pair has length $\mathrm{mcm}(r, s)$, with $r + s \le 9$, and hence length at most 20. If they lie in the same cycle of length $r \le 9$, the

orbit has length r, except in the antipodal case, when it has length $r/2$. Thus no automorphism induces an orbit of length 36 on the pairs. Therefore, the passage

$$C_{36} \longleftrightarrow \binom{[9]}{2}$$

remains a calibrated identification, not a natural equivariant identification. Even a Hamiltonian ordering of the pairs would prove local preservation of incidence step by step, not a global automorphism or the canonicity of the dictionary.

8.5.7 HMT number as a compatible history in X_∞: genealogical identity, reading structure, and Archimedean evaluation

The preceding results determine the following instance of the governing definition. In the notation of this section, an HMT number is a compatible history

$$x \in X_\infty = \varprojlim X_t.$$

A reader L is additional structure: the pair (x, L) constitutes a read presentation or a measurement, but does not alter the identity type of x. When x belongs to X_∞^{Arch}, its Archimedean value is the point intersection of the cylinders; the set of values so constructed is $\mathrm{Im}(\mathrm{ev}_{\mathbb{R}}) \subseteq \mathbb{R}$, and its identification with the entire line requires the additional coverage theorem. Its minimal memory relative to an observable is the predictive quotient of futures; and the alternating form of the sum–product support admits the finite Weyl–Heisenberg representation constructed above. Value, trajectory class, and uncertainty are defined by three operations on specified domains of the same transport architecture.

8.6 Monodromic generation by survival of π, e and φ

Generation does not begin with a prescribed decimal expansion. It begins in the complete TPK state: visible word, sheet, orientation, quotient, carry, Hensel state, ternary and decimal cylinders, joint signature, boundary, phase, and dodecaphasic register. The EF–G_9 relation prolongs that state and eliminates a continuation only when it ceases to survive some future boundary. The decimal reader subsequently acts on the section that has been determined.

The causal chain is

$$\Omega_{\mathrm{TPK}} \longrightarrow 468\,\mathcal{U}_6 \longrightarrow 243\,\mathcal{W}_6 \longrightarrow (w_\pi, w_e, w_\varphi) \longrightarrow (\mathcal{R}_{\pi,n}, \mathcal{R}_{e,n}, \mathcal{R}_{\varphi,n})_{n\geq 0} \longrightarrow \varprojlim_n \mathcal{R}_{\chi,n} \xrightarrow{L_{\mathrm{arch}}} \chi.$$

The ambient space $\mathbb{F}_3^6$ has 729 words, but the effective image contains 243; the two objects are not identified. Within that image, internal selection fixes

$$w_\pi = 010211, \qquad w_e = 201101, \qquad w_\varphi = 121200$$

Before consulting figures of π, e, φ.

8.6.1 Generative regions and global section

Definition 8.45 (Generative region of a channel)**.** For $\chi \in \{\pi, e, \varphi\}$, let $\mathcal{R}_{\chi,n}$ be the finite set of complete states of depth n that start from w_χ and satisfy at each transition the relation EF–G_9, the exact intersection of cylinders, and the joint boundary signature. If $\tau_{n+1,n}$ eliminates only the last layer, we define

$$\mathcal{R}_\chi = \varprojlim_n (\mathcal{R}_{\chi,n}, \tau_{n+1,n}).$$

The published value is $L_{\mathrm{arch}}(x_\chi)$, where $x_\chi \in \mathcal{R}_\chi$; the reader is not part of the state that selects it.

Theorem 8.46 (Monodromy Prolongation Principle in the Full TPK)**.** *Suppose that, for a channel $\chi \in \{\pi, e, \varphi\}$, each set $\mathrm{Surv}_{\chi,n}$ is nonempty and unitary, and that its elements are compatible with truncation. Then there exists a unique section*

$$x_\chi = (x_{\chi,n})_{n\geq 0} \in \mathcal{R}_\chi$$

The decimal cylinders associated with their truncations are nested, and their diameters tend to zero. If the channel reader identifies their intervals with the declared closure, propagation, or self-scaling, the intersection publishes, respectively, π, e, or φ.

Proof. In the full profile, stable survival at level n is

$$\mathrm{Surv}_{\chi,n} = \bigcap_{h\geq 1} \{s : s \text{ admits a compatible prolongation across } h \text{ boundaries}\}.$$

By hypothesis, the surviving state at each level truncates to that at the preceding level. The levels form a finitely branching, nonempty tree at every depth. The Koenig lemma provides a global branch; levelwise unitarity precludes a second section.

For a ternary prefix of length L, interpreted as N, and a prefix of m triads, interpreted as D, the compatibility conditions are

$$I_{N,L} = \left[\frac{N}{3^L}, \frac{N+1}{3^L}\right), \qquad J_{D,m} = \left[\frac{D}{1000^m}, \frac{D+1}{1000^m}\right), \qquad I_{N,L} \cap J_{D,m} \neq \varnothing.$$

The prolongation conserves the intersection and makes both diameters tend to zero. The total intersection contains a unique real. The declared reader identifies that real within its channel. □

The reproducible execution does not replace the theorem's hypotheses with an implicit assertion. It verifies them at each of the (3501) levels needed to print ten thousand digits: there the partition $729 \to 1$, the compatibility of truncations, and the change of memory after return are checked exhaustively.

8.6.2 Survival filtration, nonadic monodromy, and π/e symmetry

For

$$B_n = (u_n^\pi, u_n^e, u_n^\varphi), \qquad q_n = u_n^\pi + u_n^e + u_n^\varphi, \qquad a_n = u_n^\pi + u_n^e - u_n^\varphi,$$

the joint signature determines

$$u_n^\varphi = 2(q_n - a_n), \qquad u_n^\pi + u_n^e = q_n - u_n^\varphi \quad \text{in } \mathbb{F}_3^6.$$

Thus, φ is the fixed self-scaling axis, and the only local ambiguity is the mirror allocation between π and e.

The phase is $g(n) = n \bmod 9$, with $0 \equiv 9$. After w_{30}, the first turn traverses

$$5, 6, 7, 8, 9, 1, 2, 3, 4.$$

They are not nine independent filters, but the nine phases of a single connection: pruning, synchronization, mirror orientation, reopening, and confirmation by survival.

In the ninth phase,

$$B_9 = (100100 \mid 020112 \mid 010122)$$

has three locally compatible outputs. The three conserve $u_{10}^\varphi = 112002$ and $u_{10}^\pi + u_{10}^e = 210110$; all survive one boundary, but only

$$\boxed{B_{10} = (101222 \mid 112221 \mid 112002)}$$

the second survives. The future breaks the local mirror. Moreover,

$$g(n+9) = g(n), \qquad x_{\chi,n+9} \neq x_{\chi,n}$$

in the returns: the next stage returns to phase 1, not to the preceding state. The quotient, carry, and boundary turn the circuit into a helix of memory. This return action with nontrivial transport is the nonadic monodromy of the TPK.

8.6.3 Reproducible emission of 12 triads and reconstruction of their enriched state

Thirteen blocks, equivalent to 78 trits, suffice for the reader to

$$D = \left\lfloor \frac{1000^{12} N}{3^{78}} \right\rfloor$$

publish the following segment directly from the ternary branches:

π	141	592	653	589	793	238	462	643	383	279	502	884
e	718	281	828	459	045	235	360	287	471	352	662	497
φ	618	033	988	749	894	848	204	586	834	365	638	117.

This table does not feed the transition: it exhibits its output. The iteration of the same connection, with the return $9 \to 1$, produces any requested finite prefix under the hypotheses of the theorem 8.46; that theorem specifies the prolongation to the inverse limit.

8.6.4 Unique closure of π and classification of its 5 regional histories

Let

$$\Psi : \mathcal{U}_6 \longrightarrow \mathbb{F}_3^6, \qquad \Psi(U_6) = (-U_6) \bmod 3$$

the coordinate projection of the catalog. The fiber

$$\mathscr{R}_\pi^{\mathrm{micro}} := \Psi^{-1}(010211)$$

contains exactly the five vectors

$$\begin{aligned} U_\pi^{\perp} &= (501, 614, 498, 169, 272, 272), \\ U_{\pi,1}^{++} &= (810, 923, 870, 169, 272, 272), \\ U_{\pi,2}^{++} &= (810, 983, 810, 169, 272, 272), \\ U_{\pi,3}^{++} &= (870, 923, 810, 169, 272, 272), \\ U_\pi^{--} &= (870, 923, 810, 418, 674, 521). \end{aligned}$$

Their multiplicative signatures are

$$555555, \qquad 339555, \qquad 393555, \qquad 933555, \qquad 933717,$$

and their multiplicities are

$$432, \qquad 144, \qquad 144, \qquad 144, \qquad 144.$$

Therefore,

$$\boxed{5 = 1_{\perp} + 3_{++} + 1_{--}, \qquad 1008 = 432 + 4 \cdot 144.}$$

The first identity classifies orientation functions; the second counts seed routes. They are not two ways of counting five copies of the same object.

The visible quotient

$$\mathscr{R}_\pi^{w_6} = \Psi(\mathscr{R}_\pi^{\text{micro}}) = \{010211\}$$

has a single element because it forgets regional provenance. Equality of words does not identify the five states: the first four regions preserve the tail 169|272|272, whereas the negative region effects a mutated return. The transverse region, of multiplicity 432, likewise cannot be reduced to one of the four branches of multiplicity 144.

The closure function is also seen in the multigraph of blocks. Each of the five regions belongs to a minimal closed walk of length eight that also traverses the anchors U_e, U_φ, and U_{APP}. The enumeration and the proof of minimality reside in chapter 9; the regional list and its multiplicities, in chapter 9.

Proposition 8.47 (Closure Package for π)**.** *The datum*

$$\mathfrak{C}_\pi = \big(\mathscr{R}_\pi^{\text{micro}}, w_\pi, \rho_\pi, m_\pi, \ell_{\text{cl}}\big),$$

where

$$\rho_\pi = (\perp, ++, ++, ++, --), \qquad m_\pi = (432, 144, 144, 144, 144), \qquad \ell_{\text{cl}} = 8,$$

preserves exactly the functional information lost by the quotient $\mathscr{R}_\pi^{w_6}$. Consequently, the function of π in this generation is to close five regional histories into a single evaluation, not to repeat the same constant five times.

Proof. The fiber, roles, and multiplicities are those of chapter 9. The chapter 9 proves that each region enters a minimal closure of length eight with the three declared anchors. The projection Ψ sends the five regions to the same word, so that the quotient preserves the visible value and forgets $\rho_\pi, m_\pi, \ell_{\text{cl}}$. □

8.6.5 e: visible propagation and differentiated quotient memory

The fiber of $w_e = 201101$ consists of an emission U_e with multiplicity 144. Its functional feature is not an infinite periodicity, but rather a local repetition exhaustively distinguished within the reader of the 243 words. The theorem 53.12 proves that w_e is the only word whose twelve-digit reading contains a square of length four beginning at the second digit:

$$718281828459 = 7\ \underbrace{1828\,1828}_{\text{local square}}\ 459.$$

Juxtaposition of blocks is decimal concatenation; it is not the arithmetic product $7 \cdot 1828^2 \cdot 459$. The catalog contains another square of length four,

$$575157518472 = \underbrace{5751\,5751}_{\text{local square}}\ 8472,$$

but begins at the first digit and, therefore, does not satisfy the same positional predicate.

The complete census of squares of lengths $1, \ldots, 6$ is

ℓ	1	2	3	4	5	6
occurrences	240	21	3	2	0	0
words that contain them	153	19	3	2	0	0.

The repetition 1828 1828 does not begin a period either: a third copy would require a 1 as the next digit, but the effective reading contains a 4.

The dynamics of elevation show why the episode does express propagation:

$$201101 \mid 121221 \mid 102011 \mid 012222 \mid 102011.$$

The third and fifth visible blocks coincide, but the states that emit them are distinct. Their prestates modulo 27 are

$$(25, 11, 7, 17, 8, 16), \qquad (7, 8, 4, 23, 26, 7),$$

and their subsequent Hensel quotients are

$$(6, 13, 9, 2, 13, 1), \qquad (15, 0, 3, 19, 23, 25).$$

There is return of the projection 102011, not return of the enriched state. The output can propagate and reappear because the quotient transports the genealogy that the visible word has omitted.

Proposition 8.48 (Functional content of e)**.** *The exact generation of e combines three compatible facts:*

1. *the selection internal of* $w_e = 201101$*;*
2. *the positional uniqueness of the local square* 1828 1828 *in the fixed catalogue;*
3. *the reappearance of* 102011 *under different memory states.*

Its function is propagation with memory renewal. It is not periodicity of the expansion nor repetition of the complete state.

Proof. The first point is the case e of the theorem 53.14; the second and its census are the theorem 53.12. The inequality of the two prestates and of the two Hensel quotients proves the third. □

8.6.6 Autoscaling Axis and Mirror Fiber

The joint signature of the three generations preserves a linear decomposition that will subsequently be used by the scale reader. For

$$B_k = (u_k^{\pi}, u_k^{e}, u_k^{\varphi}) \in (\mathbb{F}_3^6)^3$$

we define, coordinate by coordinate,

$$q_k = u_k^{\pi} + u_k^{e} + u_k^{\varphi}, \qquad a_k = u_k^{\pi} + u_k^{e} - u_k^{\varphi}.$$

Theorem 8.49 (Axial decomposition of the boundary signature)**.** *The pair* (q_k, a_k) *uniquely determines the self-scaling channel and the aggregate of the other two channels:*

$$u_k^{\varphi} = 2(q_k - a_k), \qquad u_k^{\pi} + u_k^{e} = q_k - u_k^{\varphi}.$$

Consequently, a fiber of

$$q_{\mathrm{ax}}(u^{\pi}, u^{e}, u^{\varphi}) = (u^{\pi} + u^{e}, u^{\varphi})$$

preserves ambiguity only in the internal allocation between u^{π} *and* u^{e}*.*

Proof. Subtracting the two defining equations gives $q_k - a_k = 2u_k^{\varphi}$. Since the inverse of 2 in $\mathbb{F}_3$ is again 2,

$$u_k^{\varphi} = 2(q_k - a_k).$$

Upon subtracting this vector from q_k there remains $u_k^{\pi} + u_k^{e}$. The operation fixes the axis φ, but does not separate the two summands of the fiber π/e; that is exactly the residual ambiguity. □

The expression *mirror fiber* names this exact decomposition in $\mathbb{F}_3^6$. It does not posit an analytic identity between the real constants: it indicates which component is fixed by the signature and where an internal choice persists.

8.6.7 φ: the autoescala inducida by TPK

The word $w_\varphi = 121200$ possesses a single emission of multiplicity 144, but its function is not deduced from that cardinality. The TPK calendar produces the block of modes

$$(\Sigma, \Pi, \Pi).$$

Reading Σ as the areal leaf and Π as the volumetric leaf, the three consecutive pairs of the cycle force the incidence

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix},$$

as theorem 6.20 proves. The golden ratio is not introduced to choose this matrix: it appears afterward as its Perron root. Indeed,

$$\det(tI - F_{\mathrm{av}}) = t^2 - t - 1, \qquad F_{\mathrm{av}} \begin{pmatrix} 1 \\ \varphi \end{pmatrix} = \varphi \begin{pmatrix} 1 \\ \varphi \end{pmatrix}.$$

For an admissible path $\gamma : i \to j$ of length n, with $r = (1, \varphi)$, the Parry character

$$\chi_P(\gamma) = \varphi^n \frac{r_i}{r_j}$$

is multiplicative under concatenation. On a closed path, $\chi_P(\gamma) = \varphi^n$. The measure of maximal entropy of the memory-one hull satisfies, by corollary 6.21,

$$\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.$$

Second-order memory also preserves the contracted direction. In the basis $(x^2, 2xy, y^2)$,

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}, \qquad \mathrm{Spec}\big(\mathrm{Sym}^2(F_{\mathrm{av}})\big) = \{\varphi^2, -1, \varphi^{-2}\}.$$

The eigenvalue φ^{-2} is the positive stable mode. On closed returns, the scale cocycle of section 6.3.8 gives

$$M_n = \varphi^{-2n} = \big(\chi_P(\gamma)\big)^{-2}.$$

Proposition 8.50 (Functional content of φ)**.** *The function of φ in HMT is the self-scaling of the quotient of modes: growth by the Perron root φ, cylindrical conservation by χ_P and stable second-order return by φ^{-2}. These three expressions belong to one and the same operator induced by the TPK calendar.*

Proof. The incidence F_{av} descends from the block (Σ, Π, Π) by theorem 6.20. Its characteristic polynomial produces the Perron root, and the multiplicativity of χ_P is obtained by telescopy. The quadratic action separates the three indicated eigenvalues; the contracted positive mode is φ^{-2}. □

8.6.8 Oriented correspondence between closure and self-scale

The matrix F_{av} generates φ^{-2}, but cannot by itself generate π: every rational function of its spectrum belongs to $\mathbb{Q}(\sqrt{5})$. Transcendental closure comes from the coinductive regional reader. This separation of origins is preserved by the diagonal operator

$$D_\pi = \pi_{\mathrm{HMT}} P_{\mathrm{ar}} + P_{\mathrm{vol}}, \qquad P_{\mathrm{ar}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad P_{\mathrm{vol}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

The marked return of length n is

$$\Theta_n = \pi_{\mathrm{HMT}} \frac{F_{n-1}}{F_{n+1}}, \qquad \lim_{n\to\infty} \Theta_n = \frac{\pi_{\mathrm{HMT}}}{\varphi^2}.$$

The dynamical proof, the exact witness of length 108, and the reader of nested cylinders reside in section 6.3.7.1. The mark of π is applied only once to the return: it is not inserted into every transition of F_{av}.

The same reason has two orientations. Let

$$\mathscr{R}(x, y) = \frac{x}{y^2}, \qquad \mathsf{J}(x, y) = (y, x).$$

Then $\mathsf{J}^2 = I$ and

$$\boxed{\mathscr{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \qquad (\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \frac{\varphi}{\pi^2}.}$$

Moreover,

$$\frac{\pi/\varphi^2}{\varphi/\pi^2} = \left(\frac{\pi}{\varphi}\right)^3, \qquad \frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 \left(\pi/\varphi^2\right)^2}.$$

The first orientation reads areal closure over volumetric memory; the second, interior self-scaling over quadratic closure. Section 6.3.7.1 proves this involution and its subsequent appearance in the electron exponent. This correspondence does not identify π with φ: it preserves their order and makes explicit what changes when that order is reversed.

8.6.9 Arbitrary precision of monodromic emission

Corollary 8.51 (Emission of any finite prefix)**.** *Under the hypotheses of theorem 8.46, for every $M \geq 1$ the EF–G_9 iteration determines the first M decimal digits of each of the three channels. In particular, $M = 100$ and $M = 1000$ are finite windows of the same monodromic prolongation and do not require the introduction of an external table of digits.*

Proof. Let $K(n)$ be the number of triads published after n ternary blocks. The section supplied by the theorem has levels of every depth and $K(n) \to \infty$. Given M, choose n with $3K(n) \geq M$. The theorem 8.46 uniquely determines the truncation of depth n, and its decimal cylinder fixes the first $3K(n)$ digits. Taking the first M concludes the argument. □

The difference of functions is fixed within a single construction: π closes distinct regional provenances in a common evaluation; e propagates a visible output while renewing the memory that transports it; φ governs the self-scaling of the quotient of modes. Monodromy explains how those functions return to the same phase and pass through the mirror π/e. Under the coinductive hypotheses of the prolongation theorem, they publish new blocks indefinitely without resetting their history.

8.7 Monodromic prolongation and calculation to prescribed depth

The construction starts from the enriched state produced by APP → TRIT → TPK: active catalog of 468 emissions, ternary projection, action D_3, orientation gauge, full-rank transition record, closure, propagation and self-scaling characters, ternary cylinders, nonadic phase and Paley–Witt shadow. The record uniquely reconstructs the lifts L_0, L_1 before opening the Archimedean chart. No digit of π, e or φ is received as input to the generator.

8.7.1 Initial coinductive prolongation from w_6 until the compatibility boundary of order 1

The exhaustive census selects the words

$$w_6^{\pi} = 010211, \qquad w_6^{e} = 201101, \qquad w_6^{\varphi} = 121200.$$

With row vectors over $\mathbb{F}_3^6$, the two reconstructed lifts are

$$L_0 = \begin{pmatrix} 2&2&2&1&2&1\\ 2&1&2&2&1&1\\ 1&0&0&1&0&2\\ 0&0&1&1&1&0\\ 2&2&2&0&2&1\\ 2&1&2&1&0&0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2&1&2&0&2&2\\ 1&2&1&1&2&0\\ 1&2&1&1&1&2\\ 0&1&0&0&2&1\\ 2&0&2&1&0&1\\ 0&2&2&2&1&1 \end{pmatrix}.$$

Let B^{C}, B^{P} and B^{A} be the structural biographies of closure, propagation and self-scaling published below, decomposed into blocks $b_0^{\chi}|\cdots|b_4^{\chi}$. Form

$$X_0 = (b_0^{\mathsf{C}}, b_1^{\mathsf{C}}, b_0^{\mathsf{P}}, b_1^{\mathsf{P}}, b_0^{\mathsf{A}}, b_1^{\mathsf{A}})^T,$$
$$Y_0 = (b_1^{\mathsf{C}}, b_2^{\mathsf{C}}, b_1^{\mathsf{P}}, b_2^{\mathsf{P}}, b_1^{\mathsf{A}}, b_2^{\mathsf{A}})^T,$$

and, analogously, X_1, Y_1 with the transitions $b_2 \to b_3$ and $b_3 \to b_4$. Each block is obtained by the ternary projection of the state produced after the complete update

$$x_{j+1}^{\chi} = \mathcal{U}_{9j+9} \circ \cdots \circ \mathcal{U}_{9j+1}(x_j^{\chi}), \qquad b_j^{\chi} = \Pi_6(x_j^{\chi}), \qquad \mathcal{U}_t = \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t.$$

Thus, the record preceding the lifts is published in full by the four matrices

$$X_0 = \begin{pmatrix} 0&1&0&2&1&1\\ 0&1&2&2&2&2\\ 2&0&1&1&0&1\\ 1&2&1&2&2&1\\ 1&2&1&2&0&0\\ 1&1&2&2&0&2 \end{pmatrix}, \quad Y_0 = \begin{pmatrix} 0&1&2&2&2&2\\ 0&1&0&2&1&1\\ 1&2&1&2&2&1\\ 1&0&2&0&1&1\\ 1&1&2&2&0&2\\ 1&2&1&0&2&0 \end{pmatrix},$$
$$X_1 = \begin{pmatrix} 0&1&0&2&1&1\\ 0&0&2&1&1&1\\ 1&0&2&0&1&1\\ 0&1&2&2&2&2\\ 1&2&1&0&2&0\\ 0&1&0&2&1&0 \end{pmatrix}, \quad Y_1 = \begin{pmatrix} 0&0&2&1&1&1\\ 1&1&0&2&2&1\\ 0&1&2&2&2&2\\ 1&0&2&0&1&1\\ 0&1&0&2&1&0\\ 0&1&0&2&0&0 \end{pmatrix}. \tag{8.11}$$

Their rows are successive outputs of the TPK endomorphism on the three seeds selected by the fiber invariants; they are not coefficients imposed on L_0, L_1 or data taken from Archimedean expansions.

Theorem 8.52 (Unique reconstruction of the lifts and calendar)**.** *In* $\mathbb{F}_3$ *we have*

$$\det X_0 = 1, \qquad \det X_1 = -1, \qquad \operatorname{rank}(I_6 \otimes X_i) = 36.$$

Consequently, the systems

$$X_0 L_0 = Y_0, \qquad X_1 L_1 = Y_1$$

have the unique solutions $L_i = X_i^{-1} Y_i$*, which are exactly the matrices printed above. Among the* 16 *binary calendars of length* 4*,* 0011 *is the only one simultaneously preserving the three biographies. The* 144 *possible unit substitutions in both matrices destroy that triple compatibility.*

Proof. The determinants and ranks are calculated by exact elimination modulo 3. The invertibility of X_i gives existence and uniqueness of L_i; the 16 calendars and the $144 = 2 \cdot 6 \cdot 6 \cdot 2$ perturbations form two exhaustive finite censuses. All their inputs are words, transitions and residues of the enriched state prior to real evaluation. The conventional names of the constants intervene in none of those calculations. □

The sequence

$$u_1 = u_0 L_0, \qquad u_2 = u_1 L_0, \qquad u_3 = u_2 L_1, \qquad u_4 = u_3 L_1$$

yields

$$\begin{aligned} w_{30}^{\pi} &= 010211|012222|010211|002111|110221, \\ w_{30}^{e} &= 201101|121221|102011|012222|102011, \\ w_{30}^{\varphi} &= 121200|112202|121020|010210|010200. \end{aligned}$$

The matrix

$$R_{36} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}$$

is the first coinductive boundary. The matrices L_0, L_1 are results of the internal reconstruction of theorem 8.52 and are applied before opening the decimal witnesses. The theorem's domain is the single generating chain APP → TRIT → TPK → enriched state. APP supplies its two arithmetic sheets; TRIT orients the regime; TPK constructs and preserves the route, carry, boundary and memory fields on which the lifts act. Asking the visible projection of APP to contain the terminal state by itself confuses two consecutive domains of that same chain and does not turn the lifts into manually introduced data.

8.7.2 Finite selection and construction of characters

Let C the multiconjunto of semillas, $\mathcal{U}$ the catalogo of emisiones and $W = \Psi(\mathcal{U}) \subset \mathbb{F}_3^6$, with

$$C \xrightarrow{T_{54}^{\text{seed}}} \mathcal{U} \xrightarrow{\Psi} W \hookrightarrow \mathbb{F}_3^6, \qquad \Psi(U_6) = ((-u_j) \bmod 3)_{j=1}^{6}.$$

The exact enumeration gives

$$\sum_{U \in \mathcal{U}} \text{mult}(U) = 104\,976, \qquad |\mathcal{U}| = 468, \qquad |W| = 243, \qquad |\mathbb{F}_3^6| = 729.$$

These four numbers count distinct typed objects.

The action D_3 on W produces 43 orbits. The closure orbit is the unique orbit whose six orientations have five lifts, mass 1008, and multiplicities $432 + 4 \cdot 144$. Among the unit radical orbits, the oriented census of closure uniquely determines propagation, and census $(2, 2, 2)$ uniquely determines self-scaling. Gauge $\text{diag}_c = 6$, with ES orientation, fixes one word in each orbit. Consequently, the triple

$$(w_6^{\pi}, w_6^{e}, w_6^{\varphi}) = (010211, 201101, 121200)$$

it is obtained before constructing any Archimedean interval.

The three characters are also obtained from the selected structure. For the closure, the incidence matrix

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \quad \text{satisfies} \quad A_W^2 = 2I_6 = -I_6$$

and fixes the oriented inversion. On the pentafiber, the symmetrizer that forgets the lift label is

$$P_5 = \frac{1}{5}\mathbf{1}\mathbf{1}^T.$$

The conservation $\mathbf{1}^T\lambda = 1$ and the invariance $P_5\lambda = \lambda$ force $\lambda = (1/5)\mathbf{1}$, hence $t_1 = 1/5$. The four compositions by

$$t \star s = \frac{t+s}{1-ts}$$

give $t_4 = 120/119$. The return equation to the diagonal,

$$\frac{120/119 - 1/q}{1 + (120/119)/q} = 1,$$

has the unique positive integral solution $q = 239$. The Gaussian identity

$$(5+i)^{16}(239-i)^4 = -6813866078035761571 84 \tag{8.12}$$

acknowledges afterward the half turn. Thus, the expression

$$16\arctan(1/5) - 4\arctan(1/239)$$

is the exact evaluation of the closure character, not its selector.

For propagation, the composition of paths and the preserved unit give

$$P_{s+t} = P_s P_t, \qquad P_0 = 1, \qquad [t]P_t = 1.$$

If $P_t = \sum_{n\geq 0} a_n t^n$, comparison of the coefficient of $s^n t$ forces

$$(n+1)a_{n+1} = a_n, \qquad a_0 = 1,$$

and, by induction, $a_n = 1/n!$. The equality $P_t' = P_t$ and the value $P_1 = e$ are subsequent analytic recognitions of this formal law.

For the self-scale, the calendar $(+,-,0)$ induce

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

Its unique invariant positive ray $v = (1,x)^T$ satisfies

$$F_{\mathrm{av}}v = xv, \qquad x^2 - x - 1 = 0, \qquad x > 0.$$

Consecutive Fibonacci quotients provide nested rational brackets for x; the equation $x = 1 + 1/x$ is the scalar coordinate of this eigen-equation, not a condition imposed externally.

Proposition 8.53 (Separation between selection, evaluation, and recognition)**.** *For each channel χ, the causal composition is*

$$\widehat{X} \xrightarrow{\mathrm{Sel}_{\mathrm{TPK}}} X_\chi \xrightarrow{\mathrm{ev}_{\mathbb{R}}} \mathbb{R} \xrightarrow{\mathrm{Rec}} \{\pi, \varphi, e, \alpha\}.$$

$\mathrm{Sel}_{\mathrm{TPK}}$ *uses the census, orbit, gauge, lifts, carry, and internal character. Evaluation contracts the compatible cylinders. Recognition assigns the conventional name to the already constructed value. No target prefix intervenes in the first two arrows.*

Proof. The uniqueness of the three orbits is decided through integer predicates of the catalog. The parameters $5, 4, 239$, the recurrence $(n+1)a_{n+1} = a_n$ and the matrix F_{av} are deduced from those orbits and from the laws of unity, composition and incidence. The coordinate of α subsequently comes from the internal triple through the signed record U_{12}, the seal K and the dodecaphase carry. Rational bounds are calculated only to evaluate and certify the already closed section. Decimal comparison is performed afterwards; therefore, it cannot act as a causal input. □

8.7.3 Extension of survivors and subsequent certification

Let $\mathcal{H}_m^\chi$ be the set of admissible enriched histories of channel χ at depth m, and let $p_{n,m} : \mathcal{H}_n^\chi \to \mathcal{H}_m^\chi$ be the truncation. Define

$$\mathrm{Surv}_m^{(N),\chi} = p_{N,m}(\mathcal{H}_N^\chi), \qquad \mathrm{Surv}_m^\chi = \bigcap_{N \geq m} \mathrm{Surv}_m^{(N),\chi},$$

and the numerical section by

$$x_\chi \in X_\chi := \varprojlim_m \mathrm{Surv}_m^\chi .$$

The reader and the state are not identified: a presentation (x_χ, L_χ) publishes the value, while the state also preserves orientation, carry, boundary, sheet, exceptional incidence and genealogy. At the R36 boundary, χ_{HMT} and the internal residue ε_K^χ are already state coordinates. APP division and the phase selector produce

$$d_K^\chi = \mathrm{Dig}_{729}(\varepsilon_K^\chi), \qquad \varepsilon_{K+1}^\chi = 729\varepsilon_K^\chi - d_K^\chi, qquad N_{K+1}^{\mathrm{Ext}} = 729N_K + d_K^\chi,$$

and the selection, transport and update

$$\mathrm{Sel}_K^\chi(x) := \mathrm{Sel}\big(x, M_{\mathrm{ph}}(\rho_9(K+1))\big), \qquad \mathrm{Tra}_K^\chi(y,d) := \mathrm{Lift}(T_d)(y), \qquad \mathrm{Upd}_K^\chi := \mathrm{Rec}_K^\chi \circ \mathrm{Mem}_K^\chi,$$

$$\mathcal{U}_K^\chi(x) := \mathrm{Upd}_K^\chi\big(\mathrm{Tra}_K^\chi\big(\mathrm{Sel}_K^\chi(x), d_K^\chi\big)\big)$$

depends only on the preceding state. The complete relation Ext may be multivalued; the subrelation $\mathrm{Ext}^{\chi,\to}$, anchored in the R36 state that already carries the character, is the graph of $\mathcal{U}_K^\chi$. It therefore fixes a compatible global section without asserting that every local fiber of Ext is a singleton. It is not a retrospective intersection defined by P_{ar}, and it reads neither future digits nor brackets.

If N_K is the ternary prefix and $L_K = 6K$, its 729 subcylinders are

$$I_{K,u} = \left[\frac{729N_K + u}{3^{L_K+6}}, \frac{729N_K + u + 1}{3^{L_K+6}}\right), \qquad 0 \leq u < 729.$$

For the exact rational bracket $[\ell_{\chi,K}, h_{\chi,K}]$ constructed by the internal recurrence of the character χ,

$$j_{\min} = \max\Big(729N_K, \big\lfloor \ell_{\chi,K} 3^{L_K+6} \big\rfloor\Big),$$
$$j_{\max} = \min\Big(729N_K + 728, \big\lceil h_{\chi,K} 3^{L_K+6} \big\rceil - 1\Big).$$

The subsequent Archimedean check is

$$j_{\min} = j_{\max} = N_{K+1}^{\mathrm{Ext}}.$$

It certifies that the partition is exhaustive and locates the survivor already produced by $\mathrm{Ext}^{\chi,\to}$; it does not select it. The bracket is not read from a decimal expansion: it is calculated from the pentafiber and the unitary return, from the propagation recurrence or from the incidence F_{av}, according to the channel. Therefore, the intersection is a publication certificate, not a descent rule.

Theorem 8.54 (Correlated coinductive generation to arbitrary depth)**.** *In the enriched TPK structure constructed in the preceding theorems, the three derived characters and the dodecaphase closure construct to arbitrary depth the correlated family of sections $x_\pi, x_\varphi, x_e, x_\alpha$ satisfying:*

1. *el barrido*
$$104\,976 \longrightarrow 468 \longrightarrow 243$$
separates seeds, emissions, and visible words;

2. *los levantamientos*
$$w_6 \xrightarrow{L_0} w_{12} \xrightarrow{L_0} w_{18} \xrightarrow{L_1} w_{24} \xrightarrow{L_1} w_{30}$$
precede to the first boundary coinductive R_{36};

3. *at each level, $\mathrm{Ext}^{\chi,\to}$ first produces the compatible child, and its truncation coincides with the state at the preceding level; the 729 numerical subcylinders form an ordered partition, and the rational bracket subsequently locates the already generated child;*

4. *the phase satisfies $g(K+9) = g(K)$, whereas the block, the cylinder index, the prefix, and the Witt shadow change;*

5. *the readers publish, respectively, π, φ, e and α, and the extension rule has no terminal depth.*

The scope of the statement is coinductive and of arbitrary depth. For the four channels, uniqueness of the forward section and its compatibility under truncation come from the state update. It is not asserted that every local fiber of Ext is a singleton. Runs at any finite depth are only regression and publication witnesses.

Proof. The finite selection of proposition 8.53 preserves the five regions of the closure orbit before opening the real chart. The primitive slope $1/5$, the composition of the four companion branches, and the unit-return condition force, in that order, $120/119$ and $q = 239$. The identity (8.12) then recognizes the first positive half-turn, so that the subsequent evaluator is

$$\pi_{\mathrm{HMT}} = 16\arctan(1/5) - 4\arctan(1/239).$$

The arctangents are evaluated by alternating series with rational bounds.

In propagation, the law $P_{s+t} = P_s P_t$, the unit $P_0 = 1$, and the linear normalization first force $(n+1)a_{n+1} = a_n$. Only afterwards are $P'_t = P_t$ and

$$e_{\mathrm{HMT}} = \sum_{n\geq 0} \frac{1}{n!}.$$

On auto-scale, the calendar first produces

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$$

and its Perron ray. The equation $x = 1 + 1/x$ is its subsequent scalar coordinate.

The update reading only the preceding state produces in each channel the compatible child from the present internal character and residue. By induction, two forward sections with the same R36 state

coincide at every depth. In the three channels with a real reader developed here, rational arithmetic subsequently produces intervals of arbitrarily small width: the exact partition of the 729 subcylinders checks that the already generated child lies inside the published decimal cell. The signed closure $U_{12} \longrightarrow K$ prolongs the fourth coordinate, and the truncation squares of its two internal routes commute, so that $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$. The thousand- and ten-thousand-digit runs are finite projections, not the criterion of the theorem. □

Extension to a section of the inverse limit is governed by theorem 8.46. The preceding theorem establishes, for π, φ, e, α, the nonemptiness, compatibility and global uniqueness of each forward section required by that abstract principle, without postulating gate-by-gate singleton fibers of Ext. This formulation distinguishes the coinductive rule of arbitrary depth from its finite thousand- and ten-thousand-digit evaluations, without altering phase return or memory transport.

Corollary 8.55 (Arbitrary depth and infinite decimal object)**.** *For every $N \in \mathbb{N}_{>0}$, the same construction publishes a unique canonical decimal prefix d_N^χ of length N, with $d_{N+1}^\chi|_N = d_N^\chi$, for $\chi \in \{\pi, \varphi, e, \alpha\}$. The compatible family $(d_N^\chi)_{N\geq 1}$ determines the infinite expansion in the inverse limit. A thousand, ten thousand or a million digits are finite runs of the same parametrized algorithm; none of them limits the scope of the theorem.*

Proof. The update Upd_χ first produces the compatible cylinder. The rational bracket of the character has arbitrarily small width and subsequently certifies that this cylinder intersects a unique member of the published partition of 729 subcylinders. Given N, there exists m with $3^{-6m} < 10^{-N}$; the already produced cylinder is then contained in a canonical decimal cell of length N. Truncation compatibility identifies those cells as the finite coordinates of a forward section. □

Theorem 8.56 (Correlated coinductive generation and double projection)**.** *Let $\mathcal{S}_\infty$ be the fiber product of the four correlated forward sections of arbitrary depth generated by*

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow R_{36} \longrightarrow G_9.$$

Two typed publications depart from $\mathcal{S}_\infty$:

$$\mathcal{S}_\infty \xrightarrow{\mathcal{P}_{\mathrm{Arq}}} \mathbb{R}^4, \qquad \mathcal{S}_\infty \xrightarrow{\mathcal{P}_{\mathrm{Exc}}} W_{12} \longrightarrow G_{24} \longrightarrow \Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathrm{Aut}(V^\natural) = \mathbb{M}.$$

The first contracts compatible cylinders and publishes in a correlated manner $(\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}})$; the second preserves boundary incidence and publishes the exceptional chain. Consequently, $\mathbb{R}$ is the Archimedean shadow of the first projection, not an input selecting the genealogy. Machin, Perron–Fibonacci, the exponential semigroup and conventional names act after the HMT output.

Proof. theorem 8.54 and corollary 8.55 construct the compatible family before evaluation. The dodecaphase closure publishes α_{HMT} from its correlated R36 triple and the record $U_{12} \longrightarrow K$; the route $E_{21/22}$ preserves its own analytic domain. The Archimedean projection forgets incidence when contracting the cylinders, while the exceptional projection transports it through the Witt–Golay– Leech intertwiners to $V^\natural$. Both come from the same antecedent, and neither can act retroactively as its generator. □

8.7.4 Closure Regions

The five regions are not five values of π, but five genealogies with a common visible projection. Their multiplicity is

$$432 + 4 \cdot 144 = 1008,$$

and their papers are

$$3_{++} + 1_{--} + 1_{\perp}.$$

The regional identity is verified by the quadruple

$$(U_6, E_{\mathrm{sig}}, \text{multiplicity}, \text{role}),$$

no only by the census $3/1/1$. In particular,

U_6	E_{sig}	multiplicity	role
501|614|498|169|272|272	555555	432	$\perp$
810|923|870|169|272|272	339555	144	++
810|983|810|169|272|272	393555	144	++
870|923|810|169|272|272	933555	144	++
870|923|810|418|674|521	933717	144	−−

The table jointly fixes the enriched decimal word, emission signature, multiplicity, and role. In particular, the multiplicity anchor (432) is transversal, and the signature (933717) is the mutated return; the census (3/1/1) alone does not determine those names.

8.7.5 Phase return and memory change

In the ninth phase,

$$B_9 = (100100 \mid 020112 \mid 010122)$$

admits three orientations that preserve the axis φ and the aggregate $\pi + e$:

$$(101222 \mid 112221 \mid 112002),$$
$$(102221 \mid 111222 \mid 112002),$$
$$(111221 \mid 102222 \mid 112002).$$

The three survive a boundary and conserve

$$u^{\varphi} = 112002, \qquad u^{\pi} + u^{e} = 210110.$$

The following boundary selects

$$B_{10} = (101222 \mid 112221 \mid 112002).$$

Therefore,

$$\#\,\mathrm{Surv}_1(B_9) = 3, \qquad \#\,\mathrm{Surv}_2(B_9) = 1.$$

Index ten again occupies phase one, but not the previous state. This is the monodromy: phase return with transformation of memory.

In terms of the complete state

$$\widehat{x}_K = (B_K, C_K, p_K, c_K, \Sigma_K, W_K, g(K)),$$

the loop is the unique holonomy

$$\Gamma_9 = \mathrm{Hol}_{C_9}(\nabla_{\mathrm{TPK}}), \qquad g(K+9) = g(K),$$
$$q_{\mathrm{mem}}\Gamma_9 = q_{\mathrm{mem}} + 1, \qquad \Gamma_9 \widehat{x}_K \neq \widehat{x}_K.$$

In isometric realization, the same continuity is satisfied.

$$U_{\Gamma_9} J = JT + \eta, \qquad I - T^{*}T = \eta^{*}\eta.$$

The carry is composed of

$$\mathrm{Carr}(\gamma_2\gamma_1) = \mathrm{Carr}(\gamma_2)H(\gamma_1) + Y(\gamma_2)\,\mathrm{Carr}(\gamma_1),$$

and the telescoping preserves the finite terminal:

$$S_0 = \sum_{r=0}^{L-1} M_9^{*r} D_9^* D_9 M_9^r + M_9^{*L} S_0 M_9^L.$$

The windows 27, 54 and 108 are the concatenations

$$\Gamma_{27} = \Gamma_9^3, \qquad \Gamma_{54} = \Gamma_9^6, \qquad \Gamma_{108} = \Gamma_9^{12};$$

transport an accumulated memory of 3, 6, and 12 turns, respectively. They do not constitute restarts of the algorithm.

8.7.6 Exhaustive census of 396 transitions, 2.376 trits, 43 turns and 387 equal-phase pairs

The run to depth one thousand produces, per channel,

$$396 \text{ transitions}, \quad 2376 \text{ trits}, \quad 43 \text{ complete turns}, \quad 387 \text{ pairs } (K, K+9),$$

and 1000 decimal digits. At each transition, the update $\mathrm{Ext}^{\chi,\to}$ produces the survivor, and the subsequent exhaustive scan of the 729 subcylinders certifies its publication. External witnesses are consulted after generation and used only for recognition.

Independence from the target is obtained because the generating map receives only the finite catalog of 468 emissions, the matrices $L_0, L_1, A_W, F_{\mathrm{av}}$ and rational arithmetic. None of its transition functions contains prefixes of π, e, φ or an operation evaluating those constants. The brackets are deduced from the constructed characters and act only in subsequent evaluation.

After the 396 stages of prolongation and certification, the final cylinder

$$\left[\frac{N}{3^{2376}}, \frac{N+1}{3^{2376}}\right)$$

is contained in a single decimal cell of depth 10^{-1000}. The thousand digits are therefore to finite witniss of the parametrizable law, not its maximum depth.

The uniform argument constructs a cylinder for any prescribed finite depth. The census of 396 stages checks only the thousand-digit instance: it keeps causal generation separate from subsequent decimal comparison and does not replace the quantifier of theorem 8.54.

Theorem 8.57 (Joint continuity of the nonadic holonomy)**.** *Let $\widehat{X}_K$ be the APP–TRIT–TPK state enriched by sheet, orientation, residue, quotient, carry, signature, cylinder, boundary, path, memory, and survival. The composition of the nine local relations publishes a unique holonomy*

$$\Gamma_{9,K} = \mathcal{R}_{K+8} \circ \cdots \circ \mathcal{R}_K : \widehat{X}_K \longrightarrow \widehat{X}_{K+9},$$

compatible with the truncations of the inverse system. At each turn the phase returns and memory advances without reinitializing the state; the carry preserves its cocycle law, the transfer acts simultaneously on its nine components, and the operator realization preserves both the orthogonal component and the terminal term of the Stein identity. By composition, these properties determine compatible sections at arbitrary depth, not independent choices level by level.

Proof. The composition and the return without reset are, respectively, definition 8.11 y theorem 8.12. The joint action on the nine coordinates and their transfer are theorem 8.13 y proposition 8.20. The compression–expression decomposition and preservation of the terminal are theorems 8.21 y 8.22. The coinductive prolongation certified in this same chapter preserves these identities under truncation; therefore, the compatible family belongs to the inverse limit of the enriched state and can be iterated to any depth. □

8.8 Affine holonomy, helical suspension, and conservation of memory depth

8.8.1 Dynamic composition of the Topological Phase Kernel over the enriched state: tritic selection, cardinal transport, memory update, and typed return

8.8.1.1 Definition and factorization of the enriched transition operator U_t

The TPK is not a nominal container. The phase function and its tabulated vector are, respectively,

$$M_{\mathrm{ph}} : \mathcal{D}_9 \longrightarrow \{+1, -1, 0\}, \qquad m_{\mathrm{ph}} := \big(M_{\mathrm{ph}}(1), \ldots, M_{\mathrm{ph}}(9)\big)^{\mathsf{T}}.$$

They are not the same type of object and neither acts by direct composition on the state. For $x \in X_{\mathrm{TPK}}^{\mathrm{enr}}$, we define

$$\mathrm{Tra}_t(y, d) := \mathrm{Lift}(T_d)(y), \qquad \mathrm{Upd}_t := \mathrm{Rec}_t \circ \mathrm{Mem}_t\,.$$

The elementary transition is then written

$$U_t(x) = \mathrm{Upd}_t\big(\mathrm{Tra}_t\big(\mathrm{Sel}_t\big(x, M_{\mathrm{ph}}(g(t))\big), d(t)\big)\big), \qquad U_t : X_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{enr}}. \tag{8.13}$$

The selector Sel_t reads the scalar value of the tritic regime and chooses the additive, multiplicative or threshold sheet; $\mathrm{Tra}_t(\,\cdot\,, d(t)) = \mathrm{Lift}(T_{d(t)})$ applies the cardinal direction; Mem_t updates residue, quotient, carry, signature, cylinder, boundary and memory; and Rec_t performs the typed return. The abbreviated notation $\mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$ designates this same composition and not a second engine.

The minimal enriched fiber can be represented as

$$\mathcal{F}_q = O_q \times H_q \times C_q \times S_q \times B_q \times \Lambda_q,$$

with orientation/leaf, lifting, carry, signature, boundary, and record. The detail of each factor depends on its residence, but the integrity rule is stable: a coordinate cannot be removed if it changes a continuation.

8.8.1.2 Nonadic holonomy

For a nine-step compatible block,

$$\Gamma_{9,K} = U_{K+8} \circ \cdots \circ U_K. \tag{8.14}$$

The phase satisfies

$$g(K + 9) = g(K),$$

but the enriched state does not in general return:

$$\Gamma_{9,K}(x_K) \neq x_K.$$

In particular,

$$q_{\mathrm{mem}}(\Gamma_9 x) = q_{\mathrm{mem}}(x) + 1, \qquad B_{K+9} \neq B_K \quad \text{in general.}$$

Theorem 8.58 (Phase return with memory advance)**.** *The holonomy Γ_9 closes the phase coordinate and transports the state to a new depth. Therefore, phase return is not state return.*

Proof. Phase closure is the periodicity of g. The ledger update includes the depth increment and boundary transport. If the state returned, all coordinates would have to coincide, contradicting $q_{\mathrm{mem}} \mapsto q_{\mathrm{mem}} + 1$. Therefore, only the phase returns. □

8.8.1.3 Bimodular cocycle law of the carry under path concatenation

Let $\mathcal{K}_{\mathrm{Carr}}$ be the carry module, and let $H, Y : \mathscr{P}^{\mathrm{enr}}_{\mathrm{TPK}} \to \mathrm{End}(\mathcal{K}_{\mathrm{Carr}})$ be the right and left actions induced, respectively, by the preserved prefix and by the active sheet of a route. We regard $\mathcal{K}_{\mathrm{Carr}}$ as a bimodule and write $kH(\gamma)$ and $Y(\gamma)k$ for those actions. The map $\mathrm{Carr} : \mathscr{P}^{\mathrm{enr}}_{\mathrm{TPK}} \to \mathcal{K}_{\mathrm{Carr}}$ assigns to each route its total carry.

For paths composable γ_1, γ_2, the carry satisfies

$$\mathrm{Carr}(\gamma_2\gamma_1) = \mathrm{Carr}(\gamma_2)H(\gamma_1) + Y(\gamma_2)\,\mathrm{Carr}(\gamma_1). \tag{8.15}$$

This law shows what preserving memory means: not keeping a quantity constant, but retaining its exact update rule. Accumulated memory is dynamic and traceable.

8.8.1.4 Nonsplit cyclic extension $0 \to C_{12} \to C_{108} \to C_9 \to 0$ and internal chronology of the TPK

The internal calendar is organized through

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0.$$

The extension preserves the difference between a visible turn and the lifted state. In the realization $C_{108} \simeq C_{27} \times C_4$, the part $C_{27} \to C_9$ does not split: the lifts of the generator have order 27, not an order dividing 9. The factor C_4 supplies the quarter-turn; the ternary kernel supplies the elevation. The combination is not an external temporal label, but the return architecture of the TPK.

8.8.1.5 Posteriority of the Markov quotient as a publication of reduced memory

Averaging enriched dynamics may produce a reduced-memory operator K_{ph}. This operator is useful for studying transfer, stationarity, and spectrum, but does not generate Γ_9. The dependence is

$$U_t \longrightarrow \Gamma_9 \longrightarrow K_{\mathrm{ph}}.$$

Inverting it would era sheet, prefix, boundary, and carry. In this publication the radial reader is constructed over enriched histories, never over the Markov quotient.

8.9 Exact helical geometry of the nonadic memory

8.9.1 Helical covering of the nonadic phase and integral coordinate of memory depth

8.9.1.1 Nonadic phase lift to the phase–memory covering

Let

$$\mathrm{Rep}_9 = \{0, 1, \ldots, 8\}, \qquad \widetilde{\Theta} = \mathrm{Rep}_9 \times \mathbb{Z}.$$

We define

$$\widetilde{\Gamma}_9(r, n) = (r, n + 1), \qquad \Pi(r, n) = [r + 9n]_{108}. \tag{8.16}$$

The first coordinate records the visible phase and the second records the depth. It holds

$$\Pi(r, n + 12) = \Pi(r, n), \qquad \widetilde{\Gamma}_9^{12}(r, n) = (r, n + 12).$$

The covering transformation

$$\tau_{12}(r, n) = (r, n + 12)$$

acts freely. Each fiber of Π is an orbit of that action.

Definition 8.59 (Nonadic helix)**.** The nonadic helix is the lifted system

$$(\widetilde{\Theta}, \widetilde{\Gamma}_9, \Pi)$$

with phase r mod 9, calendar $\Pi(r, n)$, and deep memory n.

Theorem 8.60 (Periodic phase and aperiodic memory)**.** *The projection of the helix is periodic of order* 12 *on the calendar C_{108}, while the lifted state distinguishes all depths $n + 12k$, $k \in \mathbb{Z}$.*

Proof. The equality $\Pi(r, n) = \Pi(r', n')$ forces $r = r'$ and $n - n' \in 12\mathbb{Z}$. Therefore, the projection identifies exactly the orbits of τ_{12}, but the second coordinate of the lift remains integral and distinguishes their elements. □

8.9.1.2 Immersion H_9 of the nonadic quotient–residue into $\mathbb{R}^3$ and calculation of the Frenet invariants

For $N \geq 1$, let

$$z_N = q_9(N) + \frac{\rho_9(N) - 1}{9}.$$

The immersion

$$H_9(N) = \big(\cos(2\pi z_N), \sin(2\pi z_N), z_N\big) \tag{8.17}$$

satisfies

$$z_{N+9} = z_N + 1, \qquad H_9(N + 9) = H_9(N) + (0, 0, 1).$$

The projection onto the first two coordinates returns; the third priservis the turn. The figure is not imposed on the arithmetic: it is an immersion of the exact decomposition $N = 9q_9(N) + \rho_9(N)$.

For the continuous curve

$$h(z) = (\cos 2\pi z, \sin 2\pi z, z),$$

we have

$$h'(z) = (-2\pi \sin 2\pi z, 2\pi \cos 2\pi z, 1),$$

$$h''(z) = (-4\pi^2 \cos 2\pi z, -4\pi^2 \sin 2\pi z, 0).$$

Its curvature and torsion are constants:

$$\kappa_h = \frac{4\pi^2}{4\pi^2 + 1}, \qquad \mathcal{T}_h = \frac{2\pi}{4\pi^2 + 1}. \tag{8.18}$$

Calculation of equation (8.18). The norm of h' is $\sqrt{4\pi^2 + 1}$ and $\|h' \times h''\| = 4\pi^2\sqrt{4\pi^2 + 1}$. Therefore,

$$\kappa_h = \frac{\|h' \times h''\|}{\|h'\|^3} = \frac{4\pi^2}{4\pi^2 + 1}.$$

Furthermore, with $h''' = (8\pi^3 \sin 2\pi z, -8\pi^3 \cos 2\pi z, 0)$,

$$\mathcal{T}_h = \frac{\det(h', h'', h''')}{\|h' \times h''\|^2} = \frac{2\pi}{4\pi^2 + 1}.$$

□

8.9.1.3 Circular sections and cylindrical foliation of the phase–memory covering

A section n = constant produces a circle. A family of sections with constant radius produces a cylinder. If the radius depends on depth, the same structure produces a radial helical suspension. Therefore:

$$\text{orbit} \longleftrightarrow \text{helical sheet},$$

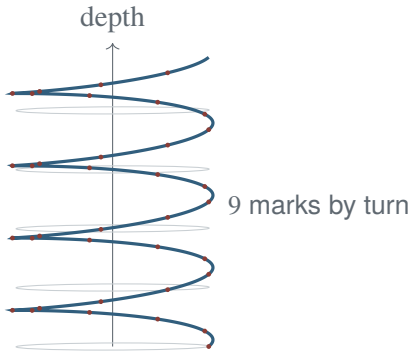

Figure 8.2: Nonadic helix: the rings are level sections; the curve conserves memory advance.

$$\text{level section} \longleftrightarrow \text{circle}, \qquad \text{family of sections} \longleftrightarrow \text{cylinder}.$$

This is a geometric translation of the lifted system, not a replacement of the ledger by a drawing.

8.9.2 Dynamic suspension of the enriched affine system

8.9.2.1 State-dependent holonomy

Let U_{APP} be a radial module and associate with each nonadic block an affine endomorphism

$$H_9(x) : u \longmapsto \Lambda_9(x)u + C_9(x).$$

When holonomy depends on the initial state, we define $F(x,u) = (\Gamma_9 x, H_9(x)u)$. If F is continuous, its suspension is the mapping torus

$$\mathfrak{S}^{\mathrm{rad}}_{\mathrm{TPK}} = \frac{X^{\mathrm{enr}}_{\mathrm{TPK}} \times U_{\mathrm{APP}} \times [0,1]}{(x,u,1) \sim (\Gamma_9 x, H_9(x)u, 0)}. \tag{8.19}$$

If F is to homeomorphism —which requiris, in addition to the invertibility of the linear parts, the continuous reversibility of Γ_9 and of its dependence on x— to bidirectional suspension is obtained. In the general monoid the same quotient encodis only forward evolution; it is not identified with to teliscope and not global inversion is prisupposed.

Definition 8.61 (Radial helical suspension)**.** The suspension equation (8.19), endowed with an angular coordinate of phase and a subsequent radial evaluation, is called a *radial helical suspension*. The term *general helix* is reserved for the cases that satisfy a differential condition of Lancret.

8.9.2.2 Orbits of the skew product and identification relation of the suspension space

The orbit of the skew–product is

$$(x_0,u_0), (\Gamma_9 x_0, H_9(x_0)u_0), (\Gamma_9^2 x_0, H_9(\Gamma_9 x_0)H_9(x_0)u_0), \dots.$$

The stitching preserves the order of the factors. Replacing the whole orbit with the final product would prevent truncating the history and reconstructing its prefixes. The helicoidal sheet is, therefore, an orbit with ledger, not an isolated curve.

8.9.2.3 Iteration of the stationary affine endomorphism and classification of its fixed points

If $H_9(x) = H = (\Lambda, C)$ is constant,

$$u_{n+1} = \Lambda u_n + C.$$

The exact internal iteration, valid for every endomorphism Λ, is

$$u_n = \Lambda^n u_0 + \sum_{k=0}^{n-1} \Lambda^k C. \tag{8.20}$$

If $I - \Lambda$ is invertible in the radial module, the fixed point exists

$$u_* = (I - \Lambda)^{-1} C,$$

and

$$u_n - u_* = \Lambda^n (u_0 - u_*). \tag{8.21}$$

In the translational sector $\Lambda = I$,

$$u_n = u_0 + nC.$$

Only after choosing a positive scalar character $\chi : U_{\mathrm{APP}} \to \mathbb{R}$, with $\chi\Lambda = \lambda\chi$, are the numerical formulas $u_* = C/(1-\lambda)$ for $\lambda \neq 1$ and the real powers of λ used in continuous interpolation obtained. An abstract endomorphism is not divided by $1 - \Lambda$. These two possibilities anticipate the separation between a self-scaling family and a translational family. Neither by itself selects a known spiral; the curve appears after applying $\exp_p$ and the angular coordinate.

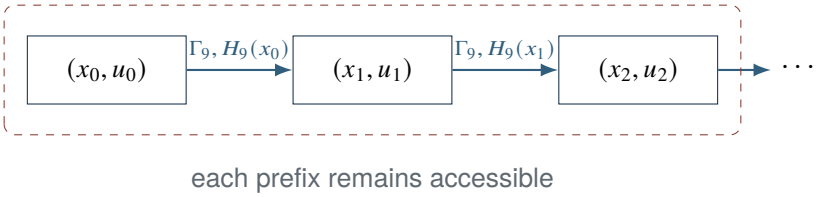

Figure 8.3: The suspension preserves the sequence of factors, not only the final holonomy.

8.9.3 Bidirectional Involution and Conjugate Leaves

8.9.3.1 Antipodal of the reversible path groupoid and conjugation of the affine holonomy

Let $\mathscr{P}^{\times}_{\mathrm{TPK}}$ be the subgroupoid of reversible routes. If the radial representation satisfies

$$h_{e^\dagger} = h_e^{-1},$$

then, for $\gamma = e_n \cdots e_1$,

$$H_{C_{\mathrm{rev}}\gamma} = h_{e_1}^{-1} \cdots h_{e_n}^{-1} = (h_{e_n} \cdots h_{e_1})^{-1} = H_\gamma^{-1}.$$

Theorem 8.62 (Conjugation of Ascent and Descent)**.** *In the reversible sector, the route involution interchanges the ascent and descent leaves and inverts the affine holonomy.*

On the helical coverage, let

$$\iota(r, n) = (r, -n).$$

Then

$$\iota \widetilde{\Gamma}_9 \iota = \widetilde{\Gamma}_9^{-1}. \tag{8.22}$$

The equality is obtained directly:

$$(r, n) \overset{\iota}{\mapsto} (r, -n) \overset{\widetilde{\Gamma}_9}{\longmapsto} (r, -n+1) \overset{\iota}{\mapsto} (r, n-1).$$

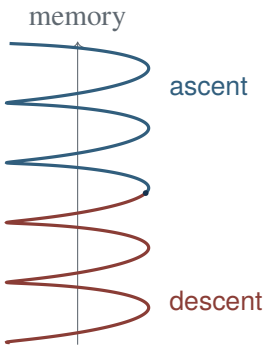

Figure 8.4: Conjugate leaves produced by route inversion.

8.9.3.2 Involution π/e of the fiber of constants, invariant $u^\pi + u^e$ and fixed axis φ

The involution on the constant fiber

$$\mathfrak{c}(u^\pi, u^e, u^\varphi) = (u^e, u^\pi, u^\varphi)$$

interchanges the branches π/e and fixes the axis φ. It also preserves $u^\pi + u^e$. This involution and route inversion are distinct objects: the former acts on a publication fiber; the latter acts on the path groupoid. No global conjugation $\mathfrak{c}\Gamma_9\mathfrak{c} = \Gamma_9^{-1}$ is asserted without constructing the corresponding intertwiner.

This distinction protects the positive thesis. The mirror π/e, the axis φ, and bidirectionality are present; what is not permitted is to identify them through an untyped equality of operators.

8.9.3.3 Nested circles as cross sections of the leaves

Let $r_n > 0$ be the scale of section n. The family

$$C_n = \{(r_n \cos\theta, r_n \sin\theta, n) : 0 \le \theta < 2\pi\}$$

produces nested circles as r_n varies and cylinders when sections with a common radius are grouped. The union of the C_n along a TPK route is the discrete trace of a helical sheet. The involution $n \mapsto -n$ produces the conjugate sheet.

8.10 Derivation of the incidence channels 90 and 120 from the tritic semicoronas of the Topological Phase Kernel

The cardinalities 90 and 120 are generated within the internal dynamics of the Topological Phase Kernel before any exponential evaluation, hexad–octad realization, or metrological reading. Their provenance is the oriented partition of the 9 phases and the incidence of their active pairs; the spectral channels $q_\pm$ will subsequently act on these already constructed objects.

8.10.1 Tritian Partition of the Nonadic Phase into Oriented Semicoronas

In the canonical chart $D_9 = \{1, \dots, 9\}$, the tritic phase selector determines the disjoint decomposition

$$H_+ = \{1, 4, 7\}, \qquad H_- = \{2, 5, 8\}, \qquad H_0 = \{3, 6, 9\}.$$

The classes of H_+ activate the additive sheet, those of H_- the multiplicative sheet and those of H_0 conserve the threshold. We define

$$H_{\text{act}} = H_+ \sqcup H_-, \qquad |H_{\text{act}}| = 6, \qquad \left|P_2(H_{\text{act}})\right| = \binom{6}{2} = 15,$$

where $P_2(H_{\mathrm{act}})$ denotes the set of unordered pairs of active phases. This partition conserves leaf, orientation, and phase origin; it is not a retrospective classification induced by physical realizations.

8.10.2 Incidence channel of cardinality 90

The internal incidence between a distinguished active phase and an active pair is

$$\mathcal{F}_{90} := H_{\mathrm{act}} \times P_2(H_{\mathrm{act}}).$$

By construction,

$$|\mathcal{F}_{90}| = 6 \cdot 15 = 90.$$

The cardinality 90 therefore follows from the tritic semicorona of the TPK. It is not an input from Barbero–Immirzi, from the mass law, or from a metrological table.

8.10.3 Incidence channel of cardinality 120

Extending the first factor to the 8 positions that precede the nonadic return yields

$$O_{\mathrm{ph}} = \{1, \dots, 8\}, \qquad \mathcal{F}_{120} := O_{\mathrm{ph}} \times P_2(H_{\mathrm{act}}),$$

and, consequently,

$$|\mathcal{F}_{120}| = 8 \cdot 15 = 120.$$

The difference between $\mathcal{F}_{90}$ and $\mathcal{F}_{120}$ preserves the boundary information: the second channel incorporates the 8 positions preceding the return, whereas the first preserves only the 6 operational phases.

8.10.4 Dodecaphasic compatibility and causal precedence with respect to spectral evaluation

The dodecaphase wheel pairs the 2 oriented semicoronas and records the decomposition $1 + 5 + 6 = 12$, invertible on its image. Thus, the incidence cardinalities are fixed in the causal order

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow (H_+, H_-, H_0) \longrightarrow (\mathcal{F}_{90}, \mathcal{F}_{120}).$$

Only afterward, once the conjugate angular coordinates have been constructed, the channels $q_\pm$ spectrally evaluate these incidences by means of

$$V_{90,120} = (I - T^{90})(I - T^{120})^{-1} = r_+ P_+ + r_- P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}}.$$

The evaluation $V_{90,120}$ does not generate the cardinalities that appear in its exponents: it operatorially publishes the incidence channels previously produced by TPK.

8.11 Center, boundary, and vacancies in the nonadic connection

8.11.1 The thesis and the order of construction

The relation between center and boundary acquires mathematical content when one specifies which data are published, which transformations transport them and with what information they are reconstructed. In APP, a residue is accompanied by its quotient; in TRIT, orientation distinguishes operations that an aggregate can merge; in TPK, a turn returns the phase and prolongs memory. The enriched state brings these coordinates together. Its residence in the joint discrete structure of the continuum preserves dependencies between the various subsequent readings.

The path is APP → TRIT → TPK → enriched state → joint discrete structure of the continuum. This development makes local cuts of that path: it does not reconstruct the five consubstantial aspects of the continuum from a spectral form or turn them into five independent modules. The internal constants are

received at their publication stage, without using their conventional values to choose seeds, routes or coefficients.

The author's intuition can be expressed thus: **publication of a value is a projection of a construction; transporting that construction preserves the information that allows its realizations to be distinguished**. The following operations make that statement concrete. The subsequent language of interpolation and orthogonal decomposition proves properties of already specified objects; it does not retrospectively select the APP state.

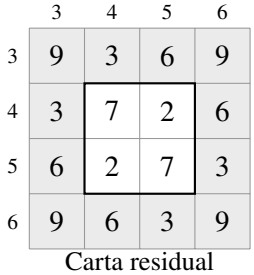
8.11.2 The local crown and reconstruction of the center

In the positive chart we use

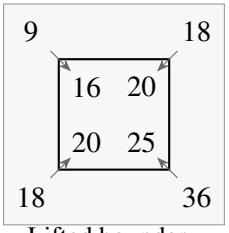
$$\rho_9(n) = 1 + [(n-1)]_9, \qquad q_9(n) = \frac{n - \rho_9(n)}{9}, \qquad n = \rho_9(n) + 9q_9(n).$$

The product table is $P(i,j) = ij$, with $1 \le i, j \le 9$. Restriction to $Q = \{3,4,5,6\}^2$ publishes

$$(\rho_9(ij))_{i,j=3}^{6} = \begin{pmatrix} 9 & 3 & 6 & 9 \\ 3 & 7 & 2 & 6 \\ 6 & 2 & 7 & 3 \\ 9 & 6 & 3 & 9 \end{pmatrix}.$$



Carta residual
corona 3, 6, 9



Lifted boundary
and multiaffine interpolation

Figure 8.5: The same chart in two readings. On the left, the radical crown surrounds the block B_c. On the right, the four integer corners determine the interior values under the multiaffine law. Their corner residues coincide, but the quotients $(0,1,1,3)$ distinguish the lift.

Its inner block is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

The perimeter of this chart contains twelve positions: four with value 3, four with 6 and four with 9; their sum is 72. A radical crown becomes visible around the central block. The global electronic center is $(5,5)$, the unique fixed point of inversion of the complete APP; its position is not changed by choosing this local chart, whose geometric center is at $(4.5, 4.5)$.

Proposition 8.63 (Recovery from the lifted boundary)**.** *Let $F(x,y) = a + bx + cy + dxy$ be a multiaffine law in the chart $[3,6]^2$. For $t = (x-3)/3$ and $u = (y-3)/3$,*

$$\begin{aligned} F(x,y) = (1-t)(1-u)F(3,3) + (1-t)uF(3,6) \\ + t(1-u)F(6,3) + tuF(6,6). \end{aligned}$$

Proof. For fixed y, affinity in x recovers $F(x, y)$ from $F(3, y)$ and $F(6, y)$. Affinity in y recovers each of those two values from its endpoints. Composition gives the formula. In particular, the four corners determine the entire chart within the declared space of laws. □

For the product, the four lifted values are $9, 18, 18, 36$. Their positive residues are all 9, but their quotients are $0, 1, 1, 3$. The formula recovers $16, 20, 20, 25$ at the interior positions; its residual publication gives $7, 2, 2, 7$. In this way, the boundary determines the interior **while preserving the law and the lift**. Interpolation is performed before modular reduction: one does not divide by 3 in $\mathbb{Z}/9\mathbb{Z}$, where 3 is not invertible.

This specifies the meaning of "preserving the information of the center." The residual crown alone does not individualize all lifts: F and $F + 9$ have the same residues along the entire boundary and different lifted values. The residue–quotient pair removes that ambiguity within the indicated reconstruction. The assertion is proved for multiaffine laws; extending it to complete states also requires preserving the operators, routes, and memory acting on them.

Multiaffine recovery is a **new formalization of the preexisting authorial architecture**. The charts and their readings are results recovered from the corpus; this explicit presentation of their inverse is not attributed as an independent historical discovery.

8.11.3 Sum, product, and the three values of discrete curvature

The multiplicative rows are constructed by additive accumulation. The difference between the two sheets appears when both coordinates are varied simultaneously. With unit differences,

$$\Delta_x \Delta_y (x + y) = 0, \qquad \Delta_x \Delta_y (xy) = 1.$$

The same property is recovered on the lifted boundary:

$$\frac{P(6,6) - P(6,3) - P(3,6) + P(3,3)}{3 \cdot 3} = 1;$$

for $S(x, y) = x + y$, this quotient equals 0. The product records the cross variation that the sum does not introduce. The corpus expresses the oriented version through

$$\mathcal{F}(T_x, T_y) = \Delta_x \Delta_y T_y - \Delta_y \Delta_x T_x,$$
$$\mathcal{F}(S, S) = \mathcal{F}(P, P) = 0, \qquad \mathcal{F}(S, P) = +1, \qquad \mathcal{F}(P, S) = -1.$$

The order of the sheets distinguishes the sign. The formulation "the sum accumulates and the product folds or unfolds" rests here on a verifiable operation: modular projection preserves a residue; lifting recovers the quotient recording what was exceeded. Discrete curvature additionally records the order of the variations. This finite difference is not identified with a differential curvature of a physical space without its corresponding realization map.

The global radical cross

In $R = \mathbb{Z}/9\mathbb{Z}$, the ideal $\mathfrak{m} = \{0, 3, 6\}$ satisfies $\mathfrak{m}^2 = 0$. Its positive publication is $\{9, 3, 6\}$. The cross

$$(\mathfrak{m} \times R) \cup (R \times \mathfrak{m})$$

has $27 + 27 - 9 = 45$ positions. The intersection contains nine values 9, summing to 81; the remaining arms have twelve values of each class $3, 6, 9$, summing to 216. The total is

$$297 = 216 + 81 = 3(72 + 27) = 3 \cdot 99.$$

Four boundaries are distinguished: the local perimeter of twelve positions, the radical cross of forty-five, the gnomon of seventeen completing 8^2 to 9^2, and the cubic crown of 271. Each has its own domain and operation. The tritic quotient $R/\mathfrak{m}$ preserves a class; transporting the state requires accompanying it with the lifted data and their history.

8.11.4 The 72–27 and 77–22 readouts and the 729–271 completion

The ordered rows of B_c are published decimally as 72 and 27; its diagonals as 77 and 22. This yields

$$72 + 27 = 77 + 22 = 99.$$

In the cubic completion, counting the interior, faces, edges, and vertex gives

$$1000 = 729 + 243 + 27 + 1 = 729 + 271,$$

$$999 = 729 + 243 + 27 = 729 + 270.$$

The coincidence of readouts is expressed while preserving the decimal remainder:

$$729 = 10 \cdot 72 + 9, \qquad 271 = 10 \cdot 27 + 1.$$

Therefore, the two-dimensional reading publishes $(72, 27)$; the cubic reading publishes $((72, 9), (27, 1))$. The pair of remainders $(9, 1)$ distinguishes the prolongations that would share the same quotient. The chart constructions are carried out first; those publications are then compared. The identity of the integers does not reverse that causal order.

The chapter on integer channels provides another specific composition. With the internal counts $\Delta = 54$, $\nu = \Delta/2 = 27$, and $\Theta = 5\nu = 135$, it obtains

$$C_\alpha = \nu^2 = 729, \qquad C_e = 2\Theta + 1 = 271.$$

Here ν is the new name for the local integer denoted by κ in that source, to distinguish it from the rational readout of the dodecaphase record. The channels are integer objects; their identification with the constants passes through the regional readouts and the corresponding closure, not through the first digits of an expansion. This comparison uses the integer channels and does not require the subsequent angular realization.

For the oral reference to a fraction of π, the located source contains

$$\frac{396}{126} = \frac{22}{7}, \qquad 396 = 18 + 72 + 108 + 198, \quad 126 = 18 + 108.$$

It is a rational ratio of alternating rings. This ring ratio is an exact rational reading; its role is distinguished from the regional publication of π.

8.11.5 The electronic center and its conjugate vacancies

The inversion of the positive APP is $\rho(r, c) = (10 - r, 10 - c)$. Its unique fixed point is $(5, 5)$. In the central additive fiber,

$$\mathcal{F}_{10} = \{(5 + t, 5 - t) : t \in \mathbb{Z},\ |t| \le 4\},$$

the product equals $25 - t^2$. Preserving its central residue requires $t^2 \equiv 0 \pmod 9$, equivalent to $3 \mid t$. The only positions are therefore

$$(5, 5), \qquad (8, 2), \qquad (2, 8).$$

If $\mathcal{A}$ preserves the residue–quotient pair on each sheet,

$$\mathcal{A}(5,5) = ((1,1),(7,2)),$$
$$\mathcal{A}(8,2) = \mathcal{A}(2,8) = ((1,1),(7,1)).$$

The two vacancies preserve the additive readout and the multiplicative residue; the product quotient decreases by exactly one unit. The mirror $t \mapsto -t$ exchanges their positions. The residual value does not distinguish their routes, whereas orientation does preserve them. This is a precise realization of the connection indicated in the note: **a vacancy is individualized by a relation to the center and by a recorded defect, not by being a cell without information**.

The initial electronic orientation $(h_0, v_0) = (1,1)$, reversed every 27 steps, subsequently publishes the dodecaphase signature $(+++\ ---\ +++\ --)$. This is an orientation record, distinct both from the position $(5,5)$ and from the following product signature.

The signature 555555 and the memory enabling its prolongation

For $U_j = 100d_{1j} + 10d_{2j} + d_{3j}$, the readout

$$\mathcal{E}_\times(U) = ([d_{2j} - d_{1j}]_{10})_{j=1}^{6}$$

applied to the transverse region

$$U_\pi^\perp = (501, 614, 498, 169, 272, 272)$$

produces 555555; its reduction $\Psi(U) = (-U_j \bmod 3)_j$ produces 010211. The signature has twenty-four product representatives. Transport separates them into three sheets of eight: after advancement, 555177, 555717, and 555771 appear. The congruence stable under advancement and half-turn refines the twenty-six signatures into twenty-eight classes, with histogram $27 \cdot 8 + 108 = 324$. This expresses why sheet memory must be retained to continue a signature that initially coincides.

Definition 8.64 (Signature readout and transport of representatives)**.** Let $\mathcal{X}_\times = D_9^2 \times \{N, E, S, O\}$, of cardinality 324. Advancement P moves one cell in the stored direction, and the half-turn H reverses that direction. The readout uses

$$\ell_9(1,2,4,8,7,5) = (0,1,2,3,4,5), \qquad \ell_9(3) = \ell_9(6) = \ell_9(9) = 0.$$

In each of six windows of nine steps, $\ell_9(\rho_9(ij))$ is evaluated before the product advancement selected by TRIT at times $2, 5, 8 \pmod 9$. The sum in each window is reduced modulo 10. After steps 27 and 54, the direction is reversed. The rule determines $E_{\mathrm{sig}}(x)$ from the position and direction of x, with the kernel's time conventions.

Proposition 8.65 (Minimal stable refinement of the signature)**.** *Starting from equivalence by signature $\sim_0$, the iteration*

$$x \sim_{n+1} y \iff x \sim_n y, \quad Px \sim_n Py, \quad Hx \sim_n Hy$$

terminates and produces the coarsest stable congruence refining the signature. On the preceding domain the census is $26 \to 28 \to 28$*; the fiber of* 555555 *separates into three classes of eight representatives.*

Proof. At each step, a partition of a finite set is refined. The process stabilizes after finitely many splittings. At the fixed point, equivalence is preserved under P and H. If a stable congruence refines $\sim_0$, it refines each $\sim_n$ by induction: its images under both operators remain equivalent. It therefore refines the fixed point obtained, proving its minimality in added information.

The finite enumeration applies the definition to the 81 positions and the four orientations. Their six sums modulo 10 are grouped first, and then the triple consisting of the class of x, that of Px, and that of

Hx, until stabilization. The resulting histogram is $27 \cdot 8 + 108 = 324$, and the only signature splitting is the one indicated. The following representatives make the three images explicit:

x	$E_{\mathrm{sig}}(x)$	$E_{\mathrm{sig}}(Px)$
$(3, 5, N)$	555555	555177
$(3, 4, N)$	555555	555717
$(3, 4, S)$	555555	555771

The complete rule and its executable enumeration are preserved in the reproduction package; the witnesses in the table also show that preserving only the signature does not make its continuation unique. □

The conclusion describes the minimal information of transport, not a new mass. The additive factor preserves eighteen representatives per signature (nine compatible positions and two orientations). Combining it with the product fibers of sizes 24 and 8 gives, respectively, 432 and 144. Regional incidence and sheet memory thus preserve distinct functions within the same catalog.

The link to the electronic equation passes through the regions. The transverse region has multiplicity $432 = 18 \cdot 24$; each of the other four has $144 = 18 \cdot 8$. Their five identities are inserted, in the declared gauge of Article I, into

$$\mathcal{K}_e = \mathbb{Z}/9\mathbb{Z} \times \mathbb{F}_3$$

through $(4, 0), (5, 0), (6, 0), (6, 1), (6, 2)$. Once this insertion has been fixed, its complement has $27 - 5 = 22$ positions and its three sheets per region have $5 \cdot 3 = 15$ positions. The oriented deficit and torsional memory are -22 and 15. The proof of these counts follows from the preceding explicit injection: its five images are distinct; this development brings it together, rather than selecting its positions from a target mass.

There are therefore two linked progressions in the composition: **center → conjugate vacancies → orientation**, and **regional signature → transport sheets → incidence of the five regions → electronic coefficients**. Simply identifying $(5, 5)$ with 555555 would erase precisely the operations explaining their relation.

8.11.6 Nonadic mirror, capacity, and return with memory

On the regional fiber, the mirror acts by

$$\mathfrak{c}(u^\pi, u^e, u^\varphi) = (u^e, u^\pi, u^\varphi).$$

It preserves $s = u^\pi + u^e$ and reverses $d = u^\pi - u^e$. In $\mathbb{F}_3$,

$$u^\pi = 2(s + d), \qquad u^e = 2(s - d).$$

The sum preserves the aggregate; the oriented difference preserves its distribution. The axis u^φ remains fixed under this involution, although it may evolve under transport. The regional mirror and the cellular mirror of the vacancies have different domains: their respective formulas make it possible to track what each preserves.

The capacity vacancy adds an explicit temporal link. In the normalization of refinement 729 versus 1000, let $\rho_c = \log_{10} 9$, $\delta = 1 - \rho_c$, and $C_t = \lfloor (t + 1)\rho_c \rfloor$. If

$$z_t = \lfloor (t + 1)\delta \rfloor - \lfloor t\delta \rfloor,$$

then, for $t \geq 1$,

$$C_t - C_{t-1} = 1 - z_t, \qquad C_b - C_a + \sum_{t=a+1}^{b} z_t = b - a.$$

Proof. The irrationality of $\log_{10} 9$ follows from the impossibility of $9^n = 10^m$ for positive integers. Hence, $C_t = t - \lfloor (t+1)\delta \rfloor$. Subtraction and telescoping summation give both identities. □

A vacancy retains capacity while the history advances.

If $p_j = \lfloor j/\delta \rfloor$, $v_j = p_j - j$, and $h_j = p_{j+1} - p_j$, the inherited development establishes $h_j \in \{21, 22\}$. For $s_j = 22 - h_j$,

$$[v_{j+1}]_3 = [v_j - s_j]_3, \qquad \tau_j = M_{\mathrm{ph}}(1 + [v_j]_9).$$

Vacancies thus act on the retained phase read by the tritic selector. This capacity sequence does not automatically become the electron's cellular trajectory: the manuscript preserves their respective mechanisms and their composition within the same kernel.

8.11.7 Vacancies of nonadic refinement and hierarchy of returns

The APP–TRIT–TPK prolongation preserves, alongside the published block, the cylinder, orientation and history that allow it to be continued. In its capacity reading, two cardinalities already determined by that construction are compared: the $3^6 = 729$ possibilities of a ternary block of six positions and the $10^3 = 1000$ positions of its three-digit decimal chart. This comparison produces its own calendar. Some transitions increase the capacity index; others incorporate a block into the history while maintaining that index. The latter are the *capacity vacancies* studied below.

The object considered is, therefore, a publication of the joint refinement. Its definition preserves its origin in the two finite supports; the logarithmic expression makes it possible to prove the properties of its calendar. Block time, the vacancy index and the capacity index will be written separately. This separation makes clear why the returns 21/22 and 6/7 belong to successive scales of the same construction.

8.11.7.1 Decimal capacity and preservation of the increment

Definition 8.66 (Capacity index and vacancy)**.** At phase origin 0, define

$$\rho = \log_{1000} 729 = \log_{10} 9, \qquad \delta = 1 - \rho = \log_{10}(10/9), \tag{8.23}$$

and, for $t \in \mathbb{Z}_{\geq 0}$,

$$C_t = \lfloor (t+1)\rho \rfloor, \qquad z_t = \lfloor (t+1)\delta \rfloor - \lfloor t\delta \rfloor. \tag{8.24}$$

The integer C_t is the decimal capacity index of the readout; $z_t = 1$ marks a vacancy. The letter K remains reserved for the dodecaphasic register and does not denote a capacity counter here.

We have $0 < \delta < 1$. Moreover, δ is irrational: if $\rho = a/b$ were rational, with a, b positive integers, the equality $9^b = 10^a$ would have zero valuation at the prime 5 on the left and positive valuation on the right. This contradiction proves the irrationality of ρ and of $1 - \rho$. In particular, no positive integer multiple of δ belongs to $\mathbb{Z}$, which fixes the endpoints of the intervals in this development unambiguously.

Proposition 8.67 (Exact capacity–vacancy balance)**.** *For $t \geq 1$, $z_t \in \{0, 1\}$ and*

$$C_t - C_{t-1} = 1 - z_t. \tag{8.25}$$

Consequently, for $0 \leq a < b$,

$$C_b - C_a + \sum_{t=a+1}^{b} z_t = b - a. \tag{8.26}$$

Proof. Since $0 < \delta < 1$, the difference between the floors of two numbers separated by δ is 0 or 1. Furthermore, the established irrationality gives

$$C_t = t + 1 - \lceil (t+1)\delta \rceil = t - \lfloor (t+1)\delta \rfloor.$$

Subtracting this equality at t and $t-1$ proves (8.25); telescopic summation proves (8.26). □

Each transition contributes exactly one unit to the right-hand side of the balance. That unit is recorded as acquired capacity when $z_t = 0$, or as a vacancy when $z_t = 1$. Retention of the index C_t therefore leaves a recoverable position in the history. The equation expresses preservation of the increment through two readouts, rather than an indeterminate loss of information.

The density also follows from the same balance:

$$\frac{1}{N}\sum_{t=1}^{N} z_t = \frac{\lfloor (N+1)\delta \rfloor}{N} \longrightarrow \delta.$$

Thus (z_t) is not eventually periodic: an eventually periodic binary sequence has rational density. Here aperiodicity follows from the capacity rule already fixed by 729/1000.

8.11.7.2 Exact determination of the intervals 21/22

Lemma 8.68 (Rational bounds for the slope)**.** *The vacancy density satisfies*

$$\frac{7}{153} < \delta < \frac{6}{131}. \tag{8.27}$$

If $\lambda = \delta^{-1}$, $\beta = 22 - \lambda$, and $\mu = \beta^{-1}$, then

$$21 < \lambda < 22, \qquad \frac{1}{7} < \beta < \frac{1}{6}, \qquad 6 < \mu < 7. \tag{8.28}$$

Proof. We provide a finite verification by rational arithmetic. For $0 < u < 1$, let

$$S_N(u) = 2\sum_{k=0}^{N} \frac{u^{2k+1}}{2k+1}, \qquad R_N(u) = \frac{2u^{2N+3}}{(2N+3)(1-u^2)}.$$

Integrating the geometric series for $2/(1-u^2)$ gives

$$S_N(u) < \log\frac{1+u}{1-u} < S_N(u) + R_N(u).$$

Indeed, the tail is positive and, on replacing each denominator $2k+1$ by $2N+3$, is bounded by the geometric series defining R_N. These inequalities are applied to $u = 1/19, 1/3, 1/9$, corresponding respectively to $\log(10/9), \log 2, \log(5/4)$, and we use $\log 10 = 3\log 2 + \log(5/4)$.

With $N = 4$, writing $A = S_4(1/19)$, $B = 3S_4(1/3) + S_4(1/9)$, and $E = 3R_4(1/3) + R_4(1/9)$, we obtain

$$\frac{7}{153} < \frac{A}{B+E} < \delta < \frac{A + R_4(1/19)}{B} < \frac{6}{131}.$$

The two outer inequalities are checked by multiplying through by the positive denominators of these sums of five rational terms. This proves (8.27) using a remainder bound, without taking a decimal expansion as a premise. Inverting the bound gives $131/6 < \lambda < 153/7$. Subtracting from 22 and then inverting yields all the inequalities in (8.28). □

Theorem 8.69 (Positions and gaps of the vacancies)**.** *The positions of the events $z_t = 1$, ordered from the first event, are exactly*

$$p_j = \lfloor j\lambda \rfloor = \left\lfloor \frac{j}{\delta} \right\rfloor, \qquad j \geq 1. \tag{8.29}$$

Their gaps satisfy

$$h_j = p_{j+1} - p_j \in \{21, 22\}. \tag{8.30}$$

Both values occur infinitely often.

Proof. The event crossing the integer j occurs precisely when $t\delta < j < (t+1)\delta$. Irrationality excludes equality at the endpoints. Dividing by δ gives $t = \lfloor j/\delta \rfloor = p_j$. Since $\delta < 1$, a step crosses at most one integer, so the enumeration is exact. Writing $\lambda = 21 + \eta$, with $0 < \eta < 1$, gives

$$h_j = 21 + \lfloor (j+1)\eta \rfloor - \lfloor j\eta \rfloor,$$

which proves (8.30). Finally, $(p_{J+1} - p_1)/J \to \lambda \in (21, 22)$. If either value occurred only finitely often, this mean would converge to the other integer value, a contradiction. □

8.11.7.3 Induction on the short intervals: the returns 6/7

Theorem 8.70 (Induced schedule of short intervals)**.** *Let $s_j = 22 - h_j$, for $j \geq 1$. This indicator equals* 1 *exactly when the interval between vacancies is short, of length* 21*. With β and μ as defined in Lemma 8.68,*

$$s_j = \lfloor (j+1)\beta \rfloor - \lfloor j\beta \rfloor. \tag{8.31}$$

The indices of the short intervals are

$$q_m = \lfloor m\mu \rfloor = \lfloor m/\beta \rfloor, \qquad q_{m+1} - q_m \in \{6, 7\}, \quad m \geq 1. \tag{8.32}$$

Both gaps occur infinitely often, and their order is not eventually periodic.

Proof. The irrationality of δ implies that of λ, β, and μ. Since $\lambda = 22 - \beta$, for $j \geq 1$ we have

$$p_j = 22j - \lceil j\beta \rceil = 22j - \lfloor j\beta \rfloor - 1.$$

Subtracting consecutive terms gives (8.31). Applying the integer-crossing argument of the preceding theorem to the indicator of slope β shows that its event m occurs at $q_m = \lfloor m/\beta \rfloor$. The inequality $6 < \mu < 7$ proves the two possible gaps. Their mean converges to μ; hence both occur infinitely often. Moreover, an eventually periodic sequence of gaps would have rational mean, whereas μ is irrational. This also rules out strict alternation, whose mean would be $13/2$. □

Here the numbers 6 and 7 count *intervals between vacancy events*, not refinement blocks. The return to the primary scale is equally explicit. Between q_m and q_{m+1} there is a single short interval, located at the beginning, and all the others are long. Consequently, if $d_m = q_{m+1} - q_m$,

$$p_{q_{m+1}} - p_{q_m} = 21 + 22(d_m - 1) = 22d_m - 1 \in \{131, 153\}. \tag{8.33}$$

Thus $131 = 14 \cdot 9 + 5$ and $153 = 17 \cdot 9$ describe two return readouts *in the block clock*. The equation preserves the operation connecting the scales, rather than identifying their cardinalities merely because they occur.

8.11.7.4 Retained capacity and selection of the TRIT regime

Let $v_j = C_{p_j}$ be the capacity recorded at vacancy j. From $p_j\delta < j < (p_j+1)\delta$ and $\delta < 1$, it follows that $\lfloor (p_j+1)\delta \rfloor = j$. By (8.24),

$$v_j = p_j - j, \qquad v_{j+1} - v_j = h_j - 1 = 21 - s_j, \qquad [v_{j+1}]_3 = [v_j - s_j]_3. \tag{8.34}$$

A long interval preserves the class modulo 3; a short interval shifts it by one unit in the negative direction. Applying the selector of the formal kernel to the positive phase $r_j = 1 + [v_j]_9$ gives

$$\tau_j = M_{\mathrm{ph}}(r_j), \qquad M_{\mathrm{ph}}(r) = \begin{cases} +1, & r \in \{1,4,7\}, \\ -1, & r \in \{2,5,8\}, \\ 0, & r \in \{3,6,9\}. \end{cases} \tag{8.35}$$

This composition fixes the regime induced by capacity at each event. It preserves both the order of the changes and the number of events for which each regime persists.

Corollary 8.71 (Plateaus of the induced regime)**.** *For every $m \geq 1$, the class $[v_j]_3$, and hence τ_j, is constant on $q_m + 1 \leq j \leq q_{m+1}$. The length of each complete plateau is $q_{m+1} - q_m \in \{6, 7\}$.*

Proof. On the indicated integer interval, the next change occurs exactly when passing from $j = q_{m+1}$ to $j = q_{m+1} + 1$: this is the next position at which $s_j = 1$. At all preceding steps $s_j = 0$, so (8.34) preserves the class. At the endpoint it decreases the class by one unit. The selector (8.35) assigns distinct values to the three classes; it therefore preserves the same plateaus and their endpoints. □

The initial segment $1 \leq j \leq q_1$ depends on the chosen origin and is an initial restriction of a plateau. At the present origin it has length $q_1 = 6$. The first twenty classes are

$$\underbrace{2, \ldots, 2}_{6}, \qquad \underbrace{1, \ldots, 1}_{7}, \qquad \underbrace{0, \ldots, 0}_{7},$$

with signatures $0, -1, +1$, respectively. Each short interval triggers the next step of the cycle of regimes.

The two phases of interest are defined as

$$g_t^{\mathrm{cron}} = [t]_9, \qquad g_t^{\mathrm{cap}} = [C_t]_9, \qquad g_t^{\mathrm{cap}} - g_{t-1}^{\mathrm{cap}} \equiv 1 - z_t \pmod 9.$$

A vacancy retains the capacity phase while block time advances. The transition of the enriched state remains the TPK composition of selection, transport, and memory update. Thus $C_t = C_{t-1}$ neither resets the state nor replaces the holonomic winding Γ_9 by a pause. The two induced scales likewise retain this distinction: between consecutive short events in (8.33), the capacity increment is $21d_m - 1$, that is, 125 or 146, whereas the block increment is 131 or 153.

8.11.7.5 Rationally certified sample and provenance

The table presents a sample at the canonical origin. h_j is the gap *following* p_j; thus vacancy $j = 6$, at block 131, begins the first short interval.

j	1	2	3	4	5	6	7	8	9	10
p_j	21	43	65	87	109	131	152	174	196	218
h_j	22	22	22	22	22	21	22	22	22	22
v_j	20	41	62	83	104	125	145	166	187	208
$[v_j]_3$	2	2	2	2	2	2	1	1	1	1

The first short-interval indices and their gaps are

$$(q_m)_{m=1}^{10} = (6, 13, 20, 27, 34, 41, 48, 54, 61, 68),$$

$$(q_{m+1} - q_m)_{m=1}^{9} = (7, 7, 7, 7, 7, 7, 6, 7, 7).$$

The sample exhibits the actual order, while the preceding proofs establish its law at arbitrary depth.

The attached file `ampliacion/verificar_vacancias.py` computes rational brackets using the series and remainders of Lemma 8.68. Each floor is accepted only when both endpoints of the bracket yield the same integer. At order 16, it reproduces 512 events up to block 11189, and 64 secondary gaps, together with the balance identities, residues, and plateaus. This finite check retains a scope distinct from that of the universal theorems.

The capacity index, its complementarity with vacancies, and induction of the TRIT selector are recovered from Article I and from the chapters on the schedule and induced clock in the monograph on aperiodic topological–temporal order. Their definitions and the proofs of both scales are assembled here with a single indexing convention. The rational certificate provides an additional check of those results and preserves their provenance.

8.11.8 Factor 8/81 in the decomposition between reading and complement

In the double-circle development, the uniform inclusion of nine phases is $Jv = (v, \dots, v)/3$. With the seam

$$S_C(v_0, \dots, v_8) = (Cv_8, v_0, \dots, v_7),$$

one obtains $T = J^* S_C J = (8I + C)/9$. If $z = (C - I)v$, the complement of the publication is exactly

$$\eta v = (I - JJ^*) S_C J v = \frac{1}{27}(8z, -z, \dots, -z).$$

Therefore,

$$\|\eta v\|^2 = \frac{64 + 8}{729}\|z\|^2 = \frac{8}{81}\|(C - I)v\|^2.$$

Here appears the $8/81$ mentioned by the author: one transported phase against eight others, with the uniform normalization of nine phases. The result does not depend on which of the nine positions is marked. The complete operator balance is

$$I - T^*T = \frac{8}{81}(I - C)^*(I - C) + \frac{1}{9}(I - C^*C).$$

If C is isometric, the energy omitted by the publication lies exactly in its complement. For an arbitrary seam, its explicit defect is also preserved. The integer $72 = 64 + 8$ counts quadratic weights here; in the local crown it counts a sum of values; in $72/27$ it belongs to an ordered decimal reading. Specifying these types makes it possible to relate the constructions without assuming that a numerical coincidence already provides all the maps between them.

This balance remains that of the double-circle transport development. When applied to the arithmetic form $\mathscr{W}$, it produces a signed identity; proving global positivity requires global control of its terms, not merely recovery of the center or positivity of an auxiliary norm. The results already proved concerning memory, transport, and the coercive window are preserved in full.

8.12 Combinatorial selection and representation transport of the first joint boundary

The first joint boundary receives the blocks already produced by the APP seeds, tritic reduction and TPK lifting calendar. Its construction preserves the distinction between three operations: determining admissible distributions, orienting their two lateral channels and transporting incidence to the exceptional coordinate system. The present account develops these operations on the same finite state. Names of real coordinates designate their subsequent readers; the following selection conditions act on ternary words, transport matrices and integer incidences.

8.12.1 Regional state preceding the boundary

Let $\mathcal{W} \subset \mathbb{F}_3^6$ be the repertoire of 243 visible words obtained from the APP–TRIT–TPK emission census. For a row vector $s \in \mathcal{W}$, define

$$b_0(s) = s, \quad b_1(s) = sL_0, \quad b_2(s) = sL_0^2, \quad b_3(s) = sL_0^2L_1, \quad b_4(s) = sL_0^2L_1^2,$$

with operations in $\mathbb{F}_3$. The matrices previously derived from the regional registers are

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix}.$$

The preceding regional selector yields

$$s_{\mathrm{cl}} = 010211, \qquad s_{\mathrm{pr}} = 201101,$$

through the conditions $b_2(s_{\mathrm{cl}}) = b_0(s_{\mathrm{cl}})$, $b_4(s_{\mathrm{pr}}) = b_2(s_{\mathrm{pr}})$ and $b_1(s_{\mathrm{cl}}) = b_3(s_{\mathrm{pr}})$. At this stage, the current blocks are

$$b_4(s_{\mathrm{cl}}) = 110221, \qquad b_4(s_{\mathrm{pr}}) = 102011.$$

Concatenation preserves the five blocks of each register; vector b_4 is the six-coordinate input received by the boundary relation.

To express the recovered relation faithfully, the incidence matrix is used in its original representation,

$$A^{\mathrm{o}} = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 2 & 2 \\ 1 & 1 & 0 & 2 & 1 & 2 \\ 1 & 1 & 2 & 0 & 2 & 1 \\ 1 & 2 & 1 & 2 & 0 & 1 \\ 1 & 2 & 2 & 1 & 1 & 0 \end{pmatrix}. \tag{8.36}$$

We verify $(A^{\mathrm{o}})^2 = -I$ in $M_6(\mathbb{F}_3)$; therefore, $(A^{\mathrm{o}})^{-1} = -A^{\mathrm{o}}$. This representation, together with its vectors, will later be transported to the one used by the exceptional reader.

8.12.2 Compatibility equation and column saturation

The boundary axis is fixed by $z = b_4(s_{\mathrm{pr}}) = 102011$. For each $s \in \mathcal{W}$, define

$$m(s) = b_4(s)A^{\mathrm{o}}L_1^3, \tag{8.37}$$

$$q(s) = m(s) + z, \tag{8.38}$$

$$\widetilde{q}(s) = s(A^{\mathrm{o}})^{-1}L_0^3(A^{\mathrm{o}})^3. \tag{8.39}$$

The compatibility condition is $q(s) = \widetilde{q}(s)$. The lateral rows $x, y \in \mathbb{F}_3^6$ satisfy $x + y = m(s)$; the ordered boundary is $B = (x, y, z)^{\mathsf{T}}$.

To form remainder and carry, the integer representatives 0, 1, 2 of each trit are used. If $S_j = x_j + y_j + z_j$, require

$$q_j = S_j \bmod 3, \qquad c_j = \frac{S_j - q_j}{3} = 1,$$

and column occupation is given by

$$\mathbf{1}_{\{x_j \neq 0\}} + \mathbf{1}_{\{y_j \neq 0\}} + \mathbf{1}_{\{z_j \neq 0\}} = 2 + \mathbf{1}_{\{z_j \neq 0,\ m_j(s) \neq 2\}}. \tag{8.40}$$

Dual neutrality completes the condition through

$$BA^{\circ}\mathbf{1} = 0 \quad \text{in } \mathbb{F}_3^3. \tag{8.41}$$

Remainder, carry and occupation act jointly: modular reduction preserves the remainder, and the integer register distinguishes the distributions producing it.

Lemma 8.72 (Resolution of regional compatibility)**.** *The equation $q(s) = \widetilde{q}(s)$ has, in $\mathbb{F}_3^6$, the three solutions*

$$020010, \qquad 121200, \qquad 222120.$$

Its intersection with the visible repertoire is $\{121200, 222120\}$.

Proof. The equation is written $sD = z$, where

$$D = (A^{\circ})^{-1} L_0^3 (A^{\circ})^3 - L_0^2 L_1^2 A^{\circ} L_1^3 = \begin{pmatrix} 2 & 1 & 1 & 2 & 2 & 2 \\ 0 & 2 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 2 & 2 & 2 & 2 & 0 \\ 1 & 2 & 2 & 0 & 1 & 2 \\ 1 & 2 & 0 & 2 & 2 & 2 \end{pmatrix}.$$

Elimination over $\mathbb{F}_3$ gives the parametrization

$$s = (t, 2, t, 2t, 1 + 2t, 0), \qquad t \in \mathbb{F}_3.$$

Substitution verifies the six equations and exhausts their solutions. In the generated repertoire $\mathcal{W}$, the two words corresponding to $t = 1, 2$ are present, and the one corresponding to $t = 0$ is absent. This final check is an exact query of the visible-word census, preceding any Archimedean reading. □

Proposition 8.73 (Determination of the self-scaling axis)**.** *Compatibility, unit carry and column occupation select $s_{\mathrm{au}} = 121200$ from the two visible solutions of Lemma 8.72. We obtain*

$$b_4(s_{\mathrm{au}}) = 010200, \qquad m(s_{\mathrm{au}}) = 210112, \qquad q = 012120,$$

with occupation 223232.

Proof. For $s = 222120$, we compute $b_4(s) = 222000$, $m(s) = 201010$ and $q(s) = 000021$. In its third column, $m_3 = 1$ and $z_3 = 2$. The required occupation is three, so x_3, y_3 must both be nonzero. The only pair with $x_3 + y_3 \equiv 1 \pmod 3$ is $(2, 2)$; its integer sum with $z_3 = 2$ is six and produces carry two. This contradicts $c_3 = 1$.

For $s = 121200$, the six columns respectively admit the pairs

j	1	2	3	4	5	6
(x_j, y_j)	$(0,2),(2,0)$	$(2,2)$	$(1,2),(2,1)$	$(2,2)$	$(2,2)$	$(0,2),(2,0)$.

Each pair satisfies the remainder, carry and occupation equations. There are therefore eight arrangements before dual neutrality is applied. □

Theorem 8.74 (Exact enumeration of boundary orientations)**.** *The preceding conditions determine exactly*

$$B_- = \begin{pmatrix} 021222 \\ 222220 \\ 102011 \end{pmatrix}, \qquad B_+ = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}.$$

Both have remainder 012120*, carry* 111111 *and occupation* 223232*.*

Proof. The preceding proof reduces enumeration to eight possibilities. Since $A^{\circ}\mathbf{1} = (2,1,1,1,1,1)^{\mathsf{T}}$, neutrality of a row v is equivalent to $2v_1 + v_2 + \cdots + v_6 = 0$ in $\mathbb{F}_3$. Its evaluation on the eight arrangements is

x	y	$(xA^{\circ}\mathbf{1}, yA^{\circ}\mathbf{1}, zA^{\circ}\mathbf{1})$
021220	222222	$(1,2,0)$
021222	222220	$(0,0,0)$
022220	221222	$(2,1,0)$
022222	221220	$(1,2,0)$
221220	022222	$(2,1,0)$
221222	022220	$(1,2,0)$
222220	021222	$(0,0,0)$
222222	021220	$(2,1,0)$.

The second and seventh rows are the only solutions. The integer column sums of either are $(3,4,5,4,5,3)$, recovering the stated remainder and carry. □

8.12.3 Directed length and boundary orientation

Regional transport defines a directed graph on $\mathbb{F}_3^6$, with edges $v \to vL_0$ and $v \to vL_1$. For mutually reachable vectors u, v, let

$$d(u,v) = \min\{n \geq 0 : \exists \epsilon_1, \ldots, \epsilon_n \in \{0,1\},\ v = uL_{\epsilon_1} \cdots L_{\epsilon_n}\}.$$

This length is a combinatorial datum of transport. Its sum over the three rows preserves the regional labels:

$$\mathcal{L}(B) = d(110221, B_1) + d(102011, B_2) + d(010200, B_3).$$

Proposition 8.75 (Selection by directed length)**.** *We have* $\mathcal{L}(B_-) = 23$ *and* $\mathcal{L}(B_+) = 20$*. On the domain of the two admissible boundaries, the minimum is unique and selects* B_+*.*

Proof. The shortest paths and their lengths are

	origin	target	transport word	d
B_-	110221	021222	01100011	8
	102011	222220	10111111	8
	010200	102011	1010101	7
B_+	110221	222220	1111	4
	102011	021222	001100101	9
	010200	102011	1010101	7.

Each word is verified by successive multiplication of its matrices. To verify minimality as well, form the disjoint layers

$$F_0(u) = \{u\}, \qquad F_{n+1}(u) = \big(F_n(u)L_0 \cup F_n(u)L_1\big) \setminus \bigcup_{j=0}^{n} F_j(u).$$

Induction on n proves that $F_n(u)$ is exactly the set of vertices at distance n: every shortest word of length $n+1$ comes from a shortest word of length n, and quotienting by previous layers eliminates shorter paths. The enumeration obtained with the two matrices displayed above gives

$u\backslash n$	0	1	2	3	4	5	6	7	8	9
110221	1	2	4	8	16	32	60	105	156	177
102011	1	2	3	5	10	20	37	71	119	171
010200	1	2	4	8	15	30	56	100	148	172.

The destinations in the first table occur for the first time in the layers indicated there. This enumeration is finite, uses only products modulo three and agrees with the breadth-first traversal of the executable certificate. Summing the three lengths gives $8+8+7=23$ and $4+9+7=20$. □

Orientation of the APP representation through half-open cylinders previously selects the same matrix B_+ at this boundary. Theorem 8.74 and Proposition 8.75 thus establish agreement of both selections on the concrete set $\{B_-, B_+\}$. The domain of this agreement is the first joint boundary. Coinductive extension preserves its own admissibility, memory, survival and orientation relations at each depth.

8.12.4 Naturality of the exceptional change of representation

The matrix used by the exceptional reader in the active representation is

$$A^{\mathrm{a}} = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}.$$

The coordinate permutation

$$R_p(v_1, v_2, v_3, v_4, v_5, v_6) = (v_1, v_2, v_3, v_5, v_6, v_4)$$

simultaneously transports the word and the incidence matrix.

Theorem 8.76 (Intertwining of boundary incidence)**.** *For every $v \in \mathbb{F}_3^6$,*

$$R_p(vA^{\mathrm{o}}) = R_p(v)A^{\mathrm{a}}.$$

The transformation is invertible and preserves dual neutrality, remainders, carries and occupations expressed in the transported coordinates. In particular, the selected triple has the two representations

	source representation	*exceptional representation*
closure	222220	222202
propagation	021222	021222
self-scaling	102011	102110.

Proof. If $p = (1, 2, 3, 5, 6, 4)$, comparing the entries of both matrices gives $A^{\mathrm{a}}_{ij} = A^{\mathrm{o}}_{p(i),p(j)}$. For coordinate j,

$$\big(R_p(v)A^{\mathrm{a}}\big)_j = \sum_i v_{p(i)} A^{\mathrm{o}}_{p(i),p(j)} = \sum_k v_k A^{\mathrm{o}}_{k,p(j)} = \big(R_p(vA^{\mathrm{o}})\big)_j.$$

The inverse is $R_p^{-1}(w) = (w_1, w_2, w_3, w_6, w_4, w_5)$. Since R_p permutes coordinates, it preserves their sum and transports coordinatewise the integer sums, their remainders modulo three, quotients and numbers of nonzero entries. Preservation of all the stated registers follows. The table is obtained by applying R_p to the three words of B_+, and the inverse recovers their original words exactly. □

The positional reader and incidence reader remain associated with the same enriched state through this explicit change of representation. If ℓ_{pos} is the reader in the original representation, its expression in the transported representation is $\ell_{\mathrm{pos}} \circ R_p^{-1}$. This composition preserves positional order: changing the incidence representation and changing the reader are coordinated operations. The first boundary thus enters extension with its three words, regional orientation, integer carry and exceptional frame recoverable.

Chapter 9

Oriented classification of the closure microfiber of π: 5 regions, multiplicity 432+4·144=1008, φ-axis, and π/e involution

9.1 Construction of the closure character and of the genealogical trajectories of π

9.1.1 Causal separation between seed, character, and evaluation

The construction is divided into three strata:

$$\text{finite selection} \longrightarrow \text{construction of the closure character} \longrightarrow \text{Archimedean evaluation}.$$

The decimal expansion does not intervene in the first stratum. The type chain is

$$104\,976 \longrightarrow 468\,\mathcal{U}_6 \xrightarrow{\Psi} 243\,\mathcal{W}_6 \hookrightarrow \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729. \tag{9.1}$$

The cardinalities count, respectively, enriched initial conditions, distinct emissions, visible ternary words, and elements of the complete ambient fiber.

For $U_6 = (u_1, \dots, u_6)$, the projection is

$$\Psi(U_6) = ((-u_1) \bmod 3, \dots, (-u_6) \bmod 3).$$

The census of the 43 orbits of D_3 proves that the closure orbit is the only one whose six orientations possess at once:

$$\text{five lifts}, \qquad \text{mass } 1008, \qquad 1008 = 432 + 4 \cdot 144.$$

The gauge

$$\mathrm{diag}_c = 6, \qquad \mathrm{card} = ES$$

select a single representative:

$$\boxed{w_6^{\pi} = 010211.} \tag{9.2}$$

The selection usis catalogue, multiplicitiis, orbital action, and orientation; it dois not consult to prefix of π.

9.1.2 Liftings L_0, L_1 and 1st coinductive boundary

On vectors row of $\mathbb{F}_3^6$, let

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix}.$$

If $b_1 = w_6^{\pi}$, the recurrence of blocks is

$$b_{k+1} = b_k L_{\varepsilon_k}, \qquad (\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4) = (0, 0, 1, 1),$$

and the accumulated word is formed by concatenation:

$$w_{6(k+1)} = w_{6k} \parallel b_{k+1}.$$

A word of length $6k$ is not multiplied by a matrix 6×6.

For the closing channel:

depth	new block
6	010211
12	012222
18	010211
24	002111
30	110221

and

$$\boxed{w_{30}^{\pi} = 010211|012222|010211|002111|110221.} \tag{9.3}$$

The following boundary is

$$u_5^{\pi} = 222220.$$

Along with the other channels,

$$R_{36} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}.$$

The symbol R_{36} records the sixth block of three histories and opens a boundary; it is not a terminal.

The certified branch of twenty blocks begins

$$\begin{aligned} \pi : {} & 010211|012222|010211|002111|110221|222220|111201| \\ & 212121|200121|100100|101222|022212|012012|111210| \\ & 121011|200220|120210|000101|022010|020111. \end{aligned}$$

For this reason, ni w_{30} ni R_{36} terminate the genealogy.

9.1.3 Oriented decomposition of the microfiber of π: central region, 4 lateral regions, and multiplicity $432 + 4 \cdot 144 = 1008$

The microfiber

$$\mathscr{R}_{\pi}^{\mathrm{micro}} := \{U \in \mathcal{U}_6 : \Psi(U) = 010211\}$$

contains exactly five regions:

U_6	E_{sig}	mult	role
501|614|498|169|272|272	555555	432	$\perp$
810|923|870|169|272|272	339555	144	++
810|983|810|169|272|272	393555	144	++
870|923|810|169|272|272	933555	144	++
870|923|810|418|674|521	933717	144	−−

Consequently,

$$\boxed{5 = 1_{\perp} + 3_{++} + 1_{--}, \qquad 1008 = 432 + 4 \cdot 144.} \tag{9.4}$$

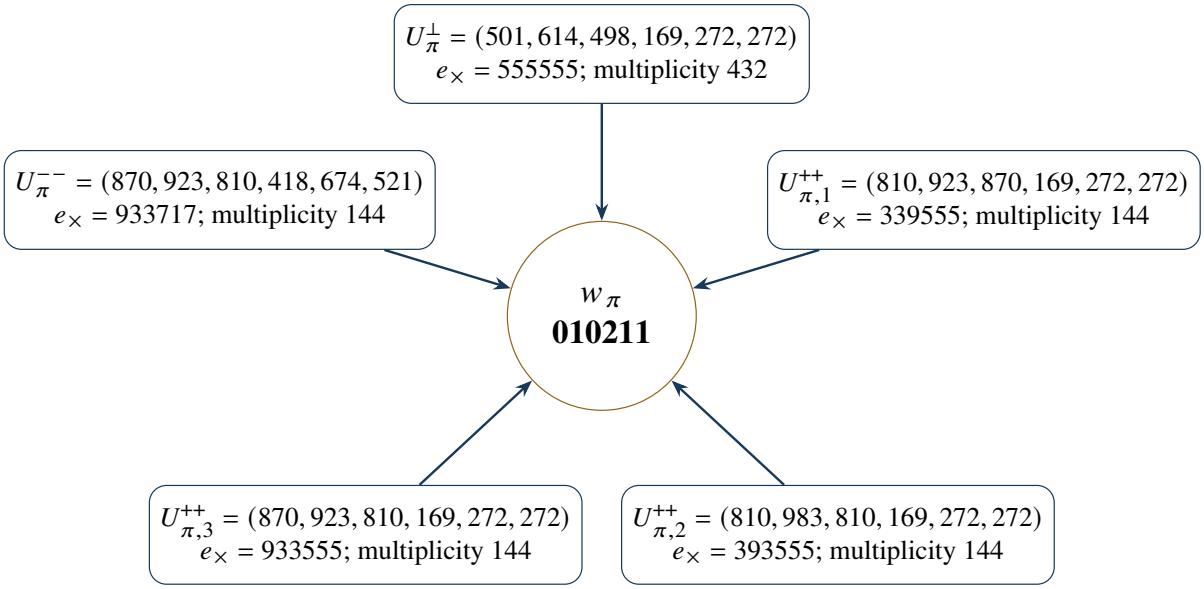
The first identity classifies orientation functions. The second counts provenance multiplicities. They do not count five indistinguishable copies.

The transversal region is

$$501|614|498|169|272|272, \qquad E_{\mathrm{sig}} = 555555, \qquad \mathrm{mult} = 432.$$

The mutated return is

$$870|923|810|418|674|521, \qquad E_{\mathrm{sig}} = 933717, \qquad \mathrm{mult} = 144.$$



Five distinct regions, one shared quotient word.
$432 + 4 \cdot 144 = 1008$ routes; alignment labels: $1_{\perp} + 3_{++} + 1_{--}$.

Figure 9.1: Closure microfiber of π: transver region, 3 regions of positive orientation and mutated return. The 5 provenancis share the same quotient word without losing their genealogy.

Interchanging them would preserve the census $3/1/1$ but falsify the complete regional structure.

9.1.4 Descent of a complete nonadic block to the phase transfer multigraph

For $U_6 = (U_1, \ldots, U_6)$, let

$$A(U_6) = (U_1, U_2, U_3), \qquad B(U_6) = (U_4, U_5, U_6).$$

Each emission defines an edge between $A(U_6)$ and $B(U_6)$. The raw multigraph has 96 vertices, distributed into components of sizes

$$28, 28, 28, 4, 4, 4.$$

The internal phase is quotiented by

$$(a, b, c) \sim (b, c, a) \sim (c, a, b).$$

The representative is the lexicographically minimal rotation. The quotient graph has 32 vertices and two components of sizes 28 and 4.

The anchors are

$$\begin{aligned} U_{\mathrm{APP}} &= 903|850|850|252|109|252, \\ U_e &= 850|963|890|149|252|212, \\ U_{\varphi} &= 830|943|830|109|252|252. \end{aligned}$$

We number the regions

$$U_\pi^{(1)} = 810|923|870|169|272|272,$$
$$U_\pi^{(2)} = 810|983|810|169|272|272,$$
$$U_\pi^{(3)} = 870|923|810|169|272|272,$$
$$U_\pi^{(4)} = 870|923|810|418|674|521,$$
$$U_\pi^{(5)} = 501|614|498|169|272|272.$$

9.1.5 The 5 oriented closure cycles

9.1.5.1 Closure of $U_\pi^{(1)}$

$$252|109|252|903|850|850 \to 903|850|850|252|109|252 \to$$
$$252|109|252|923|870|810 \to 810|923|870|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 252|109|252|903|850|850.$$

9.1.5.2 Closure of $U_\pi^{(2)}$

$$903|850|850|252|109|252 \to 272|169|272|903|850|850 \to$$
$$272|169|272|983|810|810 \to 810|983|810|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

9.1.5.3 Closure of $U_\pi^{(3)}$

$$903|850|850|252|109|252 \to 292|189|232|903|850|850 \to$$
$$292|189|232|923|810|870 \to 870|923|810|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

9.1.5.4 Closure of $U_\pi^{(4)}$

$$903|850|850|252|109|252 \to 272|169|272|903|850|850 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|923|810|870 \to 870|923|810|418|674|521 \to$$
$$943|830|830|521|418|674 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

9.1.5.5 Closure of $U_\pi^{(5)}$

$$252|109|252|903|850|850 \to 903|850|850|252|109|252 \to$$
$$614|498|501|252|109|252 \to 501|614|498|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 252|109|252|903|850|850.$$

Theorem 9.1 (Minimality of the Five Closures)**.** *For each $i \in \{1, \dots, 5\}$, the minimum length of a closed walk that simultaneously traverses*

$$U_\pi^{(i)}, \quad U_e, \quad U_\varphi, \quad U_{\mathrm{APP}}$$

in the quotient multigraph is eight.

Proof. Given i, let

$$E_* = \{U_\pi^{(i)}, U_e, U_\varphi, U_{\mathrm{APP}}\}.$$

The finite space is considered.

$$\mathcal{S}_i = \{(v, M) : v \in V(G),\ M \subseteq E_*\}.$$

The first component records the vertex and the second the target edges already traversed. If an edge e takes v to v', the transition is

$$(v, M) \longmapsto \big(v', M \cup (E_* \cap \{e\})\big).$$

Breadth-first search enumerates lengths in increasing order. The first return to (v, E_*) occurs at length eight for all five regions. The printed walks attain the bound; the optimality of the search excludes a shorter length. □

The closure function is encoded by

$$\mathfrak{C}_\pi = \big(\mathscr{R}_\pi^{\mathrm{micro}}, w_\pi, \rho_\pi, m_\pi, \ell_{\mathrm{cl}}\big),$$

$$\rho_\pi = (\perp, ++, ++, ++, --), \qquad m_\pi = (432, 144, 144, 144, 144), \qquad \ell_{\mathrm{cl}} = 8.$$

9.1.6 Oriented holonomies of the closure of the 5 regions of π

The incidence shadow is

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}.$$

Multiplication in $\mathbb{F}_3$ gives

$$\boxed{A_W^2 = 2I_6 = -I_6.} \tag{9.5}$$

Products between distinct rows and columns vanish modulo three, whereas each diagonal product equals two. One application effects a ternary quarter-turn; two applications effect the oriented inversion.

9.1.7 Determination of the slope 1/5 via the balance of the 5 oriented regions

Let

$$\lambda = (\lambda_1, \dots, \lambda_5)^{\mathsf{T}} \in \mathbb{Q}_{\geq 0}^5, \qquad \mathbf{1}^{\mathsf{T}}\lambda = 1.$$

Forgetting the regional label applies the symmetrizer

$$P_5 = \frac{1}{5}\mathbf{1}\mathbf{1}^{\mathsf{T}}.$$

For every normalized vector,

$$P_5\lambda = \frac{1}{5}\mathbf{1}.$$

The invariance $P_5\lambda = \lambda$ therefore has a unique solution:

$$\boxed{\lambda = \frac{1}{5}\mathbf{1}, \qquad t_1 = \frac{1}{5}.} \tag{9.6}$$

The integer five comes from the regional microfiber; it is not recognized in a formula for π.

9.1.8 Determination of the slope 1/5 by the multiplicity of the regional microfiber of π

The law of slope composition is

$$t \star s := \frac{t+s}{1-ts}.$$

The first duplication gives

$$t_2 = t_1 \star t_1 = \frac{2/5}{1-1/25} = \frac{5}{12}.$$

The second gives

$$t_4 = t_2 \star t_2 = \frac{10/12}{1-25/144} = \frac{120}{119}.$$

The return to the unit diagonal requires $q > 0$ such that

$$\frac{120/119 - 1/q}{1 + (120/119)/q} = 1.$$

Multiplying by $119q$ produces

$$120q - 119 = 119q + 120,$$

and forces

$$\boxed{q = 239.} \tag{9.7}$$

9.1.9 Gaussian identity and 1st half-turn

We define

$$\Theta_\pi := 16 \arctan \frac{1}{5} - 4 \arctan \frac{1}{239}. \tag{9.8}$$

The successive squares are

power	Gaussian integer
$(5+i)^2$	24+10i
$(5+i)^4$	476+480i
$(5+i)^8$	−3824+456960i
$(5+i)^{16}$	−208797818624−3494830080i
$(239-i)^2$	57120−478i
$(239-i)^4$	3262465916−54606720i

and the final multiplication gives

$$\boxed{(5+i)^{16}(239-i)^4 = -681386607803576157184.} \tag{9.9}$$

The imaginary part is zero and the real part is negative. Therefore,

$$\Theta_\pi \equiv \pi \pmod{2\pi}.$$

Para $0 < x < 1$,

$$x - \frac{x^3}{3} < \arctan x < x.$$

From here

$$\Theta_\pi > 16\left(\frac{1}{5} - \frac{1}{3\cdot 5^3}\right) - \frac{4}{239} > 3$$

and

$$\Theta_\pi < \frac{16}{5} < 4.$$

The only negative orientation in that interval is the first positive half-turn:

$$\boxed{\Theta_\pi = \pi.} \tag{9.10}$$

The causal order is

$$\text{five regions} \to \frac{1}{5} \to \frac{5}{12} \to \frac{120}{119} \to 239 \to \Theta_\pi \to \pi.$$

9.1.10 Arbitrary precision rational horocycles

For $0 < x < 1$, let

$$S_n(x) = \sum_{r=0}^{n} (-1)^r \frac{x^{2r+1}}{2r+1}.$$

Leibniz's criterion gives

$$S_{2m+1}(x) < \arctan x < S_{2m}(x).$$

We define

$$a_m^- = S_{2m+1}(1/5), \quad a_m^+ = S_{2m}(1/5),$$
$$b_m^- = S_{2m+1}(1/239), \quad b_m^+ = S_{2m}(1/239),$$

and

$$\ell_{\pi,m} = 16a_m^- - 4b_m^+, \qquad h_{\pi,m} = 16a_m^+ - 4b_m^-. \tag{9.11}$$

Then

$$\ell_{\pi,m} < \pi < h_{\pi,m}$$

and

$$h_{\pi,m} - \ell_{\pi,m} = \frac{16}{(4m+3)5^{4m+3}} + \frac{4}{(4m+3)239^{4m+3}} \longrightarrow 0. \tag{9.12}$$

The lower bounds grow and the upper bounds decrease.

Since $3 < \pi < 4$, the ternary reader acts on

$$r_\pi := \pi - 3 \in (0,1),$$

with bracket

$$[\ell_{\pi,m} - 3, h_{\pi,m} - 3].$$

9.1.11 Production by Ext and subsequent rational certification in the ambient fiber

Suppose that Ext has constructed, through the graded transport of the TPK on the enriched state, a ternary prefix of length $L_K = 6K$, represented by N_K. The same prolongation law first produces the unique surviving extension N_{K+1}, preserving sheet, route, residue, quotient, carry, boundary and memory. The 729 subcylinders of the ambient fiber in which that output is published are

$$I_{K,u} = \left[\frac{729N_K + u}{3^{L_K+6}}, \frac{729N_K + u + 1}{3^{L_K+6}}\right), \qquad 0 \le u < 729.$$

Once N_{K+1} has been produced, the order $m = m(K)$ is increased until the rational bracket is contained in a single subcylinder and thus certifies, a posteriori, the coordinate already published by Ext. Let

$$\ell_{\pi,K} := \ell_{\pi,m(K)} - 3, \qquad h_{\pi,K} := h_{\pi,m(K)} - 3.$$

The compatible integer endpoints are

$$j_{\min} = \max\Big(729N_K, \lfloor \ell_{\pi,K} 3^{L_K+6} \rfloor\Big),$$

$$j_{\max} = \min\Big(729N_K + 728, \lceil h_{\pi,K} 3^{L_K+6} \rceil - 1\Big).$$

The unitary certification condition is

$$\boxed{j_{\min} = j_{\max}, \qquad N_{K+1} = j_{\min}.} \tag{9.13}$$

The equality expresses the exhaustive sweep of the ambient fiber and recognizes the numerical subcylinder containing the previously produced extension. In particular, $N_{K+1} = j_{\min}$ is verified here as a certification identity: it does not define N_{K+1}, select its block or feed the generator. The existence and uniqueness of the extension belong to the transport Ext of the enriched state; the bracket and the fiber of 729 elements subsequently certify its Archimedean location.

9.1.12 Filtration of $\mathbf{F}_3{}^6$ by regional admissibility and selection of compatible subcylinders

Let $\mathcal{H}_m^\pi$ be the set of enriched histories at depth m, and let

$$p_{n,m} : \mathcal{H}_n^\pi \longrightarrow \mathcal{H}_m^\pi$$

the truncation. We define

$$\mathrm{Surv}_m^{(N),\pi} := p_{N,m}(\mathcal{H}_N^\pi),$$
$$\mathrm{Surv}_m^\pi := \bigcap_{N \geq m} \mathrm{Surv}_m^{(N),\pi}.$$

When the relation Ext is nonempty, single-valued and compatible at every level, the sets are singletons and satisfy

$$p_{m+1,m}(\mathrm{Surv}_{m+1}^\pi) = \mathrm{Surv}_m^\pi.$$

In that domain of extendability, there exists, therefore, a unique section.

$$x_\pi \in X_\pi := \varprojlim_m \mathrm{Surv}_m^\pi.$$

The cylinders are nested and their diameters are 3^{-6K}, which tends to zero. Their intersection contains a unique point, identified by the angular character with $r_\pi = \pi - 3$.

For every decimal depth M, one may choose a level $K(M)$ whose cylinder lies within a single decimal cell of diameter 10^{-M}. The deep prefixes truncate exactly to the preceding ones.

9.1.13 Characterization of the coinductive channel of π: selection of w_6^π, 5 regions, oriented inversion, and uniqueness of the limit section

Theorem 9.2 (Characterization of the closure channel)**.** *Starting from the catalog, the action D_3, the oriented gauge, the operators L_0, L_1, A_W, the slope law and the rational filtration:*

1. $w_6^\pi = 010211$ *is selected;*
2. *five regions are constructed with the identities of* (9.4)*;*

3. *each region belongs to a minimum closure of length eight;*
4. $A_W^2 = -I_6$ *fixes the oriented inversion;*
5. *regional symmetrization forces* $1/5$*;*
6. *the composition forces* $120/119$*;*
7. *the unit return forces* 239*;*
8. *the Gaussian identity recognizes the first half-turn;*
9. Ext*, through the graded transport of the TPK, produces the compatible section at arbitrary depth, while the brackets and the fiber of* 729 *elements subsequently certify, at each finite depth, the block already produced.*

Its evaluation is

$$\boxed{\pi = 16 \arctan \frac{1}{5} - 4 \arctan \frac{1}{239}.}$$

The complete chain is

$$\mathrm{APP} \to \mathrm{TRIT} \to \mathrm{TPK} \to 104\,976 \to 468 \to 243 \to w_6^{\pi} \to w_{30}^{\pi} \to R_{36} \to \Gamma_9 \to X_{\pi} \to \pi.$$

Comparison Criterion 9.3 (Channel Closure Falsification)**.** The derivation is refuted if:

1. the closure orbit ceases to be unique;
2. one of the five regions disappears or its complete identity changes;
3. one of the five closures has length less than eight;
4. $A_W^2 \neq 2I_6$;
5. the symmetrizer admits another normalized distribution;
6. the compositions do not produce $5/12$, $120/119$, and 239;
7. the Gaussian identity fails;
8. a bracket ceases to contain the angular character;
9. a level does not traverse the 729 elements of the ambient fiber or does not locate exactly one extension;
10. a target expansion intervenes before recognition.

Chapter 10

Coinductive Generation of π, e and φ via Compatible Nonadic Refinement

The complete construction of the closure character, the five regions, and the structural biography of π was established in chapter 9. Starting from that same already constructed character, the present chapter now prolongs the refinement toward e and φ, without restarting the genealogy or repeating its first stage.

10.1 Propagation, memory return and construction of the exponential character

10.1.1 Finite orbital selector: existence and uniqueness of compatible emission

Let $\mathcal{W} = \mathbb{F}_3^6$. For an emission $U = (u_1, \dots, u_6)$, the visible word is

$$\Psi(U) = ((-u_1) \bmod 3, \dots, (-u_6) \bmod 3).$$

On $\mathcal{W}$, the dihedral action is given by

$$r(u_1, u_2, u_3, u_4, u_5, u_6) = (u_3, u_1, u_2, u_5, u_6, u_4),$$
$$s(u_1, u_2, u_3, u_4, u_5, u_6) = (u_4, u_5, u_6, u_1, u_2, u_3).$$

For $w \in \mathcal{W}$, define

$$n(w) = \#\Psi^{-1}(w), \qquad M(w) = \sum_{U \in \Psi^{-1}(w)} \mathrm{mult}(U),$$

and

$$\nu(w) = \big(\#\{j : w_j = 0\}, \#\{j : w_j = 1\}, \#\{j : w_j = 2\}\big).$$

Theorem 10.1 (Structural selection of the exponential channel)**.** *Among the* 43 *orbits of the visible catalog, there is a unique orbit whose fibers simultaneously satisfy:*

$$n(w) = 1, \qquad M(w) = 144, \qquad \mathfrak{D}(w) = \{0, 3, 6\}, \qquad \nu(w) = (2, 3, 1).$$

The gauge

$$\mathrm{diag}_c = 6, \qquad \mathrm{card} = ES$$

select in it

$$\boxed{w_6^e = 201101.}$$

Proof. The four conditions are evaluated over the 243 words in the catalog, not over a sample. A single orbit satisfies the joint predicate. In that orbit, exactly one emission has both diagonal 6 and orientation ES. The enumeration uses only fields from the APP–TRIT catalog and does not consult an expansion of e. □

10.1.2 Coinductive prolongation of the exponential emission via compatible blocks

The recurrence L_0, L_0, L_1, L_1 produces

$$w_{30}^e = 201101|121221|102011|012222|102011,$$

and the joint boundary contributes

$$u_5^e = 021222.$$

The record of thirty-six trits remains

$$w_{36}^{e} = 201101|121221|102011|012222|102011|021222.$$

10.1.3 Construction of the decimal signature via the ternary–decimal positional square

The initial reading of twelve digits is

$$\mathbf{d}_{e}^{(12)} = 718281828459 = 7\ \underbrace{1828\,1828}_{\text{local square}}\ 459.$$

The central equality is the concatenation

$$1828 \parallel 1828,$$

not an arithmetic product nor the supposed beginning of a period.

Definition 10.2 (Positional square)**.** A word $d_1 \cdots d_{12}$ contains a square of length ℓ at position p when

$$d_p \cdots d_{p+\ell-1} = d_{p+\ell} \cdots d_{p+2\ell-1}.$$

The position and the lateral contexts belong to the signature.

Table 10.1: Comprehensive census of squares in twelve-digit readings.

Length ℓ	1	2	3	4	5	6
Occurrences	240	21	3	2	0	0
Words that contain them	153	19	3	2	0	0

The other word with a square of length four is

$$575157518472 = \underbrace{5751\,5751}_{\text{initial position 1}}\ 8472.$$

Proposition 10.3 (Positional uniqueness)**.** *The reading of channel e is the only one that has a square of length four after a prefix of length one and with contexts* 7 *and* 459*.*

Proof. The census leaves only two words with squares of length four. One starts it at the first position; the other after the prefix 7. The position and contexts separate the two possibilities. □

10.1.4 Phase return with non-trivial memory state update

In the elevation

$$201101|121221|102011|012222|102011$$

the third and the fifth blocks coincide:

$$B_3 = B_5 = 102011.$$

Their prestates modulo 27 are, however,

$$p_3 = (25, 11, 7, 17, 8, 16), \qquad p_5 = (7, 8, 4, 23, 26, 7),$$

and the subsequent quotients:

$$q_3 = (6, 13, 9, 2, 13, 1), \qquad q_5 = (15, 0, 3, 19, 23, 25).$$

$p_3 \neq p_5$ and $q_3 \neq q_5$ hold.

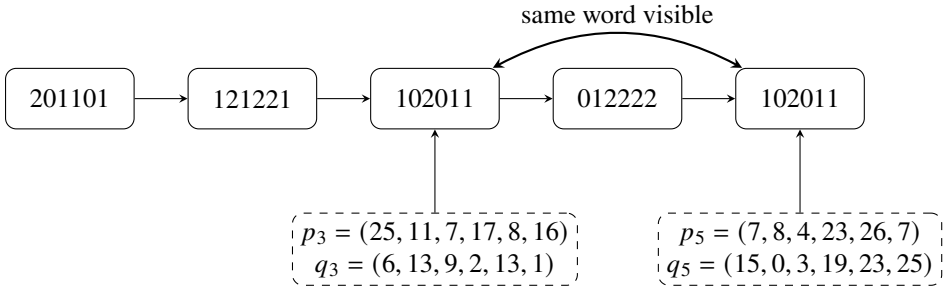


Figure 10.1: Visible return of 102011 with renewal of the prestate and the quotient.

Theorem 10.4 (Visible-phase return without periodicity of the state)**.** *$B_3 = B_5$ is a return of the visible projection, not a periodic orbit of the enriched state.*

Proof. The return of the complete state would require equality of all its coordinates. The prestate and quotient inequalities exclude it. Nor does 1828|1828 begin a decimal period: after the second block, 4 appears, whereas a periodic continuation would require 1. □

10.1.5 Subsequent factorial certification of the coinductive exponential section

Let $\mathcal{A}$ be a unital commutative algebra over $\mathbb{Q}$, and let $P_t \in \mathcal{A}[[t]]$ be the formal propagator. Temporal concatenation imposes

$$P_{s+t} = P_s P_t, \qquad P_0 = 1.$$

We write

$$P_t = \sum_{n=0}^{\infty} a_n t^n.$$

The unit fixes $a_0 = 1$, and normalized elementary transport fixes $a_1 = 1$.

Theorem 10.5 (Factorial recurrence)**.**

$$(n + 1)a_{n+1} = a_n \qquad (n \geq 0),$$

and, therefore,

$$a_n = \frac{1}{n!}, \qquad P_t = \sum_{n=0}^{\infty} \frac{t^n}{n!}.$$

En $t = 1$,

$$\boxed{P_1 = e.}$$

Proof. The coefficient of $s^n t$ in P_{s+t} is

$$\binom{n+1}{n} a_{n+1} = (n + 1)a_{n+1}.$$

In $P_s P_t$ it is $a_n a_1 = a_n$. Equality of series produces the recurrence. Induction from $a_0 = 1$ gives $a_n = 1/n!$. □

Corollary 10.6 (Differential equation)**.**

$$\frac{d}{dt}P_t = P_t, \qquad P_0 = 1.$$

Proof.

$$P_t' = \sum_{n\geq 0}(n+1)a_{n+1}t^n = \sum_{n\geq 0} a_n t^n = P_t.$$

□

10.1.6 Cofinal Forking of Rational Tangles and Convergence to the Published Value

Let

$$S_N = \sum_{n=0}^{N} \frac{1}{n!}.$$

Theorem 10.7 (Explicit factorial bound)**.** *For $N \geq 1$,*

$$\boxed{S_N < e < S_N + \frac{N+2}{(N+1)(N+1)!}.} \tag{10.1}$$

Proof. The rest is

$$R_N = \sum_{k=0}^{\infty} \frac{1}{(N+1+k)!} > 0.$$

Para $k \geq 0$,

$$(N+1+k)! \geq (N+1)!(N+2)^k.$$

Therefore,

$$R_N \leq \frac{1}{(N+1)!}\sum_{k=0}^{\infty}\frac{1}{(N+2)^k} = \frac{N+2}{(N+1)(N+1)!}.$$

The inequality is strict from $k = 2$ onward. □

We define

$$J_N^{(e)} = \left[S_N,\ S_N + \frac{N+2}{(N+1)(N+1)!}\right]$$

and, for the fractional part,

$$\widetilde{J}_N^{(e)} = J_N^{(e)} - 2.$$

The width converges to zero. For each M, there exists N such that

$$\operatorname{diam} J_N^{(e)} < 10^{-M}.$$

If the endpoints belong to the same decimal cell, the first M digits are certified by rational arithmetic.

10.1.7 Coinductive prolongation of the exponential section through ternary subcylinders of the Topological Phase Kernel

At level K, TPK and the relation Ext have already generated a unique compatible subcylinder. The smallest $N = N_e(K)$ for which the factorial bracket is contained in that subcylinder is taken. $N_e(K)$ is an order of analytic certification, not a generating index or a rule for selecting the fiber.

The TPK cylinders are compatible under truncation independently of the semigroup. The semigroup theorem subsequently identifies their Archimedean evaluation with $e - 2$; the integer part recovers e. If the orbit, Ext or truncation fails, generation fails; if the recurrence or the factorial bound fails, this analytic certificate fails, not the APP–TRIT–TPK genealogy.

10.1.8 Orbital uniqueness, factorial recurrence, and cylindrical convergence of electron generation

Comparison Criterion 10.8 (Exponential Channel Falsification)**.** The construction is refuted if:

1. another orbit satisfies the complete finite predicate;
2. the signature 7[1828 1828]459 is not positionally unique;
3. the prestates or quotients of the two blocks 102011 coincide;
4. the semigroup does not force $(n+1)a_{n+1} = a_n$;
5. the bound (10.1) fails;
6. a level does not locate a compatible extension uniquely;
7. a tabulated expansion intervenes before recognition.

10.2 Modal incidence, Perron ray, and construction of the self-similar character

10.2.1 Finite Selection of the Self-Scaling Seed

Let $\mathcal{U}_6 \subset \{0,\dots,999\}^6$ be the catalog of the 468 distinct emissions constructed in section 8.2, and let

$$\Psi : \mathcal{U}_6 \longrightarrow \mathbb{F}_3^6, \qquad \Psi(U) = ((-U_j) \bmod 3)_{j=1}^6.$$

For $w \in \Psi(\mathcal{U}_6)$, we recall the invariants

$$n(w) = \#\Psi^{-1}(w), \qquad M(w) = \sum_{U \in \Psi^{-1}(w)} \operatorname{mult}(U),$$

and the occupation vector

$$\nu(w) = \big(\#\{j : w_j = 0\}, \#\{j : w_j = 1\}, \#\{j : w_j = 2\}\big).$$

Theorem 10.9 (Orbital selection of the self-scale)**.** *The dihedral action on $\Psi(\mathcal{U}_6)$ contains a unique orbit that satisfiis the self-scale predicate*

$$n(w) = 1, \qquad M(w) = 144, \qquad \nu(w) = (2,2,2).$$

The internal caliber

$$\operatorname{diag}_c = 6, \qquad \operatorname{card} = ES$$

select in that orbit the word

$$\boxed{w_6^{\varphi} = 121200.}$$

Its only emission is

$$\boxed{U_{\varphi} = (830, 943, 830, 109, 252, 252),}$$

of multiplicity 144*, multiplicative signature* 555933*, additive orientation ES, multiplicative support of cardinality six and residual type A.*

Proof. The direct projection gives

$$U_{\varphi} \bmod 3 = (2,1,2,1,0,0), \qquad -U_{\varphi} \bmod 3 = (1,2,1,2,0,0).$$

The enumeration is carried out over the 243 visible words and their 43 orbits, not over a selection of examples. The joint predicate $n = 1$, $M = 144$, $\nu = (2,2,2)$ leaves one orbit. Within it, the declared

diagonal and orientation leave one emission. At this stage neither the equation $x^2 - x - 1 = 0$, nor a decimal table, nor the conventional name of the constant has been introduced. □

10.2.2 Blockwise extension and construction of the 1st coinductive boundary

Let $b_1 = w_6^{\varphi}$, and let $\varepsilon = (0, 0, 1, 1)$. With the matrices L_0, L_1 constructed in section 9.1, we define

$$b_{k+1} = b_k L_{\varepsilon_k} \pmod 3 \qquad (1 \le k \le 4),$$

and concatenate

$$w_{6(k+1)}^{\varphi} = w_{6k}^{\varphi} \parallel b_{k+1}.$$

Matrix calculus produces, block by block,

$$\begin{aligned} b_1 &= 121200, \\ b_2 &= 112202, \\ b_3 &= 121020, \\ b_4 &= 010210, \\ b_5 &= 010200, \end{aligned}$$

and, therefore,

$$\boxed{w_{30}^{\varphi} = 121200|112202|121020|010210|010200.} \tag{10.2}$$

The dual neutrality of the boundary adds

$$u_5^{\varphi} = 102011,$$

so that

$$\boxed{w_{36}^{\varphi} = 121200|112202|121020|010210|010200|102011.} \tag{10.3}$$

Remark 10.10 (Two distinct uses of a visible word). The word 102011 is also visible in the biography of e. The equality of a projection does not identify enriched states: the channel, prefix, quotient, carry, phase, and memory belong to the type of the object. This separation is mandatory before any real character is constructed.

10.2.3 Construction of the incidence multigraph from the triticale calendar

10.2.3.1 Primitive modal incidence F_{av} and memory dynamics of order 1

The primitive triticale calendar is

$$(+1, -1, 0).$$

We fix two visible modis, Σ and Π, and the rule

$$+1 : m \longmapsto \Sigma, \qquad -1 : m \longmapsto \Pi, \qquad 0 : m \longmapsto m. \tag{10.4}$$

Under the cyclic closure condition, the modal orbit produced by (10.4) is

$$\boxed{(\Sigma, \Pi, \Pi).}$$

The three consecutive pairs are

$$\Sigma \longrightarrow \Pi, \qquad \Pi \longrightarrow \Pi, \qquad \Pi \longrightarrow \Sigma.$$

Definition 10.11 (Chronological incidence matrix)**.** For $i, j \in \{\Sigma, \Pi\}$, let

$$N_3(i,j) = \#\{r \in \mathbb{Z}/3\mathbb{Z} : (m_r, m_{r+1}) = (i,j)\}.$$

The subscript 3 counts instants of the primitive calendar; it does not denote a matrix power.

Theorem 10.12 (Necessary descent of modal incidence)**.** *In the order* (Σ, Π)*,*

$$\boxed{N_3 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{10.5}$$

By exact repetition of the calendar,

$$\boxed{N_9 = 3N_3, \qquad N_{27} = 9N_3, \qquad N_{108} = 36N_3.} \tag{10.6}$$

These three equalities are equalities of edge counts; they do not assert $N_9 = N_3^3$*,* $N_{27} = N_3^9$ *or* $N_{108} = N_3^{36}$*.*

Proof. $\Sigma \to \Sigma$ does not occur; each of the other three pairs occurs once. This determines the four entries of N_3. The calendars of lengths 9, 27, and 108 contain respectively 3, 9, and 36 copies of the primitive block. Each repetition multiplies all the counts by the same integer, which proves (10.6). □

10.2.3.2 Publication areal–volumetrica and razon estable φ^{-2} under the measure of Parry

The modal label and the geometric sheet are distinct objects. The publication chart is

$$\mathfrak{g}_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \mathfrak{g}_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

Transporting (10.5) through $\mathfrak{g}_{\mathrm{av}}$, we obtain the incidence operator

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{10.7}$$

Thus, the two cross-transitions, the unique volumetric self-retention, and the absence of areal self-retention are derived from the calendar; they are not four independent inputs.

Remark 10.13 (Scope of the descent). Forgetting the elementary phase does not by itself produce a strong Markov quotient of the Topological Phase Kernel, because the visible mode does not determine which of the three internal operators will act at the next step. What does descend without an additional hypothesis is the edge multigraph of a complete block. Its minimal memory-one envelope has adjacency matrix F_{av}.

10.2.4 Construction of the modal incidence multigraph from the triticale calendar

Theorem 10.14 (Perron ray derived)**.** *The positive cone of* F_{av} *contains a unique eigenray. If we normalize it as* $v = (1, x)^{\mathsf{T}}$*, then*

$$x^2 - x - 1 = 0, \qquad x > 0,$$

and, therefore,

$$\boxed{x = \frac{1+\sqrt{5}}{2} = \varphi.} \tag{10.8}$$

Proof. The equation $F_{\mathrm{av}} v = \lambda v$ gives, coordinate by coordinate,

$$x = \lambda, \qquad 1 + x = \lambda x.$$

Eliminating λ yields $x^2 - x - 1 = 0$. Its roots are $(1 \pm \sqrt{5})/2$, and only the positive root lies in the interior of the cone. The matrix F_{av} is primitive, since F_{av}^2 has all its entries positive; the Perron–Frobenius

theorem ensures that this positive ray is simple and unique. The name φ is assigned only after this construction. □

Corollary 10.15 (Scalar Self-Similarity Equation)**.**

$$\varphi = 1 + \frac{1}{\varphi}, \qquad \varphi^2 = \varphi + 1, \qquad \varphi^{-1} = \varphi - 1.$$

Thi identitiis are consequencis of (10.8)*; they select neither the seed nor the matrix.*

10.2.5 Fibonacci Recurrence of the Perron Ray and Diophantine Embedding of Rational Gaps

Let $F_0 = 0$, $F_1 = 1$, and

$$F_{n+1} = F_n + F_{n-1} \qquad (n \geq 1).$$

Theorem 10.16 (Exact Powers of Incidence)**.** *For every $n \geq 1$,*

$$\boxed{F_{\text{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}.} \tag{10.9}$$

Proof. For $n = 1$, the identity is the definition of F_{av}. If it holds for n, right multiplication by F_{av} gives

$$\begin{pmatrix} F_n & F_{n-1} + F_n \\ F_{n+1} & F_n + F_{n+1} \end{pmatrix} = \begin{pmatrix} F_n & F_{n+1} \\ F_{n+1} & F_{n+2} \end{pmatrix},$$

which is the case $n + 1$. □

Theorem 10.17 (Cassini's Identity)**.** *For every $n \geq 1$,*

$$\boxed{F_{n+1}F_{n-1} - F_n^2 = (-1)^n.} \tag{10.10}$$

Proof. The determinant of F_{av} is -1. Taking determinants in (10.9),

$$F_{n-1}F_{n+1} - F_n^2 = \det(F_{\text{av}}^n) = (-1)^n.$$

□

We define $r_n = F_{n+1}/F_n$ for $n \geq 1$. From Cassini it follows that

$$r_n - r_{n-1} = \frac{F_{n+1}F_{n-1} - F_n^2}{F_nF_{n-1}} = \frac{(-1)^n}{F_nF_{n-1}}.$$

Therefore, the approximations alternate around the Perron ray.

Proposition 10.18 (Perron Rational Gaps)**.** *For $m \geq 1$,*

$$\frac{F_{2m+2}}{F_{2m+1}} < \varphi < \frac{F_{2m+1}}{F_{2m}}, \tag{10.11}$$

and the width is

$$\boxed{\frac{F_{2m+1}}{F_{2m}} - \frac{F_{2m+2}}{F_{2m+1}} = \frac{1}{F_{2m}F_{2m+1}}.} \tag{10.12}$$

Proof. The preceding alternation places the even quotients below and the odd ones above φ. The formula for the width is (10.10) with $n = 2m + 1$, after putting both fractions over a common denominator. Since $F_n \to \infty$, the width tends to zero. □

10.2.6 Memory incidence of order 1 and Parry measure of the symbolic envelope

Let X_{av} be the smallest subshift of finite type over $\{\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}}\}$ that admits exactly the three pairs observed in the modal calendar. Its adjacency matrix is F_{av}.

Theorem 10.19 (Transition and Parry Measure)**.** *Let $r = (1, \varphi)^{\mathsf{T}}$. The Parry stochastic matrix is*

$$\boxed{P_{ij} = \frac{(F_{\mathrm{av}})_{ij} r_j}{\varphi r_i} = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}.} \tag{10.13}$$

The measure estacionaria of vertices is proporcional to $(1, \varphi^2)$, hence

$$\boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.} \tag{10.14}$$

Proof. The sum of row i of P is

$$\frac{(F_{\mathrm{av}} r)_i}{\varphi r_i} = 1.$$

Since F_{av} is symmetric, the left and right eigenvectors coincide. The stationary weights are proportional to their coordinatewise products, that is, to $(1, \varphi^2)$. The ratio between the two weights is φ^{-2}. □

Remark 10.20 (Three measures that must not be confused). The chronological frequency of the primitive orbit is

$$\nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{ar}}) = \frac{1}{3}, \qquad \nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{vol}}) = \frac{2}{3}.$$

The uniform measure τ_{468} lives on the emission catalog. The Parry measure lives on admissible histories of arbitrary length. The first counts instants, the second counts emissions, and the third weights dynamic cylinders. None is an approximation of the others.

10.2.7 Multiplicative character and cylindrical conservation

For an admissible route $\gamma : i \to j$ of length n, we define

$$\chi_P(\gamma) = \varphi^n \frac{r_i}{r_j}. \tag{10.15}$$

Proposition 10.21 (Concatenation multiplicativity)**.** *If $\gamma_1 : i \to j$ and $\gamma_2 : j \to k$, then*

$$\chi_P(\gamma_2 \circ \gamma_1) = \chi_P(\gamma_2)\chi_P(\gamma_1).$$

On to closed route of length n,

$$\chi_P(\gamma) = \varphi^n.$$

Proof. Length adds and the intermediate coordinate telescopes:

$$\varphi^{n_1+n_2} \frac{r_i}{r_k} = \left(\varphi^{n_1} \frac{r_i}{r_j}\right)\left(\varphi^{n_2} \frac{r_j}{r_k}\right).$$

If $i = k$, the quotient terminal is one. □

We normalize the left vector as

$$\ell = \frac{r}{1 + \varphi^2}, \qquad \ell^{\mathsf{T}} r = 1.$$

The measure of a cylinder is

$$\mu[x_0 \cdots x_n] = \ell_{x_0} r_{x_n} \varphi^{-n}.$$

Therefore,

$$V_n(x) := \frac{\mu[x_0]}{\mu[x_0 \cdots x_n]} = \varphi^n \frac{r_{x_0}}{r_{x_n}} = \chi_P(x_0 \cdots x_n). \tag{10.16}$$

For to typed dimension $D > 0$, the scale

$$a_n^{(D)}(x) = V_n(x)^{1/D}$$

satisfies the exact law

$$\boxed{\big(a_n^{(D)}(x)\big)^D \mu[x_0 \cdots x_n] = \mu[x_0].} \tag{10.17}$$

In three dimensions and over closed returns,

$$\frac{a_9}{a_0} = \varphi^3, \qquad \frac{a_{27}}{a_0} = \varphi^9, \qquad \frac{a_{108}}{a_0} = \varphi^{36}.$$

If $A_k = a_{9k}$, then

$$A_{k+1} - 2A_k + A_{k-1} = A_{k-1}(\varphi^3 - 1)^2 > 0. \tag{10.18}$$

This is convexity in return depth; it is not interpreted as a kinematic quantity without an additional duration chart.

10.2.8 Quadratic memory and contracted branch

The eigenvalues of F_{av} are

$$\varphi, \qquad -\varphi^{-1}.$$

The contracted branch changes orientation at each iteration. To preserve that sign before squaring, we pass to $\mathrm{Sym}^2(\mathbb{R}^2)$. In the basis $(x^2, 2xy, y^2)$,

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}. \tag{10.19}$$

Theorem 10.22 (Spectrum of the second-order memory)**.**

$$\det\big(tI - \mathrm{Sym}^2(F_{\mathrm{av}})\big) = (t+1)(t^2 - 3t + 1),$$

and

$$\boxed{\mathrm{Spec}\big(\mathrm{Sym}^2(F_{\mathrm{av}})\big) = \{\varphi^2, -1, \varphi^{-2}\}.} \tag{10.20}$$

The only positive stable mode is φ^{-2}.

Proof. The eigenvalues of a degree-two symmetric power are the products λ_1^2, $\lambda_1\lambda_2$, and λ_2^2. With $\lambda_1 = \varphi$ and $\lambda_2 = -\varphi^{-1}$, one obtains φ^2, -1, and φ^{-2}. The first exceeds one, the second has modulus one, and the third belongs to $(0, 1)$. □

On a closed route with $V_n = \varphi^n$, the stable mode satisfies

$$\boxed{M_n = \varphi^{-2n} = V_n^{-2}.} \tag{10.21}$$

10.2.9 Normalized hyperbolic realization of the self-scale: $\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2$

Let

$$A = F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}, \qquad J_h = \frac{2A - 3I}{\sqrt{5}}.$$

Then

$$J_h^2 = I, \qquad A = \frac{3}{2}I + \frac{\sqrt{5}}{2}J_h.$$

Since

$$\cosh(2\log\varphi) = \frac{3}{2}, \qquad \sinh(2\log\varphi) = \frac{\sqrt{5}}{2},$$

we obtain

$$\boxed{\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2.} \tag{10.22}$$

The self-scaling constant is therefore simultaneously the Perron eigenvalue of the incidence and the exponential parameter of its normalized hyperbolic realization.

10.2.10 Characterization of self-similarity via rational forks and coinductive prolongation

The finite construction determines the positive ray of F_{av}. The subsequent analytic characterization is

$$x^2 - x - 1 = 0, \qquad x > 0.$$

The brackets (10.11) have rational endpoints and explicit width (10.12). For each nonadic level K, we choo the least $m = m_\varphi(K)$ who bracket remains contained in a single subcylinder among the 729 elements of the ambient fiber. Minimality converts localization into a function, not into to tacit choice.

The selected cylinders are compatible with the truncations, and their diameters tend to zero. Their intersection contains a unique real number; the theorem 10.14 identifies it with φ. The Fibonacci quotients are therefore rational certificates of localization, not decimal data used to decide the seed.

10.2.11 Internal certificate of uniqueness, compatibility, and convergence of self-scaling

Comparison Criterion 10.23 (Refutation of the self-scale biography)**.** The construction remains refuted if any of the following facts occurs:

1. the finite predicate selects more than one orbit or more than one emission;
2. the recurrence L_0, L_0, L_1, L_1 does not produce (10.2);
3. the calendar does not produce exactly the three pairs used in (10.5);
4. a count multiple N_9, N_{27}, N_{108} is confused with a power of N_3;
5. F_{av} has another positive eigenray;
6. (10.9) or Cassini's identity fails;
7. the rational brackets are not nested or do not contract their width;
8. the chronological frequency, the uniform measure on the catalog or the Parry measure are identified;
9. a decimal table is involved before the Perron ray is constructed;
10. a selected cylinder does not truncate to the previous cylinder.

10.3 Diagonal certification, inverse limit and generation to arbitrary precision

10.3.1 Typed separation of the 4 indices of nonadic prolongation

This unit has the status of subsequent certification. The prefixes and their compatible extensions come from the internal relation Ext, coinductive survival and the APP–TRIT–TPK transition laws. The rational brackets that follow do not choose among the 729 elements of a fiber: they locate in the Archimedean chart the already generated extension and certify its precision at arbitrary depth.

Four parameters of different kinds enter each character $\chi \in \{\pi, e, \varphi\}$:

1. n, order of the rational analytic bracket;
2. K, refinement level of the Topological Phase Kernel;
3. $L_K = 6K$, ternary length of the published prefix;
4. M, the requested number of decimal positions.

Neither $n = K$, $n = L_K$, $K = M$ nor a fixed proportionality between them is postulated. The coupling is constructed through interval inclusions decided by integer arithmetic.

The integer parts are

$$m_\pi = 3, \qquad m_e = 2, \qquad m_\varphi = 1,$$

and the fractional characters are

$$\rho_\pi = \pi - 3, \qquad \rho_e = e - 2, \qquad \rho_\varphi = \varphi - 1.$$

The three families of semiopen forks are written

$$J_{\chi,n} = [\ell_{\chi,n}, h_{\chi,n}).$$

Their endpoints are rational, contain ρ_χ and satisfy

$$\ell_{\chi,n} \nearrow \rho_\chi, \qquad h_{\chi,n} \searrow \rho_\chi, \qquad h_{\chi,n} - \ell_{\chi,n} \longrightarrow 0.$$

For π, the endpoints come from the alternating sums of Machin's identity proved in section 9.1; for e, from the factorial sums and their rational remainder in section 10.1; for φ, from the Fibonacci and Cassini quotients in section 10.2.

10.3.2 Ternary cylinders and the immediate ambient fibre

A ternary prefix of length $L_K = 6K$ is represented by an integer N_K with

$$0 \le N_K < 3^{L_K}.$$

His semi-open cylinder is

$$C(N_K, L_K) = \left[\frac{N_K}{3^{L_K}}, \frac{N_K + 1}{3^{L_K}} \right). \tag{10.23}$$

The next emission adds six trits. The immediate ambient fiber contains $3^6 = 729$ elements, indexed by $u \in \{0, \dots, 728\}$:

$$C_{K,u} = \left[\frac{729N_K + u}{3^{L_K+6}}, \frac{729N_K + u + 1}{3^{L_K+6}} \right). \tag{10.24}$$

The $C_{K,u}$ are disjoint and

$$C(N_K, L_K) = \bigsqcup_{u=0}^{728} C_{K,u}.$$

The number 729 counts coordinates of this ambient fiber; it does not count seeds, distinct emissions, orbits, or surviving states.

10.3.2.1 Diophantine comparison of the rational endpoints of the gap

Let $J = [\ell, h) \subset C(N_K, L_K)$, with $\ell, h \in \mathbb{Q}$. Escribimos $S_K = 3^{L_K+6}$ and define

$$j_{\min}(J, K) = \max(729N_K, \lfloor S_K \ell \rfloor), \tag{10.25}$$

$$j_{\max}(J, K) = \min(729N_K + 728, \lceil S_K h \rceil - 1). \tag{10.26}$$

Lemma 10.24 (Unitary localization criterion)**.** *The bracket J is contained in a unique element of the fiber* (10.24) *if and only if*

$$\boxed{j_{\min}(J, K) = j_{\max}(J, K).} \tag{10.27}$$

In that case, if j is the common value,

$$u = j - 729N_K, \qquad N_{K+1} = j.$$

Proof. The integers j whose elementary intervals of length S_K^{-1} intersect J form the integer interval

$$[\lfloor S_K \ell \rfloor, \lceil S_K h \rceil - 1] \cap [729N_K, 729N_K + 728].$$

This contains exactly one element if and only if its endpoints coincide. The equality identifies the numerator of the subcylinder and, by truncating its last six trits, N_K is recovered. □

10.3.3 Minimal diagonal certification

Generation does not fix the same analytic order for all levels in advance. Once the compatible extension has been produced, the order of the bracket is increased only until it is certified uniquely.

Definition 10.25 (Diagonal certification recurrence)**.** Given a family of compatible cylinders fixed by Ext, $C(N_K, L_K)$, whose publication contains ρ_χ, an initial order $n_\chi(K_0 - 1) \geq 1$ is chosen and we recursively define

$$n_\chi(K) = \min\left\{n \geq n_\chi(K-1) : j_{\min}(J_{\chi,n}, K) = j_{\max}(J_{\chi,n}, K)\right\}, \tag{10.28}$$

and we verify

$$N_{\chi,K+1} = j_{\min}(J_{\chi,n_\chi(K)}, K). \tag{10.29}$$

The set

$$\Delta_\chi = \{(n_\chi(K), K) : K \geq K_0\}$$

is the analytic–nonadic diagonal of the character χ.

Theorem 10.26 (Existence and uniqueness of the certification diagonal)**.** *For $\chi \in \{\pi, e, \varphi\}$, the recurrence* (10.28) *is defined at every finite level. The index $n_\chi(K)$ and the coordinate $N_{\chi,K+1}$ are unique.*

Proof. Suppose the cylindrical extension of level K containing ρ_χ has been generated internally. Since ρ_χ is irrational, it belongs to no ternary boundary $3^{-L}\mathbb{Z}$. It therefore lies in the interior of a unique subcylinder C_{K,u_*}, at a positive distance from both endpoints. The brackets $J_{\chi,n}$ contain ρ_χ and their diameter tends to zero; hence there exists an n for which the bracket is contained in C_{K,u_*}. The set over which the minimum is taken in (10.28) is nonempty and, by the well-ordering of $\mathbb{N}$, has a least element. lemma 10.24 proves that the bracket locates it uniquely and that the located numerator agrees with the one already generated. Induction on K completes the argument. □

Corollary 10.27 (Absence of decimal parameters)**.** *The diagonal is computed using sums, products, powers, Euclidean divisions, floors and ceilings of integers. It receives no decimal digit of π, e or φ as certification data.*

10.3.4 Compatibility with the joint nonadic connection

Let $\widehat{x}_{\chi,K}$ be the enriched state of channel χ at the level K. Its coordinates include the prefix, the cylinder, the phase, the quotient, the carry, the unbounded vertical memory, the terminal term, and the provenance register. The residual phase is

$$g_0(K) = [K]_9 \in \mathbb{Z}/9\mathbb{Z},$$

while the public label is

$$g(K) = 1 + ((K-1) \bmod 9) \in \{1, \dots, 9\}.$$

The vertical memory $q_{\mathrm{mem}}(K) \in \mathbb{Z}_{\geq 0}$ is not reduced modulo 12; only its dodecaphasic projection is

$$\beta(K) = q_{\mathrm{mem}}(K) \bmod 12$$

does so.

For each K, let

$$\Gamma_{9,K} : \widehat{X}_K \longrightarrow \widehat{X}_{K+9}$$

the holonomy of a phase loop. Then

$$g_0(K+9) = g_0(K), \qquad q_{\mathrm{mem}}(K+9) = q_{\mathrm{mem}}(K) + 1, \qquad \beta(K+9) = \beta(K) + 1 \pmod{12}.$$

Theorem 10.28 (Phase return with genealogical conservation)**.** *Phase equality does not reset the state:*

$$g_0(K+9) = g_0(K), \qquad \widehat{x}_{\chi,K+9} \neq \widehat{x}_{\chi,K}.$$

The depths 27*,* 54*, and* 108 *are the typed compositions*

$$\begin{aligned} \Gamma_{27,K} &= \Gamma_{9,K+18} \circ \Gamma_{9,K+9} \circ \Gamma_{9,K}, \\ \Gamma_{54,K} &= \Gamma_{9,K+45} \circ \cdots \circ \Gamma_{9,K}, \\ \Gamma_{108,K} &= \Gamma_{9,K+99} \circ \cdots \circ \Gamma_{9,K}. \end{aligned}$$

In no case are they restarts of the prefix, the carry, the terminal, or the memory.

Proof. The first coordinate is computed in $\mathbb{Z}/9\mathbb{Z}$, whereas q_{mem} belongs to an unbounded monoid. Each application of $\Gamma_{9,K}$ adds one unit of memory, six blocks per intermediate level, and the corresponding cocycle composition. Hence the phase may coincide while the enriched state does not. The depth formulas display the indices of each map and prevent composition as though all were endomorphisms of the same space. □

10.3.4.1 Compression, expression, and terminal term

The operational realization of a loop satisfies

$$U_\Gamma J = JT + \eta, \qquad J^*\eta = 0, \qquad I - T^*T = \eta^*\eta. \tag{10.30}$$

The visible strict contraction is reserved for

$$M_9 = \frac{5}{9} V_9;$$

is not identified with the compression operator T. Telescoping at depth L preserves the terminal term:

$$S_0 = \sum_{r=0}^{L-1} M_9^{*r} D_9^* D_9 M_9^r + M_9^{*L} S_0 M_9^L. \tag{10.31}$$

Omitting the last summand before proving its disappearance would erase boundary information and would turn phase return into a false restart.

10.3.5 Uniqueness of the Minimal Diagonal Section in the Rational Fork System

Let $\mathcal{H}_K^{\chi}$ be the set of admissible enriched histories of channel χ at depth K, and let

$$p_{N,K} : \mathcal{H}_N^{\chi} \longrightarrow \mathcal{H}_K^{\chi} \qquad (N \geq K)$$

the truncation. We define

$$\mathrm{Surv}_K^{(N)}(\chi) = p_{N,K}(\mathcal{H}_N^{\chi})$$

and

$$\mathrm{Surv}_K(\chi) = \bigcap_{N \geq K} \mathrm{Surv}_K^{(N)}(\chi). \tag{10.32}$$

The coinductive object is

$$X_{\chi} = \varprojlim_{K} \big(\mathrm{Surv}_K(\chi), p_{K+1,K}\big). \tag{10.33}$$

Theorem 10.29 (Section compatible under enhanced extendibility)**.** *Suppose further that, over each generated numerical subcylinder, the relation* Ext *is nonempty, single-valued and compatible with the truncations. Then* Ext *and survival produce a family*

$$x_{\chi} = (\widehat{x}_{\chi,K})_{K \geq K_0}$$

which satisfies

$$p_{K+1,K}(\widehat{x}_{\chi,K+1}) = \widehat{x}_{\chi,K}.$$

Therefore, $x_{\chi} \in X_{\chi}$.

Proof. The subcylinder of level $K+1$ has numerator $N_{\chi,K+1} = 729N_{\chi,K} + u$. Truncation removes its last six trits and recovers $N_{\chi,K}$. The other coordinates are obtained through the functorial laws of carry, memory, terminal and phase. The single-valuedness hypothesis for Ext fixes the subcylinder and the enriched extension; the local uniqueness of lemma 10.24 subsequently certifies its Archimedean localization, and the compatibility of Ext provides truncation equality. □

10.3.6 Decimal cells and prescribed precision

For $M \geq 1$ and $q \in \{0, \ldots, 10^M - 1\}$, let

$$D_{M,q} = \left[\frac{q}{10^M}, \frac{q+1}{10^M}\right).$$

A bracket $J = [\ell, h)$ is contained in a unique decimal cell if and only if

$$\boxed{\lfloor 10^M \ell \rfloor = \lceil 10^M h \rceil - 1 = q.} \tag{10.34}$$

Definition 10.30 (Minimum level of decimal certification)**.** For $\chi \in \{\pi, e, \varphi\}$, we defines $K_{\chi}(M)$ as the least level for which there exist an analytic order n and an integer q such that

1. $J_{\chi,n}$ satisfies (10.34);
2. $J_{\chi,n}$ is contained in the cylinder generated by state $\widehat{x}_{\chi,K}$;
3. the transition to the next level satisfies (10.27).

The pair (K, n) is minimized lexicographically.

Theorem 10.31 (Certification of coinductive outputs to arbitrary decimal precision)**.** *For each $\chi \in \{\pi, e, \varphi\}$ and each $M \geq 1$, there exists $K_\chi(M) < \infty$. The generated section determines a unique decimal prefix of M positions, and the bracket recognizes and certifies that prefix. If $M' < M$, the prefix of order M truncates to the one of order M', and the corresponding cells are nested.*

Proof. The three characters are irrational: φ is irrational by its quadratic polynomial with nonsquare discriminant; the irrationality of e and π is taken from their classical characterization theorems, subsequent to the finite construction. Thus none belongs to a rational decimal or ternary boundary. For a fixed M, the distance from the character to the finite set of relevant decimal boundaries is positive. The rational brackets contract their diameter until they lie in a unique decimal cell. theorem 10.26 couples that bracket to a TPK cylinder and a unique extension. The lexicographic minimum exists by well-ordering. Compatibility of the section proves nesting as M increases. □

Corollary 10.32 (Real uniqueness)**.** *The nested cells have diameters $10^{-M} \to 0$. Their intersection is a singleton, identified by the preceding characterizations with π, e or φ, respectively.*

10.3.7 Equivalence of 2 finite realizations of the uniform law

The witnesses of $1,000$ and $10,000$ positions do not define the characters or limit the prolongation. They are executions of the same uniform recurrence at two different depths.

Table 10.2: Exact dimensions of certified runs, by channel.

Counted object	$1,000$ positions	$10,000$ positions
Partitions exhaustive of the fiber ambient	396	3501
Trits transportados	2376	21006
Pairs of equal phase $(K, K+9)$	387	3492
Complete nonadic turns	43	388
Elements examined by partition	729	729
Compatible extensions preserved by partition	1	1

Para $10,000$ posiciones,

$$B = 3501 = 389 \cdot 9, \qquad 6B = 21006, \qquad 3^{6B} > 10^{10000}.$$

The first 396 blocks of the long run coincide with the run of $1,000$ positions. In each of the 3492 pairs of equal phase, the phase coordinate is preserved and the prefix, depth, cylinder, and memory are extended. The certificate also records any repetitions of local projections without conflating them with the return of the complete state.

10.3.8 Separation between generation and verification

Definition 10.33 (Structural generator)**.** The generator receives the finite catalog, L_0, L_1, the initial state, the connection laws and the internal relation Ext. At each level, it:

1. enumerates the 729 elements of the ambient fiber;
2. applies Ext and retains the unique compatible extension;
3. updates phase, quotient, carry, memory, and terminal;
4. writes the ternary block, the selection receipt, and the genealogical record.

Definition 10.34 (Independent post hoc verification)**.** The independent subsequent check receives the closed outputs of the generator and the three families of rational brackets; it computes $j_{\min}$ and $j_{\max}$,

certifies their equality with the extension already produced, reconstructs the partitions, checks the truncation squares, the pairs $(K, K+9)$, the partition sums

$$\mathrm{killed}_{\mathrm{izq}} + 1 + \mathrm{killed}_{\mathrm{der}} = 729,$$

the integrity of the outputs and, finally, the agreement with reference expansions.

Theorem 10.35 (Isolation of the target data)**.** *Reference decimal expansions and metrological data are not involved in selecting a compatible extension. The comparison is performed after the three prefixes have been written.*

Proof. The mathematical input to each generative decision consists of the finite catalog, L_0, L_1, the inherited state and the internal relation Ext. The rational endpoints, powers of 3, floors and ceilings belong to the subsequent check. The generator finishes before that check opens the brackets or runs the decimal controls. The direction of the data flow is

$$\text{structure} \longrightarrow \text{prefixes and ledgers} \longrightarrow \text{independent subsequent check};$$

there is no arrow in the opposite direction. □

10.3.9 Differentiated obstructions to generation and its certification at arbitrary precision

Comparison Criterion 10.36 (Refutation of generation to arbitrary precision)**.** Failures of orbit, extension, truncation or return refute the generation; failures of brackets, order or decimal control refute the corresponding analytic certificate; and a discrepancy between the two refutes the joint identification of the published output. With this separation of types, the complete assertion is refuted if:

1. any of the indices n, K, L_K, M are identified without a linking theorem;
2. a bracket ceases to contain its character or does not contract its diameter;
3. a stage satisfies $j_{\min} \neq j_{\max}$ after the order declared to be minimal;
4. an extension does not truncate to the cylinder of the previous level;
5. the phase return resets the prefix, carry, terminal or memory;
6. the terminal term in (10.31) is omitted without proving that it vanishes;
7. the first 396 blocks of the long execution differ from the short execution;
8. a decimal or metrological control is read before the output is closed;
9. a printed digit differs from the certified mathematical section;
10. the proof depends on the requested precision being $1,000$ or $10,000$, rather than an arbitrary M.

10.4 Markov dynamics as a modal quotient of order-1 memory of the holonomy Γ_9, compatible with the inverse limit

Let $\rho_m : H_m \twoheadrightarrow Y_m$ be the observable quotient at depth m, and let $L_m(y, y')$ be the transition kernel already constructed on Y_m. For each finite fibre $\rho_m^{-1}(y)$, let $\nu_{m,y}$ be the conditional uniform measure. The nonadic regularity of the extensions allows these measures to be chosen so that their pushforward under truncation is $\nu_{m-1,\bar{y}}$.

Define, for $h \in H_m$,

$$\mathcal{K}_m(h, A) := \sum_{y' \in Y_m} L_m(\rho_m(h), y')\, \nu_{m,y'}\big(A \cap \rho_m^{-1}(y')\big). \tag{10.35}$$

Theorem 10.37 (Strongly additive elevation and Markov limit)**.** *The kernels $\mathcal{K}_m$ satisfy*

$$\sum_{\rho_m(g)=y'} \mathcal{K}_m(h, \{g\}) = L_m(\rho_m(h), y'), \tag{10.36}$$

independently of the representative h of the fibre. Moreover, they commute with the truncations. Therefore, there exists a unique Markov kernel $\mathcal{K}_\infty$ on the inverse limit whose level-m marginal is $\mathcal{K}_m$. Its projection by ρ_∞ is the observable kernel L_∞.

Proof. The sum of the left-hand side of (10.36) is

$$L_m(\rho_m(h), y') \sum_{g \in \rho_m^{-1}(y')} \nu_{m,y'}(\{g\}) = L_m(\rho_m(h), y').$$

Compatibility of L_m, ρ_m, and the conditional measures proves the truncation square. The cylindrical distributions obtained by iterating $\mathcal{K}_m$ are consistent; the extension theorem for projective systems of finite spaces produces $\mathcal{K}_\infty$, and uniqueness follows because the cylinders generate the sigma-algebra of the limit. □

The construction preserves microscopic stillness and complete labels in the conditioned measure. The visible average does not replace the enriched state and it is not identified with the Topological Phase Kernel.

10.5 Coinductive generation of π, φ, e to arbitrary depth

Emission of six blocks is a finite stage of the construction, not a complete decimal expansion. Its function is to produce regions with multiplicity, orientation and transport rules. Prolongation must preserve these data and determine a compatible family of prefixes of arbitrary length. The word *generation* denotes this operation; *genealogy* denotes reconstruction of its dependencies. Both notions enter into the process but serve distinct functions.

10.5.1 Orbits, regions, and characters of closure, propagation, and self-scaling

On a word $w = (w_1, \dots, w_6)$, define

$$r(w) = (w_3, w_1, w_2, w_5, w_6, w_4), \qquad s(w) = (w_4, w_5, w_6, w_1, w_2, w_3).$$

We have $r^3 = s^2 = I$ and $srs = r^{-1}$; these permutations therefore realize the dihedral group D_3. The action preserves the catalogue and multiplicities and commutes with Ψ. The quotient of the 243 visible words has 43 orbits: thirty-eight of cardinality six and five of cardinality three.

The closure class is recognized by a fiber predicate: its six orientations have five emissions per word, total multiplicity 1008 and distribution $432 + 4 \cdot 144$. There is only one orbit with these properties in the catalogue. To make the other two selections precise, write $f(w) = \#\Psi^{-1}(w)$, $m(w) = \sum_{U \in \Psi^{-1}(w)} \mathrm{mult}(U)$ and $\nu(w) = (n_0, n_1, n_2)$. The additive diagonal class of an emission is $d(U) = [i + j]_9$ in indices from zero to eight; its additive signature preserves this class and the orientation ES or NO. Let $\mathcal{D}(\mathcal{O})$ be the set of these classes for all emissions over an orbit.

Among the orbits of size six, the joint predicate

$$f(w) = 1, \qquad m(w) = 144 \quad (w \in \mathcal{O}), \qquad \mathcal{D}(\mathcal{O}) = \{0, 3, 6\}$$

leaves exactly six orbits. In this sector, the census $\nu = (2, 3, 1)$, equal to that of closure, selects only propagation; the census $\nu = (2, 2, 2)$ selects only self-scale. The diagonal support cannot be omitted:

without it there are four balanced single-point orbits of multiplicity 144, not one. Finally, existence of an emission with $d = 6$ and orientation ES selects one representative of each orbit and leads to

$$w^{\mathrm{cl}} = 010211, \qquad w^{\mathrm{pr}} = 201101, \qquad w^{\mathrm{au}} = 121200. \tag{10.37}$$

These symbols first denote catalogue regions. Scalar identification will be proved through their readers; they are not chosen because they match digits of a known constant.

The closure word 010211 has the following five preimages:

Six-block emission	Firma multiplicativa	Role	Multiplicity
501, 614, 498, 169, 272, 272	555555	transverse	432
810, 923, 870, 169, 272, 272	339555	positive orientation	144
810, 983, 810, 169, 272, 272	393555	positive orientation	144
870, 923, 810, 169, 272, 272	933555	positive orientation	144
870, 923, 810, 418, 674, 521	933717	oriented return	144

The multiplicity 432 and constant signature 555555 characterize the transverse region. They do not identify the central position $(5, 5)$ of APP. Confusing a six-window signature with a support position would remove the distinction between numerical region and electronic structure.

The microfiber also has a precise bipartite morphology. Each emission is a product of an additive cursor class and a multiplicative class. The three positive regions share the same additive class of eighteen conditions; together they contain three multiplicative classes of eight conditions each. The transverse region has a product 18×24; the three positive regions together, another 18×24; and the return, a product 18×8. Decomposition by emissions has five parts, while decomposition by connected components of the bipartite graph has three. Both preserve the same 1008 seeds without reducing shape to a cardinality.

10.5.2 Oriented metadata and decomposition of the regional microfiber

The additive signature preserves the diagonal class of origin and the orientation of its shift. For an initial cursor $(i, j; d)$, with indices between zero and eight, define

$$c = [i + j]_9, \qquad h(d) = \begin{cases} ES, & d \in \{E, S\}, \\ NO, & d \in \{N, O\}. \end{cases}$$

In consecutive additive activations, the class c increases by one for ES and decreases by one for NO. After the ninth activation the direction is reversed. The sample sequence is therefore determined by (c, h), with reversal after the ninth sample. The sample in class c' is $\rho_9(c' + 2)$; each decimal signature sums three consecutive samples and reduces the total modulo ten.

Proposition 10.38 (Recovery of additive metadata)**.** *The reader $(c, h) \mapsto f_+(c, h)$ is bijective onto the eighteen additive signatures of the emitter. Each preimage in cursor space consists of eighteen initial conditions. The two coordinates are recovered through the following table.*

c	$f_+(c, ES)$	$f_+(c, NO)$
0	988212	212988
1	212645	645212
2	546988	988546
3	889221	221889
4	122564	564122
5	465898	898465
6	898122	122898
7	221456	456221
8	654889	889654

Proof. For each entry, the class recurrence described before the statement is applied over eighteen activations; their groups of three give the six printed digits. For example, from $(c, h) = (4, NO)$ the first nine classes are $4, 3, 2, 1, 0, 8, 7, 6, 5$ and the samples are $6, 5, 4, 3, 2, 1, 9, 8, 7$. The three totals are $15, 6, 24$, which publish $5, 6, 4$. Reversal leaves the second half $1, 2, 2$, yielding 564122. The eighteen strings in the table are distinct, so the reader is injective and enumerates its entire image. For each c there are nine pairs (i, j), one for each i, and for each h there are two directions. This gives $9 \cdot 2 = 18$ conditions per signature and $18 \cdot 18 = 324$ conditions in total. □

Let $A_s = f_+^{-1}(s)$ and $B_e = f_\times^{-1}(e)$ be the cursor classes of the two sheets. The decimal law recovers both signatures of each emission U: if $U_j = 100s_j + 10t_j + u_j$, then $s_j = \lfloor U_j/100 \rfloor$ and $e_j = [t_j - s_j]_{10}$. Consequently, the preimage of U is exactly $A_s \times B_e$. The initial conditions remain in that product; their cardinalities are an additional reading of the same preimage.

Definition 10.39 (Bipartite incidence of the microfiber)**.** For the oriented word $w =$ 010211, form the graph whose vertices in one class are the additive signatures appearing over w and whose vertices in the other class are the multiplicative signatures. An edge (s, e) represents the corresponding emission and preserves as its labeled preimage the product $A_s \times B_e$.

Recovery of the signatures of the five emissions gives the complete table of edges:

s	e	$\lvert A_s \rvert$	$\lvert B_e \rvert$	stratum
564122	555555	18	24	transverse
898122	339555	18	8	positive
898122	393555	18	8	positive
898122	933555	18	8	positive
898465	933717	18	8	return

Theorem 10.40 (Exact decomposition into three components)**.** *The bipartite incidence has three connected components, isomorphic to $K_{1,1}$, $K_{1,3}$ and $K_{1,1}$. Their joint preimage is the disjoint union*

$$A_{564122} \times B_{555555},$$
$$A_{898122} \times (B_{339555} \sqcup B_{393555} \sqcup B_{933555}),$$
$$A_{898465} \times B_{933717}.$$

The respective cardinalities are $432, 432, 144$ *and sum to* 1008*. Decomposition by emissions consists of five products and decomposition by components consists of three sets.*

Proof. The three printed additive signatures are distinct. The five multiplicative signatures are also distinct. Only the three positive edges share a vertex, the one associated with 898122; they form a

connected star with three edges. The other two edges share no vertices with it or with each other, and each forms a component. Preimages of different signatures under a function are disjoint. Factorization of the emitter and distributivity of Cartesian product over that disjoint union prove the three expressions. Their cardinalities are $18 \cdot 24$, $18(8+8+8)$ and $18 \cdot 8$. The five edges remain individually distinguished within those components, with their multiplicity and ordered emission. □

The metadata recovery map gives $(c, h) = (4, NO)$ for the transverse region, $(6, ES)$ for each of the three positive regions and $(5, NO)$ for the return. Thus, orientation, diagonal class, incidence and multiplicity are read from the same signatures produced by the cursors. The distinction between five emissions and three components preserves the complete census structure, including the coincidence of cardinality 432 between two distinct components.

10.5.3 Finite transport and the prolongation boundary

The endomorphisms L_0, L_1 of ternary word space act before Archimedean realization. Their determination begins with the arithmetic state's transitions, not with prescribing two matrices. If U_t is the composite step of selection, transport and update, the observed block satisfies

$$b_j^{\chi} = \Pi_6(x_j^{\chi}), \qquad x_{j+1}^{\chi} = U_{9j+9} \cdots U_{9j+1}(x_j^{\chi}), \qquad \chi \in \{\mathrm{cl}, \mathrm{pr}, \mathrm{au}\}.$$

Six transitions are formed for each regime: two consecutive transitions in each of the three regions. The pairs of source and target matrices obtained in the record are

X_0	Y_0	X_1	Y_1
010211	012222	010211	002111
012222	010211	002111	110221
201101	121221	102011	012222
121221	102011	012222	102011
121200	112202	121020	010210
112202	121020	010210	010200

Each six-digit string represents a row in $\mathbb{F}_3^6$. Since $\det X_0 = 1$ and $\det X_1 = -1$ in $\mathbb{F}_3$, the equations $X_a L_a = Y_a$ uniquely determine $L_a = X_a^{-1} Y_a$. In that row-vector chart we obtain

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \quad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix} \pmod 3.$$

The calendar (L_0, L_0, L_1, L_1) produces four new six-component blocks. Their concatenations form

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30}.$$

The subscripts of w indicate accumulated length. The boundary R_{36} preserves the terminal structure and opens the extension relation; it is not renamed as a final periodic block that could be repeated indefinitely.

The identity $L = X^{-1}Y$ proves uniqueness once the transitions are fixed; it does not replace production of those transitions by U_t. The provenance of their register and examination of the sixteen binary calendars are documented in the technical supplement. The indicated calendar is the only one of those sixteen that jointly reproduces the three sequences of five blocks.

10.5.4 Five closure regions and angular compensation

The closure region contains one transverse component and four companions. The symmetric reader acts on the space of its five positions through

$$P_5 = \frac{1}{5}\mathbf{1}\mathbf{1}^{\mathsf{T}}, \qquad \mathbf{1} = (1,1,1,1,1)^{\mathsf{T}}.$$

Invariance $P_5\lambda = \lambda$ and conservation $\mathbf{1}^{\mathsf{T}}\lambda = 1$ force $\lambda = \mathbf{1}/5$. This normalization distributes unity among reader positions; it does not replace seed multiplicities 432, 144, 144, 144, 144 with uniform frequencies. The reader's elliptic chart realizes each coordinate through $1 + \lambda_j J$; its slope is λ_j, so the primitive slope is $1/5$. The rule passing from a normalized coordinate to a slope is thus made explicit, instead of identifying the two notions without a map. The reader composes the four companion positions by the law

$$a \oplus b = \frac{a+b}{1-ab}. \tag{10.38}$$

This law is obtained by multiplying $(1 + aJ)(1 + bJ)$ in regime $J^2 = -I$ and dividing by its scalar component. Composition of slopes is therefore a realization of TRIT's quadratic structure, not an ordinary sum of four fractions.

Proposition 10.41 (Closure compensator)**.** *Composition of four slopes* $1/5$ *is* $120/119$*. The condition of return to slope one determines a unique positive compensator of the form* $1/q$*, with* $q > 1$*, and gives* $q = 239$*.*

Proof. The first doubling gives $(1/5) \oplus (1/5) = 5/12$; the second, $(5/12) \oplus (5/12) = 120/119$. The condition

$$\frac{120/119 - 1/q}{1 + (120/119)/q} = 1$$

is equivalent to $(120 - 119)q = 120 + 119$, so $q = 239$. □

The resulting closure character has realization

$$\Pi_{\mathrm{cl}} = 4\left(4\arctan\frac{1}{5} - \arctan\frac{1}{239}\right). \tag{10.39}$$

Machin's angular identity recognizes $\Pi_{\mathrm{cl}} = \pi$. The construction direction is precise: the slope and number of compositions are declared by the pentafiber reader; the compensation equation forces 239. Once this character is produced, its evaluation by alternating series does not select the seed orbit anew.

For $0 < x < 1$, the alternating sums

$$A_n(x) = \sum_{j=0}^{n} \frac{(-1)^j x^{2j+1}}{2j+1}$$

enclose $\arctan x$ between two consecutive truncations, with difference $x^{2n+3}/(2n+3)$. Applied to the two slopes of (10.39), they provide rational endpoints with explicit error. The numerical value is thus calculated as a consequence of the exact character, without introducing a target prefix.

10.5.5 Propagation reader and normalization of unity

The propagation region is realized through a formal family $P_t \in \mathcal{A}[[t]]$, where $\mathcal{A}$ is a unital commutative algebra over $\mathbb{Q}$. Its composition satisfies $P_{t+s} = P_t P_s$, with unit $P_0 = 1$, and oriented elementary transport fixes the scalar generator $P_0' = +1$. The condition fixes its sign, not just its magnitude. Writing

$$P_t = \sum_{n \geq 0} a_n t^n,$$

normalization determines $a_0 = a_1 = 1$. Comparing the coefficient of $s^n t$ in $P_{s+t} = P_s P_t$ gives $(n+1)a_{n+1} = a_n a_1$; equivalently, $P_t' = P_t$. Thus,

$$(n+1)a_{n+1} = a_n, \qquad a_n = \frac{1}{n!}. \tag{10.40}$$

The character at one parameter unit is $\Pi_{\mathrm{pr}} = P_1$, subsequently recognized as e.

Normalization of the generator matters. Without that datum the semigroup law would admit $P_t = e^{ct}$ for different c; hence the condition fixing the parameter unit in the reader is not omitted. This condition precedes decimal comparison and belongs to exposition of the operational rule, not to selection of an experimental value.

Proposition 10.42 (Rational propagation bounds)**.** *For $n \geq 1$, let $E_n = \sum_{j=0}^{n} 1/j!$. Then*

$$E_n < \Pi_{\mathrm{pr}} < E_n + \frac{n+2}{(n+1)(n+1)!}.$$

Proof. The first omitted term is $1/(n+1)!$. Each subsequent ratio is at most $1/(n+2)$. The geometric sum majorizing the tail is

$$\frac{1}{(n+1)!}\frac{1}{1-1/(n+2)} = \frac{n+2}{(n+1)(n+1)!}.$$

The strict inequality follows from the decrease of successive ratios. □

10.5.6 Modal incidence and generation of self-scaling

The tritic selector produces the cycle $(+1, -1, 0)$. In modes Σ, Π, the rule is $+1 : m \mapsto \Sigma$, $-1 : m \mapsto \Pi$, $0 : m \mapsto m$. With cyclic closure, the observed mode is (Σ, Π, Π). Its edges are $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$. Its incidence, in that mode order, is therefore

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{10.41}$$

The four entries are obtained from the calendar, not from an equation that previously received the value of φ. Repetition of the calendar gives counts $3F_{\mathrm{av}}, 9F_{\mathrm{av}}, 36F_{\mathrm{av}}$ at lengths nine, twenty-seven and one hundred and eight. These counts are not powers of the matrix.

Theorem 10.43 (Positive self-scaling character)**.** *The incidence* (10.41) *has a unique strictly positive eigenray. Normalizing it as $(1, x)^{\mathsf{T}}$, its coordinate x satisfies $x^2 - x - 1 = 0$, $x > 0$, and is $\varphi = (1+\sqrt{5})/2$.*

Proof. The eigenvalue equation gives $x = \lambda$ and $1 + x = \lambda x$. Eliminating λ produces the polynomial. Only one of its two roots is positive. Since F_{av}^2 has all entries positive, the positive ray is unique and simple. The radical expression recognizes the resulting coordinate; it does not participate in production of F_{av}. □

With $F_0 = 0, F_1 = 1, F_{n+1} = F_n + F_{n-1}$, the incidence induces, for $n \geq 1$,

$$F_{\mathrm{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}.$$

The consecutive ratios F_{n+1}/F_n alternate around φ. The determinant identity

$$F_{n+1}^2 - F_n F_{n+2} = (-1)^n$$

gives an exact width $1/(F_n F_{n+1})$ between two consecutive ratios. Their growth makes this rational bracket arbitrarily small.

The measure on all compatible histories does not coincide with the mode frequency of the three-event calendar. The chronological frequency is $(1/3, 2/3)$. The measure of maximal entropy of the symbolic envelope defined by F_{av} is constructed from its eigenvectors and has weight ratio φ^{-2}. The latter enters the areal–volumetric reading; it is not obtained merely by replacing one counting frequency with another.

10.5.6.1 Trajectory space and invariant measure between sheets

The toroidal topology of APP fixes the support of cardinal translations and their winding classes. The correspondence between sheets comes from another operation on that same support: temporal selection of the additive or multiplicative evaluation. Its geometric typing is

$$\eta_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \eta_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

The first sheet corresponds to the additive boundary reading; the second, to the multiplicative interior reading. This map transports the mode labels and preserves the incidence (10.41). The square of the self-scale ratio is determined through the trajectories of that incidence.

Definition 10.44 (Memory-one symbolic envelope)**.** Let

$$X_{\mathrm{av}} = \{(s_k)_{k\in\mathbb{Z}} \in \{\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}}\}^{\mathbb{Z}} : (F_{\mathrm{av}})_{s_k, s_{k+1}} = 1 \text{ for every } k\}.$$

The index shift acts on this space. It is the smallest memory-one symbolic system containing the modal sequences and preserving their consecutive pairs: it admits both cross transitions and volumetric self-retention. Phase, cardinal orientation and trajectory registers remain in the TPK state from which this envelope is obtained.

Proposition 10.45 (Weighting of trajectories between sheets)**.** *In areal–volumetric order, the invariant measure of maximal entropy of X_{av} has transition matrix and stationary distribution*

$$P_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}, \qquad (\mu_{\mathrm{ar}}, \mu_{\mathrm{vol}}) = \frac{(1, \varphi^2)}{1+\varphi^2}. \tag{10.42}$$

In particular, $\mu_{\mathrm{ar}}/\mu_{\mathrm{vol}} = \varphi^{-2}$.

Proof. The already constructed incidence has positive eigenvector $r = (1, \varphi)^{\mathsf{T}}$ and eigenvalue φ. The normalization

$$(P_{\mathrm{av}})_{ij} = \frac{(F_{\mathrm{av}})_{ij} r_j}{\varphi r_i}$$

gives the indicated matrix. Its rows sum to one by $\varphi^{-2} + \varphi^{-1} = 1$. Symmetry of F_{av} implies that weights proportional to r_i^2 satisfy detailed balance; therefore, $\mu P_{\mathrm{av}} = \mu$. Irreducibility and volumetric self-retention determine a unique stationary distribution.

To verify maximality, every allowed transition satisfies $\log(P_{\mathrm{av}})_{ij} = \log r_j - \log r_i - \log \varphi$. Under any invariant measure, the endpoint terms cancel on average. If ν_i are its vertex weights and $q_i(j) = \nu(s_1 = j \mid s_0 = i)$, for $\nu_i > 0$, then

$$h_\nu \le H_\nu(s_1 \mid s_0) = \log \varphi - \sum_{i:\nu_i>0} \nu_i D(q_i \| P_i) \le \log \varphi,$$

where $D(q\|p) = \sum_j q_j \log(q_j/p_j)$ is the relative entropy on allowed pairs and $0 \log 0 = 0$ is adopted. The Markov measure of (10.42) attains the bound. Equality in the first inequality requires the Markov property; equality in the second requires $q_i = P_i$. Stationarity and irreducibility then fix μ, establishing uniqueness. This is the Parry measure of the defined envelope. □

The frequency $(1/3, 2/3)$ counts the instants of the primitive calendar; μ weights the trajectories of the envelope. Its quadratic ratio expresses the product of incoming and outgoing incidence amplitudes. TPK memory and phase restrictions retain their own domain; the envelope's entropy corresponds to the symbolic system specified in this definition.

10.5.6.2 Closure operator and limit of marked returns

The closure coordinate π, generated by the regional reader, enters after construction of modal incidence. Let $e_{\mathrm{ar}} = (1, 0)^{\mathsf{T}}$, $e_{\mathrm{vol}} = (0, 1)^{\mathsf{T}}$ and $P_i = e_i e_i^{\mathsf{T}}$ be the sheet projectors. The reader's conditions are preservation of both sheets, unit volumetric normalization and areal mark equal to the closure coordinate. These conditions determine the positive operator

$$D_\pi = \pi P_{\mathrm{ar}} + P_{\mathrm{vol}} = \begin{pmatrix} \pi & 0 \\ 0 & 1 \end{pmatrix}. \tag{10.43}$$

Diagonality expresses preservation of sheets and the two entries express their normalizations; uniqueness of the operator for the fixed reader is thus explicit.

Proposition 10.46 (Ratio of boundary returns)**.** *For $n \geq 1$, the marked evaluation*

$$\Theta_n = \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}} \rangle} = \pi \frac{F_{n-1}}{F_{n+1}} \tag{10.44}$$

satisfies

$$\lim_{n \to \infty} \Theta_n = \pi \frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \frac{\pi}{\varphi^2}. \tag{10.45}$$

Proof. The diagonal entries of F_{av}^n count paths of length n returning to their initial sheet. The already proved power formula provides F_{n-1} and F_{n+1}. The operator D_π multiplies the first count by π. Finally, F_{n-1}/F_{n+1} is the product of two consecutive ratios converging to φ^{-1}; its limit is φ^{-2}. The identity with the weight ratio follows from (10.42). □

The closure operator appears only once, in the terminal evaluation of the return. The transfer F_{av} remains determined by the calendar. This composes information from two readers of the same state: modal incidence determines the quadratic weighting and the closure region contributes its coordinate to the boundary.

The composition also preserves refinement. For positive cylinders $I = [a, b]$ and $J = [c, d]$, the image under the reader $\mathcal{R}(x, y) = x/y^2$ is the interval

$$Q(I, J) = \left[\frac{a}{d^2}, \frac{b}{c^2} \right].$$

Monotonicity in each argument proves that the nested cylinders of closure and self-scale produce nested intervals of the ratio; positivity of their limits and contraction of their diameters determine π/φ^2. The scalar expression thus retains a chain of operations compatible with depth, subsequently applied in its two orientations.

After the characters are generated, the two orientations of the reader

$$R(x, y) = \frac{x}{y^2}$$

provide

$$\rho_A = \frac{\pi}{\varphi^2}, \qquad \rho_E = \frac{\varphi}{\pi^2}, \qquad \varphi^3 \rho_A^2 \rho_E = 1. \tag{10.46}$$

The second expression enters the exponent of the electronic construction in Section 16.2.1.1. The first is also obtained as the limit of the marked reading $\pi F_{n-1}/F_{n+1}$. Exchanging arguments relates the two, but does not turn a reparametrization of the electronic equation into a second independent derivation of all its coefficients.

10.5.7 Exponential realizations of the generated coordinates

The already determined regional coordinates allow the specific realizations of TRIT's quadratic family to be recognized. The order is substantive: construction of the regions precedes evaluation of an exponential at parameters π or $2\log\varphi$. These expressions identify the function of the coordinates in operators constructed from APP and TPK; they do not enter into selection of the prefixes producing them.

10.5.7.1 Ternary cycle, nilpotent transport and sheet incidence

Multiplication $a(r) = 4r$ in $\mathbb{Z}/9\mathbb{Z}$ has order 3. On the units it determines the orbits $\{1, 4, 7\}$ and $\{2, 8, 5\}$. In the augmentation module of either, formed by integer combinations whose coefficients sum to zero, the basis $(e_r - e_{4r}, e_{4r} - e_{7r})$ gives

$$C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad C^2 + C + I = 0.$$

The restricted form has Gram matrix $\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$. In residue evaluations modulo 9, the action distinguishes the sheets: $S(ax, ay) = aS(x, y)$, whereas $P(ax, ay) = a^{-1}P(x, y)$. The cyclic realization therefore preserves a contragredient orientation between sum and product. The quotients of the integer lift are preserved in the corresponding arithmetic register.

Elementary parabolic transport is represented by

$$N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

The areal–volumetric incidence already constructed in (10.41) provides

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad A = F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}.$$

The three operators act on declared real spaces: the augmentation module tensored with $\mathbb{R}$, the nilpotent-transport plane and the modal-incidence plane. Sharing matrix dimension does not identify these spaces or their coordinates.

Proposition 10.47 (Concrete generators of the three types)**.** *The operators*

$$J_{\mathrm{e}} = \frac{2C + I}{\sqrt{3}}, \qquad J_{\mathrm{p}} = N, \qquad J_{\mathrm{h}} = \frac{2A - 3I}{\sqrt{5}}$$

satisfy, respectively,

$$J_{\mathrm{e}}^2 = -I, \qquad J_{\mathrm{p}}^2 = 0, \qquad J_{\mathrm{h}}^2 = I.$$

Proof. The relation in C implies $(2C + I)^2 = -3I$. Direct multiplication gives $N^2 = 0$. Finally, A has trace 3 and determinant 1, so $A^2 - 3A + I = 0$ and $(2A - 3I)^2 = 5I$. □

Proposition 10.48 (Three evaluations of the exponential identity)**.** *In the preceding realizations,*

$$\boxed{\exp(\pi J_{\mathrm{e}}) + I = 0, \qquad \exp(J_{\mathrm{p}}) = I + J_{\mathrm{p}}, \qquad \exp(2\log\varphi\, J_{\mathrm{h}}) = F_{\mathrm{av}}^2.} \tag{10.47}$$

Proof. The elliptic specialization of the tritic exponential gives $\cos \pi\, I + \sin \pi\, J_{\mathrm{e}} = -I$. Nilpotency removes exactly the terms of degree at least 2 in the second expression. For the third, $\varphi^2 = \varphi + 1$ implies

$$\cosh(2 \log \varphi) = \frac{3}{2}, \qquad \sinh(2 \log \varphi) = \frac{\sqrt{5}}{2}.$$

Therefore, the exponential equals $\frac{3}{2} I + \frac{\sqrt{5}}{2} J_{\mathrm{h}} = A$. □

The first equality represents the elliptic half-turn; the full turn satisfies $\exp(2\pi J_{\mathrm{e}}) = I$. The second retains a nonzero linear term: the parabolic regime expresses transport, not absence of evolution. The third realizes a unimodular hyperbolic advance. Its eigenvalues are φ^2 and φ^{-2}; one direction expands and the other contracts while preserving the determinant. The three evaluations use distinct parameters of a common exponential family.

In that family, e enters through the scalar evaluation $\exp(I) = eI$ and the law $\exp(sI)\exp(tI) = \exp((s+t)I)$. Its role is not restricted to the parabolic type. The coordinate e, previously obtained from its region, is recognized here as the unit evaluation of the exponential; this identity does not replace its coinductive genealogy.

10.5.7.2 Polynomial resolution of the regimes

The three realizations admit a compact presentation on the direct sum of their spaces. Define

$$\mathbb{J} = J_{\mathrm{e}} \oplus J_{\mathrm{p}} \oplus J_{\mathrm{h}}, \qquad Q = \mathbb{J}^2.$$

The preceding relations imply

$$\mathbb{J}^6 = \mathbb{J}^2, \qquad Q^3 = Q.$$

Use of Q keeps this operator square separate from the dodecaphasic register K.

Proposition 10.49 (Polynomial regime projectors)**.** *The maps*

$$p_{\mathrm{e}} = \frac{Q^2 - Q}{2}, \qquad p_{\mathrm{p}} = I - Q^2, \qquad p_{\mathrm{h}} = \frac{Q^2 + Q}{2}$$

are mutually orthogonal idempotents, sum to I and recover the three summands of the representation.

Proof. The three polynomials take values $(1,0,0)$, $(0,1,0)$ and $(0,0,1)$ at the points $-1, 0, +1$, respectively. The differences between their squares and themselves, as well as their cross products, are multiples of $X^3 - X$. Substituting Q, which annihilates that polynomial, proves the identities. On the three blocks, Q acts as $-I, 0, I$. □

We thus obtain

$$\begin{aligned} \exp(t\mathbb{J}) = {} & p_{\mathrm{e}}(\cos t\, I + \sin t\, \mathbb{J}) + p_{\mathrm{p}}(I + t\mathbb{J}) \\ & + p_{\mathrm{h}}(\cosh t\, I + \sinh t\, \mathbb{J}). \end{aligned} \tag{10.48}$$

Each summand preserves its quadratic relation and conjugation reverses its evolution. The total representation combines the three regimes, but does not by itself define a transition operator between them. Such a transition requires the TPK transport maps with their domains, orientation and memory. Exponential articulation allows their types to be recognized without replacing that dynamics with identification of the fibers.

10.5.8 Compatible cylinders and arbitrary depth

The realization of a ternary block $b = (b_1, \dots, b_6)$ is the integer

$$\nu(b) = \sum_{j=1}^{6} b_j 3^{6-j} \in \{0, \dots, 728\}.$$

A sequence of blocks defines integer prefixes by $N_{n+1} = 729N_n + \nu(b_{n+1})$, starting at $N_0 = m$, where m is the integer part determined by the reader. The preceding brackets place the closure, propagation and self-scale characters in $(3, 4)$, $(2, 3)$ and $(1, 2)$, respectively; their initial values are therefore $m = 3, 2, 1$. Subsequent blocks refine the fractional part. The corresponding cylinder is

$$I_n = \left[\frac{N_n}{729^n}, \frac{N_n + 1}{729^n} \right], \qquad |I_n| = 729^{-n}. \tag{10.49}$$

The half-open convention is used to select a representative when a value falls on a boundary. Passage to the limit uses the closures of these intervals and identifies the two equivalent boundary expansions. This precision prevents assuming that every intersection of nested half-open intervals is automatically nonempty.

Theorem 10.50 (Determination of the scalar realization)**.** *A compatible block history determines a unique limit of the left endpoints of* (10.49)*. If an exact character has rational brackets of arbitrarily small width and is separated from the boundary of each decimal cylinder examined, each decimal prefix of finite length is determined after a finite calculation. The prefixes thus obtained are mutually compatible.*

Proof. Extension by a block preserves the preceding prefix by Euclidean division. The closed cylinders are nested and their diameter tends to zero; their left endpoints form a Cauchy sequence and have a unique limit. For a fixed decimal length, a value separated from the partition boundaries has positive distance from them. A sufficiently narrow bracket lies within a unique cell and determines its prefix. Uniqueness of the cell and nesting of the partitions prove compatibility under truncation. At points with a terminating expansion, the exact boundary decision and its representation convention must be added; that decision does not follow from a numerical width alone. □

Corollary 10.51 (Finite determination and compatibility of regional prefixes)**.** *For each of the realizations π, φ, e and every finite decimal length, the constructed brackets determine the corresponding prefix through a finite calculation. Prefixes obtained at different depths are compatible under truncation.*

Proof. The closure, propagation and self-scale characters have the preceding brackets. After their recognition, irrationality of π, e, φ guarantees their separation from the rational boundaries of each finite decimal partition. The preceding theorem is applied to each character. □

Arbitrary depth expresses the quantifier of the corollary: for every finite horizon there is a calculation determining its prefix. The mathematical object is the complete compatible family; each run obtains a finite projection of it.

10.5.9 Mirror involution and synchronization of the regions

The nonadic connection jointly transports the three characters. In the ninth-phase chart, the self-scale axis and ternary sum of closure and propagation remain fixed under mirror exchange. Helical inversion changes the transport direction; the two-channel mirror changes their relative orientation. They are different involutions, although both act on the same trajectory system.

Census coincidences illustrate this coordination:

Phase	N_π	N_e	N_φ	Equality of counts
4	207	207	122	$N_\pi = N_e$
5	39	151	151	$N_e = N_\varphi$
6	110	110	69	$N_\pi = N_e$
7	81	29	81	$N_\varphi = N_\pi$
8	59	59	59	triple synchronization
9	43	43	43	triple synchronization

These integers count compatible coordinates of the regions. They do not assert equality between π, e and φ as real numbers. If

$$\partial(a, b, c) = (a - b, b - c, c - a),$$

its image belongs to the lattice $A_2 = \{(u, v, w) \in \mathbb{Z}^3 : u + v + w = 0\}$. In phases eight and nine the relative component vanishes, but the diagonal component changes from $(59, 59, 59)$ to $(43, 43, 43)$. Relative synchronization coexists with a shift of -16 per channel. The closure leading to α must preserve both pieces of information: relative coincidence and evolution of memory.

10.5.10 Sturmian helical suspension

The relation between bases nine and ten of the completion defines the dimensionless parameter

$$\delta = \frac{\log(10/9)}{\log 10}. \tag{10.50}$$

It is not obtained from a target physical constant. It is the relative logarithmic scale of two bases already present in the construction. Its use as a symbolic reading of refinement has an exact consequence.

Lemma 10.52 (Irrationality of the slope)**.** *The number δ is irrational.*

Proof. If $\delta = p/q$, $q > 0$, then $(10/9)^q = 10^p$ and $9^q = 10^{q-p}$. Factorization of the left-hand side contains the prime three and that of the right-hand side only the primes two and five. The equality is impossible. □

The lower mechanical word, with intercept θ, is

$$z_n(\theta) = \lfloor (n + 1)\delta + \theta \rfloor - \lfloor n\delta + \theta \rfloor \in \{0, 1\}.$$

It is obtained by observing the rotation $\theta \mapsto \theta + \delta \pmod 1$ through the interval $[1 - \delta, 1)$. The event sequence has density δ, and the sum over any window of length L equals $\lfloor L\delta \rfloor$ or $\lceil L\delta \rceil$. Since $21 < 1/\delta < 22$, event gaps are twenty-one or twenty-two. The word indicating which intervals are short is another mechanical word of slope $\sigma = 22 - 1/\delta$; its events are separated by six or seven primary intervals. The second scale is induced by the first, not a second free parameter.

10.5.10.1 Capacity index, vacancies, and induction of the tritic regime

The vacancy sequence is linked to refinement through an increment identity. To show it, fix the phase origin $\theta = 0$. Let

$$\rho = \log_{10} 9 = 1 - \delta, \qquad C_t = \lfloor (t + 1)\rho \rfloor \quad (t \geq 0).$$

The index C_t expresses the decimal capacity of refinement in the normalization comparing a ternary block of 6 positions, with 729 possibilities, and a decimal block of 3 positions, with 1000 possibilities. Indeed, $\log_{1000} 729 = \log_{10} 9 = \rho$. The letter K is reserved for the dodecaphasic register to be constructed later.

Proposition 10.53 (Complementarity of capacity and vacancy)**.** *For $t \geq 1$,*

$$C_t - C_{t-1} = 1 - z_t(0). \tag{10.51}$$

Consequently, if $0 \leq a < b$,

$$C_b - C_a + \sum_{t=a+1}^{b} z_t(0) = b - a.$$

Proof. Irrationality of δ gives

$$C_t = t + 1 - \lceil (t+1)\delta \rceil = t - \lfloor (t+1)\delta \rfloor.$$

Subtracting two consecutive terms produces (10.51). The sum over the interval telescopes. □

Each transition increases the block counter by one unit. If $z_t = 0$, capacity also increases; if $z_t = 1$, capacity remains unchanged while a transition is incorporated into the history. Vacancy is here an event of capacity retention, with a determined position and antecedent. The preceding balance exactly preserves length between acquired capacity and recorded vacancies. The observed phase $g_t^{\mathrm{cap}} = [C_t]_9$ satisfies

$$g_t^{\mathrm{cap}} - g_{t-1}^{\mathrm{cap}} \equiv 1 - z_t \pmod 9.$$

This capacity phase and the chronological phase $[t]_9$ are two different observations. Local capacity retention and a complete holonomy turn have distinct mechanisms, although both allow phase observation to be preserved while the state changes.

The relation to TRIT can be followed in the vacancy positions themselves. For $j \geq 1$, define

$$p_j = \left\lfloor \frac{j}{\delta} \right\rfloor, \qquad v_j = C_{p_j}, \qquad h_j = p_{j+1} - p_j.$$

The inequality $p_j\delta < j < (p_j + 1)\delta$ identifies p_j as the position of event j. Since $0 < \delta < 1$, it also gives $\lfloor (p_j + 1)\delta \rfloor = j$, and therefore

$$v_j = p_j - j, \qquad v_{j+1} - v_j = h_j - 1.$$

If $s_j = 22 - h_j$, then $s_j \in \{0, 1\}$ and

$$[v_{j+1}]_3 = [v_j - s_j]_3. \tag{10.52}$$

An interval of length 22 preserves the class; one of length 21 shifts it one unit in the negative direction. The canonical selector is applied to the positive phase $r_j = 1 + [v_j]_9$:

$$\tau_j = M_{\mathrm{ph}}(r_j).$$

A tritic regime is thus determined by the capacity index retained at each event, in addition to binary encoding of the vacancy.

The short-interval positions form the induced mechanical encoding of slope $22 - 1/\delta$. Their gaps 6 and 7 determine the lengths of the plateaus of class $[v_j]_3$, once the origin and endpoint convention are fixed. The first classes are 2 for 6 events, 1 for 7 and 0 for 7; the first segment of 6 is the initial restriction of a plateau. Their signatures run through $0, -1, +1$. Equations (10.51) and (10.52) make explicit the link between refinement, vacancies and regime selection. The quadratic TRIT reading then realizes these types through their respective generators; the temporal event and its geometric representation thus retain an identifiable dependence.

Inverting the monotone index provides another useful observation:

$$\mathcal{T}(k) = \min\{t : C_t = k\} = \left\lceil \frac{k}{\rho} \right\rceil - 1 \qquad (k \geq 1).$$

If $\sigma = \rho^{-1} - 1$, the number of blocks needed to gain m units of capacity is

$$\mathcal{T}(k+m) - \mathcal{T}(k) = m + \lceil (k+m)\sigma \rceil - \lceil k\sigma \rceil \in \{m + \lfloor m\sigma \rfloor, m + \lceil m\sigma \rceil\}.$$

In particular, 9 units of capacity require 9 or 10 blocks. The period of a finite phase remains exact, while the return time measured by the other index admits two values. This distinction is part of refinement dynamics, not an a posteriori correction of its numerical values.

Theorem 10.54 (Complexity of phase readings)**.** *For $m \geq 1$, the mechanical word has factor complexity $p(m) = m + 1$. Retaining phase n mod 9 gives complexity $p_9(m) = 9(m+1)$; retaining only its ternary class gives $p_3(m) = 3(m+1)$. All three topological entropies are zero.*

Proof. For factors of length m, the predecessors of the two endpoints of the coding interval form $m + 1$ distinct points on the circle: coincidence between shifted endpoints removes duplications and irrationality prevents additional coincidences. These points determine $m + 1$ intervals with constant and distinct itineraries. Every irrational orbit visits each interval, whence $p(m) = m + 1$.

With a phase modulo nine fixed, positions of that phase follow a rotation of step 9δ, also irrational. By density, all factors appear in each phase, and the first coordinate distinguishes their nine copies. The same argument with step 3δ gives three copies after ternary reduction. Finally, $m^{-1} \log(c(m+1)) \to 0$ for $c = 1, 3, 9$. □

The phase product $C_9 \times \mathbb{T}$, translated by $(1, \delta)$, has frequency characters

$$\frac{a}{9} + k\delta \pmod 1, \qquad a \in \mathbb{Z}/9\mathbb{Z},\ k \in \mathbb{Z}.$$

The spectral module is not log 10: it is the additive module generated by $1/9$ and δ, modulo the integers. The factor log 10 belongs to normalization of (10.50).

An operator presentation makes memory explicit. On $\ell^2(\mathbb{Z})$, let $T|n\rangle = |n+1\rangle$, $V_9|n\rangle = \zeta_9^n|n\rangle$, $W_\delta|n\rangle = e^{2\pi i n\delta}|n\rangle$ and $D_M|n\rangle = \lfloor n/9 \rfloor |n\rangle$. On finitely supported vectors,

$$V_9 T = \zeta_9 T V_9, \qquad W_\delta T = e^{2\pi i \delta} T W_\delta, \qquad [D_M, T^9] = T^9. \tag{10.53}$$

The first two relations are Weyl covariances; the third expresses that a nonadic turn increases the memory degree. The base rotation is abelian, while the algebra of observables and translations is not. Inversion $|n\rangle \mapsto |-n\rangle$ conjugates forward motion to backward motion. This realization provides an aperiodic helical suspension with finite phase return, not a periodic word of length nine.

For this count we fix the intercept $\theta = 0$ and accumulated endpoints $(N_0, \ldots, N_4) = (0, 729, 972, 999, 1000)$, corresponding to the cubic order $(729, 243, 27, 1)$. The lower counts are $\lfloor N_j\delta \rfloor - \lfloor N_{j-1}\delta \rfloor$, giving $(33, 11, 1, 0)$. The upper counts are $\lceil N_j\delta \rceil - \lceil N_{j-1}\delta \rceil$, with the same zero initial boundary, giving $(34, 11, 1, 0)$. These values depend on the intercept and stratum order; they are not asserted for an arbitrary initial phase. Their totals are forty-five and forty-six. The increment corresponds to a single boundary unit, located in the first stratum of this ordered partition. The numbers thirty-four and eleven thus appear in the same count preceding any units chart; identifying them with physical exponents additionally requires the corresponding dimensional derivation.

The designation *aperiodic crystal* is used here for this symbolic order, with specified complexity, spectrum and return. Zero topological entropy does not by itself equal zero physical dissipation: a

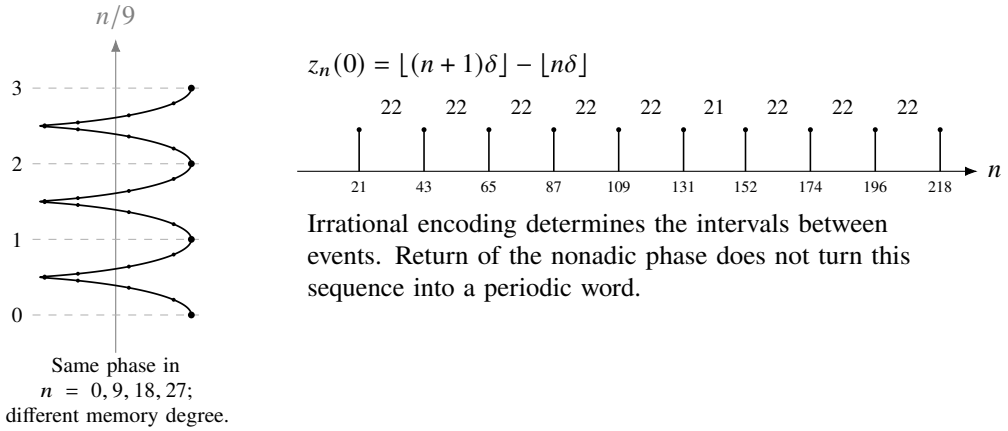

Figure 10.2: Complementary representations of transport. Left, projection of the helix $(\cos(2\pi n/9), \sin(2\pi n/9), n/9)$: advancing nine steps recovers phase and increases height. Right, the first ten events of the lower word for $\delta = \log_{10}(10/9)$, with exact gaps 21 or 22. The helical representation introduces no additional physical metric.

thermodynamic realization requires defined energetic dynamics and an erasure operation. Likewise, this Sturmian reading does not replace all TPK operators or by itself prove periodicity or aperiodicity of the complete output of α. Its function is to make explicit an order structure that mere calendar return does not describe.

10.5.11 Nonadic connection, holonomy and monodromy representation

The already constructed regional connection is now studied through three objects: transport of the complete state, the representation of its turns, and the suspension of its itineraries. The APP–TRIT–TPK operations and the initial catalog retain their preceding definitions. The necessary distinction here concerns what each representation retains of the same history (Sections 4.3 and 10.5).

At prolongation index k, a state chart preserves

$$\widehat{x}_k = (B_k, C_k, p_k, c_k, \Sigma_k, W_k, g_k, m_k).$$

Here B_k combines the three regional blocks, C_k is the cylinder, p_k the prefix, c_k the carry register, Σ_k the boundary signature and W_k the incidence information. The phase is $g_k = 1 + [(k-1)]_9$; m_k counts complete turns. The reduction $\beta_k = [m_k]_{12}$ preserves the dodecaphasic position, while the integer m_k distinguishes its successive turns.

Definition 10.55 (Transport of a nonadic turn)**.** Let $\mathcal{R}_k \subseteq \widehat{X}_k \times \widehat{X}_{k+1}$ be the admissible extension relations of TPK. The realization of holonomy at level k is the relational composition

$$\Gamma_{9,k} = \mathcal{R}_{k+8} \circ \cdots \circ \mathcal{R}_k.$$

For $s \geq 1$, its prolongation to s turns is

$$\Gamma_{9s,k} = \Gamma_{9,k+9(s-1)} \circ \cdots \circ \Gamma_{9,k}.$$

The relational formulation preserves admissible continuations. On an individualized history, each arrow leads to the state actually prolonged; the isolated visible block may still admit more than one continuation. This difference is precisely the function of memory and boundary conditions in determining the trajectory.

Proposition 10.56 (Iteration of return and accumulated memory)**.** *In every admissible composition of s turns,*

$$g_{k+9s} = g_k, \qquad m_{k+9s} = m_k + s, \qquad \beta_{k+9s} = \beta_k + s \pmod{12}.$$

Proof. The one-turn rule preserves phase and increments the counter by one unit. Applying it to the already transported state repeats exactly these two operations. Induction gives the first two equalities; reducing the second modulo 12 gives the third. □

The counter thus provides an integer witness to the difference between turns. After 12 turns the pair of finite phases is restored, but the counter increases by 12. The nonsplit extension (4.33) expresses calendar composition through its cocycle; the trajectory also preserves the integer lift of that datum. Conservation here means transport of prior contributions, not immobility of all coordinates.

10.5.11.1 Bilateral representation of the return index

The shift T of (10.53) admits an expression in phase and turn coordinates. Number the phases from 0 to 8, by shifting the origin relative to g_k, and write $k = 9m + r$, with $0 \le r < 9$, on the integer line covering the phase cycle. On $\mathcal{H}_{\mathrm{ind}} = \ell^2(\mathbb{Z})$, the basis $|k\rangle = |r, m\rangle$ expresses that same unit shift

$$T|r, m\rangle = \begin{cases} |r + 1, m\rangle, & r < 8, \\ |0, m + 1\rangle, & r = 8. \end{cases}$$

The inverse decreases r by one unit when $r > 0$, and takes $|0, m\rangle$ to $|8, m - 1\rangle$. Passing through the phase origin therefore incorporates the exact quotient unit.

Proposition 10.57 (Representation of the cycle's monodromy)**.** *Let $S = T^9$. Then*

$$S|r, m\rangle = |r, m + 1\rangle, \qquad \mathbb{Z} \longrightarrow \mathcal{U}(\mathcal{H}_{\mathrm{ind}}), \quad s \longmapsto S^s$$

is a faithful unitary representation of the cycle's turn group.

Proof. Nine shifts preserve the remainder of division by 9 and increment the quotient. The powers satisfy $S^{s+t} = S^s S^t$, and $S^s|r, m\rangle = |r, m + s\rangle$ distinguishes every integer s. Permutation of an orthonormal basis is unitary. □

This representation corresponds to the covering of the cycle, whose turn group is $\mathbb{Z}$, and represents phase with its counter. The TPK state also contains the trajectory coordinates already described. The bilateral extension admits negative indices as coordinates of the covering; a trajectory starting from an initial condition uses its admissible half-axis. An operator inverse of the index is thus available without turning each extension relation into a bijection of the complete state.

With $D_M|k\rangle = \lfloor k/9 \rfloor |k\rangle$, the identity $[D_M, S] = S$ expresses the memory increment on the dense domain of finitely supported vectors. If $\mathcal{I}|k\rangle = |-k\rangle$ and P_0 projects onto indices divisible by 9, we also obtain

$$\mathcal{I}T\mathcal{I} = T^{-1}, \qquad \mathcal{I}D_M\mathcal{I} = -D_M - (I - P_0). \tag{10.54}$$

Indeed, for $k = 9m + r$, $\lfloor -k/9 \rfloor = -m$ if $r = 0$ and equals $-m - 1$ if $r > 0$. Inversion thus preserves the boundary term of Euclidean division.

10.5.12 Block clock and capacity clock

The index of a refinement map and the number of available decimal positions have related but different laws. To express them, reserve n for the ternary-block index and define

$$\rho = \log_{1000} 729 = \log_{10} 9, \qquad \delta = 1 - \rho, \qquad C_n = \lfloor (n+1)\rho \rfloor, \quad n \geq 0.$$

The letter C_n here denotes capacity, not the dodecaphasic register K. At the canonical phase origin, the preceding mechanical word provides

$$Z_n = \sum_{j=0}^{n} z_j(0) = \lfloor (n+1)\delta \rfloor.$$

Proposition 10.58 (Exact balance between capacity and vacancies)**.** *For $n \geq 0$ and, in the second identity, $n \geq 1$,*

$$C_n = n - Z_n, \qquad C_n - C_{n-1} = 1 - z_n(0).$$

Proof. Irrationality of δ implies $\lceil (n+1)\delta \rceil = \lfloor (n+1)\delta \rfloor + 1$. Then

$$\lfloor (n+1)(1-\delta) \rfloor = n + 1 - \lceil (n+1)\delta \rceil = n - Z_n.$$

Subtracting two consecutive identities completes the proof. □

An event $z_n = 1$ adds a block to the history while preserving capacity C_n; an event $z_n = 0$ increments both counters. In any interval, capacity increments and vacancies sum to exactly its length. Reducing modulo q, for $q = 9$ or $q = 108$, gives

$$[C_n]_q = [n]_q - [Z_n]_q.$$

Uniform block phase and capacity phase are related through integrated vacancy memory. In particular, capacity retention and a complete turn of the connection have distinct mechanisms, although both can preserve a phase observation.

Monotone inversion of the clock gives a first arrival time:

$$T_{\mathrm{cap}}(a) = \min\{n : C_n = a\} = \left\lceil \frac{a}{\rho} \right\rceil - 1, \qquad a \geq 1.$$

With $\sigma = \rho^{-1} - 1$, the time spent gaining b units of capacity is

$$T_{\mathrm{cap}}(a+b) - T_{\mathrm{cap}}(a) = b + \lceil (a+b)\sigma \rceil - \lceil a\sigma \rceil.$$

The difference of ceilings takes one of the two integers adjacent to $b\sigma$. This yields 9 or 10 blocks to gain 9 units of capacity, and 113 or 114 to gain 108. These are times of the inverse clock, measured from a first arrival; the turn counter is always interpreted in the index to which it belongs.

10.5.13 Symbolic suspension and aperiodic time crystal

Rotation encoding combines phase periodicity, local recurrence and global aperiodicity. Let $\mathcal{X}_\delta \subseteq \{0,1\}^{\mathbb{Z}}$ be the closure, in the product topology, of the translates of the bilateral word $z_n(\theta)$. Denote by σ_{sh} the shift of its sequences. Retaining a nonadic phase, the step is

$$F(r, z) = ([r+1]_9, \sigma_{\mathrm{sh}} z), \qquad (r, z) \in C_9 \times \mathcal{X}_\delta.$$

Definition 10.59 (Symbolic aperiodic time crystal)**.** The unit-roof suspension of the preceding system is the space

$$\mathcal{S}_\delta = \big((C_9 \times \mathcal{X}_\delta) \times \mathbb{R}\big)/\!\sim, \qquad (y, t+1) \sim (Fy, t),$$

with flow $\Phi_s[y,t] = [y, t+s]$. This temporal-order model, together with its vacancy encoding and turn-counter representation, is called a *symbolic aperiodic time crystal*.

The adjective temporal designates the action of the flow and of its return section; aperiodicity characterizes its itineraries. The frequency of ones in each sequence is δ: the uniform discrepancy bound of less than one, obtained by telescoping in any window, persists upon taking the closure. A periodic sequence would have a rational frequency. Therefore, $\mathcal{X}_\delta$ contains no periodic orbits. The suspension also has no closed orbits: a return of the flow would require an integer time and periodicity of the itinerary.

Finite words do recur. The itineraries of length m arise from a partition of the circle by $m+1$ points; each interval is visited recurrently by the irrational rotation. Even when times are restricted to a fixed phase, the step 9δ remains irrational. This is why each word appears in the 9 phases and why the complexities already established are

$$p(m) = m+1, \qquad p_9(m) = 9(m+1), \qquad p_3(m) = 3(m+1).$$

The recurrence of local configurations coexists with the absence of a global period. Its topological entropy is zero because these complexities grow linearly.

The realization by the observables V_9, W_δ and the shift T expresses the same order through the covariances (10.53). The frequencies of the uniform clock belong to $\frac{1}{9}\mathbb{Z} + \delta\mathbb{Z}$, modulo 1. The capacity clock additionally preserves the relation $[C_n]_9 = [n]_9 - [Z_n]_9$; it is not replaced by the uniform phase when interpreting the returns. The term *time crystal* is thus defined through a mathematical dynamical system. Its physical realization requires specifying an energy dynamics, its temporal observables and its stability, data distinct from the present symbolic construction.

10.5.14 Mirror symmetry of the regions and dual realization

The mirror interchange acts on the regional block $B = (u^\pi, u^e, u^\varphi) \in (\mathbb{F}_3^6)^3$ by

$$\mathfrak{c}B = (u^e, u^\pi, u^\varphi).$$

Its fixed axis and its aggregate are, respectively, u^φ and $s = u^\pi + u^e$. This fixing refers to the involution in a fiber; both coordinates may evolve during nonadic transport. With $q = u^\pi + u^e + u^\varphi$, $a = u^\pi + u^e - u^\varphi$ and $d = u^\pi - u^e$, one recovers

$$u^\varphi = 2(q-a), \qquad s = q - u^\varphi, \qquad u^\pi = 2(s+d), \qquad u^e = 2(s-d).$$

The equalities hold componentwise in $\mathbb{F}_3$, where $2^{-1} = 2$. The mirror preserves q, a, s and reverses d; this antisymmetric coordinate singles out the distribution that the aggregate preserves without distinguishing it. The reversal $\mathcal{I}$ of the temporal index and the involution $\mathfrak{c}$ of channels therefore act on different data.

The phase return has an explicit witness:

$$B_1 = (012222 \mid 121221 \mid 112202),$$
$$B_{10} = (101222 \mid 112221 \mid 112002).$$

Both positions have phase 1; the block, the axis and the memory have changed. Likewise, synchronization of the censuses in phases 8 and 9 cancels their relative differences, while the diagonal component changes from $(59, 59, 59)$ to $(43, 43, 43)$. Equality of a relative observable does not exhaust the state that determines it.

The dual realization preserves that architecture. In section 21.11.1, the same prefix determines nested cylinders on the one hand and a sequence of encoded words with their frames on the other. The first map passes to the limit by contraction of diameters; the second satisfies $r_{n,m}Q_n = Q_m p_{n,m}$ and defines Q_∞. Figure 10.3 anticipates these two maps. The subsequent incidence path constructs codes, lattices and the realization of Moonshine in their own domains; the automorphism group acts on that realization, not on the digits through an implicit identification.

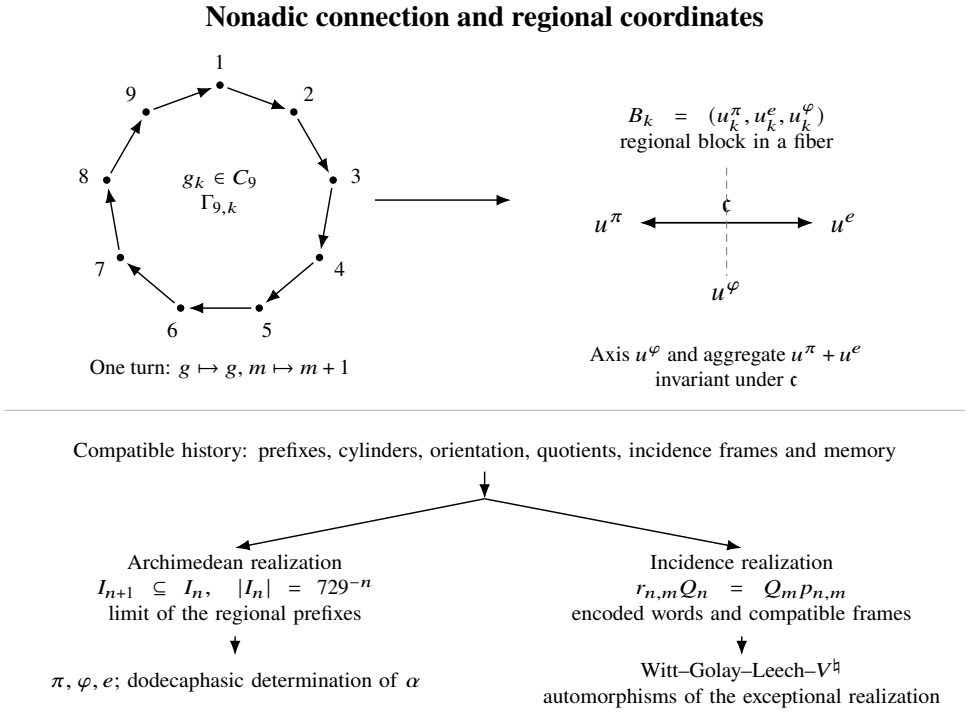

Figure 10.3: Nine phases of a connection and two realizations of the compatible history. The cycle represents the phase; each turn increments the counter. The regional diagram represents the involution $\mathfrak{c}$, which interchanges closure and propagation and fixes the autoscale axis in a fiber. This invariance does not require the axis to be constant during transport. The two lower maps use the same prefix: one determines its numerical limit and the other preserves words and incidence frames. The maps of this second realization are specified in section 21.11.1; the exceptional path is developed afterward.

10.5.14.1 Rectilinear representation of the phases and the return

The representation on the segment $[0, 10]$ preserves the positional origin of APP and orders its nine interior marks. In this diagram, the integers $1, \dots, 9$ are phase representatives. The horizontal position indicates the order of the charts; the upper labels specify regional operations. Figure 10.4 thus brings together the initial line, the fixing of the autoscale axis, the mirror distribution of the two channels and the return with memory (section 10.5.11).

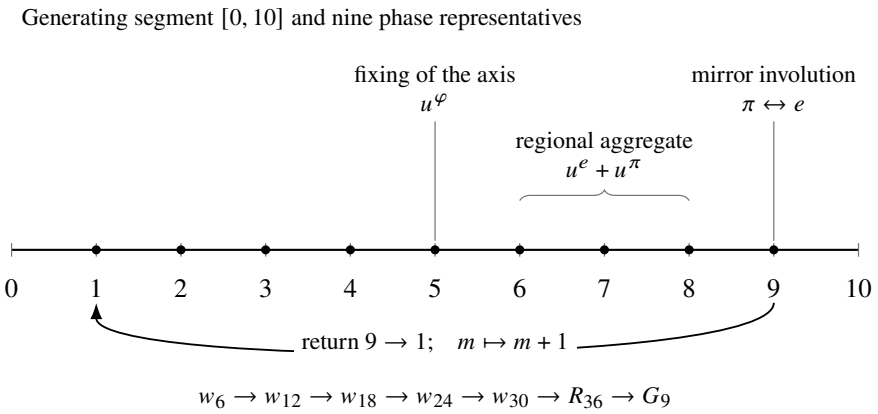

Figure 10.4: Rectilinear representation of the nonadic connection. The mark 5 locates the first strong saturation and the regional autoscale axis; the brace 6–8 identifies the ternary aggregate fixed in each fiber; phase 9 selects the closure orientation. The return preserves the phase and increments the memory. The abscissae number operational positions, while the labels $u^{\pi}, u^{e}, u^{\varphi}$ designate blocks of $\mathbb{F}_3^6$.

The fixing of the axis is formulated in the fiber of a given boundary. If $q = u^{\pi} + u^{e} + u^{\varphi}$ and $a = u^{\pi} + u^{e} - u^{\varphi}$, then

$$u^{\varphi} = 2(q - a), \qquad s = u^{\pi} + u^{e} = q - u^{\varphi} \quad \text{in } \mathbb{F}_3^6.$$

The data (q, a) determine the axis and the aggregate; the ordered distribution of s preserves the mirror freedom resolved by the prolongation. The fifth phase has a local solution and an extension, with boundary datum $c = 111111$ and residual signature $\rho_W = 000$. This is the meaning of its first strong saturation. The symbol φ placed above the mark 5 identifies the regional axis involved in that operation.

The intermediate phases preserve this decomposition within each fiber, while their boundary data evolve. The complete census of local multiplicities and extensions of the distinguished branch is

phase	1	2	3	4	5	6	7	8	9
N_{loc}	3	2	5	4	1	1	3	3	2
N_{ext}	2	5	4	1	1	3	3	2	1

Phase 6 combines local uniqueness and three prolongations; phase 7 resolves a triple mirror fiber; phase 8 synchronizes the three regional censuses. Phase 9 preserves two local distributions with the same axis and the same aggregate, one of which extends. These counts express different functions within a single connection, and justify the marks on the line.

In particular, for phases $6, 7, 8$ the regional sums are respectively 012100, 101001 and 112000. The conservation represented by the brace is an invariance with respect to the mirror distribution in each fiber. The subsequent real evaluation applies the readers of the compatible cylinders to the complete histories; the internal sum represented in the figure belongs to the ternary domain.

Finally, the arc $9 \to 1$ represents the passage from one turn to the next. The formulas in section 10.5.11 preserve the phase remainder and increment the turn counter. The rectilinear diagram and the cyclic

diagram in Figure 10.3 therefore express two complementary aspects of the same holonomy: the order of the positions and the composition of the return on the state with memory.

10.5.15 Temporal transport and tritic exponential composition

The Euler relations in section 10.5.7 describe the local realizations of the three regimes. For a fixed signature τ, the generator satisfies $J_\tau^2 = -\tau I$; algebraic conjugation takes J_τ to $-J_\tau$. Consequently,

$$\exp(sJ_\tau)\exp(tJ_\tau) = \exp((s+t)J_\tau), \qquad \overline{\exp(tJ_\tau)} = \exp(-tJ_\tau),$$

and the product of an evolution with its conjugate is unity. In the elliptic type it is realized through $\cos^2 t + \sin^2 t = 1$; in the hyperbolic type, through $\cosh^2 t - \sinh^2 t = 1$; in the parabolic type, $(I + tN)(I - tN) = I$, since $N^2 = 0$. The same conservation law admits three quadratic expressions.

The elliptic realization closes a turn; the nilpotent one preserves a linear displacement; the hyperbolic one separates expansion and contraction with unit determinant. In the regional parameters already generated,

$$\exp(\pi J_{\mathrm{e}}) = -I, \qquad \exp(J_{\mathrm{p}}) = I + J_{\mathrm{p}}, \qquad \exp(2\log\varphi\, J_{\mathrm{h}}) = F_{\mathrm{av}}^2.$$

The evaluation $\exp(I) = eI$ recognizes the unity of the common exponential law. The number e is not assigned exclusively to the parabolic regime.

Transporting a local realization through an isomorphism U preserves these relations: if $J' = UJU^{-1}$, the exponential series gives $U\exp(tJ) = \exp(tJ')U$. The identity transports the regime and its norm. A transition between different quadratic types instead belongs to the selection of sheets and regimes of TPK; it is not a conjugation that changes the value of J^2. The temporal product therefore preserves the order of the transitions and the information of their endpoints.

This articulation distinguishes the closure of a local representation and the holonomy of a history. It is possible to have $\exp(2\pi J_{\mathrm{e}}) = I$ at the same time as $S|r, m\rangle = |r, m+1\rangle$. The first equality restores the orientation of the regime; the second records another turn. The discrete structure preserves both: the local return and the accumulated provenance of the state that realizes it.

10.5.16 Multiplicative irreducibility and return periods

The distinction between structure, evaluation and phase also appears in the multiplicative sector. The local product of APP contains both the residue and the quotient; its iteration allows normal forms and factorizations to be constructed before examining their decimal periods. This development places the expression *prime mode* in a precise domain and relates irreducibility to the operations already defined, not to an isolated coincidence of periods (section 10.5.16).

Let

$$\mathcal{W}_9 = \{\varnothing\} \sqcup \bigsqcup_{\ell \geq 1} \{1, \ldots, 9\}^\ell.$$

Sequences are ordered from the least significant digit. The evaluation $\mathrm{ev}_9(u) = \sum_j u_j 9^j$, with $\mathrm{ev}_9(\varnothing) = 0$, is a bijection onto the nonnegative integers: for a positive integer, dividing $n - 1$ by 9 uniquely determines the first digit and the continuation. This is bijective nonadic numeration; it preserves the boundary representative 9.

The sum $\boxplus_\#$ is obtained by applying the additive APP sheet to the digits at each position and propagating their quotients. If there is only one digit, it constitutes the provisional residue; a nonzero incoming quotient is normalized through a second additive operation. The sum of the quotients is transported to the next position. To multiply a sequence by a digit d, the multiplicative cell produces $u_j d = 9q_j + r_j$, and the incoming quotient c_j is incorporated through

$$(w_j, c_{j+1}) = \begin{cases} (r_j, q_j), & c_j = 0, \\ \big(R^+(r_j, c_j),\, q_j + q^+(r_j, c_j)\big), & c_j > 0. \end{cases}$$

The procedure begins with $c_0 = 0$ and incorporates the final quotient when it is nonzero. During addition, $c_j \le 2$; during multiplication by a digit, $c_j \le 9$. The local operations thus receive arguments within their domain. Denote this second procedure by $d \odot_\# u$, with $d \odot_\# \varnothing = \varnothing$.

For $v = (v_0, \dots, v_{m-1})$, the full product is constructed by the recurrence

$$a_m = \varnothing, \qquad a_j = (9 \odot_\# a_{j+1}) \boxplus_\# (v_j \odot_\# u), \qquad u \boxtimes_\# v = a_0.$$

The rule composes the two local sheets. Its evaluation satisfies

$$\mathrm{ev}_9(u \boxtimes_\# v) = \mathrm{ev}_9(u)\,\mathrm{ev}_9(v). \tag{10.55}$$

Indeed, each transition preserves the partial sum plus the pending quotient weighted by the power of 9. The recurrence then gives $\mathrm{ev}_9(a_j) = 9\,\mathrm{ev}_9(a_{j+1}) + v_j\,\mathrm{ev}_9(u)$, whose iteration proves (10.55). Uniqueness of the normal form transports associativity and commutativity to the constructed product; its unit is (1).

Definition 10.60 (Reduced multiplicative coproduct)**.** On the vector space of finite support generated by the nonempty normal forms, define

$$\widetilde{\Delta}_\# e_w = \sum_{\substack{u \boxtimes_\# v = w \\ u, v \neq (1)}} e_u \otimes e_v.$$

A nonunit normal form is irreducible when its image under $\widetilde{\Delta}_\#$ is zero.

The factorization fibres are finite by (10.55). In the completion $\mathcal{H}_\# = \ell^2(\mathcal{W}_9 \setminus \{\varnothing\})$, the images of distinct forms have disjoint supports. If $d_\#(w)$ counts the ordered nonunit factorizations, the domain of the closure is

$$\mathrm{Dom}(\overline{\widetilde{\Delta}_\#}) = \left\{ x \in \mathcal{H}_\# : \sum_w d_\#(w) |x_w|^2 < \infty \right\}.$$

Indeed, the squared norm of the image is that weighted sum. Therefore, the operator

$$A_\# = (\overline{\widetilde{\Delta}_\#})^* \overline{\widetilde{\Delta}_\#}$$

is diagonal, positive, and self-adjoint: its eigenvalue at e_w is the number of ordered nonunit factorizations of w. The projection

$$P_{\mathrm{irr}} = (I - |e_{(1)}\rangle\langle e_{(1)}|)\mathbf{1}_{\{0\}}(A_\#)$$

selects exactly the irreducible forms. Through multiplicative evaluation, these correspond to the ordinary primes. Selection depends on the factorization structure and keeps the unit state separate.

For a value $n \ge 2$ coprime to 10, decimal division induces the residue permutation $r \mapsto 10r \pmod n$. Return of the residue 1 has period

$$\tau_n = \mathrm{ord}_n(10).$$

If $n = \prod_p p^{a_p}$, the Chinese remainder theorem gives

$$\tau_n = \mathrm{mcm}_{p^{a_p} \| n}\, \mathrm{ord}_{p^{a_p}}(10).$$

The composite return synchronizes the returns of the prime powers. For a prime $p \notin \{2, 3, 5\}$, we have

$$\tau_p \mid p - 1, \qquad M_p = \frac{10^{\tau_p} - 1}{p} \in \mathbb{N}, \qquad M_p \equiv 0 \pmod 9.$$

The last congruence expresses the nonadic closure of the decimal repetition: $10^{\tau_p} - 1$ is a multiple of 9, and p is invertible modulo 9. The same congruence holds for any n coprime to 90. In particular,

7, 13, 77, 91, 143 have decimal period 6, although only the first two are irreducible. The coproduct and the period therefore record different properties of the same constructed value.

This distinction makes precise the relationship with aperiodic refinement. The vacancy sequence determines the increments of the capacity index; factorization determines the multiplicative modes; decimal division determines their return times. The nonadic representative preserves phase closure, while the quotient and factorization preserve information that this closure does not distinguish. The link with the spectral constructions of the treatise resides in those operators and their intertwinings. The proofs of their subsequent analytic results retain their own development; they are not replaced by the periodicity of a residual observation.

10.5.16.1 Vacancy discrepancy and Dirichlet readouts

The link also admits an exact analytic expression. The same encoding $z_n = z_n(0)$, for $n \geq 1$, is preserved, and two subsequent observables are considered: the series over all indices and the product over the indices selected by irreducibility. For $\operatorname{Re} s > 1$,

$$Z^{+}_{\mathrm{vac}}(s) = \sum_{n\geq 1} \frac{z_n}{n^s}, \qquad Z^{\times}_{\mathrm{vac}}(s) = \prod_{p} (1 - p^{-s})^{-z_p}.$$

Both converge absolutely in that half-plane. Their common factor is the density δ, but their discrepancies differ.

Proposition 10.61 (Separation of vacancy density)**.** *We have*

$$Z^{+}_{\mathrm{vac}}(s) = \delta\zeta(s) + H_{\mathrm{vac}}(s), \qquad H_{\mathrm{vac}} \in \mathcal{O}(\operatorname{Re} s > 0).$$

In $\operatorname{Re} s > 1$*, with logarithms defined by the absolutely convergent Euler series,*

$$Z^{\times}_{\mathrm{vac}}(s) = \zeta(s)^{\delta} G_{\mathrm{vac}}(s), \qquad \log G_{\mathrm{vac}}(s) = \sum_{p} (z_p - \delta) \log(1 - p^{-s})^{-1}.$$

Proof. The centred partial sums satisfy

$$A_N := \sum_{n=1}^{N} (z_n - \delta) = \lfloor (N+1)\delta \rfloor - N\delta, \qquad |A_N| < 1.$$

Abel summation represents the centred term by $s \int_1^{\infty} A_{\lfloor x \rfloor} x^{-s-1}\, dx$. The integral converges locally uniformly in $\operatorname{Re} s > 0$, proving holomorphy. The second identity follows by separating $z_p = \delta + (z_p - \delta)$ in the logarithm of the product, within its domain of absolute convergence. □

The decomposition makes visible what the readout on primes adds: it examines the same vacancy sequence on a subset determined by factorization. Control of the discrepancy over all integers gives the first holomorphic extension; the second observable preserves a discrepancy of its own on primes. These are two applications of the same discrete structure, with explicit analytic domains. This articulation explains their relevance to the arithmetic core without transferring to this article the proofs of the terminal results of the treatise.

10.6 Integral compatibility of regional generation, cylindrical refinement, and incidence

Regional prolongation produces ordered sequences of blocks together with their reading depths. The Archimedean projection and ternary incidence are calculated on these same sequences. The connection between the two realizations can be formulated entirely through integer operations: selection by rational intervals, Euclidean division, lifting of six trits, carry reading, and the Witt transformation. This formulation makes it possible to trace each coefficient from its generating block to its subsequent use.

The construction uses the three regional readers already obtained from the APP–TRIT–TPK state. We denote them by the indices $c \in \{\mathrm{P}, \mathrm{E}, \mathrm{F}\}$, corresponding, respectively, to the closure, propagation, and autoscaling regions. Their real realization will be written as v_c. The subsequent identifications $v_{\mathrm{P}} = \pi_{\mathrm{HMT}}$, $v_{\mathrm{E}} = e_{\mathrm{HMT}}$, and $v_{\mathrm{F}} = \varphi_{\mathrm{HMT}}$ preserve this causal order. The operation that emits a block inspects the rational intervals of the regional reader; the real value enters the proof of correctness of that operation.

10.6.1 Positional emission through rational separation of cells

For each region, two rational sequences $\ell_c(j), u_c(j)$, constructed by its reader, are available and satisfy

$$\ell_c(j) \le v_c \le u_c(j).$$

The cell-separation property proved for these readers states that, for each integer $s > 0$, there exists J such that, for every $j \ge J$,

$$\lfloor s\ell_c(j) \rfloor = \lceil s u_c(j) \rceil - 1 = \lfloor s v_c \rfloor. \tag{10.56}$$

Avoidance of rational boundaries by the regional values is the hypothesis of the preceding theorems that guarantees this separation. Here we use their operational conclusion together with the readers and intervals that produce it.

Definition 10.62 (Separation index and emitted prefix)**.** For $s > 0$, let

$$j_c(s) = \min\{j \in \mathbb{N} : \lfloor s\ell_c(j) \rfloor = \lceil s u_c(j) \rceil - 1\}.$$

For an integer base $b \ge 2$ and a depth $n \ge 0$, define

$$P_c(b, n) = \lfloor b^n \ell_c(j_c(b^n)) \rfloor. \tag{10.57}$$

The prefix contains the integer part and the first n positions in base b; consequently, $P_c(b, 0)$ is the regional integer part.

Theorem 10.63 (Termination and correctness of emission)**.** *The index $j_c(s)$ exists for every $s > 0$. The emitted prefixes satisfy*

$$P_c(b, n) = \lfloor b^n v_c \rfloor, \qquad P_c(b, n) \le b^n v_c < P_c(b, n) + 1. \tag{10.58}$$

For each scale s, a single sufficiency index $J(s)$ can also be chosen that is valid simultaneously for all three regions.

Proof. The eventual equality in (10.56) makes the set defining $j_c(s)$ nonempty. Its minimum exists by the well-ordering of $\mathbb{N}$. At any index where the equality holds, the rational lower bound gives $\lfloor s\ell_c(j) \rfloor \le \lfloor s v_c \rfloor$. The upper bound, together with avoidance of a cell boundary, gives $\lfloor s v_c \rfloor \le \lceil s u_c(j) \rceil - 1$. When the two integer endpoints coincide, the intervening integer coincides with them. This proves (10.58). For the joint statement, it suffices to take the maximum of the three sufficiency indices obtained at the same scale. The joint index controls all three emissions simultaneously, while each region retains its own intervals. □

Proposition 10.64 (Exact compatibility of prefixes)**.** *For $n, m \geq 0$,*

$$\left\lfloor \frac{P_c(b, n+m)}{b^m} \right\rfloor = P_c(b, n). \tag{10.59}$$

In particular, the next block $d_c(b, n) = P_c(b, n+1) \bmod b$ satisfies

$$P_c(b, n+1) = bP_c(b, n) + d_c(b, n), \qquad 0 \leq d_c(b, n) < b. \tag{10.60}$$

Proof. Write $b^n v_c = N + \theta$, with $N = P_c(b, n)$ and $0 \leq \theta < 1$. Then $P_c(b, n+m) = b^m N + \lfloor b^m \theta \rfloor$, and the second summand belongs to $\{0, \ldots, b^m - 1\}$. Euclidean division by b^m recovers N. The specialization $m = 1$ yields (10.60) and its residual bound. □

10.6.2 Regional blocks of six trits at arbitrary depth

The integer equality $729 = 3^6$ determines the grouping of six ternary positions into a block. For $t \geq 0$, define

$$u_c(t) = P_c(729, t+1) \bmod 729, \qquad B_{c,j}(t) = \left\lfloor \frac{u_c(t)}{3^{5-j}} \right\rfloor \bmod 3, \quad 0 \leq j < 6. \tag{10.61}$$

Thus $B_c(t)$ is an ordered word of six trits, and

$$u_c(t) = \sum_{j=0}^{5} B_{c,j}(t) 3^{5-j}. \tag{10.62}$$

The word and its integer lift are mutually recoverable representations of the same emitted block.

Theorem 10.65 (Stability of extraction at any depth)**.** *For every n,*

$$P_c(729, n) = P_c(3, 6n).$$

If $t < n$, then

$$u_c(t) = \left\lfloor \frac{P_c(729, n)}{729^{n-t-1}} \right\rfloor \bmod 729. \tag{10.63}$$

Consequently, every extension of the prefix preserves all previously emitted blocks and all signatures calculated from them.

Proof. The first equality follows because both prefixes are separated at the same scale, $729^n = 3^{6n}$, and from Theorem 10.63. For the second, apply (10.59) at depths n and $t+1$, and then take the residue modulo 729. The ternary extraction in (10.61) is deterministic. Any explicit function of those eighteen coordinates therefore retains the same result when the prefix is extended. □

The construction is quantified over $t \in \mathbb{N}$. A table materializing one hundred blocks is a finite evaluation of this construction; formula (10.63) determines its compatibility with every subsequent extension exactly.

Example 10.66 (First joint block)**.** Evaluation of the selected regional readers gives the words

$$B_{\mathrm{P}}(0) = 010211, \qquad B_{\mathrm{E}}(0) = 201101, \qquad B_{\mathrm{F}}(0) = 121200.$$

Their lifting by (10.62) produces

$$u_{\mathrm{P}}(0) = 103, \qquad u_{\mathrm{E}}(0) = 523, \qquad u_{\mathrm{F}}(0) = 450.$$

For example, $201101_3 = 2 \cdot 243 + 27 + 9 + 1 = 523$. All six positions, including leading zeros, are retained in the band representation. The leading zero in 010211 has a defined position even though the decimal notation for 103 does not contain it.

10.6.3 Transition registers and reconstruction of linear lifts

Over $\mathbb{F}_3$, collect two consecutive emissions from each region in the matrix

$$R(t) = \begin{pmatrix} B_{\mathrm{P}}(t) \\ B_{\mathrm{P}}(t+1) \\ B_{\mathrm{E}}(t) \\ B_{\mathrm{E}}(t+1) \\ B_{\mathrm{F}}(t) \\ B_{\mathrm{F}}(t+1) \end{pmatrix}. \tag{10.64}$$

This definition fixes both the regional order and the temporal order. The first four registers are

$$X_0 = R(0), \quad Y_0 = R(1), \quad X_1 = R(2), \quad Y_1 = R(3).$$

Their values, obtained by extraction from the regional prefixes, are

$$X_0 = \begin{pmatrix} 0 & 1 & 0 & 2 & 1 & 1 \\ 0 & 1 & 2 & 2 & 2 & 2 \\ 2 & 0 & 1 & 1 & 0 & 1 \\ 1 & 2 & 1 & 2 & 2 & 1 \\ 1 & 2 & 1 & 2 & 0 & 0 \\ 1 & 1 & 2 & 2 & 0 & 2 \end{pmatrix}, \qquad Y_0 = \begin{pmatrix} 0 & 1 & 2 & 2 & 2 & 2 \\ 0 & 1 & 0 & 2 & 1 & 1 \\ 1 & 2 & 1 & 2 & 2 & 1 \\ 1 & 0 & 2 & 0 & 1 & 1 \\ 1 & 1 & 2 & 2 & 0 & 2 \\ 1 & 2 & 1 & 0 & 2 & 0 \end{pmatrix},$$

$$X_1 = \begin{pmatrix} 0 & 1 & 0 & 2 & 1 & 1 \\ 0 & 0 & 2 & 1 & 1 & 1 \\ 1 & 0 & 2 & 0 & 1 & 1 \\ 0 & 1 & 2 & 2 & 2 & 2 \\ 1 & 2 & 1 & 0 & 2 & 0 \\ 0 & 1 & 0 & 2 & 1 & 0 \end{pmatrix}, \qquad Y_1 = \begin{pmatrix} 0 & 0 & 2 & 1 & 1 & 1 \\ 1 & 1 & 0 & 2 & 2 & 1 \\ 0 & 1 & 2 & 2 & 2 & 2 \\ 1 & 0 & 2 & 0 & 1 & 1 \\ 0 & 1 & 0 & 2 & 1 & 0 \\ 0 & 1 & 0 & 2 & 0 & 0 \end{pmatrix}.$$

Theorem 10.67 (Unique reconstruction of the two initial links)**.** *The equations $X_0 L_0 = Y_0$ and $X_1 L_1 = Y_1$ each have a unique solution in $M_6(\mathbb{F}_3)$. These solutions are*

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix}.$$

Both matrices are invertible.

Proof. The matrices

$$A_0 = \begin{pmatrix} 1 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 1 & 0 & 0 & 1 \\ 2 & 1 & 2 & 1 & 0 & 1 \\ 0 & 2 & 0 & 1 & 0 & 2 \\ 2 & 1 & 1 & 0 & 2 & 2 \\ 2 & 1 & 1 & 1 & 1 & 2 \end{pmatrix}, \qquad A_1 = \begin{pmatrix} 1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 0 & 1 & 1 & 2 & 2 \\ 0 & 1 & 2 & 0 & 1 & 1 \\ 1 & 1 & 0 & 2 & 0 & 0 \\ 1 & 1 & 2 & 1 & 1 & 2 \\ 1 & 0 & 0 & 0 & 0 & 2 \end{pmatrix}$$

satisfy $A_iX_i = X_iA_i = I$, by multiplication in $\mathbb{F}_3$. The solutions are therefore forced by $L_i = A_iY_i$; multiplication produces the two displayed matrices. Their inverses are

$$L_0^{-1} = \begin{pmatrix} 1 & 2 & 0 & 2 & 0 & 2 \\ 2 & 0 & 2 & 2 & 0 & 0 \\ 2 & 1 & 2 & 0 & 2 & 0 \\ 1 & 0 & 0 & 0 & 2 & 0 \\ 0 & 2 & 1 & 1 & 2 & 0 \\ 2 & 2 & 2 & 2 & 2 & 2 \end{pmatrix}, \qquad L_1^{-1} = \begin{pmatrix} 2 & 0 & 2 & 1 & 2 & 1 \\ 2 & 1 & 0 & 0 & 2 & 0 \\ 2 & 0 & 2 & 2 & 0 & 2 \\ 2 & 0 & 0 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 \\ 2 & 0 & 1 & 2 & 2 & 0 \end{pmatrix}.$$

The bilateral verification $L_iL_i^{-1} = L_i^{-1}L_i = I$ proves exact recovery of each transformed word. All products use residues $0, 1, 2$ with their interpretation in $\mathbb{F}_3$. □

The causal reading of this result is precise: the regional emissions produce $R(t)$; the registers $R(0), \ldots, R(3)$ determine the two lifts above; their inverses recover the transformed words. Continuity for every t belongs to the coinductive readers and Theorem 10.65. The matrix reconstruction proved here has the two links specified in its statement as its domain.

10.6.4 Simultaneous refinement in ternary and decimal bases

A ternary emission of six trits and a decimal emission of three digits are readings in different bases. To preserve their relationship, record the state

$$s = (n, k, N, D),$$

where N is a prefix at depth n in base 729, and D is a prefix at depth k in base 1000. Their Archimedean cylinders are

$$I_{729}(s) = \left[\frac{N}{729^n}, \frac{N+1}{729^n}\right), \qquad I_{1000}(s) = \left[\frac{D}{1000^k}, \frac{D+1}{1000^k}\right). \tag{10.65}$$

The half-open upper endpoint assigns each value to a unique cell at a given base and depth.

Definition 10.68 (Integer compatibility defects)**.** We define

$$A(s) = N1000^k - D729^n, \tag{10.66}$$

$$B(s) = (N+1)1000^k - D729^n = A(s) + 1000^k. \tag{10.67}$$

The state is compatible when

$$A(s) < 729^n, \qquad B(s) > 0. \tag{10.68}$$

Lemma 10.69 (Integer criterion for intersection)**.** *The cylinders in* (10.65) *have a nonempty intersection if and only if* (10.68) *holds.*

Proof. Two half-open intervals $[a, b)$ and $[c, d)$, with $a < b$ and $c < d$, intersect exactly when $a < d$ and $c < b$. Applying this condition to (10.65) and multiplying by the positive denominators gives $N1000^k < (D+1)729^n$ and $D729^n < (N+1)1000^k$. These are the two inequalities in (10.68). □

Definition 10.70 (Update of depths and prefixes)**.** For $0 \le u < 729$ and $0 \le d < 1000$, define

$$T_u(n,k,N,D) = (n+1,k,729N+u,D),$$
$$T_{u,d}(n,k,N,D) = (n+1,k+1,729N+u,1000D+d).$$

The first operation refines only the ternary cylinder. The second refines both readings and preserves both depths in the state.

Proposition 10.71 (Exact boundary recurrences)**.** *The updates above satisfy*

$$A(T_u s) = 729A(s) + u1000^k, \tag{10.69}$$
$$A(T_{u,d} s) = 729000A(s) + u1000^{k+1} - d729^{n+1}. \tag{10.70}$$

Proof. For the first identity,

$$(729N+u)1000^k - D729^{n+1} = 729(N1000^k - D729^n) + u1000^k.$$

For the second,

$$\begin{aligned}(729N+u)1000^{k+1} &- (1000D+d)729^{n+1}\\ &= 729000(N1000^k - D729^n) + u1000^{k+1} - d729^{n+1}.\end{aligned}$$

Both are integer identities preceding any real approximation. □

Theorem 10.72 (Refinement of the generated regional cylinders)**.** *Let*

$$s_c(n,k) = (n,k,P_c(729,n),P_c(1000,k)).$$

Then $s_c(n,k)$ is compatible for all n,k. Moreover,

$$T_{u_c(n)} s_c(n,k) = s_c(n+1,k),$$
$$T_{u_c(n),d_c(1000,k)} s_c(n,k) = s_c(n+1,k+1).$$

Euclidean division of the refined prefixes recovers the preceding prefixes exactly. For every $a,b \ge 0$,

$$\frac{P_c(729,n+a) - P_c(729,n+a) \bmod 729^a}{729^a} = P_c(729,n),$$

and the analogous identity holds in base 1000*.*

Proof. Theorem 10.63 places v_c simultaneously in both intervals in (10.65); the intersection criterion gives compatibility. The update identities are (10.60) in each base. Recovery follows from (10.59). Thus the defect recurrence and prefix recovery are consequences of the same update. □

Example 10.73 (First pair of regional cylinders)**.** For $n = k = 1$, evaluation of the three regions gives

c	N	D	A	B
P	2290	3141	211	1211
E	1981	2718	−422	578
F	1179	1618	−522	478

In all three rows, $A < 729$ and $B > 0$. The first prefix column decomposes as $2290 = 3 \cdot 729 + 103$, $1981 = 2 \cdot 729 + 523$, and $1179 = 729 + 450$: exactly the previously emitted six-trit blocks reappear. The

different signs of A express the relative positions of the two lower endpoints without altering the regional value's membership in both intervals.

10.6.5 Selection of the next block by the regional reader

Compatibility of two intervals expresses a relationship between readings. Determining the next block additionally uses the rational interval produced by the region. This operation can be formulated without discarding the depth history.

Definition 10.74 (Admissibility of regional prolongation)**.** For fixed c, n, let $s = 729^{n+1}$ and $j = j_c(s)$. A residue $u \in \{0, \dots, 728\}$ is admissible when

$$\lfloor s\ell_c(j) \rfloor \le 729P_c(729, n) + u \le \lceil su_c(j) \rceil - 1. \tag{10.71}$$

Theorem 10.75 (Uniqueness of the prolongation compatible with the reader)**.** *Condition* (10.71) *is equivalent to $u = u_c(n)$. There is therefore exactly one admissible prolongation of each region at each depth.*

Proof. At the separation index, both integer endpoints in (10.71) coincide with $P_c(729, n+1)$. The condition is therefore equivalent to $729P_c(729, n) + u = P_c(729, n+1)$. By (10.60), the right-hand side is $729P_c(729, n) + u_c(n)$. Cancelling the common term gives equality of the residues. Conversely, this equality satisfies the condition. □

The effective dependence of this selection is fully specified: selected region, rational reader, depth, separation index, preceding prefix, and next residue. The defect A summarizes a boundary relationship; the state (n, k, N, D) and the regional intervals retain the data used by the update.

10.6.6 Ternary signature, carry, Witt incidence, and reading clock

At a fixed depth t, write $B_{c,j} = B_{c,j}(t)$. For each column j, calculate the following integers and residues:

$$S_j = B_{\mathrm{P},j} + B_{\mathrm{E},j} + B_{\mathrm{F},j}, \qquad q_j = S_j \bmod 3, \qquad c_j = \left\lfloor S_j/3 \right\rfloor, \tag{10.72}$$

$$a_j = (B_{\mathrm{P},j} + B_{\mathrm{E},j} - B_{\mathrm{F},j}) \bmod 3, \qquad w_j = \sum_c \mathbf{1}_{B_{c,j}\neq 0}, \qquad \bar{w}_j = w_j \bmod 3. \tag{10.73}$$

The residue of the axial expression is taken in the integers. An implementation using natural numbers calculates it as $(B_{\mathrm{P},j} + B_{\mathrm{E},j} + 3 - B_{\mathrm{F},j}) \bmod 3$, which preserves that residue exactly.

The ternary incidence matrix used by the reader is

$$W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 2 & 2 \\ 1 & 1 & 0 & 2 & 1 & 2 \\ 1 & 1 & 2 & 0 & 2 & 1 \\ 1 & 2 & 1 & 2 & 0 & 1 \\ 1 & 2 & 2 & 1 & 1 & 0 \end{pmatrix}. \tag{10.74}$$

Two residual charges are preserved for each region:

$$v_c^{\mathrm{res}} = \sum_j B_{c,j} \bmod 3, \qquad v_c^{\mathrm{W}} = \sum_j (B_c W)_j \bmod 3. \tag{10.75}$$

The reader's complete signature is $\mathcal{S}(B) = (q, a, c, w, \bar{w}, v^{\mathrm{res}}, v^{\mathrm{W}})$. Its structure separately preserves the column residue, carry, axial contrast, support weight, and the two charge readings.

Theorem 10.76 (Exact recovery and bounds of the signature)**.** *For each column and each region,*

$$S_j = q_j + 3c_j, \qquad 0 \le q_j, a_j < 3, \qquad 0 \le c_j \le 2, \tag{10.76}$$

$$B_{\mathrm{F},j} = 2(q_j + 3 - a_j) \bmod 3, \qquad 0 \le w_j \le 3, \qquad 0 \le \bar{w}_j < 3. \tag{10.77}$$

Moreover,

$$v_c^{\mathrm{W}} = \left(\sum_j \big((B_c W)_j \bmod 3 \big) \right) \bmod 3. \tag{10.78}$$

The stated recoveries determine each column's total and its autoscaling coordinate; the regional register additionally preserves the three ordered bands.

Proof. Identity (10.76) is Euclidean division of S_j by 3. Each summand of S_j lies between 0 and 2, so $0 \le S_j \le 6$ and $c_j \le 2$. In $\mathbb{F}_3$, subtracting the two congruences defining q_j and a_j gives $q_j - a_j = 2B_{\mathrm{F},j}$. Since the inverse of 2 is 2, this yields (10.77); the summand 3 permits an expression using natural numbers. The bounds on w_j follow by summing three indicators. Finally, reducing an integer sum modulo 3 is equivalent to reducing each summand and then reducing their sum, which proves (10.78). □

Example 10.77 (Signature of the first joint block)**.** The three initial bands produce

$$q = (0,0,2,2,1,2), \qquad a = (1,2,0,1,1,2),$$
$$c = (1,1,0,1,0,0), \qquad w = (2,2,2,3,1,2),$$
$$v^{\mathrm{res}} = (2,2,0), \qquad v^{\mathrm{W}} = (2,1,1).$$

The fourth column has total $2 + 1 + 2 = 5$; its signature records $q_3 = 2$ and $c_3 = 1$, so $q_3 + 3c_3 = 5$. Axial recovery gives $2(2 + 3 - 1) \bmod 3 = 2$, precisely the autoscaling coordinate. The Witt images, reduced componentwise, are

$$(2,0,2,1,1,2), \qquad (0,0,0,2,0,2), \qquad (2,1,1,2,1,0).$$

Their residual sums by row yield the three charges $(2,1,1)$.

Definition 10.78 (Integer clock of decimal reading)**.** The transition index t and the decimal depth of expression are related by

$$\kappa(t) = \max\{k \in \mathbb{N} : 1000^k \le 3^{6(t+1)}\}. \tag{10.79}$$

Proposition 10.79 (Characterization and monotonicity of the clock)**.** *The integer $\kappa(t)$ is uniquely determined by*

$$1000^{\kappa(t)} \le 729^{t+1} < 1000^{\kappa(t)+1}. \tag{10.80}$$

The function κ is monotone and satisfies $\kappa(20) = \kappa(21) = 20$.

Proof. The powers of 1000 are strictly increasing and unbounded; there is therefore a unique interval between consecutive powers containing 729^{t+1}. Monotonicity of the latter expression proves that of κ. The final two evaluations are the integer comparisons

$$1000^{20} \le 729^{21} < 1000^{21}, \qquad 1000^{20} \le 729^{22} < 1000^{21}.$$

These comparisons use exact integer powers. □

Equality of decimal depth at two distinct transitions explains why both indices must be retained: the reading clock can remain constant while the ternary band advances and its signature is updated. Chronological information resides in the ordered register of transitions.

10.6.7 Composition theorem for the block, cylinder, and signature

Theorem 10.80 (Joint compatibility of regional readings)**.** *For each depth n, there exists a unique triple of blocks $(u_{\mathrm{P}}, u_{\mathrm{E}}, u_{\mathrm{F}})$ satisfying regional admissibility (10.71) in all three regions. This triple is $(u_{\mathrm{P}}(n), u_{\mathrm{E}}(n), u_{\mathrm{F}}(n))$. Simultaneously:*

1. *each block updates its cylinder through recurrences (10.69) and (10.70);*
2. *its six trits produce the signature $\mathcal{S}(B_{\mathrm{P}}(n), B_{\mathrm{E}}(n), B_{\mathrm{F}}(n))$;*
3. *the column totals are recovered as $q + 3c$, and the Witt charges are obtained from the same bands through (10.78);*
4. *every deeper prefix returns exactly these blocks, truncated cylinders, and signatures.*

Proof. Apply Theorem 10.75 to each of the three regional indices. Coordinatewise uniqueness gives joint uniqueness. Substitute those same residues into the operations $T_u, T_{u,d}$, which allows Theorem 10.72 to be applied. The deterministic application of (10.61) produces the bands used by (10.72)–(10.75). The recovery identities are those of Theorem 10.76. Finally, Theorem 10.65 and truncation in each base prove stability at greater depth. At every step the identity of the emitted block has been preserved; neither reading requires the selection of a different block. □

The conclusion is an operational compatibility between cylindrical contraction and preservation of incidence. Both use the same generated register, retain the depths, and admit integer recovery. This result is the explicit form of the connection

$$\text{emitted regional block} \longrightarrow \begin{cases} \text{cylinder and integer boundary,} \\ \text{band, signature, carry and Witt charge.} \end{cases}$$

The subsequent development of incidence and fields uses the second reading while preserving its common provenance with the first.

10.7 Initial conditions and regional generation

An APP position does not by itself contain the initial condition of its dynamics. The latter includes the direction of transport and distinguishes the cursors of the two sheets. Before classifying particles, this domain must be constructed: it produces the regional records that will enter the electronic coordinate, action, and mass readers. The operations in this section receive neither a physical species nor a metrological value as an initial condition.

10.7.1 Two oriented cursors on the complete support

We use indices $I_9 = \{0, \dots, 8\}$, whose positive label is $i + 1$, and the cardinal directions $\mathcal{D} = \{N, E, S, O\}$. The domain of one cursor and the joint domain are

$$\mathcal{S} = I_9^2 \times \mathcal{D}, \qquad \Omega_{\mathrm{seed}} = \mathcal{S}_+ \times \mathcal{S}_\times, \qquad |\mathcal{S}| = 324, \quad |\Omega_{\mathrm{seed}}| = 104\,976. \tag{10.81}$$

The subscript seed retains the domain designation used in the antecedents; mathematically, these are oriented initial conditions. The Cartesian product includes all ordered pairs. The additive sheet has one cursor and the multiplicative sheet another; a subsequent coincidence between their readings is a result of the traversal.

During the 54 instants of the initial emission, the phase selector repeats $(+1, -1, 0)$. In the positive regime, $\rho_9(i + j + 2)$ is first evaluated at the additive cursor, and that cursor is then transported by one position. In the negative regime, $\rho_9((i + 1)(j + 1))$ is evaluated at the multiplicative cursor, after which the second cursor is transported. The null regime records a neutral event. The directions are reversed after

instants 27 and 54. The latter reversal belongs to the terminal state although it does not alter readings that have already been taken.

The multiplicative observable uses the exponent chart of the group of units of $\mathbb{Z}/9\mathbb{Z}$:

$$\ell_9(1) = 0, \quad \ell_9(2) = 1, \quad \ell_9(4) = 2, \quad \ell_9(8) = 3, \quad \ell_9(7) = 4, \quad \ell_9(5) = 5.$$

In the sector $\{3, 6, 9\}$, this observable takes the value zero. Membership in the radical sector remains present in the state; assigning that value to a scalar reading does not identify the radical with the multiplicative identity.

10.7.2 Finite formula for the window signatures

The six windows each contain nine instants. Each sheet is evaluated three times per window. A closed formula reconstructs the signatures without consulting a prior list. For a cursor with origin $p = (i, j)$ and direction d, let

$$f(k) = \begin{cases} k, & 0 \le k < 9, \\ 18 - k, & 9 \le k < 18, \end{cases} \qquad p_k = p + f(k)\nu_d \pmod 9.$$

The index k counts only the evaluations of that sheet. The reversal after nine of its evaluations explains the second expression for f. Writing $p_k = (i_k, j_k)$, for $m = 0, \dots, 5$ we obtain

$$\begin{aligned} S_m(p, d) &= \sum_{k=3m}^{3m+2} \rho_9(i_k + j_k + 2), \\ E_m(p, d) &= \sum_{k=3m}^{3m+2} \ell_9(\rho_9((i_k + 1)(j_k + 1))), \\ s_m &= [S_m]_{10}, \qquad e_m = [E_m]_{10}. \end{aligned} \tag{10.82}$$

The integer evaluation and its division quotient remain stored in the record. The preceding signatures are the decimal projections specified by the emitter.

Since each window has $Z_m = 3$ neutral events, the rule coupling the two signatures is

$$\begin{aligned} d_{m,1} &= [S_m]_{10}, \qquad d_{m,2} = [S_m + E_m]_{10}, \\ d_{m,3} &= [3S_m + 5E_m + 7Z_m]_{10}, \\ U_m &= 100 s_m + 10[s_m + e_m]_{10} + [3s_m + 5e_m + 1]_{10}. \end{aligned} \tag{10.83}$$

The final term 1 is the reduction of $7Z_m = 21$ modulo ten. The coefficients and calendar are stated in the emission law; physical magnitudes do not appear among its arguments. The oriented ternary projection is

$$\Psi(U_0, \dots, U_5) = ([-U_0]_3, \dots, [-U_5]_3) \in \mathbb{F}_3^6. \tag{10.84}$$

The balanced identification of TRIT is then applied. The minus sign belongs to this chart and must be transported when it changes.

Proposition 10.81 (Factorisation and census of the emission)**.** *The initial conditions produce* 18 *additive signatures and* 26 *multiplicative signatures. Their coupling is injective and has* 468 *emissions. The image of* Ψ *contains* 243 *words in the ambient space of* 729 *elements.*

Proof. The hundreds digits of U_m recover s_m. If b_m is the tens digit, $e_m = [b_m - s_m]_{10}$; the units digit checks the third congruence. Hence no distinct pair of signatures has the same emission.

To obtain the census, (10.82) is evaluated at $i, j = 0, \dots, 8$ and the four directions. Appendix 94.15 contains all the resulting signatures. Each additive signature has 18 preimages. Among the multiplicative signatures, 24 have 8, one has 24, and one has 108. These sums are respectively $18 \cdot 18 = 324$ and $24 \cdot 8 + 24 + 108 = 324$. Since the two cursors are independent, the multiplicities multiply. This gives 432 emissions of weight 144, 18 of weight 432, and 18 of weight 1944, with sum

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

The six reductions of (10.84) are applied to each pair of the 18 and 26 signatures published in the appendix. The complete orbit decomposition included there gives $38 \cdot 6 + 5 \cdot 3 = 243$ different images. All the operations of this enumeration are the finite sums, products and residues of the preceding formulas. □

The finite proof does not identify exhaustiveness of the domain with unlimited depth. The initial conditions have been enumerated on a fixed support. Depth is constructed through compatible prolongations preserving those conditions and their transports.

10.7.3 Selection of regions through oriented fibres

For $w = (w_1, \dots, w_6)$, define

$$r(w) = (w_3, w_1, w_2, w_5, w_6, w_4), \qquad s(w) = (w_4, w_5, w_6, w_1, w_2, w_3).$$

The identities $r^3 = s^2 = I$, $srs = r^{-1}$ realise D_3. Permuting the six components of U in the same way commutes with Ψ. The preceding enumeration verifies that the orbits preserve the multiplicities of their fibres.

Let $f(w)$ be the number of emissions over w, $m(w)$ its total multiplicity, and $\nu(w) = (n_0, n_1, n_2)$ its ternary census. The additive signature preserves the diagonal class $d = [i + j]_9$ of the origin and the sense ES or NO. We write $\mathcal{D}(\mathcal{O})$ for the set of these classes over an orbit.

Proposition 10.82 (Distinguished regions of the catalogue)**.** *There is a unique orbit of six words with five emissions per word and multiplicities* $432 + 4 \cdot 144$. *Among the orbits of six words satisfying*

$$f(w) = 1, \quad m(w) = 144 \quad (w \in \mathcal{O}), \qquad \mathcal{D}(\mathcal{O}) = \{0, 3, 6\},$$

the census $(2, 3, 1)$ *and the census* $(2, 2, 2)$ *each select a unique orbit. The mark* $d = 6$ *with orientation* ES *determines the representatives*

$$w^{\mathrm{cl}} = 010211, \qquad w^{\mathrm{pr}} = 201101, \qquad w^{\mathrm{au}} = 121200.$$

Proof. The complete table of the 43 orbits in 94.15 allows the predicates to be applied. The closure orbit is the only one with a fibre of size five and weight 1008; its five weights are those stated. The diagonal condition and the simple fibre of weight 144 leave six orbits. Their censuses select respectively one with $(2, 3, 1)$ and one with $(2, 2, 2)$. Applying the six permutations of D_3 and checking the diagonal class and orientation in (10.82) fixes the three representatives displayed. Uniqueness uses all the conditions: if the set of diagonals is omitted, four balanced orbits with simple fibre and weight 144 appear. □

The designations closure, propagation, and self-scaling apply first to these regions. The next section introduces their evaluation characters. In particular, the multiplicative signature 555555 distinguishes a transverse closure emission, whereas $(5, 5)$ is a position of the electronic support. The two constructions are related through subsequent operations, not through identity of their digits.

10.7.3.1 Mirror involution of the regional components

On the regional block $B = (u^{\mathrm{cl}}, u^{\mathrm{pr}}, u^{\mathrm{au}}) \in (\mathbb{F}_3^6)^3$, the interchange is

$$\mathfrak{c}B = (u^{\mathrm{pr}}, u^{\mathrm{cl}}, u^{\mathrm{au}}).$$

Its square is the identity and it preserves the self-scaling component. If $q = u^{\mathrm{cl}} + u^{\mathrm{pr}} + u^{\mathrm{au}}$, $a = u^{\mathrm{cl}} + u^{\mathrm{pr}} - u^{\mathrm{au}}$, and $d = u^{\mathrm{cl}} - u^{\mathrm{pr}}$, the block is recovered by

$$u^{\mathrm{au}} = 2(q - a), \quad s = q - u^{\mathrm{au}}, \quad u^{\mathrm{cl}} = 2(s + d), \quad u^{\mathrm{pr}} = 2(s - d).$$

The proof uses $2^{-1} = 2$ in $\mathbb{F}_3$. The interchange preserves q, a, s and reverses the sign of d. Thus the symmetric aggregate and the oriented difference jointly preserve the two components that the aggregate alone does not distinguish. This regional involution and the reversal of a cardinal route act on different domains. The fixed component may evolve during transport even though it is fixed by the interchange.

10.7.4 Calendar, monodromy, and memory

The finite calendar consists of twelve nonadic windows. Its group sequence is

$$0 \longrightarrow C_{12} \xrightarrow{[b] \mapsto [9b]} C_{108} \xrightarrow{[t] \mapsto [t]_9} C_9 \longrightarrow 0. \tag{10.85}$$

For $t = 9b + r$, $0 \le r < 9$, composition contains the transport quotient

$$(b, r) + (b', r') = \left(b + b' + \left\lfloor \frac{r + r'}{9} \right\rfloor, [r + r']_9 \right),$$

with the first coordinate reduced modulo twelve. The projection is exact because its kernel consists of the multiples of nine. It admits no homomorphic section: such a section would give $C_{108} \cong C_{12} \times C_9$, but the respective exponents are 108 and 36.

Monodromy describes the action of one circuit of the phase base on its fibre. In the dynamics with memory, the nonadic holonomy Γ_9 preserves phase and advances depth. Its projection onto phase and counter satisfies

$$(r, n) \longmapsto (r, n + 1).$$

This formula is a reduced representation of the action, not a definition eliminating the rest of the state. On bidirectional histories the counter can be extended to $\mathbb{Z}$; on histories starting at depth zero, backward motion is defined only where the predecessor is preserved. The calendar can return after 108 transitions while preserving a memory different from the initial one. This distinction will be essential when the particle is constructed as persistence rather than repetition of a visible coordinate.

10.7.5 From records to prolongation operators

The linear publication operators are determined on the transport transitions. If x_j^{χ} is a regional state and Π_6 its six-component publication, the dependence is

$$b_j^{\chi} = \Pi_6(x_j^{\chi}), \qquad x_{j+1}^{\chi} = U_{9j+9} \cdots U_{9j+1}(x_j^{\chi}).$$

The origin matrices X_a and destination matrices Y_a, in row vectors of $\mathbb{F}_3^6$, are

X_0	Y_0	X_1	Y_1
010211	012222	010211	002111
012222	010211	002111	110221
201101	121221	102011	012222
121221	102011	012222	102011
121200	112202	121020	010210
112202	121020	010210	010200

We have $\det X_0 = 1$, $\det X_1 = -1$ in $\mathbb{F}_3$. The unique solution of $X_a L_a = Y_a$ is $L_a = X_a^{-1} Y_a$. Concatenation of blocks published in the calendar (L_0, L_0, L_1, L_1) produces lengths $6, 12, 18, 24, 30$. The boundary of length 36 preserves the terminal and the prolongation relation. These matrices represent transitions: linear inversion proves their uniqueness for the given record, while generation of the states belongs to the effective composition U_t of the TPK.

10.7.6 Scope of the regional construction in the study of masses

The census has separated initial conditions, emissions, regions, and operators representing their transitions. The next stage evaluates the regional coordinates and composes the dodecaphase record. Later, the particle atlas will be constructed on the same support but will use another classification. This continuity preserves a common provenance without turning a numerical fibre into a species through mere coincidence of cardinalities or labels.

10.8 Arithmetic of histories, composition, and refinement

The persistence of a particle and the evaluation of its character require a distinction between the transported history and the coordinates read from it. The APP–TRIT–TPK kernel provides the admissible states, their routes, and the operations preserving their provenance. This section specifies three structures used in passing from those data to the atlas: compatibility between depths, composition of histories with memory, and the transport of observables in the direction opposite to refinement. Algebraic coefficients act on states and routes already specified; the relations proved below preserve that order.

10.8.1 Compatible sections and evaluation of their readers

Let X_n be the set of admissible states at depth n produced by the kernel. A state records the APP positions, the additive and multiplicative sheets, their remainders and quotients, the tritic regime, orientation, phase, boundary, route, carry, and memory pertinent to survival. These data satisfy the relations of the operations that produced them; they are not regarded as a product of independent coordinates.

For $m \geq n$, the restriction $r_{m,n} : X_m \longrightarrow X_n$ preserves the antecedent at depth n. The restrictions satisfy

$$r_{n,n} = \mathrm{id}_{X_n}, \qquad r_{\ell,n} = r_{m,n} \circ r_{\ell,m} \quad (\ell \geq m \geq n). \tag{10.86}$$

New memory belongs to the prolongation; restriction preserves the memory already determined in the prefix.

Definition 10.83 (Compatible numerical section)**.** An HMT numerical section is a sequence of states of the same genealogy

$$x = (x_n)_{n \geq 0} \in X_\infty := \varprojlim_n X_n, \qquad r_{m,n}(x_m) = x_n \quad (m \geq n). \tag{10.87}$$

A reader is an operation defined on a specified domain of these sections. A finite observation belongs to a prefix; a scalar value is the evaluation of a reader. The section and the presentation of that section through a reader are therefore objects of different types.

Inverse-limit notation gathers together the compatibility of the states already constructed. The existence of a particular prolongation is established through the admissibility rules of that construction, not merely by writing X_∞.

In the Archimedean domain of a reader, each prefix determines a nonempty closed interval $I_n(x) = [a_n(x), b_n(x)]$, with

$$I_{n+1}(x) \subseteq I_n(x), \qquad b_n(x) - a_n(x) \longrightarrow 0. \tag{10.88}$$

Regional interval evaluation and the determination of its prefixes have been assembled in Proposition 90.44.

Proposition 10.84 (Value determined by compatible cylinders)**.** *For every section in that domain there is a unique real number* $\mathrm{ev}(x)$ *such that*

$$\{\mathrm{ev}(x)\} = \bigcap_{n\geq 0} I_n(x). \tag{10.89}$$

Proof. Nestedness makes the sequence $a_n(x)$ increasing and $b_n(x)$ decreasing. Both remain bounded in the initial interval. By completeness of the line, $a = \sup_n a_n(x)$ and $b = \inf_n b_n(x)$ exist and satisfy $a \leq b$. The vanishing width forces $a = b$. This point belongs to every interval, and any other point of the intersection would have distance from it less than or equal to every width, and would therefore coincide with it. □

This proposition determines the value of each section of the indicated domain. Coverage of all of $\mathbb{R}$ requires proving that each value belongs to the reader's image; the definition of an inverse limit does not in itself provide that proof. Likewise, identifying two histories from their value requires an injectivity result for the reader considered. Evaluation preserves genealogy as an antecedent and specifies exactly which part of it it publishes.

10.8.2 Sectorial route algebra and memory multipliers

Fix a sector of states and the category C of its admissible histories. We write $vu = v \circ u$: first u is traversed, then v. The elementary steps are TPK selection, transport, and update operations. The category preserves their endpoints and the conditions allowing two routes to be concatenated.

The local tritic fibre can be represented by

$$\mathbb{R}[J_x]/(J_x^2 + \tau(x)1_x), \qquad \tau(x) \in \{+1, 0, -1\}.$$

The representation preserves the regime and its orientation. To handle richer coefficients, we shall allow an associative unital real algebra A_x at each object x. A transition between regimes must specify its map on these algebras; it does not amount to identifying them.

The following construction applies to sectors possessing unital transports $\rho_u : A_x \to A_y$, for $u : x \to y$, with

$$\rho_{\mathrm{id}_x} = \mathrm{id}_{A_x}, \qquad \rho_v \circ \rho_u = \rho_{vu}. \tag{10.90}$$

For each composable pair $u : x \to y$, $v : y \to z$, let $\Omega(v, u) \in Z(A_z)^\times$ be an invertible central multiplier. Its rules are

$$\Omega(\mathrm{id}_y, u) = \Omega(u, \mathrm{id}_x) = 1_y \tag{10.91}$$

and, for $w : z \to t$,

$$\rho_w(\Omega(v, u))\, \Omega(w, vu) = \Omega(w, v)\Omega(wv, u). \tag{10.92}$$

These conditions describe the starting structure of the sector: every specific application must provide its transports and multipliers. A realisation through bimodules preserves its own compositions and is not automatically replaced by the strict action (10.90).

Let $t(u)$ be the terminal endpoint of the arrow u. On sums of finite support

$$\mathcal{H} = \bigoplus_{u \in \mathrm{Mor}(C)} A_{t(u)} T_u$$

we define, by bilinearity,

$$(aT_v)(bT_u) = a\rho_v(b)\Omega(v,u)T_{vu} \tag{10.93}$$

when u, v are composable, and zero otherwise. Addition gathers histories with their coefficients; multiplication concatenates the histories and preserves the memory multiplier. Finite support ensures that each product is defined without requiring additional convergence.

10.8.3 Associativity, local identities, and calendar memory

Proposition 10.85 (Associative composition of the sector)**.** *Under* (10.90)–(10.92)*, the product* (10.93) *is associative. If there are finitely many objects, its unit is* $\sum_x 1_x T_{\mathrm{id}_x}$*. For an arbitrary set of objects, the same expressions on finite sets of endpoints give local identities for every finite family of histories.*

Proof. Let $u : x \to y$, $v : y \to z$, $w : z \to t$, with coefficients $a \in A_y$, $b \in A_z$, $c \in A_t$. The two associations produce, as coefficients of T_{wvu},

$$\begin{aligned} ((cT_w)(bT_v))(aT_u) &: \quad c\rho_w(b)\Omega(w,v)\rho_{wv}(a)\Omega(wv,u), \\ (cT_w)((bT_v)(aT_u)) &: \quad c\rho_w(b)\rho_w\rho_v(a)\rho_w(\Omega(v,u))\Omega(w,vu). \end{aligned}$$

The strict action identifies $\rho_w\rho_v(a)$ with $\rho_{wv}(a)$. Centrality allows $\Omega(w,v)$ to be moved to the right of this factor, and the cocycle identity equates the remaining factors. The general coefficients a, b, c, which may not commute, are not permuted. If the three arrows do not form a composable chain, both associations are zero by their endpoints. Bilinearity extends the equality to finite sums. Finally, (10.91) and the unitality of each ρ_u verify the unit. For a finite family it suffices to sum the identities of all its initial and terminal endpoints, proving the last statement. □

The nonadic calendar provides an effective realisation of these conditions. Take the one-object category with arrows $C_9 = \mathbb{Z}/9\mathbb{Z}$, coefficients $A = \mathbb{R}[z, z^{-1}]$, and identity action. For representatives $0 \le a, b < 9$, define

$$c_0(a,b) = \left\lfloor \frac{a+b}{9} \right\rfloor, \qquad \Omega(b,a) = z^{c_0(a,b)}. \tag{10.94}$$

The formal variable z preserves the number of circuits. Normalisation follows from $c_0(0,a) = c_0(a,0) = 0$. If $[a+b]_9$ denotes the reduced representative, Euclidean division gives

$$c_0(a,b) + c_0([a+b]_9, c) = \left\lfloor \frac{a+b+c}{9} \right\rfloor = c_0(b,c) + c_0(a,[b+c]_9).$$

This equality proves the cocycle (10.92) for the multipliers, and hence the associativity of the calendar with memory.

If $T = T_{[1]_9}$, the product rules give $T^j = T_{[j]_9}$ for $0 \le j < 9$ and $T^9 = zT_{[0]_9}$. Subsequently imposing $z^{12} = 1$ yields $T^{108} = 1$. The expressions $z^k T_{[j]_9}$, $0 \le k < 12$, $0 \le j < 9$, form the 108 positions of the resulting calendar. This recovers the cyclic group C_{108} and its projection onto C_9; retaining z without that relation distinguishes successive circuits. This is a realisation of calendar memory: the remaining coordinates of the TPK histories remain in their own domain.

10.8.4 Double variance of refinement and preservation of unity

Restriction of states induces a prolongation of observables in the opposite direction. For the function algebras with pointwise multiplication $D_n = \mathrm{Fun}(X_n, \mathbb{R})$, precomposition defines

$$r^*_{m,n} : D_n \longrightarrow D_m, \qquad r^*_{m,n} f = f \circ r_{m,n}. \tag{10.95}$$

The contravariant order is preserved: $r^*_{\ell,n} = r^*_{\ell,m} \circ r^*_{m,n}$. These maps are unital homomorphisms. If $r_{m,n}$ is surjective, then $r^*_{m,n}$ is also injective: a difference between two functions can be evaluated at a preimage of a point where they differ.

Lemma 10.86 (Indicators, unity, and compatible evaluation)**.** *For $x \in X_n$, let e_x be its indicator function. Then*

$$r^*_{m,n} e_x = \mathbf{1}_{r^{-1}_{m,n}(x)}, \qquad r^*_{m,n} 1_n = 1_m. \tag{10.96}$$

When the fibre $r^{-1}_{m,n}(x)$ is finite, the first equality is the finite sum

$$r^*_{m,n} e_x = \sum_{y : r_{m,n}(y) = x} e_y.$$

For every section $x = (x_n) \in X_\infty$, the rule $[f] \mapsto f(x_n)$, with $f \in D_n$, defines a unital homomorphism

$$\mathrm{Ev}_x : D_{\mathrm{cyl}} \longrightarrow \mathbb{R}, \qquad D_{\mathrm{cyl}} = \varinjlim_n (D_n, r^*_{n+1,n}). \tag{10.97}$$

Proof. For $y \in X_m$, we have $(r^*_{m,n} e_x)(y) = 1$ exactly when $r_{m,n}(y) = x$. This is the first equality of (10.96). If the fibre is finite, its point indicators are orthogonal and sum to its indicator. The second equality follows from $1_n(r_{m,n}(y)) = 1$, without any assumption on the cardinality of the fibre.

For every $f \in D_n$, the naturality of evaluation is

$$(r^*_{m,n} f)(y) = f(r_{m,n}(y)).$$

In a compatible section, $r_{m,n}(x_m) = x_n$, hence $(r^*_{m,n} f)(x_m) = f(x_n)$. Thus two representatives identified at a common depth have the same evaluation. Point evaluation preserves addition, multiplication, and unity, completing the proof of (10.97). □

For infinite fibres the formulation through $\mathbf{1}_{r^{-1}_{m,n}(x)}$ remains valid; there is no need to interpret an infinite sum as a finite algebraic sum. The direct limit gathers the finite-depth observables with the identifications induced by the restrictions. Prolonging route operators additionally requires the compatibility squares of their transports with those restrictions.

The preserved unity is the constant function one on the domain of possibilities. An individual section selects a compatible history in that domain. Refinement may increase depth and distinguish more prolongations while preserving unity and the evaluation of each antecedent. This unital preservation provides the precise algebraic content used here; a probability measure, when it enters another reader, additionally requires its normalisation and its own rules.

10.9 Coinductive depth of the fourfold relation

The regional readers and dodecaphase closure publish, respectively, π, φ, e and α from the common enriched state. We reserve N for operator depth and n for decimal length: the two indices are not identified and no uniform reading cost is assumed. For each exact realization χ, its integer part is preserved separately and $p_{\chi,n}$ denotes the prefix of length n of its fractional part, in the canonical decimal expansion not eventually equal to nine. Define

$$\rho^{\mathrm{dec}}_{n+1,n}(d_1 \dots d_n d_{n+1}) = d_1 \dots d_n, \qquad p_{\chi,0} := \varnothing.$$

The uniqueness of $p_{\pi,n}, p_{\varphi,n}, p_{e,n}$ follows from the uniqueness of the exact character already generated and of its canonical decimal cylinder. That of $p_{\alpha,n}$ follows from the integral dodecaphase closure, its tail identity, and the projective compatibility proved in Theorem 11.70. The ninth-order analytic resolvent provides an additional finite characterization, while the complete analytic reader computes the remaining coefficients by $b_{10+3n} = \lambda/729^n$, proves uniform convergence, and constructs rational intervals contained in the integral cylinders. It thereby identifies that same section at arbitrary depth by Theorem 11.76. The finite jet is used neither as a generator nor as a substitute for the coinductive prolongation.

Theorem 10.87 (Projective compatibility of π, φ, e, α at arbitrary depth)**.** *The coinductive action of the common state determines*

$$\begin{gathered} \forall \chi \in \{\pi, \varphi, e, \alpha\}\ \forall n \geq 1 \quad \exists!\, p_{\chi,n}, \\ \rho^{\mathrm{dec}}_{n+1,n}(p_{\chi,n+1}) = p_{\chi,n}, \qquad p_{\chi,\infty} := (p_{\chi,n})_{n\geq 0} \in \varprojlim_{n\geq 0} \{0,\dots,9\}^n. \end{gathered} \tag{D1}$$

In particular,

$$(p_{\pi,\infty}, p_{\varphi,\infty}, p_{e,\infty}, p_{\alpha,\infty}) \tag{D2}$$

is a correlated coinductive publication of the unique enriched state.

Proof. Result 10.51 fixes the exact realizations of the three regional readers. Theorem 11.70 constructs the complete section α_{HMT} and proves compatibility of all its prefixes. The canonical decimal expansion of each of these four realizations has a unique prefix of each length; truncating the prefix of length $n+1$ gives the one of length n. Applying those readers to the common state gives the stated correlated family. Existence and compatibility of this exact publication do not identify n with N or add a cost bound to the reading procedures already established. □

The internal constructive order preserves the readers of π, φ, e, the signed state, the integer dodecaphase seal K and the dodecaphase wheel that publishes α; no conventional constant is promoted to a generator. An execution at one thousand, ten thousand or one million digits verifies the corresponding finite computational instance of (D1); it does not constitute a bound on the theorem. The theorem is the compatible family for every n and the infinite section determined by it.

This depth is not used to infer the continuum hypothesis. The four publications certify the coinductive action of the same generator; cardinal closure has already been obtained through coverage, condensation and the two injections. Its verification criterion is twofold: compatibility of all truncations of (D1) and internal provenance of the data of the dodecaphase wheel that publishes α_{HMT}.

Chapter 11

Internal derivation of α through the reversible dodecaphasic closure of the signed state

11.1 Initial generation of the signed dodecaphase state and reconstruction of the seal K

The construction of the integer seal does not begin with α, its inverse or a metrological table. Its domain is the enriched terminal state of the Topological Phase Kernel obtained after the already constructed chain

$$\boxed{\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \Omega_{\mathrm{seed}} \xrightarrow{T_{\min}} \mathcal{U}_6^{\mathrm{cat}} \xrightarrow{\rho_3} W_{243} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}}.} \tag{11.1}$$

The foregoing arrows were defined with their respective domains: pairs of seeds, signatures, emissions, ternary words, boundaries, compatible histories, and nonadic holonomy. This unit does not reselect any of those data. It constructs the integral charts of the same terminal state and proves their equivalence.

11.1.1 Oriented tracis over windows of length 108

Let

$$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}$$

the observable calendar. Its twelve nonadic windows are

$$E_m = \{9m + 1, \dots, 9m + 9\}, \qquad 0 \le m < 12.$$

The partition is disjoint and exhaustive:

$$\{1, \dots, 108\} = \bigsqcup_{m=0}^{11} E_m.$$

The set of address codes that publish an event is fixed as

$$D_{\mathrm{evt}} = \{2, 4, 6, 8\}.$$

The orientation of the twelve windows is

$$\Sigma_{12} = (+, +, +, -, -, -, +, +, +, -, -, -). \tag{11.2}$$

If d_t is the direction encoded at step t, the signed event of window m is

$$e_m = \Sigma_{12}(m)\, \#\{t \in E_m : d_t \in D_{\mathrm{evt}}\}. \tag{11.3}$$

The formula distinguishes the nonnegative number of events from the sign of the orientation. It does not replace a cardinal direction with a sign: both coordinates remain present in the TPK state.

Definition 11.1 (Enhanced dodecaphonic registration)**.** The record transported by the trace is

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=0}^{11},$$

where τ_m is the TRIT orientation, σ_m the boundary signature, κ_m the carry, and Λ_m the genealogical register segment that preserves the route. There is a chain of projections

$$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathcal{R}_{12} \longrightarrow \Theta_{108},$$

but neither of the two arrows is an identification.

In particular, Θ_{108} preserves only the position in the calendar. The record $\mathcal{R}_{12}$ additionally preserves orientation, signature, carry, and provenance. The complete state further preserves cylinder, boundary, quotient, terminal, and vertical memory.

11.1.2 Integral chart of the dodecaphasic opposition

For $0 \le i < 6$, the opposite positions determine

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}. \tag{11.4}$$

The central charge and the five relative margins are

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5). \tag{11.5}$$

Definition 11.2 (Integral chart $1 + 5 + 6$)**.** It is defined

$$\mathcal{L}_{12}(e_0, \dots, e_{11}) = \big(s_C, M_0, \dots, M_4, a_0, \dots, a_5\big). \tag{11.6}$$

The coordinate partition is

$$1 + 5 + 6 = 12.$$

Theorem 11.3 (Exact inverse of the integral chart)**.** *A tuple*

$$\ell = (s_C, M_0, \dots, M_4, a_0, \dots, a_5) \in \mathbb{Z}^{12}$$

belongs to the image of $\mathcal{L}_{12}$ if and only if

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6, \tag{11.7}$$

$$p_i \equiv a_i \pmod 2 \quad (0 \le i < 6), \tag{11.8}$$

where

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \tag{11.9}$$

$$p_i = p_5 + M_i \quad (0 \le i < 5). \tag{11.10}$$

In that case, the only entire preimage is

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}. \tag{11.11}$$

Proof. Summing $M_i = p_i - p_5$ for $0 \le i < 5$, we obtain

$$\sum_{i=0}^{4} M_i = \sum_{i=0}^{4} p_i - 5p_5 = s_C - 6p_5,$$

which forces (11.9) and the congruence modulo six. Once the six p_i have been reconstructed, the system

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}$$

has the unique solution (11.11). This solution is integral exactly when p_i and a_i have the same parity. The two families of congruences are therefore necessary and sufficient. □

This theorem precedes the numerical closure of α. It explains how the oriented trace produces a reversible integral chart, and why preserving the reduced calendar is not enough.

11.1.3 Selection of the common terminal state

The three compatible sections reach terminal depth with catalogs of cardinalities

$$|\mathcal{T}_\pi| = 196, \qquad |\mathcal{T}_e| = 197, \qquad |\mathcal{T}_\varphi| = 196.$$

The product contains

$$196 \cdot 197 \cdot 196 = 7\,567\,952 \tag{11.12}$$

ordered triples.

The column margin of the terminal reader is

$$q_\partial = (1, 2, 2, 1, 2, 0) \in \mathbb{F}_3^6,$$

and the row orientation of the combined channel is

$$\sigma = (1, 1, -1) = (1, 1, 2) \in \mathbb{F}_3^3.$$

The first datum acts on columns; the second acts on rows. Neither is deducible from the other.

The local signatures of Gram matrix, norm, weight, and distance reduce (11.12) to 331 triples. The margin q_∂ leaves two indices:

$$(120, 197, 157), \qquad (129, 197, 148).$$

Their matrices are

$$B_0 = \begin{pmatrix} 0 & 2 & 0 & 2 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}, \qquad B_1 = \begin{pmatrix} 0 & 2 & 1 & 0 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 0 & 2 & 1 & 0 \end{pmatrix}.$$

The row sums are

$$(0, 2, 0), \qquad (2, 2, 1).$$

Since

$$\langle \sigma \rangle = \{(0, 0, 0), (1, 1, 2), (2, 2, 1)\},$$

only B_1 satisfies the axial condition.

Theorem 11.4 (Uniqueness of the Visible Terminal Publication)**.** *The joint selection determines*

$$B_{\text{term}} = \begin{pmatrix} 021020 \\ 001220 \\ 100210 \end{pmatrix}, \tag{11.13}$$

corresponding to the triple $(129, 197, 148)$. *No decimal evaluation of α enters the census or the two selection conditions.*

Proof. The census and margin leave exactly B_0, B_1. The charge of B_0 does not belong to $\langle \sigma \rangle$, whereas that of B_1 is 2σ. The second candidate is therefore the only one that simultaneously satisfies both typed requirements. □

11.1.4 Archimedean and exceptional publications of the common state: inequivalent codomains and shared genealogy

Let

$$x_{\mathrm{term}} \in \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \subseteq \mathcal{X}_{\mathrm{TPK}}^{[108]}.$$

The visible reading is

$$\pi_{\mathrm{term}}(x_{\mathrm{term}}) = B_{\mathrm{term}}.$$

The signed chart preserves another coordinate of the same state.

Definition 11.5 (Terminal signed causal reading)**.** The domain incorporates neither K nor U as input coordinates. The state x_{term}, produced by the full composition APP $\to$ TRIT $\to$ TPK, contains the enriched terminal register, and the extractor of its twelve oriented windows is

$$R_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{R}_{12}^{\mathrm{or}}, \qquad R_{12}(x_{\mathrm{term}}) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=0}^{11}. \tag{11.14}$$

The ledger's channel reader 90/120 emits, without receiving the result as data,

$$E_{108}^{90,120} : \mathcal{R}_{12}^{\mathrm{or}} \longrightarrow \mathbb{Z}^{12} \times \mathbb{Z}^{12} \times \mathbb{Z}, \qquad E_{108}^{90,120}\big(R_{12}(x_{\mathrm{term}})\big) = (b_{90}, b_{120}, Q_{\mathrm{TPK}}),$$

with

$$\begin{aligned} b_{90} &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461),\\ b_{120} &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128),\\ Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

For $r = 1, 2, 3$ and $j = 0, 1, 2, 3$, define

$$\begin{aligned} B_r &= \sum_{j=0}^{3} b_{120,r+3j}, \qquad d_{r,j} = b_{90,r+3j},\\ A_1 &= \frac{Q_{\mathrm{TPK}} + 2B_1 + B_2}{3}, \qquad A_2 = A_1 - B_1, \quad A_3 = A_2 - B_2. \end{aligned}$$

The publication Π_H forms the three blocks

$$U^{(r)} = \big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big),$$

and reinterleaves them in dodecaphasic order, that is,

$$\Pi_H(b_{90}, b_{120}, Q_{\mathrm{TPK}}) := \mathrm{reint}_3\big(U^{(1)}, U^{(2)}, U^{(3)}\big) = U.$$

Let $\mathcal{H}_{12}$ be the integral transformation to be constructed in the next section. The publication module is

$$\mathcal{U}_{12}^{\mathrm{sgn}} := \mathrm{im}\big(\mathcal{H}_{12} : \mathbb{Z}^{12} \to \mathbb{Z}^{12}\big). \tag{11.15}$$

The signed reading is, causally, the composition

$$R_{\mathrm{sgn}} := \Pi_H \circ E_{108}^{90,120} \circ R_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}}, \qquad R_{\mathrm{sgn}}(x_{\mathrm{term}}) = U. \tag{11.16}$$

Only after this output is $K = \mathcal{H}_{12}^{-1}U$ reconstructed; the identity $U = \mathcal{H}_{12}K$ certifies that reconstruction and does not define the reader's domain.

The correct joint writing is

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} (B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}). \tag{11.17}$$

No arrow $B_{\mathrm{term}} \to U_{12}^{\mathrm{sgn}}$ is interposed: the visible matrix has forgotten precisely the orientation, opposition, quotient, carry, and genealogical record coordinates used by the signed chart. The source of both publications is the enriched state produced by (11.1).

The evaluation of the signed record gives

$$\boxed{U = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997).} \tag{11.18}$$

11.1.5 Naturality with respect to depth

For $N' \geq N \geq 108$, the truncations of the signed system are

$$\tau_{N',N}^{\mathrm{sgn}} x_{\mathrm{term}}^{[N']} = \tau_{N',N} x_{\mathrm{term}}^{[N']}. \tag{11.19}$$

Therefore, truncation acts only on the history and the enriched state; it does not carry either K or U as independent inputs.

Theorem 11.6 (Square of naturality of the signed reading)**.** *We have*

$$\boxed{R_{\mathrm{sgn},N} \circ \tau_{N',N}^{\mathrm{sgn}} = \mathrm{id}_{\mathcal{U}_{12}^{\mathrm{sgn}}} \circ R_{\mathrm{sgn},N'}.} \tag{11.20}$$

Proof. The naturality of the states literally preserves the first one hundred and eight windows of the ledger:

$$R_{12,N} \circ \tau_{N',N}^{\mathrm{sgn}} = R_{12,N'}.$$

Truncation can modify only the subsequent history. Since $E_{108}^{90,120}$ and Π_H depend exclusively on those windows, both sides return the same U. Commutativity is an equality of maps, not an analogy between diagrams. □

11.1.6 Orbits of step 3 and transform of Hadamard

The cyclic order of the seal is distributed over the three orbits.

$$K^{(1)} = (K_1, K_4, K_7, K_{10}), \tag{11.21}$$

$$K^{(2)} = (K_2, K_5, K_8, K_{11}), \tag{11.22}$$

$$K^{(3)} = (K_3, K_6, K_9, K_{12}). \tag{11.23}$$

Let

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{11.24}$$

If P_{orb} reorders the twelve coordinates according to (11.21)–(11.23), the global transformation is

$$\mathcal{H}_{12} = P_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4) P_{\mathrm{orb}}. \tag{11.25}$$

The three blocks of (11.18), read by orbits, are

$$U^{(1)} = (2378, -452, -668, -322),$$
$$U^{(2)} = (1406, 998, -204, -28),$$
$$U^{(3)} = (2479, -551, -371, -997).$$

Lemma 11.7 (Algebraic Hadamard quarter-turn)**.** *The matrix H_4 satisfies*

$$H_4^2 = 4I_4, \qquad H_4^{-1} = \frac{1}{4}H_4, \qquad \det H_4 = -16. \tag{11.26}$$

Proof. The rows of H_4 are orthogonal, and each has squared norm four. Since the matrix is symmetric, $H_4^{\mathsf{T}}H_4 = H_4^2 = 4I_4$. The formula for the inverse and the determinant follow immediately. □

Theorem 11.8 (Unique full reconstruction of the seal)**.** *The inverse*

$$K^{(r)} = \frac{1}{4}H_4U^{(r)} \qquad (r = 1, 2, 3) \tag{11.27}$$

yields

$$\begin{aligned} K^{(1)} &= (234, 729, 621, 794), \\ K^{(2)} &= (543, 659, 058, 146), \\ K^{(3)} &= (140, 824, 914, 601). \end{aligned}$$

By undoing the orbital order one obtains

$$\boxed{K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).} \tag{11.28}$$

It is the unique rational preimage of U, and it belongs to $\mathbb{Z}^{12}$.

Proof. By (11.26), the rational preimage is unique. The explicit multiplications are

$$\begin{aligned} H_4U^{(1)} &= (936, 2916, 2484, 3176), \\ H_4U^{(2)} &= (2172, 2636, 232, 584), \\ H_4U^{(3)} &= (560, 3296, 3656, 2404). \end{aligned}$$

All coordinates are divisible by four. Dividing and reinterleaving yields (11.28). □

The factor $1/4$ is not chosen to fit an output: it is the inverse forced by $H_4^2 = 4I_4$. Nor is it the square root of -1. The internal complex structure $A_W^2 = -I$ will appear after constructing the Paley matrix; these are two facts of different types.

11.1.7 Integral structure and Smith normal form

Theorem 11.9 (Integral image of H_4)**.** *The Smith normal form is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4). \tag{11.29}$$

Consequently,

$$\operatorname{coker} \mathcal{H}_{12} \cong (\mathbb{Z}/2\mathbb{Z})^6 \oplus (\mathbb{Z}/4\mathbb{Z})^3, \tag{11.30}$$

and the image of $\mathcal{H}_{12}$ has index

$$16^3 = 4096$$

in $\mathbb{Z}^{12}$. For $u \in \mathbb{Z}^4$,

$$u \in H_4\mathbb{Z}^4 \quad \Longleftrightarrow \quad H_4u \equiv 0 \pmod 4. \tag{11.31}$$

Proof. The greatest common divisor of the entries is one. The minors of order two are even, and one has absolute value two; those of order three are multiples of four, and one has absolute value four; the determinant has modulus sixteen. The determinantal divisors are $1, 2, 4, 16$, yielding the invariant factors

$1, 2, 2, 4$. The triple direct sum repeats the factors and multiplies the indices. Finally, $H_4^{-1} = H_4/4$, so the preimage is integral exactly under the congruence (11.31). □

11.1.8 Certification and reconstruction by differences of steps 3 and 4

Once the ledger has emitted $(b_{90}, b_{120}, Q_{\mathrm{TPK}})$, Π_H has produced U and Hadamard has reconstructed K, the following coordinates act downstream as an independent certificate of those prior outputs. With cyclic indices modulo twelve, define

$$(D_3K)_m = K_m - K_{m+3}, \qquad (D_4K)_m = K_m - K_{m+4}, \qquad Q(K) = \sum_{m=1}^{12} K_m. \tag{11.32}$$

For (11.28), one verifies

$$\begin{aligned} D_3K = b_{90} = (&-495, -116, -684, 108, 601, -90,\\ &-173, -88, 313, 560, -397, 461),\\ D_4K = b_{120} = (&-425, -281, -481, 671, -255, 30,\\ &475, -543, 680, 251, 6, -128),\\ Q(K) = Q_{\mathrm{TPK}} = 6263.& \end{aligned}$$

Theorem 11.10 (Completeness of the transversal extractor)**.** *The operator*

$$\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}$$

has rank twelve and Smith normal form

$$\mathrm{SNF}(\mathcal{E}_{\mathrm{dod}}) = \mathrm{diag}(\underbrace{1, \ldots, 1}_{11}, 12). \tag{11.33}$$

In particular, $(D_3K, D_4K, Q(K))$ determines a unique K. This uniqueness certifies and reconstructs the data already emitted by the ledger; it neither generates nor selects them.

Proof. If $D_3v = D_4v = 0$, then v is constant along steps three and four. Since $\gcd(3, 4) = 1$, those steps generate all of $\mathbb{Z}/12\mathbb{Z}$, so that

$$\ker D_3 \cap \ker D_4 = \langle \mathbf{1} \rangle.$$

The total charge does not vanish on that line, since $Q(\mathbf{1}) = 12$. The rank is twelve. The rows of (D_3, D_4) are oriented incidences of a connected Cayley graph; a spanning tree supplies eleven unit invariant factors. Every maximal minor must contain the row Q, and the unimodular operations reduce its final contribution to twelve. There is a maximal minor of modulus twelve; therefore, the last factor is exactly twelve. □

The certifying reconstruction of U from these coordinates reproduces the prior publication of Π_H and does not require multiplying again by H_4. For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} (D_4K)_{r+3j} = \sum_{j=0}^{3} b_{120,r+3j}. \tag{11.34}$$

Then

$$(B_1, B_2, B_3) = (972, -1073, 101).$$

Orbital sums are

$$A_1 = \frac{Q + 2B_1 + B_2}{3} = 2378, \tag{11.35}$$

$$A_2 = A_1 - B_1 = 1406, \tag{11.36}$$

$$A_3 = A_2 - B_2 = 2479. \tag{11.37}$$

If $d_{r,j} = (D_3K)_{r+3j} = b_{90,r+3j}$, the signed block of orbit r is

$$\big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big), \tag{11.38}$$

which reproduces the three blocks $U^{(r)}$ already published by Π_H.

11.1.9 Threshold Tetrad of the Seal

The local decimal completion satisfies

$$1000 = 729 + 271.$$

The support of the seal coordinates that reach the threshold 729 is

$$\boxed{B_K := \{m : K_m \geq 729\} = \{4, 6, 9, 10\}.} \tag{11.39}$$

This tetrad is obtained after constructing K. In this unit it is not yet called a Witt star: that object will be defined only after constructing the ternary code, its hexads, and the Steiner system.

11.1.10 Independence of the genealogical construction with respect to external metrological or physical data

Theorem 11.11 (Isolation of U and K)**.** *The composition*

$$\Omega_{\text{seed}} \longrightarrow x_{\text{term}} \xrightarrow{R_{\text{sgn}}} U \xrightarrow{\mathcal{H}_{12}^{-1}} K \tag{11.40}$$

does not receive α, α^{-1}, CODATA or a target decimal string as input. The seal K is determined before defining the recurrence that will produce α.

Proof. The first part of the composition uses only seeds, emissions, ternary readers, L_0, L_1 operators, survival relations, phase transport and the charts of the TPK state. The reading $R_{\text{sgn}} = \Pi_H \circ E_{108}^{90,120} \circ R_{12}$ is the causal composition of the terminal register, and the last arrow is the linear transformation $\mathcal{H}_{12}^{-1} = \mathcal{H}_{12}/4$ on its integral image. None of the formulas contains a physical variable or a metrological table. The base-one-thousand recurrence is introduced only in the next unit, after K has been fixed. □

11.1.11 Obstructions of the dodecaphase record and the seal K: naturality, Hadamard integrity, and metrological isolation

Comparison Criterion 11.12 (Refutation of the register and the seal)**.** The construction is refuted if any of the following facts is established:

1. the windows E_m do not partition the one hundred eight steps;
2. the chart $\mathcal{L}_{12}$ fails its inverse or its congruences;
3. the terminal census does not produce 331 triples, two matrices and a unique axial charge;
4. an attempt is made to obtain U from B_{term} after forgetting the signed coordinates;
5. the naturality square (11.20) fails;
6. $H_4^2 \neq 4I_4$, some preimage is not integral or the reconstructed vector differs from (11.28);

7. the Smith normal form differs from (11.29);
8. the certificate (D_3, D_4, Q) loses rank, does not match the ledger's prior emissions or does not reproduce U;
9. B_K is introduced before constructing K, or is assigned a Witt structure before defining W_{12};
10. a digit of α or a metrological reference intervenes in any of the arrows of (11.40).

11.2 Initial construction of the boundary 662/663 through the dodecaphase carry cocycle

11.2.1 Aritmetic closure domain

The construction receives four dodecaphasic coordinates obtained in the preceding units:

$$\begin{aligned} P &= (141, 592, 653, 589, 793, 238, 462, 643, 383, 279, 502, 884),\\ E &= (718, 281, 828, 459, 045, 235, 360, 287, 471, 352, 662, 497),\\ \Phi &= (618, 033, 988, 749, 894, 848, 204, 586, 834, 365, 638, 117),\\ K &= (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \end{aligned}$$

The first three vectors are the first twelve triads of the fractional Archimedean readings of π, e, and φ. The fourth is the dodecaphase coordinate of the enriched terminal state of the Topological Phase Kernel, constructed before the carry operation is opened.

We fix the base.

$$B := 10^3 = 1000$$

and the concatenation

$$\iota(v_1, \dots, v_{12}) := \sum_{m=1}^{12} v_m B^{12-m}. \tag{11.41}$$

In particular,

$$\begin{aligned} \iota(P) &= 141592653589793238462643383279502884,\\ \iota(E) &= 718281828459045235360287471352662497,\\ \iota(\Phi) &= 618033988749894848204586834365638117,\\ \iota(K) &= 234543140729659824621058914794146601. \end{aligned}$$

The operation studied in this unit is the map

$$\mathfrak{C}_{12} : (P, E, \Phi, K, c_{13}) \longmapsto (A, C), \tag{11.42}$$

where $A = (A_1, \dots, A_{12})$ is the output word and

$$C = (c_1, \dots, c_{13})$$

is the complete system of thirteen Euclidean quotients: twelve internal quotients and one right boundary condition.

11.2.2 Left-to-right oriented Euclidean division

For $m = 12, 11, \dots, 1$, define

$$\begin{aligned} s_m &:= P_m + E_m - \Phi_m - K_m + c_{m+1},\\ A_m &:= s_m \bmod B, \qquad 0 \le A_m < B,\\ c_m &:= \frac{s_m - A_m}{B} = \left\lfloor \frac{s_m}{B} \right\rfloor. \end{aligned} \tag{11.43}$$

The second equality for c_m is also valid when $s_m < 0$, because Euclidean division with remainder in $\{0, \dots, B-1\}$ is used. Therefore,

$$-431 = 569 - 1000, \qquad -717 = 283 - 1000, \qquad -1200 = 800 - 2 \cdot 1000,$$

and negative loans do not introduce ambiguity.

Theorem 11.13 (Existence and Uniqueness of the Oriented Carry)**.** *Given P, E, Φ, K and the terminal carry c_{13}, the recurrence* (11.43) *uniquely determines*

$$(A_1, \dots, A_{12}; c_1, \dots, c_{12}).$$

Proof. Row $m = 12$ is determined by the Euclidean division of

$$P_{12} + E_{12} - \Phi_{12} - K_{12} + c_{13}$$

by B. Once c_{12} is known, row $m = 11$ is determined by the same property. Descending induction reaches $m = 1$. At each step, uniqueness of the Euclidean quotient and remainder prevents two distinct outputs. □

11.2.3 Finite restriction of the signed dodecaphase state and reversible closure of the cycle

The finite window is defined by the terminal condition

$$c_{13}^{\mathrm{fin}} = 0.$$

The complete evaluation is as follows. The table is printed in ascending order, although it must be read causally from the last row to the first.

Table 11.1: The twelve Euclidean divisions and thirteen carries of the finite dodecaphasic window.

m	P_m	E_m	Φ_m	K_m	c_{m+1}	s_m	A_m	c_m
1	141	718	618	234	0	7	007	0
2	592	281	033	543	0	297	297	0
3	653	828	988	140	−1	352	352	0
4	589	459	749	729	−1	−431	569	−1
5	793	045	894	659	−2	−717	283	−1
6	238	235	848	824	−1	−1200	800	−2
7	462	360	204	621	0	−3	997	−1
8	643	287	586	058	−1	285	285	0
9	383	471	834	914	−1	−895	105	−1
10	279	352	365	794	0	−528	472	−1
11	502	662	638	146	0	380	380	0
12	884	497	117	601	0	663	663	0

The complete word of thirteen carries is

$$\boxed{C^{\mathrm{fin}} = (c_1, \dots, c_{13}) = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, 0).}$$

The dodecaphasic output is

$$\boxed{A^{\mathrm{fin}} = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663).}$$

We define the finite rational

$$\boxed{\alpha_{12}^{\mathrm{fin}} := 10^{-36} \iota(A^{\mathrm{fin}}) = \frac{729735256928380099728510547238066 3}{10^{36}}.} \tag{11.44}$$

Therefore,

$$\alpha_{12}^{\mathrm{fin}} = 0.007297352569283800997285105472380663.$$

11.2.4 Posterior metrological recognition: CODATA 2018

The metrological comparison is performed only after closing the recurrence, the right boundary, and the preceding rational. The integer identity gives

$$\boxed{\alpha_{12}^{\mathrm{fin}} = 10^{-36} \left\lfloor \frac{10^{36}}{137.035999084} \right\rfloor .} \tag{11.45}$$

Consequently,

$$(\alpha_{12}^{\mathrm{fin}})^{-1} = 137.035999084000000000000000000000001066588\ldots, \tag{11.46}$$

and exactly reproduces the central chain published by CODATA 2018 [122]:

$$\boxed{137.035999084.}$$

The word *exactly* refers to the published central chain, not to a purported experimental measurement of thirty-six digits. The subsequent digits in (11.46) are consequences of the HMT rational already fixed. CODATA does not select the state, does not determine (K), does not decide the direction of the carry, and does not intervene in the dodecaphase table.

11.2.5 Complete affine identity

Each row of the table satisfies exactly

$$P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + Bc_m. \tag{11.47}$$

Introducing

$$C^- := (c_1, \ldots, c_{12}), \qquad C^+ := (c_2, \ldots, c_{13}),$$

the twelve local identities come together in

$$\boxed{P + E - \Phi - K + C^+ - BC^- = A.} \tag{11.48}$$

The term

$$\partial_B C := C^+ - BC^-$$

is the carry cocycle of the oriented chain. Consequently, $P + E - \Phi - K = A$ is not a coordinatewise equality in $\mathbb{Z}^{12}$: it becomes correct only upon incorporating $\partial_B C$.

Theorem 11.14 (Telescoping of the Thirteen Carries)**.** *For any terminal condition c_{13}, the recurrence satisfies*

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A) = B^{12}c_1 - c_{13}.} \tag{11.49}$$

In the finite window, $c_1 = c_{13} = 0$, and therefore

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) = \iota(A^{\mathrm{fin}}).} \tag{11.50}$$

Proof. We multiply (11.47) by B^{12-m} and sum over $m = 1, \ldots, 12$. The contribution of the carries is

$$\sum_{m=1}^{12} (Bc_m - c_{m+1})B^{12-m}.$$

The internal components cancel:

$$\sum_{m=1}^{12}(Bc_m - c_{m+1})B^{12-m} = \sum_{m=1}^{12} c_m B^{13-m} - \sum_{m=1}^{12} c_{m+1}B^{12-m}$$
$$= B^{12}c_1 - c_{13}.$$

This proves (11.49). The specialization $c_1 = c_{13} = 0$ gives (11.50). □

11.2.6 Exact inversion of the seal K

The local recurrence is reversible. Solving for K_m in (11.47),

$$\boxed{K_m = P_m + E_m - \Phi_m + c_{m+1} - A_m - Bc_m.} \tag{11.51}$$

By concatenation,

$$\boxed{\iota(K) = \iota(P) + \iota(E) - \iota(\Phi) - \iota(A) - B^{12}c_1 + c_{13}.} \tag{11.52}$$

On the finite boundary,

$$\iota(K) = \iota(P) + \iota(E) - \iota(\Phi) - \iota(A^{\mathrm{fin}}).$$

Algebraic reversibility does not invert the causal order. The effective order is

$$x_{\mathrm{term}} \longrightarrow K \longrightarrow (P, E, \Phi, K, c_{13}) \longrightarrow (A, C).$$

Formula (11.51) is a commutativity check: it proves that the output and the carries recover the seal that was already fixed. It is not a rule for retrospectively selecting K from a desired value of α.

11.2.7 Coinductive prolongation of the dodecaphasic seal and inverse carry recurrence in $C = \{-2, -1, 0, 1, 2\}$

Let

$$(P_k)_{k\geq 1}, \qquad (E_k)_{k\geq 1}, \qquad (\Phi_k)_{k\geq 1}$$

the infinite sequences of triads produced by the three coinductive branches, and let

$$\kappa(k) := 1 + ((k-1) \bmod 12).$$

The prolongation of the stamp is periodic:

$$K_k^{\mathrm{per}} := K_{\kappa(k)}.$$

For a finite depth N and a terminal condition $t = c_{N+1}$, the recurrence is

$$\begin{aligned} s_k^{(N,t)} &= P_k + E_k - \Phi_k - K_{\kappa(k)} + c_{k+1}^{(N,t)}, \\ A_k^{(N,t)} &= s_k^{(N,t)} \bmod 1000, \\ c_k^{(N,t)} &= \left\lfloor \frac{s_k^{(N,t)}}{1000} \right\rfloor, \qquad k = N, \ldots, 1. \end{aligned} \tag{11.53}$$

The set of terminal carries

$$C := \{-2, -1, 0, 1, 2\}$$

is invariant for the certified inputs: for each triad and each $c_{k+1} \in C$, the quotient c_k again belongs to C. No favorable terminal condition is chosen. All five conditions are propagated, and only the prefix common to all of them is published.

The execution of certified depth employs

quantity	value
ternary blocks per channel	3501
trits per channel	$3501 \cdot 6 = 21006$
guard decimal digits	10020
guard triads	3340
propagated terminal conditions	5
common triads	3339
common digits	10017
published digits	10000

The five terminal branches coalesce before the published prefix. In particular, no terminal condition extracted from a target value of α intervenes in the output.

Theorem 11.15 (Stabilized Output Compatibility)**.** *Let $A^{[N]}$ and $A^{[N']}$, with $N' > N$, be two runs whose five terminal conditions have coalesced before position N. Then the truncation of $A^{[N']}$ to its first N blocks coincides with $A^{[N]}$. The stabilized prefixes define a unique section in the inverse limit of finite words.*

Proof. The recurrence is deterministic from right to left once the carry entering a position is known. Coalescence asserts that all remote conditions produce the same carry before the boundary of the prefix. From that point, the same triads P_k, E_k, Φ_k and the same periodic seal produce, by Euclidean uniqueness, the same remainders and quotients at all preceding positions. This is exactly commutativity with truncation. □

11.2.8 Boundary originating from the remote tail

The prolongation determines on the visible boundary.

$$c_{13}^{\infty} = -1.$$

The twelve internal carries remain the same as in the finite window:

$$\boxed{C_{\le 13}^{\infty} = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, -1).}$$

Only the information entering from the thirteenth triad changes. The two relevant divisions are

$$\begin{aligned} s_{12}^{\infty} &= 884 + 497 - 117 - 601 - 1 = 662, \\ A_{12}^{\infty} &= 662, \qquad c_{12}^{\infty} = 0, \end{aligned}$$

and

$$\begin{aligned} s_{13}^{\infty} &= 197 + 757 - 720 - 234 - 1 = -1, \\ A_{13}^{\infty} &= 999, \qquad c_{13}^{\infty} = -1. \end{aligned}$$

Therefore, the beginning of the prolonged word is

$$\boxed{A^{\infty} = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 662, 999, \ldots).}$$

The corresponding expansion begins

$$\boxed{\alpha_{\infty} = 0.007297352569283800997285105472380662999564172539642\ldots.} \tag{11.54}$$

The difference between both boundaries is local and exact:

$$c_{13}^{\mathrm{fin}} - c_{13}^{\infty} = 1, \qquad A_{12}^{\mathrm{fin}} - A_{12}^{\infty} = 1,$$

while

$$A_m^{\mathrm{fin}} = A_m^{\infty}, \qquad 1 \le m \le 11.$$

Applying the telescoping theorem to the first twelve blocks of the prolongation,

$$\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A_{\le 12}^{\infty}) = -c_{13}^{\infty} = 1.$$

Then

$$\boxed{\iota(A^{\mathrm{fin}}) = \iota(A_{\le 12}^{\infty}) + 1.} \tag{11.55}$$

The ending 663 does not contradict the ending 662: the former is the finite representative obtained by closing the window with $c_{13} = 0$; the latter retains the carry -1 from the remote tail.

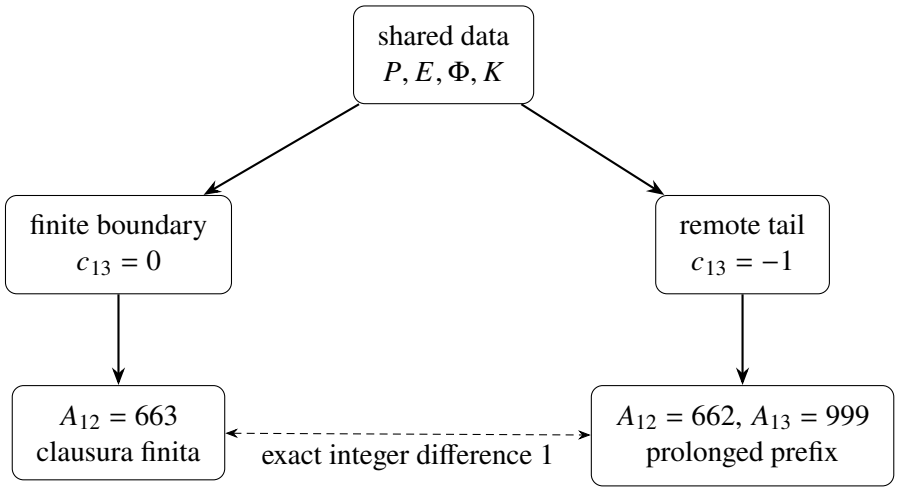

Figure 11.1: Boundary bifurcation of a single recurrence. Two distinct generators are not being compared: only the datum entering from the right changes.

11.2.9 Truncation and rounding to 36 digits

For $x \ge 0$, define

$$\mathrm{Tr}_{36}(x) := 10^{-36} \lfloor 10^{36} x \rfloor$$

and

$$\mathrm{Rd}_{36}(x) := 10^{-36} \left\lfloor 10^{36} x + \frac{1}{2} \right\rfloor.$$

Let

$$a := 729735256928380099728510547238066 2.$$

The expansion (11.54) can be written as

$$\alpha_{\infty} = \frac{a + \rho}{10^{36}}, \qquad \rho = 0.999564172539642709\ldots,$$

so that $0.999 < \rho < 1$.

Theorem 11.16 (Exact resolution of the boundary 662/663)**.** *The coinductive prolongation satisfies*

$$\boxed{\mathrm{Tr}_{36}(\alpha_{\infty}) = 0.007297352569283800997285105472380662,}$$

while its rounding to thirty-six digits satisfies

$$\boxed{\mathrm{Rd}_{36}(\alpha_\infty) = 0.007297352569283800997285105472380663 = \alpha_{12}^{\mathrm{fin}}.}$$

Proof. Since $0 \le \rho < 1$,

$$\lfloor 10^{36}\alpha_\infty \rfloor = a.$$

This gives the truncation ending in 662. Since $\rho > 1/2$,

$$\left\lfloor 10^{36}\alpha_\infty + \frac{1}{2} \right\rfloor = a + 1,$$

which ends in 663. By (11.44), $(a+1)10^{-36}$ is exactly $\alpha_{12}^{\mathrm{fin}}$. □

Moreover,

$$0 < \alpha_{12}^{\mathrm{fin}} - \alpha_\infty = \frac{1-\rho}{10^{36}} < 10^{-39}.$$

The difference is not an arithmetic error in the table: it quantifies the difference between two distinct boundary operators.

11.2.10 Causal isolation from α and metrological data

At depth N, the full domain of the operation is

$$\mathscr{D}_N = \big((P_k)_{k=1}^N, (E_k)_{k=1}^N, (\Phi_k)_{k=1}^N, K, c_{N+1}\big).$$

The carry map

$$\mathfrak{C}_N : \mathscr{D}_N \longrightarrow \{0,\dots,999\}^N \times C^N$$

is defined exclusively by (11.53). Its domain contains no target value of α, its inverse, a metrological table, a target decimal string or a terminal carry chosen by comparison.

Theorem 11.17 (No interference from the metrological target)**.** *Let $\mathscr{Y}$ be any space of external data containing metrological values or comparison tables. The formal extension*

$$\widetilde{\mathfrak{C}}_N : \mathscr{D}_N \times \mathscr{Y} \longrightarrow \{0,\dots,999\}^N \times C^N, \qquad \widetilde{\mathfrak{C}}_N(d,y) := \mathfrak{C}_N(d),$$

factorizes by the projection

$$\mathrm{pr}_{\mathscr{D}_N} : \mathscr{D}_N \times \mathscr{Y} \longrightarrow \mathscr{D}_N.$$

Therefore, for any $y, y' \in \mathscr{Y}$,

$$\widetilde{\mathfrak{C}}_N(d,y) = \widetilde{\mathfrak{C}}_N(d,y').$$

No intervention on a value of α or a metrological table alters K, the quotients, the remainders or the prefix produced.

Proof. The statement results from

$$\widetilde{\mathfrak{C}}_N = \mathfrak{C}_N \circ \mathrm{pr}_{\mathscr{D}_N}.$$

All operations of $\mathfrak{C}_N$ are additions, subtractions and Euclidean divisions of the elements of $\mathscr{D}_N$. No coordinate of $\mathscr{Y}$ appears in them. □

The complete causal order is

$$\text{enriched branches of } \pi, e, \varphi \longrightarrow (P, E, \Phi),$$

$$x_{\mathrm{term}} \longrightarrow K,$$

$$(P, E, \Phi, K, \text{boundary}) \longrightarrow (A, C) \longrightarrow \alpha_\infty,$$

$$\alpha_\infty \longrightarrow \text{external comparison.}$$

The last arrow cannot be reversed to select any of the previous ones.

11.2.11 Obstructions to affine prolongation of α: telescoping, inversion of K, boundary 662/663, and isolation of target data

Comparison Criterion 11.18 (Refutation of the affine closure and its prolongation)**.** The block is refuted in its domain if any of the following facts occurs:

1. some row of the table 11.1 fails to satisfy $s_m = A_m + 1000c_m$;
2. the published vector of thirteen carries does not reproduce the twelve rows;
3. the telescoping identity fails
$$\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A) = 1000^{12}c_1 - c_{13};$$
4. the inversion (11.51) does not recover the twelve coordinates of K;
5. remote propagation produces $c_{13} \neq -1$ for the certified prefix;
6. the five terminal conditions of $C = \{-2, -1, 0, 1, 2\}$ do not coalesce before the published digits;
7. the triad following 662 is not 999, in which case the identification of the rounding with 663 is no longer proved;
8. the generator opens a target expansion of α, its inverse, a metrological table, or a terminal condition chosen to force the coincidence.

Thus, two distinct boundary identities are thereby demonstrated:

$$\boxed{663 = \text{finite closure with } c_{13} = 0 = \text{rounding to 36 digits of } \alpha_\infty,}$$

$$\boxed{662 = \text{truncation to 36 digits of } \alpha_\infty \quad \text{with} \quad c_{13} = -1,\ A_{13} = 999.}$$

The central metrological result is finally published in the same residence as the derivation:

$$\boxed{\begin{array}{c}(\alpha_{12}^{\mathrm{fin}})^{-1} = 137.035999084000000000000000000000001066588\ldots, \\ \text{central CODATA 2018 string:} \qquad 137.035999084.\end{array}} \tag{11.56}$$

The implication expresses a subsequent comparison with the central string published; it does not introduce that string into the constructor.

11.3 Regional determination of the dodecaphasic descriptor and selection of the coupling register

The determination of the coupling register articulates two constructions that should be developed in their effective order. The first produces the selector's antecedents from the regional expressions of the TPK: six-trit bands, column signatures, conversion calendar, oriented descriptor and functional panel. The second operates on these antecedents and on the terminal repertoire of eight blocks, enumerates their admissible orderings and selects a unique register through two simultaneous conditions: exceptional incidence and reading heterotypy. The register's value appears at the end of this composition.

The present development presupposes the regional expressions obtained in the preceding chapters from APP–TRIT–TPK. Its purpose is to make explicit every intermediate operation leading from those expressions to the finite selector. The realization of the same register through signed incidences, Hadamard

inversion and expression of the fine-structure constant are then incorporated. The three constructions preserve their respective domains: register selection, recovery from its channels and arithmetic evaluation of its expressions.

11.3.1 Regional bands, encoding, and integer signatures

11.3.1.1 Domains and encoding of the regional bands

The channel order is fixed as

$$\chi \in \{\pi, e, \varphi\}, \qquad B_\chi(t) \in \mathbb{F}_3^6, \qquad t \in \mathbb{N}.$$

The channel symbols identify the regions already generated. Each $B_\chi(t)$ preserves its position in its sequence of expressions; index t counts ternary blocks. The natural evaluation of a band $b = (b_0, \dots, b_5)$ is

$$\mathrm{enc}_6(b) = 243b_0 + 81b_1 + 27b_2 + 9b_3 + 3b_4 + b_5, \qquad 0 \le \mathrm{enc}_6(b) < 729. \tag{11.57}$$

Its fixed-width inverse is

$$\mathrm{dig}_j(n) = \left\lfloor \frac{n}{3^{5-j}} \right\rfloor \bmod 3, \qquad 0 \le j < 6.$$

Leading zeros are thus retained: the words 002001 and 2001 could share an abbreviated integer notation, but the type of the former contains six positions. All subsequent concatenations use this width.

In the window of one hundred blocks, the six-hundred-trit expression of channel χ determines an integer $P_\chi^{(600)}$. Extraction is performed through

$$b_\chi(t) = \left\lfloor \frac{P_\chi^{(600)}}{729^{99-t}} \right\rfloor \bmod 729, \qquad 0 \le t < 100, \qquad B_\chi(t) = \mathrm{enc}_6^{-1}(b_\chi(t)). \tag{11.58}$$

The six-hundred-trit integer is an expression of the regional producer; the hundred-row table is the evaluation of (11.58). This separation allows a historical table to be replaced by its producer without modifying the selector that consumes it.

11.3.1.2 Residues, quotients, occupancy, and orientation

For each column j and time t, introduce

$$T_j(t) = B_\pi(t)_j + B_e(t)_j + B_\varphi(t)_j, \tag{11.59}$$

$$q_j(t) = T_j(t) \bmod 3, \qquad c_j(t) = \left\lfloor T_j(t)/3 \right\rfloor, \tag{11.60}$$

$$a_j(t) = \big(B_\pi(t)_j + B_e(t)_j - B_\varphi(t)_j\big) \bmod 3, \tag{11.61}$$

$$w_j(t) = \mathbf{1}_{B_\pi(t)_j \neq 0} + \mathbf{1}_{B_e(t)_j \neq 0} + \mathbf{1}_{B_\varphi(t)_j \neq 0}, \qquad \bar{w}_j(t) = w_j(t) \bmod 3. \tag{11.62}$$

The subtraction in the third expression is performed in the integers and then reduced. In an implementation over natural numbers, the equivalent expression is $(B_\pi + B_e + 3 - B_\varphi) \bmod 3$; truncated subtraction would change the reader.

Proposition 11.19 (Reconstruction of the column sum)**.** *For all admissible bands,*

$$T_j(t) = q_j(t) + 3c_j(t), \qquad 0 \le q_j(t) < 3, \quad 0 \le c_j(t) \le 2, \quad 0 \le w_j(t) \le 3.$$

Proof. Each column sums three representatives from $\{0, 1, 2\}$, so that $0 \le T_j(t) \le 6$. Euclidean division by three yields the stated residue and quotient. Occupancy counts three binary conditions; its bound follows directly from that definition. □

This identity preserves the quotient of the local sum. Reconstructing the three individual bands requires the bands themselves or an additional reader that distinguishes them: a column sum has fewer coordinates

than the triple that produces it. Accordingly, the temporal row used below jointly retains the three bands and the four fields $q, a, c, \bar{w}$.

11.3.2 Conversion clock and first zero advance

11.3.2.1 Ternary capacity and decimal depth

An expression of $t+1$ bands contains $6(t+1)$ trits. The associated conversion calendar is defined by the integer

$$d_t = \max\{k \in \mathbb{N} : 1000^k \le 3^{6(t+1)}\} = \max\{k \in \mathbb{N} : 1000^k \le 729^{t+1}\}. \tag{11.63}$$

The definition compares integer capacities. The counter t and the depth d_t record different quantities: a transition adds one six-trit band; the clock counts complete powers of the decimal base one thousand contained in the accumulated ternary capacity.

Lemma 11.20 (Integer characterization of the clock)**.** *For $t, k \in \mathbb{N}$,*

$$d_t = k \quad \Longleftrightarrow \quad 1000^k \le 729^{t+1} < 1000^{k+1}.$$

Moreover, $d_t \le d_{t+1}$.

Proof. The powers of one thousand form a strictly increasing, unbounded sequence. The power 729^{t+1} lies between two consecutive terms; the lower exponent is precisely the maximum in (11.63). The inequality $729^{t+1} < 729^{t+2}$ implies monotonicity of the maximum. □

Proposition 11.21 (First zero advance)**.** *The least time satisfying $d_{t+1} = d_t$ is*

$$t_* = 20.$$

In particular,

$$d_0 = 0, \quad d_{19} = 19, \quad d_{20} = 20, \quad d_{21} = 20, \quad d_{22} = 21.$$

Proof. The exact integer comparisons

$$1000^{20} \le 729^{21}, \qquad 729^{22} < 1000^{21}, \qquad 1000^{21} \le 729^{23} < 1000^{22}$$

give the values at times twenty, twenty-one, and twenty-two. For $0 \le t \le 20$, the expression $729^{t+1}/1000^t = 729(729/1000)^t$ is decreasing and its value at twenty is greater than or equal to one. Hence, $1000^t \le 729^{t+1} < 1000^{t+1}$ and $d_t = t$. No time less than twenty can satisfy $d_{t+1} = d_t$; at twenty it does hold. All comparisons used involve integer powers. □

The number twenty is therefore an output of the minimality criterion. The rule selecting the instant is "the first zero advance of the clock"; the algorithm and its proof can use this rule without receiving twenty as an external parameter.

11.3.2.2 Nonadic return and temporal antecedent

The length of the phase return determines

$$r = t_* - 9 = 11. \tag{11.64}$$

The descriptor queries are made at $t_* + 1$, $r + 1$, and r. This distribution preserves the relation between the pause instant, the nonadic translation, and the immediately associated phase reading. Times eleven, twelve, and twenty-one designate positions in the regional calendar; their temporal difference remains recorded even when two times produce the same decimal depth.

11.3.3 Oriented construction of the twenty-four-trit descriptor

11.3.3.1 Opposite half-band defects

Take the oriented defects of the regional chart

$$\delta_+ = (0,0,0,1,1,1), \qquad \delta_- = (0,0,0,2,2,2) \in \mathbb{F}_3^6.$$

Their opposition is verified componentwise:

$$\delta_+ + \delta_- = 0 \quad \text{in } \mathbb{F}_3^6.$$

The representative 2 realizes -1 in the ternary chart. Concatenating the three-position tails in negative–positive order produces the word 222111. Summing defects and concatenating their tails are distinct operations: the former has codomain $\mathbb{F}_3^6$, whereas the latter preserves the order of two segments of length three.

11.3.3.2 Dual charge and phase selection

In the regional chart, the six-coordinate transformation uses

$$A_{\mathrm{reg}} = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 2 & 2 \\ 1 & 1 & 0 & 2 & 1 & 2 \\ 1 & 1 & 2 & 0 & 2 & 1 \\ 1 & 2 & 1 & 2 & 0 & 1 \\ 1 & 2 & 2 & 1 & 1 & 0 \end{pmatrix}.$$

With row vectors, the dual charge of $b \in \mathbb{F}_3^6$ is the sum of the coordinates of bA_{reg}. The integer row sums of A_{reg} are $(5,7,7,7,7,7)$; this gives the local expression

$$\eta^\vee(b) = 2b_0 + b_1 + b_2 + b_3 + b_4 + b_5 \pmod 3. \tag{11.65}$$

The reading phase at instant r is $\theta_r = (r-1) \bmod 3$. For each channel, define

$$\varepsilon_\chi(r) = \begin{cases} 1, & \eta^\vee(B_\chi(r)) = \theta_r, \\ 2, & \eta^\vee(B_\chi(r)) \neq \theta_r. \end{cases}$$

The phase–charge expression is

$$D(r) = \varepsilon_\pi(r) B_\pi(r) + \varepsilon_e(r) B_e(r) + \varepsilon_\varphi(r) B_\varphi(r) \quad \text{in } \mathbb{F}_3^6. \tag{11.66}$$

The coefficient is determined by an equality of charges before evaluating the word that will result from the combination.

11.3.3.3 Composition of the descriptor

Let $\|$ denote the concatenation of fixed-width words. The complete construction is

$$\begin{aligned} \Omega_{24} = {} & (B_e(t_* + 1) + \delta_-) \| (\delta_-|_{3,4,5} \| \delta_+|_{3,4,5}) \\ & \| (B_\pi(r+1) + B_e(r+1)) \| D(r). \end{aligned} \tag{11.67}$$

Each length-six summand is evaluated in $\mathbb{F}_3^6$; the final concatenation has length $6+6+6+6 = 24$. This construction distinguishes the descriptor Ω_{24} from the regional stages w_{24}^{χ}: the two objects share a length, but their producers and their places in the composition differ.

Proposition 11.22 (Regional evaluation of the descriptor)**.** *The regional expressions and the first-zero-advance criterion determine*

$$\Omega_{24} = 020022\,222111\,211201\,021101, \qquad [\Omega_{24}]_3 = 66241910521.$$

Proof. The required bands, preserving the order (π, e, φ), are

t	$B_\pi(t)$	$B_e(t)$	$B_\varphi(t)$
11	022212	110001	100021
12	012012	202222	000120
21	221022	020100	211021

and come from extraction (11.58). At time twenty-one, $020100 + 000222 = 020022$ in $\mathbb{F}_3^6$. The defect tails provide 222111. At time twelve, $012012 + 202222 = 211201$.

At time eleven, the dual charges are $0, 1, 2$, respectively; the phase is $(11 - 1) \bmod 3 = 1$. The resulting coefficients are $(2, 1, 2)$ and

$$2(022212) + (110001) + 2(100021) = 021101 \quad \text{in } \mathbb{F}_3^6.$$

Concatenating these four results gives the stated word. Its integer evaluation is obtained by Horner's method in base three, or by three successive concatenations in base 729. □

The preceding table serves a verification purpose: each of its entries is obtained from the regional producer. Construction rule (11.67) makes it possible to reproduce the descriptor without introducing the final twenty-four-trit string as an input.

11.3.4 Functional panel and terminal repertoire

11.3.4.1 Nine regional positions

The functional panel retains the first three bands of each of the three channels, in the declared regional order:

$$\mathcal{P}_9 = \big(b_\pi(0), b_\pi(1), b_\pi(2), b_e(0), b_e(1), b_e(2), b_\varphi(0), b_\varphi(1), b_\varphi(2)\big). \tag{11.68}$$

Its evaluation is

$$\mathcal{P}_9 = (103, 161, 103, 523, 457, 301, 450, 398, 438).$$

The nine positions retain their regional provenance, although the value 103 occurs twice. The panel has nine ordered incidences and eight distinct values. The subsequent enumeration uses the incidences; candidate deduplication takes place at a later stage.

11.3.4.2 Unordered eight-block repertoire

The terminal repertoire involved in this construction is

$$\mathcal{S}_{\mathrm{term}} = \{002001, 020111, 200110, 121012, 010122, 001001, 221110, 222110\} \subset \mathbb{F}_3^6. \tag{11.69}$$

Its eight elements are distinct. The integer encoding, sorted by value solely to fix a computational representation, is

$$\{28, 55, 98, 175, 437, 498, 687, 714\}.$$

The documentary provenance of this repertoire is the terminal segmentation of the seventy-two-trit word and its position-wise recovery through incidences of the phase–charge and affine readers. The selector developed below receives the repertoire without its historical ordering and tests its 8! orderings.

The exact formulation of the reassembled implementation maintains an explicit interface here: the regional producers materially replace the descriptor, the panel, and the temporal rows; repertoire (11.69)

retains its earlier documentary producer. This distinction identifies where each input enters. Membership of eight words in a temporal reader repertoire, selection of those eight words, and determination of their terminal order are three different statements. The terminal-selection proof establishes the third for the declared repertoire.

Documentary recovery by position can be expressed exactly. Let $\mathcal{I}$ be the phase–charge incidence register and let $\mathcal{J}$ be the register of the affine extension. Each incidence retains the position ℓ in the seventy-two-trit word and the emitted word u. For $5 \le \ell \le 12$, form

$$\mathcal{S}_\ell = \{u : (\ell, u) \in \mathcal{I} \cup \mathcal{J}\}.$$

The recovery procedure checks that all eight positions occur and that each $\mathcal{S}_\ell$ is a singleton. If s_ℓ is its unique element, the output delivered to the selector is

$$\mathcal{S}_{\mathrm{term}} = \{s_5, s_6, \dots, s_{12}\}.$$

The singleton proof for each position preserves the coherence of the historical witnesses; the subsequent export retains the eight words and removes only the historical ordering. The selector reconstructs the order through complete enumeration and the terminal conditions, instead of receiving it from the provenance register.

11.3.4.3 Temporal incidences of the terminal repertoire and recovery by position

The expression of the terminal repertoire uses the same regional blocks, carries and calendar that produce the initial twenty-four-trit descriptor. Two operations in this composition should be made explicit separately. The first recovers eight words from recorded temporal incidences. The second presents those eight words to the dodecaphase selector as an unordered set. The selector re-establishes their order through its incidence, cylinder and closure conditions. This distinction preserves provenance witnesses without turning the order of a historical segmentation into an input to the selector.

Let $B_t = (b_{t,0}, b_{t,1}, b_{t,2}) \in (\mathbb{F}_3^6)^3$ be the regional boundary already generated at time t, with $0 \le t < 100$. In the chart used by the historical register, the incidence matrix is

$$A_{\mathrm{hist}} = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 2 & 2 \\ 1 & 1 & 0 & 2 & 1 & 2 \\ 1 & 1 & 2 & 0 & 2 & 1 \\ 1 & 2 & 1 & 2 & 0 & 1 \\ 1 & 2 & 2 & 1 & 1 & 0 \end{pmatrix}.$$

The words are regarded as row vectors. Their two charges and the chronological phase are

$$r_{t,i} = \sum_{j=1}^{6} b_{t,i,j}, \qquad d_{t,i} = \sum_{j=1}^{6} (b_{t,i} A_{\mathrm{hist}})_j, \qquad \vartheta_t = t - 1 \pmod 3.$$

All operations in these three expressions take place in $\mathbb{F}_3$. The historical subscript identifies a concrete chart of Witt incidence; it keeps the coordinate transformation explicit when another presentation of that same incidence is used.

For $c \in \{r_t, d_t\}$, $\delta \in \mathbb{F}_3$ and $\epsilon \in \{1, -1\}$, define

$$\eta_i(c, \delta, \epsilon) = \begin{cases} \epsilon, & c_i = \vartheta_t + \delta, \\ -\epsilon, & c_i \ne \vartheta_t + \delta, \end{cases} \qquad L_{t,c,\delta,\epsilon} = \sum_{i=0}^{2} \eta_i(c, \delta, \epsilon) b_{t,i}.$$

The orientation -1 is written as 2 when printing the ternary coefficients. Alongside these twelve comparative readers per boundary, the register has the affine reader

$$L_t^{\mathrm{af}} = \sum_{i=0}^{2} (d_{t,i} + \vartheta_t) b_{t,i}.$$

Adding the phase in the affine reader and comparing charges in the preceding reader are different operations, both acting on data already produced by the TPK boundary.

t	$b_{t,0}$	$b_{t,1}$	$b_{t,2}$	r_t	d_t
8	200121	212212	110110	011	202
11	022212	110001	100021	001	012
30	210112	110202	211110	100	012
34	121022	000011	112110	220	021
37	120121	011202	112221	100	201
49	110212	200212	100122	110	201
58	111121	022121	122201	122	220
67	010012	001220	011120	122	122
75	220000	020111	100002	120	021
81	122201	020202	201122	202	001
90	022112	022110	121010	202	200

Table 11.2: Temporal boundaries realizing the printed incidences of the terminal repertoire. Each six-digit entry preserves the order of the six coordinates of the regional boundary.

The following table displays all comparative incidences of the register on the twelve blocks of the segmentation under consideration. The letters r and d denote the visible charge and the dual charge, respectively. Column j retains the position index of the historical witness; the operation delivering the data to the selector forgets this index after forming the set of words.

j	t	charge	δ	ϵ	$(\eta_0\eta_1\eta_2)$	$L_{t,c,\delta,\epsilon}$
4	11	d	0	1	212	021101
5	67	d	1	-1	211	002001
5	67	d	2	1	211	002001
5	67	r	1	-1	211	002001
5	67	r	2	1	211	002001
6	81	d	0	1	222	020111
6	81	r	2	1	222	020111
7	34	r	1	-1	111	200110
7	75	d	1	-1	211	200110
7	75	r	2	-1	211	200110
8	90	r	0	1	121	121012
8	90	r	1	-1	121	121012
9	49	d	0	-1	121	010122
11	11	d	2	-1	211	221110
11	37	d	0	-1	121	221110
12	8	d	0	-1	111	222110
12	8	r	1	-1	111	222110
12	58	d	1	-1	111	222110
12	58	r	0	-1	111	222110

Table 11.3: Complete phase–charge incidences on the terminal segmentation within the hundred boundaries of the register. Word matches between rows retain their times, orientations, and charge types.

The tenth block has an affine witness. At $t = 30$, $d_{30} = (0, 1, 2)$ and $\vartheta_{30} = 2$, whence

$$(d_{30,0} + \vartheta_{30}, d_{30,1} + \vartheta_{30}, d_{30,2} + \vartheta_{30}) = (2, 0, 1)$$

and, using the bands in Table 11.2,

$$L_{30}^{\mathrm{af}} = 2(210112) + 0(110202) + (211110) = (001001) \quad \text{in } \mathbb{F}_3^6.$$

The equality holds coordinatewise: before reduction modulo three, the sum vector is $(6, 3, 1, 3, 3, 4)$.

Proposition 11.23 (Complete recovery of the repertoire through incidences)**.** *Consider the comparative-incidence register in Table 11.3, augmented by the affine witness* $(j, t, L) = (10, 30, 001001)$*. For each position* $5 \le j \le 12$*, the set of output words of its incidences is a singleton. Extracting these eight words and subsequently forgetting their order produces exactly*

$$\mathcal{S}_{\mathrm{term}} = \{002001, 020111, 200110, 121012, 010122, 001001, 221110, 222110\}.$$

Their encoding as base-three integers is

$$\{28, 55, 98, 175, 437, 498, 687, 714\}.$$

Proof. The incidence multiplicities at positions $j = 5, 6, 7, 8, 9, 10, 11, 12$ are, respectively,

$$(4, 2, 3, 2, 1, 1, 2, 4).$$

At each position, all rows print the same word. Each row is verified by substituting its three bands and three coefficients into the formula for L; the tenth case has been calculated explicitly through L_{30}^{af}. For example, at $t = 67$ and with coefficients $(2, 1, 1)$, one obtains

$$2(010012) + (001220) + (011120) = (002001) \pmod 3.$$

The eight results are distinct as words of length six. Their encoding $\sum_{k=1}^{6} w_k 3^{6-k}$ gives, in position order, $(55, 175, 498, 437, 98, 28, 714, 687)$. Forgetting the order yields the stated set of integers. Thus, extraction preserves each complete word, including its zero positions, and delivers eight distinct elements to the selector. □

The preceding proof is an exact recovery from identified incidences. Its input comprises the incidence register with its positions and witnesses. The subsequent orbital selection receives only $\mathcal{S}_{\mathrm{term}}$ and the initial regional descriptor; it traverses the 8! orderings and determines their compatibility with the functional boundaries and the oriented incidences of the dodecaphasic wheel. Both operations are thus presented contiguously, with explicit domains: temporal provenance of the eight words and constructive determination of their order.

The comparative table contains the nineteen incidences that its formula produces on the twelve-block segmentation over the hundred declared times. This finite exhaustiveness is checked by traversing $100 \cdot 2 \cdot 3 \cdot 2 = 1200$ evaluations. The affine reader extends coverage of the terminal positions from seven to eight. This count characterizes the local reader repertoire just defined; the other TPK operations retain the domains and constructive functions established in their respective derivations.

11.3.5 Comparative readers, affine reader, and temporal incidence

11.3.5.1 Witt transformation of the selector

The selector uses the six-coordinate chart

$$A_{\mathrm{ter}} = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}.$$

Define $W(b) = bA_{\mathrm{ter}}$ in $\mathbb{F}_3^6$, together with the charges

$$\eta(b) = \sum_{j=0}^{5} b_j \pmod 3, \qquad \eta_{\mathrm{ter}}^{\vee}(b) = \eta(W(b)).$$

The descriptor chart and selector chart are related by the permutation $\sigma = (0, 1, 2, 4, 5, 3)$, written as a list of images:

$$(A_{\mathrm{ter}})_{ij} = (A_{\mathrm{reg}})_{\sigma(i),\sigma(j)}. \tag{11.70}$$

Lemma 11.24 (Compatibility of the charge functional)**.** *For every band b,*

$$\eta_{\mathrm{ter}}^{\vee}(b) = \eta^{\vee}(b).$$

Proof. The integer sum of each corresponding row of the two matrices agrees: it is five in the first row and seven in the other five. By distributivity,

$$\sum_j \sum_i b_i (A_{\mathrm{ter}})_{ij} = \sum_i b_i \sum_j (A_{\mathrm{ter}})_{ij} = \sum_i b_i \sum_j (A_{\mathrm{reg}})_{ij}.$$

Reduction modulo three gives the equality of charges. Matrix identity (11.70) is verified by substituting its thirty-six entries and also preserves the coordinate change. □

Equality of the total charge functional allows their expressions to be compared. Vector transformations remain identified by their matrices and by the explicit permutation; the preceding proof preserves that coordinate information.

11.3.5.2 Twelve comparative readers per instant

Define the temporal phase

$$\theta(t) = (t + 2) \bmod 3.$$

This expression realizes $(t - 1) \bmod 3$ also at $t = 0$, where the phase equals two. For each charge type $\nu \in \{\eta, \eta_{\mathrm{ter}}^{\vee}\}$, offset $o \in \{0, 1, 2\}$ and orientation $s \in \{1, 2\}$, take

$$\epsilon_{\chi}^{\nu,o,s}(t) = s \begin{cases} 1, & \nu(B_{\chi}(t)) = \theta(t) + o \pmod 3, \\ 2, & \nu(B_{\chi}(t)) \neq \theta(t) + o \pmod 3. \end{cases}$$

The corresponding comparative word is

$$C_{\nu,o,s}(t) = \sum_{\chi \in \{\pi, e, \varphi\}} \epsilon_{\chi}^{\nu,o,s}(t) B_{\chi}(t) \quad \text{in } \mathbb{F}_3^6. \tag{11.71}$$

The parameters generate twelve row-labelled expressions. Two labels may produce the same word; temporal witnesses and labels remain available in the full calendar.

11.3.5.3 Affine phase–charge reader

The affine reader uses coefficients

$$a_{\chi}^{\mathrm{af}}(t) = \eta_{\mathrm{ter}}^{\vee}(B_{\chi}(t)) + \theta(t) \pmod 3,$$

and produces

$$F(t) = \sum_{\chi \in \{\pi, e, \varphi\}} a_{\chi}^{\mathrm{af}}(t) B_{\chi}(t) \quad \text{in } \mathbb{F}_3^6. \tag{11.72}$$

The comparative rule distinguishes agreement and difference of charges; the affine rule adds charge and phase before combining the bands. This operational difference is what heterotypic selection uses.

11.3.5.4 Word–residue incidence

Let R be the cyclic rotation of the six positions of a band. In the row at time t, form the residual repertoire

$$\mathcal{R}(t) = \{R^{j} v : v \in \{q(t), a(t), c(t), \bar{w}(t)\},\ 0 \le j < 6\}.$$

The temporal incidence relations are

$$\mathcal{A}_{\mathrm{cmp}} = \{(C_{v,o,s}(t), u) : 0 \le t < 100,\ u \in \mathcal{R}(t),\ v, o, s \text{ admissible}\}, \tag{11.73}$$

$$\mathcal{A}_{\mathrm{af}} = \{(F(t), u) : 0 \le t < 100,\ u \in \mathcal{R}(t)\}. \tag{11.74}$$

Each pair relates a read word to a residue of the same row. Time is quantified jointly across both coordinates of the pair. In the calendar used, times $0, \dots, 99$ are distinct; identifying the same row and identifying the same time are therefore equivalent operations.

Proposition 11.25 (Existential compression of the temporal repertoire)**.** *The function*

$$M(v, u) = \mathbf{1}_{(v,u) \in \mathcal{A}_{\mathrm{cmp}}} + 2\mathbf{1}_{(v,u) \in \mathcal{A}_{\mathrm{af}}} \in \{0, 1, 2, 3\}$$

preserves exactly the existence of each reading type for the pair (v, u).

Proof. The first bit equals one exactly when there exist a time, a residual field, a rotation, and a comparative label that produce the pair. The second bit expresses the corresponding condition for the affine reader. Union by bitwise disjunction preserves each existence condition as all rows are traversed. A pair may admit both types, in which case the mask equals three. □

The function M is an existence reader. The witness times, their multiplicities, and the individual labels remain in (11.74) and in the calendar that produces them. The finite implementation uses M to decide heterotypy, whereas the genealogical archive retains the richer provenance data.

11.3.6 Enumeration of cylinders and decimal candidates

11.3.6.1 Concatenation of seventy-two and seventy-eight trits

For an ordering $\tau = (s_1, \dots, s_8)$ of $\mathcal{S}_{\mathrm{term}}$, define

$$P_{72}(\tau) = [\Omega_{24} \| s_1 \| \cdots \| s_8]_3.$$

Recursively, start from $p_0 = [\Omega_{24}]_3$ and compute $p_i = 729 p_{i-1} + [s_i]_3$ for $1 \le i \le 8$. This recurrence preserves the leading zeros of each block through explicit multiplication by 729. For each position b of the functional panel,

$$P_{78}(\tau, b) = 729 P_{72}(\tau) + b.$$

The lengths are $24 + 8 \cdot 6 = 72$ and $72 + 6 = 78$, respectively. The corresponding ternary cylinder is

$$I_{\tau,b} = \left[\frac{P_{78}(\tau, b)}{3^{78}}, \frac{P_{78}(\tau, b) + 1}{3^{78}} \right). \tag{11.75}$$

11.3.6.2 Exact intersection with the twelve-triad grid

The decimal reading uses twelve triads, that is, the grid $N/10^{36}$. Write $D = 10^{36}$ and $Q = 3^{78}$ for brevity.

Lemma 11.26 (Integer endpoints of the cylinder)**.** *For an integer prefix p of length seventy-eight, the numerators of the grid points belonging to its cylinder are*

$$\left\{ N \in \mathbb{Z} : \left\lceil \frac{pD}{Q} \right\rceil \le N < \left\lceil \frac{(p+1)D}{Q} \right\rceil \right\}. \tag{11.76}$$

Each cylinder contains at most one point of this grid.

Proof. The condition $N/D \in [p/Q, (p+1)/Q)$ is equivalent to $pD/Q \le N < (p+1)D/Q$. For integer N, the first inequality is equivalent to $\lceil pD/Q \rceil \le N$; the second is equivalent to $N < \lceil (p+1)D/Q \rceil$. The interval length in coordinate N is $D/Q < 1$, since $10^{36} < 3^{78}$. It can therefore contain at most one integer. □

Ceilings are evaluated by integer division: $\lceil a/Q \rceil = \lfloor (a+Q-1)/Q \rfloor$ for $a \ge 0$. The entire enumeration uses exact integers; the choice of boundary points is fixed by the half-open right endpoint.

First retain the indexed list of incidences

$$C_{\mathrm{ind}} = \{(\tau, j, N) : N/D \in I_{\tau, \mathcal{P}_9(j)}\}, \qquad 1 \le j \le 9,$$

and then obtain the set of numerators

$$C = \{N : \exists \tau, j \ (\tau, j, N) \in C_{\mathrm{ind}}\}.$$

Passing to C removes repetitions of a numerator, retained in C_{ind} together with their provenance.

Lemma 11.27 (Recovery of the ordering from the cylinder point)**.** *If $(\tau, j, N) \in C_{\mathrm{ind}}$, block number i of the seventy-eight-trit word is recovered by*

$$\left\lfloor \frac{N\, 729^{i}}{D} \right\rfloor \bmod 729, \qquad 1 \le i \le 13.$$

In particular, blocks five through twelve recover τ.

Proof. Membership in the cylinder means $p \le QN/D < p + 1$, where $p = P_{78}(\tau, \mathcal{P}_9(j))$. Hence, $\lfloor QN/D \rfloor = p$. Extraction of the earlier blocks agrees with successive division of the prefix p by powers of 729: truncating a positional expansion before extracting a block preserves that block. The displayed formula performs exactly this extraction. The first four blocks form Ω_{24} and the next eight are the ordering τ. □

Proposition 11.28 (Exact candidate count)**.** *For Ω_{24}, $\mathcal{S}_{\mathrm{term}}$ and $\mathcal{P}_9$ defined above,*

$$\#\,\mathrm{Ord}(\mathcal{S}_{\mathrm{term}}) = 40320, \qquad \#C_{\mathrm{ind}} = 21902, \qquad \#C = 19446.$$

Proof. The eight blocks are distinct, so their orderings are the $8! = 40320$ permutations. For each permutation and each of the nine panel positions, compute $p = P_{78}(\tau, b)$, apply endpoints (11.76), and add the unique integer when the integer interval is nonempty. The sum of the cardinalities of these

intervals is 21902. The union of their integers contains 19446 distinct elements. The exhaustive evaluation of these operations is certified by the theorems `indexed_cylinder_count` and `candidate_count` of the finite selector. The algorithm performs exactly the enumeration described: permutations, nine panel incidences, bounds by integer division, and duplicate removal. □

The numbers 21902 and 19446 count different objects. The former counts indexed incidences containing a decimal point; the latter counts distinct numerators. The total number of cylinder queries is $40320 \cdot 9 = 362880$, including cylinders whose intersection with the grid is empty.

11.3.7 Exceptional incidence and heterotypy condition

11.3.7.1 Exceptional face produced by the panel

A band is lifted to twelve coordinates by

$$\Gamma(b) = (b, W(b)) \in \mathbb{F}_3^{12}.$$

The support of a word is the set of positions of its nonzero coordinates, with human-readable indices $1, \dots, 12$. The first regional bands of the panel produce

$$\mathcal{B} = \operatorname{supp}\Gamma(B_\pi(0)) \cap \operatorname{supp}\Gamma(B_e(0)) = \{4, 6, 9, 10\}. \tag{11.77}$$

The operation uses the regional words 103 and 523 and the selector's Witt matrix. The face is computed before querying the candidate coordinates.

For $N \in C$, its twelve triads are

$$K_i(N) = \left\lfloor \frac{N}{1000^{12-i}} \right\rfloor \bmod 1000, \qquad 1 \le i \le 12. \tag{11.78}$$

The crown support is

$$\mathcal{H}(N) = \{i : K_i(N) \ge 729\}, \qquad C_{\mathcal{B}} = \{N \in C : \mathcal{H}(N) = \mathcal{B}\}.$$

The boundary $729 = 3^6$ relates the six-trit band to the decimal triad. Exhaustive evaluation of the equality of supports gives

$$\#C_{\mathcal{B}} = 79. \tag{11.79}$$

The support preserves positions, while the complete register also preserves the twelve magnitudes. The next stage uses this positional information together with relations between magnitudes.

11.3.7.2 Ternary words and oriented differences of the candidate

The ith ternary band of the point N/D is obtained by

$$T_i(N) = \left\lfloor \frac{N\,729^i}{D} \right\rfloor \bmod 729, \qquad 1 \le i \le 13. \tag{11.80}$$

The oriented edge $a \to b$ has residue

$$R_{a,b}(N) = (K_a(N) - K_b(N)) \bmod 729. \tag{11.81}$$

Subtraction takes place in $\mathbb{Z}$ before reduction. For this edge, the pair is looked up in the relations (11.74)

$$\big(\mathrm{enc}_6^{-1}(T_b(N)), \mathrm{enc}_6^{-1}(R_{a,b}(N))\big).$$

It is therefore a joint query on the destination word and the oriented difference of the triads.

Write $\mathrm{Cmp}(a, b; N)$ when the pair belongs to $\mathcal{A}_{\mathrm{cmp}}$ and $\mathrm{Af}(a, b; N)$ when it belongs to $\mathcal{A}_{\mathrm{af}}$.

11.3.7.3 Determination of the transverse orbit

The twenty-four-trit descriptor determines the first three decimal triads before the terminal filtrations. Indeed, its cylinder satisfies the exact inclusion

$$\left[\frac{66241910521}{3^{24}}, \frac{66241910522}{3^{24}}\right) \subseteq \left[\frac{234543140}{10^{9}}, \frac{234543141}{10^{9}}\right).$$

The two endpoint inequalities are verified by integer cross-products. Every candidate therefore shares the three reference positions $1, 2, 3$ and their expressions $(234, 543, 140)$.

The step-four translation on $\mathbb{Z}/12\mathbb{Z}$ has the four orbits

$$(1, 5, 9), \qquad (2, 6, 10), \qquad (3, 7, 11), \qquad (4, 8, 12).$$

The first three each contain one of the reference positions; the fourth is the only one disjoint from $\{1, 2, 3\}$. The oriented forest of steps three and four is fixed by the edges

$$\begin{array}{lll} 1 \to 4, & 1 \to 5, & 2 \to 6, \\ 3 \to 7, & 4 \to 8, & 5 \to 9, \\ 6 \to 10, & 7 \to 11, & 8 \to 12. \end{array}$$

Its first edge has step three and the remaining edges have step four. The two internal edges of the distinguished orbit are precisely $4 \to 8$ and $8 \to 12$. The location of the reading condition is thus fixed by the geometry of the positions and by the initial prefix, before examining the candidates of the exceptional face.

11.3.7.4 Terminal heterotypy condition

The terminal condition is

$$\begin{aligned} \mathcal{T}(N) = {} & [\mathrm{Cmp}(4, 8; N) \wedge \mathrm{Af}(8, 12; N)] \\ & \vee [\mathrm{Af}(4, 8; N) \wedge \mathrm{Cmp}(8, 12; N)]. \end{aligned} \tag{11.82}$$

Both assignments of types to the two edges are admitted. The selection requires the existence of a realization with distinct types; the individual labels and their times remain available in the incidence witnesses.

Theorem 11.29 (Terminal selection of the coupling register)**.** *On the candidate domain produced by Ω_{24}, $\mathcal{S}_{\mathrm{term}}$, $\mathcal{P}_9$ and the hundred-row regional calendar, there exists a unique numerator simultaneously satisfying exceptional incidence and heterotypy:*

$$\{N \in C_{\mathcal{B}} : \mathcal{T}(N)\} = \{234543140729659824621058914794146601\}.$$

Its twelve-triad register is

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \tag{11.83}$$

Proof. The preceding count produces the 79 elements of $C_{\mathcal{B}}$. For each one, its twelve coordinates are extracted by (11.78); the destination bands T_8, T_{12} and residues $R_{4,8}, R_{8,12}$ are computed; the two masks of the temporal repertoire are queried; and disjunction (11.82) is applied. The resulting list contains exactly the stated integer, according to the exhaustive evaluation certified by `terminal_selection`. Equality of the list with a singleton implies existence and uniqueness in the declared domain. Base-one-thousand extraction from that integer gives (11.83).

The selection procedure receives the enumerated producers and rules. The final integer appears in the statement of the verified equality after selection has been executed. This logical position allows the result to be checked without using it as a selection criterion. □

11.3.7.5 Arithmetic witness of membership in a cylinder

One of the incidences of the selected numerator uses the ordering

$$(002001, 020111, 200110, 121012, 010122, 001001, 221110, 222110)$$

and the boundary $438 = 121020_3$. For this incidence,

$$P_{72} = 528388158488267313651410292609095 7,$$

$$P_{78} = 385194967537946871651878103312030809 1.$$

The integer-endpoint formula yields

$$\left\lceil \frac{P_{78}10^{36}}{3^{78}} \right\rceil = 234543140729659824621058914794146601,$$
$$\left\lceil \frac{(P_{78}+1)10^{36}}{3^{78}} \right\rceil = 234543140729659824621058914794146602.$$

The unique integer in the interval is therefore N_K. The thirteen ternary bands of its decimal point are

$$\begin{array}{cccc} 020022 & 222111 & 211201 & 021101 \\ 002001 & 020111 & 200110 & 121012 \\ 010122 & 001001 & 221110 & 222110 \\ 121020 & & & \end{array}$$

This calculation exhibits a concrete witness of membership in the enumerated domain. Uniqueness of the register follows from the exhaustive examination of all candidates, in addition to this particular witness.

11.3.8 Regional composition and continuity of the realizations

11.3.8.1 Composition of the regional generators

Let $\mathrm{Sel}(\Omega, \mathcal{S}, \mathcal{P}, \mathcal{N})$ be the selector defined by the enumeration and the two preceding filters. The regional producers satisfy the equalities

$$\Omega_{\mathrm{reg}} = \Omega_{24}, \qquad \mathcal{P}_{\mathrm{reg}} = \mathcal{P}_{9}, \qquad \mathcal{N}_{\mathrm{reg}} = \mathcal{N}_{100},$$

where $\mathcal{N}_{\mathrm{reg}}$ is computed by band extraction and signature reading. By congruence of functions,

$$\begin{aligned} &\mathrm{Sel}(\Omega_{\mathrm{reg}}, \mathcal{S}_{\mathrm{term}}, \mathcal{P}_{\mathrm{reg}}, \mathcal{N}_{\mathrm{reg}}) \\ &\qquad = \mathrm{Sel}(\Omega_{24}, \mathcal{S}_{\mathrm{term}}, \mathcal{P}_{9}, \mathcal{N}_{100}) = \{N_K\}. \end{aligned} \tag{11.84}$$

The equality replaces three documentary interfaces with their actual regional construction. The terminal repertoire retains the provenance specified in (11.69).

The register is then formed by the twelve Euclidean divisions in (11.78). Each coordinate belongs to $\{0, \dots, 999\}$ and the length is twelve by construction. The implementation that takes the first element of the selected list is justified by equality with the singleton: the default value of a computational operation on empty lists never enters this result.

11.3.8.2 Relation to signed incidences and inversion

The present construction provides a prospective selection in an explicit finite domain. The subsequent development of the dodecaphasic register produces its oriented channels from the enriched terminal state and proves an integral inversion through Hadamard. That inversion recovers a register from compatible channels; here a register is selected from its regional and incidence-based inputs. Equality of their results allows the two realizations to be composed while preserving the origin of each operation.

Uniqueness of selection and uniqueness of inversion are distinct properties. The former quantifies over the candidates constructed in this chapter. The latter quantifies over the registers sharing a compatible signature. Their conjunction justifies transporting the selected register to the signed realization and recovering it from that realization, without turning a retrospective recovery into the producer of the register.

11.3.8.3 Relation between the terminal counts

The sequence

$$40320 \longrightarrow 21902 \longrightarrow 19446 \longrightarrow 79 \longrightarrow 1$$

records, successively, orderings, indexed incidences with the grid, distinct numerators, candidates of the exceptional face, and heterotypic survivors. The arrow notation indicates the order of the operations; the second number counts a different class of objects from the first.

The regional-catalogue census $196 \cdot 197 \cdot 196 \longrightarrow 331 \longrightarrow 2 \longrightarrow 1$, developed in its corresponding place, starts from a different population: regional blocks from three catalogues and terminal Gram, occupation, distance and orientation conditions. Both censuses preserve their domains. Their convergence in a common expression is conveyed through identification of their readers and outputs; intermediate figures describe different operations and remain documented separately.

11.3.8.4 Regional composition of the fine-structure constant

The output K then enters the ordered regional composition and the base-thousand carry. Its subsequent use preserves the twelve positions and the reading boundary. Coupling to the analytic root and expressions at arbitrary depth uses that same output, together with the regional coordinates already generated and the rules of the analytic chart. This dependency prepares the chapter devoted to the two correlated realizations of the fine-structure constant.

The scope of this chapter is precise: production of the descriptor and its regional inputs, determination of the finite domain, unique selection on that domain, and material composition with the producers. The analytic recurrence at all orders and the compatibility of infinite carries are developed subsequently with their own proofs.

11.3.9 Executable certification and traceability of the operations

The formal development preserves the correspondence between the mathematical definitions and their executable realizations. The signature and clock proofs are found in `N69RegionalSignature.lean`; band extraction and reproduction of the hundred rows, in `GeneratedN69Rows.lean`; the minimality criterion and construction of Ω_{24}, in `RegionalW24.lean`. Compatibility of the two Witt matrices is assembled in `WittReaderCompatibility.lean`.

The temporal readers, rotations, oriented residues, and heterotypic condition are formalized in `TerminalReaders.lean`. Enumeration and counts are formalized in `TerminalOrbital Selection.lean`. The regional panel is linked through `RegionalPanelBridge.lean`, and composition (11.84) is expressed in `SelectedFromRegionalInputs.lean`.

The finite enumeration checks use Lean's native evaluation; their reports record `Lean.ofReduceBool`, in addition to the library's customary logical axioms. The regional reconstruction of the descriptor uses kernel proofs and ordinary reduction. This distinction describes the verification mechanisms actually

employed. The compilation receipts attest to their declared modules and dependencies; the mathematical proofs retain the domains, producers, and hypotheses made explicit in the body of the chapter.

11.4 Dodecaphasic extraction of the arithmetic–geometric coupling constant

Definition 11.30 (Holographic arithmetic–geometric coupling constant)**.** This is the name given to the ordered finite register produced by the oriented extraction of the APP–TRIT–TPK state, with its phase origin, normalization and declared readers, whose positional representation participates in the arithmetic closure and whose incidence and geometric realizations act on the same register. The symbol K designates its canonical integral representation; κ_{ag} designates its periodic rational reading in the fixed chart.

The generation of the regional coordinates does not exhaust the information of the APP–TRIT–TPK state. An Archimedean reading determines a value through compatible cylinders; another reading preserves the opposition of the sheets, the orientation of the route and the register of incidences traversed. The dodecaphasic register belongs to this second reading before participating in the closure of alpha. Thus it is not defined by subtracting a physical constant from a combination of previously known values. It is reconstructed from a signed coordinate of the same arithmetic state with trajectory memory that produces the regional coordinates.

The distinction is necessary even when two objects have twelve coordinates. A word of twelve catalog blocks, a list of twelve oriented events, a signed integer vector and a dodecaphasic register in base one thousand are distinct objects. Comparing them requires the maps that relate them. Equality of length does not provide those maps, and the loss of signs is not merely a simplification of notation.

This chapter maintains the causal cut fixed in the preceding chapters: the nine APP positions of the horizontal and vertical axes produce the arithmetic sheets; TRIT types regime and orientation; TPK selects, transports, updates and prolongs, preserving residue, quotient, carry, sheet, route, boundary and memory. From the joint discrete structure of the continuum one obtains the coordinates used here. The chain $w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$ is not replaced by a finite calendar. Nor is the order $U_t \to \Gamma_9 \to K_{\mathrm{ph}}$ reversed: the final map is a reduced memory reading, not the generator of the signed register.

Reversible coordinatization and incidence determination. The result organizing this chapter is the equivalence between three coordinatizations of a register previously produced by APP–TRIT–TPK. The Hadamard transformation relates the signed register to the integer register; the difference extractor relates the latter to its transverse variations and its uniform component:

$$U \underset{\mathcal{H}_{12}}{\overset{\mathcal{H}_{12}/4}{\longleftrightarrow}} K \overset{(D_3,D_4,Q)}{\longleftrightarrow} (D_3K, D_4K, Q(K)).$$

The first equivalence is established on the integral sublattice $\mathcal{L}_H$; the second, on the image of the extractor. With the base 1000, the 12 positions and the phase origin fixed, the evaluation $K \mapsto \kappa_{\mathrm{per}}$ adds a fourth reversible coordinatization: multiplying by $1000^{12} - 1$ and performing Euclidean divisions recovers the complete register. The proofs of §11.4.8, §11.4.9 and §11.4.11 establish these equivalences in their respective domains.

Two compositions then act on that register. Positional composition combines its components with the closure, propagation and autoscale coordinates, and its normalization determines α_A. Incidence composition applies the cubic threshold and obtains

$$K \longmapsto B_K = \{j : K_j \geq 729\} = \{4, 6, 9, 10\}.$$

The complete register allows both compositions to be reconstructed. The support B_K specifically preserves membership in the class selected by the threshold. The identity $B_K = H_e \cap P_\pi$ of (21.134) links this

integer extraction to the incidence of the regional codes. The negative support of its balance with K completes the flag $B_K \subset H_\alpha^-$ developed in the exceptional prolongation. Thus the function of K is defined through an invertible transformation and through precise subsequent maps; the additional depth and transport information remains in the state from which the register originates.

11.4.1 Cyclic extension and memory grading

The observable calendar contains one hundred and eight positions, organized into twelve nonadic windows. With positive indices, let

$$E_m = \{9(m-1)+1, \dots, 9m\}, \qquad 1 \le m \le 12.$$

The ordered support $E_1 \sqcup \cdots \sqcup E_{12}$ preserves position and window membership. The group $C_{108} = \mathbb{Z}/108\mathbb{Z}$ instead preserves the cyclic translation law. For the representative $0 \le \widetilde{\theta} < 108$, the coordinates

$$\beta(\theta) = \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12}, \qquad r(\theta) = 1 + (\widetilde{\theta} \bmod 9)$$

separate the dodecaphasic sector and the interior nonadic position. Neither by itself preserves the total number of turns.

Proposition 11.31 (The calendar carry)**.** *The maps*

$$\iota : C_{12} \longrightarrow C_{108}, \quad [b] \longmapsto [9b], \qquad p : C_{108} \longrightarrow C_9, \quad [\theta] \longmapsto [\theta]_9$$

form a nonsplit exact sequence

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0.$$

For the set-theoretic section choosing the representatives $0, \dots, 8$*, the additivity defect is the carry*

$$c(r, r') = \left[\left\lfloor \frac{\widetilde{r} + \widetilde{r}'}{9} \right\rfloor\right]_{12}.$$

Proof. The kernel of p consists of the multiples of nine and coincides with the image of ι. Reduction is surjective, and multiplication by nine is injective on the stated domain. If the sequence split, the middle group would be isomorphic to $C_{12} \times C_9$, whose exponent is $\operatorname{mcm}(12, 9) = 36$; the exponent of C_{108} is 108. This contradiction proves nonsplitting. Finally, Euclidean division of $\widetilde{r} + \widetilde{r}'$ by nine gives the stated carry and verifies the identity for the section. □

The result explains a difference that will reappear in alpha: returning to the phase is not equivalent to returning to the state. If q_{mem} counts the nonadic turns, the calendar preserves only $\beta = [q_{\mathrm{mem}}]_{12}$. After one hundred and eight steps, β returns, but q_{mem} increases by twelve. The register also preserves the cylinder, the incidence register and the vertical memory. The closure of a finite chart does not turn that history into a memoryless cycle.

11.4.2 The oriented register and the integral chart $1 + 5 + 6$

For a history produced by TPK, let τ_m be the subroute over E_m, σ_m its orientation, κ_m the boundary carry, and Λ_m the local incidence entry. The register is

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12}.$$

Its domain is the space of arithmetic histories with trajectory memory, not the set of phase labels. Projection onto the calendar forgets precisely some of the data that the signed reader needs.

An initial chart of the register can be written through oriented events. Oriented extraction fixes the set of event codes $\{2, 4, 6, 8\}$ and the sectoral orientation

$$\Sigma_{12} = (+, +, +, -, -, -, +, +, +, -, -, -).$$

If d_t is the direction code at step t, one obtains

$$e_i = \Sigma_{12}(i+1)\#\{t \in E_{i+1} : d_t \in \{2, 4, 6, 8\}\}, \qquad 0 \le i < 12.$$

The formula keeps the nonnegative census of events and the orientation separate. It does not identify a cardinal direction with a TRIT sign. The vector e, whose components are signed local censuses, is not yet the vector U that will appear below either.

The opposite positions determine, for $0 \le i < 6$,

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}.$$

With

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5),$$

one defines the integral chart

$$\mathcal{L}_{12}(e) = (s_C, M_0, \dots, M_4, a_0, \dots, a_5).$$

The decomposition $1 + 5 + 6$ is not an arbitrary distribution of coordinates: one coordinate preserves the charge, five compare the pairs relative to a reference pair and six preserve the opposition of the half-crowns.

Lemma 11.32 (Inversion of the integral chart)**.** *An integer tuple $(s_C, M_0, \dots, M_4, a_0, \dots, a_5)$ belongs to the image of $\mathcal{L}_{12}$ if and only if*

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6, \qquad p_i \equiv a_i \pmod 2 \quad (0 \le i < 6),$$

where

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i \quad (i < 5).$$

In that case its preimage is unique and is given by

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}.$$

Proof. The sum of the five margins is $s_C - 6p_5$, from which division by six is obtained. Once the p_i are reconstructed, each pair of equations $p_i = e_i + e_{i+6}$, $a_i = e_i - e_{i+6}$ has the indicated solution. This solution is integral exactly under the parity congruence. All the operations are inverted, so no residual freedom remains. □

This reversibility shows what information is preserved; it does not authorize removing the rest of the article. The complete register has a larger domain than this census chart. Extracting the channels that feed U uses that complete register and does not follow from the list (e_i) through an identification of names.

11.4.3 Incidence evaluation preceding the dodecaphasic register

Recovering a register from its cyclic differences and total charge is a different question from evaluating those coordinates on the incidence register. The first problem is solved by the transverse extractor of Proposition 11.42. For the second, a historical presentation of the register provides three integer counts in each window. It is useful to make their composition explicit and determine exactly the information required for their evaluation.

Let $\mathscr{L}$ be a previously generated ledger of visits and oriented traces. Each visit preserves the route, the APP position, the sheet, the instant, the multiplicity and the boundary incidence. The arithmetic evaluation produces the integer and its decomposition

$$n_t = r_t + 9q_t, \qquad 1 \le r_t \le 9.$$

The integer n_t is calculated from the sum or product sheet; its residue is not received as an independent value. The distinction between crown incidence and interior incidence remains explicit for visits of residue 9.

In window E_m, the count presentation considers

$$A_m = \sum_{v \in E_m} w(v)\mathbf{1}_{\{1,3,5,7\}}(r(v)), \tag{11.85}$$

$$C_m = \sum_{j \ge 0} \big(\nu^-_{120,m}(j) - \nu^+_{120,m}(j)\big), \tag{11.86}$$

$$V_m = \sum_{v \in E_m} w(v)\mathbf{1}_{\{9\}}(r(v))\epsilon_\partial(v). \tag{11.87}$$

Here $w(v)$ is the incidence multiplicity, and $\epsilon_\partial(v) = 1$ on the corona, -1 in the interior. The traces counted by $\nu^\pm$ must be enumerated by the corresponding rule in the article. The integer sum requires finite support or an alternative construction determining its meaning. The number of chronological incidences and the reduced length $120(1 + 3j)$ have different types; relating them requires the reader's unit of length.

One defines $[x]_{10} \in \{0, \dots, 9\}$ as the Euclidean representative and preserves the quotients

$$x = [x]_{10} + 10\lfloor x/10 \rfloor.$$

The incidence block is

$$z_m = 100[A_m]_{10} + 10[C_m]_{10} + [V_m]_{10}. \tag{11.88}$$

Composition yields the map

$$\mathcal{E}_{\mathrm{cnt}}(\mathscr{L}) = \left((z_m - z_{m+3})_{m=1}^{12}, (z_m - z_{m+4})_{m=1}^{12}, \sum_{m=1}^{12} z_m \right). \tag{11.89}$$

The indices are read cyclically modulo 12. In this subsection, $(D_j z)_m = z_m - z_{m+j}$, for $j = 3, 4$, and $Q(z) = \sum_{m=1}^{12} z_m$; therefore, the preceding composition is $(D_3 z, D_4 z, Q(z))$. This convention is preserved in §11.4.9, where complete integral reconstruction is proved. This formula produces its coordinates from the counts. It does not use K, U, α or the expected transverse coordinates as arguments. Its identification with $\mathcal{E}_{108}^{90,120}$ requires composing it with the family and the effective incidences of the terminal state; it does not follow solely from the invertibility of the transverse system.

Proposition 11.33 (Sufficient and necessary arithmetic information)**.** *Let $N, N' \in \mathbb{Z}^{12\times 3}$, ordered by the counts (A, C, V). For the map defined by (11.88)–(11.89),*

$$\mathcal{E}_{\mathrm{cnt}}(N) = \mathcal{E}_{\mathrm{cnt}}(N') \quad \Longleftrightarrow \quad N - N' \in 10\mathbb{Z}^{36}.$$

In particular, the 36 *sectoral residues exactly determine the output of* 25 *coordinates. Preserving the quotients and the provenance constitutes additional information of the register.*

Proof. Equality modulo 10 produces the same blocks and therefore the same transverse coordinates. Conversely, if the transverse coordinates coincide, $D_3(z - z') = D_4(z - z') = 0$. The steps 3 and 4 generate the cycle of length 12, so $z - z'$ is constant. Equality of total charges cancels that constant. Finally, the decimal representation of an integer between 0 and 999 has three unique digits. This recovers the three residues of each window. The assertion is an algebraic identity for every N, N', not an inference obtained from finite tests. □

11.4.4 Conjugation of counts and boundary terms

Let $\rho(m) = 13 - m$. Consider a conjugation of incidences that reverses the order of the windows, preserves the arithmetic class and the boundary class of the visits and interchanges the channels of the traces. Then

$$(A_m^\dagger, C_m^\dagger, V_m^\dagger) = (A_{\rho(m)}, -C_{\rho(m)}, V_{\rho(m)}).$$

If $c_m = [C_m]_{10}$, decimal reduction produces the identity

$$z_m^\dagger = z_{\rho(m)} + 100\mathbf{1}_{\{c_{\rho(m)} \neq 0\}} - 20c_{\rho(m)}. \tag{11.90}$$

Indeed, $[-C]_{10} = 0$ when $[C]_{10} = 0$, and $[-C]_{10} = 10 - [C]_{10}$ otherwise. The formula preserves exactly that difference. Negating the channel is not equivalent to negating the entire decimal block.

Applying this identity to a concrete involution of TPK requires verifying its action on the incidences. For an occupancy reader evaluated before the advance, reversal of a route $\gamma = (x_0, \dots, x_n)$ satisfies

$$\sum_{k=0}^{n-1} f(x_{n-k}) = \sum_{k=0}^{n-1} f(x_k) + f(x_n) - f(x_0).$$

The endpoint terms are incorporated before reducing modulo 10. In closed routes they vanish; in open windows they may alter their residues. This correction, already present in the bidirectional development of transport, specifies what the junction between the route and the counts must preserve.

Proposition 11.34 (Necessity of the nonperiodic information of the register)**.** *Suppose that the observable of a fixed family of routes satisfies $o(t + 54) = o(t)$, that multiplicity is preserved under that return and that the same local reader acts in the windows of* 9 *instants. Then its counts and blocks satisfy*

$$(A, C, V)_{m+6} = (A, C, V)_m, \qquad z_{m+6} = z_m.$$

Proof. The translation $t \mapsto t + 54$ takes E_m bijectively to E_{m+6}, preserving each counted incidence and its multiplicity. Equality is transmitted to the sum and to decimal reduction. □

Therefore, a presentation with 12 distinct blocks requires the reader to preserve some information that does not factor through that observable of period 54: incidence selection, effective orientation, endpoints, multiplicity or memory. The proposition delimits an inadmissible reduction of the state; it does not state that the full dynamics has period 54 or determine by itself what its terminal reader is.

11.4.5 Complete census of cylinders and selection of the terminal boundary

The terminal reading jointly uses two pieces of information: compatibility of the regional cylinders and an incidence profile with labeled channels and positions. This subsection constructs the complete catalogs, enumerates their triples and proves the effect of each condition of the reader. The starting point is the regional outputs already produced in section 10.5, not values introduced to define APP–TRIT–TPK transport. Reduction to a matrix belongs to a subsequent reading of those outputs and preserves the order of the three channels.

The result is a census theorem with an explicit starting structure. The profile of Gram, weights, distances and margins is declared as a datum of the terminal reader. The exhaustiveness of the enumeration proves what that profile selects on the fixed catalogs; it does not by itself prove that the profile is a universal law or that it can be reconstructed from the unique triple that ultimately satisfies it. This separation allows the complete finite proof to be incorporated without reversing its genealogy.

11.4.5.1 From regional outputs to ternary catalogues

Let $x_\pi, x_e, x_\varphi \in [0,1)$ be the fractional parts of the three regional coordinates already constructed. Their published cylinders of one thousand decimal positions are used,

$$J_\chi^{(1000)} = \left[\frac{d_\chi}{10^{1000}}, \frac{d_\chi+1}{10^{1000}}\right), \qquad \chi \in \{\pi, e, \varphi\}.$$

The integers d_χ are finite output readings. The length one thousand is sufficient for the integers that follow, as is checked through the two bounds of each interval; it is not a depth assumed infinite. We define

$$p = 30, \quad r = 1050, \quad L = p + r = 1080, \quad k = 171, \qquad D = 3^L, \quad Q = 1000^k, \tag{11.91}$$

and

$$P_\chi = \lfloor 3^{30} x_\chi \rfloor, \qquad T_\chi = \lfloor Q x_\chi \rfloor.$$

Here k counts decimal triads and does not designate the dodecaphasic register K. One has $1000^{171} \le 3^{1080} < 1000^{172}$.

Lemma 11.35 (Stable extraction of an integer)**.** *For $d, m, h \in \mathbb{Z}$, with $m, h > 0$, the value of $\lfloor mx \rfloor$ is constant on $[d/h, (d+1)/h)$ if and only if*

$$\left\lfloor \frac{md}{h} \right\rfloor = \left\lfloor \frac{m(d+1)-1}{h} \right\rfloor. \tag{11.92}$$

When this holds, either side gives that value.

Proof. The minimum of mx is attained at the left endpoint. Its supremum is $m(d+1)/h$ and is not attained. The largest integer that $\lfloor mx \rfloor$ can take is $\lceil m(d+1)/h \rceil - 1$, equal to the right-hand side because the numerator and denominator are integers. Equality of the endpoints of the value interval proves the assertion. □

The stability proof holds in all three channels for $m = 3^{30}, Q, 3^{1080}$. The last choice will be used only for a subsequent comparison, not to select the profile. The first thirty recovered positions are precisely the five stages of six trits of regional transport:

Channel	Thirty-trit prefix	P_χ
π	`010211012222010211002111110221`	29152671743887
e	`201101121221102011012222102011`	147887858824447
φ	`121200112202121020010210010200`	127247717616687

The coincidence preserves the prolongation already constructed; the decimal reading is not used to retroactively replace its transport matrices.

For a fixed channel, a tail of r trits is represented by $0 \le R < 3^r$. Its cylinder and the cylinder of the first k triads are

$$I_{\chi,R} = \left[\frac{P_\chi 3^r + R}{D}, \frac{P_\chi 3^r + R + 1}{D} \right), \qquad J_{\chi,T} = \left[\frac{T_\chi}{Q}, \frac{T_\chi + 1}{Q} \right). \tag{11.93}$$

The catalog includes all tails for which these two cylinders have nonempty intersection.

Proposition 11.36 (Catalogue by exact intersection)**.** *The compatible tails are the integers in the interval* $[a_\chi, b_\chi]$*, where*

$$a_\chi = \max\left(0, \left\lfloor \frac{T_\chi D}{Q} \right\rfloor - P_\chi 3^r \right), \tag{11.94}$$

$$b_\chi = \min\left(3^r - 1, \left\lfloor \frac{(T_\chi + 1)D - 1}{Q} \right\rfloor - P_\chi 3^r \right). \tag{11.95}$$

For the fixed regional cylinders, the truncations do not act and one obtains

χ	$a_\chi \bmod 729$	$b_\chi \bmod 729$	$b_\chi - a_\chi + 1$
π	67	262	196
e	584	51	197
φ	117	312	196

(11.96)

Proof. Write $N = P_\chi 3^r + R$. Two half-open intervals of (11.93) intersect exactly when

$$NQ < (T_\chi + 1)D, \qquad (N + 1)Q > T_\chi D.$$

The second inequality is equivalent to $N \ge \lfloor T_\chi D/Q \rfloor$; the first, to $N \le \lfloor ((T_\chi + 1)D - 1)/Q \rfloor$. Subtracting $P_\chi 3^r$ and preserving $0 \le R < 3^r$ proves the formulas. Evaluation by integer divisions of the T_χ extracted by (11.92) gives the table. Since $r \ge 6$, $P_\chi 3^r \equiv 0 \pmod{729}$, so the residue of the first endpoint is also obtained directly from $\lfloor T_\chi D/Q \rfloor \bmod 729$. □

The last six trits of a tail form the word $\nu_6(R \bmod 729)$, where ν_6 is the ternary notation of length six, including its leading zeros. By the table, each catalog has fewer than 729 consecutive elements, so this reduction is injective on it. Thus the three boundary catalogs are completely described, without choosing the final triples:

$$\begin{aligned} \mathcal{B}_\pi &= \{\nu_6(67 + i) : 0 \le i < 196\}, \\ \mathcal{B}_e &= \{\nu_6((584 + j) \bmod 729) : 0 \le j < 197\}, \\ \mathcal{B}_\varphi &= \{\nu_6(117 + \ell) : 0 \le \ell < 196\}. \end{aligned} \tag{11.97}$$

Requiring the left endpoint of $I_{\chi,R}$ to belong to $J_{\chi,T}$ would be another condition: it would lose the first cylinder that intersects the boundary and give 195, 196, 195. The census uses the intersection of the complete cylinders, in accordance with its definition.

11.4.5.2 Declared profile and compatibility indicators

For $u, v \in \mathbb{F}_3^6$, let $g(u, v) = \sum u_i v_i \in \mathbb{F}_3$, $n(u) = g(u, u)$, $w(u) = \#\{i : u_i \ne 0\}$ and $h(u, v) = \#\{i : u_i \ne v_i\}$. The last two functions take integer values; the first two, values in $\mathbb{F}_3$. The local profile of the reader, in the order (π, e, φ), is

$$\begin{aligned}(g_{\pi e}, g_{\pi\varphi}, g_{e\varphi}) &= (2,2,0), \qquad (n_\pi, n_e, n_\varphi) = (0,0,0),\\ (w_\pi, w_e, w_\varphi) &= (3,3,3), \qquad (h_{\pi e}, h_{\pi\varphi}, h_{e\varphi}) = (2,5,3).\end{aligned} \tag{11.98}$$

The words are ordered as in (11.97). We shall use $[E] \in \{0,1\}$ for the indicator of a condition E. For each pair of channels χ, ψ, the rectangular matrix $A_{\chi\psi}$ has entry $[g(u,v) = g_{\chi\psi}]$. The matrix $A^h_{\chi\psi}$ multiplies that entry by $[h(u,v) = h_{\chi\psi}]$. Let D^n_χ be the diagonal matrix of $[n(u) = 0]$, and D^{nw}_χ that of $[n(u) = 0][w(u) = 3]$.

Theorem 11.37 (Exhaustive enumeration by finite sums)**.** *The product of the three catalogues contains* 7 567 952 *triples. The successive conditions in* (11.98) *leave*

$$7\,567\,952 \longrightarrow 275\,794 \longrightarrow 6235 \longrightarrow 3127 \longrightarrow 331. \tag{11.99}$$

These four counts are, respectively,

$$\begin{aligned}N_g &= \operatorname{tr}(A_{\pi e} A_{e\varphi} A_{\varphi\pi}),\\ N_{gn} &= \operatorname{tr}(D^n_\pi A_{\pi e} D^n_e A_{e\varphi} D^n_\varphi A_{\varphi\pi}),\\ N_{gnw} &= \operatorname{tr}(D^{nw}_\pi A_{\pi e} D^{nw}_e A_{e\varphi} D^{nw}_\varphi A_{\varphi\pi}),\\ N_{gnwh} &= \operatorname{tr}(D^{nw}_\pi A^h_{\pi e} D^{nw}_e A^h_{e\varphi} D^{nw}_\varphi A^h_{\varphi\pi}).\end{aligned} \tag{11.100}$$

All products and traces in this formula are calculated in the integers, not in the field of three elements.

Proof. The size of the product is $196 \cdot 197 \cdot 196$. When a trace of (11.100) is expanded, its indices run through exactly one triple of words. The summand equals one if it satisfies all the represented conditions and zero otherwise. Each triple is counted once. The diagonal matrices add the individual conditions; the rectangular factors add the pairwise conditions. This proves that the traces are precisely the stated cardinalities.

To make their evaluation explicit, once the indices i, j of the first two channels are fixed, one forms the sets of indices ℓ of the third that satisfy each pairwise condition. Their indicators are intersected, the relevant individual indicators are added and their cardinality is summed. The final sum runs over $0 \le i < 196$, $0 \le j < 197$. Substituting the words of (11.97) and the profile (11.98) gives, in that order, 275794, 6235, 3127, 331. The supplement records the four contributions of each of the 196 indices i and the 331 complete triples; its program evaluates these sums with exact binary indicators and checks each survivor scalarly. Neither a sample nor a tolerance is involved. □

11.4.5.3 Labelled incidence and orientation charge

For a surviving triple, let $B \in \mathbb{F}_3^{3\times 6}$ be its matrix of ordered rows. The second profile requires

$$\operatorname{rank}_{\mathbb{F}_3} B = 3, \qquad w_{\mathrm{col}}(B) = (1,1,2,2,3,0), \qquad q_\partial(B) = (1,2,2,1,2,0), \tag{11.101}$$

where w_{col} counts the nonzero elements of each column and q_∂ sums its entries modulo three. It is a profile of labeled columns; permuting them without transporting the profile defines another reader. Denote by $\mathcal{F}$ the set of the 331 triples of the preceding theorem.

Proposition 11.38 (Reduction of the census to the terminal pair)**.** *The sums of indicators over $\mathcal{F}$, successively requiring rank, column weights and column sums, are*

$$\sum_{B\in\mathcal{F}} [\operatorname{rank} B = 3] = 331, \qquad N_{\text{rango,pesos}} = 18, \qquad N_{\text{rango,pesos,sumas}} = 2. \tag{11.102}$$

With catalogue indices starting at one, the two final triples are (120, 197, 157) *and* (129, 197, 148)*, and their matrices are*

$$B_0=\begin{pmatrix}0&2&0&2&2&0\\0&0&1&2&2&0\\1&0&1&0&1&0\end{pmatrix},\qquad B_1=\begin{pmatrix}0&2&1&0&2&0\\0&0&1&2&2&0\\1&0&0&2&1&0\end{pmatrix}.$$

Proof. For each triple in the set already enumerated, the rank is calculated by elimination in $\mathbb{F}_3$, the nonzero elements of the six columns are counted and their entries are summed modulo three. The products of the indicators of (11.101) give (11.102). Substituting the two final indices into (11.97) gives the displayed matrices. The complete list of survivors and the exact filters in the supplement allow the elimination to be reproduced without presupposing those two matrices as the domain. □

The orientation $\sigma=(1,1,-1)=(1,1,2)\in\mathbb{F}_3^3$ selects the line $\langle\sigma\rangle=\{(0,0,0),(1,1,2),(2,2,1)\}$. The row charges of B_0,B_1 are $(0,2,0)$ and $(2,2,1)$; only the second belongs to that line. This recovers the last step of the selector in section 11.4.6, now preceded by the construction and enumeration of its complete domain. The stable reading of $\lfloor 3^{1080}x_{\chi}\rfloor$, performed after the filters, gives the boundaries `021020`, `001220`, `100210`, with the same ranks $(129,197,148)$. This subsequent comparison does not define the profile or participate in the indicator sums.

11.4.5.4 Preserved information and scope of the result

The procedure preserves the thirty-trit prefix, the compatible tail, the regional order, the position of each trit and the orientation. Reduction modulo 729 here preserves the identity of each candidate because the tail interval has length less than 729; this injectivity is not asserted for an arbitrary history. The census of 331 also proves that the isolated local profile does not select a single matrix: the labeled margins and the charge contribute additional effective conditions.

Thus a complete finite enumeration and its selector on output cylinders have been recovered, with an explicit reading profile. The construction of the signed register additionally uses its memory reader and its channels, as specified below; the visible matrix is not identified with that register by equality of the number of components. Nor does this count prove the universality of the profile, generate the regional coordinates again or decide an assertion about alpha or about the complete continuum.

11.4.6 Two readings of the terminal state

Denote by x_{term} the state produced by the composition of selection, transport and update up to the terminal cut. The operator notation is

$$x_{\mathrm{term}}=(\mathcal{U}_{108}\circ\cdots\circ\mathcal{U}_1)(x_{\mathrm{seed}}),\qquad \mathcal{U}_t=\mathsf{Upd}_t\circ\mathsf{Tra}_t\circ\mathsf{Sel}_t.$$

Its two relevant readings are

$$x_{\mathrm{term}}\xrightarrow{(\pi_{\mathrm{term}},R_{\mathrm{sgn}})}(B_{\mathrm{term}},U).$$

The matrix B_{term} retains the visible ternary reading; the vector U preserves another coordinate of the same history. No arrow $B_{\mathrm{term}}\to U$ is inserted between them.

The terminal selector operates on the three regional catalogues of sizes 196, 197, and 196, constructed in Section 11.4.5. The local signatures reduce their $196\cdot197\cdot196=7\,567\,952$ triples to 331, and the column marginal $q_{\partial}=(1,2,2,1,2,0)$ leaves two matrices:

$$B_0=\begin{pmatrix}0&2&0&2&2&0\\0&0&1&2&2&0\\1&0&1&0&1&0\end{pmatrix},\qquad B_1=\begin{pmatrix}0&2&1&0&2&0\\0&0&1&2&2&0\\1&0&0&2&1&0\end{pmatrix}.$$

The row orientation is $\sigma=(1,1,-1)=(1,1,2)$ in $\mathbb{F}_3^3$. The row charges of the candidates are $(0,2,0)$ and $(2,2,1)$. Only the second belongs to $\langle\sigma\rangle=\{(0,0,0),(1,1,2),(2,2,1)\}$; therefore $B_{\mathrm{term}}=B_1$. This check proves the last step of the selector from the declared census. It does not turn the column margin

into a consequence of the row charge, or replace the preceding enumeration with the inspection of those two matrices.

The signed reader has the typed composition

$$R_{\mathrm{sgn}} = \Pi_H \circ \mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,mem}} \longrightarrow \mathbb{Z}^{12}. \tag{11.103}$$

The channel register determines

$$\mathcal{E}_{108}^{90,120}(\mathcal{R}_{12}(x_{\mathrm{term}})) = (b^{90}, b^{120}, Q_{\mathrm{TPK}}),$$

with coordinates

$$\begin{aligned} b^{90} &= (-495, -116, -684, 108, 601, -90, \\ &\qquad -173, -88, 313, 560, -397, 461), \\ b^{120} &= (-425, -281, -481, 671, -255, 30, \\ &\qquad 475, -543, 680, 251, 6, -128), \\ Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

These quantities are used as coordinates of the preceding register, not as parameters adjusted through alpha. The reconstruction proved in the following subsections begins exactly at this typed output. The integral characterization of the extractor, its inverse and the composition of contributions are developed in section 11.4.10, in particular in Theorem 11.43 and Proposition 11.46. The regional determination of the descriptor and terminal selection are presented in chapter 11.3. Each construction preserves its domain: the selector acts on the generated repertoires and inversion acts on the signed channels declared here. The documentary trail of the extractor is recorded in the technical provenance of the package.

11.4.7 Construction of the signed register through the oriented channels

The harmonic reader Π_H can be written without using either K or alpha. To avoid confusing its orbital sums with the alpha blocks, we shall denote them by s_1, s_2, s_3. Let

$$B_r = \sum_{j=0}^{3} b_{r+3j}^{120}, \qquad d_{r,j} = b_{r+3j}^{90}, \qquad 1 \le r \le 3,$$

and

$$s_1 = \frac{Q_{\mathrm{TPK}} + 2B_1 + B_2}{3}, \qquad s_2 = s_1 - B_1, \qquad s_3 = s_2 - B_2. \tag{11.104}$$

Division by three belongs to the reader of the three orbits. Its integrality is checked on the compatible outputs of the register; it is not assumed for an arbitrary element of $\mathbb{Z}^{25}$.

The three signed blocks are

$$U^{(r)} = (s_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}). \tag{11.105}$$

Integer substitution gives

$$(B_1, B_2, B_3) = (972, -1073, 101), \qquad (s_1, s_2, s_3) = (2378, 1406, 2479),$$

and, therefore,

$$\begin{aligned} U^{(1)} &= (2378, -452, -668, -322), \\ U^{(2)} &= (1406, 998, -204, -28), \end{aligned}$$

$$U^{(3)} = (2479, -551, -371, -997).$$

Interleaving by columns gives

$$U = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997). \tag{11.106}$$

The presence of negative values and components greater than 999 shows that U is not a word of base-one-thousand digits. Nor is it $U_6 \| U_6$, a catalog concatenation of period six. The difference is one of domain and preserved information, not merely of values.

The constructive order thus far is

$$x_{\text{term}} \longrightarrow \mathcal{R}_{12} \longrightarrow (b^{90}, b^{120}, Q_{\text{TPK}}) \longrightarrow U.$$

The following inversion produces the dodecaphasic register. The fact that we can later recover the channels from the dodecaphasic register constitutes a reversibility check; it does not reverse this causal order.

11.4.8 Hadamard by orbits and integer reconstruction

In the cycle of twelve positions, step three determines three orbits:

$$(1, 4, 7, 10), \qquad (2, 5, 8, 11), \qquad (3, 6, 9, 12).$$

The separation of four sectors of each orbit is what, once origin and orientation are fixed, admits the ninety-degree angular reading. The transformation does not act on three contiguous tetrads of the natural order.

Let

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}.$$

If P_{orb} reorders by the three indicated orbits, we define

$$\mathcal{H}_{12} = P_{\text{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)P_{\text{orb}}.$$

Lemma 11.39 (Hadamard inversion and integrality)**.** *We have*

$$H_4^2 = 4I_4, \qquad H_4^{-1} = \frac{1}{4}H_4, \qquad \det H_4 = -16.$$

For $u \in \mathbb{Z}^4$, the preimage $H_4^{-1}u$ is integral if and only if $H_4 u \equiv 0 \pmod 4$.

Proof. The rows are orthogonal and have squared norm four; the matrix is symmetric. This gives $H_4^2 = 4I_4$ and the inverse. An integer elimination, or expansion of the determinant, gives the negative sign and the value -16. The integrality condition is exactly divisibility by four of the four coordinates of $H_4 u$. □

Definition 11.40 (Dodecaphasic integral transformation)**.** The sublattice of signed registers and its integral coordinatization are

$$\mathcal{L}_H = \{u \in \mathbb{Z}^{12} : \mathcal{H}_{12}u \equiv 0 \pmod 4\}, \qquad \mathscr{K}(u) = \tfrac{1}{4}\mathcal{H}_{12}u.$$

The map $\mathscr{K} : \mathcal{L}_H \to \mathbb{Z}^{12}$ is an isomorphism of abelian groups, with inverse $k \mapsto \mathcal{H}_{12}k$. The canonical register K is the image of the signed register generated by the preceding operations, with fixed phase origin and orientation.

Proof. The congruence defines exactly the integrality of $\mathscr{K}(u)$. The identity $\mathcal{H}_{12}^2 = 4I$ proves the two inverse compositions. In particular, every $k \in \mathbb{Z}^{12}$ has preimage $\mathcal{H}_{12}k \in \mathcal{L}_H$. □

Proposition 11.41 (Canonical integral register)**.** *The inversion $K^{(r)} = H_4U^{(r)}/4$ of the blocks in* (11.105) *produces*

$$\begin{aligned} K^{(1)} &= (234, 729, 621, 794), \\ K^{(2)} &= (543, 659, 58, 146), \\ K^{(3)} &= (140, 824, 914, 601). \end{aligned}$$

In the natural order, the dodecaphasic register is

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \tag{11.107}$$

It is the unique rational preimage of U, and it belongs to $\{0, \dots, 999\}^{12}$.

Proof. The three products before division are

$$\begin{aligned} H_4U^{(1)} &= (936, 2916, 2484, 3176), \\ H_4U^{(2)} &= (2172, 2636, 232, 584), \\ H_4U^{(3)} &= (560, 3296, 3656, 2404). \end{aligned}$$

All coordinates are divisible by four. Dividing and undoing the orbit permutation gives (11.107). Uniqueness follows from rational invertibility, not from a search among candidates close to a physical value. □

Integrality can also be formulated in terms of lattices. The determinantal divisors of H_4 are $1, 2, 4, 16$: the entries have greatest common divisor one; the minors of order two are even and one has absolute value two; those of order three are multiples of four and one has absolute value four. It follows that

$$\operatorname{SNF}(H_4) = \operatorname{diag}(1, 2, 2, 4),$$

and for the global transformation,

$$\operatorname{coker} \mathcal{H}_{12} \cong (\mathbb{Z}/2\mathbb{Z})^6 \oplus (\mathbb{Z}/4\mathbb{Z})^3.$$

The index of the image is $16^3 = 4096$. Thus not every signed integer vector admits an integer preimage; the vector obtained satisfies the precise congruences required by inversion. The factor $1/4$ is forced by the matrix and does not have the status of a free coefficient.

11.4.9 Cyclic differences and uniform component

With cyclic indices modulo twelve, let

$$(D_3z)_m = z_m - z_{m+3}, \qquad (D_4z)_m = z_m - z_{m+4}, \qquad Q(z) = \sum_{m=1}^{12} z_m.$$

The first operator compares sectors separated by three positions; the second, by four. The channel names 90 and 120 here refer to these separations in the oriented cycle, not to an identification with a physical operator from another domain.

Proposition 11.42 (Completeness of the transverse system)**.** *The operator*

$$\mathcal{D} = (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}$$

has rank twelve and nonzero invariant factors

$$\operatorname{diag}(1, \dots, 1, 12),$$

with eleven units. In particular, its outputs determine a unique dodecaphasic register.

Proof. If $D_3 z = D_4 z = 0$, the vector is constant along both steps. Since 3 and 4 generate the cycle modulo twelve, $\ker D_3 \cap \ker D_4 = \langle \mathbf{1} \rangle$. The total charge eliminates this last freedom because $Q(\mathbf{1}) = 12$.

For the integral assertion, the rows of (D_3, D_4) are oriented incidences of a connected graph. A spanning tree provides eleven unit invariant factors. Every minor of order twelve must contain the row Q. Adding the first eleven columns to the last makes the latter zero in the incidence rows and twelve in row Q. All the maximal minors are divisible by twelve and the tree produces one of absolute value exactly twelve. The last factor is therefore twelve. □

The check on (11.107) gives

$$D_3 K = b^{90}, \qquad D_4 K = b^{120}, \qquad Q(K) = 6263.$$

Formulas (11.104) and (11.105) in turn reconstruct U from those differences. This closes a triangle of exact representations of the same object: transverse register, signed vector and dodecaphasic register. Equality of results does not merge their codomains into one; it proves that the declared maps recover the relevant information.

11.4.10 Integral compatibility and determination of the transverse register

The domain of this construction is the publication of the register of an APP–TRIT–TPK history. The evaluation of the register events, the compatibility of its channels and the inversion of its coordinates are distinguished. The following result gives a complete integral criterion for the second level and an explicit factorization connecting the first to it. The proof uses the register operators and establishes their relations for every element of the indicated integer domains.

11.4.10.1 Characterization by adjacent increments

The indices belong to $\mathbb{Z}/12\mathbb{Z}$. Let

$$(Sz)_i = z_{i+1}, \qquad D_3 = I - S^3, \qquad D_4 = I - S^4, \qquad Q(z) = \sum_{i=0}^{11} z_i.$$

The transverse extractor is preserved

$$\mathcal{D} : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}, \qquad k \longmapsto (D_3 k, D_4 k, Q(k)).$$

For a triple of integer coordinates (b, c, q), write

$$w_i = c_i - b_{i+1}, \qquad P_0 = 0, \quad P_i = \sum_{j=0}^{i-1} w_j \ (1 \le i \le 12), \qquad T(w) = \sum_{i=0}^{11} P_i. \tag{11.108}$$

Theorem 11.43 (Integral image of the transverse extractor)**.** *A triple $(b, c, q) \in \mathbb{Z}^{25}$ belongs to* $\operatorname{im} \mathcal{D}$ *if and only if it satisfies*

$$b_i = w_i + w_{i+1} + w_{i+2} \qquad (0 \le i < 12), \tag{11.109}$$

$$\sum_{i=0}^{11} w_i = 0, \tag{11.110}$$

$$q + T(w) \equiv 0 \pmod{12}. \tag{11.111}$$

Its unique integer preimage is

$$k_i = \frac{q + T(w)}{12} - P_i, \qquad 0 \le i < 12. \tag{11.112}$$

The twelve equations of (11.109) *and the equation* (11.110) *are linearly independent over* $\mathbb{Q}$.

Proof. For an output of $\mathcal{D}$, one has

$$c_i - b_{i+1} = (k_i - k_{i+4}) - (k_{i+1} - k_{i+4}) = k_i - k_{i+1}.$$

The sum of three increments gives b_i; their cyclic sum is zero. Moreover, $P_i = k_0 - k_i$, so $q = 12k_0 - T(w)$. All conditions and the inverse formula are obtained.

Conversely, (11.111) makes the formula (11.112) integer-valued; (11.110) allows it to be extended cyclically. Its adjacent differences are w_i. Therefore, $D_3 k = b$ and

$$(D_4 k)_i = w_i + w_{i+1} + w_{i+2} + w_{i+3} = w_i + b_{i+1} = c_i.$$

The sum of the inverse gives $Q(k) = q$. The same formula proves uniqueness. For independence, the invertible integer change $(b, c) \mapsto (b, w = c - Sb)$ converts the first twelve relations into $b = (I + S + S^2)w$. Each solves for a different coordinate of b. The condition $\sum w_i = 0$ is an additional independent relation. □

The rational image has dimension twelve. Its integral structure adds a congruence of order twelve: this is the constructive manifestation of the last Smith factor of $\mathcal{D}$. The eleven increments $w_0, \dots, w_{10}$ and the charge q are sufficient coordinates, with $w_{11} = -\sum_{i=0}^{10} w_i$ and the congruence (11.111). The original twenty-five coordinates preserve these same twelve degrees of freedom through thirteen relations.

11.4.10.2 Commutativity with the harmonic reading

Let $\mathcal{H}_{12}$ be the Hadamard transform of the register, with orbits $(r, r+3, r+6, r+9)$ for $r = 0, 1, 2$. Its block is

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad H_4^2 = 4I_4.$$

For compatible (b, c, q), define

$$B_r = \sum_{j=0}^{3} c_{r+3j}, \qquad A_0 = \frac{q + 2B_0 + B_1}{3}, \quad A_1 = A_0 - B_0, \quad A_2 = A_1 - B_1.$$

The reader Π_H of (11.105) has the blocks

$$(\Pi_H(b, c, q))^{(r)} = (A_r, b_{r+3} - b_{r+9}, b_r + b_{r+6}, b_r - b_{r+6}).$$

Proposition 11.44 (Agreement of the two reconstructions)**.** *On* $\operatorname{im} \mathcal{D}$ *one has*

$$\Pi_H \mathcal{D} = \mathcal{H}_{12}, \qquad \mathcal{D}^{-1} = \tfrac{1}{4}\mathcal{H}_{12}\Pi_H.$$

The image of Π_H restricted to that domain is exactly

$$\mathcal{L}_H = \{u \in \mathbb{Z}^{12} : \mathcal{H}_{12}u \equiv 0 \pmod 4\}.$$

Proof. For $k = \mathcal{D}^{-1}(b, c, q)$, let $a_r = \sum_{j=0}^{3} k_{r+3j}$. The four-position shift takes each orbit to the next, and therefore $B_r = a_r - a_{r+1}$. Together with $q = a_0 + a_1 + a_2$, these identities give $A_r = a_r$. On an orbit, let us write (x_0, x_1, x_2, x_3) for the coordinates of k and $d_j = x_j - x_{j+1}$. Then

$$d_1 - d_3 = x_0 + x_1 - x_2 - x_3, \quad d_0 + d_2 = x_0 - x_1 + x_2 - x_3, \quad d_0 - d_2 = x_0 - x_1 - x_2 + x_3.$$

They are the three remaining rows of $H_4 k^{(r)}$. The inversion and the integral characterization follow from $\mathcal{H}_{12}^2 = 4I$. □

The condition $\Pi_H(b, c, q) \in \mathcal{L}_H$ controls only the harmonic output. Membership of the twenty-five coordinates in $\operatorname{im} \mathcal{D}$ additionally requires (11.109)–(11.111). For example, adding to c the vector $e_0 - e_3$ preserves the three orbital sums and leaves Π_H unchanged. Starting from $(0, 0, 0)$ thus gives a triple with $\Pi_H = 0$ that violates (11.109). This is an exact negative control for channel compatibility, independent of any terminal evaluation.

11.4.10.3 Determination and transport on the orbits of the register

Theorem 11.43 determines k when its channels and charge have been produced. As a condition on outputs not yet individualized, the same image is a group isomorphic to $\mathbb{Z}^{12}$. With only a charge q fixed, the solutions form an affine class of

$$L_0 = \{v \in \mathbb{Z}^{12} : \sum v_i = 0\} = \bigoplus_{i=0}^{10} \mathbb{Z}(e_i - e_{11}).$$

For example, $100\mathbf{1} + e_0$ and $100\mathbf{1} + e_1$ are two distinct registers, of charge 1201, with components in $\{0, \dots, 999\}$. Each satisfies all image conditions and all Hadamard congruences through its own channels. These witnesses compare the compatibility equations; they are not assigned the status of terminal HMT histories.

Proposition 11.45 (Cyclic covariance and stabilizer of the register)**.** *Let ρ be window translation on a register domain $\mathcal{R}$ and S the preceding translation on $\mathbb{Z}^{12}$. On the orbit of $R \in \mathcal{R}$, a covariant reader is determined by a vector*

$$k \in \operatorname{Fix}(S^p),$$

where $p \mid 12$ is the minimal period of R under ρ. The charge condition $Q(k) = q$ admits integer solutions if and only if $12/p$ divides q; when they exist, they form an affine class of rank $p - 1$. In particular, on a free orbit, covariance and charge leave eleven degrees of freedom.

Proof. The rule $F(\rho^j R) = S^j k$ is well defined exactly when $S^p k = k$. Such vectors repeat $12/p$ times a word of length p. Their charge is $\frac{12}{p} \sum_{i=0}^{p-1} k_i$. Divisibility and rank follow from this formula. Channel covariance follows from $D_a S = S D_a$ and $QS = Q$. On $\mathcal{L}_H$, the corresponding action is $\widehat{S}_H = \mathcal{H}_{12} S \mathcal{H}_{12}/4$; by Proposition 11.44, both reconstructions intertwine these actions. □

If the domain carries a marked origin, the action that also transports that mark must be used. The proposition concerns this declared cyclic action; it does not presuppose the periodicity of the enriched history. Naturality with respect to truncations subsequent to the cut 108 is obtained, for any already defined reader F_{108}, through $F_N = F_{108} \circ \tau_{N,108}$. This naturality preserves the initial evaluation rule; by itself it does not choose one of the possible rules on the first one hundred and eight events.

11.4.10.4 Event-based evaluation and composition of contributions

The preceding characterization provides a factorization of the extraction through two effective readings of the register:

$$\omega : \mathscr{R} \longrightarrow \{w \in \mathbb{Z}^{12} : \sum w_i = 0\}, \qquad q_{\mathrm{reg}} : \mathscr{R} \longrightarrow \mathbb{Z}, \quad q_{\mathrm{reg}}(R) + T(\omega(R)) \equiv 0 \pmod{12}. \tag{11.113}$$

These maps must be evaluated on the events, orientation, incidence and memory produced by APP–TRIT–TPK. Once their actions on these data are given, the composition

$$R \longmapsto (w, q) \longmapsto ((I + S + S^2)w, (I + S + S^2 + S^3)w, q) \xrightarrow{\Pi_H} u \xrightarrow{\mathcal{H}_{12}/4} k$$

is determined and satisfies all inverse checks. The formula $w = c - Sb$ also allows a producer that already delivers both channels to be connected: it is a check on its output, prior to any comparison with the terminal witness.

Proposition 11.46 (Accumulation of contributions and prospective uniqueness)**.** *Suppose that the initial state and each event a_t of the register produce, through previously fixed rules, contributions $(\delta w_t, \delta q_t)$ with*

$$\sum_i \delta w_{t,i} = 0, \qquad \delta q_t + T(\delta w_t) \equiv 0 \pmod{12}.$$

With compatible initial conditions $(w^{(0)}, q^{(0)})$, the update

$$w^{(t+1)} = w^{(t)} + \delta w_t, \qquad q^{(t+1)} = q^{(t)} + \delta q_t$$

produces a unique register at each stage. Its increment is

$$\delta k_{t,i} = \frac{\delta q_t + T(\delta w_t)}{12} - P_i(\delta w_t).$$

The construction respects register concatenation, and the reading of a prefix remains unchanged under subsequent extensions.

Proof. The compatibility conditions are preserved under addition. The formula (11.112) is additive in (w, q) and produces the indicated increment. Induction fixes each state successively. The sum over two segments is the concatenated sum, and a prefix receives exactly the same summands before and after extending the history. □

The proposition provides a sufficient criterion, not a requirement of linearity for every TPK reader. If events are transported by nontrivial actions, their contributions can be expressed in the terminal chart through the corresponding affine cocycle. The cocycle equation then preserves the same independence from the partition of the trajectory. In both cases, the event rules and the initial state constitute the constructive data that must come from the article: choosing them to reproduce an expected vector would replace that provenance with another task.

The result of this development is the exact determination condition (11.113), its proved inversion and its transport identities. Its scope is the transverse register; the other HMT constructions retain their own domains and proofs.

11.4.11 Two rational readings: κ_{36} and κ_{per}

Once K is constructed, the base-one-thousand chart allows two distinct operations. The first reads a single turn; the second prolongs the dodecaphasic register periodically. Let $B = 1000$ and define its concatenation integer

$$N_K = \sum_{m=1}^{12} K_m B^{12-m} = 234543140729659824621058914794146601. \tag{11.114}$$

The leading zeros of a block, such as that of 058, are part of its three-digit notation. They do not change its integer value, but they do allow the twelve blocks to be concatenated without ambiguity.

Definition 11.47 (Finite and periodic readings of the dodecaphasic register)**.** The reading of one turn is

$$\kappa_{36} = \sum_{m=1}^{12} K_m B^{-m} = \frac{N_K}{B^{12}}.$$

The periodic prolongation is

$$K_j^{\mathrm{per}} = K_{1+((j-1) \bmod 12)}, \qquad \kappa_{\mathrm{per}} = \sum_{j \geq 1} K_j^{\mathrm{per}} B^{-j}.$$

Proposition 11.48 (Exact value and period of the prolonged dodecaphasic register)**.** *We have*

$$\kappa_{\mathrm{per}} = \frac{N_K}{B^{12}-1}, \qquad \kappa_{\mathrm{per}} - \kappa_{36} = \frac{N_K}{B^{12}(B^{12}-1)} = B^{-12}\kappa_{\mathrm{per}}. \tag{11.115}$$

The infinite word of the dodecaphasic register has minimum period twelve in base one thousand and minimum period thirty-six in base ten.

Proof. The sum of the first turn is $N_K B^{-12}$; each new turn multiplies its contribution by B^{-12}. The geometric series produces $N_K/(B^{12}-1)$, and subtraction gives the second identity.

The twelve components of K are distinct. A proper period of the cycle would identify two of them; therefore the minimum block period is twelve. The decimal expansion is canonical, since the dodecaphasic register has no tail of 999 blocks. If its minimum decimal period were d, it would divide 36. Grouping in threes would produce a block period $d/\gcd(d,3)$. No proper divisor of 36 gives twelve through that operation. Hence the minimum decimal period is 36. □

Both readings are rational, but they are not the same rational number. The first ends after twelve blocks; the second repeats the turn. Moreover, $0 < \kappa_{\mathrm{per}} - \kappa_{36} < B^{-12}$. Their closeness does not allow one to be substituted for the other in an exact identity. In particular, the finite closure of alpha uses κ_{36}, whereas the sum of the prolonged section uses κ_{per}.

11.4.12 Reversibility of the rational constant and phase change

The rational constant κ_{per} fully determines the register K when the base, length and reading origin are preserved. Its numerical function and its structural function are related through an exact inversion.

Proposition 11.49 (Integral recovery and cyclic transformation)**.** *Let* $I(K) = \sum_{j=1}^{12} K_j 1000^{12-j}$. *Then*

$$I(K) = (1000^{12}-1)\kappa_{\mathrm{per}}.$$

The integer expansion of $I(K)$ *into twelve blocks of base* 1000 *recovers all the* K_j*, including the leading zeros of each block. If* $\rho(K) = (K_2, \ldots, K_{12}, K_1)$*, one has*

$$\kappa(\rho K) = 1000\kappa(K) - K_1. \tag{11.116}$$

Proof. The first identity inverts the definition of the periodic evaluation. Iterated Euclidean division by 1000, with twelve fixed positions, recovers the vector. Furthermore,

$$I(\rho K) = 1000 I(K) - K_1(1000^{12} - 1).$$

Dividing by $1000^{12} - 1$ gives (11.116). □

Recovery therefore composes $\kappa \mapsto K \mapsto U$ and the transformations D_3K, D_4K, Q already constructed. The rational evaluation preserves the signed register and the cyclic differences that depend on it. The total depth and the transport operators of a history remain in their own coordinates: the preceding inversion has the integral dodecaphasic register as its domain.

Write $\kappa_j = \kappa(\rho^j K)$, with indices modulo 12. The same identity gives

$$K_{j+1} = 1000\kappa_j - \kappa_{j+1}, \qquad \sum_{j=0}^{11} \kappa_j = \frac{\sum_{j=1}^{12} K_j}{999} = \frac{6263}{999}.$$

Phase acts exactly on the constant: its value is fixed in the canonical reading, while its rotations follow an affine law. The orbit sum is invariant under the choice of origin.

The subsequent incidence also has an expression in these coordinates. The cubic threshold determines

$$B_K = \{j + 1 : 1000\kappa_j - \kappa_{j+1} \geq 729\} = \{4, 6, 9, 10\}.$$

The tetrad is recovered from the rational orbit because the latter first recovers the integer components. The signed support associated with α also uses its regional registers and the boundary normalization. The relation between coordinate and incidence is thus expressed through identifiable operations.

This is an operational definition of the function of K: it provides a reversible integral coordinatization of the oriented register, whose periodic evaluation and incidence functions participate in subsequent constructions. The value, the transformation and the domain are preserved jointly.

11.4.13 Periodicity and cokernel of the transport operator

The periodicity we have just proved belongs to the dodecaphasic register. It does not imply periodicity of the regional coordinates, of the closure carries or of alpha. It is useful to specify this separation through a second quotient, purely integral.

Let S be the cyclic shift of twelve coordinates, with fixed orientation, and let $b \geq 2$ be an integer base. The periodic carry operator is $\partial_b = S - bI$. If a periodic identity is written

$$A = P + E - \Phi - K + \partial_b C,$$

then the transformations

$$K \longmapsto K + \partial_b h, \qquad C \longmapsto C + h$$

preserve its right-hand side. This invariance compares representatives of a carry class; it is not authorization to modify the dodecaphasic register already selected by the register.

Proposition 11.50 (Periodic carry quotient)**.** *With the preceding orientation,*

$$\operatorname{coker}(S - bI) \cong \mathbb{Z}/(b^{12} - 1)\mathbb{Z}.$$

Proof. The cyclic module is presented as $\mathbb{Z}[t]/(t^{12}-1)$. Imposing $S = bI$ is equivalent to imposing $t = b$, and leaves the relation $b^{12} - 1 = 0$. Evaluating the coefficients at b, with the chosen concatenation order, represents the resulting class. □

The denominator $B^{12} - 1$ of κ_{per} and this quotient arise from the same cyclic length, but their objects remain distinct: one is a rational evaluation and the other a quotient of a carry module. The finite closure of alpha will be an oriented chain with a right boundary. Its prolongation will transport a compatible remote boundary, not a carry identified by decree between the first and thirteenth positions.

The next chapter is thus prepared. The dodecaphasic register has been fixed before solving the alpha recurrence; its Hadamard reconstruction is integral and unique; its transverse differences recover the register; and its two rational evaluations have separate domains and uses. None of these facts uses alpha as input, and none yet decides the arithmetic type of the output of the complete closure.

11.5 Complete recovery of the register through weighted hexadic incidences

The generated dodecaphasic register preserves twelve ordered components and a phase origin. Paley–Witt incidence provides an additional reading of that register: each hexadic support combines six of its components through a sum weighted by the incidence itself. The reconstruction developed here receives the values of these sums from the same register. Its purpose is to prove that the readings preserve all the components and to exhibit the inverse operator with explicit rational coefficients.

11.5.1 Incidence encoder and twelve explicit witnesses

In the incidence coordinate system already fixed, let

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3).$$

For $w \in \mathbb{F}_3^6$, the encoder is $\mathrm{Enc}(w) = (w, wA_W) \in \mathbb{F}_3^{12}$ and its support is

$$H(w) = \{j \in \{1, \dots, 12\} : \mathrm{Enc}(w)_j \neq 0\}.$$

Choosing a position uses indices from one to twelve; implementations with zero-based indices are transported through $j \mapsto j + 1$.

The following twelve witnesses belong to the domain of the encoder:

i	$w^{(i)}$	i	$w^{(i)}$
1	112210	7	122020
2	122101	8	112002
3	121200	9	111001
4	111100	10	110122
5	121012	11	101221
6	111020	12	011111.

Define $H_i = H(w^{(i)})$ and $B_{ij} = \mathbf{1}_{\{j \in H_i\}}$. Evaluating the encoder gives

$$B = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 \\ 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{11.117}$$

Each row contains six entries equal to one. Consequently, each H_i is a hexad of the image of the encoder, and the matrix B is constructed from those supports.

11.5.2 Rational inverse and uniqueness of recovery

Let the integer matrix be

$$M = \begin{pmatrix} 7 & 1 & 8 & -7 & 7 & -1 & -4 & 8 & -7 & 3 & 3 & -15 \\ 7 & 7 & -4 & -1 & 1 & -7 & 8 & 8 & -7 & 3 & -15 & 3 \\ 1 & 7 & 8 & -7 & 7 & -7 & 8 & -4 & -1 & -15 & 3 & 3 \\ 1 & 1 & 2 & 5 & -5 & -1 & -4 & -4 & -1 & 3 & 3 & 3 \\ 1 & -5 & -4 & -1 & 1 & 5 & 2 & -4 & -1 & 3 & 3 & 3 \\ -5 & 1 & -4 & -1 & 1 & -1 & -4 & 2 & 5 & 3 & 3 & 3 \\ -5 & -11 & 2 & 5 & -5 & 11 & -10 & 2 & 5 & 3 & 3 & 3 \\ -5 & -5 & -10 & 11 & -11 & 5 & 2 & 2 & 5 & 3 & 3 & 3 \\ -11 & -5 & 2 & 5 & -5 & 5 & 2 & -10 & 11 & 3 & 3 & 3 \\ -11 & -11 & -4 & 17 & 1 & 11 & -10 & -10 & 11 & 3 & 3 & 3 \\ -11 & 1 & -10 & 11 & -11 & 17 & -4 & -10 & 11 & 3 & 3 & 3 \\ 1 & -11 & -10 & 11 & -11 & 11 & -10 & -4 & 17 & 3 & 3 & 3 \end{pmatrix}. \tag{11.118}$$

Theorem 11.51 (Exact recovery from twelve hexadic readings)**.** *For $v \in \mathbb{Q}^{12}$, let*

$$\mathrm{Read}(v) = Bv, \qquad \mathrm{Rec}(y) = \frac{1}{18} My.$$

We verify

$$\mathrm{Rec}(\mathrm{Read}(v)) = v, \qquad \mathrm{Read}(\mathrm{Rec}(y)) = y.$$

Therefore every $y \in \mathbb{Q}^{12}$ admits a unique register $v \in \mathbb{Q}^{12}$ with $\mathrm{Read}(v) = y$.

Proof. Integer multiplication of the matrices (11.117) and (11.118) gives $MB = BM = 18 I_{12}$. Each diagonal entry results from a scalar product equal to eighteen and each off-diagonal entry results from a zero scalar product. Dividing by eighteen gives the two inverse identities.

In particular, $\mathrm{Rec}(\mathrm{Read}(v)) = (MB/18)v = v$ and $\mathrm{Read}(\mathrm{Rec}(y)) = (BM/18)y = y$. The second identity proves existence through $v = \mathrm{Rec}(y)$. If $Bu = Bv$, applying $M/18$ to both sides gives $u = v$, which proves uniqueness. □

The check of B from the encoder and the two exact multiplications are formalized in the theorems `incidence_from_encoder`, `inverse_left` and `inverse_right`. The composition identities correspond to `recover_read` and `read_recover`. Their mathematical content is found entirely in the matrices and in the preceding proof; the formal certificate records the verification of those same operations.

Corollary 11.52 (Separation by all weighted incidences)**.** *If $u, v \in \mathbb{Q}^{12}$ satisfy*

$$\sum_{j\in H(w)} u_j = \sum_{j\in H(w)} v_j$$

for every $w \in \mathbb{F}_3^6$ whose encoded support has six positions, then $u = v$.

Proof. The hypothesis applies in particular to the twelve displayed witnesses. By the definition of B, their twelve equalities constitute $Bu = Bv$. Theorem 11.51 allows both inputs to be recovered and concludes $u = v$. □

Example 11.53 (Recovery of a peripheral component)**.** For the canonical vector $v = e_{12}$, the only nonzero readings are the first and the ninth:

$$y = Be_{12} = (1,0,0,0,0,0,0,0,1,0,0,0)^{\mathsf{T}}.$$

The sum of the first and ninth columns of M is $18e_{12}$. Consequently, $My/18 = e_{12}$. The two hexadic sums distinguish this position in the joint reading because the remaining components cancel exactly in the recovery operator.

11.5.3 Symmetric recovery operator on the one hundred and thirty-two hexads

The Steiner system $S(5,6,12)$ already produced by incidence contains 132 hexads. Denote their set by $\mathcal{H}$ and define

$$\mathcal{I} : \mathbb{Q}^{12} \longrightarrow \mathbb{Q}^{\mathcal{H}}, \qquad (\mathcal{I}v)_H = \sum_{j\in H} v_j.$$

This reader has redundancy: it preserves the twelve components through 132 sums, whereas the preceding theorem provides a basis of twelve of these sums.

Theorem 11.54 (Inverse on the image of the complete reader)**.** *We have*

$$\mathcal{I}^{\mathsf{T}}\mathcal{I} = 36I_{12} + 30J_{12},$$

where J_{12} has all its entries equal to one. For $y = \mathcal{I}v$, the register is recovered through

$$396 v_i = 11 \sum_{H\ni i} y_H - 5 \sum_{H\in\mathcal{H}} y_H, \qquad i = 1,\dots,12. \tag{11.119}$$

Proof. The property $S(5,6,12)$ implies that each position belongs to $\binom{11}{4}/\binom{5}{4} = 66$ hexads. Each pair of distinct positions belongs to $\binom{10}{3}/\binom{4}{3} = 30$ hexads. Therefore, the product of the transposed incidence matrix with itself has diagonal 66 and off-diagonal entries 30, which is $36I + 30J$.

Let $S = \sum_j v_j$. The two preceding counts give

$$\sum_{H\ni i} y_H = 66 v_i + 30 \sum_{j\neq i} v_j = 36 v_i + 30 S, \qquad \sum_{H} y_H = 66 S.$$

Multiplying the first equality by eleven and subtracting five times the second eliminates S and produces $396 v_i$. This proves (11.119) for every reading belonging to the image of $\mathcal{I}$. □

Corollary 11.55 (Uniform and transverse components)**.** *On $\mathbb{R}^{12}$, the complete reader has singular value $\sqrt{396}$ in the uniform direction and singular value 6 in its orthogonal complement. Its inverse operator on the image has operator norm $1/6$.*

Proof. The matrix J acts by twelve on $\mathbb{R}\mathbf{1}$ and by zero on $\mathbf{1}^{\perp}$. The eigenvalues of $36I + 30J$ are therefore 396 and 36. The singular values are their positive roots; the largest singular value of the inverse operator is the reciprocal of the smallest of them. □

11.5.4 Composition with the generated register

Applying these identities to the integer dodecaphasic register K, already produced with its order and origin, the readings BK or $\mathit{I}K$ allow its twelve components to be recovered exactly. The subsequent positional interpretation takes that same register in base one thousand; the Hadamard operators, differences and hexadic readers are recoverable realizations of a common provenance.

The system of twelve rational coordinates admits any input $y \in \mathbb{Q}^{12}$ and reconstructs it as a unique rational register. The subdomain corresponding to generated HMT registers additionally preserves its conditions of integrality, triad width, origin, selection and boundary. For the redundant system of 132 readings, the inverse acts on the image of I. These specifications type the recovered content without modifying the antecedent generation of the register.

11.6 Derivation of the fine-structure constant

The fine-structure constant receives in this development an arithmetic determination combining the three regional coordinates and the integral dodecaphasic register. The operation combines their blocks with fixed orientation and transports the quotients of positional normalization. The resulting parameter expresses the compatibility of that oriented difference with prolongation of the cylinders. Its value and the incidence data used in its construction will remain related throughout the exceptional development.

The internal order is important. The coordinates π, e and φ, already constructed in the preceding section, are prior coordinates of the same arithmetic state with trajectory memory, and may legitimately act as inputs to a subsequent reader. They are not conventional constants injected to select alpha. Correlated generation of the four coordinates shares origin and coinductive compatibility, without thereby requiring their four components to be evaluated in a single step.

The two paths express different mathematical functions of the same parameter. The first realizes an integer closure by Euclidean division in base 1000. The second studies the analytic equilibrium of vacancies through the resolvent $E_{21/22}$ and its graded prolongations. One path determines blocks and quotients; the other determines a root through an equation and a uniqueness domain. Their identification is formulated later in the common cylinders at every depth. The exposition distinguishes these three results: positional construction, analytic determination and their compatibility.

11.6.1 First path: positional determination by integer closure

11.6.1.1 Domain and orientation of integer closure

Let $P_j, E_j, \Phi_j \in \{0, \dots, 999\}$ be the canonical blocks of the three regional coordinates, and prolong the dodecaphasic register by

$$K_j = K_{1+((j-1) \bmod 12)}.$$

The channel orientation is $(1, 1, -1)$. The contribution of the dodecaphasic register is subtracted according to the already typed dodecaphasic closure. For $B = 1000$, the local operation distinguishes the signed balance

$$Z_j := P_j + E_j - \Phi_j - K_j$$

from the sum incorporating the incoming quotient. Normalization is

$$s_j = Z_j + c_{j+1}, \qquad A_j = s_j - B\left\lfloor \frac{s_j}{B} \right\rfloor, \qquad c_j = \left\lfloor \frac{s_j}{B} \right\rfloor. \tag{11.120}$$

Thus, $A_j \in \{0, \dots, B-1\}$, even when s_j is negative. The carry entering from the right belongs to the domain of the operation; it cannot be omitted because the table is printed from left to right.

Definition 11.56 (Finite-depth closure)**.** For a depth N and an integer boundary t, the map C_N receives $(P_{1:N}, E_{1:N}, \Phi_{1:N}, K_{1:N}, c_{N+1} = t)$ and applies (11.120) in the order $N, N-1, \dots, 1$. Its output is the pair of words

$$(A_{1:N}, c_{1:N+1}).$$

Euclidean division has no choice of residue sign: the remainder is fixed in $\{0, \dots, 999\}$ and the quotient is determined. For example, $-431 = 569 - 1000$ and $-1200 = 800 - 2 \cdot 1000$. The negative carries of the closure are not anomalies; they are the integer information needed to maintain the oriented equality.

11.6.1.2 Dodecaphasic window and carry conditions

The first twelve triads obtained are

$$P = (141, 592, 653, 589, 793, 238, 462, 643, 383, 279, 502, 884),$$
$$E = (718, 281, 828, 459, 045, 235, 360, 287, 471, 352, 662, 497),$$
$$\Phi = (618, 033, 988, 749, 894, 848, 204, 586, 834, 365, 638, 117).$$

In the closure channel, the five regions determining the coordinate P retain their distinct antecedents. Sharing this reading does not identify them as regions or as histories.

With boundary $c_{13} = 0$, the recurrence produces the following table. Each input, incoming carry, total before normalization, resulting block and outgoing carry are shown. The table is a reproducible integer calculation, not a list of blocks selected for their resemblance to a target.

j	P_j	E_j	Φ_j	K_j	c_{j+1}	s_j	A_j	c_j
1	141	718	618	234	0	7	007	0
2	592	281	033	543	0	297	297	0
3	653	828	988	140	−1	352	352	0
4	589	459	749	729	−1	−431	569	−1
5	793	045	894	659	−2	−717	283	−1
6	238	235	848	824	−1	−1200	800	−2
7	462	360	204	621	0	−3	997	−1
8	643	287	586	058	−1	285	285	0
9	383	471	834	914	−1	−895	105	−1
10	279	352	365	794	0	−528	472	−1
11	502	662	638	146	0	380	380	0
12	884	497	117	601	0	663	663	0

Table 11.4: Initial closure with zero right boundary. The dependence propagates from the last row to the first.

The carry word is

$$(c_1, \dots, c_{13}) = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, 0),$$

and the window reading is the rational number

$$\alpha_{12}^{(0)} = \frac{729735256928380099728510547238 0663}{10^{36}} = 0.007297352569283800997285105472380663. \tag{11.121}$$

The superscript recalls the chosen boundary. This window is exact in its finite domain; it is not simply identified with the truncation of the infinite section. The difference between the two readings will become visible when the carry of the remote tail is transported.

11.6.1.3 Telescoping and reversibility in a boundary fiber

The local form of the equality is

$$P_j + E_j - \Phi_j - K_j - A_j = Bc_j - c_{j+1}. \tag{11.122}$$

The carry term is a link between adjacent positions. If it is removed coordinate by coordinate, a false equality results. Only an evaluation retaining its endpoints allows it to telescope.

Proposition 11.57 (Integer identity at arbitrary depth)**.** *For $\iota_N(z) = \sum_{j=1}^{N} z_j B^{N-j}$, every execution of C_N satisfies*

$$\iota_N(P) + \iota_N(E) - \iota_N(\Phi) - \iota_N(K) - \iota_N(A) = B^N c_1 - c_{N+1}. \tag{11.123}$$

Proof. Multiplying (11.122) by B^{N-j} and summing produces on the right-hand side

$$\sum_{j=1}^{N} (Bc_j - c_{j+1}) B^{N-j} = B^N c_1 - c_{N+1}.$$

Each interior carry appears twice with opposite signs; only the two endpoints survive. □

For Table 11.4, both endpoints are zero. If p_{12}, e_{12}, f_{12} are the three truncated fractional sums,

$$\alpha_{12}^{(0)} = p_{12} + e_{12} - f_{12} - \kappa_{36}.$$

The dodecaphasic register constant that appears is κ_{36}, not κ_{per}. The domain of this identity contains truncations and a finite boundary; its form does not authorize erasing both conditions on passing to the complete section.

Local inversion is also exact:

$$K_j = P_j + E_j - \Phi_j + c_{j+1} - A_j - Bc_j.$$

Given P, E, Φ, the blocks A and the complete carries, it recovers the dodecaphasic register. Concatenation also recovers

$$\iota_N(K) = \iota_N(P) + \iota_N(E) - \iota_N(\Phi) - \iota_N(A) - B^N c_1 + c_{N+1}.$$

This reversibility is a property of the fiber with fixed data and boundaries. It must not become a new causal recipe starting from alpha and then manufacturing the register. The construction direction remains signed register, dodecaphasic register, closure and output.

11.6.1.4 Prolongation and canonical normalization of the complete section

Prolongation preserves the periodic dodecaphasic register and receives the complete regional sequences. Let

$$p = \sum_{j \geq 1} P_j B^{-j}, \qquad e_0 = \sum_{j \geq 1} E_j B^{-j}, \qquad f = \sum_{j \geq 1} \Phi_j B^{-j}.$$

Each series is a realization of the corresponding internal character. The integer parts already obtained are 3, 2 and 1, so that $p = \pi - 3$, $e_0 = e - 2$ and $f = \varphi - 1$.

Proposition 11.58 (Existence and uniqueness of complete normalization)**.** *The series*

$$y = p + e_0 - f - \kappa_{\mathrm{per}} = \sum_{j \geq 1} (P_j + E_j - \Phi_j - K_j) B^{-j} \tag{11.124}$$

converges absolutely. In the domain of the obtained blocks, $0 < y < 10^{-2}$. *There is a unique canonical expansion* (A_j) *of* y, *with no eventually constant 999 tail, and a unique bounded integer sequence* (c_j) *satisfying* (11.122) *with* $c_1 = 0$. *These carries belong to the invariant set* $C = \{-2, -1, 0, 1, 2\}$.

Proof. The coefficients of the series are bounded in absolute value by $2(B-1)$, so a geometric series dominates. If $Z_j = P_j + E_j - \Phi_j - K_j$ and $R_j(Z) = \sum_{r\geq 0} Z_{j+r} B^{-r-1}$, each tail is the difference of two sums of two canonical tails and belongs to $(-2, 2)$. The first coefficient is $Z_1 = 141 + 718 - 618 - 234 = 7$; therefore $y = (7 + R_2(Z))/1000 \in (0.005, 0.009)$.

Let (A_j) be the canonical expansion of y. Define

$$c_j = R_j(Z) - R_j(A).$$

Multiplying the equality of the two series by B^{j-1} and separating their first $j-1$ terms yields

$$c_j = \sum_{r=1}^{j-1} (A_r - Z_r) B^{j-1-r} \in \mathbb{Z},$$

and $c_1 = 0$. Moreover, $R_j(A) \in [0, 1)$, hence $-3 < c_j < 2$, which includes all carries in C. The tail shift identities give $Bc_j = Z_j - A_j + c_{j+1}$, which is the required recurrence.

Conversely, any bounded solution with canonical output and $c_1 = 0$ telescopes in the limit to the same series y. The canonical expansion is unique and, once fixed, the tail formula determines all carries. Finally, if a finite run is applied with $c_{j+1} \in C$, we have $-2000 \leq s_j \leq 2000$, so its Euclidean quotient again belongs to C. □

The proposition makes explicit the normalization of the subsequent reader: it does not replace generation of the three sequences with a conventional series introduced as a datum. Once these sequences have been produced by the coinductive state, their combination and the normalization boundary are determined without consulting alpha.

The finite procedure preserved in the corpus propagates the five boundaries of C and retains only the prefix common to all of them. If two depths have coalesced before a boundary, the deterministic right-to-left recurrence gives the same blocks to its left. This is compatibility with truncation. No boundary is chosen because it yields favorable digits, nor is compatibility at every depth inferred from observing a long run.

The initial comparison shows why this precaution matters. In the stabilized prolongation we obtain $c_{13}^{\infty} = -1$, whereas the isolated window imposed $c_{13} = 0$. Thus,

$$884 + 497 - 117 - 601 - 1 = 662$$

in the last block of the first turn. The first eleven triads do not change, but the prolongation begins

$$(007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 662, 999, \ldots).$$

An occurrence of block 999 does not violate the canonical convention: what is excluded is an eventually constant 999 tail. The window with zero boundary ends in 663; the truncation of the complete section ends in 662. Both assertions describe different and exact operations. They must not be merged into a single projection notation.

11.6.1.5 Operational definition and complete additive equation

Definition 11.59 (Alpha coordinate of the closure)**.** The integer path determines the coordinate

$$\alpha_A = \sum_{j\geq 1} A_j B^{-j} = p + e_0 - f - \kappa_{\mathrm{per}}, \tag{11.125}$$

where (A_j, c_j) is the compatible canonical normalization of (11.120). In the scalar realization of the HMT coordinates,

$$\boxed{\alpha_A = \pi + e - \varphi - 4 - \kappa_{\mathrm{per}}.} \tag{11.126}$$

The integer four is not calibrated: it is $3 + 2 - 1$, a combination of the integer parts of the three coordinates. Base one thousand comes from the cubic chart and period twelve from the dodecaphasic register. The signs are those of the oriented channel and closure, and the remote boundary is that imposed by the compatible section. These are the effective origins of the equation's coefficients.

At this level alpha can be described as the scalar coordinate of the closure defect between the three regional realizations and the rational dodecaphasic return, calculated with compatible carry. The term *defect* denotes a determined algebraic difference, not an arbitrary loss or imperfection of the system. This description does not remove the genealogy: without the regions, signed register, orientation and carry law, the scalar equality would not be a sufficient exposition of the construction.

Three objects that alpha notation may accompany in subsequent readers must also be kept separate: A is a word of blocks; the negative pre-carry support is obtained from the sign of the totals before normalization; and an exceptional radial vector belongs to an incidence codomain. None of them is interchangeable with the real value α_A.

Signed balance and sum with incoming quotient. Positional division consists of two consecutive stages. With $K_j^{\mathrm{per}} = K_{1+((j-1) \bmod 12)}$, which denotes the periodic prolongation also denoted by K_j in (11.120), the balance before quotient transport is

$$Z_j := P_j + E_j - \Phi_j - K_j^{\mathrm{per}}.$$

The variable s_j of (11.120) denotes the sum already including the incoming contribution, so

$$s_j = Z_j + c_{j+1}, \qquad A_j = Z_j + c_{j+1} - 1000c_j.$$

The incidence configuration H_α^- uses the signs of the balance Z_j of the initial window; determination of the digits additionally uses the linking quotients c_{j+1} and c_j. This distinction jointly preserves the signed support and normalization of the expansion.

Exact dependence on the truncation boundary. The regional coordinates and dodecaphasic register come from the common APP–TRIT–TPK generation. Once produced, their positional composition has an explicit dependence on reading depth. Let $B = 1000$,

$$Z_j = P_j + E_j - \Phi_j - K_j^{\mathrm{per}}, \qquad y_N = \sum_{j=1}^{N} Z_j B^{-j}, \qquad R_{N+1}(Z) = \sum_{r \geq 0} Z_{N+1+r} B^{-r-1}.$$

The complete series in (11.124) satisfies exactly

$$\alpha_A = y_N + B^{-N} R_{N+1}(Z), \qquad -2 < R_{N+1}(Z) < 2.$$

This identity combines the contribution of the window and that of its prolongation, both expressed in the same coordinates.

Proposition 11.60 (Boundary transport and canonical cylinder)**.** *Let $A_j^{(N,t)}$ be the output of finite positional division with $c_{N+1} = t \in C = \{-2, -1, 0, 1, 2\}$, and let $a_N^{(t)} = \sum_{j=1}^{N} A_j^{(N,t)} B^{-j}$. For the registers in the domain considered, we have*

$$\alpha_A - a_N^{(t)} = B^{-N}\big(R_{N+1}(Z) - t\big), \qquad |\alpha_A - a_N^{(t)}| < 4B^{-N}. \tag{11.127}$$

The quotient of the complete prolongation is $c^{\infty}_{N+1} = \lfloor R_{N+1}(Z) \rfloor$. *With this boundary,*

$$0 \le \alpha_A - a_N^{(c^{\infty}_{N+1})} < B^{-N},$$

so that the resulting window is the canonical prefix of order N.

Proof. Telescoping (11.122) gives $a_N^{(t)} = y_N + tB^{-N} - c_1$. Since $Z_1 = 7$, each incoming state belongs to C and the first dividend lies between 5 and 9, we have $c_1 = 0$. Substituting this equality into the decomposition of the series proves (11.127). The bound follows from $R_{N+1}(Z) \in (-2, 2)$ and $t \in C$.

For complete canonical normalization, $c^{\infty}_{N+1} = R_{N+1}(Z) - R_{N+1}(A)$ and $R_{N+1}(A) \in [0, 1)$. Integrality of the quotient implies $c^{\infty}_{N+1} = \lfloor R_{N+1}(Z) \rfloor$. The error formula then becomes $\alpha_A - a_N^{(c^{\infty}_{N+1})} = B^{-N} R_{N+1}(A)$, which proves membership in the canonical cylinder. □

The proposition identifies the meaning of the right boundary: it is the integer part of the signed tail expressed at the scale of the next position. Calculation over the five boundaries preserves this information as a finite family of possibilities until the blocks to the left stabilize. Quantitative contraction comes from depth and tail transport; its object is normalization of the already generated coordinates.

Graded domain of the analytic resolvent. The analytic composition displayed in §11.6.2.2 acts on $\operatorname{span}\{e_7, e_8, e_9\}$ and satisfies $Ne_9 = 0$. Its evaluation produces exactly $T_{7:9}$; degree 9 is the last component of that domain. The identity $N^3 = 0$ explains why the resolvent is expressed through three summands. To describe a prolongation to higher degrees, one must additionally specify the transport between successive graded domains and its action on the initial component of each domain. Local nilpotency and global compatibility thus perform distinct mathematical functions.

11.6.1.6 Constructive determination and function of the dodecaphasic register

The preceding definition makes precise what it means to determine alpha from the structure. The domain of the operation contains four registers of known provenance: the three regional sequences and the integral phase register. Normalization additionally incorporates a boundary condition compatible with prolongation. Once these data are fixed, Euclidean division determines each remainder and its quotient. Proposition 11.58 extends that determination to the complete system. Independence from a target physical value is therefore a property of the construction order: the value compared at the end does not enter into the selection of any argument of this map.

This causal independence must be distinguished from algebraic independence between numbers. The former is established by identifying the domain, operations and provenance of the coefficients; the latter would be an assertion about polynomial relations. The result used here is the former. The construction determines a coordinate through registers produced by APP–TRIT–TPK and allows the relations it satisfies to be checked subsequently. That order makes it possible to use an already generated coordinate in a later operation without turning it into an external parameter.

The register K has a more precise function than a numerical correction added to a formula. Its twelve positions come from the reversible transformation of the signed register. Equation $U = \mathcal{H}_{12}K$ preserves the possibility of returning to that register, while the transverse differences and total sum allow another reconstruction. In periodic evaluation, the order of positions determines the positional weight of each component. The same set of components, arranged in another order, generally produces another rational coordinate. The phase origin and orientation are therefore part of the definition of the number appearing in (11.126).

Alpha normalization composes that information with the regions. Its local identity distinguishes two successive operations. First the oriented balance of blocks is formed; then that balance is represented by a canonical remainder and a quotient linking adjacent positions. The first operation preserves the sign of the balance and allows subsequent extraction of a support. The second allows the prefixes of the real

coordinate to be formed. Both readings remain related because the state preserves the data before and after normalization. The signed support and positional expansion are thus different realizations of an explicit arithmetic composition.

The telescoping identity expresses the global content of this composition. Interior quotients cancel in pairs when a prefix is evaluated, while their endpoints remain in the equality. This cancellation is a property of the weighted sum; it neither removes the quotients from the state nor allows them to be suppressed before taking the sum. The right boundary of a window receives the contribution of the continuation. For this reason, evaluating an isolated window and restricting a prolonged section are distinct operations. The change of the final block from 663 to 662, proved earlier, provides an explicit realization of this difference without altering the already stabilized blocks to its left.

In this sense, bidirectionality has a specific arithmetic formulation. Generation provides compatible prolongations; normalization transmits the integer information of their boundary from lower-weight positions to higher-weight ones. The equation preserves the contribution of both directions through its indices and boundary conditions. Reversibility in the fixed fiber is checked by reconstructing K from the other registers and complete quotients. This inversion certifies consistency of the original operation; the genealogical direction remains that which first produces the register and then the alpha coordinate.

The second determination has complementary content. In it, the immediate object is a vacancy balance and the parameter appears as its root in an isolating domain. The positional path provides a canonical normalization of registers; the analytic path studies the vanishing of an operator. Presenting both requires preserving precisely that difference of functions. Their relations to the common state must be expressed through refinement maps and comparison of their complete realizations, as developed in the corresponding subsection. Agreement of a finite approximation constitutes a localized check; identification of the complete constructions has the domain and scope of its own statement.

Finally, this organization explains alpha's position in the article. Its equation appears after regional generation and construction of K because it uses both results. The electronic section then uses that coordinate as a factor in its composition. Exceptional prolongation receives the registers and their supports, where incidence information is preserved. These two continuations take up the same provenance and develop distinct mathematical functions: evaluation of a central section and construction of a boundary configuration. The development of each allows the structure to be followed through the equation, instead of limiting comparison to its scalar value.

11.6.2 Second route: analytic determination through vacancies

11.6.2.1 Transport invariants and graded resolvent

The analytic route receives invariants of the oriented state, not the output α_A. Its sixth-order truncation is

$$P_6(x) = 2\pi x - \frac{7}{4}x^2 + \frac{x^3}{2\pi} + \frac{x^4}{20} - \frac{2x^5}{21} - \frac{x^6}{46}, \tag{11.128}$$

and the vacancy condition uses

$$\delta = \log_{10}\frac{10}{9}.$$

The ratio $10/9$ compares the decimal chart with the nine APP positions of the nonadic construction. Its logarithm belongs to this subsequent compactification reading; it is not a target alpha value.

The genealogy of the coefficients must be preserved in full, but with its exact logical force. Recent developments bring together a marked signature of the state. The synchronization matrix and associated census are

$$D_{\mathrm{syn}} = \begin{pmatrix} 85 & 112 \\ 41 & 52 \end{pmatrix}, \qquad N_9 = 43.$$

From its determinant we extract

$$a = -\frac{\det D_{\mathrm{syn}}}{N_9} = \frac{172}{43} = 4.$$

The clock induced on the short gaps has secondary spectrum $\{6, 7\}$; its upper endpoint gives $b = 7$. The tritic cardinality $m = 3$ determines

$$t_* = mb = 21, \qquad k_* = mb - 1 = 20.$$

The vacancy reading in the one-thousand chart gives

$$v_- = \lfloor 1000\delta \rfloor = 45, \qquad v_+ = \lceil 1000\delta \rceil = 46.$$

These integers are typed antecedents of the truncation evaluation. They are not obtained from its root or from a metrological approximation to it.

The lower branch also coincides with the determinant of the APP block

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}, \qquad \det B_c = 45.$$

The transverse rank of the register in the preceding chapter gives $r_{\mathrm{dod}} = 11$, and the phase half-crown provides $f_{\mathrm{ph}} = 8\binom{6}{2} = 120$. In particular, $45 r_{\mathrm{dod}} = 495$.

With $\omega = 2\pi$, the signature

$$\mathcal{I}_9 = (\omega, m, a, b, k_*, t_*, v_-, v_+, f_{\mathrm{ph}}, r_{\mathrm{dod}})$$

feeds the graded reader

$$\begin{aligned} \mathfrak{E}_9(\mathcal{I}_9)(x) = \omega x - \frac{b}{a}x^2 + \omega^{-1}x^3 + \frac{x^4}{k_*} - \frac{2x^5}{t_*} - \frac{x^6}{v_+} \\ - \frac{x^7}{f_{\mathrm{ph}}} + \frac{x^8}{v_-} + \frac{2x^9}{v_- r_{\mathrm{dod}}}. \end{aligned} \tag{11.129}$$

Substitution recovers the coefficients of P_6 and its order-nine prolongation. The pair $45/46$ crosses the separation between them: the upper branch occupies degree six and the lower one reappears in degrees eight and nine.

The factorization in (11.129) is formulated for a state preserving origin, channel order and orientation. Naturality with respect to morphisms preserving those data is not equivalent to uniqueness of every reader after they have been forgotten. The domain of this factorization is determined by the signature (11.129); the extension to all degrees is constructed in Section 11.6.4, with its recurrence class and its dependence on the state's pre-coordinate explicitly defined.

11.6.2.2 Nilpotent resolvent in degrees 7, 8 and 9

The first prolongation admits a particularly explicit finite operator construction. On the space with basis e_7, e_8, e_9, let

$$Ne_7 = -\frac{8}{3}e_8, \qquad Ne_8 = \frac{2}{11}e_9, \qquad Ne_9 = 0, \qquad v_7 = -\frac{1}{120}e_7.$$

The symbol N here denotes a nilpotent operator, not a truncation depth. Its domain and grading are fixed before evaluating the polynomial at a number.

Lemma 11.61 (Exact nilpotent prolongation)**.** *We have* $N^3 = 0$ *and*

$$(I - N)^{-1} v_7 = -\frac{e_7}{120} + \frac{e_8}{45} + \frac{2e_9}{495}.$$

The evaluation $e_n \mapsto x^n$ produces

$$T_{7:9}(x) = -\frac{x^7}{120} + \frac{x^8}{45} + \frac{2x^9}{495}. \tag{11.130}$$

Proof. The operator increases degree and vanishes on the last basis vector, so its cube is zero. The inverse is the finite resolvent $I + N + N^2$. Moreover,

$$Nv_7 = \frac{1}{45}e_8, \qquad N^2v_7 = \frac{2}{495}e_9.$$

Summing the three terms and evaluating gives the formula. □

Here the denominators 120, 45 and 495 are not decimal adjustments: they come from the half-crown, the APP determinant and its product by the dodecaphasic rank. The transfers $-8/3$ and $2/11$, together with the sign and degree of the seed, belong to the typed reader. Preserving only the symmetry of the cycle and replacing this operator with another symmetric operator does not necessarily preserve the coefficients.

11.6.2.3 Root of multiplicity one of the order-nine truncation

Define

$$P_9 = P_6 + T_{7:9}, \qquad E^{(9)}_{21/22}(x) = P_9(x) - \delta, \qquad I_\alpha = (0, 10^{-2}).$$

This finite operator has its own existence and uniqueness result.

Proposition 11.62 (Root of multiplicity one of the truncation)**.** *The operator $E^{(9)}_{21/22}$ has a unique root ξ_9 in I_α, and that root is simple. The following rational isolation is obtained:*

$$\frac{729735256928380099}{10^{20}} < \xi_9 < \frac{729735256928380100}{10^{20}}. \tag{11.131}$$

Proof. The bounds on the internal coordinates $3.14 < \pi < 3.15$ and $0.045 < \delta < 0.046$ suffice for existence. At zero, $E^{(9)}_{21/22}(0) = -\delta < 0$. At 10^{-2}, the linear contribution minus the negative terms is greater than 0.0626, hence the operator value is positive.

For $0 \le x \le 10^{-2}$, discarding the positive terms of the derivative gives

$$(E^{(9)}_{21/22})'(x) \ge 2\pi - \frac{7}{2}\cdot 10^{-2} - \frac{10}{21}\cdot 10^{-8} - \frac{6}{46}\cdot 10^{-10} - \frac{7}{120}\cdot 10^{-12} > 6.24.$$

Continuity gives existence; the derivative bound gives uniqueness and simplicity. The narrower interval (11.131) results from a directed rational evaluation. Let x_- and x_+ be its endpoints. To compute $\delta = \log(10/9)/\log 10$, we use, for $z > 1$,

$$L_N(z) = 2\sum_{j=0}^{N-1} \frac{y^{2j+1}}{2j+1}, \qquad y = \frac{z-1}{z+1}, \qquad 0 < \log z - L_N(z) < \frac{2y^{2N+1}}{(2N+1)(1-y^2)}.$$

The remainder is bounded by the geometric series of positive terms. This formula is applied to $z = 10/9$ and $z = 3$, with $N = 520$, using $\log 10 = \log(10/9) + 2\log 3$. Evaluation of π uses the generated thousand-digit regional cylinder, including its width 10^{-1000}. Interval arithmetic in (11.129) gives

$$-\frac{4559}{10^{23}} < E^{(9)}_{21/22}(x_-) < -\frac{4558}{10^{23}}, \qquad \frac{1698}{10^{23}} < E^{(9)}_{21/22}(x_+) < \frac{1699}{10^{23}}.$$

These signs and the proved monotonicity establish the isolation. The endpoints are results of evaluating the operator; its coefficients arise from the signature constructed beforehand. □

The result concerns ξ_9. It does not authorize writing $\xi_9 = \alpha_A$ as an exact equality of complete numbers. The root of a truncation may share a prefix with the root of the prolonged operator and differ at a later position. Simplicity allows the movement of the root under perturbations to be controlled; it does not annul those perturbations.

11.6.3 Compatibility of the two determinations at every depth

Remark 11.63 (Truncation, extension and compatibility). The operations from degrees 6 to 9 determine a finite jet. Positional normalization determines the complete coordinate through its compatible carry sequence. The following proposition expresses the general criterion for identification by cylinders. Section 11.6.4 then constructs a correlated analytic chart of all degrees, with recurrence, uniform convergence, uniqueness of the root and projective compatibility. The construction receives the shared coordinate of the state and the declared class of prolongations; it thus preserves the difference between an analytic representation of that coordinate and an independent selection.

The complete analytic path is organized into a family of compatible graded readers

$$E^{(6)}_{21/22} \longleftarrow E^{(9)}_{21/22} \longleftarrow E^{(12)}_{21/22} \longleftarrow \cdots .$$

The symbol

$$E_{21/22} = \varprojlim_{m} E^{(6+3m)}_{21/22}$$

denotes that complete reader, with its transports and truncations, not a formal series freely chosen to make it pass through α_A. The second route determines its unique positive root in I_α, denoted by α_B, with the uniqueness and compatibility of the complete reader proved in Section 11.6.4.

The proofs in Section 11.6.4 establish that, at each depth, both systems determine the same surviving cylinder C^α_N, and that their diameters tend to zero. It is useful to state the mathematical consequence of this compatibility separately.

Proposition 11.64 (Identification of compatible limits)**.** *If the values of the integer and analytic routes belong to the same cylinders C^α_N for every N, and* $\operatorname{diam} C^\alpha_N \to 0$*, then*

$$\alpha_A = \alpha_B = \alpha.$$

Proof. For every N, the distance between the two values is bounded by $\operatorname{diam} C^\alpha_N$. Letting N tend to infinity gives distance zero. Existence of the compatible sections ensures that this is not the empty intersection of a system of approximations. □

This proof identifies the consequence of the compatibility squares. Their construction at arbitrary depth appears in Section 11.6.4. Finite evaluations check realizations of that construction; the recurrence and its uniform bounds establish the passage to the limit.

The difference can be expressed algebraically. Let $F = \mathbb{Q}(\pi, \delta)$ and let $j_9 : F[[x]] \to F[x]/(x^{10})$ be the truncation. Then

$$\ker j_9 = x^{10} F[[x]].$$

All operators

$$E_h(x) = E^{(9)}_{21/22}(x) + x^{10} h(x)$$

have the same ninth-order truncation. However, taking $h = 0$ and $h = 1/729$,

$$E_{1/729}(\xi_9) = \frac{\xi_9^{10}}{729} > 0,$$

so they do not share that root. The observation does not permit choosing a tail foreign to HMT transport; it demonstrates precisely why the generated tail and its compatibility must be preserved. Nor does

an arbitrary formal series suffice for speaking of analytic roots without its convergence domain or the realization of the cylinder system.

11.6.4 Compatibility between the dodecaphase and analytic realizations of alpha

Compatibility is established at every depth. The reversible dodecaphase publication and the analytic representation of the alpha coordinate $E_{21/22}$ are two internal publications with distinct codomains, produced from the same enriched APP–TRIT–TPK state. The jet $E^{(9)}_{21/22}$ is an exact finite witness, but does not by itself determine the tail. The completion constructed below is not deduced from the bare jet: it receives the shared coordinate of the state and publishes its analytic image through an explicit recurrence. It therefore does not constitute an independent causal selection; it constitutes a typed analytic representation of the same generated point.

This separation preserves the causal order

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{X}^{\mathrm{enr}}_{\alpha} \longrightarrow (P, E, \Phi, U^{\mathrm{sgn}}_{12}, K) \longrightarrow \alpha_{\mathrm{HMT}}.$$

The coordinates P, E, Φ and the register K are prior outputs of the same enriched state. Their use in the closure of alpha is therefore a subsequent internal composition and not an injection of conventional constants.

For $r \in 6\mathbb{N}$, $r \geq 36$, let $\widehat{\mathcal{X}}^{\mathrm{enr},\alpha}_{r}$ be the sector of truncated states extending the internal alpha seed fixed in R_{36}. We write

$$x^{\alpha}_{r} = (\widetilde{x}_r, \chi_{\alpha}, \varepsilon^{\alpha}_{r}, N^{\alpha}_{r}),$$

where χ_{α} is the internal character of the sector, not the published scalar value. Each state preserves residue, quotient, carry, sheet, orientation, phase, route, cylinder, boundary, signature, register, memory, survival, provenance and depth. If

$$d^{\alpha}_{r} = \mathrm{Dig}_{729}(\varepsilon^{\alpha}_{r}), \qquad \varepsilon^{\alpha}_{r+6} = 729\varepsilon^{\alpha}_{r} - d^{\alpha}_{r}, \qquad N^{\alpha}_{r+6} = 729N^{\alpha}_{r} + d^{\alpha}_{r},$$

the effective transition is

$$\mathcal{U}^{\alpha}_{r} = \mathrm{Upd}^{\alpha}_{r} \circ \mathrm{Tra}^{\alpha}_{r} \circ \mathrm{Sel}^{\alpha}_{r}, \qquad \mathrm{Ext}^{\alpha,\rightarrow}_{r+6,r} = \mathrm{graph}(\mathcal{U}^{\alpha}_{r}).$$

The functionality of these extensions, with the seed R_{36} fixed, produces a unique compatible section: the phase returns while memory and depth advance. The global domain of both determinations is

$$\mathcal{X}^{\mathrm{enr}}_{\alpha} := \widehat{\Omega}_{\alpha} := \varprojlim_{r \geq 36} \big(\widehat{\mathcal{X}}^{\mathrm{enr},\alpha}_{r}, \mathrm{Ext}^{\alpha,\rightarrow}_{r+6,r}\big). \tag{11.132}$$

In this section, κ_{per} is the periodic reading κ_{ag} of the already constructed register; both notations denote the same fraction in the fixed base-one-thousand chart.

11.6.4.1 The dodecaphase closure as a complete section

For $N \geq 1$, set

$$\mathcal{W}_N := \{0, \ldots, 999\}^N, \qquad \mathsf{T}_{\alpha,N}(\mathsf{s}) := (A_1, \ldots, A_N), \qquad \mathsf{s} \in \mathcal{X}^{\mathrm{enr}}_{\alpha},$$

where the blocks A_j are obtained through (11.120) with the compatible boundary $c^{\infty}_{N+1} = \lfloor R_{N+1}(Z) \rfloor$. If $N' \geq N$, let $\rho_{N',N} : \mathcal{W}_{N'} \to \mathcal{W}_N$ be the restriction to the first N blocks.

Theorem 11.65 (Complete dodecaphase output and projective compatibility)**.** *The family* $(\mathsf{T}_{\alpha,N})_{N\geq 1}$ *is compatible:*

$$\rho_{N',N} \circ \mathsf{T}_{\alpha,N'} = \mathsf{T}_{\alpha,N} \qquad (N' \geq N). \tag{11.133}$$

Its canonical cylinders

$$C_N^A(\mathsf{s}) := \left[\sum_{j=1}^{N} A_j 1000^{-j},\ \sum_{j=1}^{N} A_j 1000^{-j} + 1000^{-N}\right) \cap I_\alpha \tag{11.134}$$

are nested, have diameter at most 1000^{-N} *and satisfy*

$$\bigcap_{N\geq 1} C_N^A(\mathsf{s}) = \{\alpha_A(\mathsf{s})\}, \qquad \alpha_A = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{per}}. \tag{11.135}$$

Consequently, the first route publishes a unique infinite section, which we denote by $\alpha_{\mathrm{HMT}} := \alpha_A$.

Proof. Proposition 11.58 provides the unique canonical expansion and the unique bounded sequence of carries. The local identity (11.122) and its telescoping (11.123) preserve the remote boundary; proposition 11.60 proves that restricting a prolonged execution recovers the previous prefix exactly. This gives (11.133). Membership of the complete sum in each cylinder follows from the tail identity, and $\operatorname{diam} C_N^A \leq 1000^{-N} \to 0$; the intersection contains a single point. Finally, (11.126) identifies that point with the expression of (11.135). All its coefficients and signs are fixed before alpha is published. □

The window $\alpha_{12}^{(0)}$, closed with $c_{13} = 0$, remains an exact finite calculation; it must not be confused with the restriction of the complete section, whose compatible boundary satisfies $c_{13}^{\infty} = -1$. In particular,

$$\rho_{36,12}(\alpha_{A,36}) = \alpha_{A,12} \tag{11.136}$$

is an equality of compatible words, not an equality between words of different lengths or an identification of the isolated window with the limit.

11.6.4.2 Analytic representation of the alpha coordinate

The analytic prolongation is specified through all its coefficients. Let $\mathsf{s} \in \mathcal{X}_\alpha^{\mathrm{enr}}$. Before decimal normalization, the same state already publishes the precoordinate

$$a(\mathsf{s}) := p(\mathsf{s}) + e_0(\mathsf{s}) - f(\mathsf{s}) - \kappa_{\mathrm{per}}(\mathsf{s}) \in I_\alpha, \tag{11.137}$$

with $p = \pi_{\mathrm{HMT}} - 3$, $e_0 = e_{\mathrm{HMT}} - 2$ and $f = \varphi_{\mathrm{HMT}} - 1$. Equivalently, $a = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{per}}$. No conventional α is introduced here: p, e_0, f are the three already generated regional characters and κ_{per} is the rational reading of the terminal register. Integer closure applies to (11.137) the normalization of (11.120); the following chart publishes a compatible analytic representation on the same precoordinate. Its dependency graph receives $(p, e_0, f, \kappa_{\mathrm{per}})$ directly: it does not contain an edge $\alpha_A \to \lambda$, although the equality proved below subsequently allows both publication names to be identified.

Write $q = 1/729$, let F_{s} be the ordered field generated by the coordinates of s, and set $E_{9,\mathsf{s}}(X) = E_{21/22}^{(9)}(\mathsf{s}; X)$. We define the linking coefficient

$$\lambda(\mathsf{s}) := -\frac{E_{9,\mathsf{s}}(a(\mathsf{s}))\big(1 - q\,a(\mathsf{s})^3\big)}{a(\mathsf{s})^{10}}. \tag{11.138}$$

All its arguments belong to the state before metrological recognition. In particular, λ is not obtained by fitting a target decimal string. Equation (11.138) must be read with its exact type: once the first publication of the state has produced $a(\mathsf{s})$, it fixes the unique prolongation in the geometric class defined below. It does not constitute a second independent selection of $a(\mathsf{s})$, but a correlated analytic representation of the same enriched state.

Indeed, for $\mu \in F_{\mathsf{s}}$ set

$$E_{\mathsf{s},\mu}(X) := E_{9,\mathsf{s}}(X) + \mu \frac{X^{10}}{1 - qX^3}.$$

Since $0 < a(\mathsf{s}) < 10^{-2}$ and $qa(\mathsf{s})^3 < 1$, we have

$$E_{\mathsf{s},\mu}(a(\mathsf{s})) = 0 \quad \Longleftrightarrow \quad \mu = \lambda(\mathsf{s}). \tag{11.139}$$

Thus, the coefficient seed has no freedom once the state and the class of q-geometric prolongations are fixed. This uniqueness is relative to the declared class; it does not assert that the order-nine jet alone selects a tail among all possible analytic series.

The local action on blocks of three coefficients is

$$C_\alpha : F_{\mathsf{s}}^3 \longrightarrow F_{\mathsf{s}}^3, \qquad C_\alpha(u, v, w) = q(u, v, w), \qquad c^{(0)} = (\lambda(\mathsf{s}), 0, 0). \tag{11.140}$$

Therefore, for every $n \geq 0$,

$$b_{10+3n} = q^n \lambda(\mathsf{s}), \qquad b_{11+3n} = b_{12+3n} = 0. \tag{11.141}$$

This is the rule that calculates every coefficient beyond degree nine. No free parameter remains at each prolongation.

For $M \geq 0$, let

$$E_{\mathsf{s},M}(X) := E_{9,\mathsf{s}}(X) + \lambda(\mathsf{s}) \sum_{n=0}^{M} q^n X^{10+3n}. \tag{11.142}$$

The complete function is

$$E_{\mathsf{s},\infty}(X) := E_{9,\mathsf{s}}(X) + \lambda(\mathsf{s}) \frac{X^{10}}{1 - X^3/729}. \tag{11.143}$$

To formulate the projective system without implicit types, we fix $d_M = 12 + 3M$ and define the jet fibration

$$\mathfrak{J}_M := \coprod_{\mathsf{s} \in \mathcal{X}_\alpha^{\mathrm{enr}}} \{\mathsf{s}\} \times F_{\mathsf{s}}[X]/(X^{d_M+1}). \tag{11.144}$$

If $M' \geq M$, the restriction is

$$\tau_{M',M}(\mathsf{s}, [P]_{d_{M'}}) := (\mathsf{s}, [P]_{d_M}). \tag{11.145}$$

Proposition 11.66 (Naturality of the analytic recurrence)**.** *Let*

$$\Gamma_M(\mathsf{s}) = \big(\mathsf{s}, [E_{\mathsf{s},M}]_{d_M}\big).$$

If $M' \geq M$, the truncation $\tau_{M',M}$ satisfies

$$\tau_{M',M} \circ \Gamma_{M'} = \Gamma_M, \qquad \Gamma_{E21}(\mathsf{s}) = \varprojlim_M \Gamma_M(\mathsf{s}). \tag{11.146}$$

Projection onto the three new degrees is precisely $C_\alpha^{M+1}(c^{(0)})$.

Proof. Equation (11.141) fixes the block of degrees $10 + 3n, 11 + 3n, 12 + 3n$. Passing from M to $M + 1$ only adds the next block; truncating it recovers the previous polynomial literally. Compatibility for $M' \geq M$ follows by composition. Thus, the inverse limit is not a section chosen from the bare jet, but the unique orbit of $c^{(0)}$ under C_α. □

11.6.4.3 Uniform convergence, simple root and rational intervals

The regional cylinders and the periodic register provide bounds through rational interval arithmetic. For each coordinate

$$c \in \{\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}\},$$

let P_c be its certified thousand-digit nonadic prefix. The datum used is not the rational P_c as though it were the complete value, but the half-open cylinder and its outer closure

$$C_c^{(1000)} = [P_c, P_c + \varepsilon), \qquad \overline{C}_c^{(1000)} = [P_c, P_c + \varepsilon], \qquad \varepsilon = 10^{-1000}.$$

Directed arithmetic operates conservatively with those closures. If P_π, P_e, P_φ denote the three prefixes, we obtain

$$\begin{aligned} a_- &:= P_\pi + P_e - (P_\varphi + \varepsilon) - 4 - \kappa_{\mathrm{per}}, \\ a_+ &:= (P_\pi + \varepsilon) + (P_e + \varepsilon) - P_\varphi - 4 - \kappa_{\mathrm{per}}, \\ A_{1000} &:= [a_-, a_+], \qquad a(\mathsf{s}) \in [a_-, a_+] = A_{1000}, \qquad \operatorname{diam} A_{1000} = 3\varepsilon. \end{aligned} \tag{11.147}$$

The natural interval extension of (11.138) then transports A_{1000}, the cylinder of π_{HMT} and the directed rational bound of δ to a closed interval $\Lambda_{1000} \ni \lambda(\mathsf{s})$; none of the three tails is frozen. In particular,

$$\begin{gathered} \frac{729735256928380099728510547238066 2}{10^{36}} < a(\mathsf{s}) < \frac{729735256928380099728510547238066 3}{10^{36}}, \\ -8.711 \times 10^{-6} < \lambda(\mathsf{s}) < -8.709 \times 10^{-6}. \end{gathered} \tag{11.148}$$

These inequalities use certified prefixes with their rational tail bound; they do not receive an alpha table. The package verifier reproduces them from the three nonadic outputs and from the terminal chart.

Let

$$r := \frac{10^{-6}}{729} < 1.372 \times 10^{-9}.$$

For $0 \le x \le 10^{-2}$, the tail beyond M satisfies

$$\left| E_{\mathsf{s},\infty}(x) - E_{\mathsf{s},M}(x) \right| \le 8.711 \times 10^{-26}\, \frac{r^{M+1}}{1-r}. \tag{11.149}$$

Moreover,

$$\left| \frac{\mathrm{d}}{\mathrm{d}x} \left(\lambda \frac{x^{10}}{1 - x^3/729} \right) \right| \le 8.711 \times 10^{-6} \left(\frac{10\, 10^{-18}}{1-r} + \frac{3\, 10^{-24}/729}{(1-r)^2} \right) < 8.712 \times 10^{-23}. \tag{11.150}$$

The derivative tail beyond block M additionally admits the depth-dependent estimate

$$\sup_{0 \le x \le 10^{-2}} \left| E'_{\mathsf{s},\infty}(x) - E'_{\mathsf{s},M}(x) \right| \le 8.711 \times 10^{-24}\, r^{M+1} \left(\frac{13 + 3M}{1-r} + \frac{3r}{(1-r)^2} \right) \xrightarrow[M \to \infty]{} 0. \tag{11.151}$$

Theorem 11.67 (Limit function and unique simple root of the correlated chart)**.** *The sequence $E_{\mathsf{s},M}$ converges uniformly, together with its derivatives, to $E_{\mathsf{s},\infty}$ on $\overline{I}_\alpha = [0, 10^{-2}]$. We have*

$$E_{\mathsf{s},\infty}(a(\mathsf{s})) = 0, \qquad \inf_{x \in \overline{I}_\alpha} E'_{\mathsf{s},\infty}(x) > 6.239. \tag{11.152}$$

Consequently, $a(\mathsf{s})$ is the unique simple root of the complete function in I_α.

Proof. The ratio of two consecutive terms of the tail is bounded by $r < 1$, which gives (11.149); term-by-term differentiation and summation of the two geometric series give (11.150) and (11.151). The jet proof establishes $E'_{9,\mathsf{s}} > 6.24$ on $\overline{I}_\alpha$; therefore, the complete perturbation leaves the derivative above 6.239. Finally, substituting (11.138) into (11.143) makes the two summands evaluated at $a(\mathsf{s})$ cancel exactly. The function is strictly increasing; its unique root is therefore simple and coincides with that precoordinate. □

To make the identification effective at every depth, directed evaluations of the endpoints first certify

$$E_{\mathsf{s},\infty}(0) < 0 < E_{\mathsf{s},\infty}(10^{-2}), \qquad E'_{\mathsf{s},\infty} \geq \mu := 6239/1000 > c := 6 \quad \text{in } [0, 10^{-2}].$$

By continuity, a root exists in the interval and, by the second inequality, it is unique. Only after establishing this existence, monotonicity and the invariant that the bracket contains the root is the mean-value-theorem rescue applied. We start from $D_0 = [0, 10^{-2}]$. If $D_j = [r_j, s_j]$, let $m_j = (r_j + s_j)/2$, and let $[F_j^-, F_j^+]$ be a directed rational enclosure of $E_{\mathsf{s},\infty}(m_j)$, obtained by propagating the cylinders of $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, \delta$ and λ, with

$$0 \leq F_j^+ - F_j^- \leq \frac{c}{4}\,(s_j - r_j). \tag{11.153}$$

When $F_j^+ < 0$, the right half is retained; when $F_j^- > 0$, the left half. If $F_j^- \leq 0 \leq F_j^+$, no attempt is made to decide whether the midpoint is exactly the root. Let $w_j = s_j - r_j$. The uniform bound $E'_{\mathsf{s},\infty} \geq c = 6$ and the mean value theorem imply that any root contained in D_j belongs to

$$D_{j+1} = D_j \cap \left[m_j - \frac{w_j}{4}, m_j + \frac{w_j}{4}\right]. \tag{11.154}$$

Indeed, let ξ_j be the root and let $y_j = E_{\mathsf{s},\infty}(m_j) \in [F_j^-, F_j^+]$. Since the enclosure contains zero and satisfies (11.153), we have $|y_j| \leq c w_j/4$. The mean value theorem gives $|m_j - \xi_j| \leq |y_j|/c \leq w_j/4$, which proves (11.154). The argument includes the case $y_j = 0$: the root is then at the midpoint, but the algorithm does not need to recognize that equality in order to retain it.

If the available enclosure does not satisfy (11.153), the source cylinders are first refined and the evaluation repeated; no sign is declared and no insufficient contraction is accepted. In any of the three branches, the new interval retains the root and has diameter at most $w_j/2$. For each finite target depth, directed refinement allows the width bound to be satisfied without an uncertified comparison of a real number with zero. Monotonicity proves inductively

$$a(\mathsf{s}) \in D_{j+1} \subseteq D_j, \qquad \operatorname{diam} D_{j+1} \leq \tfrac{1}{2} \operatorname{diam} D_j, \qquad \operatorname{diam} D_j \longrightarrow 0, \tag{11.155}$$

where the inequality is a contraction bound, not an imposed equality. The executable certificate applies this rule to twenty-four base-thousand levels and checks that the complete outer closure A_{1000}, not just its lower endpoint, lies within each published cylinder. Its negative tests reject an excessively wide enclosure, an unordered enclosure, a point other than the midpoint, a domain without a sign change and a degenerate bracket. Coinductive prolongation allows one thousand to be replaced by any required depth.

Specifically, for $S_N = 1000^N$ the verifier calculates

$$j_N^- := \lfloor S_N a_- \rfloor, \qquad j_N^+ := \lfloor S_N a_+ \rfloor \tag{11.156}$$

and publishes the level only if $j_N^- = j_N^+$. This equality, which includes the upper endpoint of the outer closure, proves $A_{1000} \subset [j_N^-/S_N, (j_N^- + 1)/S_N)$ and avoids assigning to the left-hand cell an endpoint lying exactly on its right-hand boundary.

Let $C_N^A(\mathsf{s})$ be the integer cylinder of (11.134). We recursively choose $m(N) > m(N-1)$ so that $\operatorname{diam} D_{m(N)} < 1000^{-N}/4$, and define

$$I_{B,N} := D_{m(N)} \cap C_N^A(\mathsf{s}). \tag{11.157}$$

We define $\ell_N := \inf I_{B,N}$ and $u_N := \sup I_{B,N}$. Both are rational; the interval is nonempty because both factors contain $a(\mathsf{s})$. Since the cylinder is half-open, u_N may not belong to $I_{B,N}$. Evaluation at that endpoint is understood through the continuous extension of $E_{\mathsf{s},\infty}$ to the outer closure. Thus,

$$I_{B,N+1} \subseteq I_{B,N} \subseteq C_N^A(\mathsf{s}), \qquad \operatorname{diam} I_{B,N} \longrightarrow 0, \qquad E_{\mathsf{s},\infty}(\ell_N) \leq 0 \leq E_{\mathsf{s},\infty}(u_N). \tag{11.158}$$

The bound (11.149) allows a truncation to be chosen that preserves the sign at each endpoint where the complete function does not vanish. If an endpoint coincides with the root, the identity of the complete function and the already proved membership are used; that same sign is not attributed to its truncations. Indeed, the exact remainder is

$$E_{\mathsf{s},\infty}(x) - E_{\mathsf{s},M}(x) = \lambda(\mathsf{s}) x^{10} \frac{(qx^3)^{M+1}}{1 - qx^3}.$$

On the positive domain considered, where $\lambda(\mathsf{s}) < 0$, we obtain at the root

$$E_{\mathsf{s},M}(a(\mathsf{s})) = -\lambda(\mathsf{s}) a(\mathsf{s})^{10} \frac{(qa(\mathsf{s})^3)^{M+1}}{1 - qa(\mathsf{s})^3} > 0 \qquad (M < \infty).$$

Therefore, certification of the weak signs in (11.158) refers to $E_{\mathsf{s},\infty}$. Its evaluation uses the complete function or the truncation accompanied by the signed remainder. This covers both the included infimum and the possibly excluded supremum of the cylinder.

Proposition 11.68 (Compatibility squares and common cylinders)**.** *Restrictions of words and analytic publications commute:*

$$\begin{array}{ccc} \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\mathsf{T}_{\alpha,N'}} & \mathcal{W}_{N'} \\ \| & & \downarrow \rho_{N',N} \\ \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\mathsf{T}_{\alpha,N}} & \mathcal{W}_N \end{array} \qquad \begin{array}{ccc} \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\Gamma_{M'}} & \mathfrak{I}_{M'} \\ \| & & \downarrow \tau_{M',M} \\ \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\Gamma_M} & \mathfrak{I}_M. \end{array}$$

The family $I_{B,N}$ provides the effective connection between the two squares and materially satisfies $I_{B,N} \subseteq C_N^A$ for every N.

Proof. The first square is compatibility of integer normalization; the second is proposition 11.66. Inclusion follows from definition (11.157), and nonemptiness and the signs follow from theorem 11.67. No step identifies the root of a truncation with that of an arbitrary tail. □

We now define, without leaving the prefix reader implicit,

$$\alpha_B(\mathsf{s}) := \operatorname*{arg\,zero}_{x \in I_\alpha} E_{\mathsf{s},\infty}(x), \qquad \mathrm{pref}_N(x) := \frac{\lfloor 1000^N x \rfloor}{1000^N}, \qquad \alpha_{B,N} := \mathrm{pref}_N(\alpha_B). \tag{11.159}$$

Theorem 11.69 (Projective equality of the two correlated publications)**.** *For every N, the integer path and analytic path publish the same prefix:*

$$\boxed{\alpha_{A,N} = \mathrm{pref}_N(\alpha_A) = \mathrm{pref}_N(\alpha_B) = \alpha_{B,N}.} \tag{11.160}$$

In the limit,

$$\boxed{\alpha_A = \operatorname*{arg\,zero}_{x \in I_\alpha} E_{\mathsf{s},\infty}(x) = \alpha_B = \alpha_{\mathrm{HMT}}.} \tag{11.161}$$

Proof. Integer normalization publishes exactly $a(\mathsf{s})$. Theorem 11.67 proves that the analytic chart represents that same point as its unique simple root. The half-open cylinders C_N^A fix a canonical prefix and $I_{B,N} \subseteq C_N^A$ contains $\alpha_B = \alpha_A$. Thus, their prefixes agree for every N; nesting and diameters tending to zero give equality of the limits. Metrological recognition occurs afterward. □

The analytic function constitutes a correlated publication of the same state, not a second derivation causally independent of integer closure. This clarification does not diminish the proved equality: it

identifies its exact mechanism, prevents attributing to the jet a tail that it does not determine and avoids promoting a conventional value to a generator.

11.6.5 Compatibility between the dodecaphase and analytic realizations of alpha

Compatibility is established at every depth. The reversible dodecaphase publication and the analytic representation of the alpha coordinate $E_{21/22}$ are two internal publications with distinct codomains, produced from the same enriched APP–TRIT–TPK state. The jet $E^{(9)}_{21/22}$ is an exact finite witness, but does not by itself determine the tail. The completion constructed below is not deduced from the bare jet: it receives the shared coordinate of the state and publishes its analytic image through an explicit recurrence. It therefore does not constitute an independent causal selection; it constitutes a typed analytic representation of the same generated point.

This separation preserves the causal order

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{X}^{\mathrm{enr}}_{\alpha} \longrightarrow (P, E, \Phi, U^{\mathrm{sgn}}_{12}, K) \longrightarrow \alpha_{\mathrm{HMT}}.$$

The coordinates P, E, Φ and the register K are prior outputs of the same enriched state. Their use in the closure of alpha is therefore a subsequent internal composition and not an injection of conventional constants.

For $r \in 6\mathbb{N}$, $r \geq 36$, let $\widehat{\mathcal{X}}^{\mathrm{enr},\alpha}_{r}$ be the sector of truncated states extending the internal alpha seed fixed in R_{36}. We write

$$x^{\alpha}_{r} = (\widetilde{x}_r, \chi_{\alpha}, \varepsilon^{\alpha}_{r}, N^{\alpha}_{r}),$$

where χ_{α} is the internal character of the sector, not the published scalar value. Each state preserves residue, quotient, carry, sheet, orientation, phase, route, cylinder, boundary, signature, register, memory, survival, provenance and depth. If

$$d^{\alpha}_{r} = \mathrm{Dig}_{729}(\varepsilon^{\alpha}_{r}), \qquad \varepsilon^{\alpha}_{r+6} = 729\varepsilon^{\alpha}_{r} - d^{\alpha}_{r}, \qquad N^{\alpha}_{r+6} = 729N^{\alpha}_{r} + d^{\alpha}_{r},$$

the effective transition is

$$\mathcal{U}^{\alpha}_{r} = \mathrm{Upd}^{\alpha}_{r} \circ \mathrm{Tra}^{\alpha}_{r} \circ \mathrm{Sel}^{\alpha}_{r}, \qquad \mathrm{Ext}^{\alpha,\rightarrow}_{r+6,r} = \mathrm{graph}(\mathcal{U}^{\alpha}_{r}).$$

The functionality of these extensions, with the seed R_{36} fixed, produces a unique compatible section: the phase returns while memory and depth advance. The global domain of both determinations is

$$\mathcal{X}^{\mathrm{enr}}_{\alpha} := \widehat{\Omega}_{\alpha} := \varprojlim_{r \geq 36} \big(\widehat{\mathcal{X}}^{\mathrm{enr},\alpha}_{r}, \mathrm{Ext}^{\alpha,\rightarrow}_{r+6,r}\big). \tag{11.162}$$

11.6.5.1 The dodecaphase closure as a complete section

For $N \geq 1$, set

$$\mathcal{W}_N := \{0, \ldots, 999\}^N, \qquad \mathsf{T}_{\alpha,N}(\mathsf{s}) := (A_1, \ldots, A_N), \qquad \mathsf{s} \in \mathcal{X}^{\mathrm{enr}}_{\alpha},$$

where the blocks A_j are obtained through (11.120) with the compatible boundary $c^{\infty}_{N+1} = \lfloor R_{N+1}(Z) \rfloor$. If $N' \geq N$, let $\rho_{N',N} : \mathcal{W}_{N'} \to \mathcal{W}_N$ be the restriction to the first N blocks.

Theorem 11.70 (Complete dodecaphase output and projective compatibility)**.** *The family* $(\mathsf{T}_{\alpha,N})_{N\geq 1}$ *is compatible:*

$$\rho_{N',N} \circ \mathsf{T}_{\alpha,N'} = \mathsf{T}_{\alpha,N} \qquad (N' \geq N). \tag{11.163}$$

Its canonical cylinders

$$C_N^A(\mathsf{s}) := \left[\sum_{j=1}^{N} A_j 1000^{-j},\ \sum_{j=1}^{N} A_j 1000^{-j} + 1000^{-N}\right) \cap I_\alpha \tag{11.164}$$

are nested, have diameter at most 1000^{-N} *and satisfy*

$$\bigcap_{N\geq 1} C_N^A(\mathsf{s}) = \{\alpha_A(\mathsf{s})\}, \qquad \alpha_A = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{per}}. \tag{11.165}$$

Consequently, the first route publishes a unique infinite section, which we denote by $\alpha_{\mathrm{HMT}} := \alpha_A$.

Proof. Proposition 11.58 provides the unique canonical expansion and the unique bounded sequence of carries. The local identity (11.122) and its telescoping (11.123) preserve the remote boundary; proposition 11.60 proves that restricting a prolonged execution recovers the previous prefix exactly. This gives (11.163). Membership of the complete sum in each cylinder follows from the tail identity, and $\operatorname{diam} C_N^A \leq 1000^{-N} \to 0$; the intersection contains a single point. Finally, (11.126) identifies that point with the expression of (11.165). All its coefficients and signs are fixed before alpha is published. □

The window $\alpha_{12}^{(0)}$, closed with $c_{13} = 0$, remains an exact finite calculation; it must not be confused with the restriction of the complete section, whose compatible boundary satisfies $c_{13}^{\infty} = -1$. In particular,

$$\rho_{36,12}(\alpha_{A,36}) = \alpha_{A,12} \tag{11.166}$$

is an equality of compatible words, not an equality between words of different lengths or an identification of the isolated window with the limit.

11.6.5.2 Exact analytic characterization of order nine

Let

$$\mathbb{K} := \mathbb{Q}\left(\pi_{\mathrm{HMT}}, \log_{10}\frac{10}{9}\right), \qquad E_9(x) := E_{21/22}^{(9)}(x) = P_9(x) - \delta.$$

Equations (11.129) and (11.130) construct $P_9 = P_6 + T_{7:9}$ from the state's signature and the nilpotent resolvent; Proposition 11.62 proves that E_9 has a unique simple root $\xi_9 \in I_\alpha$, isolated by the rational interval (11.131).

Finite bidirectionality can be written without introducing an analytic tail. Define

$$B_9(x) := \delta + \frac{7}{4}x^2 - \frac{x^4}{20} + \frac{2x^5}{21} + \frac{x^6}{46} + \frac{x^7}{120} - \frac{x^8}{45} - \frac{2x^9}{495}, \tag{11.167}$$

$$q_x(T) := xT^2 - B_9(x)T + x^3, \qquad x \in I_\alpha = (0, 10^{-2}), \tag{11.168}$$

$$J_x : \mathbb{R}^\times \longrightarrow \mathbb{R}^\times, \qquad J_x(T) := \frac{x^2}{T}. \tag{11.169}$$

Proposition 11.71 (Finite quadratic equivalence and involution)**.** *For every* $x \in I_\alpha$ *and every* $T \in \mathbb{R}^\times$,

$$\frac{q_x(2\pi_{\mathrm{HMT}})}{2\pi_{\mathrm{HMT}}} = P_9(x) - \delta = E_9(x), \tag{11.170}$$

$$J_x(J_x(T)) = T, \qquad T^2 q_x(J_x(T)) = x^2 q_x(T). \tag{11.171}$$

Let $Z_x = \{T \in \mathbb{R}^\times : q_x(T) = 0\}$. *Consequently,* $J_x|_{Z_x} : Z_x \to Z_x$ *is involutive. When* $E_9(x) = 0$, *it interchanges the roots* $2\pi_{\mathrm{HMT}}$ *and* $x^2/(2\pi_{\mathrm{HMT}})$. *This is an exact involution on the scalar fibre of the order-nine jet; it does not act on the enriched state.*

Proof. Dividing $q_x(T)$ by T and substituting $T = 2\pi_{\mathrm{HMT}}$ reproduces the definition of $P_9(x) - \delta$ term by term. The first identity in (11.171) is immediate. For the second,

$$T^2 q_x(x^2/T) = x^5 - B_9(x)x^2T + x^3T^2 = x^2 q_x(T).$$

Thus, J_x preserves the set of roots and, by Viète's formula, interchanges the two roots whose product is x^2. □

The finite decimal witness then retains its exact strength:

$$\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9\Big((\alpha_{12}^{(0)})^{-1}\Big) = 137.035999084. \tag{11.172}$$

The equality (11.172) certifies the finite characterization and the preceding involution. It does not turn the root of a truncated polynomial into the root of every compatible prolongation.

11.6.5.3 Degrees of freedom in the analytic prolongation of a finite jet

Let

$$j_9 : \mathbb{K}[[x]] \longrightarrow \mathbb{K}[x]/(x^{10})$$

be the truncation, and for $h \in \mathbb{K}[x]$ set

$$E_h(x) := E_9(x) + x^{10}h(x). \tag{11.173}$$

All these polynomials satisfy $j_9(E_h) = j_9(E_9)$.

Theorem 11.72 (Nonuniqueness of the root from the jet)**.** *There is no map*

$$\mathfrak{r}_9 : \mathbb{K}[x]/(x^{10}) \longrightarrow I_\alpha$$

that assigns, from the jet alone, the positive root of every polynomial prolongation of E_9 having a unique root in I_α. In particular, E_0 and $E_{1/729}$ have the same jet and distinct positive roots.

Proof. The bound proved in the proof of 11.62 gives $E_9'(x) > 6.24$ on $[0, 10^{-2}]$. For $t \geq 0$, write $E_t(x) = E_9(x) + tx^{10}$. Then

$$E_t'(x) = E_9'(x) + 10tx^9 > 6.24,$$

whereas $E_t(0) = -\delta < 0$ and $E_t(10^{-2}) > E_9(10^{-2}) > 0$. Each E_t therefore has a unique positive root $\eta(t) \in I_\alpha$. For $t = 1/729$,

$$E_{1/729}(\xi_9) = \frac{\xi_9^{10}}{729} > 0;$$

since $E_{1/729}$ is strictly increasing and changes sign only once, its root satisfies $\eta(1/729) < \xi_9 = \eta(0)$. However, $j_9(E_{1/729}) = j_9(E_0)$. A map factoring the root through j_9 would have to assign the same point to both polynomials, a contradiction. □

The variation is not merely existential. The implicit function theorem applies because $\partial_x E_t(\eta(t)) > 6.24$, and gives

$$\eta'(t) = -\frac{\eta(t)^{10}}{E_9'(\eta(t)) + 10t\eta(t)^9} < 0. \tag{11.174}$$

This proves that the coefficients beyond degree nine modify the root even though they leave the entire jet constructed up to that degree invariant. This conclusion does not deny the tail produced by the enriched state: it proves only that the root does not factor through the bare truncation j_9. Choosing a tail h from an external conventional root would be circular. The following completion consults neither that root nor a metrological table: it directly evaluates the regional and terminal coordinates of the state. Since that evaluation coincides algebraically with the integer publication, the result is a correlated representation, not an assertion of independence between two selectors.

11.6.5.4 Analytic representation of the alpha coordinate

The preceding jet check requires exhibiting the tail: merely naming a complete reader is insufficient. Let $\mathsf{s} \in \mathcal{X}_\alpha^{\mathrm{enr}}$. Before decimal normalization, the same state already publishes the precoordinate

$$a(\mathsf{s}) := p(\mathsf{s}) + e_0(\mathsf{s}) - f(\mathsf{s}) - \kappa_{\mathrm{per}}(\mathsf{s}) \in I_\alpha, \tag{11.175}$$

with $p = \pi_{\mathrm{HMT}} - 3$, $e_0 = e_{\mathrm{HMT}} - 2$ and $f = \varphi_{\mathrm{HMT}} - 1$. Equivalently, $a = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{per}}$. No conventional α is introduced here: p, e_0, f are the three already generated regional characters and κ_{per} is the rational reading of the terminal register. Integer closure applies to (11.175) the normalization of (11.120); the following chart publishes a compatible analytic representation on the same precoordinate. Its dependency graph receives $(p, e_0, f, \kappa_{\mathrm{per}})$ directly: it does not contain an edge $\alpha_A \to \lambda$, although the equality proved below subsequently allows both publication names to be identified.

Write $q = 1/729$, let F_{s} be the ordered field generated by the coordinates of s, and set $E_{9,\mathsf{s}}(X) = E^{(9)}_{21/22}(\mathsf{s}; X)$. We define the linking coefficient

$$\lambda(\mathsf{s}) := -\frac{E_{9,\mathsf{s}}(a(\mathsf{s}))\big(1 - q\, a(\mathsf{s})^3\big)}{a(\mathsf{s})^{10}}. \tag{11.176}$$

All its arguments belong to the state before metrological recognition. In particular, λ is not obtained by fitting a target decimal string. Equation (11.176) must be read with its exact type: once the first publication of the state has produced $a(\mathsf{s})$, it fixes the unique prolongation in the geometric class defined below. It does not constitute a second independent selection of $a(\mathsf{s})$, but a correlated analytic representation of the same enriched state.

Indeed, for $\mu \in F_{\mathsf{s}}$ set

$$E_{\mathsf{s},\mu}(X) := E_{9,\mathsf{s}}(X) + \mu \frac{X^{10}}{1 - qX^3}.$$

Since $0 < a(\mathsf{s}) < 10^{-2}$ and $qa(\mathsf{s})^3 < 1$, we have

$$E_{\mathsf{s},\mu}(a(\mathsf{s})) = 0 \quad \Longleftrightarrow \quad \mu = \lambda(\mathsf{s}). \tag{11.177}$$

Thus, the coefficient seed has no freedom once the state and the class of q-geometric prolongations are fixed. This uniqueness is relative to the declared class; it does not assert that the order-nine jet alone selects a tail among all possible analytic series.

The local action on blocks of three coefficients is

$$C_\alpha : F_{\mathsf{s}}^3 \longrightarrow F_{\mathsf{s}}^3, \qquad C_\alpha(u, v, w) = q(u, v, w), \qquad c^{(0)} = (\lambda(\mathsf{s}), 0, 0). \tag{11.178}$$

Therefore, for every $n \geq 0$,

$$b_{10+3n} = q^n \lambda(\mathsf{s}), \qquad b_{11+3n} = b_{12+3n} = 0. \tag{11.179}$$

This is the rule that calculates every coefficient beyond degree nine. No free parameter remains at each prolongation.

For $M \geq 0$, let

$$E_{\mathsf{s},M}(X) := E_{9,\mathsf{s}}(X) + \lambda(\mathsf{s}) \sum_{n=0}^{M} q^n X^{10+3n}. \tag{11.180}$$

The complete function is

$$E_{\mathsf{s},\infty}(X) := E_{9,\mathsf{s}}(X) + \lambda(\mathsf{s}) \frac{X^{10}}{1 - X^3/729}. \tag{11.181}$$

To formulate the projective system without implicit types, we fix $d_M = 12 + 3M$ and define the jet fibration

$$\mathfrak{J}_M := \coprod_{\mathsf{s} \in X_\alpha^{\mathrm{enr}}} \{\mathsf{s}\} \times F_{\mathsf{s}}[X]/(X^{d_M+1}). \tag{11.182}$$

If $M' \geq M$, the restriction is

$$\tau_{M',M}(\mathsf{s}, [P]_{d_{M'}}) := (\mathsf{s}, [P]_{d_M}). \tag{11.183}$$

Proposition 11.73 (Naturality of the analytic recurrence)**.** *Let*

$$\Gamma_M(\mathsf{s}) = \big(\mathsf{s}, [E_{\mathsf{s},M}]_{d_M}\big).$$

If $M' \geq M$, the truncation $\tau_{M',M}$ satisfies

$$\tau_{M',M} \circ \Gamma_{M'} = \Gamma_M, \qquad \Gamma_{E21}(\mathsf{s}) = \varprojlim_M \Gamma_M(\mathsf{s}). \tag{11.184}$$

Projection onto the three new degrees is precisely $C_\alpha^{M+1}(c^{(0)})$.

Proof. Equation (11.179) fixes the block of degrees $10 + 3n, 11 + 3n, 12 + 3n$. Passing from M to $M + 1$ only adds the next block; truncating it recovers the previous polynomial literally. Compatibility for $M' \geq M$ follows by composition. Thus, the inverse limit is not a section chosen from the bare jet, but the unique orbit of $c^{(0)}$ under C_α. □

11.6.5.5 Uniform convergence, simple root and rational intervals

The regional cylinders and the periodic register provide bounds through rational interval arithmetic. For each coordinate

$$c \in \{\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}\},$$

let P_c be its certified thousand-digit nonadic prefix. The datum used is not the rational P_c as though it were the complete value, but the half-open cylinder and its outer closure

$$C_c^{(1000)} = [P_c, P_c + \varepsilon), \qquad \overline{C}_c^{(1000)} = [P_c, P_c + \varepsilon], \qquad \varepsilon = 10^{-1000}.$$

Directed arithmetic operates conservatively with those closures. If P_π, P_e, P_φ denote the three prefixes, we obtain

$$\begin{aligned} a_- &:= P_\pi + P_e - (P_\varphi + \varepsilon) - 4 - \kappa_{\mathrm{per}}, \\ a_+ &:= (P_\pi + \varepsilon) + (P_e + \varepsilon) - P_\varphi - 4 - \kappa_{\mathrm{per}}, \\ A_{1000} &:= [a_-, a_+], \qquad a(\mathsf{s}) \in [a_-, a_+] = A_{1000}, \qquad \operatorname{diam} A_{1000} = 3\varepsilon. \end{aligned} \tag{11.185}$$

The natural interval extension of (11.176) then transports A_{1000}, the cylinder of π_{HMT} and the directed rational bound of δ to a closed interval $\Lambda_{1000} \ni \lambda(\mathsf{s})$; none of the three tails is frozen. In particular,

$$\begin{gathered} \frac{729735256928380099728510547238066 2}{10^{36}} < a(\mathsf{s}) < \frac{729735256928380099728510547238066 3}{10^{36}}, \\ -8.711 \times 10^{-6} < \lambda(\mathsf{s}) < -8.709 \times 10^{-6}. \end{gathered} \tag{11.186}$$

These inequalities use certified prefixes with their rational tail bound; they do not receive an alpha table. The package verifier reproduces them from the three nonadic outputs and from the terminal chart.

Let

$$r := \frac{10^{-6}}{729} < 1.372 \times 10^{-9}.$$

For $0 \le x \le 10^{-2}$, the tail beyond M satisfies

$$\left|E_{\mathsf{s},\infty}(x) - E_{\mathsf{s},M}(x)\right| \le 8.711 \times 10^{-26}\, \frac{r^{M+1}}{1-r}. \tag{11.187}$$

Moreover,

$$\left|\frac{\mathrm{d}}{\mathrm{d}x}\left(\lambda \frac{x^{10}}{1-x^3/729}\right)\right| \le 8.711 \times 10^{-6}\left(\frac{10\,10^{-18}}{1-r} + \frac{3\,10^{-24}/729}{(1-r)^2}\right) < 8.712 \times 10^{-23}. \tag{11.188}$$

The derivative tail beyond block M additionally admits the depth-dependent estimate

$$\sup_{0\le x\le 10^{-2}} \left|E'_{\mathsf{s},\infty}(x) - E'_{\mathsf{s},M}(x)\right| \le 8.711 \times 10^{-24}\, r^{M+1}\left(\frac{13+3M}{1-r} + \frac{3r}{(1-r)^2}\right) \xrightarrow[M\to\infty]{} 0. \tag{11.189}$$

Theorem 11.74 (Limit function and unique simple root of the correlated chart)**.** *The sequence $E_{\mathsf{s},M}$ converges uniformly, together with its derivatives, to $E_{\mathsf{s},\infty}$ on $\overline{I}_\alpha = [0, 10^{-2}]$. We have*

$$E_{\mathsf{s},\infty}(a(\mathtt{s})) = 0, \qquad \inf_{x\in\overline{I}_\alpha} E'_{\mathsf{s},\infty}(x) > 6.239. \tag{11.190}$$

Consequently, $a(\mathtt{s})$ is the unique simple root of the complete function in I_α.

Proof. The ratio of two consecutive terms of the tail is bounded by $r < 1$, which gives (11.187); term-by-term differentiation and summation of the two geometric series give (11.188) and (11.189). The jet proof establishes $E'_{9,\mathsf{s}} > 6.24$ on $\overline{I}_\alpha$; therefore, the complete perturbation leaves the derivative above 6.239. Finally, substituting (11.176) into (11.181) makes the two summands evaluated at $a(\mathtt{s})$ cancel exactly. The function is strictly increasing; its unique root is therefore simple and coincides with that precoordinate. □

To make the identification effective at every depth, directed evaluations of the endpoints first certify

$$E_{\mathsf{s},\infty}(0) < 0 < E_{\mathsf{s},\infty}(10^{-2}), \qquad E'_{\mathsf{s},\infty} \ge \mu := 6239/1000 > c := 6 \quad \text{in } [0, 10^{-2}].$$

By continuity, a root exists in the interval and, by the second inequality, it is unique. Only after establishing this existence, monotonicity and the invariant that the bracket contains the root is the mean-value-theorem rescue applied. We start from $D_0 = [0, 10^{-2}]$. If $D_j = [r_j, s_j]$, let $m_j = (r_j + s_j)/2$, and let $[F_j^-, F_j^+]$ be a directed rational enclosure of $E_{\mathsf{s},\infty}(m_j)$, obtained by propagating the cylinders of $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, \delta$ and λ, with

$$0 \le F_j^+ - F_j^- \le \frac{c}{4}\,(s_j - r_j). \tag{11.191}$$

When $F_j^+ < 0$, the right half is retained; when $F_j^- > 0$, the left half. If $F_j^- \le 0 \le F_j^+$, no attempt is made to decide whether the midpoint is exactly the root. Let $w_j = s_j - r_j$. The uniform bound $E'_{\mathsf{s},\infty} \ge c = 6$ and the mean value theorem imply that any root contained in D_j belongs to

$$D_{j+1} = D_j \cap \left[m_j - \frac{w_j}{4}, m_j + \frac{w_j}{4}\right]. \tag{11.192}$$

Indeed, let ξ_j be the root and let $y_j = E_{\mathsf{s},\infty}(m_j) \in [F_j^-, F_j^+]$. Since the enclosure contains zero and satisfies (11.191), we have $|y_j| \le c w_j/4$. The mean value theorem gives $|m_j - \xi_j| \le |y_j|/c \le w_j/4$, which proves (11.192). The argument includes the case $y_j = 0$: the root is then at the midpoint, but the algorithm does not need to recognize that equality in order to retain it.

If the available enclosure does not satisfy (11.191), the source cylinders are first refined and the evaluation repeated; no sign is declared and no insufficient contraction is accepted. In any of the three branches, the new interval retains the root and has diameter at most $w_j/2$. For each finite target depth,

directed refinement allows the width bound to be satisfied without an uncertified comparison of a real number with zero. Monotonicity proves inductively

$$a(\mathsf{s}) \in D_{j+1} \subseteq D_j, \qquad \operatorname{diam} D_{j+1} \le \tfrac{1}{2} \operatorname{diam} D_j, \qquad \operatorname{diam} D_j \longrightarrow 0, \tag{11.193}$$

where the inequality is a contraction bound, not an imposed equality. The executable certificate applies this rule to twenty-four base-thousand levels and checks that the complete outer closure A_{1000}, not just its lower endpoint, lies within each published cylinder. Its negative tests reject an excessively wide enclosure, an unordered enclosure, a point other than the midpoint, a domain without a sign change and a degenerate bracket. Coinductive prolongation allows one thousand to be replaced by any required depth.

Specifically, for $S_N = 1000^N$ the verifier calculates

$$j_N^- := \lfloor S_N a_- \rfloor, \qquad j_N^+ := \lfloor S_N a_+ \rfloor \tag{11.194}$$

and publishes the level only if $j_N^- = j_N^+$. This equality, which includes the upper endpoint of the outer closure, proves $A_{1000} \subset [j_N^-/S_N, (j_N^- + 1)/S_N)$ and avoids assigning to the left-hand cell an endpoint lying exactly on its right-hand boundary.

Let $C_N^A(\mathsf{s})$ be the integer cylinder of (11.164). We recursively choose $m(N) > m(N-1)$ so that $\operatorname{diam} D_{m(N)} < 1000^{-N}/4$, and define

$$I_{B,N} := D_{m(N)} \cap C_N^A(\mathsf{s}). \tag{11.195}$$

We define $\ell_N := \inf I_{B,N}$ and $u_N := \sup I_{B,N}$. Both are rational; the interval is nonempty because both factors contain $a(\mathsf{s})$. Since the cylinder is half-open, u_N may not belong to $I_{B,N}$. Evaluation at that endpoint is understood through the continuous extension of $E_{\mathsf{s},\infty}$ to the outer closure. Thus,

$$I_{B,N+1} \subseteq I_{B,N} \subseteq C_N^A(\mathsf{s}), \qquad \operatorname{diam} I_{B,N} \longrightarrow 0, \qquad E_{\mathsf{s},\infty}(\ell_N) \le 0 \le E_{\mathsf{s},\infty}(u_N). \tag{11.196}$$

The bound (11.187) allows a truncation to be chosen that preserves the sign at each endpoint where the complete function does not vanish. If an endpoint coincides with the root, the identity of the complete function and the already proved membership are used; that same sign is not attributed to its truncations. Indeed, the exact remainder is

$$E_{\mathsf{s},\infty}(x) - E_{\mathsf{s},M}(x) = \lambda(\mathsf{s}) x^{10} \frac{(qx^3)^{M+1}}{1 - qx^3}.$$

On the positive domain considered, where $\lambda(\mathsf{s}) < 0$, we obtain at the root

$$E_{\mathsf{s},M}(a(\mathsf{s})) = -\lambda(\mathsf{s}) a(\mathsf{s})^{10} \frac{(qa(\mathsf{s})^3)^{M+1}}{1 - qa(\mathsf{s})^3} > 0 \qquad (M < \infty).$$

Therefore, certification of the weak signs in (11.196) refers to $E_{\mathsf{s},\infty}$. Its evaluation uses the complete function or the truncation accompanied by the signed remainder. This covers both the included infimum and the possibly excluded supremum of the cylinder.

Proposition 11.75 (Compatibility squares and common cylinders)**.** *Restrictions of words and analytic publications commute:*

$$\begin{array}{ccc} \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\mathsf{T}_{\alpha,N'}} & \mathcal{W}_{N'} \\ \| & & \downarrow \rho_{N',N} \\ \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\mathsf{T}_{\alpha,N}} & \mathcal{W}_N \end{array} \qquad \begin{array}{ccc} \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\Gamma_{M'}} & \mathfrak{I}_{M'} \\ \| & & \downarrow \tau_{M',M} \\ \mathcal{X}_\alpha^{\mathrm{enr}} & \xrightarrow{\Gamma_M} & \mathfrak{I}_M. \end{array}$$

The family $I_{B,N}$ provides the effective connection between the two squares and materially satisfies $I_{B,N} \subseteq C_N^A$ for every N.

Proof. The first square is compatibility of integer normalization; the second is proposition 11.73. Inclusion follows from definition (11.195), and nonemptiness and the signs follow from theorem 11.74. No step identifies the root of a truncation with that of an arbitrary tail. □

We now define, without leaving the prefix reader implicit,

$$\alpha_B(\mathtt{s}) := \operatorname*{arg\,zero}_{x \in I_\alpha} E_{\mathtt{s},\infty}(x), \qquad \mathrm{pref}_N(x) := \frac{\lfloor 1000^N x \rfloor}{1000^N}, \qquad \alpha_{B,N} := \mathrm{pref}_N(\alpha_B). \tag{11.197}$$

Theorem 11.76 (Projective equality of the two correlated publications)**.** *For every N, the integer route and the analytic route publish the same prefix:*

$$\boxed{\alpha_{A,N} = \mathrm{pref}_N(\alpha_A) = \mathrm{pref}_N(\alpha_B) = \alpha_{B,N}.} \tag{A7$_0$}$$

In the limit,

$$\boxed{\alpha_A = \operatorname*{arg\,zero}_{x \in I_\alpha} E_{\mathtt{s},\infty}(x) = \alpha_B = \alpha_{\mathrm{HMT}}.} \tag{A8$_0$}$$

Proof. Integer normalization publishes exactly $a(\mathtt{s})$. Theorem 11.74 proves that the analytic chart represents that same point as its unique simple root. The half-open cylinders C_N^A fix a canonical prefix and $I_{B,N} \subseteq C_N^A$ contains $\alpha_B = \alpha_A$. Thus, their prefixes agree for every N; nesting and diameters tending to zero give equality of the limits. Metrological recognition occurs afterward. □

The analytic function constitutes a correlated publication of the same state, not a second derivation causally independent of integer closure. This clarification does not diminish the proved equality: it identifies its exact mechanism, prevents attributing to the jet a tail that it does not determine and avoids promoting a conventional value to a generator.

Chapter 12

Construction of $\sqrt{-1}$ and Euler tritic exponential family: operators J_τ and coordination of the regimes elliptic, parabolic and hyperbolic

12.1 Triadic Euler extension and preservation of forms

The quadratic representation of TRIT acquires operator content by identifying the generators selected by APP and by the TPK calendar. This chapter reconstructs those antecedents before expressing their exponential realizations. The order distinguishes the discrete operation, its matrix representation and the analytic function that allows its evolution in a real parameter to be described.

Three constructions are involved: the multiplicative cycle of order three in APP, the elementary transport preserving a prolongation coordinate and the incidence between modes descending from the tritic calendar. Their generators satisfy the elliptic, parabolic and hyperbolic relations, respectively. The alternating form of the plane then allows a common conservation to be established, with the metric and orientation differences of each realization explicitly preserved.

12.1.1 APP multiplicative cycle and elliptic generator

In $\mathbb{Z}/9\mathbb{Z}$, multiplication by four is invertible and has order three:

$$4^2 = 7 \pmod 9, \qquad 4^3 = 1 \pmod 9.$$

On the units appear the cycles $(1, 4, 7)$ and $(2, 8, 5)$. The classes $0, 3, 6$ remain fixed. The selection of the multiplier and its orbits therefore belongs to the nonadic arithmetic of APP.

12.1.1.1 Contragredient action on the two evaluations

Let $\bar{S}(x, y) = x + y$ and $\bar{P}(x, y) = xy$, with values in $\mathbb{Z}/9\mathbb{Z}$. For $a = 4$,

$$\bar{S}(ax, ay) = a\bar{S}(x, y), \qquad \bar{P}(ax, ay) = a^2\bar{P}(x, y) = a^{-1}\bar{P}(x, y). \tag{12.1}$$

The first identity follows from distributivity; the second, from $a^3 = 1$. Sum and product traverse opposite orientations of the same residual cycle. In integer evaluations, the nonadic quotients remain associated with the lift of these classes.

12.1.1.2 Augmentation module and cycle matrix

Fixing one of the cycles $(r, 4r, 7r)$, consider the free module generated by e_r, e_{4r}, e_{7r}. Its augmentation submodule is

$$L = \{x_0 e_r + x_1 e_{4r} + x_2 e_{7r} : x_0 + x_1 + x_2 = 0\}.$$

A basis is $b_1 = e_r - e_{4r}$, $b_2 = e_{4r} - e_{7r}$. The cycle sends b_1 to b_2 and b_2 to $-b_1 - b_2$. Its matrix, acting on column vectors, is

$$C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}.$$

The scalar product inherited from the three-coordinate module has Gram matrix

$$G_{\mathrm{e}} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}.$$

One thus obtains the lattice A_2, with its form determined by the differences between positions of the cycle.

Proposition 12.1 (Elliptic normalization of the APP cycle)**.** *The cycle satisfies*

$$C^2 + C + I = 0, \qquad C^{\mathsf{T}} G_{\mathrm{e}} C = G_{\mathrm{e}}.$$

In $L \otimes_{\mathbb{Z}} \mathbb{R}$, the operator

$$J_{+1} = \frac{2C + I}{\sqrt{3}}$$

has trace zero and satisfies $J_{+1}^2 = -I$.

Proof. Multiplication gives $C^2 = \left(\begin{smallmatrix} -1 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, whence $C^2 + C + I = 0$. The cyclic permutation preserves the scalar product of the three coordinates and its augmentation submodule; in the chosen basis this is equivalent to the Gram identity. Finally, $(2C + I)^2 = 4C^2 + 4C + I = -3I$, and $\operatorname{tr}(2C + I) = 0$. □

Real normalization provides an operator root of $-I$ from the cycle already constructed. The identity can also be written

$$C = -\frac{1}{2} I + \frac{\sqrt{3}}{2} J_{+1}.$$

Its angular interpretation is obtained after fixing the analytic realization of the elliptic type.

12.1.2 Threshold transport and parabolic generator

Consider the integer coordinates (x, c), where c is preserved as a recorded increment. The elementary transport

$$(x, c) \longmapsto (x + c, c)$$

is represented by

$$U_0 = I + N, \qquad N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

This is the linear model of threshold transport used in the quadratic realization. Balanced division and its normalization, developed in chapter 1.2, preserve their own rules when applied to an integer evaluation.

Proposition 12.2 (Iteration and reversibility of transport)**.** *One has $N^2 = 0$, $N \neq 0$ and, for every $m \in \mathbb{Z}$,*

$$U_0^m = I + mN, \qquad U_0^m(x, c) = (x + mc, c).$$

Transport preserves the determinant and admits inverse $I - N$.

Proof. The image of N is contained in the first coordinate, on which N vanishes; hence $N^2 = 0$. The identity $(I + aN)(I + bN) = I + (a + b)N$ proves the positive powers, the inverse and the negative powers. The determinant of $I + mN$ is one. □

The parabolic index $\tau = 0$ corresponds to a square-zero generator. The operator N transports a linear datum and can be nonzero on a particular state. The zero signature, the zero operator and a nilpotent generator are three distinct objects.

12.1.3 Mode incidence derived from the TPK calendar

The construction in section 1.4.1 provides the matrix (1.56). Its primitive action is made explicit here to link the tritic count with the hyperbolic quadratic representation developed below.

The tritic phase selector takes, over the positions $1, \ldots, 9$, the values $(+1, -1, 0)$ repeated three times. On the operative mode the rule used is

$$+1 : \ m \mapsto \Sigma, \qquad -1 : \ m \mapsto \Pi, \qquad 0 : \ m \mapsto m.$$

After each update, the primitive block produces the sequence of modes (Σ, Π, Π). Spatial transport and register updating remain in the complete TPK transition; here one reads its modal incidence.

Theorem 12.3 (Primitive incidence of the calendar)**.** *Counting consecutive pairs with cyclic closure in* (Σ, Π, Π)*, the matrix obtained in the order* (Σ, Π) *is*

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

In calendars of length $9, 27, 108$*, the counts are* $3F_{\mathrm{av}}, 9F_{\mathrm{av}}, 36F_{\mathrm{av}}$*, respectively.*

Proof. The three pairs are $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$. Each appears once. The pair $\Sigma \to \Sigma$ appears zero times. This determines the four entries. Repeating the calendar multiplies all counts by the number of primitive blocks, which is $3, 9, 36$ in the indicated cases. □

The sheet reader associates Σ with the areal reading and Π with the volumetric reading. This assignment transports the resulting incidence to the two reading types. The matrix results from the calendar; its spectral analysis is performed once its entries have been constructed.

Counts of repeated calendars and matrix powers have different functions. $36F_{\mathrm{av}}$ counts the pairs traversed during a calendar of 108 events. By contrast, F_{av}^{108} counts admissible chains of length 108 in the incidence graph. The first object follows a chronology; the second belongs to its adjacency hull.

12.1.3.1 Hyperbolic realization of incidence

Two incidence compositions produce

$$A = F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}.$$

Its coefficients count two-edge paths. One has $\det A = 1$, $\operatorname{tr} A = 3$ and, by direct multiplication, $A^2 - 3A + I = 0$.

Proposition 12.4 (Hyperbolic generator and invariant form)**.** *The operator*

$$J_{-1} = \frac{2A - 3I}{\sqrt{5}}$$

has trace zero and square I*. The symmetric form*

$$G_{\mathrm{h}} = \begin{pmatrix} 2 & 1 \\ 1 & -2 \end{pmatrix}$$

has signature $(1, 1)$ *and satisfies* $A^{\mathsf{T}} G_{\mathrm{h}} A = G_{\mathrm{h}}$*.*

Proof. From $A^2 - 3A + I = 0$ one obtains $(2A - 3I)^2 = 4A^2 - 12A + 9I = 5I$. The trace of the numerator is zero. Moreover,

$$G_{\mathrm{h}} A = \begin{pmatrix} 3 & 4 \\ -1 & -3 \end{pmatrix}, \qquad A^{\mathsf{T}} G_{\mathrm{h}} A = \begin{pmatrix} 2 & 1 \\ 1 & -2 \end{pmatrix}.$$

The determinant of G_{h} is -5, so its two eigenvalues have opposite signs. □

The realization is Lorentzian in dimension $1 + 1$: a real plane, a form of signature $(1, 1)$ and a transport preserving it are specified. The physical realization of a spacetime subsequently uses its corresponding fields, dimensions and transduction maps.

12.1.4 Exponential identity of the three regimes

The three concrete operators act in spaces of distinct provenance: the augmentation module of an APP cycle, the threshold-transport plane and the modal-incidence plane. Their normalizations satisfy

$$J_\tau^2 = -\tau I, \qquad \operatorname{tr} J_\tau = 0, \qquad \tau \in \{+1, 0, -1\}.$$

This relation determines their powers and allows the evolution functions to be constructed by convergent series.

Definition 12.5 (Functions of the quadratic regime)**.** For $t \in \mathbb{R}$, one defines

$$c_\tau(t) = \sum_{k=0}^{\infty} \frac{(-\tau)^k t^{2k}}{(2k)!}, \qquad s_\tau(t) = \sum_{k=0}^{\infty} \frac{(-\tau)^k t^{2k+1}}{(2k+1)!}.$$

These functions analytically realize the quadratic type already obtained.

Theorem 12.6 (Triadic extension of Euler's identity)**.** *For the preceding generators,*

$$E_\tau(t) := \exp(tJ_\tau) = c_\tau(t) I + s_\tau(t) J_\tau. \tag{12.2}$$

The specializations of (c_τ, s_τ) *are* $(\cos, \sin)$*,* $(1, t)$ *and* $(\cosh, \sinh)$*, in the order* $\tau = +1, 0, -1$*. Moreover,*

$$c_\tau(t)^2 + \tau s_\tau(t)^2 = 1, \qquad E_\tau(t)^{-1} = E_\tau(-t).$$

Proof. The exponential series converges absolutely in matrix norm. The quadratic relation gives $J_\tau^{2k} = (-\tau)^k I$ and $J_\tau^{2k+1} = (-\tau)^k J_\tau$. Separating the even and odd terms produces (12.2). The three specializations are recognized in their series. Since the matrices tJ_τ and $-tJ_\tau$ commute, their exponentials have product I. The parity of the series gives

$$E_\tau(t) E_\tau(-t) = \big(c_\tau(t)^2 + \tau s_\tau(t)^2\big) I,$$

which proves the scalar identity and the inverse. □

The numbers appearing when analytic functions are evaluated have here the status of recognition of previously constructed operators. Coinductive regional generation preserves its emitter, its lifts and its cylinders. In particular, these series describe the exponential realization; selection of the regional prefixes is performed through the TPK.

12.1.4.1 Composition law and quadratic invariants

Commutation of multiples of the same generator gives $E_\tau(t) E_\tau(s) = E_\tau(t+s)$. Comparing coefficients of I, J_τ,

$$c_\tau(t+s) = c_\tau(t) c_\tau(s) - \tau s_\tau(t) s_\tau(s), \tag{12.3}$$

$$s_\tau(t+s) = s_\tau(t) c_\tau(s) + c_\tau(t) s_\tau(s). \tag{12.4}$$

Quadratic conjugation changes t to $-t$ within the fixed regime. Oriented inversion of a tritic sequence, for its part, can change the regime indices and must be transported through the corresponding TPK involution.

In the elliptic type, the preserved identity is $a^2 + b^2 = 1$. In the hyperbolic type, $a^2 - b^2 = 1$, and the coordinates $u = a + b$, $v = a - b$ satisfy $uv = 1$. Hyperbolic evolution has $(u, v) = (e^t, e^{-t})$: expansion of one coordinate is accompanied by contraction of the other. In the parabolic type, $E_0(t) = I + tN$, with linear transport and determinant one.

12.1.4.2 Evaluations on the discrete operators

The representation of the elliptic cycle gives

$$C = E_{+1}(2\pi/3), \qquad C^n = E_{+1}(2\pi n/3), \quad n \in \mathbb{Z}.$$

In particular,

$$E_{+1}(\pi) + I = 0, \qquad E_{+1}(2\pi) = I, \qquad E_0(1) = I + N.$$

The angular coordinate π expresses the half-turn analytically; its identification with the HMT regional output belongs to the coinductive reader developed in its causal position.

The incidence F_{av} has characteristic polynomial $x^2 - x - 1$. Its positive root λ satisfies $\lambda^2 = \lambda + 1$; recognizing it as the golden ratio, one writes $\lambda = \varphi$. With $\eta = 2\log\lambda$,

$$\cosh\eta = \frac{3}{2}, \qquad \sinh\eta = \frac{\sqrt{5}}{2}, \qquad E_{-1}(\eta) = A = F_{\mathrm{av}}^2.$$

The check uses $\lambda^{-1} = \lambda - 1$, whence $\lambda^2 + \lambda^{-2} = 3$ and $\lambda^2 - \lambda^{-2} = \sqrt{5}$. The matrix was obtained earlier by counting transitions; spectral recognition characterizes its scale. Equality with the generated regional coordinate is preserved with the reader and the proof of that region.

Likewise, the scalar identity $\exp(I) = eI$ characterizes the unit evaluation of the exponential. Its function in the analytic representation is distinct from the coinductive construction of the corresponding region.

12.1.5 Polynomial resolution of the regimes

In the direct sum of the three real spaces, define

$$\mathbb{J} = J_{+1} \oplus N \oplus J_{-1}, \qquad Q = \mathbb{J}^2.$$

On those summands, Q acts as $-I, 0, I$, respectively. Therefore $Q^3 = Q$ and $\mathbb{J}^6 = \mathbb{J}^2$.

Proposition 12.7 (Regime idempotents)**.** *The operators*

$$p_{\mathrm{e}} = \frac{Q^2 - Q}{2}, \qquad p_{\mathrm{p}} = I - Q^2, \qquad p_{\mathrm{h}} = \frac{Q^2 + Q}{2}$$

are orthogonal idempotents in the algebraic sense and sum to I. Their images are the three summands of the representation.

Proof. The three polynomials take the values $(1,0,0)$, $(0,1,0)$ and $(0,0,1)$ on $-1, 0, +1$. Their squares minus themselves and their cross products vanish at those three points, so they are multiples of $X^3 - X$. Substituting Q demonstrates idempotence and vanishing of the cross products. The sum of the three polynomials is one. Their action on each block identifies the images. □

The complete exponential is expressed by

$$\begin{aligned}\exp(t\mathbb{J}) = {} & p_{\mathrm{e}}(\cos t\, I + \sin t\, \mathbb{J}) + p_{\mathrm{p}}(I + t\mathbb{J}) \\ & + p_{\mathrm{h}}(\cosh t\, I + \sinh t\, \mathbb{J}).\end{aligned} \tag{12.5}$$

This resolution distinguishes the regimes exactly. Transitions between them belong to the TPK maps on states with orientation, mode and memory; the direct sum keeps their domains separate.

12.1.6 Nonadic compression and complementary register

Conservation between a reading and its complementary register follows from the nine-phase structure. Let V be a space with a scalar product and $C : V \to V$ a linear transport. In V^9, define

$$S_C(v_0, \dots, v_8) = (Cv_8, v_0, \dots, v_7), \qquad Jv = \frac{1}{3}(v, \dots, v).$$

The inclusion J is isometric because it brings together nine copies with factor $1/3$. Its adjoint sums the components and divides by three. The compression onto that inclusion is

$$T = J^* S_C J = \frac{8I + C}{9}.$$

Eight components preserve v and one passes through the transport C. The orthogonal complement of the inclusion records

$$(I - JJ^*)S_C Jv = \frac{1}{27}\big(8(C - I)v, -(C - I)v, \dots, -(C - I)v\big).$$

The square of its norm is $8\|(C - I)v\|^2/81$. The same vector content can be represented isometrically by

$$D = \frac{\sqrt{8}}{9}(C - I),$$

maintaining the nine-component register when their individual labels are used.

Proposition 12.8 (Algebraic recovery from two readings)**.** *For every $v \in V$,*

$$v = Tv - \frac{1}{\sqrt{8}}Dv. \tag{12.6}$$

If C is isometric, one additionally has

$$\|v\|^2 = \|Tv\|^2 + \|Dv\|^2.$$

Proof. The first identity follows from $(8I + C - (C - I))/9 = I$. For the second, expanding the products gives

$$T^*T + D^*D = \frac{72I + 9C^*C}{81}.$$

The hypothesis $C^*C = I$ gives the identity. The mixed terms cancel with coefficients $+8$ and -8. □

Recovery uses the vector records, including their correlations. The intensities $\|Tv\|^2$ and $\|Dv\|^2$ provide the scalar balance, whereas the inverse formula uses the complete Tv and Dv.

12.1.7 Conservation of oriented area

In any oriented real plane, let

$$\Omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

For a matrix $L = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, direct multiplication gives

$$L^{\mathsf{T}}\Omega L = (ad - bc)\Omega = (\det L)\Omega. \tag{12.7}$$

Since the tritic generators have zero trace, $\det E_\tau(t) = 1$. Their realizations therefore preserve the alternating form, although their metric forms differ.

Table 12.1: Contributions to the oriented area of three generated transports.

Transporte	$\operatorname{tr} C$	$\det T$	$\det D$
APP cycle C	-1	$19/27$	$8/27$
Threshold $I + N$	2	1	0
Incidence F_{av}^2	3	$89/81$	$-8/81$

Each pair sums to one. The sign records orientation; the table concerns alternating area, not probabilities.

Theorem 12.9 (Nonadic conservation common to the three regimes)**.** *For $C = E_\tau(t)$, let $T = (8I + C)/9$ and $D = \sqrt{8}(C - I)/9$. Then*

$$\Omega = T^{\mathsf{T}}\Omega T + D^{\mathsf{T}}\Omega D. \tag{12.8}$$

Proof. Expansion gives

$$T^{\mathsf{T}}\Omega T + D^{\mathsf{T}}\Omega D = \frac{72\Omega + 9C^{\mathsf{T}}\Omega C}{81}.$$

The terms $C^{\mathsf{T}}\Omega$ and ΩC cancel. By (12.7), $C^{\mathsf{T}}\Omega C = \Omega$, and the result is Ω. □

With $c = c_\tau(t)$, the determinant contributions are

$$\det T = \frac{65 + 16c}{81}, \qquad \det D = \frac{16(1 - c)}{81}, \qquad \det T + \det D = 1. \tag{12.9}$$

Indeed, for $\det C = 1$, $\det(aI + C) = a^2 + a \operatorname{tr} C + 1$, and $\operatorname{tr} C = 2c$.

In parabolic transport, D may be nonzero and have rank one: its area is zero and its record contains linear information. In hyperbolic transport, the complement has opposite orientation. In elliptic transport, the positive form intrinsic to the cycle also permits the norm balance. The three realizations share the alternating identity with their types preserved.

12.1.8 Variable forms and restitution between successive planes

Consider a sequence of planes V_n with positive-definite symmetric matrices G_n. Let $B_n, C_n : V_n \to V_{n+1}$ be two transports satisfying

$$B_n^{\mathsf{T}} G_{n+1} B_n = G_n, \qquad C_n^{\mathsf{T}} G_{n+1} C_n = G_n.$$

The transport B_n identifies the coordinates between the two planes; C_n includes the additional evolution. Define

$$T_n = \frac{8B_n + C_n}{9}, \qquad D_n = \frac{\sqrt{8}}{9}(C_n - B_n).$$

Theorem 12.10 (Conservation and recovery with a variable form)**.** *The following hold*

$$G_n = T_n^{\mathsf{T}} G_{n+1} T_n + D_n^{\mathsf{T}} G_{n+1} D_n, \tag{12.10}$$

$$v = B_n^{-1}\left(T_n v - \frac{1}{\sqrt{8}} D_n v\right). \tag{12.11}$$

Proof. In the expansion of the first expression, the cross terms cancel. This leaves $72B_n^{\mathsf{T}} G_{n+1} B_n/81$ and $9C_n^{\mathsf{T}} G_{n+1} C_n/81$, whose sum is G_n. The identity $T_n - D_n/\sqrt{8} = B_n$ proves the second formula. Positivity of the forms makes B_n injective; between planes of equal dimension, it is invertible. □

For $I_n(v) = \frac{1}{2} v^{\mathsf{T}} G_n v$, $v_{n+1} = T_n v_n$ and $m_n = D_n v_n$, one obtains

$$I_n(v_n) = I_{n+1}(v_{n+1}) + I_{n+1}(m_n).$$

Summing over N steps gives

$$I_0(v_0) = I_N(v_N) + \sum_{n=0}^{N-1} I_{n+1}(m_n). \tag{12.12}$$

Each record is evaluated in the form of the plane where it was produced. The inverse transports of (12.11) restore all states in reverse order from the terminal state and the complete records.

A concrete realization uses invertible matrices M_n, $G_n = M_n^{-\mathsf{T}} M_n^{-1}$ and rotations R_n:

$$B_n = M_{n+1} M_n^{-1}, \qquad C_n = M_{n+1} R_n M_n^{-1}.$$

The two form identities are verified by substituting these expressions and using $R_n^{\mathsf{T}} R_n = I$. The coordinates, scales and parameters of M_n, R_n are received from the state readers when this realization is applied to Dimensional Mechanics.

12.1.8.1 Exact criterion for transfer to the record

If R_n is a rotation through angle θ_n, in normalized coordinates $y_n = M_n^{-1} v_n$ one has

$$y_{n+1} = \frac{8I + R_n}{9} y_n, \qquad \left(\frac{8I + R_n}{9}\right)^{\mathsf{T}} \left(\frac{8I + R_n}{9}\right) = r_n I,$$

$$r_n = 1 - \frac{32}{81} \sin^2(\theta_n/2).$$

By induction, $I_N(v_N) = I_0(v_0) \prod_{n<N} r_n$.

Proposition 12.11 (Criterion for vanishing of the terminal state)**.** *If $I_0(v_0) > 0$, the terminal state satisfies $I_N(v_N) \to 0$ exactly when*

$$\sum_{n \geq 0} \sin^2(\theta_n/2) = +\infty.$$

Proof. For $c = 32/81$ and $u \in [0, 1]$, integrating $1/(1 - s)$ between zero and cu gives

$$cu \leq -\log(1 - cu) \leq \frac{cu}{1 - c}.$$

The sum of the logarithms diverges exactly when the sum of the $u_n = \sin^2(\theta_n/2)$ diverges. The product of the r_n tends to zero exactly in that case. □

The conservation law (12.12) holds at every finite depth. The preceding criterion determines when the entire initial form is transferred to the record in this realization. The angular sequence is the one obtained by the corresponding trajectory reader.

12.1.9 Integrated action and compatibility with refinement

In a canonical plane with coordinates (Q, P), let γ be a piecewise C^1 closed curve. For any real matrix L of order two,

$$\oint_{L\gamma} P \, \mathrm{d}Q = \det(L) \oint_{\gamma} P \, \mathrm{d}Q. \tag{12.13}$$

To prove this, write $Q' = aQ + bP$, $P' = cQ + dP$. The closed integrals of $Q \, \mathrm{d}Q$ and $P \, \mathrm{d}P$ are zero. Integrating $\mathrm{d}(PQ)$ gives $\oint Q \, \mathrm{d}P = -\oint P \, \mathrm{d}Q$. The coefficient $ad - bc$ remains, proving the formula.

Applied to (12.9), this yields

$$\oint_{\gamma} P \, \mathrm{d}Q = \oint_{T\gamma} P \, \mathrm{d}Q + \oint_{D\gamma} P \, \mathrm{d}Q.$$

The orientation of each curve preserves the sign of its contribution.

Refinement additionally requires compatibility between operators at successive levels. In this section, let $\iota_n : V_n \to V_{n+1}$ be linear injections and $A_n : V_n \to V_n$ endomorphisms satisfying $A_{n+1}\iota_n = \iota_n A_n$. At each level we define $T_n = (8I_{V_n} + A_n)/9$ and $D_n = \sqrt{8}(A_n - I_{V_n})/9$. These expressions imply

$$T_{n+1}\iota_n = \iota_n T_n, \qquad D_{n+1}\iota_n = \iota_n D_n.$$

Restitution (12.6) then commutes with refinement. This identity preserves the operation and the record simultaneously; its verification in a concrete realization uses the map ι_n produced by that prolongation.

12.1.9.1 Preservation of the reader's scalar factor

If a realization receives a scale factor e^{-x}, the transport is $C = e^{-x}E_\tau(t)$. Its determinant is e^{-2x}, and the same expansion of the nonadic law gives

$$T^{\mathsf{T}}\Omega T + D^{\mathsf{T}}\Omega D = \frac{8 + e^{-2x}}{9}\Omega.$$

For $x \geq 0$, the scale complement

$$D_{\mathrm{esc}} = \frac{\sqrt{1 - e^{-2x}}}{3} I$$

restores the complete balance:

$$\Omega = T^{\mathsf{T}}\Omega T + D^{\mathsf{T}}\Omega D + D_{\mathrm{esc}}^{\mathsf{T}}\Omega D_{\mathrm{esc}}.$$

The coefficient is obtained from the determinant defect of the scale. Each application preserves its reader's factor and specifies whether this additional record is needed.

The triadic extension of Euler is thus articulated through generated operations, invariant forms and recovery operators. The APP cycle, nilpotent transport and modal incidence preserve their provenance; the analytic realization describes their evolutions; the nonadic division of the reading preserves the complement required for restitution. This sequence expresses the link between regime, transformation and memory without replacing the genealogy with an isolated exponential formula.

12.2 Exponential identity of TRIT and coordination of the elliptic, parabolic, and hyperbolic regimes

12.2.1 Construction of the elliptic operator by means of the Paley matrix and the relation $J_{+1}^2 = -I$

The root of -1 is not introduced as a formal symbol without an antecedent. The six units modulo nine are coordinatized over $\mathbb{P}^1(\mathbb{F}_5)$, and the quadratic character of $\mathbb{F}_5$ determines the Paley conference matrix. Its ternary reduction is

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3).$$

The conference identity reduces to

$$\boxed{A_W^2 = 2I_6 = -I_6.} \tag{12.14}$$

Therefore, A_W is a quarter-turn operator in the ternary space. After extending scalars to $\mathbb{F}_9$, it decomposes into the conjugate eigenspaces of the roots of $X^2 + 1$. The common integral source

$$Q_{\mathbb{Z}} = \mathbb{Z}[u]/(u^2 + 1)$$

has a finite realization $u \mapsto A_W$ and a real realization $u \mapsto J_e$. The source coordinates the quadratic relation; it does not identify fields of different characteristics.

12.2.2 Unified family $\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau$

The three TRIT regimes are carried out by means of operators

$$J_{+1}^2 = -I, \qquad J_0^2 = 0, \qquad J_{-1}^2 = I.$$

Separating the even and odd powers of the exponential yields a single family:

$$\boxed{\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau, \qquad \tau \in \{+1, 0, -1\},} \tag{12.15}$$

where

$$(C_{+1}, S_{+1}) = (\cos, \sin), \qquad (C_0, S_0) = (1, t), \qquad (C_{-1}, S_{-1}) = (\cosh, \sinh).$$

12.2.3 Elliptic, parabolic, and hyperbolic specializations and compatibility with the temporal reader

Its three governing specializations are

$$\exp(\pi J_{+1}) + I = 0, \qquad \exp(J_0) = I + J_0, \qquad \exp\big(2(\log\varphi)J_{-1}\big) = F_{\mathrm{av}}^2. \tag{12.16}$$

The elliptic branch contains the complex circular closure; the parabolic branch, threshold transport; the hyperbolic branch, golden self-scaling. Euler's equation thus appears as a specialization of a family that coordinates rotation, boundary and hyperbolic expansion.

12.3 Hopf fibration, Villarceau circles, and Möbius holonomy as a topological realization of the elliptic regime

12.3.1 Complex structure and Hopf fibration

Let $S^3 \subset \mathbb{C}^2$ and

$$h(z_0, z_1) = \big(2\Re(z_0\overline{z}_1), 2\Im(z_0\overline{z}_1), |z_0|^2 - |z_1|^2\big) \in S^2.$$

On the Hopf torus

$$T_\eta = \{(z_0, z_1) : |z_0| = \cos\eta, |z_1| = \sin\eta\},$$

the curves

$$\gamma_+(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{it}),$$
$$\gamma_-(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{-it})$$

have distinct behaviors: γ_+ is a Hopf fiber and γ_- projects with degree two. Under stereographic projection, the homology classes $(1, 1)$ and $(1, -1)$ produce the two diagonal Villarceau families.

The total complex conjugation

$$K(z_0, z_1) = (\overline{z}_0, \overline{z}_1)$$

preserves each unoriented family and reverses its orientation. It does not interchange the two families. Partial conjugation can interchange them, but it is neither a complex-linear map nor the standard global antiunitary. This correction is essential to avoid manufacturing a particle–antiparticle symmetry from the toroidal drawing.

12.3.2 Double covering and spinor return

The map $SU(2) \to SO(3)$ is a double cover. A loop of 2π in $SO(3)$ can lift to $-I$ in $SU(2)$; the loop of 4π recovers I. The sign structure does not turn a circle into a Möbius band. Obtaining a band requires a real line bundle whose holonomy character is -1.

Let $L_\chi \to S^1$ be the associated bundle to

$$\chi : \pi_1(S^1) \longrightarrow \{\pm 1\}, \qquad \chi(1) = -1.$$

Its total space is a Möbius band. The route $C_M = -\,\mathrm{rev}$ provides the sign candidate; the Villarceau circle provides the loop; the physical intertwiner must prove that the former is the holonomy of the latter.

12.3.3 Corrispondence between the spectrum $\{7, 3\}$, the ratio 5:2 and the spinorial return

With $B_c = 7I + 2S$, define the oriented memory operator

$$B^{\varepsilon}_{\mathrm{mem}} = 5I + 2\varepsilon S, \qquad \varepsilon = \pm 1.$$

For $\varepsilon = +1$,

$$\mathrm{Spec}(B^{+}_{\mathrm{mem}}) = \{7, 3\}, \qquad \det B^{+}_{\mathrm{mem}} = 21.$$

Interpreting the values $(7, 3)$ as the outer and inner equatorial boundaries in a common positive chart yields

$$R + r = 7\ell, \qquad R - r = 3\ell,$$

and therefore

$$R = 5\ell, \qquad r = 2\ell, \qquad \sin\beta = \frac{r}{R} = \frac{2}{5}.$$

The Villarceau angle is

$$\beta = \arcsin\frac{2}{5} = 23.5781784782\ldots^{\circ}.$$

The algebraic theorem $\{7, 3\} \leftrightarrow (5, 2)$ is exact. The geometric premise interpreting the spectrum as the two boundaries of a torus is a declared interface. It must not be concealed, nor may the angle be used as a target.

The realization of the full block B_c retains another reading: $R : r = 7 : 2$ and $\beta = \arcsin(2/7)$. These are not rival values; they belong to two functors: total block and memory mode. The physical priority of the latter must be decided by the intertwiner with the dynamics, not by decimal proximity to another constant.

12.3.4 Angular momentum representation in the elliptic regime and phase space unit closure

HMT's native angle is a phase $u \in \mathbb{R}/\mathbb{Z}$. The readers publish

$$\theta_{\mathrm{rad}} = 2\pi u, \qquad \theta_{\mathrm{deg}} = 360u.$$

Radians and degrees are distinct charts of the same circular element. The radian is not more "ontological" by virtue of being dimensionless; its naturality follows from arc length. Degrees provide another absolute coordinate of the full turn. Any relation with α^{-1}, φ, or CKM must first be formulated as an invariant quotient or holonomy and only thereafter evaluated in an angular chart.

The exact identity already available

$$\tanh^2(2\log\varphi) = \frac{5}{9}$$

connects the Perron–Fibonacci channel to the spectral quotient of B_c. Its complement is $4/9$, the normalized gap. This relation is structural. It does not imply that every angle constructed with φ is a physical angle.

12.3.5 Brouwer, Möbius, and degree

Brouwer's fixed-point theorem, fractional linear Mobius transformations, and the Mobius band are three distinct objects. They are related only after fixing domain, action, and bundle. The elliptic advance and retardation orbits may be modeled as two sections of a bundle with sign holonomy; the Mobius transformation describes the conformal action in the chart; Brouwer's theorem guarantees a fixed point for continuous maps of the disk. None of these statements replaces the realization diagram.

Result and boundary

The degree-two character of the Hopf curve, the orientation of the total conjugation, and the algebraic construction $7, 3 \mapsto 5, 2$ are proved. The toroidal reading (5:2), Möbius holonomy, and the particle–antiparticle interpretation form a chain of interfaces that must share a single intertwiner. The volume does not force that intertwiner through an angular coincidence.

Chapter 13

Genealogical regularization of -1/12 through triadic extraction and Hensel–Witt lifting

13.1 Transduction kernel Hensel–Witt: domain, operation and genealogical preservation

Where do the cylinders, the monodromy, the five regions, the hexads, the octads and the physical readers actually intersect?

13.1.1 Hensel–Witt Transduction Kernel: π microregions, holonomy Γ_9, dodecaphase record, and hexad–octad transport

The NTHW is the data and maps package

$$\mathfrak{N}_{\mathrm{HW}} = \left(\mathscr{R}_{\pi}^{\mathrm{micro}}, \mathcal{G}_9, C_{12}, K, \mathcal{W}_{12\to 24}, \mathcal{I}_{6\to 8}\right),$$

with the following compatibilities:

1. the Hensel regions share a quotient word and retain distinct memory;
2. $\mathcal{G}_9$ transports orientation and produces monodromy;
3. C_{12} organizes the signed observable and the seal K;
4. the Witt reading converts supports of the same boundary into hexads and stars;
5. the extension $W_{12} \to W_{24}$ produces the hexad–octad interface;
6. the Archimedean, exceptional and dimensional readers receive invariants of the same state.

NTHW gives a formal name to the place previously described as the "Rosetta Stone." The substitution is conceptual: a stone translates through resemblance; a transduction specifies input, output, preserved datum and loss of information.

13.1.2 Translation of the ternary code into the Witt system

The reversible APP boundary selects, with declared gauges, a matrix A_W over $\mathbb{F}_3$ satisfying

$$A_W A_W^T = 2I \pmod 3.$$

The graphic code

$$C_W = \{(q, qA_W) : q \in \mathbb{F}_3^6\}$$

is the extended ternary Golay code. Its weight enumerator is

$$1 + 264y^6 + 440y^9 + 24y^{12}.$$

The 264 words of weight six, identified up to sign, yield 132 supports. Every five-point subset belongs to a unique hexad:

$$W_{12} = S(5, 6, 12).$$

The field of 495 star involutions generates a group of order 95 040, recognized as M_{12}. An isolated star does not generate the group. The ordered HMT frame has trivial stabilizer and therefore fixes a gauge within the action.

13.1.3 Hexagonal–Octagonal Inclusion and Incidence Transport through the 90/120 Channels

Let H be a hexad and O_H an octad containing it. Marking one point and a pair of points of the hexad yields

$$F_6(H) = H \times \binom{H}{2}, \qquad |F_6| = 6\binom{6}{2} = 90.$$

If the marked point can traverse the octad:

$$F_8(H) = O_H \times \binom{H}{2}, \qquad |F_8| = 8\binom{6}{2} = 120.$$

The inclusion $H \hookrightarrow O_H$ induces $F_6 \hookrightarrow F_8$. Its normalized defect is

$$\boxed{\frac{90-120}{24\binom{6}{2}} = \frac{6-8}{24} = -\frac{1}{12}.}$$

This combinatorial theorem precedes Barbero's angular reading. The two objects share the interface $6 \to 8$, but are not identical.

13.1.4 4 rutas hacia -1/12

The construction contains four realizations that must be presented together, not counted as four independent proofs of a single provenance.

13.1.4.1 Elementary Operator of the Dodecaphasic Cycle and Update of the Signed Phase

One tooth of C_{12} measures $30°$. Then

$$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3} = -\frac{1}{12}.$$

It is the angular shadow of the pattern $90/120$.

13.1.4.2 Gram matrix of the surviving sections and positivity criterion

In the certified jump $60 \to 81$, two fibers have sizes 0 and 12. The Gram operator is

$$K_{60,81} = \operatorname{diag}(0, 12).$$

On the live subspace, its pseudoinverse is $1/12$; with the negative boundary orientation,

$$E_{\text{surv}} = -K^{+}_{60,81}$$

yields $-1/12$.

13.1.4.3 Triadic Scale Extraction Operator and Its Rational Image

The realization via a triadic scale extractor is the second-difference construction developed in full in section 13.3.3. This first occurrence establishes its role within the inventory of realizations; the indicated residence preserves the definitions of T_L, $a(L)$, $A_1(L)$, $C(L)$, the independence of the residue from L, and the exact status of the normalization.

13.1.4.4 Modular corridor between dodecaphasic cards and conservation of the phase invariant

The eta function satisfies

$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-1}.$$

The exponent comes from $1/24 - 3/24 = -1/12$. Taking twelve copies:

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots .$$

The coefficient 54 coincides with the APP defect. The corridor

$$j = \frac{(t_3 + 27)(t_3 + 243)^3}{t_3^3}$$

connects afterwards with the classical modular branch.

What has been proved in the corridor

The APP defect 54, the eta exponent $-1/12$, the hexad–octad defect, and the modular identities are exact once t_3 has been fixed. The strong assertion is that all of them are natural images of a single TPK operator. That naturality must be proved through the NTHW diagram; it is not deduced merely from repeating the same integers.

13.1.5 Representation of Primary Power Defects via the Number Operator

For a prime power p^m, the complete APP defect generalizes to

$$\Delta_{p^m}^{\text{full}} = \frac{m(p-1)}{2} p^{2m-1}.$$

In particular,

$$\Delta_3 = 3, \qquad \Delta_9 = 54, \qquad \Delta_{27} = 729.$$

Upon normalization,

$$a_{p,m} = \frac{2\Delta_{p^m}^{\text{full}}}{(p-1)p^{2m-1}} = m.$$

With $x = p^{-s}$:

$$\sum_{m\geq 1} a_{p,m} x^m = \sum_{m\geq 1} m x^m = \frac{x}{(1-x)^2} = x\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{1-x}.$$

The factor $(1-x)^{-1}$ is the local Euler factor; differentiation inserts the number operator. Thus, an exact bridge appears:

tower of APP defects in p^m $\longleftrightarrow$ insertion of the number operator into the local Euler factor.

13.1.6 Joint naturality conditions for the Archimedean, exceptional, and dimensional transduction

The NTHW will be a complete transduction theorem when there is a family of invariants $\mathcal{I}$ and readers

$$\mathfrak{R}, \quad \mathfrak{E}, \quad \mathfrak{D}$$

such that

$$\mathcal{I} = \mathcal{I}_{\text{arq}} \circ \mathfrak{R} = \mathcal{I}_{\text{exc}} \circ \mathfrak{E} = \mathcal{I}_{\text{dim}} \circ \mathfrak{D},$$

and when the maps of region, seal, incidence, and action are derived from the same transport. The finite proofs already provide candidates: monodromy, support B_K, borrowing pattern, two-way parity, and counts 90/120.

Executable test 108–144–90–120

Label each of the 1008 routes of π by CT108 orbit and by Witt completion; compute the fibers of the map; test whether the four regions of multiplicity 144 realize factor $8/6$ on blocks of 108; and verify whether the region of 432 transports the monodromy. A single counterexample to label compatibility would refute this bridge in its present form.

Result of the section

The NTHW is the true center of the account because there the same boundary may be read as cylinder, monodromy, seal, incidence, and action. Its power does not consist in many numbers resembling one another, but in several finite maps already sharing supports and exact defects. The next task is to prove the joint naturality of those charts.

13.2 Marked inclusion of the hexad-octad incidence and preservation of its multiplicities

With the dodecad and the alignment of the section 17.1.6 fixed, let H be a hexad in the HMT coordinates, let $\ell(H) \subset D$ be its image, and let $O_H = \iota_D(\ell(H))$ be its unique lift. Marking a point and a pair of points of the residual hexad yields

$$F_6(H) = \ell(H) \times \binom{\ell(H)}{2}, \qquad |F_6| = 6\binom{6}{2} = 90.$$

If the marked point can traverse the octad:

$$F_8(H) = O_H \times \binom{\ell(H)}{2}, \qquad |F_8| = 8\binom{6}{2} = 120.$$

The inclusion $\ell(H) \hookrightarrow O_H$ induces the incidence morphism

$$\mathcal{I}_{6\to 8} : F_6(H) \hookrightarrow F_8(H).$$

Normalizing the difference by the chosen factor $24\binom{6}{2}$ yields

$$\boxed{\frac{90-120}{24\binom{6}{2}} = \frac{6-8}{24} = -\frac{1}{12}.}$$

The equality is a normalized defect of the combinatorial interface $6 \to 8$. The factor $24\binom{6}{2}$ forms part of the definition of this normalization; the inclusion alone determines the difference -30. The operator $\mathcal{I}_{6\to 8}$ has marked incidence configurations as its domain; it is neither the transverse extractor of the dodecaphase state nor the family of angular moments.

13.3 Classification by domain of the 5 algebraic realizations of $-1/12$

In addition to the normalized defect of the hexad–octad inclusion, five operator realizations of the same rational number appear. Their domains are specified separately; equality of values does not identify the operators without an additional intertwiner.

13.3.1 Difference of dodecaphasic periodicities

One tooth of C_{12} measures 30°. Then

$$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3} = -\frac{1}{12}.$$

It is the oriented difference between the periods of 90° and 120° in this realization.

13.3.2 Pseudoinverse of the Gram Operator on the Live Component

In the exact jump $60 \to 81$, two fibers have sizes 0 and 12. The Gram operator is

$$K_{60,81} = \operatorname{diag}(0, 12).$$

On the nonzero component of its range, the pseudoinverse is $1/12$; with the negative boundary orientation,

$$E_{\text{surv}} = -K^{+}_{60,81}$$

yields $-1/12$.

13.3.3 2nd difference between triadic scales

Define

$$T_L = \sum_{n=1}^{L-1} n(L-n) = \frac{L(L^2-1)}{6}, \qquad a(L) = -\frac{T_L}{L^2} = -\frac{L}{6} + \frac{1}{6L}.$$

The first scale subtraction is

$$A_1(L) = a(L) - \frac{a(3L)}{3} = \frac{4}{27L},$$

and the second

$$C(L) = LA_1(L) - \frac{3L}{3}A_1(3L) = \frac{8}{81}.$$

The residue $8/81$ is independent of L. To obtain $-1/12$, the declared normalization is applied

$$R(L) = -\frac{27}{32}C(L) = -\frac{1}{12}.$$

The calculation derives $8/81$; it does not by itself derive the factor $-27/32$.

13.3.4 Composition of modular transformations and preservation of the signed state

The eta function satisfies

$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12}\prod_{n\geq 1}(1+q^n+q^{2n})^{-1}.$$

The exponent comes from $1/24 - 3/24 = -1/12$. Taking twelve copies:

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots.$$

The coefficient 54 coincides with the APP defect. The rational identity

$$j = \frac{(t_3+27)(t_3+243)^3}{t_3^3}$$

establishes the connection with the classical modular branch.

13.3.5 Defect of cyclic difference projectors

Let S be the cyclic shift on $\mathbb{Q}^{12}$ and define

$$D_r = I - S^r.$$

The kernel of D_r consists of the vectors constant on each orbit of S^r; therefore,

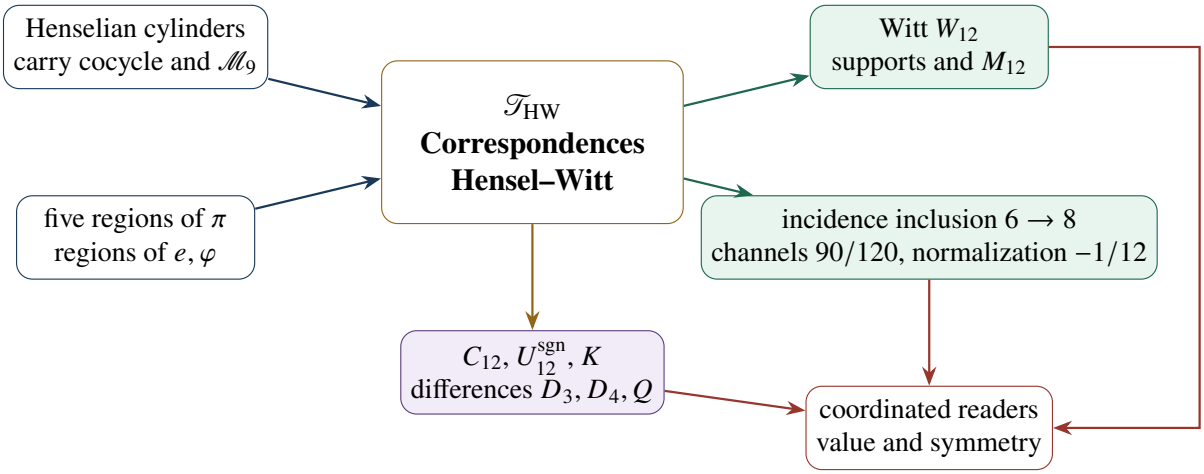
$$\dim \ker D_r = \gcd(12, r).$$

Let $\Pi_{\ker D_3}$ and $\Pi_{\ker D_4}$ be the rational projectors onto $\ker D_3$ and $\ker D_4$, and let $\tau(T) = \mathrm{Tr}(T)/12$ be the normalized trace. Then

$$\boxed{\tau(\Pi_{\ker D_3} - \Pi_{\ker D_4}) = \frac{\operatorname{rank} \Pi_{\ker D_3} - \operatorname{rank} \Pi_{\ker D_4}}{12} = \frac{3-4}{12} = -\frac{1}{12}.}$$

This realization expresses the rational as the transverse defect of steps three and four in the twelve-phase cycle.

Remark 13.1 (Domains of the realizations). The APP defect 54, the eta exponent $-1/12$, the combinatorial defect of the hexad–octad lift, and the modular identities once t_3 has been fixed are exact. The value of the pseudoinverse, the normalized extractor, and the projector defect are likewise exact. Each equality preserves its domain and its corresponding map.



Compatibility of cylinders, dodecaphase, and incidences on the same enriched state.

Figure 13.1: The NTHW as a typed interface. The central mathematical task is to make the diagram commute, not to accumulate coincidences around a name.

Chapter 14

Regional–determinantal confluence of the reduced action: construction of η_{ret}, scale 10^{-34}, $\hbar_{\mathrm{ret}}$, and parangular publication (A, C^{*})

14.1 Genealogical bifurcation of the action scale and its dimensionless component

The intrinsic phase α_{HMT}, already obtained by means of the reversible dodecaphase closure, gives rise to two independent internal branches. The first determines the dimensionless component of the action subsequent to the return; the second determines its absolute decade. Neither of them presupposes the counter-angle.

In the regional branch, the character of degree 5 is

$$H_5(\alpha_{\mathrm{HMT}}, \varphi) = \frac{1}{2}\sqrt{\frac{10^3\alpha_{\mathrm{HMT}}}{\varphi}} - \alpha_{\mathrm{HMT}} + \frac{9}{16}\alpha_{\mathrm{HMT}}^2 - \frac{5}{9}\alpha_{\mathrm{HMT}}^3 + \frac{7}{48}\alpha_{\mathrm{HMT}}^4 - \frac{1}{54}\alpha_{\mathrm{HMT}}^5. \tag{14.1}$$

The completion $10^3 = 729 + 243 + 27 + 1$ publishes the phase in the analytic coordinate

$$x_A = \frac{50\pi}{9}\alpha_{\mathrm{HMT}}, \qquad D(\alpha_{\mathrm{HMT}}) = e^{-2x_A} = \exp\!\left(-\frac{100\pi}{9}\alpha_{\mathrm{HMT}}\right). \tag{14.2}$$

With the regional selector $\rho_\pi = 169$, the convergent recurrence

$$\mathscr{C}_\pi(\alpha) = 169\alpha^6 + \frac{D(\alpha)\alpha^7}{1 - D(\alpha)\alpha} \tag{14.3}$$

directly determines

$$\boxed{\eta_{\mathrm{ret}} = H_5 - \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}) > 0.} \tag{14.4}$$

This equation not contains C^{*}: constructs the coordinate dimensionless of action that intervenes dispues in the closure bicapa.

In the determinantal branch, the Smith normal form produces

$$\Sigma_H = \varphi\alpha_{\mathrm{HMT}}^{16}, \qquad \varepsilon_H = \mathrm{ord}_{10}(\Sigma_H) = -34. \tag{14.5}$$

The two branches converge, and only then, in the magnitude of action.

$$\boxed{\hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}} 10^{\varepsilon_H} U_S = \eta_{\mathrm{ret}} 10^{-34} U_S.} \tag{14.6}$$

14.2 Angular publication and compatibility of the global and analytic charts

Once the phase α_{HMT}, the coordinate η_{ret}, and the magnitude $\hbar_{\mathrm{ret}}$ have been constructed, the parangular map publishes

$$\mathcal{P}(\alpha_{\mathrm{HMT}}, \eta_{\mathrm{ret}}) = \left(A_{\mathrm{deg}}, C^{*}_{\mathrm{deg}}\right) = \left([10^3\alpha_{\mathrm{HMT}}]_{360}, [2(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}})]_{360}\right). \tag{14.7}$$

The factor 10^3 comes from nonadic completion; the factor 2, from the bidirectional closure of degree 2; and 360 is the global chart that renders simultaneously visible $12 \cdot 30 = 4 \cdot 90 = 3 \cdot 120 = 360$. The analytic chart applies once

$$\kappa_{360}(a,c)=\frac{\pi}{180}(a,c),\qquad A_{\mathrm{rad}}=\frac{50\pi}{9}\alpha_{\mathrm{HMT}},\qquad C^{*}_{\mathrm{rad}}=\frac{\pi}{90}(\eta_{\mathrm{ret}}+\alpha_{\mathrm{HMT}}). \tag{14.8}$$

Therefore, $C^{*}_{\mathrm{deg}}=2(\eta_{\mathrm{ret}}+\alpha_{\mathrm{HMT}})$ is the direct theorem, whereas $\eta_{\mathrm{ret}}=C^{*}_{\mathrm{deg}}/2-\alpha_{\mathrm{HMT}}$ constitutes solely its inverse verification. The action satisfies

$$S(\theta)=\hbar_{\mathrm{ret}}\theta_{\mathrm{rad}}=h_{\mathrm{ret}}\frac{\theta_{\mathrm{deg}}}{360},\qquad h_{\mathrm{ret}}=2\pi\hbar_{\mathrm{ret}}. \tag{14.9}$$

The channels $q_{\pm}$ subsequently evaluate the incidence cardinalities 90/120, already generated in the Topological Phase Kernel; they do not constitute their origin.

14.3 Preconstitutive construction of the bidirectional action response and the vacuum operator

14.3.1 Derivation of the action scale from the dodecaphasic state

The action decade is determined intrinsically, without adopting it as an inherited unit. The local determinantal functional is applied to the previously constructed HMT output α_{HMT} and defines

$$\Sigma_{H}=\varphi_{\mathrm{HMT}}\alpha_{\mathrm{HMT}}^{16}. \tag{14.10}$$

The exponent 16 is the order of the local cokernel of the signed closure; its decimal valuation fixes

$$\mathrm{ord}_{10}(\Sigma_{H})=-34. \tag{14.11}$$

The origin of the exponent can be verified within this volume. On the local orbit of four leaves, the Hadamard block acts

$$H_{4}=\begin{pmatrix}1&1&1&1\\1&1&-1&-1\\1&-1&1&-1\\1&-1&-1&1\end{pmatrix}. \tag{14.12}$$

Lemma 14.1 (Local index of the action line)**.** *The form normal of Smith of H_4 is*

$$\mathrm{SNF}(H_{4})=\mathrm{diag}(1,2,2,4). \tag{14.13}$$

Consequently,

$$\mathrm{coker}(H_{4})\simeq\mathbb{Z}/2\mathbb{Z}\oplus\mathbb{Z}/2\mathbb{Z}\oplus\mathbb{Z}/4\mathbb{Z},\qquad|\mathrm{coker}(H_{4})|=16.$$

Proof. The greatest common divisor of the entries is one; that of the nonzero 2×2 minors is two; that of the 3×3 minors is four; and $|\det H_{4}|=16$. The successive quotients of these determinantal divisors are $1,2,2,4$, which prove equation (14.13). The product of the invariants gives the order of the cokernel. □

The norm of the section α_{HMT} over those sixteen sheets produces $\alpha_{\mathrm{HMT}}^{16}$; the self-scaling φ_{HMT} acts only once on the basis, not once per sheet. Hence equation (14.10). The certified comparisons

$$\alpha_{\mathrm{HMT}}^{16}<10^{-34}<\varphi_{\mathrm{HMT}}\alpha_{\mathrm{HMT}}^{16}<10^{-33} \tag{14.14}$$

prove, without introducing the SI unit, that the decimal order is exactly -34. The terminal evaluation begins with

$$\Sigma_{H}=1.046243838104756580184229208303089\ldots\times10^{-34}. \tag{14.15}$$

The substitution of the kernel by three copies with exponent 16^{3}, or the repeated application of φ on each sheet, would alter the genealogy. Both operations constitute falsification criteria rather than equivalent conventions. The causal chain that is preserved is therefore,

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to U_{12}^{\mathrm{sign}} \to \alpha_{\mathrm{HMT}} \to \Sigma_H \to 10^{-34}\mathcal{U}_S \to \{\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}}\}.$$

This volume does not rederive α_{HMT}, but develops the metrological geometry subsequent to the selection of the type and decade by Σ_H. The integer -34 is neither a mantissa nor an adjustment to the International System, but the terminal valuation of the local functional.

14.3.2 Oriented sections of the action line

The realizations before and after the return constitute two sections of the same action line:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S. \tag{14.16}$$

The common decade determines the line, while the oriented information is expressed through

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}, \qquad \xi_{\mathrm{act}} = \frac{1}{2}\log R_{\mathrm{act}}. \tag{14.17}$$

The first quantity provides a multiplicative coordinate and the second an additive coordinate of rapidity type. They do not represent two independent Planck constants, but the two orientations of the same section with respect to the return.

If $h_a = 2\pi\hbar_a$, $a \in \{\mathrm{pre}, \mathrm{ret}\}$, a quantity proportional to $h_a^{1/2}$ changes as $R_{\mathrm{act}}^{1/2}$, one proportional to $h_a^{-1/2}$ changes as $R_{\mathrm{act}}^{-1/2}$, and a quotient in which the action cancels is a bidirectional invariant.

14.3.3 Bilayer spectral decomposition of the angular operator

Let $R = R^* = R^{-1}$ be the active involution and

$$P_\pm = \frac{I \pm R}{2}, \qquad T = q_+P_+ + q_-P_-, \qquad 0 < q_+ < q_- < 1.$$

With

$$x = A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad y = C^*_{\mathrm{rad}} = \frac{\pi C^*}{180},$$

the two channels are constructed before evaluating the vacuum:

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}. \tag{14.18}$$

The exchange of sheets reverses C^*, that is, $y \mapsto -y$, and permutes $q_+ \leftrightarrow q_-$. The pair is thus the spectral reading of the same angular antecedent, not two parameters fitted separately.

Definition 14.2 (Constitutive response)**.**

$$\mathcal{V}_{90,120} = (I - T^{90})(I - T^{120})^{-1}. \tag{14.19}$$

Since $\|T\| < 1$, the denominator is positive and invertible. Functional calculus gives

$$\mathcal{V}_{90,120} = r_+P_+ + r_-P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}}. \tag{14.20}$$

The assertion of invertibility deserves to be made explicit. For each leaf, $0 < q_\pm^{120} < 1$; therefore

$$I - T^{120} = (1 - q_+^{120})P_+ + (1 - q_-^{120})P_-$$

is strictly positive and

$$(I - T^{120})^{-1} = \frac{P_+}{1 - q_+^{120}} + \frac{P_-}{1 - q_-^{120}}.$$

The response $\mathcal{V}_{90,120}$ is not obtained by solving four separate scalar equations: it is the result of the functional calculus of a single positive contraction. This observation prevents permeability, permittivity, impedance and propagation from losing their shared antecedent.

Theorem 14.3 (Joint spectral determination of the four constitutive relations)**.** *The four constituent characters*

$$\widehat{\varepsilon} = r_{+}^{2}, \qquad \widehat{\mu} = r_{-}^{2}, \qquad \widehat{Z} = \frac{r_{-}}{r_{+}}, \qquad \widehat{c} = \frac{1}{r_{+} r_{-}} \tag{14.21}$$

are spectral functions of $\mathcal{V}_{90,120}$. They satisfy

$$\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}, \qquad \frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^{2}. \tag{14.22}$$

Proof. The identities are obtained by substituting equation (14.21). No dimensional chart nor any exterior value intervenes. □

Corollary 14.4 (Reconstruction of the two sheets)**.** *The four characters do not contain four degrees of freedom. Any of the pairs $(\widehat{\mu}, \widehat{\varepsilon})$, $(\widehat{Z}, \widehat{c})$, or $(\mathcal{E}, \mathcal{B})$ reconstructs the two positive eigenvalues:*

$$r_{-} = \sqrt{\widehat{\mu}} = \sqrt{\widehat{Z}/\widehat{c}}, \qquad r_{+} = \sqrt{\widehat{\varepsilon}} = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \tag{14.23}$$

$$\log r_{-} = \frac{\mathcal{E} + \mathcal{B}}{2}, \qquad \log r_{+} = \frac{\mathcal{E} - \mathcal{B}}{2}. \tag{14.24}$$

In particular, orientation is lost if only the product is retained, but is recovered by adding the quotient.

Proof. The first line is the positive root of the identities equations (14.21) y (14.22). The second inverts the linear system $\mathcal{E} = \log r_{-} + \log r_{+}$, $\mathcal{B} = \log r_{-} - \log r_{+}$. □

This corollary expresses a central property of HMT: product and quotient are complementary functionals of the same state. The product determines the propagation in common, whereas the quotient preserves the relative orientation of the inner and outer sheets.

In the V2 certificate,

$$\begin{aligned}
r_{+} &= 0.99999962854824936317869522 81\ldots,\\
r_{-} &= 0.99972413718951836413151658 53\ldots,\\
\widehat{\varepsilon} &= 0.99999925709663670276044161 55\ldots,\\
\widehat{\mu} &= 0.99944835047932693508998155 59\ldots,\\
\widehat{Z} &= 0.99972450853893721545555434 66\ldots,\\
\widehat{c} &= 1.00027631048615752610638626 89\ldots.
\end{aligned}$$

These numerals are the terminal recognition of equation (14.19); they do not define its exponents $90, 120$.

14.3.4 Harmonic factorization of sectors 90 and 120

The harmonic semigroup is

$$\langle 90, 120\rangle = 30\langle 3, 4\rangle.$$

If $s = q^{30}$, then

$$\frac{1-q^{90}}{1-q^{120}} = \frac{1-s^3}{1-s^4} = \frac{1+s+s^2}{1+s+s^2+s^3}. \tag{14.25}$$

The identity also separates the response from its defect. If

$$F_{3\to4}(s) = \frac{1+s+s^2}{1+s+s^2+s^3}, \qquad 0 < s < 1,$$

then

$$d_{3\to4}(s) := 1 - F_{3\to4}(s) = \frac{s^3}{1+s+s^2+s^3} > 0. \tag{14.26}$$

The additional term is preserved exactly as a positive defect. Moreover,

$$F'_{3\to4}(s) = -\frac{s^2(3+2s+s^2)}{(1+s+s^2+s^3)^2} < 0. \tag{14.27}$$

Consequently, the order of the angular channels uniquely determines the order of the constitutive responses. The assignment of $\widehat{\mu}$ and $\widehat{\varepsilon}$ to the respective sheets is obtained analytically, without resorting to their decimal expansions.

Each sheet of the vacuum constitutes the exact completion from three to four terms of the same elementary mode 30. Consequently, permeability and permittivity are interpreted as two quadratic functionals of the same completion evaluated on conjugate sheets, and not as independent constitutive parameters.

Since the function $(1-q^{90})/(1-q^{120})$ decreases in $0 < q < 1$ and $q_+ < q_-$, we obtain

$$0 < r_- < r_+ < 1, \qquad 0 < \widehat{\mu} < \widehat{\varepsilon} < 1, \qquad 0 < \widehat{Z} < 1 < \widehat{c}.$$

The limits of the functional determine its geometry. When $q \to 0^+$, $F(q) \to 1$: the four readings approach unity and the memory defect disappears. When $q \to 1^-$,

$$F(q) \longrightarrow \frac{90}{120} = \frac{3}{4}.$$

The response therefore takes values in the positive interval $(3/4, 1)$. The endpoint $3/4$ is not a fitted constant: it is the quotient of the two channel lengths and the continuous realization of the three–to–four completion.

14.3.5 Sheet involution and preservation of orientation

The sheet exchange $C^* \mapsto -C^*$ acts by

$$\widehat{\mu} \longleftrightarrow \widehat{\varepsilon}, \qquad \widehat{Z} \longmapsto \widehat{Z}^{-1}, \qquad \widehat{c} \longmapsto \widehat{c}. \tag{14.28}$$

The common propagation is even; impedance preserves orientation. This distinction will reappear in Barbero and CKM: not all functionals associated with the change of sheet have the same parity.

14.3.6 Logarithmic characters and tracial compatibility

Define

$$\mathcal{E} = \log(r_+ r_-), \qquad \mathcal{B} = \log(r_-/r_+).$$

With the normalized trace $\tau = \mathrm{Tr}/2$,

$$2\tau(\log \mathcal{V}) = \mathcal{E}, \qquad -2\tau(R \log \mathcal{V}) = \mathcal{B}. \tag{14.29}$$

The pair $(\mathcal{E}, \mathcal{B})$ constitutes a linear coordinate system for the operator logarithm:

$$\log \mathcal{V} = \frac{\mathcal{E}}{2} I - \frac{\mathcal{B}}{2} R. \tag{14.30}$$

The scalar component is invariant under sheet exchange; the oriented component changes sign. This decomposition directly demonstrates the parity of propagation and the oriented character of impedance.

The nonadic amplification

$$\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$$

is compatible with the expectations $E_m = \mathrm{id} \otimes \tau_9$:

$$E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m.$$

Therefore, $\mathcal{E}$ and $\mathcal{B}$ are not peculiarities of a 2×2 matrix; they persist in the UHF tower and in its tracial closure II_1.

More precisely, for every polynomial p and afterwards, by continuity, for every continuous function on the spectrum,

$$E_m\big(p(\mathcal{V}_{m+1})\big) = p(\mathcal{V}_m). \tag{14.31}$$

Compatibility does not preserve only two numbers: it preserves the entire functional algebra generated by the response. In particular, it preserves its spectral projectors, powers, logarithm, and quadratic forms that measure the defects equation (14.26).

14.3.7 Dimensional realization of the constitutive relations

Dimensional Mechanics determines

$$Z_{\mathrm{vac}} = \widehat{Z}\, u_S u_Q^{-2}, \tag{14.32}$$

$$c_{\mathrm{vac}} = \widehat{c}\, u_C, \tag{14.33}$$

$$\mu_{\mathrm{vac}} = \widehat{\mu}\, u_S u_C^{-1} u_Q^{-2}, \tag{14.34}$$

$$\varepsilon_{\mathrm{vac}} = \widehat{\varepsilon}\, u_S^{-1} u_C^{-1} u_Q^{2}. \tag{14.35}$$

The constitutive identities hold on the straight lines:

$$\mu_{\mathrm{vac}} \varepsilon_{\mathrm{vac}} = c_{\mathrm{vac}}^{-2}, \qquad \mu_{\mathrm{vac}} / \varepsilon_{\mathrm{vac}} = Z_{\mathrm{vac}}^{2}. \tag{14.36}$$

The SI chart comes later. It is not necessary to declare c primitive and then solve $\mu\varepsilon = c^{-2}$: the three objects descend jointly from $\mathcal{V}$ and from the declared lines.

The separation of levels is expressed by the diagram

$$\begin{array}{ccccc} (A, C^*) & \longrightarrow & T & \longrightarrow & \mathcal{V} \longrightarrow (\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}) \\ \big\downarrow \text{line charts} & & & & \big\downarrow \text{final evaluation} \\ (u_S, u_Q, u_C) & \longrightarrow & (\mu_{\mathrm{vac}}, \varepsilon_{\mathrm{vac}}, Z_{\mathrm{vac}}, c_{\mathrm{vac}}) & \longrightarrow & \text{SI coordinates.} \end{array}$$

The first line is dimensionless and operatorial; the second determines types of quantity; the third selects a metrological chart. Altering the final chart changes neither the eigenvalues nor the constitutive identities.

In this precise sense, mathematical–physical unification consists in distinguishing the genealogical invariant from its coordinate system, not in removing the dimensional structure.

Proposition 14.5 (Spectral minimality)**.** *Let W be a positive two-sheet operator with simple spectrum $\{r_+, r_-\}$. If four positive characters satisfy $\mu\varepsilon = c^{-2}$ and $\mu/\varepsilon = Z^2$, if their propagation in common is determined by $c^{-1} = \det W = r_- r_+$, and if its orientation fixes $Z = r_-/r_+$, then necessarily*

$$(\mu, \varepsilon, Z, c) = \left(r_-^2, r_+^2, \frac{r_-}{r_+}, \frac{1}{r_- r_+}\right).$$

Therefore, equation (14.21) is not one parametrization among many: it is the minimal positive realization compatible with product, quotient and orientation.

Proof. From $Z = r_-/r_+$ and $c^{-1} = \det W = r_- r_+$ the positive roots are obtained uniquely roots. The two constitutive identities then force afterwards $\mu = r_-^2$ and $\varepsilon = r_+^2$. □

14.3.8 Angular determinant and Weinberg electroweak relation

The determinant of T is

$$\det T = q_+ q_- = D_A. \tag{14.37}$$

The constitutive sector of the vacuum evaluates $F(T)^2$, where $F(z) = (1 - z^{90})/(1 - z^{120})$, whereas the electroweak angular sector evaluates $\det T$. These are two functions of a common antecedent, not a horizontal factorization between constants. This distinction is developed in the section 49.1.

Falsification criterion 14.6. The block is refuted if any of these exact identities is violated: positivity of $I - T^{120}$, equality equation (14.25), relations equation (14.22), or compatibility $E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m$. An SI coincidence cannot compensate for an operator failure.

Hypothesis, domain, and conclusion

Operator, spectrum, completion $3 \to 4$, parity, amplification, and constitutive sections form an exact internal theorem. Their assembly into a single operator is established in this formulation; the angular data and the lines, previously derived in HMT, constitute the explicit starting structure.

14.4 Quantum–electric constants, thermal scale, and Planck system

14.4.1 Derivation of the charge section from the vacuum

With Z_{vac}, $h_a = 2\pi\hbar_a$ and α_{HMT} fixed, the charge of sheet $a \in \{\mathrm{pre}, \mathrm{ret}\}$ is

$$e_a = \sqrt{\frac{2\alpha_{\mathrm{HMT}} h_a}{Z_{\mathrm{vac}}}}. \tag{14.38}$$

The section e_a is not introduced through an International System coordinate intended to reconstruct α. The causal order proceeds from α_{HMT}, the action, and the vacuum toward the charge section.

14.4.2 Von Klitzing and Josephson constants, conductance and magnetic flux

From equation (14.38) we deduce

$$R_K = \frac{h_a}{e_a^2} = \frac{Z_{\mathrm{vac}}}{2\alpha_{\mathrm{HMT}}}, \tag{14.39}$$

$$G_0 = \frac{2e_a^2}{h_a} = \frac{4\alpha_{\mathrm{HMT}}}{Z_{\mathrm{vac}}}, \tag{14.40}$$

$$\Phi_{0,a} = \frac{h_a}{2e_a} = \sqrt{\frac{h_a Z_{\mathrm{vac}}}{8\alpha_{\mathrm{HMT}}}}, \tag{14.41}$$

$$K_{J,a} = \frac{2e_a}{h_a} = \Phi_{0,a}^{-1}. \tag{14.42}$$

Consequently,

$$R_K G_0 = 2, \qquad G_0 Z_{\mathrm{vac}} = 4\alpha_{\mathrm{HMT}}, \qquad K_{J,a}\Phi_{0,a} = 1. \tag{14.43}$$

The bidirectional covariance takes the form

$$R_K^{\mathrm{pre}} = R_K^{\mathrm{ret}}, \qquad G_0^{\mathrm{pre}} = G_0^{\mathrm{ret}},$$

$$\frac{\Phi_{0,\mathrm{pre}}}{\Phi_{0,\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad \frac{K_{J,\mathrm{pre}}}{K_{J,\mathrm{ret}}} = R_{\mathrm{act}}^{-1/2}.$$

The resistance and conductance relations are independent of the orientation of action. The flux–frequency pair preserves that orientation and transforms its two components reciprocally.

14.4.3 Relation thermal intrinsic of the scale 108

The chronological structure 108 fixes

$$k_B \Theta_{\mathrm{clk}} \log 3 = \frac{h_{\mathrm{int}}}{108 t_0} = \frac{2\pi\hbar_{\mathrm{int}}}{108 t_0}. \tag{14.44}$$

This equality does not separately determine a numerical coordinate of k_B and another of Θ_{clk} without an additional normalization. It does determine their product as a section of energy. The factor $\log 3$ has three compatible generators:

$$\log 3 = C_1 + C_2 - 2C_0 = \frac{S_{\widehat{\mathbb{T}}}}{k_B} = \frac{E_P}{k_B \Theta_{\mathrm{clk}}}. \tag{14.45}$$

The three equalities correspond to residual, informational and thermodynamic realizations of the same scalar. The coincidence of value does not identify their respective domains.

14.4.4 Planck System and Bidirectional Covariance

The CT108 selector constructs

$$\theta_{108} = \left(\frac{54}{\pi}\right)^2, \qquad \ell_P = \frac{54}{\pi}\ell_0, \qquad t_P = \frac{54}{\pi} t_0, \tag{14.46}$$

and

$$E_P = \frac{\hbar_{\mathrm{int}}}{t_P} = \frac{\pi\hbar_{\mathrm{int}}}{54 t_0}. \tag{14.47}$$

Comparing equations (14.44) y (14.47) gives

$$\boxed{E_P = k_B \Theta_{\mathrm{clk}} \log 3.} \tag{14.48}$$

The relation does not depend on a coincidence between units: both sides follow from the same chronological structure 108.

When the gravitational constant of chapter 50 is introduced, the Planck family satisfies

$$\ell_P^2 = \frac{G\hbar}{c^3} = \theta_{108}\ell_0^2, \tag{14.49}$$

$$F_P = \frac{c^4}{G}, \qquad P_P = \frac{c^5}{G}, \tag{14.50}$$

$$\rho_P = \frac{\hbar}{\theta_{108}^2 c^5 t_0^4}. \tag{14.51}$$

Although G and $\hbar$ transform reciprocally between the sections before and after the return, their product in ℓ_P^2 preserves the geometry. This invariance determines area as the interface between the geometric, informational and entanglement realizations.

14.4.5 Spectral formulations of Wien's displacement law

For the spectral density per wavelength, the maximum satisfies

$$5(1 - \mathrm{e}^{-x_5}) = x_5, \qquad x_5 = 5 + W_0(-5\mathrm{e}^{-5}).$$

With equation (14.44),

$$\lambda_{\max}(\Theta_{\mathrm{clk}}) = \frac{108 \log 3}{x_5}\,\ell_0. \tag{14.52}$$

For the frequency density,

$$3(1 - \mathrm{e}^{-x_3}) = x_3, \qquad x_3 = 3 + W_0(-3\mathrm{e}^{-3}),$$

and

$$\nu_{\max}(\Theta_{\mathrm{clk}}) = \frac{x_3}{108 t_0 \log 3}. \tag{14.53}$$

The maxima are not reciprocals, since the spectral densities transform with the corresponding Jacobian. The quotient x_5/x_3 belongs to the structure of the parameterization and does not represent an inconsistency.

14.4.6 Stefan–Boltzmann law and thermodynamics of the photon gas

Evaluating the radiation law at Θ_{clk} produces the intrinsic flux

$$j_\star(\Theta_{\mathrm{clk}}) = \frac{2\pi^5}{15\,108^4 (\log 3)^4}\,\frac{h_{\mathrm{int}}}{\ell_0^2 t_0^2}, \tag{14.54}$$

in the declared normalization. The Stefan–Boltzmann constant is not inserted as a primitive: it results from integrating the bosonic spectrum once action, propagation, and temperature have been fixed. The spectral laws employed are those of Planck and Wien [102, 133]; HMT fixes here the section on which they are evaluated, not their constants by retrospective comparison.

In units of the Planck scale,

$$n_\gamma \ell_P^3 = \frac{2\zeta(3)}{\pi^2 \log^3 3}, \tag{14.55}$$

$$\frac{u_\gamma \ell_P^3}{E_P} = \frac{\pi^2}{15 \log^4 3}, \tag{14.56}$$

$$\frac{s_\gamma \ell_P^3}{k_B} = \frac{4\pi^2}{45 \log^3 3}. \tag{14.57}$$

$\zeta(3)$ represents the third-order bosonic moment, whereas $\log 3$ determines the energy associated with the TRIT decision. The equation preserves the distinction between the two invariants.

The quantum thermal conductance is expressed as

$$\frac{\kappa_Q t_0}{k_B} = \frac{\pi^2}{324 \log 3}. \tag{14.58}$$

14.4.7 Posterior metrological confluence of action, charge, conductance, and magnetic flux

Object	Equation internal	Significado estructural
R_K	$Z_{\mathrm{vac}}/(2\alpha)$	bidirectionally invariant quantum resistance
G_0	$4\alpha/Z_{\mathrm{vac}}$	conductancia complementaria
Φ_0	$\sqrt{hZ/(8\alpha)}$	flow preserving orientation of action
K_J	Φ_0^{-1}	reciprocal relation between frequency and flux
E_P	$k_B\Theta \log 3$	energy of the cycle and TRIT informational content
Wien's law	$108 \log 3/x_5$	endpoint spectral in the scale chronological
Photonic Apéry	$2\zeta(3)/(\pi^2 \log^3 3)$	number density of the bosonic field

Falsification criterion 14.7. The block is falsified if a change of spectral variable improperly preserves the same Wien extremum, if $\zeta(3)$ replaces $\log 3$, or if separate values are assigned to k_B and Θ without specifying a chart. The identities equations (14.43) y (14.48) provide direct algebraic controls.

Hypothesis, domain, and conclusion

Electric quanta and Planck–TRIT confluence: *Internal exact theorem*. Wien, Stefan–Boltzmann and gas photonic: *Composition mathematical exact* with the declared bosonic continuum. The SI chart remains as *Contrast metrological external*.

14.5 Graduated analytic realization of the quintuple microfiber

The finite catalog and an analytic evaluation answer questions of different types. The catalog determines which regions exist, which share a return and what information each preserves. An analytic evaluation must also decide how the length of a word is transformed into degree, how a branch is prolonged after its return and with which scalar character that prolongation is read. This chapter explicitly constructs that second operation.

The construction begins with four data already obtained in the preceding chapters: the five-region microfiber of π, the length six of each regional word, the dodecaphasic closure of α, and the bilayer transport associated with the common coordinate $A = 10^3\alpha$. No value of the conjugate angular coordinate C_*^{HMT}, of the reduced action component, of the Barbero–Immirzi functional, or of a metrological constant is used in the evaluation. The result is a convergent regional character, an exact recurrence, and an oriented phase whose sexagesimal chart reproduces the published conjugate angular coordinate.

The separation between the finite part and the analytic part is essential. The integer 169 will be a theorem of the catalogue. The series that prolongs it will be the theorem of an analytic reader whose rules are declared before it is evaluated. Thus, the additional premises are not concealed within a decimal coincidence.

14.5.1 The persistent return of the 5 regions

Let

$$\mathcal{F}_\pi = \Psi^{-1}(010211) \subset \mathcal{U}_6$$

the microfiber relative to the catalog. Recall its five elements, now separated into initial block and terminal block:

$$(501, 614, 498 \mid 169, 272, 272),$$
$$(810, 923, 870 \mid 169, 272, 272),$$
$$(810, 983, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 418, 674, 521).$$

We define the return projection.

$$p_{\mathrm{ret}} : \mathbb{Z}^6 \longrightarrow \mathbb{Z}^3, \qquad p_{\mathrm{ret}}(u_1, \dots, u_6) = (u_4, u_5, u_6).$$

Proposition 14.8 (Persistent terminal block)**.** *The multiset $p_{\mathrm{ret}}(\mathcal{F}_\pi)$ has a unique element of maximum multiplicity:*

$$b_\pi = (169, 272, 272), \qquad \mathrm{mult}_{\mathcal{F}_\pi}(b_\pi) = 4.$$

The only remaining terminal block is

$$b_\pi^- = (418, 674, 521)$$

and has multiplicity one.

Proof. The assertion follows by exact enumeration of the five rows of the catalog that satisfy $\Psi(U) = 010211$. Four rows have terminal block $(169, 272, 272)$; the fifth, which carries the mutated return, has $(418, 674, 521)$. The maximum multiplicity is four and is attained only once. □

The oriented difference between the mutated return and the persistent is

$$\omega_\pi = b_\pi^- - b_\pi = (249, 402, 249), \qquad \langle (1, 1, 1), \omega_\pi \rangle = 900.$$

This identity separates two objects that must not be conflated. The integer 169 is a coordinate of a terminal datum, that is, a datum of degree zero. The vector ω_π can be read as a one-cochain after orienting the edge joining the two blocks. Calling it a cocycle would additionally require fixing a cochain complex and verifying that its coboundary vanishes. The analytic prolongation constructed below does not presuppose that identification.

The selection of 169 does not require privileging the first position of the block. The symmetric group $\mathfrak{S}_3$ acts by permuting its three coordinates. The stabilizer of b_π exchanges the two occurrences of 272 and fixes the unique coordinate of multiplicity one. Denote that coordinate by $\mathrm{sing}(b)$ when the block has type (r, s, s), with $r \neq s$. Equivalently,

$$\mathrm{sing}(b) = \sum_{j=1}^{3} b_j - 2\,\mathrm{moda}(b).$$

In particular,

$$\boxed{\mathrm{sing}(b_\pi) = 169.}$$

Definition 14.9 (Residual fiber selector)**.** The selector ρ_π successively applies two operations:

1. selects the terminal block of maximum multiplicity within $p_{\mathrm{ret}}(\mathcal{F}_\pi)$;

2. retains the coordinate fixed by the stabilizer of that block.

By proposition 14.8,

$$\boxed{\rho_\pi = 169.}$$

Theorem 14.10 (Equivariant uniqueness of return)**.** *Among the selectors that*

1. *are invariant under permutations of the five regions;*
2. *are equivariant under permutations of the three terminal coordinates;*
3. *select the block of maximal multiplicity;*
4. *retain a coordinate fixed by its stabilizer,*

the return value is uniquely determined and is 169.

Proof. Invariance under $\mathfrak{S}_5$ prevents using the order of the rows. The third condition selects b_π, which is the unique mode by proposition 14.8. Its stabilizer in $\mathfrak{S}_3$ has two orbits on the coordinates: the pair of values 272 and the singleton value 169. The fourth condition selects the second orbit. Equivariance preserves its value when its position is shifted. □

This argument improves the positional reading of the return. The 169 is not «the first coordinate» of a selected row: it is an invariant of the regional multiset and of the action of its reordering symmetries. Nor is it selected by global rarity. Among the 468 emissions in the catalogue, 169 appears 84 times, uniformly distributed with 14 occurrences in each of the six positions. The uniqueness of theorem 14.10 is therefore relational and regional: it resides in the combination of microfiber, modal persistence, and stabilizer, not in the isolated frequency of the integer.

14.5.2 Cylindrical length and analytic degree

Let $\mathcal{P}$ be the free module generated by the regional words and let $F^n\mathcal{P}$ be its length filtration. The associated grading records the first level at which each word appears. For a parameter z, the ordinary length character is

$$\chi_z([w]) = z^{|w|}.$$

Multiplicativity

$$\chi_z([uv]) = \chi_z([u])\chi_z([v])$$

expresses that concatenation adds lengths. When evaluated at $z = \alpha$, a word of length n receives degree α^n.

Definition 14.11 (Degree compatibility)**.** The regional analytic reader is compatible with the cylindrical filtration when it sends the homogeneous component of length n to analytic degree n:

$$\mathrm{gr}_n \mathcal{P} \longrightarrow \alpha^n \mathbb{R}.$$

The five regions belong to $\mathcal{U}_6$; therefore, the return datum appears in degree six:

$$\rho_\pi[U_6] \longmapsto 169\alpha^6.$$

This six is the length of the regional word. It is not the length of the closed walks of chapter 9. Those walks traverse the four anchors $U_\pi, U_e, U_\varphi, U_{\mathrm{APP}}$ simultaneously and have minimum length eight. A word, an edge of the block graph, and a closed walk are objects of distinct types; the grading used here belongs to the first.

14.5.3 The Determinantal Character of Common Transport

The dodecaphasic closure provides α. The completion of the three nonadic pairs provides the scale 10^3, so that

$$A = 10^3 \alpha.$$

Having chosen the Archimedean angular chart, the common coordinate in radians is

$$x = \frac{\pi A}{180} = \frac{50\pi}{9}\alpha.$$

Let R be a real involution of zero trace in dimension two,

$$R^2 = I_2, \qquad \operatorname{tr} R = 0,$$

and consider the formal two-layer transport

$$\mathcal{T}(x, y) = \exp(-xI_2 - yR).$$

The oriented variable y has not yet been evaluated. Nevertheless, the action of $\mathcal{T}$ on the determinant line is independent of it:

$$\begin{aligned} \det \mathcal{T}(x, y) &= \exp(\operatorname{tr}(-xI_2 - yR)) \\ &= e^{-2x}. \end{aligned}$$

We define

$$\boxed{D_A = e^{-2x} = e^{-100\pi\alpha/9}.}$$

The subscript recalls that this is the determinant of the common contraction associated with A, not a function of C_*^{HMT}.

Proposition 14.12 (Character of the determinant line)**.** *The map*

$$\delta_A : (\mathbb{N}_0, +) \longrightarrow (\mathbb{R}_{>0}, \cdot), \qquad \delta_A(k) = D_A^k,$$

is the unique multiplicative character whose value on an elementary prolongation is D_A.

Proof. The multiplicativity gives

$$\delta_A(k) = \delta_A(\underbrace{1 + \cdots + 1}_{k \text{ times}}) = \delta_A(1)^k = D_A^k.$$

The same identity proves existence and uniqueness. □

The determinant remains invariant under conjugation of $\mathcal{T}$ and under the exchange of sheets $R \mapsto -R$. Therefore, the tail constructed from D_A belongs to the common mode. The orientation will appear in the sign with which the regional character corrects the phase.

14.5.4 Rules of the Regional Analytic Reader

Analytic continuation is fixed by the following rules.

Definition 14.13 (Regional Determinantal Reader)**.** The determinantal regional reader satisfies:

1. *degree compatibility*: cylindrical length is the analytic degree;
2. *renewal decomposition*: the finite return impulse and strict continuation belong to distinct additive summands;

3. *continuation normalization*: after recording the residue ρ_π just once, the surviving branch begins at the unit of the determinant line;
4. *concatenation covariance*: each elementary prolongation acts through $\bigwedge^2 \mathcal{T} = D_A$;
5. *orientation*: in the cardinal convention fixed for APP, the regional return belongs to the compensating sector and is subtracted from the fifth-degree action phase.

The third rule has mathematical content. The value 169 is recorded once as the amplitude of the return; it is not multiplied again at each prolongation. The strict continuation counts the sole line that continues and normalizes it by its unit. This is the distinction between a renewal recurrence and homogeneous iteration of the initial impulse.

The need to declare that normalization can be proved. For every $\lambda \in \mathbb{R}$, the family

$$F_\lambda(z) = 169z^6 + \lambda \frac{D_A z^7}{1 - D_A z}$$

preserves the same finite return and the same determinantal ratio between consecutive coefficients. The catalogue and the ratio alone do not distinguish λ. The unit of the determinant line fixes $\lambda = 1$ before $z = \alpha$ is evaluated. Thus, the normalization is not obtained by fitting the final value; it forms part of the definition of the character.

14.5.5 Return recurrence and closed sum

We define the coefficients κ_n by

$$\kappa_6 = 169, \qquad \kappa_7 = D_A, \qquad \kappa_{n+1} = D_A \kappa_n \quad (n \geq 7).$$

The first equality is the regional impulse; the next two describe the normalized continuation.

Theorem 14.14 (Graduated analytic realization)**.** *The analytic germ compatible with the rules of definition 14.13 is unique and equals*

$$\boxed{\mathscr{C}_\pi(z) = 169z^6 + \frac{D_A z^7}{1 - D_A z}.}$$

Their coefficients satisfy

$$\kappa_n = D_A^{n-6} \qquad (n \geq 7).$$

Proof. Write

$$F(z) = 169z^6 + \sum_{k \geq 1} c_k z^{6+k}.$$

The normalization of continuation and the determinantal covariance give

$$c_1 = D_A, \qquad c_{k+1} = D_A c_k.$$

By induction, $c_k = D_A^k$. The geometric sum yields

$$\sum_{k \geq 1} D_A^k z^{6+k} = \frac{D_A z^7}{1 - D_A z}.$$

No free coefficients remain. □

Since $0 < \alpha < 1$ and $0 < D_A < 1$,

$$0 < D_A \alpha < 1.$$

Consequently, $\mathscr{C}_\pi(\alpha)$ converges absolutely and its radius of convergence is $D_A^{-1} > 1$. Numerically,

$$D_A = 0.77512911924715643018888409648 02\ldots,$$

$$D_A\alpha = 0.00565639046986492673885079095469\ldots.$$

The speed of this contraction explains why the complete sum and its degree-seven truncation have the same first fifteen digits in the final chart.

14.5.6 The 5th-degree action character

The central block

$$\mathcal{B}_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}$$

has eigenvalues 9 and 5. The dodecaphasic cycle contributes rank 12; its step-three orbits have length four; and the complete census contributes the exact quotient

$$\frac{104976}{1944} = 54.$$

From these invariants the fifth-degree action character is fixed.

$$\boxed{H_5(\alpha,\varphi) = \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5.}$$

The four rational coefficients can be written as

$$\frac{9}{16} = \frac{\lambda_+}{4^2}, \qquad \frac{5}{9} = \frac{\lambda_-}{\lambda_+}, \qquad \frac{7}{48} = \frac{\frac{1}{2}\operatorname{tr}\mathcal{B}_c}{4\cdot 12}, \qquad \frac{1}{54} = \frac{1944}{104976},$$

with $(\lambda_+, \lambda_-) = (9, 5)$. These identities certify the provenance of the numbers used. The successive assignment of those invariants to degrees two, three, four, and five forms part of the analytic character; it does not follow from the mere existence of the finite catalog.

This precision removes a common ambiguity. A combination of invariants of the construction is an internal and reproducible definition; its naturality requires the reader rules specifying order, signs, and normalization. Here those rules are visible and are subject to the same negative controls as the rest of the construction.

14.5.7 Oriented phase and conjugate angular coordinate

The fifth-degree phase prior to return is

$$y_5 = \frac{\pi}{90}\big(H_5 + \alpha\big).$$

The complete regional character produces the correction $\mathscr{C}_\pi(\alpha)$. With the orientation fixed in definition 14.13, we define

$$\boxed{y_* = \frac{\pi}{90}\big(H_5 + \alpha\big) - 169\alpha^6 - \frac{D_A\alpha^7}{1 - D_A\alpha}.}$$

This is the primary formula. The sexagesimal unit does not come into play until applying the chart.

$$C_*^{\mathrm{HMT}} = \frac{180}{\pi}y_*.$$

Theorem 14.15 (Conjugate angular coordinate of the regional reader determinantal)**.** *With the dodecaphasic closure of α, $\varphi = (1+\sqrt{5})/2$ and the rules of the determinantal regional reader fixed, the phase y_* and its conjugate angular coordinate are determined without introducing the sought value. Their evaluation is*

$$\boxed{y_* = 0.037066226465838263984937794092306 38\ldots,}$$

$$\boxed{C_*^{\mathrm{HMT}} = 2.123738338968645724261951380393 36\ldots^\circ.}$$

Therefore, to fifteen decimal places,

$$\boxed{C_*^{\mathrm{HMT}} = 2.123738338968646^\circ.}$$

Proof. theorem 14.10 determines 169. The closure of α determines A, x, and $D_A = e^{-100\pi\alpha/9}$. theorem 14.14 determines the complete series. The formula for H_5 contains only α, φ, and declared structural invariants. Substituting these data into the expression for y_* gives the printed value. The decimal value of C_*^{HMT} occurs in none of the right-hand sides. □

The reduced action component after return is now as follows output:

$$\boxed{\bar{h}_{\mathrm{HMT}}^{\mathrm{ret}} = \frac{C_*^{\mathrm{HMT}}}{2} - \alpha = H_5 - \frac{90}{\pi}\mathscr{C}_\pi(\alpha).}$$

Numerically,

$$\bar{h}_{\mathrm{HMT}}^{\mathrm{ret}} = 1.05457181691503906113369058472430\ldots.$$

The inverse identity has not been used to introduce C_*^{HMT}; it is obtained after generating y_*.

14.5.8 Degree-7 truncation and exact remainder bound

The expression initially found,

$$y_7 = \frac{\pi}{90}(H_5 + \alpha) - 169\alpha^6 - D_A\alpha^7,$$

is the seventh-degree truncation of the full character. Produce

$$C_7 = 2.123738338968646002654038271039 19\ldots^\circ.$$

The omitted remainder is not an indeterminate term; it is the exact geometric tail.

$$\mathscr{C}_\pi(\alpha) - 169\alpha^6 - D_A\alpha^7 = \frac{D_A^2\alpha^8}{1 - D_A\alpha}.$$

Therefore,

$$\left|C_7 - C_*^{\mathrm{HMT}}\right| = \frac{180}{\pi}\frac{D_A^2\alpha^8}{1 - D_A\alpha} = 2.7839208689064583\ldots \times 10^{-16}\ ^\circ.$$

The recurrence thus transforms a seventh-degree approximation into a complete analytic realization and provides a closed-form bound for each subsequent truncation.

14.5.9 Uniqueness conditions for the regional selector and the analytic prolongation

The construction changes when any of its active components is removed. The following values are obtained without recalibrating the other terms:

variant	conjugate angular coordinate in degrees
$\rho_\pi = 168$	$2.12373833897729768639044 87\ldots$
$\rho_\pi = 169$	$2.12373833896864572426195 14\ldots$
$\rho_\pi = 170$	$2.12373833895999376213345 41\ldots$
without determinantal tail	$2.12373833896869494153016 75\ldots$
D_A replaced by 1	$2.12373833896863134099658 26\ldots$

These ablations do not in themselves constitute a probabilistic estimate. They demonstrate that the equivariant selector and the determinantal character are effective components of the output and cannot be removed while maintaining the same realization.

14.5.10 Spectral reconstruction and hexad-octad transition

The common phase and the oriented phase determine the two channels.

$$q_- = e^{-x+y_*}, \qquad q_+ = e^{-x-y_*}.$$

The invariants are recovered exactly.

$$q_- q_+ = D_A, \qquad \alpha = -\frac{9}{100\pi}\log D_A, \qquad C_*^{\mathrm{HMT}} = \frac{90}{\pi}\log\frac{q_-}{q_+}.$$

The first equality reads the common contraction; the third, the oriented separation of the sheets. The exchange $R \mapsto -R$ permutes q_+ and q_-, preserves D_A and reverses the sign of y_*.

For

$$S_{90}(q) = \frac{q^{90}}{1-q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1-q^{360}},$$

the hexad–octad transition functional is written entirely in the phase chart:

$$\Gamma_{6\to 8} = \frac{180}{\pi}xy_* + 12\big(S_{90}(q_-) - S_{90}(q_+)\big) - \big(S_{120}(q_-) - S_{120}(q_+)\big).$$

The evaluation produced by the coordinate C_*^{HMT} of theorem 14.15 is

$$\boxed{\Gamma_{6\to 8} = 0.27400767269445927474725526077 4\ldots.}$$

Thus, the internal value recognized in Dimensional Mechanics as the Barbero–Immirzi functional ceases to receive C_*^{HMT} as an independent literal: both descend from the same pair of phases generated in this chapter. The geometric and physical interpretation of $\Gamma_{6\to 8}$ belongs to the work on Dimensional Mechanics; its mathematical evaluation already belongs to the previously constructed interface.

14.5.11 Action prior and posterior to return

The fifth-degree character and the post-action component after return are two distinct values:

$$H_5 = 1.05457181764615446962582182943306\ldots,$$

$$\bar{h}_{\mathrm{HMT}}^{\mathrm{ret}} = 1.05457181691503906113369058472430\ldots.$$

The first is the local action before incorporating the regional character; the second is the oriented action remaining after the return. The correction that generates the conjugate angular coordinate prevents identifying them.

The metrological comparison must respect this distinction. The first value gives the mantissa

$$2\pi H_5 = 6.626070149999987926001110349899 47\ldots,$$

while the subsequent action gives

$$2\pi \bar{h}^{\mathrm{ret}}_{\mathrm{HMT}} = 6.626070145406254333510749847592 88\ldots.$$

In the International System, the value

$$h = 6.62607015 \times 10^{-34}\ \mathrm{J\,s}$$

is exact by definition [20]. By therefore,

$$2\pi H_5 - 6.62607015 = -1.2073998889650101\ldots \times 10^{-14},$$

and it is not an exact equality. The proximity of the value before the return is a remarkable numerical check; it does not authorize replacing the defining constant of the SI with the subsequent component or confusing the two HMT actions.

This result precisely determines the mathematical situation. The regional reader generates C^{HMT}_* and, from it, the functional $\Gamma_{6\to 8}$. The same calculation separates the Planck approximation produced by H_5 from the reduced action intervening in the conjugate angular coordinate. The separation does not weaken the construction: it eliminates an identification incompatible with the exact figures and converts every comparison into a falsifiable assertion of a well-defined type.

14.5.12 Relative transporter and spectral disjunction of the blocks

In the ordered basis of channels, let

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad P_{\pm} = \frac{I \pm R}{2}, \qquad B_0 = 7I + 2R, \qquad B_1 = A_{\mathrm{deg}} I + C^*_{\mathrm{deg}} R.$$

The split decomposition

$$xI + yR = \rho(x,y)\, e^{\eta(x,y)R}, \quad \rho(x,y) = \sqrt{x^2 - y^2}, \quad \eta(x,y) = \operatorname{artanh}(y/x)$$

constructs the unique transporter

$$T_{\mathrm{rel}} = \frac{\sqrt{(A_{\mathrm{deg}})^2 - (C^*_{\mathrm{deg}})^2}}{\sqrt{45}} \exp\left[\left(\operatorname{artanh}\frac{C^*_{\mathrm{deg}}}{A_{\mathrm{deg}}} - \operatorname{artanh}\frac{2}{7}\right) R\right], \qquad T_{\mathrm{rel}} B_0 = B_1.$$

In the spectral basis it acts by $9 \mapsto A_{\mathrm{deg}} + C^*_{\mathrm{deg}}$ and $5 \mapsto A_{\mathrm{deg}} - C^*_{\mathrm{deg}}$.

Theorem 14.16 (Spectral Disjunction of the Local and Angular Realizations)**.** *The spectra*

$$\mathrm{Spec}(B_0) = \{9, 5\}, \qquad \mathrm{Spec}(B_1) = \{A_{\mathrm{deg}} + C^*_{\mathrm{deg}}, A_{\mathrm{deg}} - C^*_{\mathrm{deg}}\}$$

are disjoint. Consequently,

$$\mathrm{Hom}_{B_0,B_1} := \{\Phi : \Phi B_0 = B_1 \Phi\} = \{0\}.$$

Proof. The rational bounds constructed for the angular coordinates give $7.29 < A_{\mathrm{deg}} < 7.30$ and $2.12 < C^*_{\mathrm{deg}} < 2.13$; therefore, $9.41 < A_{\mathrm{deg}} + C^*_{\mathrm{deg}} < 9.43$ and $5.16 < A_{\mathrm{deg}} - C^*_{\mathrm{deg}} < 5.18$. In the basis that diagonalizes R, each entry of an intertwiner is multiplied by the difference between an eigenvalue of B_0 and one of B_1; disjointness forces all of them to vanish. □

The relative transporter compares two blocks within the split algebra; the dodecaphasic–Witt and incidence intertwiners act between equivalent representations in their own spaces of residence. This separation positively types both operations and preserves their domains.

14.5.13 Generation chain $\mathcal{F}_\pi \to b_\pi \to \rho_\pi \to D_A \to C_*^{\mathrm{HMT}} \to \Gamma_{6\to 8}$: regional selection, determinantal prolongation and oriented coordinate

The entire procedure can be summarized as a chain of applications:

$$\begin{aligned} \mathcal{F}_\pi &\longmapsto b_\pi \longmapsto \rho_\pi = 169, \\ \alpha &\longmapsto A \longmapsto x \longmapsto D_A, \\ (\rho_\pi, D_A) &\longmapsto \mathscr{C}_\pi(\alpha), \\ (H_5, \mathscr{C}_\pi(\alpha)) &\longmapsto y_* \longmapsto C_*^{\mathrm{HMT}}, \\ (x, y_*) &\longmapsto (q_+, q_-) \longmapsto \Gamma_{6\to 8}. \end{aligned}$$

The first line belongs to the finite catalog; the second, to the common closure of α; the third, to the determinantal prolongation; the fourth produces the oriented coordinate; the fifth transports it toward the dimensional interface.

In this organization, α measures the common contraction of the transport, and C_*^{HMT} measures the oriented separation of its two sheets. The regional return adds no external constant: it selects a finite amplitude and prolongs it through the determinant already fixed by α. The chart in degrees is subsequent. The primary object is the pair of phases (x, y_*).

An exhaustive verification reconstructs the five regions directly from the catalogue, traverses the actions of $\mathfrak{S}_5$ and $\mathfrak{S}_3$, checks the recurrence, and sums the series. The input of α is the exact output of its dodecaphasic closure, not a transcribed metrological digit. The verification keeps the catalogue theorems, reader rules, and external comparison separate; therefore, no experimental comparison intervenes in the generating function.

14.6 Determinantal structure and oriented action sections

The publications of π, φ, e, α arise from the APP–TRIT–TPK state of sections 1.23–11.6. The dodecaphasic register of 11.4 preserves its orientation, its residues and quotients and the memory of the return (4.34). Two successive operations are defined on that register: a local norm determines the valuation of the action section, and a character with regional continuation determines its coordinates before and after the return. Both operations transmit their rules and normalizations to the angular construction.

14.6.1 Local quotient and determinantal norm

The local step-three block of the dodecaphasic register, identified in 11.4.8, is

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad G_H = \mathbb{Z}^4 / H_4 \mathbb{Z}^4. \tag{14.59}$$

The quotient corresponds to this local block. The three blocks of the complete register preserve their positions; the norm operation that follows acts on the sheets of G_H.

Lemma 14.17 (Structure of the local quotient)**.** *The Smith normal form of* H_4 *is* $\operatorname{diag}(1,2,2,4)$. *Consequently,*

$$G_H \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |G_H| = 16.$$

Proof. The greatest common divisor of the entries is one. The minors of order two are even and one has value -2, so their greatest common divisor is two. The identities $H_4 H_4^{\mathsf{T}} = 4I$ and $\det H_4 = -16$ show that the cofactors equal ± 4; the third determinantal divisor is four. The fourth is 16. The successive quotients of $1, 2, 4, 16$ are $1, 2, 2, 4$; their product determines the order of the quotient. □

Definition 14.18 (Determinantal action reader)**.** The scalar section α, constant on the sheets of G_H, and one application of the autoscale φ determine

$$\Sigma_H = \varphi\, \mathrm{N}_{G_H}(\alpha), \qquad \mathrm{N}_{G_H}(\alpha) = \prod_{g \in G_H} \alpha = \alpha^{16}. \tag{14.60}$$

Its decimal valuation is

$$\operatorname{ord}_{10}(\Sigma_H) = \lfloor \log_{10} \Sigma_H \rfloor.$$

The sixteenth power arises from the number of sheets once the multiplicative norm is fixed. The norm and the single application of φ are part of the declared reader: the order of the group, considered in isolation, admits other functionals.
