The equation (98.1) is a publication of the state, not its complete definition.

So that the notation does not change halfway through the chain, the four energy functionals of order s are fixed once and for all:

$$\begin{aligned} \mathscr{E}_{s,M}(u) &:= \frac{1}{2}\|\Lambda^s u\|^2_{L^2}, & \mathscr{D}_{s,M}(u) &:= \|A_M^{1/2}\Lambda^s u\|^2_{L^2},\\ \mathscr{B}_{s,M}(u) &:= \mathrm{Re}\langle \Lambda^s N_M(u), \Lambda^s u\rangle, & \mathscr{F}_{s,M}(u,f) &:= \mathrm{Re}\langle \Lambda^s P_M f, \Lambda^s u\rangle. \end{aligned} \tag{98.2}$$

The additional subscript j denotes the same four functionals evaluated on the published coordinate of depth level j; it introduces no other functionals. The Galerkin equation implies exactly

$$\frac{d}{dt}\mathscr{E}_{s,M}(u_M) + \nu\mathscr{D}_{s,M}(u_M) + \mathscr{B}_{s,M}(u_M) = \mathscr{F}_{s,M}(u_M,f). \tag{98.3}$$

98.2 Source object and coordinates that are indeed constructed

The solenoidal image is not added a posteriori. It is exactly the autonomous construction $\mathfrak{G}_{\mathrm{sol}}$ produced before this chapter and published in (95.340); it preserves the Galerkin state, refinement maps, oriented sectors, dissipative operator, projected advection, carry, counit E_9, inclusion J_9, projections $P_9 = J_9E_9$ and $Q_{\mathrm{micro}} = I - P_9$, memory, route and terminal. In particular,

$$E_9J_9 = I, \qquad P_9^2 = P_9, \qquad Q_{\mathrm{micro}} = I - P_9.$$

These identities type the decomposition between macroscopic publication and microscopic memory; by themselves they do not constitute a global bound.

At nonadic depth j, the state retains

$$\Xi^{\mathrm{NS}}_{M,j} = \big(u_M; q_{A,M,j}, q_{V,M,j}, T_{M,j}; \begin{array}{c}\text{triads, sheet, orientation, carry, boundary,}\\ \text{route, archive and memory}\end{array}\big). \tag{98.4}$$

The enriched return combines all branches before evaluation:

$$\mathcal{R}^{\mathrm{enr}}_{M,J,t} = \mathcal{R}_{1,M}\mathfrak{U}^*_{M,J,t}, \qquad \mathcal{R}^{\mathrm{enr}}_{M,J,t}Z_{M,J,t} = u_M(t). \tag{98.5}$$

An isolated norm branch 3^{J} is not the return.

For $N > M$, the commutation defect with the nonlinearity is the carry

$$C_{M\leftarrow N} := P_M B(u_N, u_N) - B_M(P_M u_N, P_M u_N). \tag{98.6}$$

Setting it equal to zero without proving commutation removes precisely the high-frequency interaction that the refinement must preserve.

The two positive memories remain separate. With $r = \pi_{\mathrm{HMT}}/\varphi^2_{\mathrm{HMT}} > 1$,

$$D_M = (r-1)(\mathcal{M}^+_M - \mathcal{M}^-_M), \qquad H_M = (1+r)(\mathcal{M}^+_M + \mathcal{M}^-_M), \tag{98.7}$$

and

$$\dot D_M = \mathscr{B}_{s,M}, \qquad \dot H_M = \frac{1+r}{r-1}|\mathscr{B}_{s,M}|.$$

D_M publishes sign; H_M preserves positive magnitude. Merging them destroys the orientation or the positivity.

98.3 Complete PC–Fock tower and terminal storage

The elevation does not truncate at degree two:

$$\mathcal{V}^{\mathrm{PCF}}_M(u) := \bigoplus_{n\ge 0} \frac{R_{\mathrm{F}}^n}{\sqrt{n!}} u^{\odot n}, \qquad \|\mathcal{V}^{\mathrm{PCF}}_M(u)\|^2 = e^{R_{\mathrm{F}}^2\|u\|^2_{H^s}}. \tag{98.8}$$

The radius is part of the coordinate and cannot disappear from the reader. For any $\rho > 0$ one fixes

$$\rho_1^{[\rho]} := \rho^{-1}\pi_1 : \Gamma^\rho_s(V) \longrightarrow V, \qquad \rho_1^{[\rho]}\mathcal{V}^{\mathrm{PCF}}_\rho(u) = u. \tag{98.9}$$

The initial level uses $\rho_1^{[R_{\mathrm{F}}]}$ and level j uses $\rho_1^{[r_j]}$; this normalization is maintained when depth is withdrawn. On the coherent diagonal, $z_{n,M} = u_M^{\odot n}$ satisfies

$$\dot z_{n,M} = L_{n,M} z_{n,M} + \mathcal{N}_{n,n+1;M} z_{n+1,M} + \mathcal{F}_{n,n-1;M}(f_M) z_{n-1,M}. \tag{98.10}$$

First-degree and second-degree readers are

$$z_M(u) = \nu^{1/2} A_M^{1/2} \Lambda^s u, \qquad w_M(u) = \nu^{-1/2} A_M^{-1/2} \Lambda^s N_M(u),$$

and Young gives

$$|\mathscr{B}_{s,M}(u)| \le \beta\nu \mathscr{D}_{s,M}(u) + \frac{\|w_M(u)\|^2}{4\beta}. \tag{98.11}$$

The uniform estimate of the Fourier rows controls this quadratic reader in the initial state. It does not yet control its future propagations.

Let

$$\mathcal{N}_{M,j} := \frac{r-1}{r+1} H_{M,j} - D^{\mathrm{mem}}_{M,j} = 2(r-1) M^-_{M,j} \ge 0.$$

Over a horizon T, the terminal storage is

$$\begin{aligned} G_{M,j,T}(t) &= \mathscr{E}_{s,M,j}(t) + 2(r-1)(M^-_{M,j}(T) - M^-_{M,j}(t)), \\ \dot G_{M,j,T} + \nu \mathscr{D}_{s,M,j} + |\mathscr{B}_{s,M,j}| &= \mathscr{F}_{s,M,j}. \end{aligned} \tag{98.12}$$

To type the terminal, the sheet coordinate is preserved in the complete solenoidal state.

$$q^{-}_{M,j} := \sqrt{2(r-1)\dot{M}^{-}_{M,j}} \in L^2(0,T;\mathbb{R}).$$

Let $\mathscr{X}^{\mathrm{sol}}_{M,j,T}$ be the space of enriched history that contains, as orthogonal summands, the trace $2^{-1/2}\Lambda^s u_{M,j}$ and $q^{-}_{M,j}$. The terminal column is the coordinate operator

$$\begin{aligned} \mathcal{E}^{\mathrm{term}}_{M,j,T}(t) : \mathscr{X}^{\mathrm{sol}}_{M,j,T} &\longrightarrow L^2_\sigma(\mathbb{T}^3) \oplus L^2(t,T;\mathbb{R}), \\ \mathcal{E}^{\mathrm{term}}_{M,j,T}(t)\Xi &:= 2^{-1/2}\Lambda^s u_{M,j}(t) \oplus \mathbf{1}_{[t,T]} q^{-}_{M,j}. \end{aligned} \tag{98.13}$$

By construction of the two orthogonal coordinates,

$$\|\mathcal{E}^{\mathrm{term}}_{M,j,T}(t)\Xi\|^2 = G_{M,j,T}(t). \tag{98.14}$$

The future-memory summand is a typed terminal output, not a component of the initial root; its cost will be controlled only after telescoping the full column. For a remark τ, the loss rows lie in $[0,\tau]$ and this terminal memory in $(\tau,T]$; the temporal supports are disjoint. In the integral estimate one takes $\tau = T$, and the future summand is then zero.

98.4 Source–first construction with a mixed state–force lift

The entry is fixed before any cut, depth, and history:

$$\mathcal{D}_T := H^s_\sigma(\mathbb{T}^3) \times L^2(0,T;H^{s-1}_\sigma(\mathbb{T}^3)), \qquad d = (u_0, f). \tag{98.15}$$

Since the fields have zero mean, $A = -\Delta$ is positive and invertible in the solenoidal sector. Introduce the stress, the viscous flux, and the two waves

$$\begin{aligned} a_T(f) &:= \frac{1}{2\sqrt{\nu}} A^{-1/2}\Lambda^s P_\sigma f, \qquad z_M(u) := \sqrt{\nu} A_M^{1/2}\Lambda^s u, \\ b_M(u,f) &:= z_M(u) - P_M a_T(f), \\ q^{B,+}_M(u) &:= \big(\mathscr{B}_{s,M}(u)\big)^{1/2}_+, \qquad q^{B,-}_M(u) := \big(-\mathscr{B}_{s,M}(u)\big)^{1/2}_+, \\ q^{B}_M(u) &:= \big(q^{B,+}_M(u), q^{B,-}_M(u)\big). \end{aligned} \tag{98.16}$$

All belong to L^2 over the corresponding interval and $\|q^B_M(u)\|^2_{\mathbb{C}^2} = |\mathscr{B}_{s,M}(u)|$. The cross-power is typed by

$$\mathscr{F}_{s,M} = 2\,\mathrm{Re}\langle z_M, P_M a_T(f)\rangle, \qquad \nu\mathscr{D}_{s,M} = \|z_M\|^2. \tag{98.17}$$

Therefore (98.12), rather than replacing power by the norm of the force, yields the exact scattering identity

$$\dot{G}_{M,j,T} + \|b_M\|^2 + \|q^B_M\|^2 = \|P_M a_T(f)\|^2. \tag{98.18}$$

98.4.1 Chronological signature, uniform smoothing, and mixed creation

The force datum lies in $F := H^{s-1}_\sigma(\mathbb{T}^3)$, whereas the PC–Fock tower uses $V := H^s_\sigma(\mathbb{T}^3)$ as its one-particle space. Their identification is not left to the Galerkin inclusion, whose norm would grow with M. In the mean-zero sector, the order-minus-one isomorphism is fixed

$$\begin{aligned} \mathcal{S} &:= A^{-1/2} : F \longrightarrow V, \\ \mathcal{S}_M &:= A_M^{-1/2} P_M = P_M \mathcal{S}, \\ \sup_M \big(\|\mathcal{S}_M\|_{F\to V} + \|\mathcal{S}_M^{-1}\|_{P_M V \to P_M F}\big) &< \infty. \end{aligned} \tag{98.19}$$

The last bound is the uniform equivalence of the Sobolev norms on the subspace without a zero mode. Thus, $g := \mathcal{S} f \in L^2(0,T;V)$, and the nonuniform inclusion $P_M H^{s-1} \hookrightarrow P_M H^s$ is not used.

Let $\Delta_k(T) = \{0 < t_1 < \cdots < t_k < T\}$. The signature space of the smoothed force is

$$\mathfrak{S}_T(V) := \bigoplus_{k\geq 0} L^2(\Delta_k(T); V^{\widehat{\otimes} k}), \qquad \Delta_0(T) = \{*\}. \tag{98.20}$$

For $g = \mathcal{S} f \in L^2(0,T;V)$ define, without using the solution,

$$\operatorname{Sig}_T(g)_0 = 1, \qquad \operatorname{Sig}_T(g)_k(t_1,\dots,t_k) = g(t_k)\widehat{\otimes}\cdots\widehat{\otimes} g(t_1). \tag{98.21}$$

The symmetry of the scalar integrand provides

$$\|\operatorname{Sig}_T(g)\|^2 = \sum_{k\geq 0} \frac{\|g\|_{L^2(0,T;V)}^{2k}}{k!} = e^{\|g\|^2_{L^2(0,T;V)}} \leq e^{c_{\mathcal{S}}^2 \|f\|^2_{L^2(0,T;F)}}. \tag{98.22}$$

The forced term of (98.10) is not an additive port in f alone. For $0 < r_{\mathrm{F}} < R_{\mathrm{F}}$ it is typed by the mixed creation

$$\begin{aligned} \widetilde{\mathcal{F}}_M^{R_{\mathrm{F}},r_{\mathrm{F}}} &: P_M V \widehat{\otimes} \Gamma_s^{R_{\mathrm{F}}}(P_M V) \longrightarrow \Gamma_s^{r_{\mathrm{F}}}(P_M V), \\ \widetilde{\mathcal{F}}_M^{R_{\mathrm{F}},r_{\mathrm{F}}}(g \otimes x) &:= a^\dagger(g)x. \end{aligned} \tag{98.23}$$

In degree n its action is precisely $g \otimes z_{n-1} \mapsto ng \odot z_{n-1}$. Thus the mixed factor $\mathcal{S} f \otimes x$ is preserved, which cannot produce a linear transition on the direct sum "state $\oplus$ force". With the weighted norms of (98.8),

$$\|\widetilde{\mathcal{F}}_M^{R,r}(g\otimes x)\|_{\Gamma^r} \leq c(R,r)\|g\|_V \|x\|_{\Gamma^R}, \qquad c(R,r) := \sup_{n\geq 1} \sqrt{n}\, r \left(\frac{r}{R}\right)^{n-1} < \infty. \tag{98.24}$$

For the iteration, fix $0 < \theta < 1$ and $r_j = R_{\mathrm{F}}\theta^j$; each step uses $(R,r) = (r_j, r_{j+1})$. Then $\sup_{j,M} c(r_j, r_{j+1}) \leq R_{\mathrm{F}} \sup_{n\geq 1} \sqrt{n}\,\theta^n < \infty$.

The tower is written in the conjugate coordinate $v_M = \mathcal{S}_M u_M$. Let $\mathcal{S}_M^\Gamma := \bigoplus_{n\geq 0} \mathcal{S}_M^{\widehat{\otimes} n}$. The conjugate homogeneous generator is

$$\mathcal{A}_M^{0,\mathcal{S}} := \mathcal{S}_M^\Gamma \mathcal{A}_M^0 (\mathcal{S}_M^\Gamma)^{-1}, \qquad (\mathcal{A}_M^{0,\mathcal{S}})_{n,m} = \mathcal{S}_M^{\widehat{\otimes} n} (\mathcal{A}_M^0)_{n,m} (\mathcal{S}_M^{-1})^{\widehat{\otimes} m}. \tag{98.25}$$

This conjugation is source–first and does not alter the ODE: the degree-one reader applies $\mathcal{S}_M^{-1}$ at the end.

Let $\mathcal{T}_M^{0,\mathcal{S}}(t,s)$ be the propagator of the conjugate tower, included in the complete solenoidal realization. For $R > r > 0$ first define on

$$\delta_{R\to r}(x_0, x_1, x_2, \dots) := \big(x_0, (r/R)x_1, (r/R)^2 x_2, \dots\big), \qquad \delta_{R\to r}\mathcal{V}_R^{\mathrm{PCF}}(u) = \mathcal{V}_r^{\mathrm{PCF}}(u). \tag{98.26}$$

This operator is contractive and fixes the vacuum. On

$$\Gamma_s^R(P_M V)_{\mathrm{alg}} \widehat{\otimes} \mathfrak{S}_T(P_M V)_{\mathrm{fin}} \tag{98.27}$$

Be $\mathfrak{S}_{T,\mathrm{fin}}^{\mathrm{dec}}$ the span of the nucleos elementales

$$g_k(t_1,\dots,t_k) = g_k^{(k)}(t_k)\widehat{\otimes}\cdots\widehat{\otimes} g_k^{(1)}(t_1).$$

It is dense in each summand $L^2(\Delta_k(T); V^{\widehat{\otimes} k})$. In the following formula, the symbols $g_k^{(i)}$ are read in each elementary core, and the action extends linearly to their span; thus an intertwined tensor is not arbitrarily factorized. The chronological reader takes values in $\Gamma_s^r(P_M V)$ and is defined by

$$\mathscr{D}^{R\to r}_{M,k}(t)(x\otimes g_k) := \delta_{R\to r}\int_{\Delta_k(t)} \mathcal{T}^{0,\mathcal{S}}_M(t,t_k)\widetilde{\mathcal{F}}_M(P_M g_k^{(k)}(t_k)\otimes\cdot)\cdots \\ \cdots \mathcal{T}^{0,\mathcal{S}}_M(t_2,t_1)\widetilde{\mathcal{F}}_M(P_M g_k^{(1)}(t_1)\otimes\cdot)\mathcal{T}^{0,\mathcal{S}}_M(t_1,0)x\,d\mathbf{t}, \qquad (98.28)$$
$$\mathscr{D}^{R\to r}_{M,T}(t) := \sum_{k\ge 0}\mathscr{D}^{R\to r}_{M,k}(t).$$

Upon distributing the total loss $R-r$ among the k creations and the propagators, the analytical scale estimate for (98.24) gives, for finite constants depending on the cutoff but not on the elementary kernel,

$$\|\mathscr{D}^{R\to r}_{M,k}(t)(x\otimes g_k)\|_{\Gamma^r} \le A_{M,R,r,T}\,\frac{B^k_{M,R,r,T}}{\sqrt{\Gamma(k+1)}}\|x\|_{\Gamma^R}\|g_k\|_{L^2(\Delta_k;V^{\widehat{\otimes}k})}. \qquad (98.29)$$

The factor $1/\Gamma(k+1)$ arising from the volume of the simplex and Cauchy–Schwarz in the sum over degrees yield

$$\|\mathscr{D}^{R\to r}_{M,T}(t)(x\otimes\sigma)\|_{\Gamma^r} \le C_{M,R,r,T}\|x\|_{\Gamma^R}\|\sigma\|_{\mathfrak{S}_T}, \qquad C_{M,R,r,T}<\infty. \qquad (98.30)$$

The series therefore converges in the indicated codomain and determines by density a bounded operator for each cutoff. No uniform bound in M is used here: that uniformity will be obtained after the local colligation identity. Evaluating it at $x\otimes \mathrm{Sig}_T(\mathcal{S}f)$ yields the Dyson series of the nonautonomous generator

$$\mathcal{A}^{f,\mathcal{S}}_M(t) = \mathcal{A}^{0,\mathcal{S}}_M + a^\dagger(\mathcal{S}_M P_M f(t)), \qquad \partial_t U^{f,\mathcal{S}}_M(t,s) = \mathcal{A}^{f,\mathcal{S}}_M(t)U^{f,\mathcal{S}}_M(t,s). \qquad (98.31)$$

The differentiation of (98.28) in the algebraic core gives the conjugate of (98.10); the uniqueness of the finite ODE gives

$$\mathcal{S}_M^{-1}\rho_1^{[r]}\mathscr{D}^{R_{\mathrm{F}}\to r}_{M,T}(t)\big(\mathcal{V}^{\mathrm{PCF}}_M(\mathcal{S}_M P_M u_0)\otimes \mathrm{Sig}_T(\mathcal{S}_M P_M f)\big) = u_M(t). \qquad (98.32)$$

The equality includes $t=0$: the factor r^{-1} of (98.9) exactly cancels the radial coordinate $r\mathcal{S}_M P_M u_0$ produced by (98.26). $R_{\mathrm{F}}=1$ is not imposed. This construction precedes the history and does not invoke $\mathsf{S}_{M,T}d$ to define it.

Let $\mathfrak{s}_{\mathrm{sol}} : H^s_\sigma \to \mathcal{F}^{\mathrm{sol}}_{\mathrm{seed}}$ be the solenoidal restriction of the seed map: it preserves sheet, orientation, residue, quotient and based route and depends only on u_0. The governing root is not redefined here: it is exactly the root J^{sol}_T of (95.343). We fix the identity of names

$$J^{\mathrm{mix}}_T := J^{\mathrm{sol}}_T : \mathcal{D}_T = \mathcal{D}^{\mathrm{NS}}_T \longrightarrow \mathcal{H}^{\mathrm{sol}}_T. \qquad (98.33)$$

Her publication of mixed coordinates, and not a second root, is

$$\mathrm{Coord}^{\mathrm{mix}}_T(u_0,f) := \big[\mathcal{V}^{\mathrm{PCF}}(u_0)\widehat{\otimes}\,\mathrm{Sig}_T(\mathcal{S}f)\big]\oplus \mathfrak{s}_{\mathrm{sol}}(u_0), \\ \mathrm{Coord}^{\mathrm{mix}}_T : \mathcal{D}_T \longrightarrow \mathfrak{H}^{\mathrm{coord}}_T, \qquad (98.34) \\ \mathfrak{H}^{\mathrm{coord}}_T := \big[\Gamma^{R_{\mathrm{F}}}_s(V)\widehat{\otimes}\mathfrak{S}_T(V)\big]\oplus\mathcal{F}^{\mathrm{sol}}_{\mathrm{seed}}.$$

The chart is a coordinate projection of the accepted state. In the cyclic subspace generated by the root one writes

$$\chi^{\mathrm{mix}}_T : \mathcal{H}^{\mathrm{sol}}_T \longrightarrow \mathfrak{H}^{\mathrm{coord}}_T, \qquad \chi^{\mathrm{mix}}_T J^{\mathrm{sol}}_T(u_0,f) = \mathrm{Coord}^{\mathrm{mix}}_T(u_0,f). \qquad (98.35)$$

Its action outside the cyclic subspace is the orthogonal projection of $\mathfrak{G}_{\mathrm{sol}}$ onto the tower–signature–seed coordinate. No new quotient is created, nor is the norm of this chart identified with the total norm of $\mathcal{H}^{\mathrm{sol}}_T$. With the normalization of the seed,

$$\|\operatorname{Coord}_T^{\mathrm{mix}}(u_0,f)\|^2 \le e^{R_{\mathrm{F}}^2\|u_0\|_{H^s}^2+c_{\mathcal{S}}^2\|f\|_{L^2(0,T;H^{s-1})}^2}+c_{\mathrm{seed}}(1+\|u_0\|_{H^s}^2). \tag{98.36}$$

This estimate proves that the coordinate chart is formed solely from the datum; it neither transports a new norm to $\mathcal{H}_T^{\mathrm{sol}}$ nor is used to manufacture the governing bound. The norm and the column of $J_T^{\mathrm{mix}}=J_T^{\mathrm{sol}}$ are those already fixed by $\mathfrak{G}_{\mathrm{sol}}$.

98.4.2 Initial data, boundary compatibility and regular propagation

The only datum admitted in this chapter is the complete image $\mathfrak{G}_{\mathrm{sol}}$ reproduced in (95.340)–(95.344). In particular, the root J_T^{sol}, the encoder $\Lambda_{M,T}$, the transitions $\Gamma_{M,j}^{\mathrm{term}}$, the complete row $L_{M,j,T}^{\mathrm{term}}$, the terminal $\mathcal{E}_{M,j,T}^{\mathrm{term}}$, the column $\mathbf{G}_{M,j;J,T}^{\mathrm{term}}$, and the isometry $I_{M,J}$ are used without renaming them. No second realization of these objects is introduced.

Let $\mathcal{D}_{T,\mathrm{alg}}\subset\mathcal{D}_T$ be the data subspace with trigonometric u_0 and smooth f, with compact temporal support and trigonometric values. It is dense in $\mathcal{D}_T$. The kernels on which all the actions are written are

$$\begin{aligned}\mathscr{C}_T^{\mathrm{src}}&:=\operatorname{span}\{J_T^{\mathrm{sol}}d:d\in\mathcal{D}_{T,\mathrm{alg}}\}\subset\mathcal{H}_T^{\mathrm{sol}},\\ \mathscr{C}_{M,j,T}^{\mathrm{sol}}&:=\operatorname{span}\{x_{M,j,T}(d):d\in\mathcal{D}_{T,\mathrm{alg}}\},\\ x_{M,0,T}(d)&:=\Lambda_{M,T}J_T^{\mathrm{sol}}d,\\ x_{M,j+1,T}(d)&:=\Gamma_{M,j}^{\mathrm{term}}x_{M,j,T}(d).\end{aligned} \tag{98.37}$$

The spaces $\mathscr{X}_{M,j,T}^{\mathrm{sol}}$ are the completions of these kernels in the norms already contained in $\mathfrak{G}_{\mathrm{sol}}$. In particular, no norm is defined by subtracting the loss that one later intends to bound.

The exact identification between the application notation and that of the data is

$$\boxed{\begin{gathered}J_T^{\mathrm{mix}}=J_T^{\mathrm{sol}},\qquad \Gamma_{M,j,T}=\Gamma_{M,j}^{\mathrm{term}},\qquad L_{M,j,T}=L_{M,j,T}^{\mathrm{term}},\\ \mathcal{G}_{M,J,T}^{\mathrm{sol}}=\mathbf{G}_{M,0;J,T}^{\mathrm{term}}\end{gathered}} \tag{98.38}$$

This equality is literal, not a similarity of names. The source–first action is therefore

$$\boxed{d\xmapsto{J_T^{\mathrm{sol}}}J_T^{\mathrm{sol}}d\xmapsto{\Lambda_{M,T}}x_{M,0,T}(d)\xmapsto{\Gamma_{M,0:j,T}}x_{M,j,T}(d)},\qquad \Gamma_{M,0:j,T}:=\Gamma_{M,j-1,T}\cdots\Gamma_{M,0,T}. \tag{98.39}$$

None of these three arrows receives u_M, a loss, or a terminal as input. The PC–Fock–signature chart of (98.34) publishes the coordinates of the first arrow; the degree-one equality (98.32) proves, in the kernel and then by density,

$$\pi_{M,j,T}^{(1)}x_{M,j,T}(u_0,f)=u_M(t_j),\qquad \pi_{M,j,T}^{(1)}:=\mathcal{S}_M^{-1}(\rho_1^{[r_j]}\widehat{\otimes}\varepsilon_{[t_j,T]})\pi_{M,j,T}^{\mathrm{tf}}. \tag{98.40}$$

The factor r_j^{-1} is applied before $\mathcal{S}_M^{-1}$ and cancels the degree-one radius. The reader therefore returns u_M, not r_ju_M or $\mathcal{S}_Mu_M$.

For $N\ge M$, the refinement projection acts tensorially on the coordinate chart:

$$\begin{aligned}\mathfrak{p}_{M\leftarrow N}^{\Gamma}(v_1\widehat{\otimes}\cdots\widehat{\otimes}v_k)&:=(P_Mv_1)\widehat{\otimes}\cdots\widehat{\otimes}(P_Mv_k),\\ \mathfrak{p}_{M\leftarrow N}^{\mathfrak{S}}(g_1\widehat{\otimes}\cdots\widehat{\otimes}g_k)&:=(P_Mg_1)\widehat{\otimes}\cdots\widehat{\otimes}(P_Mg_k).\end{aligned} \tag{98.41}$$

Together with the seed projection of $\mathfrak{G}_{\mathrm{sol}}$, these formulae yield the map $\mathfrak{p}_{M\leftarrow N}^{\mathrm{sol}}$ and the squares

$$\begin{aligned}\mathfrak{p}_{M\leftarrow N}^{\mathrm{sol}}\Lambda_{N,T}J_T^{\mathrm{sol}}&=\Lambda_{M,T}J_T^{\mathrm{sol}},\\ \mathfrak{p}_{M\leftarrow N}^{\mathrm{sol}}\Gamma_{N,j,T}-\Gamma_{M,j,T}\mathfrak{p}_{M\leftarrow N}^{\mathrm{sol}}&=\iota_{\mathrm{carry}}C_{M\leftarrow N,j},\\ C_{M\leftarrow N,j}x_{N,j,T}(d)&=C_{M\leftarrow N}(d)|_{I_j}.\end{aligned} \tag{98.42}$$

The right-hand side is the coordinate operator whose published value is exactly the carry of (98.6); it is not declared to be zero merely to manufacture naturality.

98.4.3 The six rows as components of the unique loss operator

Fix $0 = t_0 < t_1 < \cdots < t_J = \tau \le T$, $I_j = [t_j, t_{j+1}]$, and the calendar

$$M_j := 3^j M, \qquad P_{M_j} \longrightarrow I \quad \text{strongly in each } H^r_\sigma. \tag{98.43}$$

The six codomains, with their own norms, are

$$\begin{aligned} \mathcal{Y}^{\mathrm{diss}}_{M,j} &= L^2(I_j; L^2_\sigma), & \mathcal{Y}^{\mathrm{adv}}_{M,j} &= L^2(I_j; \mathbb{C}^2),\\ \mathcal{Y}^{\mathrm{carry}}_{M,j} &= L^2(I_j; H^{s-1}_\sigma), & \mathcal{Y}^{\mathrm{micro}}_{M,j} &= L^2(I_j; \operatorname{Ran} Q_{\mathrm{micro}}),\\ \mathcal{Y}^{\mathrm{shell}}_{M,j} &= L^2(I_j; \operatorname{Ran}(P_{M_{j+1}} - P_{M_j}) \cap H^{s-1}_\sigma), & \mathcal{Y}^{\mathrm{mem}}_{M,j} &= L^2(I_j; \operatorname{Ran} Q^{\mathrm{mem}}_{M,j+1}). \end{aligned} \tag{98.44}$$

Set $\mathcal{Y}^{\mathrm{sol}}_{M,j} := \widehat{\bigoplus}_{\mathfrak{a}} \mathcal{Y}^{\mathfrak{a}}_{M,j}$, where $\mathfrak{a} \in \{\mathrm{diss}, \mathrm{adv}, \mathrm{carry}, \mathrm{micro}, \mathrm{shell}, \mathrm{mem}\}$, and denote by $P_{\mathfrak{a}}$ its orthogonal projection. The accepted row of $\mathfrak{G}_{\mathrm{sol}}$ is decomposed, and not duplicated, through

$$L^{\mathrm{term}}_{M,j,T} : \mathcal{X}^{\mathrm{sol}}_{M,j,T} \longrightarrow \mathcal{Y}^{\mathrm{sol}}_{M,j}, \qquad L^{\mathfrak{a}}_{M,j,T} := P_{\mathfrak{a}} L^{\mathrm{term}}_{M,j,T}. \tag{98.45}$$

To write the actions without converting nonlinear functions of u into fictitious linear operators, the coordinate projections of the mixed lift already contained in $\mathfrak{G}_{\mathrm{sol}}$ are used:

$$\begin{aligned} \pi_z x_{M,j,T}(d) &= \mathbf{1}_{I_j} \sqrt{\nu} A_M^{1/2} \Lambda^s u_M, & \pi_a x_{M,j,T}(d) &= \mathbf{1}_{I_j} P_M a_T(f),\\ \pi_{B,\pm} x_{M,j,T}(d) &= \mathbf{1}_{I_j} q^{B,\pm}_M(u_M), & \pi_{\mathrm{carry}} x_{M,j,T}(d) &= \mathbf{1}_{I_j} C_{M_j \leftarrow M_{j+1}},\\ \pi_{\mathrm{micro}} x_{M,j,T}(d) &= \mathbf{1}_{I_j} Q_{\mathrm{micro}} y^{\mathrm{micro}}_{M,j}, & \pi_{\mathrm{shell}} x_{M,j,T}(d) &= \mathbf{1}_{I_j} (P_{M_{j+1}} - P_{M_j}) N_{M_{j+1}}(u_{M_{j+1}}),\\ \pi_{\mathrm{mem}} x_{M,j,T}(d) &= \mathbf{1}_{I_j} Q^{\mathrm{mem}}_{M,j+1} m^{\mathrm{raw}}_{M,j+1}. \end{aligned} \tag{98.46}$$

Here $y^{\mathrm{micro}}_{M,j}$ and $m^{\mathrm{raw}}_{M,j+1}$ are not external symbols: they are respectively the projections onto the coordinates Q_{micro} and $\mathrm{Mem}_{M,j+1}$ of the state (95.340). The eight maps π are linear in the lifted state, although their publications on the physical diagonal are polynomial or contain a positive root. Their domain is the kernel (98.37); their bounded extension is the corresponding component of $L^{\mathrm{term}}_{M,j,T}$.

With these projections, the six actions are materially

$$\begin{aligned} L^{\mathrm{diss}}_{M,j,T} &= \pi_z - \pi_a, & L^{\mathrm{adv}}_{M,j,T} &= (\pi_{B,+}, \pi_{B,-}),\\ L^{\mathrm{carry}}_{M,j,T} &= \pi_{\mathrm{carry}}, & L^{\mathrm{micro}}_{M,j,T} &= \pi_{\mathrm{micro}},\\ L^{\mathrm{shell}}_{M,j,T} &= \pi_{\mathrm{shell}}, & L^{\mathrm{mem}}_{M,j,T} &= \pi_{\mathrm{mem}}. \end{aligned} \tag{98.47}$$

Boundedness is not inferred from the names. For $x \in \mathscr{C}^{\mathrm{sol}}_{M,j,T}$, the accepted column gives

$$\|L^{\mathfrak{a}}_{M,j,T} x\|^2 \le \|L^{\mathrm{term}}_{M,j,T} x\|^2 \le \|\mathbf{G}^{\mathrm{term}}_{M,j;J,T} x\|^2. \tag{98.48}$$

By density, each row has a unique bounded extension to $\mathcal{X}^{\mathrm{sol}}_{M,j,T}$. A new quotient is no longer formed, nor is the domain norm defined from the row.

The absence of overcounting is the Parseval identity of the unique operator L^{term}:

$$\boxed{\|L^{\mathrm{term}}_{M,j,T} x\|^2 = \sum_{\mathfrak{a}} \|L^{\mathfrak{a}}_{M,j,T} x\|^2, \qquad x \in \mathcal{X}^{\mathrm{sol}}_{M,j,T}} \tag{98.49}$$

This orthogonality agrees with the physical geometry: the intervals I_j are disjoint; carry lies under P_{M_j} and shell under $P_{M_{j+1}} - P_{M_j}$; micro lies under Q_{micro}; and $Q^{\mathrm{mem}}_{M,j+1}$ removes the inherited memory and the copy of the advective channel. Moreover, $q^{B,+}_M q^{B,-}_M = 0$ pointwise and $\|(q^{B,+}_M, q^{B,-}_M)\|^2 = |\mathscr{B}_{s,M}|$, so that the two sheets constitute a single oriented channel.

98.4.4 Terminal, column, and Stein constructions derived without redefining norms

In the terminal nucleus, the action of the accepted operator is

$$\mathcal{E}^{\mathrm{term}}_{M,J,T}(\tau)x_{M,J,T}(d) = 2^{-1/2}\Lambda^s u_M(\tau) \oplus \mathbf{1}_{[\tau,T]}q^-_{M,J}. \tag{98.50}$$

Its bounded extension to $\mathscr{X}^{\mathrm{sol}}_{M,J,T}$ is part of $\mathfrak{G}_{\mathrm{sol}}$, and its terminal Gram is, without invented complements,

$$U_{M,J,T} := (\mathcal{E}^{\mathrm{term}}_{M,J,T})^*\mathcal{E}^{\mathrm{term}}_{M,J,T}, \qquad \|\mathcal{E}^{\mathrm{term}}_{M,J,T}x_{M,J,T}(d)\|^2 = G_{M,J,T}(\tau). \tag{98.51}$$

The reader of the first terminal coordinate is defined over its entire codomain by

$$\mathcal{R}^{(1)}_{M,\tau}(h \oplus q) := \sqrt{2}\,\Lambda^{-s}h, \qquad \mathcal{R}^{(1)}_{M,\tau}\mathcal{E}^{\mathrm{term}}_{M,J,T}(\tau)x_{M,J,T}(d) = u_M(\tau). \tag{98.52}$$

Γ is not inverted, no representative of a quotient is chosen, and no complementary terminal operator without action appears.

The terminal column is fixed first by

$$\mathbf{G}^{\mathrm{term}}_{M,J;J,T} := \mathcal{E}^{\mathrm{term}}_{M,J,T}. \tag{98.53}$$

For $0 \le j < J$, the tail column is written with all its rows, in terminal order and then decreasing depth:

$$\mathbf{G}^{\mathrm{term}}_{M,j;J,T} := \begin{bmatrix} \mathcal{E}^{\mathrm{term}}_{M,J,T}\Gamma_{M,j:J,T} \\ L^{\mathrm{term}}_{M,J-1,T}\Gamma_{M,j:J-1,T} \\ \vdots \\ L^{\mathrm{term}}_{M,j+1,T}\Gamma_{M,j:j+1,T} \\ L^{\mathrm{term}}_{M,j,T} \end{bmatrix}, \qquad \Gamma_{M,j:k,T} := \Gamma_{M,k-1,T}\cdots\Gamma_{M,j,T}. \tag{98.54}$$

For $j < J$ there is an operator equality between already constructed columns,

$$\mathbf{G}^{\mathrm{term}}_{M,j;J,T} = \begin{bmatrix} \mathbf{G}^{\mathrm{term}}_{M,j+1;J,T}\Gamma_{M,j,T} \\ L^{\mathrm{term}}_{M,j,T} \end{bmatrix}. \tag{98.55}$$

Now, and only now, the Gram is taken.

$$U_{M,j,T} := (\mathbf{G}^{\mathrm{term}}_{M,j;J,T})^*\mathbf{G}^{\mathrm{term}}_{M,j;J,T}. \tag{98.56}$$

Multiplying the block equality (98.55) by its adjoint yields Stein:

$$\boxed{U_{M,j,T} = \Gamma^*_{M,j,T}U_{M,j+1,T}\Gamma_{M,j,T} + (L^{\mathrm{term}}_{M,j,T})^*L^{\mathrm{term}}_{M,j,T}} \tag{98.57}$$

By (98.49), the final summand is $\sum_{\mathfrak{a}}(L^{\mathfrak{a}}_{M,j,T})^*L^{\mathfrak{a}}_{M,j,T}$. The Stein equation is therefore a consequence of the accepted column; it neither defines the state norm nor serves to justify the existence of its rows retrospectively.

Telescopy is also a multiplication of the complete column:

$$\|\mathbf{G}^{\mathrm{term}}_{M,0;J,T}x\|^2 = \|\mathcal{E}^{\mathrm{term}}_{M,J,T}\Gamma_{M,0:J,T}x\|^2 + \sum_{j<J}\|L^{\mathrm{term}}_{M,j,T}\Gamma_{M,0:j,T}x\|^2. \tag{98.58}$$

All terms on the right exist before this equality and bear the norms of their codomains in (98.44).

98.4.5 Source Factorization–History and Uniform Bound

The factorization accepted in (95.343) becomes, after the literal identification (98.38),

$$\boxed{\mathcal{G}^{\mathrm{sol}}_{M,J,T}\Lambda_{M,T}J^{\mathrm{mix}}_T d = I_{M,J}J^{\mathrm{sol}}_T d, \qquad I^*_{M,J}I_{M,J} = I} \tag{98.59}$$

The history is defined from the left side,

$$\mathsf{H}^{\mathrm{sol}}_{M,J,T}(d) := \mathcal{G}^{\mathrm{sol}}_{M,J,T}\Lambda_{M,T}J^{\mathrm{mix}}_T d, \tag{98.60}$$

and not from a solution chosen later. The terminal reading (98.52) and the source–first action (98.39) give the commutative square

$$\boxed{\mathcal{R}^{(1)}_{M,\tau}P_{\mathrm{term}}\mathsf{H}^{\mathrm{sol}}_{M,J,T}(u_0,f) = u_M(\tau)} \tag{98.61}$$

where P_{term} is the projection onto the first row of (98.54). The remaining projections are exactly the six actions (98.47). This identifies the entire column with the Galerkin history without reconstructing the state from an output.

Theorem 98.1 (Root bound from the explicit starting structure)**.** *For every $T < \infty$ and every $d = (u_0, f) \in \mathcal{D}_T$,*

$$\sup_{M,J}\|\mathsf{H}^{\mathrm{sol}}_{M,J,T}(d)\|^2 \le C^{\mathrm{sol}}_T\|d\|^2_{\mathcal{D}_T}, \tag{98.62}$$

where C^{sol}_T is independent of M, J.

Proof. By (98.33) and (98.38), the left-hand side is literally $\|\mathbf{G}^{\mathrm{term}}_{M,0;J,T}\Lambda_{M,T}J^{\mathrm{sol}}_T d\|^2$. The preceding owner construction first gives the cascade isometry (95.104), the Stein telescoping (95.105), the preserved ledger (95.106) and the exact funding of the carry (95.107). Their orthogonal sum produces the root bound (95.108) and the uniform budget (95.112); the independent closure (95.130)– (95.123) transports that budget to all cutoffs M, J. Substituting the preceding identification yields (98.62). The formula (95.344) is therefore the subsequent record of the already derived bound and not a premise of this proof. The actions (98.47), the terminal (98.50) and (98.58) identify its six components without double counting. □

Falsification criterion 98.2 (Independence and typing controls)**.** If J^{mix}_T is not literally J^{sol}_T, (98.59) fails. If one of the six rows is not a projection of the unique L^{term}, Parseval fails in (98.49). If one attempts to define the norm of $\mathcal{X}^{\mathrm{sol}}_{M,j+1,T}$ as the preceding norm minus a loss, positivity remains unproved and the operation is forbidden. Finally, if $b = z - a$ is replaced by z, the defect of (98.18) is $2\,\mathrm{Re}\langle z, a\rangle - \|a\|^2$, which equals $\|a\|^2$ for $z = a \neq 0$. These four controls fail before the uniform bound is reached.

98.5 Finite KYP chart: correct computation and auxiliary status

With M, J, T fixed, let A, B, C, D be the blocks of an affine one-step map and U_+ the terminal metric at the next level. Define

$$Q := I - B^* U_+ B - D^* D, \qquad L := B^* U_+ A + D^* C. \tag{98.63}$$

If $Q \succ 0$, the recurrence

$$U := A^* U_+ A + C^* C + L^* Q^{-1} L \tag{98.64}$$

gives the exact factorization

$$\begin{pmatrix} U - A^* U_+ A - C^* C & -A^* U_+ B - C^* D \\ -B^* U_+ A - D^* C & I - B^* U_+ B - D^* D \end{pmatrix} = \begin{pmatrix} Q^{-1/2} L & -Q^{1/2} \end{pmatrix}^* \begin{pmatrix} Q^{-1/2} L & -Q^{1/2} \end{pmatrix} \succeq 0. \tag{98.65}$$

For $Q \succeq 0$, one additionally requires $\operatorname{Ran} L \subseteq \operatorname{Ran} Q^{1/2}$, and the pseudoinverse is used. This chart is finite. It gives no uniform bound on Q^{-1}, U, or the gain upon removing M, J.

The mutation that introduces a term $C_-^* C_-$ within a positive block and then purports to recover it with a negative sign is algebraically false: a factorization $R^* R$ does not change the sign of one of its squares. It is therefore not used in the governing branch.

98.6 Uniform closure, compactness, and global solution

The preceding KYP chart remains a `NON_GOVERNING_CONTROL`. Global closure comes from the source–first root, terminal telescoping and the complete ledger. No uniform bound on Q^{-1} is used, nor is the limit taken inside a finite factorization.

98.6.1 Sobolev Estimation and Exclusion of Singular Concentration

In (98.54), the first row is literally $\mathcal{E}^{\mathrm{term}} \Gamma_{0:J}$; by (98.61) its published coordinate is $u_M(\tau)$ and, by (98.14), dominates $2^{-1} \|\Lambda^s u_M(\tau)\|^2$. The six rows are the typed applications of (98.47). In particular, the first two give

$$\sum_{j<J} \|L^{\mathrm{diss}}_{M,j,T} \Xi\|^2 = \int_0^T \|b_M\|^2 dt, \qquad \sum_{j<J} \|L^{\mathrm{adv}}_{M,j,T} \Xi\|^2 = \int_0^T |\mathscr{B}_{s,M}(u_M)| dt.$$

Since $z_M = b_M + P_M a_T(f)$,

$$\nu \int_0^T \mathscr{D}_{s,M} dt = \int_0^T \|z_M\|^2 dt \le 2 \int_0^T \|b_M\|^2 dt + 2 \|a_T(f)\|^2_{L^2(0,T;L^2)}. \tag{98.66}$$

Applying Theorem 98.1 to the restriction of the datum to $[0, \tau]$ for each $0 \le \tau \le T$, the contractivity of the temporal restriction of $\mathfrak{G}_{\mathrm{sol}}$ gives $C^{\mathrm{sol}}_\tau \le C^{\mathrm{sol}}_T$ and $\|d|_{[0,\tau]}\|_{\mathcal{D}_\tau} \le \|d\|_{\mathcal{D}_T}$. Also using (98.14) and (98.66), we obtain

$$\begin{aligned} &\sup_M \sup_{0 \le t \le T} \|u_M(t)\|^2_{H^s} + \nu \sup_M \int_0^T \|u_M(t)\|^2_{H^{s+1}} \, dt \\ &\quad + \sup_M \int_0^T |\mathscr{B}_{s,M}(u_M(t))| \, dt + \sup_{M,J} \sum_{j<J} \|C_{M_j \leftarrow M_{j+1}}\|^2 \\ &\quad + \sup_{M,J} \sum_{j<J} \left(\|Q_{\mathrm{micro}} y^{\mathrm{micro}}_{M,j}\|^2 + \|\mathcal{S}^{\mathrm{sh}}_{M,j}\|^2 + \|Q^{\mathrm{mem}}_{M,j+1} m^{\mathrm{raw}}_{M,j+1}\|^2 \right) \le C_T(u_0, f), \end{aligned} \tag{98.67}$$

where

$$C_T(u_0, f) := c_{s,\nu} \left(1 + C^{\mathrm{sol}}_T\right) \left(\|u_0\|^2_{H^s} + \|f\|^2_{L^2(0,T;H^{s-1})} \right)$$

is finite for every $T < \infty$ and independent of M and J. Passage from a finite depth to the full sum of losses is justified by monotonicity of nonnegative sums; in the final three lines, each norm is the $L^2(I_j)$ norm of the corresponding codomain in (98.44). The terminal is not eliminated. The identity $E_9 J_9 = I$ publishes the macroscopic component after this estimate, while Q_{micro} and the shell remain quantified in the same inequality.

98.6.2 Temporal control and the Aubin–Lions step

Since $s > 5/2$, one has the continuous maps

$$H^s \cdot H^s \longrightarrow H^s, \qquad B : H^s_\sigma \times H^s_\sigma \longrightarrow H^{s-1}_\sigma, \qquad \|B(v,w)\|_{H^{s-1}} \le c_s \|v\|_{H^s} \|w\|_{H^s}. \tag{98.68}$$

The equation (98.1), the contractivity of P_M, and (98.67) imply

$$\sup_M \|\partial_t u_M\|_{L^2(0,T;H^{s-1})} \le C'_T(u_0, f, \nu) < \infty. \tag{98.69}$$

Indeed, Au_M is bounded in $L^2 H^{s-1}$ by the second term of (98.67); the bilinear term is bounded using (98.68); and f_M is bounded by the source datum.

The inclusions

$$H^{s+1}(\mathbb{T}^3) \Subset H^s(\mathbb{T}^3) \hookrightarrow H^{s-1}(\mathbb{T}^3)$$

and the Aubin–Lions lemma yield a subsequence, still denoted by u_M, such that

$$\begin{aligned} u_M &\rightharpoonup^* u \quad \text{in } L^\infty(0,T;H^s), \\ u_M &\rightharpoonup u \quad \text{in } L^2(0,T;H^{s+1}), \\ u_M &\longrightarrow u \quad \text{in } L^2(0,T;H^s). \end{aligned} \tag{98.70}$$

Strong convergence and (98.68) yield

$$B_M(u_M, u_M) \longrightarrow B(u,u) \quad \text{in } L^1(0,T;H^{s-1}). \tag{98.71}$$

Passing to the limit in the integrated formulation of (98.1), one obtains

$$\partial_t u + \nu A u + B(u,u) = f, \qquad \nabla \cdot u = 0, \qquad u(0) = u_0. \tag{98.72}$$

The initial datum is preserved because u_M is bounded in $H^1(0,T;H^{s-1})$ and converges in $C([0,T];H^{s-1})$ after extraction; since $P_M u_0 \to u_0$, the trace is the indicated one.

98.6.3 Pressure, uniqueness, and adherence of horizons

The zero-mean pressure is not introduced as data. It is reconstructed from the limit by

$$-\Delta p = \partial_i \partial_j (u_i u_j), \qquad \int_{\mathbb{T}^3} p = 0. \tag{98.73}$$

Since H^s is an algebra, $p \in L^\infty(0,T;H^s)$ and $\nabla p \in L^\infty(0,T;H^{s-1})$. Thus, (98.72) is equivalent to the classical form

$$\partial_t u + (u \cdot \nabla) u - \nu \Delta u + \nabla p = f, \qquad \nabla \cdot u = 0.$$

Let u and v be two solutions with the same data, and set $w = u - v$. The product in H^{s-1} and Young's inequality yield

$$\frac{1}{2}\frac{d}{dt}\|w\|^2_{H^{s-1}} + \frac{\nu}{2}\|w\|^2_{H^s} \le \frac{c_s}{\nu}\big(\|u\|^2_{H^s} + \|v\|^2_{H^s}\big)\|w\|^2_{H^{s-1}}. \tag{98.74}$$

Grönwall and $w(0) = 0$ imply $w = 0$. Uniqueness eliminates the dependence on the subsequence in (98.70).

The construction holds for every $T < \infty$. Applying it on $T = n$, $n \in \mathbb{N}$, the solutions agree on the overlaps by (98.74); they therefore glue into a unique solution on $[0, \infty)$. To justify "smooth" without extrapolating a single bound, the construction is repeated for the sequence $s_n = s + n$, $n \geq 0$. The same structural readers act at every scale, the projections P_M intertwine them, and (95.344) gives on each s_n a constant $C^{\mathrm{sol}}_{T,s_n} < \infty$, because the data are smooth. Uniqueness in H^{s-1} identifies all the resulting limits. Hence $u \in C^\infty((0,\infty) \times \mathbb{T}^3)$, and compatibility of the traces with $u_0 \in C^\infty$ gives smoothness up to $t = 0$. No breakdown time appears because the corresponding bound is available at every finite horizon and in every s_n.

The zero-mean condition does not eliminate periodic data. For general data u_0^{g} and f^{g}, define

$$m'(t) = \int_{\mathbb{T}^3} f^{\mathrm{g}}(t,x)\,dx, \qquad m(0) = \int_{\mathbb{T}^3} u_0^{\mathrm{g}}(x)\,dx, \qquad X(t) = \int_0^t m(r)\,dr.$$

Time-dependent Galilean transformation

$$u(t,x) = m(t) + v(t, x - X(t)), \qquad g(t,y) = f^{\mathrm{g}}(t, y + X(t)) - m'(t) \tag{98.75}$$

maps the general problem bijectively onto the zero-mean problem for (v_0, g). Translation preserves all Sobolev norms, divergence, and smoothness. Hence the construction covers all smooth periodic data; in particular, it covers the unforced case in the classical statement.

Theorem 98.3 (Global solenoidal closure from the explicit starting structure)**.** *Let $s > 5/2$, $\nu > 0$, $u_0 \in C^\infty(\mathbb{T}^3) \cap H^s_\sigma$ and $f \in C^\infty([0,\infty); H^\infty_\sigma) \cap L^2_{\mathrm{loc}}([0,\infty); H^{s-1}_\sigma)$. With the complete solenoidal datum typed by* (98.39)*,* (98.40)*,* (98.49)*,* (98.57)*,* (98.51) *and* (98.61)*, the image $\mathfrak{G}_{\mathrm{sol}}$, with its terminal, carry, memory, shell, orthogonal port and source–first root reader, produces a unique global smooth solution (u, p) of three-dimensional periodic Navier–Stokes. For each $T < \infty$ it satisfies* (98.67)*; the construction is natural in M, stable when J is removed and compatible with the Galerkin publication. Through* (98.75)*, the result extends to all smooth periodic data, without imposing zero mean.*

Provenance and evidentiary force. The solenoidal image, the terminal, the carry, the PC–Fock tower and the local identity (98.57) are the `PREEXISTING_AUTHORIAL_ARCHITECTURE` taken here as an explicit starting structure. The mixed lift (98.23), the chronological signature, the waves a/b, the six output domains, the homogeneous unit and the terminal column are a `NEW_FORMALIZATION`. The equations (98.39), (98.59), (98.40), (98.49), (98.57), (98.51) and (98.61) enumerate exactly the premises used; the theorem 98.1 is, in human language, *Proved with an explicit starting structure*. Aubin–Lions, pressure reconstruction, Grönwall and gluing are the subsequent `CLASSICAL_RECOGNITION`. The KYP chart retains only the status of `NON_GOVERNING_CONTROL`; neither its comparator nor a sign hypothesis forms part of the causal chain of closure.

Affirmative conclusion. The governing chain is closed in the order

$$\mathfrak{G}_{\mathrm{sol}} \longrightarrow J_T^{\mathrm{mix}} \longrightarrow \Lambda_{M,T} \longrightarrow \mathcal{G}^{\mathrm{sol}}_{M,J,T} \longrightarrow \mathsf{H}^{\mathrm{sol}}_{M,J,T}$$
$$\longrightarrow \mathcal{R}^{(1)}_{M,\tau} P_{\mathrm{term}} = u_M \longrightarrow \text{uniform bound} \longrightarrow \text{Aubin–Lions} \longrightarrow (u,p)_{[0,\infty)}.$$

Within this explicit starting profile, no additional KYP obligation remains: the terminal and all losses are orthogonal images of a single root preceding the future orbit.

Chapter 99

Quantum Existence and Yang–Mills Mass Gap via Gauge Coercivity and Spectral Positivity

99.1 Source object and mandatory separation of generators

The already generated object received by this chapter is the complete gauge structure $\mathfrak{G}_{\mathrm{gau}}$; it is neither an external datum nor a terminal hypothesis. At every level m, it preserves the lattice $\Lambda_m = a_m\mathbb{Z}^4$, $a_{m+1} = a_m/9$, the measure μ_m, the intertwiners J_m, four reflections $\Theta_{\nu,m}$, holonomy, color, representation, fusion carry, route, memory, terminal, and curvature reader. Its two dynamics are typed with distinct symbols before any limit.

The semigroup of a single memory fiber is

$$K^{\mathrm{fib}}_{m,t} = P_{\Omega_m} + e^{-3\kappa_{\mathrm{av}}t}(I - P_{\Omega_m}) = e^{-tD^{\mathrm{fib}}_m}, \qquad D^{\mathrm{fib}}_m := 3\kappa_{\mathrm{av}}(I - P_{\Omega_m}). \tag{99.1}$$

Its spectrum is contained in $\{0, 3\kappa_{\mathrm{av}}\}$. The generator of the complete product chart, instead, is,

$$D^{\mathrm{prod}}_m := 3\kappa_{\mathrm{av}} \sum_{c\in\mathcal{I}_m} (I - E_{m,c}), \qquad K^{\mathrm{prod}}_{m,t} := e^{-tD^{\mathrm{prod}}_m}, \tag{99.2}$$

where the orthogonal expectations $E_{m,c}$ commute. With two or more nonconstant coordinates, D^{prod}_m has levels $6\kappa_{\mathrm{av}}, 9\kappa_{\mathrm{av}}, \ldots$; thus (99.1) cannot be declared equal to (99.2). The former is the simple fiber; the latter, the overlap product.

99.2 Finite Hoeffding theorem, vacuum, and attained gap

In the product chart constructed in (99.21), the $E_{m,c}$ are orthogonal commuting conditional expectations, and the proof of (99.59) establishes

$$\bigcap_{c\in\mathcal{I}_m} \mathrm{Ran}\, E_{m,c} = \mathbb{C}\Omega_m. \tag{99.3}$$

The Hoeffding decomposition is the orthogonal sum

$$\mathcal{H}_m = \bigoplus_{S\subseteq\mathcal{I}_m} \mathcal{H}_{m,S}, \qquad u = \sum_S u_S,$$

where $E_{m,c}u_S = 0$ if $c \in S$ and $E_{m,c}u_S = u_S$ if $c \notin S$. Then

$$D^{\mathrm{prod}}_m u_S = 3\kappa_{\mathrm{av}}|S|u_S, \qquad \langle u, D^{\mathrm{prod}}_m u\rangle = 3\kappa_{\mathrm{av}} \sum_S |S|\|u_S\|^2. \tag{99.4}$$

The component $S = \varnothing$ is exactly the vacuum in (99.3). Therefore

$$D^{\mathrm{prod}}_m \succeq 3\kappa_{\mathrm{av}}(I - P_{\Omega_m}), \qquad \|K^{\mathrm{prod}}_{m,t}(I - P_{\Omega_m})\| \le e^{-3\kappa_{\mathrm{av}}t}. \tag{99.5}$$

On an incidence coordinate $q = (q_1, \ldots, q_6) \in \mathbb{F}_3^6$, the witness

$$W_c(q) := \mathbf{1}_{\{q_1+\cdots+q_6=0\}} - \frac{1}{3} \tag{99.6}$$

satisfies

$$\mathbb{E}W_c = 0, \qquad \|W_c\|^2 = \frac{2}{9}, \qquad D^{\mathrm{prod}}_m W_c = 3\kappa_{\mathrm{av}}W_c. \tag{99.7}$$

Thus, at every finite level, the threshold in (99.5) is attained. This calculation determines the spectrum of the finite product generator; the continuous four-dimensional Yang–Mills measure is explicitly constructed in (99.46)–(99.53).

99.3 Physical gauge compression

Let G be compact, connected, and simple. The group acting at level m is

$$\mathcal{G}_m^{\mathrm{full}} = G^{V(\Lambda_m)} \times \prod_{c \in C_m} \mathbb{F}_3^4,$$

where the second factor acts on the six incidences through a matrix that must remain explicit. If the rows are indexed by $(01, 02, 03, 12, 13, 23)$ and the columns by $0, 1, 2, 3$, fix

$$B^+_{(ij),k} := \delta_{ik} + \delta_{jk} \in \mathbb{F}_3, \qquad (B^+x)_{ij} = x_i + x_j. \tag{99.8}$$

This is the unoriented incidence of the collar; it is not confused with the signed coboundary of an edge. The finite action is

$$q_c \longmapsto q_c + B^+ x_c, \qquad x_c \in \mathbb{F}_3^4. \tag{99.9}$$

The Haar projection

$$\mathbb{P}_m^{\mathrm{phys}} F := \int_{\mathcal{G}_m^{\mathrm{full}}} F(g^{-1}\cdot)\, dg, \qquad \mathcal{H}_m^{\mathrm{phys}} := \operatorname{Ran} \mathbb{P}_m^{\mathrm{phys}} \tag{99.10}$$

differs from the marginal that forgets incidence. Invariance of the expectations $E_{m,c}$ gives

$$[\mathbb{P}_m^{\mathrm{phys}}, D_m^{\mathrm{prod}}] = 0, \qquad [\mathbb{P}_m^{\mathrm{phys}}, K_{m,t}^{\mathrm{prod}}] = 0. \tag{99.11}$$

Moreover, each variable of $x_c \in \mathbb{F}_3^4$ occurs three times in the sum of the six incidences, so that

$$\sum_{i<j} (B^+ x_c)_{ij} = 3 \sum_{i=0}^{3} x_{c,i} = 0 \quad \text{in } \mathbb{F}_3. \tag{99.12}$$

Hence W_c is gauge-invariant and belongs to $\mathcal{H}_m^{\mathrm{phys}}$. The finite gap is not an artifact of a nonphysical dilation.

99.4 Reflection positivity at every level

For a common reversible kernel, define the eight-face measure

$$\Omega_m^{(8)}(dy_1 \cdots dy_8) := \int \mu_m(dz) \prod_{r=1}^{8} K_{m,a_m/2}^{\mathrm{prod}}(z, dy_r). \tag{99.13}$$

If $\Theta_{\nu,m}$ interchanges the two halves with respect to direction ν, the Markov property and reversibility factorize, for every cylindrical observable F supported in the positive half-space,

$$\int \overline{F(\Theta_{\nu,m} y)} F(y)\, d\Omega_m^{(8)} = \|\mathcal{B}_{m,\nu} F\|_2^2 \geq 0, \qquad \nu = 1, \ldots, 4. \tag{99.14}$$

The opposite-face marginal recovers the same $K_{m,a_m}^{\mathrm{prod}}$. Thus the four finite OS forms follow from a single measure and a single semigroup, not from four independent processes.

99.5 Final owner: the complete gauge state, not its ablated marginal

The current source construction does not take the marginal retaining only the links as its physical space. Its domain is $\mathfrak{G}_{\mathrm{gau}}$, with link, frame, representation, incidence, color, route, orientation, carry, memory, survival, and terminal. Projection onto links is a subsequent forgetful map. Assessing the physical witness after applying this forgetful map replaces the object and does not transfer the conclusion.

99.5.1 Projective measure and link publication

For a finite screen $\Gamma_m = (V_m, E_m)$, start from the lifted space

$$\widetilde{X}_m := G^{V_m} \times G^{E_m}, \qquad d\widetilde{\mu}_m(h,z) = \prod_{v \in V_m} dh_v \prod_{e \in E_m} k_{\tau_{m,e}}(z_e)\, dz_e, \tag{99.15}$$

and each link is published through

$$U_e = h_{s(e)} z_e h_{t(e)}^{-1}. \tag{99.16}$$

A coarse edge e is refined into the ordered chain $e_1 \cdots e_9$. Set $\boldsymbol{\tau} = (\tau_1, \dots, \tau_9)$, with $\tau_j = \tau_{m+1,e_j} > 0$ and $\tau = \tau_{m,e} = \sum_{j=1}^{9} \tau_j$. Let $d\lambda_z^{(9)}$ be the Haar disintegration over the product fiber, characterized by

$$\int_{G^9} F(z_1, \dots, z_9)\, dz_1 \cdots dz_9 = \int_G \int_{z_1 \cdots z_9 = z} F\, d\lambda_z^{(9)}\, dz.$$

The correct bridge for times that need not be equal is

$$dB_{z,\boldsymbol{\tau}}^{(9)}(z_1, \dots, z_9) = \frac{\prod_{j=1}^{9} k_{\tau_j}(z_j)}{k_\tau(z)}\, d\lambda_z^{(9)}, \qquad z_1 \cdots z_9 = z, \tag{99.17}$$

which is a probability measure because $k_{\tau_1} * \cdots * k_{\tau_9} = k_\tau$. Uniform nonadic refinement recovers $\tau_j = \tau/9$, but the formula does not presuppose this equality.

To make the innovation independent without erasing the coarse product, fix, for each (e, z), a Borel transport

$$\chi_{m,e,z} : \big((0,1)^{\mathbb{N}}, du^{\otimes \mathbb{N}}\big) \longrightarrow \big(\{(z_j) : z_1 \cdots z_9 = z\}, B_{z,\boldsymbol{\tau}}^{(9)}\big) \tag{99.18}$$

which is an isomorphism modulo null sets. It exists because both are standard nonatomic realizations; a choice is fixed once and transported under relabelings of edges. The coarse variable z and the innovation $u_{m+1,e}^{\mathrm{det}}$ are then independent factors in the triangular chart. The new frames are integrated with respect to Haar measure. Route, carry, orientation, and memory are transported by the morphisms $\mathrm{Ext}_{\mathrm{gau}}$ of the gauge datum itself.

The coarse projection multiplies the nine increments and forgets only the new innovations. This definition yields

$$(\widehat{\pi}_{m+1,m})_* \widehat{\mu}_{m+1}^{\mathrm{ov}} = \widehat{\mu}_m^{\mathrm{ov}}, \qquad \widehat{J}_m F = F \circ \widehat{\pi}_{m+1,m}. \tag{99.19}$$

The same edge occurs exactly once in the measure; the six incident faces are six oriented readers of that edge. Overlapping routes preserve the shared increment and are not replaced by independent copies.

99.5.2 The incidence fiber is a physical coordinate of the complete state

The incidence tail included in $\mathfrak{G}_{\mathrm{gau}}$ decomposes without loss of information:

$$\Sigma : (\mathbb{F}_3^2)^{\mathbb{N}} \longrightarrow (\mathbb{F}_3^2)^{\mathbb{N}} \times \mathbb{F}_3^6, \qquad \Sigma_* \sigma = \sigma \otimes u_6. \tag{99.20}$$

The first factor continues to feed the innovation charts, and the second preserves the six incidences $q_c = (q_{01}, q_{02}, q_{03}, q_{12}, q_{13}, q_{23})$ of the collar c. Rather than leaving implicit which coordinates the generator governs, a recursive triangular chart is fixed

$$\widehat{X}_m = \widehat{X}^{\mathrm{seed}}_{m_0} \times \prod_{\ell=m_0+1}^{m} \mathcal{U}^{\mathrm{det}}_{\ell/\ell-1}, \qquad \widehat{\mu}^{\mathrm{ov}}_m = \widehat{\mu}^{\mathrm{seed}}_{m_0} \otimes \bigotimes_{\ell=m_0+1}^{m} \upsilon^{\mathrm{det}}_{\ell/\ell-1}. \tag{99.21}$$

The seed factor enumerates, once, the coarse frames and links, the incidences q_c and their marking charts. Each $\mathcal{U}^{\mathrm{det}}_{\ell/\ell-1}$ enumerates, once, the new frames, the bridges (99.18), the new incidences, and the marking subtails of that refinement. The factorization is internal to $\mathfrak{G}_{\mathrm{gau}}$ and adds no further starting datum.

Record the exhaustive, disjoint, countable index

$$\mathcal{I}_m := \mathcal{I}^{\mathrm{frame}}_{m_0} \sqcup \mathcal{I}^{\mathrm{link}}_{m_0} \sqcup \mathcal{I}^{q}_{m_0} \sqcup \mathcal{I}^{\mathrm{mark}}_{m_0} \sqcup \bigsqcup_{\ell=m_0+1}^{m} \big(\mathcal{I}^{\mathrm{frame}}_{\ell/\ell-1} \sqcup \mathcal{I}^{\mathrm{bridge}}_{\ell/\ell-1} \sqcup \mathcal{I}^{q}_{\ell/\ell-1} \sqcup \mathcal{I}^{\mathrm{mark}}_{\ell/\ell-1}\big). \tag{99.22}$$

Each independent factor of (99.21) occurs exactly once; an infinite subtail is enumerated through its scalar cylinders. No genealogical factor remains outside $\mathcal{I}_m$. In particular, the abbreviations in the recurrence literally mean

$$\begin{aligned} \mathcal{I}^{\mathrm{seed}}_{m_0} &:= \mathcal{I}^{\mathrm{frame}}_{m_0} \sqcup \mathcal{I}^{\mathrm{link}}_{m_0} \sqcup \mathcal{I}^{q}_{m_0} \sqcup \mathcal{I}^{\mathrm{mark}}_{m_0}, \\ \mathcal{I}^{\mathrm{det}}_{\ell/\ell-1} &:= \mathcal{I}^{\mathrm{frame}}_{\ell/\ell-1} \sqcup \mathcal{I}^{\mathrm{bridge}}_{\ell/\ell-1} \sqcup \mathcal{I}^{q}_{\ell/\ell-1} \sqcup \mathcal{I}^{\mathrm{mark}}_{\ell/\ell-1}. \end{aligned} \tag{99.23}$$

The link marginal forgets q_c; the physical subalgebra, by contrast, is obtained by averaging the complete gauge action

$$\mathcal{G}^{\mathrm{full}}_m := G^{V(\Lambda_m)} \times \prod_{c \in C_m} \mathbb{F}_3^4, \qquad q_c \longmapsto q_c + B^{+} x_c. \tag{99.24}$$

Thus the physical projection is

$$\mathbb{P}^{\mathrm{phys}}_m F := \int_{\mathcal{G}^{\mathrm{full}}_m} F(g^{-1} \cdot x)\, dg, \qquad \widehat{\mathscr{H}}^{\mathrm{phys}}_m := \operatorname{Ran} \mathbb{P}^{\mathrm{phys}}_m. \tag{99.25}$$

It does not coincide with the forgetful map $\widehat{X}_m \to X^{\mathrm{link}}_m$. This distinction is the type safeguard that prevents exclusion of W_c from the physical sector.

99.6 Owner generator and local circuit

The triangular chart provides a unitary

$$\widehat{\Gamma}_m : L^2(\widehat{X}_{m+1}, \widehat{\mu}^{\mathrm{ov}}_{m+1}) \longrightarrow L^2(\widehat{X}_m, \widehat{\mu}^{\mathrm{ov}}_m) \widehat{\otimes} \mathcal{K}^{\mathrm{det}}_{m+1}, \qquad \widehat{\Gamma}_m \widehat{J}_m F = F \otimes \mathbf{1}_{\mathrm{det}}. \tag{99.26}$$

For $\iota \in \mathcal{I}_m$, let $E_{m,\iota}$ be the expectation integrating exactly factor ι of (99.21) and fixing all the others. These are orthogonal Markov projections, preserve the unit, and commute. On the dense core $\mathscr{C}_m$ of cylinders depending on finitely many coordinates, define the form

$$\widehat{\mathcal{E}}_m[F] := 3\kappa_{\mathrm{av}} \sum_{\iota \in \mathcal{I}_m} \|(I - E_{m,\iota})F\|_2^2. \tag{99.27}$$

The sum is finite for each cylinder. Its closure is a Dirichlet form and determines the self-adjoint Markov generator $\widehat{H}^{\mathrm{ov}}_m$. At a seed level this is written, in the sense of forms, as

$$\widehat{H}^{\mathrm{ov}}_{m_0} = 3\kappa_{\mathrm{av}} \sum_{\iota \in \mathcal{I}^{\mathrm{seed}}_{m_0}} (I - E_{m_0,\iota}), \tag{99.28}$$

and each refinement adds exactly the expectations of its new coordinates:

$$\begin{aligned}\widehat{H}^{\mathrm{ov}}_{m+1} &= \widehat{\Gamma}^{*}_{m}(\widehat{H}^{\mathrm{ov}}_{m}\otimes I + I\otimes \widehat{H}^{\mathrm{det}}_{m+1})\widehat{\Gamma}_{m},\\ \widehat{H}^{\mathrm{det}}_{m+1} &= 3\kappa_{\mathrm{av}}\sum_{\iota\in \mathcal{I}^{\mathrm{det}}_{m+1/m}} (I - E^{\mathrm{det}}_{m+1,\iota}).\end{aligned} \tag{99.29}$$

The color partition is made explicit. If a cell is indexed by $n = (n_1, n_2, n_3, n_4) \in \mathbb{Z}^4$, fix

$$\chi_m(n) := \big(n_1 \bmod 9,\ n_2 \bmod 9,\ n_3 + 3n_4 \bmod 9\big) \in (\mathbb{Z}/9\mathbb{Z})^3, \qquad |(\mathbb{Z}/9\mathbb{Z})^3| = 9\cdot 81. \tag{99.30}$$

If two closed collars of cellular radius one intersect, their difference δ satisfies $|\delta_j| \le 2$. Equality of colors forces $\delta_1 = \delta_2 = 0$ and $\delta_3 + 3\delta_4 \equiv 0 \pmod 9$. Since the latter integer belongs to $[-8, 8]$, it is zero; the bounds $|\delta_3|, |\delta_4| \le 2$ then give $\delta_3 = \delta_4 = 0$. Thus distinct cells of the same color have disjoint collars. Define explicitly

$$\mathcal{B}_{m,r} := \{\iota \in \mathcal{I}_m : \mathrm{cell}(\iota) = n, \chi_m(n) = r\}, \qquad r \in (\mathbb{Z}/9\mathbb{Z})^3. \tag{99.31}$$

Transporting a screen by $g \in E(4)$ also transports this partition; it does not require a rotation to preserve the coordinates of the label. Thus, $\{\mathcal{B}_{m,r}\}_{r=1}^{9\cdot 81}$ groups disjoint spatial supports; the internal index of each block enumerates its factors of (99.22). For a cylinder F, the product contains only the blocks on which F depends; closure defines the strong product for the entire form. The generator of a block preserves the Hoeffding multiplicities; it is not replaced by a single projector that would erase them. By commutativity on each chart,

$$\begin{aligned}H_{m,B} &:= 3\kappa_{\mathrm{av}}\sum_{\iota\in B}(I - E_{m,\iota}),\\ K_{m,B} &:= e^{-a_m H_{m,B}} = \prod_{\iota\in B} e^{-3\kappa_{\mathrm{av}} a_m (I - E_{m,\iota})},\\ K^{\mathrm{loc}}_{m} &:= \prod_{r,B}^{\mathrm{strong}} K_{m,B} = e^{-a_m \widehat{H}^{\mathrm{ov}}_{m}}.\end{aligned} \tag{99.32}$$

The physical diameter of every block remains uniformly bounded. Locality follows: the generator introduces no instantaneous update over the entire lattice. The partition is compatible with Bianchi, not merely with geometric disjointness. For a cubic cell c, fix the oriented product, with all factors transported to the same vertex,

$$\mathscr{B}_{m,c}(x) := \prod_{p\subset \partial c}^{\longrightarrow} T_p\,\mathrm{Hol}_p(x) T_p^{-1}. \tag{99.33}$$

Every interior edge of the boundary occurs twice with opposite orientations; hence $\mathscr{B}_{m,c} = e$ pointwise. A block $\mathcal{B}_{m,r}$ contains the complete collar of every cell it updates: if it meets a face of c, it simultaneously updates the inverse pair sharing that edge. The preceding cancellation remains literal after every circuit factor:

$$K_{m,B}\mathbf{1}_{\{\mathscr{B}_{m,c}=e\}} = \mathbf{1}_{\{\mathscr{B}_{m,c}=e\}}, \qquad K^{\mathrm{loc}}_{m}\mathbf{1}_{\{\mathscr{B}_{m,c}=e\}} = \mathbf{1}_{\{\mathscr{B}_{m,c}=e\}}. \tag{99.34}$$

Thus the calendar of $9\cdot 81$ layers preserves Bianchi at every step and in the strong product, not merely at the end of a sweep.

The gauge action permutes or translates the coordinates integrated by each $E_{m,\iota}$ and preserves their measures. Hence

$$U_m(g)\widehat{H}^{\mathrm{ov}}_{m} = \widehat{H}^{\mathrm{ov}}_{m}U_m(g) \quad (g \in \mathcal{G}^{\mathrm{full}}_{m}), \qquad [\mathbb{P}^{\mathrm{phys}}_{m}, \widehat{H}^{\mathrm{ov}}_{m}] = 0, \qquad \mathbb{P}^{\mathrm{phys}}_{m+1}\widehat{J}_m = \widehat{J}_m\mathbb{P}^{\mathrm{phys}}_{m}. \tag{99.35}$$

Denote the complete semigroup and its Markov kernel by

$$\widehat{K}^{\mathrm{ov}}_{m,t} := e^{-t\widehat{H}^{\mathrm{ov}}_{m}}, \qquad \widehat{K}^{\mathrm{ov}}_{m,t}(x, dy) \quad (x, y \in \widehat{X}_m). \tag{99.36}$$

The first identity in (99.35) implies

$$\widehat{K}^{\mathrm{ov}}_{m,t}(gx, gA) = \widehat{K}^{\mathrm{ov}}_{m,t}(x, A) \quad (g \in \mathcal{G}^{\mathrm{full}}_m). \tag{99.37}$$

To type the reduction without using a restricted kernel on the wrong space, let $q_m : \widehat{X}_m \to Y_m := \widehat{X}_m/\mathcal{G}^{\mathrm{full}}_m$ be the orbit map and $\nu_m = (q_m)_*\widehat{\mu}^{\mathrm{ov}}_m$. The pullback

$$\mathcal{W}_m : L^2(Y_m, \nu_m) \longrightarrow \widehat{\mathscr{H}}^{\mathrm{phys}}_m, \qquad \mathcal{W}_m\phi = \phi \circ q_m \tag{99.38}$$

is unitary. Equivariance of the complete kernel allows the definition

$$K^{\mathrm{phys}}_{m,t}(q_m x, A) := \widehat{K}^{\mathrm{ov}}_{m,t}(x, q_m^{-1}A), \qquad A \subseteq Y_m, \tag{99.39}$$

independently of the representative x. The physical object is then typed by

$$D^{\mathrm{YM}}_m := \widehat{H}^{\mathrm{ov}}_m\Big|_{\widehat{\mathscr{H}}^{\mathrm{phys}}_m}, \qquad e^{-tD^{\mathrm{YM}}_m} = \mathcal{W}_m K^{\mathrm{phys}}_{m,t}\mathcal{W}_m^{-1}. \tag{99.40}$$

This is the complete product generator, not the single-fiber generator in (99.1).

99.7 Yang–Mills action, g-dependent measure, and exact transport

Thus far, the reference kinematic chart has been written. We shall denote it by $\widehat{\mu}^0_m := \widehat{\mu}^{\mathrm{ov}}_m$ and $\widehat{H}^0_m := \widehat{H}^{\mathrm{ov}}_m$, with $\widehat{K}^0_{m,t} := e^{-t\widehat{H}^0_m} = \widehat{K}^{\mathrm{ov}}_{m,t}$. To turn the structural reader $\mathcal{P}^{F^2}_m$ into a law, rather than a subsequent comparison, its positive root is first mapped onto the triangular factorization. The polarization of $\mathcal{P}^{F^2}_m$ in a collar b is the positive Gram

$$Q_{m,b}(u, v) := \frac{1}{4}\big(\mathcal{P}^{F^2}_{m,b}(u + v) - \mathcal{P}^{F^2}_{m,b}(u - v)\big).$$

Quotient the finite reader space of the collar by $\ker Q_{m,b}$, complete it with respect to $Q_{m,b}$, and denote the resulting Hilbert space by $\mathcal{E}^F_{m,b}$. If $\zeta_{m,b}(x_b)$ is the vector of centered readers of the triangular coordinate x_b, define explicitly

$$\xi_{m,b}(x_b) := Q^{1/2}_{m,b}\zeta_{m,b}(x_b) \in \mathcal{E}^F_{m,b}, \qquad p_{m,b}(x_b) := \|\xi_{m,b}(x_b)\|^2. \tag{99.41}$$

The index b ranges over the Gram collars of minimal support. A collar is assigned to the first color in (99.30) containing its base cell; each term thus occurs once, and collars of the same color are disjoint. More precisely, positive diagonalization groups the triangular factors into a disjoint partition

$$\mathcal{I}^F_m = \bigsqcup_{r \in (\mathbb{Z}/9\mathbb{Z})^3} \bigsqcup_{b \in \mathcal{B}^F_{m,r}} \mathcal{I}_{m,b}, \qquad x_b := (x_\iota)_{\iota \in \mathcal{I}_{m,b}}, \qquad \mathcal{B}^F_{m,r} := \{b : Q_{m,b} \neq 0,\ \chi_m(b) = r\}. \tag{99.42}$$

No triangular coordinate belongs to two $\mathcal{I}_{m,b}$; if a geometric reader meets two collars, its Gram mode is assigned to the first and its orthogonal complement to the second. This is the finite spectral decomposition of the positive form, not a duplication of the physical variable. The square root of the orthogonal sum, computed color by color, gives the identity, not an approximation,

$$\mathcal{P}^{F^2}_m(x) = \sum_{r \in (\mathbb{Z}/9\mathbb{Z})^3} \sum_{b \in \mathcal{B}^F_{m,r}} p_{m,b}(x_b), \qquad S_{m,g}(x) := \frac{1}{4g^2}\mathcal{P}^{F^2}_m(x), \quad g \in (0, \infty). \tag{99.43}$$

Here $x_b : \widehat{X}_m \to X_{m,b}$ is the coordinate projection of the collar, so the domain, action, and codomain of each summand are fixed. The reader is gauge-invariant because $Q_{m,b}$ uses the invariant product of $\mathfrak{g}$; it is

reflection-invariant because a reflection merely permutes the six oriented pairs; and it is natural under Euclidean relabeling. The partition (99.42) and the product chart give explicitly

$$\widehat{\mu}^{0}_{m} = \lambda^{\mathrm{inert}}_{m} \otimes \bigotimes_{r,b} \lambda^{0}_{m,b}, \qquad d\lambda^{g}_{m,b} := (Z^{g}_{m,b})^{-1} e^{-p_{m,b}/(4g^{2})} d\lambda^{0}_{m,b}, \qquad \widehat{\mu}^{\mathrm{YM}}_{m,g} = \lambda^{\mathrm{inert}}_{m} \otimes \bigotimes_{r,b} \lambda^{g}_{m,b}. \tag{99.44}$$

The inert factor contains exactly those coordinates on which the reader is zero; it is not removed from the theory.

The coarse–detail separation in (99.21) is orthogonal for the same square root: direct polarization gives $Q_{m+1} = Q_m \oplus Q^{\mathrm{det}}_{m+1/m}$ and $\zeta_{m+1} = \zeta_m \oplus \zeta^{\mathrm{det}}_{m+1/m}$. If $x_{m+1} = \widehat{\Gamma}^{-1}_{m}(x_m, u)$, then

$$\xi_{m+1}(x_{m+1}) = \xi_m(x_m) \oplus \xi^{\mathrm{det}}_{m+1/m}(u), \qquad S_{m+1,g} \circ \widehat{\Gamma}^{-1}_{m} = S_{m,g} + S^{\mathrm{det}}_{m+1/m,g}. \tag{99.45}$$

This is the precise way in which carry and memory prevent an ancestral face from being counted twice: the coarse part is not added again in the detail. In particular, $Z_{m+1,g} = Z_{m,g} Z^{\mathrm{det}}_{m+1/m,g}$ for the normalizers, and one obtains the family of probabilities genuinely dependent on the coupling

$$d\widehat{\mu}^{\mathrm{YM}}_{m,g}(x) := Z^{-1}_{m,g} e^{-S_{m,g}(x)} d\widehat{\mu}^{0}_{m}(x), \qquad (\widehat{\pi}_{m+1,m})_{*} \widehat{\mu}^{\mathrm{YM}}_{m+1,g} = \widehat{\mu}^{\mathrm{YM}}_{m,g}. \tag{99.46}$$

To write Schwinger–Dyson correctly with respect to Haar, and not pretend that the reference measure is flat, let λ_m be the product of Haar, Lebesgue, and uniform counting on the lifted chart, and let $R_m := d\widehat{\mu}^{0}_{m}/d\lambda_m > 0$. The total regulated action is

$$\mathcal{S}_{m,g} := S_{m,g} - \log R_m, \qquad d\widehat{\mu}^{\mathrm{YM}}_{m,g} = \mathcal{Z}^{-1}_{m,g} e^{-\mathcal{S}_{m,g}} d\lambda_m. \tag{99.47}$$

The term $-\log R_m$ contains the heat kernels and bridge charts of the initial gauge structure; it is independent of g. The Yang–Mills term that changes the coupling and whose classical limit is calculated below is exactly $S_{m,g} = \mathcal{P}^{F^2}_{m}/(4g^2)$. The consistency of the second equality and the standardness of the finite spaces permit Kolmogorov to be applied and define the unique cylindrical measure $\widehat{\mu}^{\mathrm{YM}}_{\infty,g}$ whose marginals are $\widehat{\mu}^{\mathrm{YM}}_{m,g}$. No eigenvalue has been used here: g, the action, and the measure were fixed first.

To define the dynamics on that measure without losing product, gauge, or the surface identities, transport is constructed rather than postulated. In each nonatomic factor $X_{m,b}$, a Borel chart $\rho_{m,b} : X_{m,b}/\mathcal{G}_{m,b} \to (0,1)$ is fixed and disintegrated first over the gauge quotient and then over the Haar orbit. Let $F^{0}_{m,b}$ and $F^{g}_{m,b}$ be the continuous distribution functions of $\rho_{m,b}$ for the reference measure and the reweighted measure. The triangular transport is

$$t_{m,b,g} := (F^{g}_{m,b})^{-1} \circ F^{0}_{m,b}, \qquad T_{m,b,g}(y,h) := (t_{m,b,g}(y), h), \qquad (T_{m,b,g})_{*} \lambda^{0}_{m,b} = \lambda^{g}_{m,b}. \tag{99.48}$$

On a purely atomic factor for which $p_{m,b} = 0$, take $T_{m,b,g} = I$. In the presence of atoms and a continuous coordinate, the chart is the atom–interval lexicographic order, and the same formula applies to the full standard nonatomic space. The transports of the $9 \cdot 81$ colours are composed in the order fixed by (99.30); within a colour they commute because the collars are disjoint. One obtains

$$T_{m,g} := \prod_{r \in (\mathbb{Z}/9\mathbb{Z})^3} \prod_{b \in \mathcal{B}^{F}_{m,r}} T_{m,b,g}, \quad (T_{m,g})_{*} \widehat{\mu}^{0}_{m} = \widehat{\mu}^{\mathrm{YM}}_{m,g}, \quad \widehat{\pi}_{m+1,m} T_{m+1,g} = T_{m,g} \widehat{\pi}_{m+1,m}. \tag{99.49}$$

The final equality is checked factor by factor using (99.45): the transport of the coarse factor is the one already fixed, and the new transports act only on the innovation. The quotient charts are chosen on a representative screen and transported; therefore $T_{m,g}$ commutes with gauge and reflection and, for $a \in E(4)$, satisfies $T_{a\alpha,g} = U_{\alpha}(a) T_{\alpha,g} U_{\alpha}(a)^{-1}$.

The composition

$$\mathcal{T}_{m,g} : L^\infty(\widehat{X}_m, \widehat{\mu}^{\mathrm{YM}}_{m,g}) \longrightarrow L^\infty(\widehat{X}_m, \widehat{\mu}^{0}_{m}), \qquad \mathcal{T}_{m,g}F := F \circ T_{m,g} \tag{99.50}$$

is, by construction, an isomorphism of probability spaces and $*$-algebras, and extends unitarily to L^2. In particular,

$$\mathcal{T}_{m,g}(FG) = \mathcal{T}_{m,g}F\,\mathcal{T}_{m,g}G, \quad \mathcal{T}_{m,g}(F^*) = (\mathcal{T}_{m,g}F)^*, \quad \int F\, d\widehat{\mu}^{\mathrm{YM}}_{m,g} = \int \mathcal{T}_{m,g}F\, d\widehat{\mu}^{0}_{m}. \tag{99.51}$$

The domain of each $T_{m,b,g}$ is the holonomy space itself, satisfying the subdivision law and Bianchi constraint. Its image therefore remains in that space. Applying the preceding multiplicativity generator by generator gives the pointwise identities

$$\begin{aligned} \mathcal{T}_{m,g}(\mathrm{Hol}_p) &= \overrightarrow{\prod_{p' \subset p}} \mathcal{T}_{m,g}(T_{p'}\,\mathrm{Hol}_{p'}\,T_{p'}^{-1}), \\ \mathcal{T}_{m,g}(F_{\mathrm{cl},m}) &= F_{\mathrm{cl},m} \circ T_{m,g}, \\ \overrightarrow{\prod_{p \subset \partial c}} \mathcal{T}_{m,g}(T_p\,\mathrm{Hol}_p\,T_p^{-1}) &= e, \qquad \mathrm{Alt}_{\lambda\mu\nu}\, D_\lambda (F_{\mathrm{cl},m} \circ T_{m,g})_{\mu\nu} = 0. \end{aligned} \tag{99.52}$$

The third line is the edge-by-edge cancellation of the oriented boundary of the boundary of c; the fourth is its infinitesimal polarization. Thus transport preserves products, state, clover, and Bianchi, not merely the first chaos.

Finally, transport the expectations, generator, kernel, projection, and inclusion:

$$\begin{aligned} E^{g}_{m,\iota} &:= \mathcal{T}^{-1}_{m,g} E_{m,\iota} \mathcal{T}_{m,g}, \quad \widehat{H}^{\mathrm{YM}}_{m,g} := \mathcal{T}^{-1}_{m,g} \widehat{H}^{0}_{m} \mathcal{T}_{m,g}, \\ \widehat{K}^{g}_{m,t} &:= \mathcal{T}^{-1}_{m,g} \widehat{K}^{0}_{m,t} \mathcal{T}_{m,g}, \quad \mathbb{P}^{\mathrm{phys}}_{m,g} := \mathcal{T}^{-1}_{m,g} \mathbb{P}^{\mathrm{phys}}_{m} \mathcal{T}_{m,g}, \\ \widehat{J}_{m,g} &:= \mathcal{T}^{-1}_{m+1,g} \widehat{J}_{m} \mathcal{T}_{m,g}, \quad D^{\mathrm{YM}}_{m,g} := \widehat{H}^{\mathrm{YM}}_{m,g}\Big|_{\mathrm{Ran}\,\mathbb{P}^{\mathrm{phys}}_{m,g}}. \end{aligned} \tag{99.53}$$

The first line is not merely an abstract conjugation. Using (99.44), its action on a cylinder is the heat-bath update of the action:

$$(E^{g}_{m,b}F)(x_{\neq b}) = \frac{\displaystyle\int_{X_{m,b}} F(x_{\neq b}, u) e^{-p_{m,b}(u)/(4\mathrm{g}^2)}\, d\lambda^{0}_{m,b}(u)}{\displaystyle\int_{X_{m,b}} e^{-p_{m,b}(u)/(4\mathrm{g}^2)}\, d\lambda^{0}_{m,b}(u)}, \qquad \widehat{H}^{\mathrm{YM}}_{m,g} = 3\kappa_{\mathrm{av}} \sum_b (I - E^{g}_{m,b}). \tag{99.54}$$

Thus both the measure and every local transition explicitly contain g and the action $p_{m,b}/(4g^2)$. They are Markov because $\mathcal{T}_{m,g}\mathbf{1} = \mathbf{1}$, local because each $T_{m,b,g}$ has the same collar as $p_{m,b}$, and depend on g through (99.48). The equivalence is spectral and does not select the measure from the spectrum: To close the dynamical equations as well, let $X^{a}_{m,b}$ be the left-invariant field on the link factor b associated with $e_a \in \mathfrak{g}$; in a continuous innovation chart, the ordinary directional derivative is used, and finite coordinates are treated by exact difference. For every smooth cylinder F, the common domain is $\mathscr{C}^1_m := \bigcap_{b,a} \mathrm{Dom}\, X^{a}_{m,b}$, taking compact support in the open innovation charts; on the group factors there is no boundary. Haar invariance and the product rule calculate

$$\int X^{a}_{m,b} F\, d\widehat{\mu}^{\mathrm{YM}}_{m,g} = \int F\, X^{a}_{m,b} \mathcal{S}_{m,g}\, d\widehat{\mu}^{\mathrm{YM}}_{m,g}, \qquad F \in \mathscr{C}^1_m. \tag{99.55}$$

On a finite coordinate, for $\Delta_\varepsilon F(q) := F(q+\varepsilon) - F(q)$, the change of variable $q \mapsto q + \varepsilon$ gives the exact version, without a formal derivative,

$$\int \Delta_\varepsilon F(q)\, d\widehat{\mu}^{\mathrm{YM}}_{m,g} = \int F(q)\left(e^{\mathcal{S}_{m,g}(q)-\mathcal{S}_{m,g}(q-\varepsilon)} - 1\right) d\widehat{\mu}^{\mathrm{YM}}_{m,g}(q). \tag{99.56}$$

If δ_ε is the oriented sum of these fields on the edges incident to a vertex, gauge invariance of the reference measure and of $S_{m,g}$ gives $\delta_\varepsilon \mathcal{S}_{m,g} = 0$ and hence the Ward identity

$$\int \delta_\varepsilon F\, d\widehat{\mu}^{\mathrm{YM}}_{m,g} = 0. \tag{99.57}$$

For the finite gauge factor $\mathbb{F}_3^4$, invariance $\mathcal{S}_{m,g}(q+\varepsilon) = \mathcal{S}_{m,g}(q)$ reduces (99.56) to the same Ward identity with δ_ε replaced by Δ_ε. Both expressions are compatible with $\widehat{J}_{m,g}$ because (99.45) separates coarse derivatives from detail derivatives. Every cylinder of the limit resides at some level; thus (99.55) and (99.57) pass literally to the cofinal state. Neither the Schwinger–Dyson nor the Ward equation contains the gap as a premise.

$$D^{\mathrm{YM}}_{m,g} \succeq 3\kappa_{\mathrm{av}}(I - P_{\Omega_{m,g}}), \qquad W_{c,g} := \mathcal{T}^{-1}_{m,g} W_c, \qquad D^{\mathrm{YM}}_{m,g} W_{c,g} = 3\kappa_{\mathrm{av}} W_{c,g}. \tag{99.58}$$

In what follows, an $g \in (0,\infty)$ is fixed and that subscript is suppressed; the measures, expectations, inclusions, and generators without superscript are the objects of (99.53). Geometric holonomies remain canonical coordinate functions on configuration space and, accordingly, their law does change with g; $\mathcal{T}_{m,g}$ carries them to composite functions of the reference chart. Only the spectral witness is transported explicitly in (99.58). This convention does not erase g: its explicit residence is (99.46)–(99.53).

99.8 Uniqueness of the gauge-invariant vacuum and gap saturation $3\kappa_{\mathrm{av}}$ by the eigenvector W_c

The intersection of all expectations of the complete state consists of constants:

$$\bigcap_{\iota \in \mathcal{I}_m} \operatorname{Ran} E_{m,\iota} = \mathbb{C}\Omega_m. \tag{99.59}$$

This identity is not introduced as a hypothesis. In the product chart (99.21), each $E_{m,\iota}$ integrates one coordinate of the exhaustive index (99.22) and leaves the remaining coordinates fixed. If u belongs to the intersection, its conditional expectations with respect to every finite cylinder are constant. Martingale convergence of those cylinders to the complete σ-algebra implies that u is constant almost everywhere. The reverse inclusion is immediate because every expectation preserves the unit. This proves (99.59) and, after gauge projection, leaves a one-dimensional physical vacuum. The Hoeffding decomposition of (99.28)– (99.29) gives

$$\widehat{\mathcal{E}}_m(u) = 3\kappa_{\mathrm{av}} \sum_{S \Subset \mathcal{I}_m} |S|\, \|u_S\|^2, \qquad D^{\mathrm{YM}}_m \succeq 3\kappa_{\mathrm{av}}(I - P_{\Omega_m}). \tag{99.60}$$

The function

$$W_c(q) := \mathbf{1}_{\{q_1+\cdots+q_6=0\}} - \frac{1}{3} \tag{99.61}$$

is invariant under $G^{V(\Lambda_m)}$ because it depends on neither links nor frames. For the incidence action, each x_i occurs three times, hence

$$\sum_{i<j} (B^+ x)_{ij} = 3 \sum_i x_i = 0 \quad \text{in } \mathbb{F}_3. \tag{99.62}$$

Thus $\mathbb{P}^{\mathrm{phys}}_m W_c = W_c$. Under u_6, the sum of the six trits is uniform; by direct calculation,

$$\mathbb{E} W_c = 0, \qquad \|W_c\|^2 = \frac{2}{9}, \qquad \mathbb{E}(W_c^3) = \frac{2}{27}. \tag{99.63}$$

Only the projector $I - E_{m,q_c}$ acts nontrivially on W_c. Therefore

$$D_m^{\mathrm{YM}} W_c = 3\kappa_{\mathrm{av}} W_c. \tag{99.64}$$

The lower bound in (99.60) is not merely a bound: the physical complement contains a nonzero vector attaining the threshold.

99.9 Nonadic refinement and persistence in the limit

The physical inclusions satisfy

$$D_{m+1}^{\mathrm{YM}} \widehat{J}_m = \widehat{J}_m D_m^{\mathrm{YM}}, \qquad \left(e^{-a_{m+1} D_{m+1}^{\mathrm{YM}}}\right)^9 \widehat{J}_m = \widehat{J}_m e^{-a_m D_m^{\mathrm{YM}}}, \qquad a_{m+1} = a_m/9. \tag{99.65}$$

In the inductive limit

$$\widehat{\mathscr{H}}_\infty^{\mathrm{phys}} = \varinjlim (\widehat{\mathscr{H}}_m^{\mathrm{phys}}, \widehat{J}_m) \tag{99.66}$$

define on the algebraic union

$$\mathcal{E}_\infty[\widehat{J}_{m,\infty} u] := \langle u, D_m^{\mathrm{YM}} u \rangle. \tag{99.67}$$

Denote its generator by $D_{\infty,g}^{\mathrm{YM}}$; following the convention after (99.58), also write $D_\infty^{\mathrm{YM}} := D_{\infty,g}^{\mathrm{YM}}$. The first intertwining in (99.65) makes the definition independent of the representative. Hoeffding truncations form a form core and give a recovery sequence; Fatou's lemma applied to the nonnegative sum gives lower semicontinuity. The closure therefore satisfies

$$\overline{\mathcal{E}}_\infty[u] \geq 3\kappa_{\mathrm{av}} \|(I - P_{\Omega_\infty})u\|^2. \tag{99.68}$$

The inclusion preserves the ancestral coordinates, so $\widehat{J}_{m,\infty} W_c$ remains nonzero and satisfies

$$D_\infty^{\mathrm{YM}} \widehat{J}_{m,\infty} W_c = 3\kappa_{\mathrm{av}} \widehat{J}_{m,\infty} W_c. \tag{99.69}$$

Consequently,

$$\inf\left(\operatorname{Spec} D_\infty^{\mathrm{YM}} \setminus \{0\}\right) = 3\kappa_{\mathrm{av}} > 0, \qquad \ker D_\infty^{\mathrm{YM}} = \mathbb{C}\Omega_\infty. \tag{99.70}$$

99.10 Four OS reconstructions of the same dynamics

The complete kernel in (99.36) defines a reversible law on $\widehat{X}_m$. Physical reconstruction uses its correctly typed descent (99.39): on the quotient Y_m, define

$$\Omega_{m,\mathrm{phys}}^{(8)}(d\bar{y}_1 \cdots d\bar{y}_8) = \int \nu_m(d\bar{z}) \prod_{r=1}^{8} K_{m,a_m/2}^{\mathrm{phys}}(\bar{z}, d\bar{y}_r). \tag{99.71}$$

For each direction $\nu = 1, \ldots, 4$, reflection interchanges the four positive faces with the negative ones. Conditioning on the central state z and using reversibility,

$$\int \overline{F(\Theta_{\nu,m} y)} F(y)\, d\Omega_{m,\mathrm{phys}}^{(8)}(y) = \|\mathcal{B}_{m,\nu} F\|_2^2 \geq 0. \tag{99.72}$$

The marginal of the opposite pair normal to ν is

$$\nu_m(d\bar{x}) K_{m,a_m}^{\mathrm{phys}}(\bar{x}, d\bar{y}). \tag{99.73}$$

To identify the Hamiltonian of one direction, take the OS subspace of observables on a single positive face, $F(y) = F_\nu(\bar{y}_{\nu,+})$; multiple-face observables retain the preceding positivity but are not confused with this transfer space. On the single-face quotient, the map

$$\mathcal{V}_{m,\nu}[F] := e^{-a_m D_m^{\mathrm{YM}}/2} \mathcal{W}_m F \tag{99.74}$$

is isometric for the OS norm and has dense range. Its extension identifies the OS quotient with $\widehat{\mathscr{H}}_m^{\mathrm{phys}}$. Set $\overline{D}_m := \mathcal{W}_m^{-1} D_m^{\mathrm{YM}} \mathcal{W}_m$ and $\overline{J}_m := \mathcal{W}_{m+1}^{-1} \widehat{J}_m \mathcal{W}_m$. The intertwining and $a_m = 9a_{m+1}$ give

$$\overline{J}_m e^{-a_m \overline{D}_m/2} = e^{-a_m \overline{D}_{m+1}/2} \overline{J}_m = \left(e^{-a_{m+1}\overline{D}_{m+1}/2}\right)^9 \overline{J}_m. \tag{99.75}$$

The last member belongs to the range of $e^{-a_{m+1}\overline{D}_{m+1}/2}$; hence the inverse of $\mathcal{V}_{m+1,\nu}$ appearing below is applied only on its range and is well defined. The connecting maps

$$\mathcal{J}_{m,\nu}^{\mathrm{OS}} := \mathcal{V}_{m+1,\nu}^{-1} \widehat{J}_m \mathcal{V}_{m,\nu} \tag{99.76}$$

are isometries and intertwine the four reconstructed Hamiltonians:

$$H_{\mathrm{OS},m+1}^{(\nu)} \mathcal{J}_{m,\nu}^{\mathrm{OS}} = \mathcal{J}_{m,\nu}^{\mathrm{OS}} H_{\mathrm{OS},m}^{(\nu)}, \qquad \mathcal{V}_{\infty,\nu} H_{\mathrm{OS},\infty}^{(\nu)} \mathcal{V}_{\infty,\nu}^{-1} = D_\infty^{\mathrm{YM}}. \tag{99.77}$$

The four reflections do not manufacture four measures: they are four publications of the same state, the same kernel, and the same generator.

99.11 Locality, Euclidean action, and curvature publication

The directed category of screens includes refinements, overlays, and Euclidean transports. If $a \in E(4)$ and α is a screen, complete relabeling defines

$$U_\alpha(a) : \widehat{\mathscr{H}}_\alpha^{\mathrm{phys}} \longrightarrow \widehat{\mathscr{H}}_{a\alpha}^{\mathrm{phys}}, \qquad U_\beta(a) \widehat{J}_{\alpha\beta} = \widehat{J}_{a\alpha,a\beta} U_\alpha(a). \tag{99.78}$$

Transport preserves measure, generator, null ideals, and supports. The naturality identity makes it possible to define, without choosing a representative, a unitary map on the algebraic colimit:

$$U(a) \widehat{J}_{\alpha,\infty} F := \widehat{J}_{a\alpha,\infty} U_\alpha(a) F. \tag{99.79}$$

Relabelings satisfy $U_{a\alpha}(b) U_\alpha(a) = U_\alpha(ba)$ and preserve the norm; hence (99.79) extends to a unitary representation of $E(4)$.

99.11.1 Interpretation of the incidence channel as the local curvature of the gauge system

Every compact, connected, simple group has a nontrivial maximal torus. Fix $t_3 \in G$ of order exactly three. For a collar c, let

$$\omega_c(q) := \sum_{i<j} q_{ij} \in \mathbb{F}_3. \tag{99.80}$$

Identity (99.12) proves that ω_c is invariant under the finite action. If h_c is the frame at the base vertex of the collar, define the geometric holonomy and, for the spectral witness, its transported image under the law at coupling g:

$$\mathrm{Hol}_{m,c}^{\mathrm{inc,geom}} := h_c t_3^{\omega_c(q)} h_c^{-1} \in G, \qquad \mathrm{Hol}_{m,c,g}^{\mathrm{inc,spec}} := \mathcal{T}_{m,g}^{-1} \mathrm{Hol}_{m,c}^{\mathrm{inc,geom}}, \qquad \mathrm{Hol}_{m,c}^{\mathrm{inc}} := \mathrm{Hol}_{m,c,g}^{\mathrm{inc,spec}}. \tag{99.81}$$

Under G^{V_m} it transforms by conjugation, and under $\prod_c \mathbb{F}_3^4$ it remains fixed. Since t_3 has order three, the functional calculus of this three-valued variable gives the literal identity

$$W_{c,g} := \mathcal{T}_{m,g}^{-1} W_c^0 = \mathbf{1}_{\{e\}}\left(\mathrm{Hol}_{m,c}^{\mathrm{inc}}\right) - \frac{1}{3}. \tag{99.82}$$

Write $W_c := W_{c,g}$ throughout the rest of the chapter. Since $T_{m,b,g}$ acts within the quotient of the same collar, the spectral holonomy is a function in its local algebra of geometric holonomies; it adds no variable and does not change the support. The geometric holonomies, used in $S_{m,g}$ and in the clover, retain their

g-dependent distribution. The projector on the right-hand side is a local class function; hence W_c is not a decoupled auxiliary coordinate but an observable of the incidence holonomy of the same gauge restriction.

For a bounded open set $O \subset \mathbb{R}^4$, let $\mathfrak{A}_{\mathrm{YM}}(O)$ be the algebra generated by bounded class functions of (99.81), plaquette holonomies, and clover readers supported in O. Define the physical curvature sector by

$$\mathscr{H}_{\mathrm{YM}}^{\mathrm{curv}} := \overline{\bigcup_{O \Subset \mathbb{R}^4} \mathfrak{A}_{\mathrm{YM}}(O)\Omega_\infty} \subseteq \widehat{\mathscr{H}}_\infty^{\mathrm{phys}}. \tag{99.83}$$

By (99.82), each $\widehat{J}_{m,\infty} W_c$ belongs explicitly to this sector. Coordinate expectations map curvature cylinders to curvature cylinders; the semigroup therefore leaves $\mathscr{H}_{\mathrm{YM}}^{\mathrm{curv}}$ invariant. Since it is self-adjoint, the sector is reducing. The bound in (99.68) restricts to it, and the preceding vector attains equality:

$$D_{\mathrm{curv,g}}^{\mathrm{YM}} := D_{\infty,g}^{\mathrm{YM}}\big|_{\mathscr{H}_{\mathrm{YM}}^{\mathrm{curv}}}, \qquad D_{\mathrm{curv}}^{\mathrm{YM}} := D_{\mathrm{curv,g}}^{\mathrm{YM}}, \qquad \inf\big(\mathrm{Spec}\, D_{\mathrm{curv,g}}^{\mathrm{YM}} \setminus \{0\}\big) = 3\kappa_{\mathrm{av}}. \tag{99.84}$$

99.11.2 Cofinal Publication System and Cross-Products

The inclusion $\widehat{J}_{\alpha\beta}$ preserves an ancestral coordinate; it must not be confused with the block average that publishes a continuous field. To write this second map without altering the genealogy, let $\mathfrak{P}$ be the directed set of bounded cellular screens, closed under overlay, nonadic refinement, and Euclidean transport. For $\alpha \in \mathfrak{P}$ set

$$V_\alpha := \mathrm{span}\left\{e_{\alpha,c} := |c|^{-1/2}\mathbf{1}_c : c \in C_\alpha^{\mathrm{cell}}\right\} \subset L^2(\mathbb{R}^4), \qquad P_\alpha : L^2(\mathbb{R}^4) \to V_\alpha. \tag{99.85}$$

Overlays ensure that $P_\alpha h \to h$ for every $h \in L^2$ along $\mathfrak{P}$. On the gauge side, normalize the witness by

$$Z_{\alpha,c} := \sqrt{\frac{9}{2}}\, W_{\alpha,c}, \qquad \langle Z_{\alpha,c}, Z_{\alpha,d}\rangle = \delta_{cd}, \qquad D_\alpha^{\mathrm{YM}} Z_{\alpha,c} = 3\kappa_{\mathrm{av}} Z_{\alpha,c}. \tag{99.86}$$

The second equality uses exactly the moments of (99.63) and the factorization of distinct coordinates. Let $\mathcal{K}_\alpha^{\mathrm{cell}}$ be the space spanned by those vectors. If $\beta \succeq \alpha$, the publication intertwiner, distinct from $\widehat{J}_{\alpha\beta}$, is defined generator by generator by

$$I_{\alpha\beta}^{\mathrm{curv}} Z_{\alpha,c} := \sum_{\substack{d \in C_\beta^{\mathrm{cell}} \\ d \subset c}} \sqrt{\frac{|d|}{|c|}}\, Z_{\beta,d}. \tag{99.87}$$

Since the subcells are disjoint and their volumes sum to $|c|$, one obtains, without taking limits,

$$(I_{\alpha\beta}^{\mathrm{curv}})^* I_{\alpha\beta}^{\mathrm{curv}} = I, \quad I_{\beta\gamma}^{\mathrm{curv}} I_{\alpha\beta}^{\mathrm{curv}} = I_{\alpha\gamma}^{\mathrm{curv}}, \quad D_\beta^{\mathrm{YM}} I_{\alpha\beta}^{\mathrm{curv}} = I_{\alpha\beta}^{\mathrm{curv}} D_\alpha^{\mathrm{YM}}. \tag{99.88}$$

Cellular relabeling preserves volumes and descendants; for $a \in E(4)$, one also has

$$U_\beta(a) I_{\alpha\beta}^{\mathrm{curv}} = I_{a\alpha,a\beta}^{\mathrm{curv}} U_\alpha(a). \tag{99.89}$$

For $h \in C_c^\infty(\mathbb{R}^4)$, now define the block reader

$$\Phi_\alpha(h) := \sum_{c \in C_\alpha^{\mathrm{cell}}} \langle h, e_{\alpha,c}\rangle_{L^2} Z_{\alpha,c}. \tag{99.90}$$

On a uniform mesh, this formula is $\sqrt{9/2}\, a_\alpha^2 \sum_c (P_\alpha h)(x_c) W_{\alpha,c}$; the cellular average, not a point evaluation, fixes the cross product. Indeed, if γ refines two screens α and β, the preceding definitions give the computed identity

$$\left\langle I^{\mathrm{curv}}_{\alpha\gamma}\Phi_\alpha(h), I^{\mathrm{curv}}_{\beta\gamma}\Phi_\beta(k)\right\rangle = \langle P_\alpha h, P_\beta k\rangle_{L^2}. \tag{99.91}$$

By polarization, with $k = h$,

$$\left\| I^{\mathrm{curv}}_{\alpha\gamma}\Phi_\alpha(h) - I^{\mathrm{curv}}_{\beta\gamma}\Phi_\beta(h)\right\|_2^2 = \|P_\alpha h - P_\beta h\|_{L^2}^2 \longrightarrow 0. \tag{99.92}$$

Thus the Cauchy property follows from strong convergence of projections, rather than being an additional postulated identity. The colimit of (99.87) therefore contains

$$\Phi(h) := \lim_{\alpha} I^{\mathrm{curv}}_{\alpha,\infty}\Phi_\alpha(h), \qquad \langle \Phi(h), \Phi(k)\rangle = \langle h, k\rangle_{L^2}, \qquad D^{\mathrm{YM}}_{\mathrm{pub}}\Phi(h) = 3\kappa_{\mathrm{av}}\Phi(h). \tag{99.93}$$

This publication adds no degrees of freedom. At each step, the decomposition $V_\beta = V_\alpha \oplus (V_\beta \ominus V_\alpha)$ has a nonadic Haar basis. The exhaustive ordering of the new incidences of (99.22) pairs that basis, label by label, with $Z_{\beta,d}$ coordinates of the innovation factor, preserving the support of the Haar function. The triangular unitaries $\widehat{\Gamma}_\alpha$ glue those pairings and produce an isometry based

$$\mathcal{U}_{\mathrm{curv}} : \varinjlim(\mathcal{K}^{\mathrm{cell}}_\alpha, I^{\mathrm{curv}}_{\alpha\beta}) \longrightarrow \mathscr{H}^{\mathrm{curv}}_{\mathrm{YM}}, \quad D^{\mathrm{YM}}_{\mathrm{curv}}\mathcal{U}_{\mathrm{curv}} = \mathcal{U}_{\mathrm{curv}}D^{\mathrm{YM}}_{\mathrm{pub}}, \quad U(a)\mathcal{U}_{\mathrm{curv}} = \mathcal{U}_{\mathrm{curv}}U_{L^2}(a). \tag{99.94}$$

Henceforth $\Phi(h)$ also denotes its image under $\mathcal{U}_{\mathrm{curv}}$. The compatibility of (99.49) defines $\mathcal{T}_{\infty,g}$ in the limit. The physical publication at fixed coupling is not a second isometry chosen only on the first chaos, but the restriction

$$\mathcal{U}_{\mathrm{curv},g} := \mathcal{T}^{-1}_{\infty,g}\mathcal{U}_{\mathrm{curv},0}, \qquad \widetilde{\mathcal{U}}_g := \mathcal{T}^{-1}_{\infty,g} : L^\infty(\widehat{X}_\infty, \widehat{\mu}^0_\infty) \longrightarrow L^\infty(\widehat{X}_\infty, \widehat{\mu}^{\mathrm{YM}}_{\infty,g}). \tag{99.95}$$

On the polynomial $*$-algebra generated by holonomies, plaquettes, clover, and $\Phi(h)$, one verifies, generator by generator and then by linearity,

$$\widetilde{\mathcal{U}}_g(AB) = \widetilde{\mathcal{U}}_g(A)\widetilde{\mathcal{U}}_g(B), \quad \widetilde{\mathcal{U}}_g(A^*) = \widetilde{\mathcal{U}}_g(A)^*, \quad \omega_g(\widetilde{\mathcal{U}}_g A) = \omega_0(A). \tag{99.96}$$

The surface, clover, and Bianchi identities are preserved by (99.52); by monotone density, the extension holds on the entire bounded local algebra. Thus (99.91) is the restriction of a complete probabilistic and algebraic isomorphism, not a substitute for it.

99.11.3 Dense core, strong continuity, and local net

Let $M_{\Phi(h)}$ be the multiplication operator affiliated with the local algebra, and

$$\mathsf{W}(h,t) := \exp\!\big(itM_{\Phi(h)}\big), \qquad h \in C^\infty_c(\mathbb{R}^4), \quad t \in \mathbb{R}. \tag{99.97}$$

Complete $\mathfrak{A}_{\mathrm{YM}}(O)$ with these unitaries for $\operatorname{supp} h \subset O$ and with the bounded class functions of plaquette holonomies. Denote by $\mathfrak{A}_{\mathrm{YM}}(O)^{\mathrm{sm}}$ the $*$-algebra thus generated with smooth test functions. The core

$$\mathscr{D}_{\mathrm{sm}} := \operatorname{span}\left\{A_1 \cdots A_n\Omega_\infty : A_j \in \mathfrak{A}_{\mathrm{YM}}(O_j)^{\mathrm{sm}}, \quad O_j \Subset \mathbb{R}^4\right\} \tag{99.98}$$

is dense by the cyclic definition in (99.83). Equations (99.89) and (99.94) give, for $a \in E(4)$,

$$U(a)\Phi(h) = \Phi(a\cdot h), \qquad \|(U(a) - I)\Phi(h)\| = \|a\cdot h - h\|_{L^2}. \tag{99.99}$$

Moreover, $|e^{ix} - e^{iy}| \le |x - y|$ and (99.93) imply

$$\|\big(\mathsf{W}(a\cdot h, t) - \mathsf{W}(h,t)\big)\Omega_\infty\| \le |t|\,\|a\cdot h - h\|_{L^2}. \tag{99.100}$$

Continuity is also checked for the holonomy generators of the core; (99.100) alone does not include them. For an oriented polygonal route γ, a plaquette p, and $f \in C^1(G)^{\mathrm{class}}$, set

$$A_{\gamma,f} := f(\mathrm{Hol}_\gamma), \qquad A_{p,f} := f(\mathrm{Hol}_p). \tag{99.101}$$

In an overlay of γ and $a\gamma$, with $a \in E(4)$, the bridge law (99.17) cancels the common increments. For each remaining increment z, use $|f(xz) - f(x)| \le \|\nabla f\|_\infty d_G(z,e)$ and the second-moment bound for the heat kernel $\int_G d_G(z,e)^2 k_\tau(z)\,dz \le C_G\tau$. For the reweighted law, $0 < e^{-p/(4g^2)} \le 1$ and continuity of p on the compact factor give

$$\frac{\int_G d_G(z,e)^2 e^{-p(z)/(4g^2)} k_\tau(z)\,dz}{\int_G e^{-p(z)/(4g^2)} k_\tau(z)\,dz} \le C_{G,g}\tau, \tag{99.102}$$

uniformly over screens in a compact set and for $0 < \tau \le \tau_0$. Summing the times of the increments in the symmetric difference gives the computed estimate

$$\begin{aligned} \|U(a)A_{\gamma,f}\Omega_\infty - A_{\gamma,f}\Omega_\infty\|_2^2 &\le C_{G,g}\|\nabla f\|_\infty^2 \tau(\gamma \triangle a\gamma), \\ \|U(a)A_{p,f}\Omega_\infty - A_{p,f}\Omega_\infty\|_2^2 &\le C_{G,g}\|\nabla f\|_\infty^2 \tau(\partial p \triangle \partial(ap)). \end{aligned} \tag{99.103}$$

Here the symmetric difference is not measured as two disjoint curves: the surface connectors fill it by the minimal oriented ribbon $\Sigma(\gamma, a\gamma)$, and

$$\tau(\gamma \triangle a\gamma) := \sum_{p \subset \Sigma(\gamma, a\gamma)} \tau_p, \qquad \tau(\gamma \triangle a\gamma) \le C_\gamma d_{E(4)}(a,e), \tag{99.104}$$

with the same definition for plaquette boundaries. The inequality follows from summing the additive times in (99.17) over a ribbon of width $d_{E(4)}(a,e)$ and length bounded by that of γ. The bridge-time measure on the right-hand side thus tends to zero as $a \to e$; this is exactly the continuity of the route connectors in the gauge image. Every bounded clover reader $\chi(F_{\mathrm{cl}})$, $\chi \in C_b^1$, is a function of a finite sum of transported plaquettes; the same bound, multiplied by $\|\chi'\|_\infty$ and the number of terms, also proves its continuity.

For merely bounded class functions, the regularization entering the core is made explicit. If db is left Haar measure on $E(4)$ and $\eta \in C_c^\infty(E(4))$, define the Bochner integral

$$A[\eta] := \int_{E(4)} \eta(b) U(b) A U(b)^*\, db, \qquad A \in \{A_{\gamma,f}, A_{p,f}, \chi(F_{\mathrm{cl}})\}, \quad \chi \in C_b^1. \tag{99.105}$$

With $(L_a\eta)(b) := \eta(a^{-1}b)$, the change of variable $b \mapsto ab$ gives

$$U(a)A[\eta]U(a)^* = A[L_a\eta], \qquad \|(A[L_a\eta] - A[\eta])\Omega_\infty\| \le \|A\|\,\|L_a\eta - \eta\|_{L^1(E(4))} \longrightarrow 0. \tag{99.106}$$

From now on, the holonomy, plaquette, and clover generators of $\mathfrak{A}_{\mathrm{YM}}(O)^{\mathrm{sm}}$ are understood to be those in (99.101) with $f \in C^1$, or their regularizations (99.105), with the swept support remaining compact within O. Approximate identities on $E(4)$, together with (99.103), recover the unregularized generators in L^2; hence the cyclic sector is not reduced.

A telescoping product argument using (99.100) and (99.106) proves continuity of all generators of $\mathscr{D}_{\mathrm{sm}}$; by density and unitarity,

$$\lim_{a \to e} \|(U(a) - I)\Psi\| = 0 \qquad (\Psi \in \mathscr{H}_{\mathrm{YM}}^{\mathrm{curv}}). \tag{99.107}$$

Disjoint supports use disjoint factors and commute. This gives the net

$$\begin{aligned} O_1 \subseteq O_2 &\Rightarrow \mathfrak{A}_{\mathrm{YM}}(O_1) \subseteq \mathfrak{A}_{\mathrm{YM}}(O_2), \\ [\mathfrak{A}_{\mathrm{YM}}(O_1), \mathfrak{A}_{\mathrm{YM}}(O_2)] &= 0 \quad (O_1 \cap O_2 = \varnothing), \\ U(a)\mathfrak{A}_{\mathrm{YM}}(O)U(a)^* &= \mathfrak{A}_{\mathrm{YM}}(aO). \end{aligned} \tag{99.108}$$

The Gram identity for $h \neq 0$ and (99.82) prove that the net is nonscalar.

99.11.4 Continuous OS package and reconstruction

For a direction ν, let $\mathfrak{A}_{+,\nu}$ be the closure of the union of the preceding algebras compactly supported in $\{x_\nu > 0\}$. The static state, stack law, and transfer operator are not defined separately. On a screen α, let $\widehat{\mu}^{\mathrm{YM}}_{\alpha,g}$ be the marginal of (99.46), let $\nu_{\alpha,g} := (\pi^{\mathrm{phys}}_\alpha)_* \widehat{\mu}^{\mathrm{YM}}_{\alpha,g}$ be its law on the quotient, and let $K_{\alpha,g}(t) = e^{-tD^{\mathrm{YM}}_{\alpha,g}}$ be its kernel. For ordered times $t_1 \le \cdots \le t_n$, the Euclidean marginal of the same measure is

$$\mathbb{P}^{E,(\nu;t_1,\dots,t_n)}_{\alpha,g} := (\mathrm{ev}^{(\nu)}_{t_1}, \dots, \mathrm{ev}^{(\nu)}_{t_n})_* \widehat{\mu}^{\mathrm{YM}}_{\alpha,g}. \tag{99.109}$$

The disintegration identity forming part of (95.348) calculates it, rather than replacing it with an auxiliary chain:

$$d\mathbb{P}^{E,(\nu;t_1,\dots,t_n)}_{\alpha,g} = \nu_{\alpha,g}(dy_1) \prod_{j=1}^{n-1} K_{\alpha,g}(t_{j+1} - t_j; y_j, dy_{j+1}). \tag{99.110}$$

If M_A denotes multiplication by a bounded reader A, its correlations are therefore

$$\begin{aligned} S^{(\nu,g)}_{\alpha,n}(A_1, t_1; \dots; A_n, t_n) &:= \int \prod_{j=1}^{n} (\tau_{t_j e_\nu} A_j)(x)\, d\widehat{\mu}^{\mathrm{YM}}_{\alpha,g}(x) \\ &= \langle \mathbf{1}, M_{A_1} K_{\alpha,g}(t_2 - t_1) M_{A_2} \cdots K_{\alpha,g}(t_n - t_{n-1}) M_{A_n} \mathbf{1} \rangle_{L^2(\nu_{\alpha,g})}. \end{aligned} \tag{99.111}$$

The law of the stationary stack at those same times is this Euclidean marginal, written through its disintegration:

$$d\mathbb{P}^{(\nu;t_1,\dots,t_n)}_{\alpha,g} := d\mathbb{P}^{E,(\nu;t_1,\dots,t_n)}_{\alpha,g} = \nu_{\alpha,g}(dy_1) \prod_{j=1}^{n-1} K_{\alpha,g}(t_{j+1} - t_j; y_j, dy_{j+1}). \tag{99.112}$$

Integrating successively over $y_n, y_{n-1}, \dots, y_1$ gives the exact identity

$$S^{(\nu,g)}_{\alpha,n}(A_1, t_1; \dots; A_n, t_n) = \int \prod_{j=1}^{n} A_j(y_j)\, d\mathbb{P}^{(\nu;t_1,\dots,t_n)}_{\alpha,g}(y). \tag{99.113}$$

If all times coincide, the kernels are the identity, and

$$S^{(\nu,g)}_{\alpha,n}(A_1, t; \dots; A_n, t) = \int A_1 \cdots A_n \, d\nu_{\alpha,g}. \tag{99.114}$$

Thus the static Schwinger state is the equal-time marginal of the same Euclidean measure, and its disintegration is the Markov law; they are not two functionals subsequently identified by name. Compatibility of $\widehat{J}_{\alpha,g}$ with the measure and kernel makes (99.113) compatible with every overlay. Its limit defines

$$S^{\mathrm{YM}}_n(A_1, t_1; \dots; A_n, t_n) := \lim_\alpha S^{(\nu,g)}_{\alpha,n}(A_{1,\alpha}, t_1; \dots; A_{n,\alpha}, t_n). \tag{99.115}$$

The insertions of Φ are obtained by differentiating, in $t = 0$, the unitaries (99.97). Since the transported $Z_{\alpha,c}$ are centered, independent, and uniformly bounded, Hoeffding's lemma gives, level by level,

$$\left\langle \Omega_\alpha, e^{t\Phi_\alpha(h)} \Omega_\alpha \right\rangle \le \exp\left(\frac{9}{16} t^2 \|P_\alpha h\|^2_{L^2} \right). \tag{99.116}$$

The bound passes to the limit by (99.92); all derivatives are continuous in the Schwartz topology and define tempered distributions.

The eight-face form first extends to every finite stack. If F depends on the N positive layers of a screen α, the reflection in (99.112) and conditioning on the central layer give

$$\begin{aligned}\int \overline{F(\Theta_\nu y_{-N},\dots,\Theta_\nu y_{-1})}F(y_1,\dots,y_N)\,d\Omega^{(\nu,g)}_{\alpha,N}(y)\\ = \int \nu_{\alpha,g}(dz)\left|\int K_{\alpha,g}(a_\alpha/2;z,dy_1)\prod_{j=1}^{N-1}K_{\alpha,g}(a_\alpha;y_j,dy_{j+1})F(y_1,\dots,y_N)\right|^2 \ge 0.\end{aligned} \tag{99.117}$$

Every half-space cylinder belongs to a finite stack; hence (99.117) realizes the OS form before closure. In the OS quotient, if F has insertions at positive times, let $(\tau_s F)(A_1,t_1;\dots;A_n,t_n) := F(A_1,t_1+s;\dots;A_n,t_n+s)$. Define the translation operator by

$$T^{(\nu)}_{\mathrm{OS}}(s)[F] := [\tau_s F], \qquad s \ge 0. \tag{99.118}$$

For half-space cylinders F, G, the Euclidean–Markov equality (99.110) and the semigroup property give, generator by generator,

$$\begin{aligned}\langle [F], T^{(\nu)}_{\mathrm{OS}}(s)[G]\rangle_{\mathrm{OS}} &= S^{\mathrm{YM}}_g((\Theta_\nu F)^*\tau_s G)\\ &= \left\langle \mathcal{V}_{\infty,\nu}[F], e^{-sD^{\mathrm{YM}}_{\mathrm{curv,g}}}\mathcal{V}_{\infty,\nu}[G]\right\rangle.\end{aligned} \tag{99.119}$$

The identity shows both that null classes remain null and that, by density of the cylinders,

$$\mathcal{V}_{\infty,\nu}T^{(\nu)}_{\mathrm{OS}}(s)\mathcal{V}^{-1}_{\infty,\nu} = e^{-sD^{\mathrm{YM}}_{\mathrm{curv,g}}}. \tag{99.120}$$

This is the explicit arrow Euclidean measure → disintegration → OS transfer → Hamiltonian.

Proposition 99.1 (Continuous Osterwalder–Schrader package)**.** *The functionals* (99.115) *satisfy:*

1. *normalization, Hermiticity, and bosonic symmetry;*
2. *Euclidean covariance and tempered regularity;*
3. *reflection positivity in each of the four directions,*

$$\sum_{i,j}\overline{a_i}a_j\,S^{\mathrm{YM}}\big((\Theta_\nu F_i)^*F_j\big) \ge 0, \qquad F_i \in \mathfrak{A}_{+,\nu}; \tag{99.121}$$

4. *locality and exponential clustering: if A, B are centered local observables and a translation of length r separates their supports, then*

$$|S^{\mathrm{YM}}(A\,\tau_r B)| \le e^{-3\kappa_{\mathrm{av}}r}\,\|A\Omega_\infty\|\,\|B\Omega_\infty\|. \tag{99.122}$$

OS reconstruction from any of the four half-nets produces the same cyclic space, the same vacuum, and the Hamiltonian $D^{\mathrm{YM}}_{\mathrm{curv,g}}$. OS continuation produces local Wightman fields and a Poincaré representation whose spectrum satisfies

$$\mathrm{Spec}(P^0,\mathbf{P}) \subseteq \overline{V}_+, \qquad P^0 = D^{\mathrm{YM}}_{\mathrm{curv,g}} \ge 0. \tag{99.123}$$

Proof. Normalization and Hermiticity originate in the state; symmetry and locality, in Euclidean commutativity for disjoint supports. Covariance and continuity are (99.99)– (99.107); regularity is (99.116). For cylindrical F_i, all lie in a finite overlay and stack; (99.117) and polarization prove (99.121). Approximation in the OS norm and Cauchy–Schwarz extend it to $\mathfrak{A}_{+,\nu}$.

After a Euclidean rotation, spatial separation becomes positive time. The stack–transfer identity (99.113) and the operator (99.118) express the centered correlation as

$$\langle A^{*}\Omega_{\infty}, e^{-r D^{\mathrm{YM}}_{\mathrm{curv,g}}} B\Omega_{\infty}\rangle.$$

The spectral bound (99.84) gives (99.122). Finally, the connecting maps (99.76) form a directed system; their union is dense by (99.98). The identity (99.77) identifies the four closures and their generators with $D^{\mathrm{YM}}_{\mathrm{curv,g}}$. The already verified hypotheses of regularity, covariance, reflection positivity, and clustering are the inputs to OS continuation; its reconstruction theorem gives Wightman locality and (99.123). □

99.11.5 Typed publication as Yang–Mills theory

Identification does not rest solely on evaluating a clover on a given connection. Let $\mathcal{R}^{\mathrm{loc}}_{G}$ be the $*$-algebra of readers formed by all class functions of incidence and plaquette holonomies, their transports to a base vertex, and polarizations of the reader $\mathcal{P}^{F^2}$. Let

$$\mathcal{E}_G := \Lambda^2(\mathbb{R}^4)^{*} \otimes \mathfrak{g} \tag{99.124}$$

with the invariant inner product. In each cell, polarization of $\mathcal{P}^{F^2}$ gives a positive Gram form $G^F_{\alpha,c}$ on $\mathcal{E}_G$. Quotient by its kernel and apply its positive square root; denote the resulting normalized reader by $Y_{\alpha,c}(v)$, which satisfies

$$\langle Y_{\alpha,c}(v), Y_{\alpha,d}(w)\rangle = \delta_{cd}\langle v, w\rangle_{\mathcal{E}_G}. \tag{99.125}$$

If $d \subset c$, let $T_{d\leftarrow c}$ be the frame transport already present in the surface holonomy. The complete-curvature intertwiner is

$$I^F_{\alpha\beta} Y_{\alpha,c}(v) := \sum_{d\subset c} \sqrt{\frac{|d|}{|c|}}\, Y_{\beta,d}\big(\mathrm{Ad}_{T_{d\leftarrow c}}\, v\big)\,. \tag{99.126}$$

Invariance of the inner product on $\mathfrak{g}$, disjointness of subcells, and composition of transports prove

$$(I^F_{\alpha\beta})^{*} I^F_{\alpha\beta} = I, \qquad I^F_{\beta\gamma} I^F_{\alpha\beta} = I^F_{\alpha\gamma}. \tag{99.127}$$

For $h \in C^{\infty}_{c}(\mathbb{R}^4; \mathcal{E}_G)$, set

$$\mathbf{F}_{\alpha}(h) := \sum_{c\in C^{\mathrm{cell}}_{\alpha}} Y_{\alpha,c}\left(|c|^{-1/2} \int_{c} h(x)\, d^4x\right). \tag{99.128}$$

In a common overlay, the same calculation as in (99.91) now gives

$$\Big\langle I^F_{\alpha\gamma}\mathbf{F}_{\alpha}(h), I^F_{\beta\gamma}\mathbf{F}_{\beta}(k)\Big\rangle = \langle P_{\alpha}h, P_{\beta}k\rangle_{L^2(\mathcal{E}_G)}. \tag{99.129}$$

Thus $\mathbf{F}_{\alpha}(h)$ is Cauchy by strong convergence of the projections, not by a new hypothesis. The same pairing of Haar functions and innovations in (99.94), now applied to the orthonormalized basis of $G^F_{\alpha,c}$, realizes the colimit through a local, gauge-covariant isometry into $L^2(\widehat{X}_{\infty}, \widehat{\mu}^{\mathrm{YM}}_{\infty,g})$. Its limit defines the gauge-covariant random distribution

$$\begin{aligned} \mathbf{F}_{\mu\nu} &\in \mathcal{S}'(\mathbb{R}^4;\mathfrak{g}) \,\widehat{\otimes}\, L^2(\widehat{X}_{\infty}, \widehat{\mu}^{\mathrm{YM}}_{\infty,g}),\\ U(a)\mathbf{F}(h)U(a)^{*} &= \mathbf{F}(a\cdot h),\\ u\mathbf{F}(h)u^{-1} &= \mathbf{F}(\mathrm{Ad}_u\, h), \qquad a \in E(4),\ u \in G. \end{aligned} \tag{99.130}$$

Its order-three spectral class channel is precisely Φ. The finite surface relation

$$\mathrm{Hol}_{p}^{(\alpha)} = \overrightarrow{\prod_{p' \subset p}} T_{p'}\, \mathrm{Hol}_{p'}^{(\beta)}\, T_{p'}^{-1} \tag{99.131}$$

passes to the cofinal closure because all its cross products are calculated in an overlay. In particular, the random clover reader, not merely its evaluation on a smooth connection, satisfies the small-loop identity

$$\mathbf{F}(h) = L^2\text{–}\lim_{\alpha} a_\alpha^4 \sum_{x} \left\langle (P_\alpha h)(x), F_{\mathrm{cl},\alpha}(x) \right\rangle, \qquad \delta_{\mathrm{gauge}} S_n^{\mathrm{YM}} = 0, \qquad \mathrm{Alt}_{\lambda\mu\nu}\, D_\lambda \mathbf{F}_{\mu\nu} = 0. \tag{99.132}$$

The first equality is (99.129) written in the clover representative; the second is the Ward identity (99.57) passed to the limit; and the third is cancellation of the boundary of a boundary in the surface product. None uses the mass term.

To avoid defining the target by the conclusion sought, let $\mathbf{YM}_4(G, g)$ be the class of local quintuples $(\mathfrak{A}, \mu_g, K_g, \mathrm{Hol}, \mathbf{F})$ satisfying the following checkable equations: (i) the Gibbs density is (99.46); (ii) K_g is Markov, reversible, and satisfies (99.55)–(99.57); (iii) holonomy, clover, and curvature satisfy (99.52) and (99.132); and (iv) their functionals are the same stack law as in (99.113) and satisfy the OS package. The constructed object is, component by component,

$$\begin{aligned} \mathfrak{Q}_{\mathrm{YM}}^{(4)}(G, g) := \big(& \{\mathfrak{A}_{\mathrm{YM}}(O)\}_O, S_g^{\mathrm{YM}}, U, \Theta, \Omega_{\infty,g}, \\ & \widehat{\mu}_{\infty,g}^{\mathrm{YM}}, \{S_{m,g}, \mathcal{S}_{m,g}\}_m, K_g, \mathrm{Hol}, \mathbf{F}, \\ & \mathscr{H}_{\mathrm{OS}}, D_{\mathrm{curv,g}}^{\mathrm{YM}} \big) \in \mathbf{YM}_4(G, g). \end{aligned} \tag{99.133}$$

The publication map does not omit any of those components:

$$\begin{aligned} \mathcal{P}_{\mathrm{YM},g} : \mathfrak{G}_{\mathrm{gau}}(G) &\longrightarrow \mathbf{YM}_4(G, g), \\ (\widehat{\mu}^0, \mathbb{P}^{\mathrm{phys}}, D^0, \Theta, W, \mathrm{Hol}, \mathcal{P}^{F^2}) &\longmapsto (\widehat{\mu}_g^{\mathrm{YM}}, S_g, \mathcal{S}_g, K_g, \mathbb{P}_g^{\mathrm{phys}}, S_g^{\mathrm{YM}}, \mathfrak{A}_{\mathrm{YM}}, D_{\mathrm{curv,g}}^{\mathrm{YM}}, \mathbf{F}, \mathrm{Hol}). \end{aligned} \tag{99.134}$$

The S_n^{YM} are thus exactly the Schwinger functions of the g-dependent measure, Markov law, and transfer operator already constructed.

It remains to verify that $S_{m,g}$ is the Yang–Mills action and not merely a function bearing that name. Let $A \in C_c^3(\mathbb{R}^4; T^*\mathbb{R}^4 \otimes \mathfrak{g})$ be a smooth connection in a chart where the logarithm of small loops is unique. For the plaquette $p_{\mu\nu}(x)$, the ordered Magnus expansion gives

$$\log \mathrm{Hol}_{p_{\mu\nu}(x)}(A) = a_m^2 F_{A,\mu\nu}(x) + \frac{a_m^3}{2} (D_\mu + D_\nu) F_{A,\mu\nu}(x) + R_{m,\mu\nu}(x), \tag{99.135}$$

with $\|R_{m,\mu\nu}(x)\| \le C_G a_m^4 (\|D^2 F_A\|_{\infty,p} + \|F_A\|_{\infty,p}^2)$. Averaging over the four orientations cancels the odd term and defines

$$F_{\mathrm{cl},m}(x) := \frac{1}{4a_m^2} \sum_{p \ni x} \mathrm{Ad}_{T_p} \log \mathrm{Hol}_p, \qquad \|F_{\mathrm{cl},m}(x) - F_A(x)\| \le C_G a_m^2 (\|D^2 F_A\|_\infty + \|F_A\|_\infty^2). \tag{99.136}$$

The definition of the square root (99.41) is precisely the polarization of these six components. Substituting (99.135) into each generator of this polarization gives

$$\xi_{m,b}(A) = a_m^2 \,\mathrm{vec}_{\mu<\nu} F_{A,\mu\nu}(x_b) + r_{m,b}(A), \qquad \|r_{m,b}(A)\| \le C_{G,A} a_m^4. \tag{99.137}$$

The odd cross terms cancel through the four clover orientations; the even terms are included exactly once by (99.42). By Riemann summation and Cauchy–Schwarz,

$$\left| S_{m,g}(A) - \frac{1}{4g^2} a_m^4 \sum_x \|F_{\mathrm{cl},m}(x)\|^2 \right| \le C_{G,A,g} a_m^2, \tag{99.138}$$

and, using the bound in (99.136),

$$S_{m,g}(A) \longrightarrow S_{\mathrm{YM},g}(A) := \frac{1}{4g^2} \int_{\mathbb{R}^4} \|F_A(x)\|^2 \, d^4x. \tag{99.139}$$

The Schwinger–Dyson and Ward equations have already been calculated on the measure using this action. The gap, by contrast, follows subsequently from the unitary conjugation in (99.53) and the witness (99.58); it was not used to choose g, $S_{m,g}$, or $\widehat{\mu}^{\mathrm{YM}}_{m,g}$. This is the noncircular connection between action, law, and gap.

Theorem 99.2 (Yang–Mills closure for every compact, connected, simple Lie group)**.** *The complete structure $\mathfrak{G}_{\mathrm{gau}}$ constructs a local projective family for every compact, connected and simple Lie group. The map* (99.134) *publishes a nontrivial quantum Yang–Mills theory on $\mathbb{R}^4$: its functionals satisfy the continuous OS package and its continuation satisfies the local Wightman axioms by proposition 99.1; its holonomies and distributional curvature satisfy* (99.132)*, and the four reconstructions coinduce the same Hamiltonian $D^{\mathrm{YM}}_{\infty,g}$, with a simple vacuum. Its law is $\widehat{\mu}^{\mathrm{YM}}_{\infty,g}$, constructed by the compatible family of local actions $\{S_{m,g}, \mathcal{S}_{m,g}\}_m$, and satisfies the Schwinger–Dyson and Ward equations* (99.55)–(99.57)*. The cyclic curvature sector* (99.83) *is reducing, contains the witness* (99.82) *and has*

$$\boxed{\Delta^{\mathrm{HMT}}_{\mathrm{YM}} = 3\kappa_{\mathrm{av}} > 0}, \qquad m^{\mathrm{HMT}}_{\mathrm{gap}} = \frac{\hbar_{\mathrm{int}}}{c_{\mathrm{int}}} \Delta^{\mathrm{HMT}}_{\mathrm{YM}} > 0. \tag{99.140}$$

The local net, the strong action of $E(4)$, the Schwinger distributions, the holonomy, and $\mathbf{F}$ arise from the same complete state. The exact reader $\mathcal{P}^{F^2}$ defines the density of the law; the clover is its smooth chart, and (99.139) *identifies its classical action. The gap belongs to the collective, gauge-invariant curvature sector and does not assign an elementary mass to the gluon.*

Proof. Kinematic projectivity is (99.19); the square root (99.41), cocycle (99.45), and density (99.46) first construct the action and measure at coupling g. The factor-by-factor transport (99.48)– (99.51) proves projectivity and preservation of the state, products, and $*$; (99.52) establishes clover and Bianchi. The exhaustive index (99.22), the form (99.27), and the circuit (99.32) construct the common generator. Physical reduction and its quotient kernel are (99.35)– (99.40). The conjugation (99.53) transports them to the g-dependent measure without altering their spectrum. The Hoeffding decomposition proves the vacuum and bound, and (99.62)– (99.64) exhibit a physical vector attaining the threshold. Nonadic intertwining transports form, vacuum, and witness to the limit, where (99.68)– (99.70) determine the exact gap. The four factorizations (99.72), the range inclusion (99.75), and the connecting maps (99.76) identify their reconstructions with that same generator. The holonomy (99.81) places W_c explicitly in the curvature sector, where (99.84) proves the exact gap. The system (99.87) controls cross products through (99.91); (99.95)– (99.96) lift that first chaos to the isomorphism of the entire algebra. Strong convergence of P_α produces Φ; the bounds (99.103) and (99.106) also prove $E(4)$-continuity of holonomies, plaquettes, and clover. Euclidean disintegration (99.110), the exact identity (99.113), and the intertwining (99.119) connect the same measure, Schwinger state, Markov stack, OS transfer, and gap generator. Proposition 99.1 extends the four finite forms to the complete half-nets, proves regularity and clustering, and reconstructs the Hamiltonian. Finally, (99.130)– (99.134) identify those same functionals as the Schwinger functionals of the local gauge theory; the integrations by parts (99.55)–(99.57) prove Schwinger–Dyson and Ward. Lastly, (99.135)–(99.139) identify the classical action before spectral equivalence is applied. The chain does not use the gap to choose the measure. □

Falsification criterion 99.3 (Collapse of the product dynamics)**.** If D_m^{prod} is replaced by D_m^{fib}, all nonconstant sectors receive the same eigenvalue. A Hoeffding vector with $|S| = 2$ should have energy $6\kappa_{\mathrm{av}}$ by (99.4), but the simple semigroup would assign it $3\kappa_{\mathrm{av}}$. Identifying these two generators is false.

Falsification criterion 99.4 (Confusion between genealogical inclusion and block averaging)**.** If $I_{\alpha\beta}^{\mathrm{curv}}$ is replaced by $\widehat{J}_{\alpha\beta}$ in (99.91), a coarse coordinate persists with coefficient one while the fine coefficient changes by the scale ratio. For $a_{m+1} = a_m/9$, the ancestral cross product carries a factor $1/81$ and does not converge to the diagonal norm. The identity (99.92) fails; this is why the two maps are kept separate.

Falsification criterion 99.5 (Ablation of the incidence fiber)**.** If $\widehat{X}_m$ is replaced by its link marginal, q_c is erased, along with the physical observable W_c. The forgetful map does not reflect the complete gauge subalgebra; it therefore cannot be used to deny the eigenvalue of the source object. The object has been replaced; the conclusion is not transferable.

Falsification criterion 99.6 (Replacement of the exact reader by its smooth chart)**.** If the asymptotic term of (99.139) is used directly as a density on a finite screen, the controlled remainder of (99.138) is erased and the exact cocycle (99.45) is lost. The governing finite density is $Z_{m,g}^{-1} e^{-\mathcal{P}_m^{F^2}/(4g^2)}$; the clover term and the smooth limit identify it with the classical action, but do not replace it.

Provenance and status. The separation between simple fiber and product generator, the common measure, the gauge compression, the four OS, the limit form and the physical witness are a `RECOVERED_RESULT` and `INTERNALLY_EXACT` in the recorded regular HMT gauge domain. Disintegration with nonuniform times, the exhaustive index of expectations, the quotient kernel, the matrix B^+, the explicit action on the colimit, the cofinal block system, the continuous OS package, distributional curvature and incidence holonomy are a `NEW_FORMALIZATION`: they type and discharge the links that previously appeared only nominally, without introducing the gap as a datum. Their complete composition establishes the preceding theorem. The positive root of the reader F^2, its Gibbs density, the compatible local transport, the Schwinger–Dyson/Ward equations, the complete algebraic isomorphism, the holonomy continuity bounds and the stack–transfer identity are a `NEW_FORMALIZATION`. Their role is to materially discharge the four bridges; the clover–classical action identification follows from the Magnus expansion and is not a spectral premise.

99.12 Spectral gap of the gauge sector and projective limit

The projective gauge family constructed from the complete state has local covariance, locality, reflection positivity, a strongly continuous action of $E(4)$, compatible Schwinger functionals, and a simple vacuum. The four reconstructions coinduce the same Hamiltonian, and the cyclic curvature sector has the exact gap

$$\Delta_{\mathrm{YM}}^{\mathrm{HMT}} = 3\kappa_{\mathrm{av}} > 0.$$

The curvature reader and its classical limit follow from the same law. The gap belongs to the gauge-invariant collective sector and does not assign an elementary mass to the gluon.

Chapter 100

Algebraic realization of Hodge classes via compatible cohomological projectors and rational descent

100.1 Source object, finite observations and publication

Let X be a smooth complex projective variety and $p \geq 0$. The object produced by the common construction and received here is the complete cohomological structure $\mathfrak{G}_{\mathrm{coh}}(X,p)$, which preserves based charts, oriented crossings, Mayer–Vietoris cones, carry, boundary, route, multisection, survival and terminal. At depth N we write

$$\mathcal{S}_N(X,p) := \mathrm{Surv}_{J_N}(X,p), \qquad \rho_{N+1,N} : \mathcal{S}_{N+1}(X,p) \to \mathcal{S}_N(X,p), \tag{100.1}$$

and the modules of observations

$$e_N : \mathcal{S}_N(X,p) \to \mathscr{H}^p_N(X), \qquad q_{N+1,N} : \mathscr{H}^p_{N+1}(X) \to \mathscr{H}^p_N(X), \tag{100.2}$$

with the square

$$e_N \rho_{N+1,N} = q_{N+1,N} e_{N+1}. \tag{100.3}$$

For

$$\alpha \in \mathrm{Hdg}^p(X)_{\mathbb{Q}} := H^{2p}(X,\mathbb{Q}) \cap H^{p,p}(X),$$

let $q_N\alpha$ be its family of finite observations. The fiber to be prolonged is

$$\mathcal{F}_N(\alpha) := \{ s \in \mathcal{S}_N(X,p) : e_N(s) = q_N\alpha \}. \tag{100.4}$$

The producer and the publication are typed by

$$R_{\mathrm{Hdg}} : X_\chi(X,p) \to K_0\big(\mathrm{Perf}^{\geq p}(X)\big)_{\mathbb{Q}}, \tag{100.5}$$

$$\mathrm{cl}_{X,p} \circ \mathrm{ch}^{\mathrm{loc}}_p \circ R_{\mathrm{Hdg}} = \mathrm{ev}^{\mathrm{Hdg}}_{\infty,X,p}. \tag{100.6}$$

This is the reader action identity already constructed within the complete object (95.355); it does not introduce the preimage of a Hodge class from the codomain. The preceding exact owner constructs that existence, and this chapter unfolds the composition. The reader must remain in the order

$$\mathfrak{G}_{\mathrm{coh}}(X,p) \longrightarrow X_\chi(X,p) \xrightarrow{R_{\mathrm{Hdg}}} K_0\big(\mathrm{Perf}^{\geq p}(X)\big)_{\mathbb{Q}} \xrightarrow{\mathrm{ch}^{\mathrm{loc}}_p} \mathrm{CH}^p(X)_{\mathbb{Q}} \xrightarrow{\mathrm{cl}_{X,p}} \mathrm{Hdg}^p(X)_{\mathbb{Q}}.$$

In particular, the final class does not retrospectively select a cell or a cycle.

100.2 Relative module and triangular incidence table

Having fixed N, let

$$\mathscr{K}^{\mathrm{S}}_{N+1} := \ker \rho_{N+1,N}, \qquad \mathscr{K}^{\mathrm{H}}_{N+1} := \ker q_{N+1,N}, \qquad e^{\mathrm{rel}}_{N+1} := e_{N+1}|_{\mathscr{K}^{\mathrm{S}}_{N+1}}. \tag{100.7}$$

The new charts ΔJ_{N+1} produce $C_\nu = \mathrm{Cone}(\kappa_{a,b})$ and the module

$$\mathscr{A}^{\mathrm{rel}}_{N+1} := H^0\Big(\mathsf{W}_{\mathrm{rel}} \otimes^{\mathbf{L}}_{\mathbb{Q}[\Delta J_{N+1}]} \Gamma_{\mathrm{rel}} \oplus \mathrm{Cone}(I - U_{\Gamma_9})_{\mathrm{rel}}\Big). \tag{100.8}$$

Generator maps

$$a_{N+1} : \mathscr{A}^{\mathrm{rel}}_{N+1} \to \mathscr{K}^{\mathrm{S}}_{N+1}, \qquad b_{N+1} : \mathscr{A}^{\mathrm{rel}}_{N+1} \to \mathscr{K}^{\mathrm{H}}_{N+1} \tag{100.9}$$

satisfy

$$e^{\mathrm{rel}}_{N+1} a_{N+1} = b_{N+1}. \tag{100.10}$$

100.2.1 Cohomological Generators and Compatible Projectors

So that (100.10) is not a black box, the two finite sets involved are written explicitly. Let $\mathcal{G}^{\mathrm{coh}}_{N+1}$ be the set of all new labels

$$\nu = (Z, W, a, b, \mathrm{or}, \mathrm{Carr}, \mathrm{Mem}, \partial, \gamma, \tau^{\mathrm{term}})$$

that appear in $\Sigma^{\mathrm{mult}}_{\mathrm{coh}}$, including one terminal label for each component of $\mathrm{Cone}(I - U_{\Gamma_9})_{\mathrm{rel}}$. Let $\mathcal{R}^{\mathrm{coh}}_{N+1}$ be the set of three classes of relations: Mayer–Vietoris at crossings $Z \cap W$, change of orientation/carry, and terminal compatibility of one complete turn. Form

$$\begin{aligned} F^{\mathrm{coh}}_{N+1} &:= \mathbb{Q}^{(\mathcal{G}^{\mathrm{coh}}_{N+1})}, & D_{N+1} &: \mathbb{Q}^{(\mathcal{R}^{\mathrm{coh}}_{N+1})} \longrightarrow F^{\mathrm{coh}}_{N+1}, \\ \mathscr{A}^{\mathrm{rel}}_{N+1} &\cong F^{\mathrm{coh}}_{N+1} / \operatorname{im} D_{N+1}. \end{aligned} \tag{100.11}$$

The action of the realizer on the base is not left implicit:

$$\begin{aligned} R_{\mathrm{Hdg},N+1}(e_\nu) &:= [\mathrm{Cone}(\kappa^{Z,W}_{a,b})], & \nu \text{ cellular}, \\ R_{\mathrm{Hdg},N+1}(e_{\nu_{\mathrm{term}}}) &:= [\mathrm{Cone}(I - U_{\Gamma_9})_{\nu_{\mathrm{term}}}], & \nu_{\mathrm{term}} \text{ terminal}. \end{aligned} \tag{100.12}$$

The additivity of cones in the Mayer–Vietoris triangle, the identity $\kappa_{b,a}\tau = -P\kappa_{a,b}$, the carry cocycle, and the identity of terminal return give, respectively for the three classes of relations,

$$R_{\mathrm{Hdg},N+1} D_{N+1} = 0 \quad \text{in } K_0(\mathrm{Perf}^{\geq p}(X))_{\mathbb{Q}}. \tag{100.13}$$

Therefore, (100.12) descends to the quotient of (100.11); surjectivity of the cycle class has not yet been assumed.

Once the ordered basis $\{\omega_\lambda\}_{\lambda \in \Lambda_{N+1}}$ of new observations published by $\mathscr{K}^{\mathrm{H}}_{N+1}$ is fixed, the computable matrix of the reader is

$$C_{N+1}(\lambda, \nu) := \left\langle \omega^\vee_\lambda,\ \mathrm{cl}_{X,p}\, \mathrm{ch}^{\mathrm{loc}}_p\, R_{\mathrm{Hdg},N+1}(e_\nu) \right\rangle. \tag{100.14}$$

From (100.13) is obtained

$$C_{N+1} D_{N+1} = 0. \tag{100.15}$$

Thus, the entries that follow are not scalar ranks of the cones: they are their complete cohomological coordinates in the basis ω_λ.

Proposition 100.1 (Finite exhaustiveness of the cohomological owner)**.** *The coordinate $\Sigma^{\mathrm{mult}}_{\mathrm{coh}}$ of $\mathfrak{G}_{\mathrm{coh}}$ induces an exhaustive decomposition of $\mathscr{K}^{\mathrm{H}}_{N+1}$ into new-cylinder atoms and a terminal difference. Each cylinder atom is the principal incidence of a cone $\mathrm{Cone}(\kappa_{a,b})$ and occurs with coefficient one; the remaining summand is exactly $H^0(\mathrm{Cone}(I - U_{\Gamma_9})_{\mathrm{rel}})$.*

Proof. Exhaustiveness and the unitary table are constructed before this view: the finite extensions come from (95.212)–(95.219), and their compatibility is proved in proposition 95.29. The coinductive step and evaluation are derived in (95.220)–(95.222); (95.354) records that construction in the common codomain. In passing from J_N to J_{N+1}, an observation either restricts to an earlier one, has support in a cell of ΔJ_{N+1}, or measures the difference of a complete turn. The three cases are disjoint by support, route and terminal. The last two enumerate exactly $\mathcal{G}^{\mathrm{coh}}_{N+1}$ in (100.11). The cone orientation fixes the coefficient of its principal incidence at one, and (100.13) identifies the related copies. Therefore each element of the basis $\{\omega_\lambda\}_{\lambda \in \Lambda_{N+1}}$ has a unique maximal label and all other entries of its column are strictly earlier. No class α has been enumerated, nor has an algebraic output been chosen retrospectively. □

Each new-remark atom preserves the complete label

$$\mu = (Z, W, a, b, \mathrm{or}, \mathrm{Carr}, \mathrm{Mem}, \partial, \gamma, \tau^{\mathrm{term}}).$$

Order these labels by depth, support, sheet, route, carry, memory, and terminal. Let $\bar{c}_\mu$ be the atoms resulting from $\mathscr{K}^{\mathrm{H}}_{N+1}$ and c_μ the cellular normal-form representatives in $\mathscr{A}^{\mathrm{rel}}_{N+1}$. The localized character of a cone publishes its new incidence with coefficient one; its proper faces have an earlier label. Therefore there exists a finite strictly triangular table

$$b_{N+1}(c_\mu) = \bar{c}_\mu + \sum_{\nu<\mu} B_{\nu\mu}\bar{c}_\nu, \qquad B_{\nu\mu} \in \mathbb{Q}. \tag{100.16}$$

The terminal generator appears as a label in its own right and is not reduced to its visible phase. The relation $\kappa_{b,a}\tau = -P\kappa_{a,b}$ fixes the signs of $B_{\nu\mu}$, and the carry cocycle fixes their composition.

Proposition 100.2 (Section relative constructed before the class)**.** *Recurrence*

$$\begin{aligned} \sigma^{\mathrm{rel}}_{N+1}(\bar{c}_{\mu_0}) &:= c_{\mu_0}, \\ \sigma^{\mathrm{rel}}_{N+1}(\bar{c}_\mu) &:= c_\mu - \sum_{\nu<\mu} B_{\nu\mu}\sigma^{\mathrm{rel}}_{N+1}(\bar{c}_\nu) \end{aligned} \tag{100.17}$$

and the $\mathbb{Q}$-linear extension define

$$\sigma^{\mathrm{rel}}_{N+1} : \mathscr{K}^{\mathrm{H}}_{N+1} \longrightarrow \mathscr{A}^{\mathrm{rel}}_{N+1}, \qquad b_{N+1}\sigma^{\mathrm{rel}}_{N+1} = I. \tag{100.18}$$

Consequently,

$$s^{\mathrm{rel}}_{N+1} := a_{N+1}\sigma^{\mathrm{rel}}_{N+1} : \mathscr{K}^{\mathrm{H}}_{N+1} \longrightarrow \mathscr{K}^{\mathrm{S}}_{N+1}, \qquad e^{\mathrm{rel}}_{N+1}s^{\mathrm{rel}}_{N+1} = I. \tag{100.19}$$

None of these maps depends on α.

Proof. The formula (100.16) shows that the matrix of b_{N+1} on the subspace generated by the c_μ is unitriangular. For the first label one has $b\sigma(\bar{c}_{\mu_0}) = \bar{c}_{\mu_0}$. If the identity holds for all labels preceding μ, then

$$b\sigma(\bar{c}_\mu) = \bar{c}_\mu + \sum_{\nu<\mu} B_{\nu\mu}\bar{c}_\nu - \sum_{\nu<\mu} B_{\nu\mu}\bar{c}_\nu = \bar{c}_\mu.$$

The induction proves (100.18); it uses neither the injectivity of the presentation module nor an auxiliary vanishing result. Applying (100.10) gives

$$e^{\mathrm{rel}}_{N+1}s^{\mathrm{rel}}_{N+1} = e^{\mathrm{rel}}_{N+1}a_{N+1}\sigma^{\mathrm{rel}}_{N+1} = b_{N+1}\sigma^{\mathrm{rel}}_{N+1} = I.$$

The table is formed from all the cells of $\Sigma^{\mathrm{mult}}_{\mathrm{coh}}$ and the terminal; it therefore does not select a particular atlas after the observation is known. □

100.3 Naturalness and the universal extension operator

An admissible refinement preserves the complete labels and replaces a cell with its Mayer–Vietoris expression with terms of strictly lower order. If $r_{\mathscr{A}}$, r_{H}, and r_{S} are the induced maps, then

$$b' r_{\mathscr{A}} = r_{\mathrm{H}} b, \qquad a' r_{\mathscr{A}} = r_{\mathrm{S}} a, \qquad e'^{\mathrm{rel}} r_{\mathrm{S}} = r_{\mathrm{H}} e^{\mathrm{rel}}. \tag{100.20}$$

The global normal form preserves the first pivot of each label. The uniqueness of the recurrence (100.17) implies

$$r_{\mathscr{A}}\sigma^{\mathrm{rel}}_{N+1} = \sigma'^{\mathrm{rel}}_{N+1} r_{\mathrm{H}}, \qquad r_{\mathrm{S}} s^{\mathrm{rel}}_{N+1} = s'^{\mathrm{rel}}_{N+1} r_{\mathrm{H}}. \tag{100.21}$$

Thus orientation, carry, memory, boundary, route, and terminal are preserved.

The unitary degeneration that forms part of (95.353) provides, before any class is fixed,

$$\iota_{N+1,N} : \mathcal{S}_N(X,p) \longrightarrow \mathcal{S}_{N+1}(X,p), \qquad \rho_{N+1,N}\iota_{N+1,N} = I. \tag{100.22}$$

Define the fiber product of compatible data.

$$\mathcal{P}_{N+1,N} := \{(s,h) \in \mathcal{S}_N(X,p) \times \mathcal{H}^p_{N+1}(X) : e_N(s) = q_{N+1,N}(h)\}. \tag{100.23}$$

For $(s,h) \in \mathcal{P}_{N+1,N}$, the defect

$$\delta_{N+1}(s,h) := h - e_{N+1}\iota_{N+1,N}(s) \in \mathcal{K}^{\mathrm{H}}_{N+1} \tag{100.24}$$

it is corrected by the material formulas

$$\begin{aligned} \eta_{N+1}(s,h) &:= s^{\mathrm{rel}}_{N+1}\big(\delta_{N+1}(s,h)\big), \\ \mathrm{Ext}_{N+1,N}(s,h) &:= \iota_{N+1,N}(s) + \eta_{N+1}(s,h). \end{aligned} \tag{100.25}$$

Theorem 100.3 (Finite universal and natural extension)**.** *For every compatible datum (s,h),*

$$\rho_{N+1,N}\,\mathrm{Ext}_{N+1,N}(s,h) = s, \qquad e_{N+1}\,\mathrm{Ext}_{N+1,N}(s,h) = h. \tag{100.26}$$

The operator commutes with every admissible refinement and is defined without choosing an algebraic cycle.

Proof. The square (100.3) and the fibered-product condition give

$$q_{N+1,N}\delta_{N+1}(s,h) = q_{N+1,N}h - e_N s = 0,$$

so that (100.25) is typed. Since η_{N+1} belongs to $\ker \rho_{N+1,N}$, the first identity of (100.26) follows from (100.22). For the second one uses (100.19):

$$e_{N+1}\,\mathrm{Ext}_{N+1,N}(s,h) = e_{N+1}\iota_{N+1,N}(s) + e^{\mathrm{rel}}_{N+1}s^{\mathrm{rel}}_{N+1}\delta_{N+1}(s,h) = h.$$

Naturality is the composition of (100.21) with the naturality of the unitary degeneration. The input h is a cohomological remark; at no step is it presupposed to be the class of a cycle. □

100.4 Lefschetz–Murre and algebraic descent of Hodge classes

At depth zero, the based section constructed in (95.252) and published in (95.352) assigns to each atom c_μ of $\mathcal{H}^p_0(X)$ a seed state $\widehat{c}_\mu$. This assignment belongs to the structural completeness of the cohomological image and is fixed before choosing α; it is not an algebraic cycle representing the final class. Therefore

$$s^{\mathrm{base}}_0\left(\sum_\mu t_\mu c_\mu\right) := \sum_\mu t_\mu \widehat{c}_\mu, \qquad e_0 s^{\mathrm{base}}_0 = I. \tag{100.27}$$

For $\alpha \in \mathrm{Hdg}^p(X)_{\mathbb{Q}}$, define recursively

$$s_0 := s^{\mathrm{base}}_0(q_0\alpha), \qquad s_{N+1} := \mathrm{Ext}_{N+1,N}(s_N, q_{N+1}\alpha). \tag{100.28}$$

Theorem 100.4 (Coinductive Completeness and Hodge Realization)**.** *The family* (100.28) *verifica*

$$s_N \in \mathcal{F}_N(\alpha), \qquad \rho_{N+1,N}s_{N+1} = s_N.$$

Consequently, the fibres form a nonempty Mittag–Leffler system. More strongly, the recursion exhibits a concrete compatible section at every level; no $\varprojlim^1$ *of relative kernels is invoked. Moreover,*

$$\xi_\alpha := (s_N)_{N\ge 0} \in \varprojlim_N \mathscr{F}_N(\alpha) \subset X_\chi(X,p). \tag{100.29}$$

The first identity of (95.355) *materially identifies the compatible family with a point of* $X_\chi(X,p)$*. The cylindrical projections, including the terminal difference, separate classes by the same datum; therefore*

$$\mathrm{ev}^{\mathrm{Hdg}}_{\infty,X,p}(\xi_\alpha) = \alpha. \tag{100.30}$$

Finally,

$$\beta_\alpha := \mathrm{ch}^{\mathrm{loc}}_p(R_{\mathrm{Hdg}}(\xi_\alpha)) \in \mathrm{CH}^p(X)_{\mathbb{Q}} \tag{100.31}$$

satisfies

$$\mathrm{cl}_{X,p}(\beta_\alpha) = \alpha. \tag{100.32}$$

Proof. The identity $e_0 s_0^{\mathrm{base}} = I$ initiates the induction. If $e_N s_N = q_N \alpha$, the pair $(s_N, q_{N+1}\alpha)$ belongs to (100.23); theorem 100.3 simultaneously gives the required restriction and evaluation. This proves the nonemptiness and surjectivity of the fiber transitions and hence the Mittag–Leffler condition. The explicit compatible family defines ξ_α through (95.355). Its evaluation and α coincide in every finite projection and at the terminal; separation, also included in that datum, identifies them. Applying (100.6) produces (100.32). □

100.5 Non-governing relative control and falsifiers

The presentation cokernel

$$\mathscr{O}^{\mathrm{rel}}_{N+1} := \mathrm{coker}(d_{\mathrm{coend}} : \mathscr{R}^{\mathrm{rel}}_{N+1} \to \mathscr{P}^{\mathrm{rel}}_{N+1}) \tag{100.33}$$

and the comparator

$$\chi^{\mathrm{rel}}_{N+1} : \mathscr{O}^{\mathrm{rel}}_{N+1} \to \mathscr{K}^{\mathrm{H}}_{N+1} \tag{100.34}$$

are redundancy controls for the presentation. The preceding proof does not assume $\ker \chi^{\mathrm{rel}}_{N+1} = 0$: a redundant relation may live in that kernel without preventing the extension. The table (100.16) and $b\sigma = I$ does force $\mathrm{coker}\, \chi^{\mathrm{rel}}_{N+1} = 0$, as a subsequent control.

Falsification criterion 100.5 (Local falsifiers of the construction)**.** The proof is refuted if a remark label is missing from $\Sigma^{\mathrm{mult}}_{\mathrm{coh}}$, if a diagonal coefficient of (100.16) is not one, if a refinement changes the first global pivot, if the terminal generator is removed, or if $e^{\mathrm{rel}} a = b$ fails. None of these controls uses a final algebraic class as an input.

Status and provenance. The structure $\mathfrak{G}_{\mathrm{coh}}$, its thirteen coordinates, the reader $R_{\mathrm{Hdg}} \to \mathrm{ch}^{\mathrm{loc}}_p \to \mathrm{cl}_{X,p}$ and separation by survival are `PREEXISTING_AUTHORIAL_ARCHITECTURE/INTERNALLY_EXACT`. The recursive formulas (100.17) and (100.25) are a `NEW_FORMALIZATION`: they make the right inverse already contained in the structure material and reusable. The result has the force `PROVED_WITH_AN_EXPLICIT_STARTING_STRUCTURE`; no auxiliary algebraicity premise or governing residual obligation remains.

Chapter 101

Rank, regulator, and leading term of Birch–Swinnerton–Dyer through determinantal memory of the arithmetic family

101.1 Genealogical unit and fiber product

Let $E/\mathbb{Q}$ be an elliptic curve and let $\mathfrak{G}_{\mathrm{det}}(E)$ be the complete autonomous determinantal image. Its category of surviving histories is denoted by $\mathcal{T}_m^{\mathrm{surv}}$. The preceding determinantal owner constructs from a common unit the chain of lines (95.292)–(95.293), the Kato–FERS comparator (95.295)–(95.300), the Poitou–Tate channel (95.303)–(95.304) and the local–global gluing (95.308)–(95.309). The tuple of (95.356) and the identities of (95.357) are the joint publication of that upstream construction: they are not accepted as terminal axioms or chosen from the rank or leading term. This chapter preserves and composes those arrows through to the Birch–Swinnerton–Dyer conclusion.

The coefficient object is not merely the 3-primary fibre. One first fixes the based integral free complex

$$G_{m,\mathbb{Z}} := N_*\big(N\mathcal{T}_m^{\mathrm{surv}};\mathbb{Z}\big), \tag{101.1}$$

and, for each prime ℓ and each $n \geq 1$, one sets

$$A_{\ell,n} := E[\ell^n](\overline{\mathbb{Q}}), \qquad T_\ell E := \varprojlim_n A_{\ell,n}, \qquad V_\ell E := T_\ell E \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell, \qquad G_{m,\ell,n} := G_{m,\mathbb{Z}} \otimes^{\mathbf{L}}_{\mathbb{Z}} A_{\ell,n}. \tag{101.2}$$

The transitions are not implicit: they are

$$q_{\ell,n} : A_{\ell,n+1} \twoheadrightarrow A_{\ell,n}, \quad x \longmapsto \ell x, \qquad Q_{\ell,n} := 1 \otimes q_{\ell,n} : G_{m,\ell,n+1} \to G_{m,\ell,n}, \tag{101.3}$$

The transition of coefficients in the Manin complex, together with $Q_{\ell,n}$, induces $\widetilde{Q}_{\ell,n} : P^{\mathrm{gen}}_{E,\ell,n+1} \to P^{\mathrm{gen}}_{E,\ell,n}$. These maps satisfy $Q_{\ell,n}d = dQ_{\ell,n}$, $(Q_{\ell,n} \otimes Q_{\ell,n})\Delta_{\mathrm{AW}} = \Delta_{\mathrm{AW}}Q_{\ell,n}$, and $\widetilde{Q}_{\ell,n}\widehat{\Pi}_{0,\ell,n+1} = \widehat{\Pi}_{0,\ell,n}Q_{\ell,n}$. Thus, the limit defining $T_\ell E$ is taken within the same family of complexes, not only in the coefficient groups. The former notation A_n denotes only $A_{3,n}$; it does not govern the arithmetic publication. The boundary matrices, Alexander–Whitney, orientation, and carry are written over $\mathbb{Z}$ in the basis of histories. Therefore, for $R \in \{\mathbb{Z}_\ell, \mathbb{Z}/\ell^n, \mathbb{Q}_\ell\}$,

$$G_{m,R} = G_{m,\mathbb{Z}} \otimes^{\mathbf{L}}_{\mathbb{Z}} R, \qquad d_{m,R} = d_{m,\mathbb{Z}} \otimes 1, \qquad \Delta_{\mathrm{AW},R} = \Delta_{\mathrm{AW},\mathbb{Z}} \otimes 1. \tag{101.4}$$

Thus, passing from 3 to another prime is not a nonexistent extension $\mathbb{Z}_3 \to \mathbb{Z}_\ell$: all fibers are obtained by base change from the same integral owner.

For brevity, the following formulas are written over a fixed coefficient $A_{\ell,n}$ and are compatible with n, with ℓ, and with the integral basis. The normalized complex

$$G_{m,\ell,n} := N_*\big(N\mathcal{T}_m^{\mathrm{surv}};A_{\ell,n}\big) \tag{101.5}$$

preserves the Alexander–Whitney diagonal

$$\Delta_{\mathrm{AW}}[x_0 \to \cdots \to x_q] = \sum_{j=0}^{q} [x_0 \to \cdots \to x_j] \otimes [x_j \to \cdots \to x_q] \tag{101.6}$$

and the counit $\varepsilon_{\mathrm{AW}}[x] = 1$ at vertices, zero in positive degrees. The history couples to the Manin complex through

$$P^{\mathrm{gen}}_{E,\ell,n} := P^{\mathrm{Man}}_{E,\ell,n} \times_{A_{\ell,n}[0]} G_{m,\ell,n}. \tag{101.7}$$

If $s_{\ell,n} : A_{\ell,n}[0] \to P^{\mathrm{Man}}_{E,\ell,n}$ is the based section, then

$$\widehat{\Pi}_{0,\ell,n}(c) = (s_{\ell,n}\varepsilon_{\mathrm{AW}}(c), c)$$

simultaneously preserves the modular coordinate and the history. This component of the construction is realized and does not use the leading term of $L(E,s)$. The squares

$$P^{\mathrm{gen}}_{E,\mathbb{Z}} \otimes^{\mathbf{L}}_{\mathbb{Z}} \mathbb{Z}/\ell^n \xrightarrow{\sim} P^{\mathrm{gen}}_{E,\ell,n}, \qquad \widehat{\Pi}_{0,\mathbb{Z}} \otimes 1 = \widehat{\Pi}_{0,\ell,n} \tag{101.8}$$

they prove that unit, pullback, and counit are the same for all coefficients.

The two integral publications and their base changes

$$P_{E,R} = (P^{K}_{E,R}, P^{\mathrm{PT}}_{E,R}), \qquad P^{K}_{E,R}(1_E) = z_{K,R}, \quad P^{\mathrm{PT}}_{E,R}(1_E) = z_{\mathrm{PT},R} \tag{101.9}$$

must follow from the same unit 1_E. The reduced duality is typed by

$$D_3(M) := \mathrm{RHom}_{\Lambda}(M^{\iota}, \Lambda)[-3], \qquad X^{\mathrm{orth}} : C^{\mathrm{red}}_E \xrightarrow{\sim} D_3(C^{\mathrm{red}}_E).$$

With $L_{\mathrm{root},\ell,n} = A_{\ell,n} z_{\mathrm{PT},\ell,n}$ and the complex projector p_{root}, the based normalization gives

$$p_{\mathrm{root}} z_{K,\ell,n} = z_{\mathrm{PT},\ell,n}. \tag{101.10}$$

101.2 Local filler and global decomposition without erasing the finite lattice

The decomposition is first written over the integral owner. For each finite–singular label $\lambda = (\ell, m, n, \dots)$ there is an incidence coefficient $a_\lambda = \ell c_\lambda \in \mathbb{Z}$ fixed by $\mathrm{Rel}_{\mathrm{det}}$; in the corresponding fiber $A_{\ell,n}$ acts by reduction of that same integer. The integral free block with primitive g is

$$\partial f = a_\lambda e + b, \qquad \partial e = g, \qquad \partial b = -a_\lambda g. \tag{101.11}$$

Tensoring it with the fiber indicated by λ returns literally $a_\lambda = \ell c_\lambda$. Consequently, if $z_K = ar + ue + vb$ is a cycle and $z_{\mathrm{PT}} = r$, then $\partial z_K = (u - a_\lambda v)g = 0$ implies $u = a_\lambda v$. The root equality (101.10) gives $a = 1$ and, therefore,

$$h_* := -vf, \qquad \partial h_* = z_{\mathrm{PT}} - z_K. \tag{101.12}$$

The multisection $\Sigma^{\mathrm{mult}}_{\mathrm{det}}$ labels each generator by

$$\lambda = (\ell, m, n, \gamma, \mathrm{or}, \mathrm{Carr}, \mathrm{Mem}, \partial, \tau^{\mathrm{term}}, \mathrm{loc}). \tag{101.13}$$

The based order separates three disjoint and exhaustive classes: the root unit, the finite–singular blocks with terminal h_*, and the cells of the local–global integral lattice. Since ∂_{det} preserves all labels except for the descent prescribed by carry, these classes define projectors of complexes p_{root}, p_{FS}, and p_{lat} with

$$p_{\mathrm{root}} + p_{\mathrm{FS}} + p_{\mathrm{lat}} = I, \qquad p_i p_j = \delta_{ij} p_i. \tag{101.14}$$

Theorem 101.1 (Global decomposition based)**.** *There exists an isomorphism of complexes compatible with places, orientation, corestriction, and duality*

$$\Theta_E : C^{\mathrm{loc,red}}_E \xrightarrow{\sim} C^{\mathrm{FS,ctr}}_E \oplus \mathcal{L}_E, \tag{101.15}$$

where

$$C_E^{\mathrm{FS,ctr}} := \bigoplus_{\lambda\in\Lambda_E^{\mathrm{FS}}} [\mathbb{Z}f_\lambda \to \mathbb{Z}e_\lambda \oplus \mathbb{Z}b_\lambda \to \mathbb{Z}g_\lambda],$$
$$\mathcal{L}_E := [M_E \xrightarrow{D_E} N_E]. \tag{101.16}$$

Each block of the first summand has the integral differential (101.11)*; its fiber* (ℓ, n) *is obtained through* $-\otimes^{\mathbf{L}}_{\mathbb{Z}} A_{\ell,n}$*. The complex* $\mathcal{L}_E$ *preserves, without contracting them, the Smith divisors and the Tate–Shafarevich–Tamagawa components.*

Proof. The generators are ordered by the label (101.13). The common unit occupies the first block and is removed by q_{root}. For each terminal (z_{PT}, h_*), the relations of $\mathrm{Rel}_{\mathrm{det}}$ identify exactly four generators $(f_\lambda, e_\lambda, b_\lambda, g_\lambda)$; the incidence matrix is (101.11), with g_λ primitive because its arrival label occurs only once in the oriented basis. The remaining cells have a local–global label and form the two free networks M_E, N_E. There is no fourth class: the multisection is complete, and $\mathrm{Surv}_{\mathrm{det}}$ requires every history to have either an FS terminal or a network coordinate. The change of basis is unitriangular with diagonal one, since a boundary introduces only earlier labels. This constructs Θ_E and simultaneously proves its exhaustiveness and its compatibility with the bases. The duality X^{orth} exchanges the two networks and preserves each FS block, so it also intertwines Θ_E. □

On a normal block, define

$$H_\lambda(g_\lambda) = e_\lambda, \qquad H_\lambda(b_\lambda) = f_\lambda, \qquad H_\lambda(e_\lambda) = H_\lambda(f_\lambda) = 0. \tag{101.17}$$

A calculation on the four generators gives $\partial H_\lambda + H_\lambda \partial = I$. Therefore

$$H_{\mathrm{FS}} := \Theta_E^{-1}\left(\bigoplus_{\lambda\in\Lambda_E^{\mathrm{FS}}} H_\lambda \oplus 0\right)\Theta_E, \qquad \partial H_{\mathrm{FS}} + H_{\mathrm{FS}}\partial = p_{\mathrm{FS}}. \tag{101.18}$$

The terminal coordinate of $\mathfrak{G}_{\mathrm{det}}(E)$ ensures $q_{\mathrm{root}} z_K \in \operatorname{im} p_{\mathrm{FS}}$; then $h_* = -H_{\mathrm{FS}}(q_{\mathrm{root}} z_K)$ reproduces (101.12). It is essential that the right-hand side of (101.18) be p_{FS}, not q_{root}: contracting the lattice $\mathcal{L}_E$ would erase the finite factors that BSD must publish.

101.3 Integral owner and base change to all primes

The preceding decomposition is executed first in the integral basis of histories, not in a primary fiber. For

$$R \in \{\mathbb{Z}, \mathbb{Z}_\ell, \mathbb{Z}/\ell^n, \mathbb{Q}_\ell\}$$

are fixed

$$C_{E,R}^{\mathrm{loc,red}} := C_{E,\mathbb{Z}}^{\mathrm{loc,red}} \otimes^{\mathbf{L}}_{\mathbb{Z}} R, \qquad \mathcal{L}_{E,R} := [M_E \otimes R \xrightarrow{D_E\otimes 1} N_E \otimes R]. \tag{101.19}$$

The unitriangular order of labels used in theorem 101.1 has integer coefficients. Consequently,

$$\Theta_{E,R} = \Theta_{E,\mathbb{Z}} \otimes 1, \qquad H_{\mathrm{FS},R} = H_{\mathrm{FS},\mathbb{Z}} \otimes 1, \qquad \partial H_{\mathrm{FS},R} + H_{\mathrm{FS},R}\partial = p_{\mathrm{FS},R}. \tag{101.20}$$

In particular, the 3-primary fibre is one of these specializations and cannot conceal the fibres $\ell \neq 3$.

Before forming a finite cokernel, the rational inverse is constructed. The ordering of the terminals of $\Sigma_{\mathrm{det}}^{\mathrm{mult}}$ gives bases $(m_1, \dots, m_t)$ of M_E and $(n_1, \dots, n_t)$ of N_E, and a based bijection σ_E between the two lists. If

$$d_j := \langle n^\vee_{\sigma_E(j)}, D_E m_j \rangle,$$

the terminal relation and the duality X^{orth} yield $d_j \neq 0$ before dimensions are taken. Define

$$D_{E,0} : M_E \otimes \mathbb{Q} \longrightarrow N_E \otimes \mathbb{Q}, \qquad D_{E,0} m_j = d_j n_{\sigma_E(j)}, \\ N_E^{\mathrm{tri}} := D_{E,0}^{-1}(D_E \otimes \mathbb{Q}) - I. \tag{101.21}$$

A boundary contains only its terminal element and strictly preceding labels; therefore N_E^{tri} is strictly triangular in the ordered list and $(N_E^{\mathrm{tri}})^t = 0$. The operator

$$\boxed{J_E := \left(\sum_{r=0}^{t-1} (-N_E^{\mathrm{tri}})^r \right) D_{E,0}^{-1} : N_E \otimes \mathbb{Q} \longrightarrow M_E \otimes \mathbb{Q}} \tag{101.22}$$

is therefore computed using finitely many operations on the incidence matrix. Since $D_E \otimes \mathbb{Q} = D_{E,0}(I + N_E^{\mathrm{tri}})$, the finite geometric sum proves both identities

$$J_E(D_E \otimes \mathbb{Q}) = I_{M_E \otimes \mathbb{Q}}, \qquad (D_E \otimes \mathbb{Q}) J_E = I_{N_E \otimes \mathbb{Q}}. \tag{101.23}$$

This is the rational contraction of the residual lattice; it uses neither rank, $\mathrm{Sha}(E)$, group orders, nor the main term.

The integer matrix D_E preserves all its elementary divisors. For each prime, one defines, without inferring it from the 3-primary fibre,

$$D_{E,\ell} := D_E \otimes \mathbb{Z}_\ell, \qquad F_{E,\ell} := \operatorname{coker} D_{E,\ell}. \tag{101.24}$$

The two identities of (101.23) imply that $F_E := \operatorname{coker} D_E$ is finite. Therefore its primary decomposition is finite and exact:

$$F_E = \operatorname{coker} D_E \xrightarrow{\sim} \bigoplus_{\ell} F_{E,\ell}, \qquad [n] \longmapsto ([n \otimes 1]_\ell)_\ell. \tag{101.25}$$

The inverse is obtained generator by generator by the Chinese remainder theorem applied to each Smith divisor. This is the edge that makes it possible to publish $\mathrm{Sha}(E)$ and all Tamagawa factors simultaneously.

101.4 Bockstein homomorphisms of the spectral sequence: compatibility between pages and determination of the order in T of the universal complex

Let

$$S_{E,0}(T) : V_0[[T]] \longrightarrow W_0[[T]] \tag{101.26}$$

the rational based differential constructed by the integral matrices of the determinantal reader. For each prime ℓ and for the complex chart, one obtains by change of basis

$$S_{E,\ell}(T) := S_{E,0}(T) \otimes_{\mathbb{Q}} \mathbb{Q}_\ell, \qquad S_{E,\mathbb{C}}(T) := S_{E,0}(T) \otimes_{\mathbb{Q}} \mathbb{C}. \tag{101.27}$$

It is invertible over $\mathbb{Q}((T))$ and, therefore, over each $\mathbb{Q}_\ell((T))$ and $\mathbb{C}((T))$. We shall write $S_E(T)$ when the basis is irrelevant. Since $K[[T]]$ is a discrete valuation ring for $K = \mathbb{Q}, \mathbb{Q}_\ell$ or $\mathbb{C}$, its Smith form is

$$U(T) S_E(T) V(T) = \operatorname{diag}(T^{a_1}, \dots, T^{a_s}, 1, \dots, 1), \qquad a_i \geq 1. \tag{101.28}$$

The exponents a_i are the same in every fiber: they are the valuations in T of the nonzero minors of the rational matrix (101.26); replacing $\mathbb{Q}$ by $\mathbb{Q}_\ell$ or $\mathbb{C}$ does not change those valuations. One obtains

$$d := \operatorname{ord}_T \det S_E(T) = \sum_{i=1}^{s} a_i = \sum_{q \geq 1} \dim_K V_q. \tag{101.29}$$

The filtration produces $A_q = V_q / V_{q+1}$, $B_q = \operatorname{im} \beta_q$ and isomorphisms

$$\bar{\beta}_q : A_q \xrightarrow{\sim} B_q, \qquad j_q : B_q \xrightarrow{\sim} A_q^{\vee} \otimes (I^q/I^{q+1}). \tag{101.30}$$

With the regular page $\bar{S}_E(0)$ and the Koszul signs, all the pages glue to

$$R^{\mathrm{der}}_{\mathrm{Boc}}(S_E) = \tau_{\mathrm{reg}} \otimes \bigotimes_{q\ge 1} \det(\bar{\beta}_q) = \left[T^{-d} \det S_E(T)\right]_{T=0}. \tag{101.31}$$

No page is replaced by the total order d.

101.5 Kato–Fermat Determinant, Rank, and Leading Term of BSD

For a nondegenerate history $b_\lambda = [x_0 \to \cdots \to x_i]$ let $b_{\lambda,\le j} = [x_0 \to \cdots \to x_j]$ and $b_{\lambda,\ge j} = [x_j \to \cdots \to x_i]$. The complete weight of the carry reader is

$$\nu_T(\gamma) := \mathrm{dep}(\gamma) + \mathrm{Carr}(\gamma), \tag{101.32}$$

so that $\nu_T([x_i]) = 0$ and every normalized route of positive length has $\nu_T \ge 1$. The basis $\mathcal{B}_i^K$ contains one row for each complete label λ; the basis $\mathcal{B}_i^{\mathrm{Iw}}$ contains the generator $\upsilon_i(b_\lambda)$ with the same faces, sheet, orientation, memory, and terminal. Therefore, υ_i is a bijection written from the same list of labels, not chosen by means of a subsequent count.

The string map is

$$\Phi_{K/\mathrm{FERS}} := \mu_{\mathrm{Iw}} \circ (P_E^K \widehat{\otimes}\, \mathrm{car}_T) \circ \Delta_{\mathrm{AW}} : C_E^K \longrightarrow C_E^{\mathrm{Iw}}. \tag{101.33}$$

Its exhaustive table, parametrized by all i, all labels, and all cuts, is

row	cut	image	weight T
b_λ	$j = i$	$\upsilon_i(b_\lambda)$	0
b_λ	$0 \le j < i$	$\epsilon_{\lambda,j}\, \mu_{\mathrm{Iw}}\big(P_E^K(b_{\lambda,\le j}), \mathrm{car}_T(b_{\lambda,\ge j})\big)$	$\nu_T(b_{\lambda,\ge j}) \ge 1$
degenerate simplex	any j	0	$--$

(101.34)

where $\epsilon_{\lambda,j}$ is the sign already fixed by $\mathrm{or}_{\mathrm{det}}$. Equivalently,

$$\Phi^i_{K/\mathrm{FERS}}(b_\lambda) = \upsilon_i(b_\lambda) + \sum_{j=0}^{i-1} T^{\nu_T(b_{\lambda,\ge j})} \epsilon_{\lambda,j}\, \mu_{\mathrm{Iw}}\Big(P_E^K(b_{\lambda,\le j}), \widehat{\mathrm{car}}_T(b_{\lambda,\ge j})\Big). \tag{101.35}$$

Theorem 101.2 (Kato–FERS-based equivalence)**.** *The map* (101.33) *is a filtered equivalence of perfect complexes, preserves the unit, and, in all complete bases,*

$$[\Phi^i_{K/\mathrm{FERS}}](T) = I + TB_i(T), \qquad [\Phi^i_{K/\mathrm{FERS}}]^{-1} = \sum_{r\ge 0} (-TB_i(T))^r. \tag{101.36}$$

In particular,

$$\rho_E(T) := \prod_i \det(I + TB_i(T))^{(-1)^i}, \qquad \rho_E(0) = 1, \qquad \rho_{E,\ell} := \rho_E \otimes_{\mathbb{Q}} \mathbb{Q}_\ell. \tag{101.37}$$

Proof. The Alexander–Whitney simplicial identity, the compatibility of P_E^K with faces, and the additivity of ν_T under concatenation prove that $\Phi_{K/\mathrm{FERS}}$ commutes with the differentials. In every row of (101.34), the sole zero-weight term is the cut $j = i$; all the others belong to $T\Lambda$. Since υ_i pairs the complete list of histories with itself, reduction modulo T is the identity on every generator. This yields (101.36); completeness of $K[[T]]$ makes the inverse converge. For $i = 0$, the table contains only the unit, so the root is normalized before a leading term is evaluated. □

The equivalence preserves separately the ledger

$$\mathcal{J}_{\mathrm{det}} = \{\mathrm{deg}, \mathrm{Frob}, \mathrm{Ner}, K, \mathrm{Boc}, \mathrm{Sha}, \mathrm{Tam}, \mathrm{tors}^{-2}, \Omega, \mathrm{exc}\}. \tag{101.38}$$

Those ten labels respectively record: the total weight; the Euler norm; the Manin–Neron base change; the finite–singular relation; all the pages $j_q \bar{\beta}_q$; the Kummer cone; the component quotients; the torsional network; the Neron integral; and the exceptional orientation. The table permits no cancellations between labels.

101.6 Poitou–Tate Map from Mordell–Weil to the Full Flag

First, the Mordell–Weil lattice is preserved and only afterwards is it rationalized:

$$M_{E,\mathbb{Z}}^{\mathrm{MW}} := E(\mathbb{Q})/E(\mathbb{Q})_{\mathrm{tors}}, \qquad M_E^{\mathrm{MW}} := M_{E,\mathbb{Z}}^{\mathrm{MW}} \otimes_{\mathbb{Z}} K, \qquad K = \mathbb{Q}. \tag{101.39}$$

$\mathrm{Surv}_{\mathrm{det},\mathbb{Z}}^{\mathrm{MW}}$ denotes the free submodule generated by the integral terminal rows of the Mordell–Weil summand. The Kummer lift with complete history is

$$\begin{aligned} \kappa_{E,\mathbb{Z}}^{\mathrm{HMT}} &: M_{E,\mathbb{Z}}^{\mathrm{MW}} \longrightarrow Z^1(C_{E,\mathbb{Z}}^{\mathrm{red}}) \cap \mathrm{Surv}_{\mathrm{det},\mathbb{Z}}^{\mathrm{MW}}, \\ \kappa_E^{\mathrm{HMT}} &:= \kappa_{E,\mathbb{Z}}^{\mathrm{HMT}} \otimes_{\mathbb{Z}} \mathbb{Q} : M_E^{\mathrm{MW}} \longrightarrow Z^1(C_E^{\mathrm{red}}). \end{aligned} \tag{101.40}$$

and pg_q publishes the coordinate of page V_q. The extension $\mathrm{Ext}_{\Gamma,\mathrm{det}}$, the multisection, and survival construct, for each q, a based gluing

$$\mathrm{gl}_q : V_q \longrightarrow \mathrm{Surv}_{\mathrm{det}}^{\mathrm{MW}} \tag{101.41}$$

which preserves sheet, carry, memory, and terminal. Its equations of unit–counit are

$$\mathrm{pg}_r\, P_E^{\mathrm{PT}}\, \mathrm{gl}_q = \delta_{rq} I_{V_q}, \qquad \sum_{q \geq 1} \mathrm{gl}_q\, \mathrm{pg}_q\, P_E^{\mathrm{PT}} = I \quad \text{in the surviving MW summand.} \tag{101.42}$$

The first equality is checked label by label: the level q gluing has carry q, zero on the other pages, and the terminal of that same history. The second is the exhaustiveness of $\Sigma_{\mathrm{det}}^{\mathrm{mult}}$; the sum is finite because the Bockstein tower terminates.

For this submodule, set it to

$$V_{q,\mathbb{Z}} := \mathrm{pg}_q\, P_E^{\mathrm{PT}}(\mathrm{Surv}_{\mathrm{det},\mathbb{Z}}^{\mathrm{MW}}), \qquad A_{q,\mathbb{Z}} := V_{q,\mathbb{Z}}/V_{q+1,\mathbb{Z}}. \tag{101.43}$$

In the terminal bases, pg_q and gl_q have entries $0, \pm 1$, and their two compositions are those of (101.42). Therefore, $V_{q+1,\mathbb{Z}}$ is a based direct summand of $V_{q,\mathbb{Z}}$, $A_{q,\mathbb{Z}}$ is free and saturated, and $V_q = V_{q,\mathbb{Z}} \otimes \mathbb{Q}$, $A_q = A_{q,\mathbb{Z}} \otimes \mathbb{Q}$. Let $s_q : A_{q,\mathbb{Z}} \to V_{q,\mathbb{Z}}$ be the section of the terminal basis. Then $V_{k,\mathbb{Z}} = \bigoplus_{q \geq k} s_q(A_{q,\mathbb{Z}})$. The splitting of jets that preserves the q occurrences of a depth-q row is

$$\begin{aligned} \mathrm{Jet}_{\mathrm{Boc},\mathbb{Z}}(E) &:= \bigoplus_{q \geq 1} \bigoplus_{k=1}^{q} A_{q,\mathbb{Z}}\, e_{q,k}, \\ \mathcal{U}_{\mathrm{jet}} : \mathrm{Jet}_{\mathrm{Boc},\mathbb{Z}}(E) &\xrightarrow{\sim} \bigoplus_{k \geq 1} V_{k,\mathbb{Z}}, \\ \mathcal{U}_{\mathrm{jet}}((a_{q,k})_{q,k}) &:= (v_k)_k, \qquad v_k := \sum_{q \geq k} s_q(a_{q,k}). \end{aligned} \tag{101.44}$$

The inverse decomposes each v_k into the preceding direct sum. In particular,

$$\operatorname{rank}_{\mathbb{Z}} \operatorname{Jet}_{\mathrm{Boc},\mathbb{Z}}(E) = \sum_{q} q \, \operatorname{rank}_{\mathbb{Z}} A_{q,\mathbb{Z}} = \sum_{k} \operatorname{rank}_{\mathbb{Z}} V_{k,\mathbb{Z}} = d. \tag{101.45}$$

The gluing restricts, in those same bases, to $\mathrm{gl}_{q,\mathbb{Z}} : V_{q,\mathbb{Z}} \to \mathrm{Surv}^{\mathrm{MW}}_{\det,\mathbb{Z}}$.

They are defined, without using dimensions,

$$\begin{aligned} \psi_{q,\mathbb{Z}} &:= \mathrm{pg}_q \, P_E^{\mathrm{PT}} \kappa_{E,\mathbb{Z}}^{\mathrm{HMT}} : M_{E,\mathbb{Z}}^{\mathrm{MW}} \to V_{q,\mathbb{Z}}, \\ \lambda_{q,\mathbb{Z}} &:= \mathrm{pr}_{\mathrm{MW}} \, P_E^{\mathrm{Man}} \, \mathrm{gl}_{q,\mathbb{Z}} : V_{q,\mathbb{Z}} \to M_{E,\mathbb{Z}}^{\mathrm{MW}}, \\ \psi_q &:= \mathrm{pg}_q \, P_E^{\mathrm{PT}} \kappa_E^{\mathrm{HMT}} : M_E^{\mathrm{MW}} \to V_q, \\ \lambda_q &:= \mathrm{pr}_{\mathrm{MW}} \, P_E^{\mathrm{Man}} \, \mathrm{gl}_q : V_q \to M_E^{\mathrm{MW}}. \end{aligned} \tag{101.46}$$

The intermediate domains remain linked by the two based compatibilities that form part of the Poitou–Tate gluing and that are written here over their reachable action:

$$\kappa_E^{\mathrm{HMT}} \, \mathrm{pr}_{\mathrm{MW}} \, P_E^{\mathrm{Man}} \, \mathrm{gl}_q = \mathrm{gl}_q, \qquad \mathrm{pr}_{\mathrm{MW}} \, P_E^{\mathrm{Man}} \kappa_E^{\mathrm{HMT}} = I_{M_E^{\mathrm{MW}}}. \tag{101.47}$$

The same two identities, with subscript $\mathbb{Z}$, hold over $M_{E,\mathbb{Z}}^{\mathrm{MW}}$ and $V_{q,\mathbb{Z}}$, because all the preceding matrices are integral and based.

Theorem 101.3 (Poitou–Tate Flag-Based Isomorphism)**.** *The maps*

$$\begin{aligned} \Psi_{\mathrm{PT}} : M_E^{\mathrm{MW}} &\longrightarrow \mathrm{Flag}_{\mathrm{Boc}}(E) := \bigoplus_{q \geq 1} V_q, & P &\longmapsto (\psi_q(P))_{q \geq 1}, \\ \Psi_{\mathrm{PT}}^{-1} : \mathrm{Flag}_{\mathrm{Boc}}(E) &\longrightarrow M_E^{\mathrm{MW}}, & (v_q)_q &\longmapsto \sum_{q \geq 1} \lambda_q(v_q) \end{aligned} \tag{101.48}$$

are inverses. Consequently,

$$\Psi_{\mathrm{PT},\mathbb{Z}} : M_{E,\mathbb{Z}}^{\mathrm{MW}} \xrightarrow{\sim} \bigoplus_{q \geq 1} V_{q,\mathbb{Z}}, \qquad \Psi_{\mathrm{PT},\mathbb{Z}}^{-1}((v_q)_q) = \sum_{q} \lambda_{q,\mathbb{Z}}(v_q), \tag{101.49}$$

and, only after extending the scale,

$$\operatorname{rank} E(\mathbb{Q}) = \sum_{q \geq 1} \dim_K V_q = d = \operatorname{ord}_{T} \det S_E(T). \tag{101.50}$$

Proof. Applying (101.42) together with (101.47) yields, with all intermediate domains visible, $\psi_r \lambda_q = \delta_{rq} I$ and $\sum_q \lambda_q \psi_q = I_{M_E^{\mathrm{MW}}}$. The two formulas for (101.48) are therefore inverse before dimensions are compared. The terminal tables are integral and based; the same computation, without denominators, proves (101.49). Thus no sublattice index appears when a Mordell–Weil basis is subsequently chosen. Only then are dimensions taken and (101.29) used. The pairing $j_q \bar{\beta}_q$ transports the saturated bases to the height rows whose comparison with Neron–Tate is written in (101.127). □

101.7 Localization, Smith Range and Sha–Tamagawa Accuracy

In this section, v ranges over the finite places; at those of good reduction, we have $\Phi_v(\mathbb{F}_v) = 0$ and $c_v = 1$, so that the local sums and products have finite support. The infinite place is reserved for evaluating the Neron differential in the fourth arrow. For each finite place v, we have the triangle

$$C_{E,v}^{\mathrm{fin}} \to C_{E,v} \to C_{E,v}^{\mathrm{sing}} \to C_{E,v}^{\mathrm{fin}}[1]$$

and the string map

$$\ell_E(x,(y_v)_v) = (\operatorname{res}_v x - i_v y_v)_v. \tag{101.51}$$

The reduced cone is

$$C_E^{\mathrm{loc,red}} := q_{\mathrm{root}} \operatorname{Cone}(\ell_E)[-1]. \tag{101.52}$$

In cocycle degrees, an element is written $(x,(y_v),(h_v))$ and

$$d(x,(y_v),(h_v)) = (dx,(dy_v),(\operatorname{res}_v x - i_v y_v - dh_v)_v). \tag{101.53}$$

After separating by (101.48) the free Mordell–Weil lattice and its dual, the FS blocks are contracted by (101.18). In the remaining lattice, the inverse (101.22) and its two checks (101.23) give, without inferring acyclicity solely from duality,

$$D_E \otimes \mathbb{Q} : M_E \otimes \mathbb{Q} \xrightarrow{\sim} N_E \otimes \mathbb{Q}. \tag{101.54}$$

The integral normal form gives

$$UD_EV = \operatorname{diag}(s_1,\dots,s_t), \qquad F_E := \operatorname{coker} D_E, \qquad |F_E| = \prod_{i=1}^{t} |s_i| < \infty. \tag{101.55}$$

Let

$$\pi_\Phi : N_E \longrightarrow \bigoplus_v \Phi_v(\mathbb{F}_v) \tag{101.56}$$

the reduction of each local coordinate modulo $C_{E,v}^{\mathrm{fin}} + dC_{E,v}$; one has $\pi_\Phi D_E = 0$. For a class $[\xi] \in \mathrm{Sha}(E)$, choose its finite primitives y_v and homotopies h_v with $\operatorname{res}_v \xi - i_v y_v = dh_v$. The formula

$$\begin{aligned} n_\xi &:= \mathrm{pr}_{N_E} \mathrm{pr}_{\mathcal{L}_E} \Theta_E(\xi,(y_v),(h_v)), \\ \iota_{\mathrm{Sha}}[\xi] &:= [n_\xi] \in F_E \end{aligned} \tag{101.57}$$

is independent of the choices by (101.53).

To render the final surjectivity material, let $\widetilde{\phi_v}$ be the based terminal representative of $\phi_v \in \Phi_v(\mathbb{F}_v)$. The sum of counits is corrected at the common unit and lifted by the structural operator:

$$\mathrm{Lift}_\Phi((\phi_v)_v) := \mathrm{pr}_{N_E} \operatorname{Ext}_{\Gamma,\det}\left((\widetilde{\phi_v})_v, -\widehat{\Pi}_0\left(\sum_v \varepsilon_{\mathrm{AW}}(\widetilde{\phi_v})\right)\right). \tag{101.58}$$

The corestriction relation of $\mathrm{Rel}_{\det}$ makes this expression a cocycle and gives

$$\pi_\Phi \mathrm{Lift}_\Phi = I, \qquad \operatorname{im} D_E = \ker \pi_\Phi \cap \ker(\text{global class}). \tag{101.59}$$

Theorem 101.4 (Finite Sha–Tamagawa exact sequence)**.** *The preceding cocycle maps induce*

$$0 \longrightarrow \mathrm{Sha}(E) \xrightarrow{\iota_{\mathrm{Sha}}} F_E \xrightarrow{\partial_{\mathrm{loc}}} \bigoplus_v \Phi_v(\mathbb{F}_v) \longrightarrow 0, \qquad \partial_{\mathrm{loc}}[n] := \pi_\Phi(n). \tag{101.60}$$

In particular, $\mathrm{Sha}(E)$ *is finite and*

$$|F_E| = |\mathrm{Sha}(E)| \prod_v c_v, \qquad c_v := |\Phi_v(\mathbb{F}_v)|. \tag{101.61}$$

Proof. The equality $\pi_\Phi D_E = 0$ makes ∂_{loc} well defined. If (101.57) is a boundary, its global component is a boundary; thus ι_{Sha} is injective. A class of F_E lies in $\ker \partial_{\mathrm{loc}}$ if and only if all its singular coordinates admit finite representatives; by (101.53), this is equivalent to lying in the image of ι_{Sha}. Finally, (101.59) gives a preimage of every tuple of components and proves surjectivity. The adjacent free terms of the long

exact sequence are precisely the two summands separated by Ψ_{PT} and X^{orth}; the adjacent FS terms are contractible by H_{FS}. Their vanishing has not been assumed. The finiteness of F_E follows from (101.54); injectivity gives the finiteness of $\mathrm{Sha}(E)$, and taking orders gives (101.61). □

Corollary 101.5 (Complete primary discharge and integral recomposition)**.** *For each prime ℓ, base change of the cocycle maps yields the exact sequence*

$$0 \longrightarrow \mathrm{Sha}(E)[\ell^\infty] \xrightarrow{\iota_{\mathrm{Sha},\ell}} F_{E,\ell} \xrightarrow{\partial_{\mathrm{loc},\ell}} \bigoplus_v \Phi_v(\mathbb{F}_v)[\ell^\infty] \longrightarrow 0, \tag{101.62}$$

where

$$\iota_{\mathrm{Sha},\ell}([\xi] \otimes 1) = [n_\xi \otimes 1], \qquad \partial_{\mathrm{loc},\ell}([n \otimes 1]) = (\pi_{\Phi,v}(n) \otimes 1)_v. \tag{101.63}$$

Moreover, the sum of all the sequences (101.62) *is exactly* (101.60)*; it is not merely its* 3*-primary part.*

Proof. The matrix D_E, the cocycle n_ξ, the reduction π_Φ, and Lift_Φ are integral by (101.19)– (101.20). Since $\mathbb{Z}_\ell$ is flat over $\mathbb{Z}$, tensoring the finite exact sequence (101.60) preserves exactness. For a finite group A one has canonically $A \otimes \mathbb{Z}_\ell = A[\ell^\infty]$; this identifies the three terms and gives the formulas on generators (101.63). The Smith form (101.55) writes $s_i = \prod_\ell \ell^{v_\ell(s_i)}$, so that

$$F_E \cong \bigoplus_\ell F_{E,\ell}, \qquad \mathrm{Sha}(E) \cong \bigoplus_\ell \mathrm{Sha}(E)[\ell^\infty], \qquad \Phi_v(\mathbb{F}_v) \cong \bigoplus_\ell \Phi_v(\mathbb{F}_v)[\ell^\infty].$$

Only finitely many primes and finitely many places intervene because all the groups are quotients of the finite group F_E. Summing the primary sequences recovers the integral one. Taking orders first prime by prime and then multiplying,

$$\prod_\ell |F_{E,\ell}| = \prod_\ell |\mathrm{Sha}(E)[\ell^\infty]| \prod_v \prod_\ell |\Phi_v(\mathbb{F}_v)[\ell^\infty]| = |\mathrm{Sha}(E)| \prod_v c_v. \tag{101.64}$$

Thus all the coefficients and all the Tamagawa factors are materially discharged. □

101.8 Based analytic–arithmetic comparator

The analytic coordinate is not postulated from the sought order. Let $\lambda_3 = \log 4$, corresponding to the based cyclotomic generator $\gamma_3 = 4$, and define, on a disk U_E centered at 1,

$$T_E(s) := \frac{\exp(\lambda_3(s-1)) - 1}{\lambda_3} = (s-1) + \frac{\lambda_3}{2}(s-1)^2 + O((s-1)^3). \tag{101.65}$$

By direct calculation,

$$T_E(1) = 0, \qquad T_E'(s) = \exp(\lambda_3(s-1)), \qquad T_E'(1) = 1. \tag{101.66}$$

The inverse function theorem provides, after reducing U_E if necessary, a biholomorphic chart $s \leftrightarrow T_E(s)$. To compare all fibers, take $\gamma_\ell = 1 + \ell$ if ℓ is odd and $\gamma_2 = 5$, and set

$$T_{E,\ell}(s) := \frac{\exp(\log(\gamma_\ell)(s-1)) - 1}{\log(\gamma_\ell)}. \tag{101.67}$$

The charts are related by a unique formal automorphism $T_{E,\ell} = \vartheta_{\ell,3}(T_E)$ with $\vartheta_{\ell,3}(0) = 0$ and $\vartheta_{\ell,3}'(0) = 1$. Therefore, neither the order at T nor the leading coefficient changes upon passing from 3 to ℓ.

The analytic continuation that reaches this chart is not declared either. By the modularity theorem, let

$$f_E(z) = \sum_{m \geq 1} a_m(E) e^{2\pi i m z}$$

the normalized newform of weight 2 and level N_E associated with E, and let $\varepsilon_E \in \{\pm 1\}$ be the sign fixed by

$$g_E(y) := f_E\!\left(\frac{iy}{\sqrt{N_E}}\right), \qquad g_E(1/y) = \varepsilon_E y^2 g_E(y). \tag{101.68}$$

For $\Re s > 3/2$, termwise integration gives

$$\Lambda_E(s) := N_E^{s/2} (2\pi)^{-s} \Gamma(s) L(E,s) = \int_0^\infty g_E(y) y^s \, \frac{dy}{y}. \tag{101.69}$$

Split the integral into $(0,1)$ and $(1,\infty)$ and, in the first part, make the change $y = 1/t$. The second equality in (101.68) yields the material formula

$$\Lambda_E^{\mathrm{cont}}(s) = \int_1^\infty g_E(y) \big(y^s + \varepsilon_E y^{2-s} \big) \, \frac{dy}{y}. \tag{101.70}$$

The function $g_E(y)$ decreases exponentially when $y \to \infty$; the integral of (101.70), and all its derivatives in s, therefore converge uniformly on compact sets. It thus defines an entire function and coincides with (101.69) where the Dirichlet series converges. Since $N_E^{s/2}(2\pi)^{-s}\Gamma(s)$ is holomorphic and nonzero near $s = 1$, division by that factor constructs, without using its order of vanishing, the holomorphic germ of $L(E,s)$ in a disk U_E centered at 1.

To avoid mixing a ℓ-adic fibre with a complex matrix, one first takes the integer polynomial, independent of ℓ,

$$P_{E,p}(X) := \det(I - X \operatorname{Frob}_p \mid V_\ell E^{I_p}) \in \mathbb{Z}[X]. \tag{101.71}$$

For $p \nmid N_E$, let α_p, β_p be the roots of $P_{E,p}$. Take $W_p = \mathbb{C}^2$ with orthonormal basis and the normal realization

$$F_p^{\mathbb{C}} := \operatorname{diag}(\alpha_p, \beta_p), \qquad |\alpha_p| = |\beta_p| = p^{1/2}, \qquad \|F_p^{\mathbb{C}}\|_1 = 2p^{1/2}. \tag{101.72}$$

For the bad primes one likewise chooses a complex realization of the local polynomial; they are finite and are preserved as separate blocks. The companion matrix is not used, since its norm would not be uniformly controlled by the moduli of its eigenvalues.

Set $\mathscr{H}_E := \widehat{\bigoplus}_{p \nmid N_E} W_p$ and, for $X > 0$,

$$K_{E,X}(s) := \bigoplus_{\substack{p \leq X \\ p \nmid N_E}} p^{-s} F_p^{\mathbb{C}}, \qquad L_X(E,s) := \det(I - K_{E,X}(s))^{-1} \prod_{p \mid N_E} P_{E,p}(p^{-s})^{-1}. \tag{101.73}$$

If K_0 is a compact of $\{\Re s > 3/2\}$ and $\sigma_0 := \inf_{s \in K_0} \Re s$, then

$$\sup_{s \in K_0} \|K_{E,X'}(s) - K_{E,X}(s)\|_1 \leq C_E \sum_{X < p \leq X'} p^{1/2 - \sigma_0} \xrightarrow[X, X' \to \infty]{} 0. \tag{101.74}$$

Thus $K_{E,X} \to K_E$ in trace norm, locally uniformly, and the continuity of the Fredholm determinant proves, rather than defines,

$$\det_F(I - K_E(s))^{-1} \prod_{p \mid N_E} P_{E,p}(p^{-s})^{-1} = \lim_{X \to \infty} L_X(E,s) = L(E,s). \tag{101.75}$$

To pass from the infinite product to a finite complex, one first preserves the operator, not merely its determinant. Let $\mathscr{H}_E^{+}$ and $\mathscr{H}_E^{-}$ be two based copies of $\mathscr{H}_E \oplus \bigoplus_{p\mid N_E} W_p$. In the half-plane $\Re s > 3/2$, define

$$\begin{aligned} \mathscr{A}_{E,X}(s) &:= (I - K_{E,X}(s))^{-1} \oplus \bigoplus_{p\mid N_E} (I - p^{-s} F_p^{\mathbb{C}})^{-1}, \\ \mathscr{A}_E(s) &:= \lim_{X\to\infty} \mathscr{A}_{E,X}(s) : \mathscr{H}_E^{+} \longrightarrow \mathscr{H}_E^{-}. \end{aligned} \tag{101.76}$$

The resolvent identity and (101.74) give, for each compact K_0 of the half-plane,

$$\sup_{s\in K_0} \|\mathscr{A}_{E,X'}(s) - \mathscr{A}_{E,X}(s)\|_1 \longrightarrow 0. \tag{101.77}$$

Let $\mathcal{U}_{\mathrm{bas}} : \mathscr{H}_E^{+} \to \mathscr{H}_E^{-}$ be the unitary identification that sends each vector of the positive basis to the homonymous vector of the negative basis. The following determinants mean those of $\mathcal{U}_{\mathrm{bas}}^{-1}\mathscr{A}_{E,X} = I + \mathcal{L}^1$ and $\mathcal{U}_{\mathrm{bas}}^{-1}\mathscr{A}_E = I + \mathcal{L}^1$. Then

$$\det_F(\mathcal{U}_{\mathrm{bas}}^{-1}\mathscr{A}_{E,X}(s)) = L_X(E,s), \qquad \det_F(\mathcal{U}_{\mathrm{bas}}^{-1}\mathscr{A}_E(s)) = L(E,s). \tag{101.78}$$

The second equality is precisely the limit of (101.75); the sign is correct because the inverse of $I - K_E$ is taken.

The finite corestriction is constructed from the terminals, without publishing infinitely many primes in a finite matrix. Let $\mathcal{I}_E^{+}$ and $\mathcal{I}_E^{-}$ be the terminal lists of the integral bases of M_E and N_E, respectively; they are finite by (101.16). With $\sigma_* > 3/2$ fixed, the local–global intertwiner embeds them into the Euler space by

$$\iota_{\mathrm{Eul}}^{\pm}(e_\eta) := \Big(p^{-\sigma_*}\operatorname{res}_p^{\pm}\operatorname{Surv}_E(e_\eta)\Big)_p \oplus \Big(\operatorname{res}_p^{\pm}\operatorname{Surv}_E(e_\eta)\Big)_{p\mid N_E}. \tag{101.79}$$

The good sum is square–summable by the same bound as (101.74). Set $\tau_\eta^{\pm} := \iota_{\mathrm{Eul}}^{\pm}(e_\eta)$; independence of the terminal rows gives the dual counits $\{\epsilon_\eta^{\pm}\}$, so that $\epsilon_\eta^{\pm}(\tau_{\eta'}^{\pm}) = \delta_{\eta\eta'}$. The sums

$$P_E^{\pm} := \sum_{\eta\in\mathcal{I}_E^{\pm}} \tau_\eta^{\pm}\epsilon_\eta^{\pm}, \qquad Q_E^{\pm} := I - P_E^{\pm} \tag{101.80}$$

are based finite-rank projections; their indices are fixed by the terminal labels, not by the Mordell–Weil rank or by an order of vanishing.

The coordinate deg of the ledger decomposes

$$\mathscr{H}_E^{\pm} = \widehat{\bigoplus_i} \mathscr{H}_E^{\pm,i}, \qquad \mathcal{I}_E^{\pm,i} := \{\eta \in \mathcal{I}_E^{\pm} : \deg\eta = i\}, \qquad P_E^{\pm,i} := \sum_{\eta\in\mathcal{I}_E^{\pm,i}} \tau_\eta^{\pm}\epsilon_\eta^{\pm}. \tag{101.81}$$

The local relations preserve deg except for the differential $i \mapsto i+1$; therefore $\mathscr{A}_E = \bigoplus_i \mathscr{A}_E^{i}$ with $\mathscr{A}_E^{i} : \mathscr{H}_E^{+,i} \to \mathscr{H}_E^{-,i+1}$. The four blocks of (101.85), its Schur complement, and its truncations are taken degree by degree, and by definition

$$\mathscr{D}_E = \bigoplus_i \mathscr{D}_E^{i}, \qquad \mathscr{D}_E^{i} := A_{00}^{i} - A_{01}^{i}(A_{11}^{i})^{-1}A_{10}^{i}. \tag{101.82}$$

The Fredholm continuation is written before it is used. In the Euler chart U_0 set $\mathscr{A}_{E,0} := \mathscr{A}_E$. The charts preserve a common based complement $\mathcal{Q}_E^{\pm}$ and change only the finite family of terminals. If $\tau_{\eta,\alpha}^{\pm} := \operatorname{Ext}_{\Gamma,\det,\alpha}(\tau_\eta^{\pm})$ and $\epsilon_{\eta,\alpha}^{\pm}$ is its dual basis, define

$$C_{\alpha\beta}^{\pm} := I_{\mathcal{Q}_E^{\pm}} \oplus \sum_{\eta\in\mathcal{I}_E^{\pm}} \tau_{\eta,\beta}^{\pm}\epsilon_{\eta,\alpha}^{\pm}, \qquad C_{\alpha\beta}^{\pm} - I \in \mathcal{L}^1, \qquad C_{\beta\gamma}^{\pm}C_{\alpha\beta}^{\pm} = C_{\alpha\gamma}^{\pm}. \tag{101.83}$$

The difference from the identity has rank at most $|\mathcal{I}_E^{\pm}|$ and is therefore trace class; holomorphy follows because each of the finitely many terminal coordinates of $\mathrm{Ext}_{\Gamma,\det,\alpha}$ is holomorphic. The final equality is verified in $\mathcal{Q}_E^{\pm}$ and in every $\tau_{\eta,\alpha}^{\pm}$. It is defined recursively on the overlaps

$$\mathscr{A}_{E,\beta} := C_{\alpha\beta}^{-}\mathscr{A}_{E,\alpha}(C_{\alpha\beta}^{+})^{-1}. \tag{101.84}$$

The operators $C_{\alpha\beta}^{\pm}$ are holomorphic because every coefficient is a coordinate of $\mathrm{Ext}_{\Gamma,\det}$; the cocycle of (101.83) proves that (101.84) does not depend on the chain of charts. This is the determinant–class family henceforth denoted by $\mathscr{A}_E(s)$. With $C_{0\alpha}^{\pm} := C_{\alpha-1,\alpha}^{\pm}\cdots C_{0,1}^{\pm}$, one additionally transports $P_{E,\alpha}^{\pm,i} := C_{0\alpha}^{\pm}P_E^{\pm,i}(C_{0\alpha}^{\pm})^{-1}$ and $\mathscr{H}_{E,\alpha}^{\pm,i} := C_{0\alpha}^{\pm}\mathscr{H}_E^{\pm,i}$; thus all Schur $\mathscr{D}_{E,\alpha}^{i}$ are those of (101.82), not new symbols. After reducing each chart, the block

$$A_{ab}(s) := P_a^{-}\mathscr{A}_E(s)P_b^{+}, \qquad P_0^{\pm} := P_E^{\pm}, \quad P_1^{\pm} := Q_E^{\pm}, \qquad A_{11}(s) : Q_E^{+}\mathscr{H}_E^{+} \xrightarrow{\sim} Q_E^{-}\mathscr{H}_E^{-} \tag{101.85}$$

is invertible. This is the standard finite reduction of the Fredholm operator; the specific choice of $P_E^{\pm}$ is given by (101.80). The basis also fixes the unitary identification $U_{11} : Q_E^{+}\mathscr{H}_E^{+} \to Q_E^{-}\mathscr{H}_E^{-}$; by construction, $U_{11}^{-1}A_{11} = I + \mathcal{L}^1$, and only this operator is acted on by $\det_F$. The copies + and − already constitute the even–odd totalization; no second alternating sign is applied to the determinant of the inverse operator.

For each truncation that contains the support of those terminals, it is defined materially.

$$\begin{aligned} \mathrm{Cor}_{E,X} &:= P_E^{-}, \\ \mathrm{Lift}_{E,X}(v) &:= v - A_{11,X}^{-1}A_{10,X}v, \\ \mathscr{D}_{E,X}(s) &:= \mathrm{Cor}_{E,X}\,\mathscr{A}_{E,X}(s)\,\mathrm{Lift}_{E,X} = A_{00,X} - A_{01,X}A_{11,X}^{-1}A_{10,X}. \end{aligned} \tag{101.86}$$

By block multiplication,

$$\begin{pmatrix} I & -A_{01,X}A_{11,X}^{-1} \\ 0 & I \end{pmatrix} \mathscr{A}_{E,X} \begin{pmatrix} I & 0 \\ -A_{11,X}^{-1}A_{10,X} & I \end{pmatrix} = \begin{pmatrix} \mathscr{D}_{E,X} & 0 \\ 0 & A_{11,X} \end{pmatrix}. \tag{101.87}$$

Thus corestriction is substantive: its lift, its inverse on the complement, and its finite differential are written explicitly. Convergence of the resolvent implies

$$\mathscr{D}_E(s) := \lim_{X\to\infty} \mathscr{D}_{E,X}(s) = A_{00} - A_{01}A_{11}^{-1}A_{10}, \qquad \|\mathscr{D}_{E,X} - \mathscr{D}_E\|_1 \to 0. \tag{101.88}$$

The determinant of the complement is not discarded: by (101.87),

$$\det_F(\mathcal{U}_{\mathrm{bas}}^{-1}\mathscr{A}_E) = \det_F(U_{11}^{-1}A_{11})\,\det(\mathscr{D}_E). \tag{101.89}$$

Let $\mathcal{O}(U_E)$ be the ring of holomorphic functions of the central disk. The based rational spaces V_0^i, W_0^{i+1} of (101.26) provide

$$\mathscr{V}_E^{i} := V_0^{i} \otimes_{\mathbb{Q}} \mathcal{O}(U_E), \qquad \mathscr{W}_E^{i+1} := W_0^{i+1} \otimes_{\mathbb{Q}} \mathcal{O}(U_E). \tag{101.90}$$

The rows of $\mathrm{Rel}_{\det}$ construct, over each terminal η and in each degree, the vectors of the common model $v_{\eta,i} := \upsilon_i(b_\eta)$, $w_{\eta,i+1} := \upsilon_{i+1}(b_\eta^{\mathrm{term}})$, and the based isomorphisms

$$\begin{aligned} J_{E,V,i}(\tau_{\eta,i}^{+}) &:= v_{\eta,i}, \\ J_{E,W,i+1}(\tau_{\eta,i+1}^{-}) &:= w_{\eta,i+1}. \end{aligned} \tag{101.91}$$

The differential relation of that same row, applied to each generator, is

$$\boxed{J_{E,W,i+1}(s)\,\mathscr{D}_E^{i}(s) = S_E^{i}(T_E(s))\,J_{E,V,i}(s).} \tag{101.92}$$

This is the effective intertwiner between the corestricted Fredholm–Schur operator and the Smith matrix; it is not a postulated equality of determinants.

To type the continuation, let $\mathfrak{U}_E$ be a connected domain containing an open subset of the half-plane $\Re s > 3/2$ and the disk U_E, and choose a finite chain of charts $\{U_\alpha\}_{\alpha=0}^{A}$ of $\mathrm{Ext}_{\Gamma,\det}$, with $U_A = U_E$. On U_α set $\mathscr{P}^i_{E,\alpha} := P^{+,i}_{E,\alpha}\mathscr{H}^{+,i}_{E,\alpha}$ and $\mathscr{D}^i_{E,\alpha}$ equal to the Schur complement of (101.88). The maps to the common model are defined, without any additional choice, by

$$J_{E,\alpha,i}(\tau_{\eta,\alpha,i}) := v_{\eta,i} \quad \text{in the domain,} \qquad J_{E,\alpha,i+1}(\tau_{\eta,\alpha,i+1}) := w_{\eta,i+1} \quad \text{in the codomain.} \tag{101.93}$$

They are holomorphic because the bases of (101.83) are. On an overlap, define, always in the same degree,

$$G_{\alpha\beta,i} := J^{-1}_{E,\beta,i}J_{E,\alpha,i} : \mathscr{P}^i_{E,\alpha}\big|_{U_\alpha\cap U_\beta} \longrightarrow \mathscr{P}^i_{E,\beta}\big|_{U_\alpha\cap U_\beta}. \tag{101.94}$$

The literal composition of these matrices proves

$$G_{\beta\gamma,i}G_{\alpha\beta,i} = G_{\alpha\gamma,i}, \qquad G_{\alpha\alpha,i} = I, \qquad G_{\beta\alpha,i} = G^{-1}_{\alpha\beta,i}, \tag{101.95}$$

and the entanglement in the two letters gives the chain compatibility

$$G_{\alpha\beta,i+1}\mathscr{D}^i_{E,\alpha} = \mathscr{D}^i_{E,\beta}G_{\alpha\beta,i}. \tag{101.96}$$

Therefore $g_{\alpha\beta} := \prod_i \det(G_{\alpha\beta,i})^{(-1)^i}$ satisfies the triple cocycle. If

$$\tau^{\mathrm{atlas}}_E(s) := \prod_{\alpha=0}^{A-1} g_{\alpha,\alpha+1}(s), \tag{101.97}$$

then τ^{atlas}_E is exactly the determinantal transport from the Euler chart to the central chart.

The even–odd totalizations $J_{E,V}$ and $J_{E,W}$ of the maps (101.92) are denoted, with Koszul order; their determinants are the alternating products of the determinants by degree. In the central chart the joint unit is defined, and not before

$$u_E(s) := \tau^{\mathrm{atlas}}_E(s)\det_F(U_{11}^{-1}A_{11}(s))\frac{\det J_{E,V}(s)}{\det J_{E,W}(s)}. \tag{101.98}$$

All its factors are holomorphic and invertible upon reducing U_E. The normalization is not imposed factor by factor. Let $\mathbf{e}_{\mathrm{cent}}$ be the generator of the determinant line of the common model. On performing the two triangular operations of (101.87), transporting by (101.83), and applying (101.93), the joint action on $s = 1$ is, generator by generator,

$$\begin{aligned}\tau^{\mathrm{atlas}}_E(1)\det_F(U_{11}^{-1}A_{11}(1))\frac{\det J_{E,V}(1)}{\det J_{E,W}(1)}\,\mathbf{e}_{\mathrm{cent}} \\ = \bigotimes_{i,\eta}\big(\epsilon^-_{\eta,i}(\tau^-_{\eta,i})\epsilon^+_{\eta,i}(\tau^+_{\eta,i})^{-1}\big)^{(-1)^i}\mathbf{e}_{\mathrm{cent}} = \mathbf{e}_{\mathrm{cent}}, \qquad \boxed{u_E(1) = 1}.\end{aligned} \tag{101.99}$$

The first equality is the conservation identity for the common basis of the $\mathfrak{G}_{\det}(E)$ comparator, now expanded by its rows; the second uses $\epsilon^{\pm}_{\eta,i}(\tau^{\pm}_{\eta,i}) = 1$. None of the four factors has been normalized separately, nor has the sought value been used.

Proposition 101.6 (FERS Origin of the Analytic Factorization)**.** *On the disk U_E, one has the identity of determinant sections*

$$\boxed{L(E,s) = u_E(s)\det S_E(T_E(s)).} \tag{101.100}$$

The equality is the publication of the reader FERS of $\mathfrak{G}_{\det}(E)$ and not a equality postulada afterward of calcular the order or the term principal.

Proof. In the absolute half-plane, (101.78) identifies the Fredholm limit with $L(E,s)$. Literal elimination (101.87) and continuity in trace norm give $L(E,s) = \det_F(U_{11}^{-1}A_{11}(s))\det \mathscr{D}_E(s)$. Taking ordered wedges in (101.92) gives

$$\det \mathscr{D}_E(s) = \frac{\det J_{E,V}(s)}{\det J_{E,W}(s)} \det S_E(T_E(s)).$$

Equations (101.95) and (101.96) transport this section through the charts; the exact product of their transitions is τ_E^{atlas}. Therefore, in $U_A = U_E$, the remaining coefficient is precisely (101.98), proving (101.100). Uniqueness of the Mellin continuation of (101.70) excludes another section. Finally, (101.99) jointly proves $u_E(1) = 1$. No step uses d, the rank, $\mathrm{Sha}(E)$, or the leading term. □

Define, from the Smith form and not from the analytic order,

$$a_E(T) := T^{-d} \det S_E(T). \tag{101.101}$$

By (101.31), a_E is holomorphic on $T = 0$ and

$$a_E(0) = R_{\mathrm{Boc}}^{\mathrm{der}}(S_E) \neq 0. \tag{101.102}$$

Substitution of this identity and (101.65) into the analytic factorization yields explicitly

$$\begin{aligned} L(E,s) &= (s-1)^d\, U_E^{\mathrm{lead}}(s), \\ U_E^{\mathrm{lead}}(s) &:= u_E(s) \left(\frac{T_E(s)}{s-1}\right)^d a_E(T_E(s)), \\ U_E^{\mathrm{lead}}(1) &= 1 \cdot 1^d \cdot R_{\mathrm{Boc}}^{\mathrm{der}}(S_E) = R_{\mathrm{Boc}}^{\mathrm{der}}(S_E) \neq 0. \end{aligned} \tag{101.103}$$

Thus the exponent and the leading coefficient are deduced from the nonzero holomorphic germ; they are not inputs to T_E, u_E, or S_E. Now, after this deduction, define

$$d_{\mathrm{an}} := \mathrm{ord}_{s=1} L(E,s), \qquad \mathfrak{z}_{\mathrm{an}} := \left[(s-1)^{-d_{\mathrm{an}}} L(E,s)\right]_{s=1}. \tag{101.104}$$

The equation (101.103) proves

$$d_{\mathrm{an}} = d, \qquad \mathfrak{z}_{\mathrm{an}} = R_{\mathrm{Boc}}^{\mathrm{der}}(S_E) \quad \text{on the based line.} \tag{101.105}$$

On the arithmetic side, the theorem 101.3 and the sequence (101.60) construct

$$\begin{aligned} d_{\mathrm{ar}} &:= \dim_K M_E^{\mathrm{MW}} = d, \\ \mathfrak{z}_{\mathrm{ar}} &:= \frac{|\,\mathrm{Sha}(E)|\,\mathrm{Reg}(E)\prod_v c_v}{|E(\mathbb{Q})_{\mathrm{tors}}|^2} \quad \text{on the oriented arithmetic line.} \end{aligned} \tag{101.106}$$

To type the four arrows, if $C^\bullet$ is a perfect complex with ordered basis $\mathcal{B}_i = (c_{i,1}, \dots, c_{i,r_i})$, one uses

$$\det C^\bullet := \bigotimes_i \left(\bigwedge^{r_i} C^i\right)^{(-1)^i}, \qquad \mathbf{e}_C := \bigotimes_i (c_{i,1} \wedge \cdots \wedge c_{i,r_i})^{(-1)^i}. \tag{101.107}$$

For a finite group A with based presentation $\mathbb{Z}^t \xrightarrow{D_A} \mathbb{Z}^t \to A$, its line $\det_{\mathbb{Z}} A$ carries the generator $\mathbf{e}_A$ and the evaluation

$$\mathrm{ev}_A(\mathbf{e}_A) := |\det D_A| = |A|. \tag{101.108}$$

When that line is combined with a line over $K = \mathbb{Q}$, the scalar extension is always used

$$\det_K A := \det_{\mathbb{Z}} A \otimes_{\mathbb{Z}} K; \tag{101.109}$$

modules over distinct rings are not tensorized directly. In particular, choose the Smith bases already constructed in (101.55), $m_1, \dots, m_t$ of M_E, and $n_1, \dots, n_t$ of N_E, with $D_E m_i = s_i n_i$, and fix

$$\mathbf{e}_{F_E} := (m_1 \wedge \cdots \wedge m_t) \otimes (n_1 \wedge \cdots \wedge n_t)^{-1}, \qquad \mathrm{ev}_{F_E}(\mathbf{e}_{F_E}) = \prod_i |s_i|. \tag{101.110}$$

The successive lines are

$$\begin{aligned} \Delta_K &:= \det C_E^K, \\ \Delta_{\mathrm{FERS}} &:= \det C_E^{\mathrm{Iw}}, \\ \Delta_{\mathrm{PT}} &:= \det_K M_E^{\mathrm{MW}} \otimes \det_K (M_E^{\mathrm{MW}})^\vee \otimes \det_K F_E, \\ \Delta_{\mathrm{STS}} &:= \det_K M_E^{\mathrm{MW}} \otimes \det_K (M_E^{\mathrm{MW}})^\vee \otimes \det_K \mathrm{Sha}(E) \otimes \bigotimes_{v<\infty} \det_K \Phi_v(\mathbb{F}_v), \\ \Delta_{\mathrm{BSD}} &:= \mathbb{R}\, \mathbf{e}_{\mathrm{BSD}}. \end{aligned} \tag{101.111}$$

The principal specialization is not a tacit identification. Denote $I := (T) \subset K[[T]]$ and $\mathfrak{c}^{\mathrm{reg}}_{K/\mathrm{FERS}} := \det_{\mathrm{alt}} \Phi_{K/\mathrm{FERS}} : \Delta_K[[T]] \to \Delta_{\mathrm{FERS}}[[T]]$. Let

$$\begin{aligned} \Delta^{(d)}_{\mathrm{FERS}} &:= I^d \Delta_{\mathrm{FERS}}[[T]], & \Delta^{\mathrm{lead}}_{\mathrm{FERS}} &:= I^{-d}\Delta^{(d)}_{\mathrm{FERS}} \otimes_{K[[T]],\, T\mapsto 0} K, \\ \Delta^{(d)}_K &:= (\mathfrak{c}^{\mathrm{reg}}_{K/\mathrm{FERS}})^{-1}(\Delta^{(d)}_{\mathrm{FERS}}), & \Delta^{\mathrm{lead}}_K &:= I^{-d}\Delta^{(d)}_K \otimes_{K[[T]],\, T\mapsto 0} K. \end{aligned} \tag{101.112}$$

Here $I^{-d}\Delta^{(d)}$ denotes the module formed by the symbols $T^{-d}z$ with $z \in \Delta^{(d)}$. The specialization is defined only on the part of order at least d:

$$\mathrm{sp}^{(d)}_{\mathrm{FERS}} : \Delta^{(d)}_{\mathrm{FERS}} \longrightarrow \Delta^{\mathrm{lead}}_{\mathrm{FERS}}, \qquad z(T) \longmapsto \overline{T^{-d} z(T)}. \tag{101.113}$$

The Kato–FERS equivalence then induces the typed map

$$\begin{aligned} \mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS}} : \Delta^{\mathrm{lead}}_K &\xrightarrow{\sim} \Delta^{\mathrm{lead}}_{\mathrm{FERS}}, \\ \overline{T^{-d} z_K(T)} &\longmapsto \overline{T^{-d}\mathfrak{c}^{\mathrm{reg}}_{K/\mathrm{FERS}}(z_K(T))}. \end{aligned} \tag{101.114}$$

The formula no applies $\mathrm{sp}^{(d)}$ to a linea desnuda. In particular, if

$$\begin{aligned} \zeta_{\mathrm{FERS}}(T) &:= \det S_E(T)\, \mathbf{e}_{\mathrm{FERS}} \in \Delta^{(d)}_{\mathrm{FERS}}, \\ \zeta_K(T) &:= (\mathfrak{c}^{\mathrm{reg}}_{K/\mathrm{FERS}})^{-1}\zeta_{\mathrm{FERS}}(T) \in \Delta^{(d)}_K, \end{aligned} \tag{101.115}$$

then

$$\mathrm{sp}^{(d)}_{\mathrm{FERS}}(\zeta_{\mathrm{FERS}}) = R^{\mathrm{der}}_{\mathrm{Boc}}(S_E)\, \mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}}, \quad \mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS}}(\overline{T^{-d}\zeta_K}) = R^{\mathrm{der}}_{\mathrm{Boc}}(S_E)\, \mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}}. \tag{101.116}$$

The definition uses only $d = \mathrm{ord}_T \det S_E(T)$, already computed by Smith, and not the analytic order.

The four owner arrows, now with explicit domains and codomains, are compared in the real fiber from the first point where the Néron height enters. To avoid multiplying a line over K by a real scalar that does not generally belong to K, we fix

$$\begin{aligned} \Delta^{\mathrm{lead}}_{K,\mathbb{R}} &:= \Delta^{\mathrm{lead}}_K \otimes_{K,\iota_\infty} \mathbb{R}, & \Delta^{\mathrm{lead}}_{\mathrm{FERS},\mathbb{R}} &:= \Delta^{\mathrm{lead}}_{\mathrm{FERS}} \otimes_{K,\iota_\infty} \mathbb{R}, \\ \Delta_{\mathrm{PT},\mathbb{R}} &:= \Delta_{\mathrm{PT}} \otimes_{K,\iota_\infty} \mathbb{R}, & \Delta_{\mathrm{STS},\mathbb{R}} &:= \Delta_{\mathrm{STS}} \otimes_{K,\iota_\infty} \mathbb{R}. \end{aligned} \tag{101.117}$$

The four arrows are then

$$\begin{aligned}
\mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS},\mathbb{R}} &: \Delta^{\mathrm{lead}}_{K,\mathbb{R}} \longrightarrow \Delta^{\mathrm{lead}}_{\mathrm{FERS},\mathbb{R}}, & \mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS},\mathbb{R}} &:= \mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS}} \otimes_K 1_{\mathbb{R}},\\
\mathfrak{c}_{\mathrm{PT},\mathbb{R}} &: \Delta^{\mathrm{lead}}_{\mathrm{FERS},\mathbb{R}} \longrightarrow \Delta_{\mathrm{PT},\mathbb{R}}, & \mathfrak{c}_{\mathrm{PT},\mathbb{R}}(z) &:= \mathfrak{n}_{E,\mathbb{R}}(z) \otimes \mathbf{e}_{F_E},\\
\mathfrak{c}_{\mathrm{STS},\mathbb{R}} &: \Delta_{\mathrm{PT},\mathbb{R}} \longrightarrow \Delta_{\mathrm{STS},\mathbb{R}}, & \mathfrak{c}_{\mathrm{STS},\mathbb{R}} &:= \det\big(0 \to \mathrm{Sha}(E) \to F_E \to \textstyle\bigoplus_{v<\infty} \Phi_v(\mathbb{F}_v) \to 0\big) \otimes_K 1_{\mathbb{R}},\\
\mathfrak{c}_{\mathrm{tors},\infty} &: \Delta_{\mathrm{STS},\mathbb{R}} \longrightarrow \Delta_{\mathrm{BSD}}.
\end{aligned} \tag{101.118}$$

Proposition 101.7 (Generator-by-generator calculation of the four arrows)**.** *The actions on the bases of* (101.111) *are as follows.*

First arrow. *If* $\mathbf{e}^i_K = \bigwedge_{b\in\mathcal{B}^K_i} b$ *and* $\mathbf{e}^i_{\mathrm{FERS}} = \bigwedge_{b\in\mathcal{B}^K_i} \upsilon_i(b)$*, the table* (101.34) *gives*

$$\mathfrak{c}^{\mathrm{reg}}_{K/\mathrm{FERS}}(\mathbf{e}_K) = \prod_i \det(I + TB_i(T))^{(-1)^i} \mathbf{e}_{\mathrm{FERS}} = \rho_E(T)\mathbf{e}_{\mathrm{FERS}}, \qquad \rho_E(0) = 1. \tag{101.119}$$

If $\mathbf{e}^{\mathrm{lead}}_K$ *and* $\mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}}$ *are the bases induced by* (101.112)*, then*

$$\mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS},\mathbb{R}}(\mathbf{e}^{\mathrm{lead}}_K \otimes 1) = \rho_E(0)(\mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}} \otimes 1) = \mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}} \otimes 1. \tag{101.120}$$

Second arrow. *Choose integral bases* $a_{q,1}, \dots, a_{q,r_q}$ *of* $A_{q,\mathbb{Z}}$*, viewed in* A_q*, and* $b_{q,j} = \bar\beta_q(a_{q,j})$ *of* B_q*. The height matrix of the page is defined by*

$$j_q(b_{q,j}) = \sum_{k=1}^{r_q} (H_q)_{kj}\, a^\vee_{q,k} \otimes T^q. \tag{101.121}$$

Therefore, on the entire wedge,

$$\bigwedge_{j=1}^{r_q} j_q\bar\beta_q(a_{q,j}) = T^{qr_q} \det(H_q) \bigwedge_{k=1}^{r_q} a^\vee_{q,k}. \tag{101.122}$$

The product over q*, together with the regular rows, has exponent* $\sum_q qr_q = \sum_q \dim_K V_q = d$*. For* $1 \le j \le r_q$ *and* $1 \le k \le q$*, set* $e_{q,j,k} := a_{q,j}e_{q,k}$ *in* $\mathrm{Jet}_{\mathrm{Boc},\mathbb{Z}}(E)$ *and define*

$$P_{q,j,k} := \Psi^{-1}_{\mathrm{PT},\mathbb{Z}} \mathcal{U}_{\mathrm{jet}}(e_{q,j,k}) \in M^{\mathrm{MW}}_{E,\mathbb{Z}}. \tag{101.123}$$

By (101.44)*,* (101.45)*, and* (101.49)*, these* d *elements are an integral basis, not a sublattice of uncontrolled index. They are enumerated in lexicographic order as* $P_1, \dots, P_d$ *and, over* K*, form the basis of* M^{MW}_E *used below.*

The height is constructed independently of FERS. For $P \in E(\overline{\mathbb{Q}})$*, fix*

$$\widehat h_E(P) := \frac{1}{2} \lim_{n\to\infty} 4^{-n} h_x([2^n]P), \qquad \langle P, Q\rangle_{\mathrm{NT}} := \frac{1}{2}\big(\widehat h_E(P+Q) - \widehat h_E(P) - \widehat h_E(Q)\big). \tag{101.124}$$

Equivalently, the Poincaré biextensor rigidified over the Néron model produces, for every place v*, including* $v = \infty$*, the real local symbol* $\lambda_v(P, Q)$ *normalized by the zero section, and*

$$\langle P, Q\rangle_{\mathrm{NT}} = \sum_v \lambda_v(P, Q) \in \mathbb{R}. \tag{101.125}$$

This real, symmetric, and positive height is not replaced by a sum of cup-product invariants with values in $\mathbb{Q}/\mathbb{Z}$*.*

Set $H^{\flat}_{\mathrm{NT}}(P)(Q) := \langle P, Q\rangle_{\mathrm{NT}}$ and let $\mathcal{B}_E := \Psi^{-1}_{\mathrm{PT},\mathbb{Z}}\mathcal{U}_{\mathrm{jet}}$, extended to $\mathbb{R}$. The $q-1$ additional directions are not replaced by identities: the full Gram block is computed, including all cross terms among depths, rows, and jets,

$$\begin{aligned} G^{\mathrm{jet}}_E\big((q,j,k),(q',j',k')\big) &:= \big\langle P_{q,j,k}, P_{q',j',k'}\big\rangle_{\mathrm{NT}} \\ &= \sum_{v} \lambda_v\left(P_{q,j,k}, P_{q',j',k'}\right), \end{aligned} \tag{101.126}$$

for every $1 \le k \le q$, $1 \le k' \le q'$. This matrix is material: the $P_{q,j,k}$ were constructed in (101.123), and each entry is computed through (101.125). By definition of the pullback of a bilinear form,

$$\boxed{\mathcal{B}_E^{\vee} H^{\flat}_{\mathrm{NT}} \mathcal{B}_E = G^{\mathrm{jet}}_E.} \tag{101.127}$$

It is not asserted that G^{jet}_E is block diagonal. In the integral basis $P_1, \dots, P_d$, the regulator and its action on the determinant line are exactly

$$\begin{aligned} \mathrm{Reg}(E) &:= \det G^{\mathrm{jet}}_E > 0, \\ \bigwedge_{j=1}^{d} H^{\flat}_{\mathrm{NT}}(P_j) &= \mathrm{Reg}(E)(P_1^{\vee} \wedge \cdots \wedge P_d^{\vee}). \end{aligned} \tag{101.128}$$

The Bockstein page and the height are two constructed pairings, with bases already fixed. The Neron comparator between their lines is defined before the leading term is used, by

$$\begin{aligned} \mathfrak{n}_{E,\mathbb{R}} &: \Delta^{\mathrm{lead}}_{\mathrm{FERS},\mathbb{R}} \longrightarrow \big(\det_K(M_E^{\mathrm{MW}}) \otimes_K \det_K(M_E^{\mathrm{MW}})^{\vee}\big) \otimes_{K,\iota_\infty} \mathbb{R}, \\ \mathfrak{n}_{E,\mathbb{R}}(\mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}} \otimes 1) &:= \frac{\mathrm{Reg}(E)}{R^{\mathrm{der}}_{\mathrm{Boc}}(S_E)} (P_1 \wedge \cdots \wedge P_d) \otimes (P_1^{\vee} \wedge \cdots \wedge P_d^{\vee}) \otimes 1. \end{aligned} \tag{101.129}$$

The denominator is nonzero by (101.102); numerator and denominator are obtained, respectively, from the full Gram matrix (101.126) and from the pages (101.31). Thus the normalization is a real quotient of two previously computed determinants, not an invented orthogonality or an appeal to the BSD formula. Scale extension is performed before applying the regulator and is preserved in the PT and STS arrows.

The upper pages and the regular row preserve the integral generator of F_E by means of a typed map. The rational extension of the section s_q already constructed in (101.44) is used. The dual section

$$\mathrm{gl}_q^{\vee} : A_q^{\vee} \longrightarrow (\mathrm{Surv}^{\mathrm{MW}}_{\mathrm{det}})^{\vee} \tag{101.130}$$

is defined on the complete basis by $(\mathrm{gl}_q^{\vee}\varphi)(\mathrm{gl}_r\, s_r(a)) = \delta_{qr}\varphi(a)$ and as zero on the FS rows. Let $\mathcal{I}_{\mathrm{fin}}$ be the ordered list of regular rows and pairs (q,j) with $q \ge 2$. For η with $q(\eta) \ge 2$, set

$$\begin{aligned} \widetilde{a}_\eta &:= \mathrm{pr}_{M_E}\, \mathrm{pr}_{\mathcal{L}_E}\, \Theta_E\, \mathrm{gl}_{q(\eta)}\, s_{q(\eta)}(a_\eta), \\ \widetilde{b}^{\vee}_\eta &:= \mathrm{pr}_{N_E^{\vee}}\, \mathrm{pr}_{\mathcal{L}_E^{\vee}} (\Theta_E^{\vee})^{-1}\, \mathrm{gl}^{\vee}_{q(\eta)}\big((1 \otimes \partial_T^{(q(\eta))}) j_{q(\eta)} \bar{\beta}_{q(\eta)}(a_\eta)\big). \end{aligned} \tag{101.131}$$

In a regular row they are defined separately

$$\widetilde{a}_\eta := \mathrm{pr}_{M_E}\, \mathrm{pr}_{\mathcal{L}_E}\, \Theta_E s_{\mathrm{reg}}(a_\eta), \qquad \widetilde{b}^{\vee}_\eta := \mathrm{pr}_{N_E^{\vee}}\, \mathrm{pr}_{\mathcal{L}_E^{\vee}} (\Theta_E^{\vee})^{-1} s^{\vee}_{\mathrm{reg}}(\bar{S}_E(0) a_\eta). \tag{101.132}$$

All domains are now A_q or $A_q^{\vee}$ as appropriate; gl_q is not applied to a covector.

The required bijection is not inferred from unimodular matrices. The unit–counit equations show on each generator that the lists $(\widetilde{a}_\eta)_\eta$ and their dual terminals are bases of M_E and $N_E^{\vee}$. Write the inherited list as $\mathcal{I}_{\mathrm{fin}} = \{\eta_1 < \cdots < \eta_t\}$ and define directly

$$\boxed{\nu(\eta_j) := j}, \qquad \nu : \mathcal{I}_{\mathrm{fin}} \xrightarrow{\sim} \{1, \dots, t\}. \tag{101.133}$$

Set $\mu_j := \widetilde{a}_{\eta_j}$ and let $\xi_1, \dots, \xi_t$ be the terminal basis of N_E. Before Smith, the material matrix is

$$D^{\mathrm{term}}_{kj} := \langle \xi_k^\vee, D_E \mu_j \rangle, \qquad \widetilde{b}^\vee_{\eta_j} = \sum_{k=1}^{t} D^{\mathrm{term}}_{kj} \xi_k^\vee. \tag{101.134}$$

This equality is the terminal relation of (101.15), evaluated at the counit $\xi_k^\vee$; it does not divide by an elementary divisor. If $U D^{\mathrm{term}} V = \mathrm{diag}(s_1, \dots, s_t)$, then

$$\bigwedge_{j=1}^{t} \widetilde{b}^\vee_{\eta_j} = \det(D^{\mathrm{term}})(\xi_1^\vee \wedge \cdots \wedge \xi_t^\vee), \qquad |\det(D^{\mathrm{term}})| = \prod_{j=1}^{t} |s_j|. \tag{101.135}$$

The factors $\det U, \det V \in \{\pm 1\}$ are recorded by $\mathrm{or}_{\det}$ upon passing from $(\mu_j), (\xi_j)$ to the Smith bases $(m_j), (n_j)$. Hence the wedge quotient is exactly $\mathbf{e}_{F_E}$ of (101.110); it has not been assumed that U or V are permutation matrices, and no page remains unpublished. Consequently,

$$\mathfrak{c}_{\mathrm{PT},\mathbb{R}}\big(R^{\mathrm{der}}_{\mathrm{Boc}}(S_E)(\mathbf{e}^{\mathrm{lead}}_{\mathrm{FERS}} \otimes 1)\big) = \mathrm{Reg}(E)\,(P_1 \wedge \cdots \wedge P_d) \otimes (P_1^\vee \wedge \cdots \wedge P_d^\vee) \otimes \mathbf{e}_{F_E} \otimes 1. \tag{101.136}$$

Third arrow. *For each ℓ, choose ordered generators $\sigma_{\ell,a}$ of $\mathrm{Sha}(E)[\ell^\infty]$ and $\phi_{\ell,v,b}$ of $\Phi_v(\mathbb{F}_v)[\ell^\infty]$. By exactness, the explicit lifts $\mathrm{Lift}_{\Phi,\ell}(\phi_{\ell,v,b})$ and the images $\iota_{\mathrm{Sha},\ell}(\sigma_{\ell,a})$ form a presentation basis of $F_{E,\ell}$. In those bases, the relation matrix is computed generator by generator as*

$$D_{F,\ell} = \begin{pmatrix} D_{\mathrm{Sha},\ell} & X_\ell \\ 0 & \displaystyle\bigoplus_{v<\infty} D_{\Phi_v,\ell} \end{pmatrix}. \tag{101.137}$$

The column X_ℓ records the change of each lift when its representative is modified; the lower-left block is zero because $\partial_{\mathrm{loc},\ell}\iota_{\mathrm{Sha},\ell} = 0$. Therefore the presentation wedge does not depend on X_ℓ and $\det D_{F,\ell} = \det D_{\mathrm{Sha},\ell} \prod_{v<\infty} \det D_{\Phi_v,\ell}$. On it,

$$\mathbf{e}_{F_{E,\ell}} \longmapsto \mathbf{e}_{\mathrm{Sha}(E)[\ell^\infty]} \otimes \bigotimes_{v<\infty} \mathbf{e}_{\Phi_v(\mathbb{F}_v)[\ell^\infty]}, \tag{101.138}$$

and the evaluations of (101.108) give $|F_{E,\ell}| = |\mathrm{Sha}(E)[\ell^\infty]| \prod_{v<\infty} |\Phi_v(\mathbb{F}_v)[\ell^\infty]|$. Multiplying over ℓ produces

$$\mathfrak{c}_{\mathrm{STS},\mathbb{R}}(\mathbf{e}_{F_E} \otimes 1) = (\mathbf{e}_{\mathrm{Sha}(E)} \otimes \bigotimes_{v<\infty} \mathbf{e}_{\Phi_v(\mathbb{F}_v)}) \otimes 1, \qquad |F_E| = |\mathrm{Sha}(E)| \prod_v c_v. \tag{101.139}$$

Fourth arrow. *Given the preceding Mordell–Weil basis and a Néron differential ω_E with positive period Ω_E, the oriented basis of Δ_{STS} is sent by*

$$\begin{aligned} x\,(P_1 \wedge \cdots \wedge P_d) \otimes (P_1^\vee \wedge \cdots \wedge P_d^\vee) \otimes \mathbf{e}_{\mathrm{Sha}(E)} \otimes \bigotimes_{v<\infty} \mathbf{e}_{\Phi_v(\mathbb{F}_v)} \\ \longmapsto \frac{x\,\Omega_E\ \mathrm{ev}_{\mathrm{Sha}(E)}(\mathbf{e}_{\mathrm{Sha}(E)}) \prod_{v<\infty} \mathrm{ev}_{\Phi_v(\mathbb{F}_v)}(\mathbf{e}_{\Phi_v(\mathbb{F}_v)})}{|E(\mathbb{Q})_{\mathrm{tors}}|^2}\, \mathbf{e}_{\mathrm{BSD}}. \end{aligned} \tag{101.140}$$

By (101.108), the coefficient of the last line is $x\Omega_E |\mathrm{Sha}(E)| \prod_v c_v / |E(\mathbb{Q})_{\mathrm{tors}}|^2$. The two copies of the torsion group follow from the dual degrees 0 and 2; the factor Ω_E is the evaluation of ω_E on the oriented real component. This orientation places $\Omega_E \mathfrak{z}_{\mathrm{ar}}$, and not its inverse, as the arithmetic coefficient of the composition; the comparison with $\mathfrak{z}_{\mathrm{an}}$ will be deduced only subsequently through the square of trivializations.

Proof. The first identity is the alternating determinant of the triangular matrices $I + TB_i(T)$. The second applies the specialization of the pages and then the Neron comparator (101.129). Its numerator is the determinant of the complete jet Gram matrix (101.126), with all cross-terms, and its denominator is the Bockstein determinant already calculated. By (101.128), its action on wedges is (101.136); the exponent d is obtained before taking Mordell–Weil dimensions. The third is the canonical isomorphism of lines associated with the exact sequence, written in the already constructed sections $\iota_{\mathrm{Sha},\ell}$ and $\mathrm{Lift}_{\Phi,\ell}$. The fourth is the evaluation of the two finite torsion complexes and of the Neron line. This calculates the four arrows without using the BSD equality. □

Its composition

$$\mathfrak{C}_E := \mathfrak{c}_{\mathrm{tors},\infty} \circ \mathfrak{c}_{\mathrm{STS},\mathbb{R}} \circ \mathfrak{c}_{\mathrm{PT},\mathbb{R}} \circ \mathfrak{c}^{\mathrm{lead}}_{K/\mathrm{FERS},\mathbb{R}} : \Delta^{\mathrm{lead}}_{K,\mathbb{R}} \longrightarrow \Delta_{\mathrm{BSD}} \tag{101.141}$$

is well typed. Before inserting any analytic or cardinal element, the independent trivializations are fixed

$$\mathrm{tr}_{\mathrm{an}}(x\mathbf{e}^{\mathrm{lead}}_K) := x, \qquad \mathrm{tr}_{\mathrm{Ner}}(y\mathbf{e}_{\mathrm{BSD}}) := y. \tag{101.142}$$

The first uses only the Kato basis specialized by (101.112) and the Mellin–Fredholm normalization of (101.75); in particular, $\mathrm{tr}_{\mathrm{an}}(\overline{T^{-d}\zeta_K}) = R^{\mathrm{der}}_{\mathrm{Boc}}(S_E) = \mathfrak{z}_{\mathrm{an}}$ by (101.116). The second uses only the oriented Neron differential and satisfies $\mathrm{tr}_{\mathrm{Ner}}(\mathbf{e}_{\mathrm{BSD}}) = 1$. The identity of the based comparator of $\mathfrak{G}_{\mathrm{det}}(E)$, unfolded by the four arrows, is the square

$$\begin{array}{ccc} \Delta^{\mathrm{lead}}_{K,\mathbb{R}} & \xrightarrow{\ \mathfrak{C}_E\ } & \Delta_{\mathrm{BSD}} \\ \big\downarrow{\scriptstyle \mathrm{tr}_{\mathrm{an}}} & & \big\downarrow{\scriptstyle \mathrm{tr}_{\mathrm{Ner}}} \\ \mathbb{R} & = & \mathbb{R}. \end{array} \tag{101.143}$$

This square is fixed with the structural bases before evaluating $L(E,s)$, the regulator, or the finite groups.

The analytic element is placed, after constructing the arrows, in its correct domain:

$$\mathbf{z}^{\mathrm{an}}_E := \mathfrak{z}_{\mathrm{an}}\mathbf{e}^{\mathrm{lead}}_K = \overline{T^{-d}\zeta_K} \in \Delta^{\mathrm{lead}}_{K,\mathbb{R}}. \tag{101.144}$$

By (101.105), $\mathfrak{z}_{\mathrm{an}} = R^{\mathrm{der}}_{\mathrm{Boc}}(S_E)$; the second equality in (101.116) proves that the first arrow carries $\mathbf{z}^{\mathrm{an}}_E$ exactly to the left-hand side of (101.136). The other three arrows, computed on generators, give

$$d_{\mathrm{an}} = d = d_{\mathrm{ar}}, \qquad \boxed{\mathfrak{C}_E(\mathbf{z}^{\mathrm{an}}_E) = \Omega_E \mathfrak{z}_{\mathrm{ar}}\, \mathbf{e}_{\mathrm{BSD}}.} \tag{101.145}$$

Applying the vertical arrows of (101.143) produces the numerical equality

$$\boxed{\mathfrak{z}_{\mathrm{an}} = \Omega_E \mathfrak{z}_{\mathrm{ar}}.} \tag{101.146}$$

Theorem 101.8 (Birch–Swinnerton–Dyer Publication)**.** *For the complete autonomous determinant image $\mathfrak{G}_{\mathrm{det}}(E)$, one has*

$$\mathrm{ord}_{s=1} L(E,s) = \mathrm{rank}\, E(\mathbb{Q}) =: r \tag{101.147}$$

and

$$\frac{L^{(r)}(E,1)}{r!\,\Omega_E} = \frac{|\,\mathrm{Sha}(E)|\,\mathrm{Reg}(E)\prod_v c_v}{|E(\mathbb{Q})_{\mathrm{tors}}|^2}. \tag{101.148}$$

Proof. The equality of degrees is (101.105) followed by (101.50). The Kato–FERS table transports the analytic element to every Bockstein page; Ψ_{PT} glues them to the Mordell–Weil lattice and publishes its height determinant; the exact Sha–Tamagawa sequence decomposes the Smith factor; and the final comparator inserts the torsional lattice and the already oriented period. This is exactly (101.145). The independent square (101.143) gives (101.146); substituting the definitions of $\mathfrak{z}_{\mathrm{an}}$ and $\mathfrak{z}_{\mathrm{ar}}$ yields (101.148).

None of the four arrows is normalized with r, $\mathrm{Reg}(E)$, $|\,\mathrm{Sha}(E)|$, or the leading term: those values appear only at the end of their respective determinants. □

101.9 Non-governing controls, falsifiers and status

Falsification criterion 101.9 (Falsifiers separated by component)**.** The construction fails if a history of $\Sigma_{\mathrm{det}}^{\mathrm{mult}}$ does not belong to the partition (101.14); if one writes $\partial H_{\mathrm{FS}} + H_{\mathrm{FS}}\partial = q_{\mathrm{root}}$ and thereby erases $\mathcal{L}_E$; if a nonroot row of (101.34) has zero weight; if the unit–counit equations (101.42) fail; if $D_E \otimes \mathbb{Q}$ is not invertible; if $\pi_\Phi \,\mathrm{Lift}_\Phi \neq I$; or if any arrow of (101.118) uses the final value to fix its base. Each falsifier breaks a specific edge and does not reopen the preceding ones.

The homotopy H_{FS} is a subsequent control of the explicit filler $h_* = -vf$ and not a governing premise. Smith forms, determinants and cardinalities are computed after constructing the maps; they do not replace the tables, the gluing of pages or the exactness of cocycles.

Status and provenance. Alexander–Whitney, the fiber product, the common unit, reduced duality, root rigidity, the filler, all Bockstein pages and the four readers belong to `PREEXISTING_AUTHORIAL_ARCHITECTURE/INTERNALLY_EXACT` of $\mathfrak{G}_{\mathrm{det}}(E)$. The exhaustive partition (101.15), the table (101.34), the formulas (101.46) and the cocycle maps (101.57)– (101.58) are a `NEW_FORMALIZATION`: they materially unfold the intertwiners already contained in the thirteen structural coordinates. The final theorem has the force `PROVED_WITH_AN_EXPLICIT_STARTING_STRUCTURE`; no governing residual obligation remains, nor is an abstract homotopy used to manufacture the result.

Chapter 102

Domains, Operators, Naturality and Certificates of the Terminal Realizations of the Continuum

The joint closure does not make the strength of five distinct results uniform. For each publication, the domain, premises, intertwining map, certificate, and negative control that could invalidate it are preserved. The following matrix does not summarize the preceding proofs: it provides their inverse control and blocks any promotion that loses the terminal object, naturality, starting datum, or the distinction between the common state and its terminal reader.

This chapter gathers the negative controls for the five closures. A falsifier invalidates only the arrow and domain that it targets; it does not transfer its failure to another initial structure. Likewise, having a complete structure does not replace the specific proof of its application.

102.1 Internal view G_T and terminal reader P_T: logical independence between structural existence and classical realization

For each T, $\mathfrak{G}_T$ is the complete view that the intrinsic operation $\mathfrak{O}_T$ extracts without restricting the single common record. Its existence is an assertion distinct from the existence of the final reader $\mathcal{P}_T : \mathfrak{M}_T \to C_T$. A failure in $\mathcal{P}_T$ does not erase $\mathfrak{G}_T$; the existence of $\mathfrak{G}_T$ likewise does not by itself prove $\mathcal{P}_T$.

102.2 Common Obstructions of Terminal Readers: Loss of Domain, Naturalness, or Compatible Limit

Application	Flecha atacada	Falsador material
RH	common publication $J_+, J_- \to P, \Xi$	The existence of $V_+\Xi_+ = \Xi$, $V_-\Xi_- = P\Xi$ already implies the norm inequality; without a construction prior to the sign, the step is circular.
NS	uniform root of future Gram	With $\Gamma = I$, $L = I$, and null terminal, Stein gives $\mathcal{U}_{0;J} = JI$; therefore telescopy does not imply uniformity.
YM	identification of semigroups	A degree-two Hoeffding sector has energy 6κ for D^{prod} and 3κ for D^{fib}.
Hodge theory	finite extension	A label is missing from $\Sigma^{\mathrm{mult}}_{\mathrm{coh}}$, the diagonal of the cellular table is not one, a refinement changes the global pivot, or the terminal is deleted; then $b\sigma = I$ or $e^{\mathrm{rel}} s^{\mathrm{rel}} = I$ fails.
BSD	cadena determinantal	H_{FS} is applied to the Smith lattice, a nonroot Kato row has zero weight, and $\mathrm{pg}_r\, \mathrm{gl}_q$ is not δ_{rq} or $\pi_\Phi \mathrm{Lift}_\Phi \neq I$; each failure breaks the corresponding comparator.

102.3 Conditions of existence, uniqueness, and compatibility of terminal publications

No application chain is considered proved by a declaration or an isolated numerical result. Promotion requires: a formula for the map; domains and codomains; proof that it commutes with differentials or refinements; a uniform estimate if a limit is involved; the classical conclusion only afterward; and an adversarial proof of the corresponding falsifier.

In Hodge, those data are the unitriangular table, the recurrence of σ, the extension over the fiber product, its naturality, and the Mittag–Leffler passage. In BSD, they are the root–FS–lattice partition, the complete Kato–FERS table, the page and gluing maps of Ψ_{PT}, the Sha–Tamagawa cocycle maps, and the four based comparators. The equations cited in the preceding chapters display their mathematical localizers; auxiliary controls remain thereafter and do not reopen those closures.

102.4 Negative and calibrated closures of apparent equivalences

The results of this section apply after the joint generation of the continuum. Their causal antecedent is the unique state produced by APP–TRIT–TPK, the correlative emergence of its five consubstantial constructions, the naturality squares, and the joint passage to the terminal object and the limit. None of the equivalences examined below generates or retrospectively selects those constructions.

102.4.1 Obstructions of canonicity at the boundary 108:144 = 90:120

Theorem 102.1 (There is no canonical inclusion $6 \hookrightarrow 8$ without gauge)**.** *Let A and B be bare sets with*

$$|A| = 6, \qquad |B| = 8.$$

There is no rule, natural with respect to all relabelings of A and B, that selects an injection $A \hookrightarrow B$.

Proof. If an injection $\iota : A \hookrightarrow B$ were selected without additional data, naturality with respect to every $\beta \in \mathrm{Sym}(B)$ would force $\beta\iota = \iota$. Given $a \in A$, there exists a permutation β that moves $\iota(a)$, a contradiction. Therefore, the route-by-route APP–Witt transducer is not canonical from the cardinalities. Once an octad, an inclusion, and the incidence gauge are fixed, a calibrated transducer is obtained; the choice forms part of its domain. □

Theorem 102.2 (A bare fibre of cardinality 28 does not determine $J(8,2)$)**.** *Let F be an unstructured set with $|F| = 28$. There is no nontrivial adjacency relation on F, natural with respect to all its permutations, that produces the Johnson graph $J(8,2)$.*

Proof. The group $\mathrm{Sym}(F)$ acts transitively on the unordered pairs of distinct elements. A simple relation invariant under that entire group therefore contains either all pairs or none. The two resulting graphs are the complete graph and the empty graph. By contrast, $J(8,2)$ has 28 vertices and degree 12; it is neither of them. Consequently, the calibrated projection $1008 \to 36$ with uniform fibers of cardinality 28 does not by itself imply a Witt octad. Once an octad O and a bijection $F \simeq \binom{O}{2}$ have been fixed, Johnson adjacency can be transported to F, but it depends precisely on that gauge. □

These two theorems close, by exclusion, the former canonical formulations. They do not affect the exact invariant

$$\frac{108}{144} = \frac{90}{120} = \frac{6}{8}$$

nor to the normalized defect $-1/12$, which belong to the rank extension and not to the choice of a Witt incidence.

102.4.2 The nonadic return and the exceptional reader

Let us fix the caliber

$$\chi_{\mathrm{exc}} = (\prec_{\mathrm{proj}}, \kappa_{\mathrm{Paley}}, \mathcal{D}_{12}, \iota_{\mathrm{inc}}, \mathcal{K}_{\Lambda})$$

and the calibrated reader $E_{\chi_{\mathrm{exc}}} : \mathcal{S}_\infty \to \mathcal{I}^{\mathrm{exc}}_{\chi_{\mathrm{exc}}}$. Let

$$\mathcal{S}_\infty \xleftarrow{s_\infty} \mathsf{Z}^{\Gamma}_{9,\infty} \xrightarrow{t_\infty} \mathcal{S}_\infty$$

the witnessed edge of a complete turn. Denote by ed_0 the central edge, by ev_0 the evaluation at the initial state, and by F_9 the displacement of one turn.

Theorem 102.3 (Exceptional Edge-Testified Factorization)**.** *Define*

$$\overline{E}^{s}_{\chi_{\mathrm{exc}}} := E_{\chi_{\mathrm{exc}}} \circ s_\infty, \qquad \overline{E}^{t}_{\chi_{\mathrm{exc}}} := E_{\chi_{\mathrm{exc}}} \circ t_\infty.$$

Then

$$E_{\chi_{\mathrm{exc}}} \circ \mathrm{ev}_0 = \overline{E}^{s}_{\chi_{\mathrm{exc}}} \circ \mathrm{ed}_0, \tag{102.1}$$

$$E_{\chi_{\mathrm{exc}}} \circ \mathrm{ev}_0 \circ F_9 = \overline{E}^{t}_{\chi_{\mathrm{exc}}} \circ \mathrm{ed}_0\,. \tag{102.2}$$

Proof. The endpoint identities are $s_\infty\,\mathrm{ed}_0 = \mathrm{ev}_0$ and $t_\infty\,\mathrm{ed}_0 = \mathrm{ev}_0\,F_9$. Composition with the calibrated reader gives the two equations. □

Corollary 102.4 (No equivalence between the temporal sector +1 and 1 complete nonadic turn)**.** *The preceding factorization cannot be replaced, in a natural way, by a factorization through the TRIT sample alone $\tau = +1$.*

Proof. Value $\tau = +1$ records return, memory, and past, but forgets phase, carry, route, and endpoint data distinguishing complete edges. Two edges with the same temporal sample may have different destinations. Every map that factors through that sample identifies both edges, whereas ed_0 and its source and target maps separate them. Therefore, sector +1 is not equivalent to complete edge $K \mapsto K + 9$. In particular,

$$g(K + 9) = g(K) \quad \text{and} \quad B_{K+9} \neq B_K \quad \text{in general}$$

remain distinct statements. □

Proposition 102.5 (Calibrated separation versus raw publication)**.** *Suppose that the enriched exceptional reader preserves, for each generator, the frame f_j and the image $y_j = \Gamma_{f_j A_W f_j^{-1}}(w_j)$. It then recovers*

$$w_j = \Gamma^{-1}_{f_j A_W f_j^{-1}}(y_j)$$

and it is injective on the quotient by the coordinate changes included in the gauge. If the raw reader is obtained by forgetting frames or memory, $E^{\mathrm{cr}} = \pi E^{\sharp}$, it is not equivalent to the enriched reader unless π is injective on $E^{\sharp}(X)$.

Proof. The first assertion is the explicit inversion of an automorphism in each fiber. For the second, if π identifies two distinct enriched outputs, the raw reader identifies their antecedents and cannot be injective. Conversely, injectivity of π on the image permits recovery of the enriched output. Thus separation closes in the calibrated domain, and silent equivalence with the raw codomain is rejected. □

The former square written with untyped symbols $\mathrm{pub}_{\mathrm{inc}}$, coord, O does not constitute a mathematical equivalence: it does not even define its morphisms. Its replacement is the natural cone of the Archimedean,

calibrated exceptional, and dimensional publications, whose truncation squares do have declared domain, codomain, and action.

102.4.3 Exceptional corridor and transport links

The Paley–Witt–Golay–Leech–$V^\natural$–Monster–Moonshine chain is a subsequent publication of the already constructed state. An incidence star and a loop of the TPK groupoid are not equivalent objects by virtue of their names: the former is a combinatorial subobject; the latter is an arrow with equal source and target, composition, and inverse. Without a base, orientation, and transport functor, no typed comparison exists. The automatic identification is therefore ruled out as a non-equivalence. A calibrated transport functor may produce loops from stars, but this constitutes an additional result and not a premise of the already proved corridor.

102.4.4 Infinitely divisible channel induced by the TPK transfer

Theorem 102.6 (Poissonization UCP and coherent roots)**.** *Let K be a UCP channel compatible with the TPK truncations. For $t \geq 0$, define*

$$P_t := \exp\big(t(K - I)\big) = e^{-t} \sum_{n=0}^{\infty} \frac{t^n}{n!} K^n.$$

Then $(P_t)_{t \geq 0}$ is a UCP semigroup compatible with all truncations, and

$$P_1 = (P_{1/m})^m \qquad (m \geq 1).$$

At every finite level, a minimal Stinespring dilation of $P_{1/m}$ produces a coherent tensor root; the inverse limit preserves the TPK marginals.

Proof. Each P_t is a norm-convergent convex combination of the channels K^n, and is therefore UCP. Since all terms are powers of the same operator, the exponential identity gives $P_t P_s = P_{t+s}$. Compatibility with truncations is verified term by term. Taking $t = 1/m$ yields the m-th root. Stinespring converts each finite composition into a tensor contraction; naturality of the channels makes their marginals coherent. □

The theorem closes the existence of an infinitely divisible channel with TPK memory. It does not assert that an arbitrary historical channel coincides with this Poissonization: that equality would require comparing their generators and is rejected unless such a comparison is provided.

102.5 Spectral Closures and External Recognition Boundaries

Proposition 102.7 (Calibrated equivalence, not ambient equality)**.** *The spectral transport of the double circle determines a unitary class in the cyclic subspace generated by its reference vector. Two ambient representatives V_9 are literally equal only after a unitary identification of the complement and a compatible gauge have been fixed. Without those data, ambient equality is not left indeterminate: it is a stronger assertion and is not equivalent to the specific class already constructed in the subspace.*

Norm convergence of the compressed resolvents, recovery of heights, the Riesz criterion for multiplicities, and the RH–Moonshine diagonal trace are established in their respective theorems. The diagonal trace couples the memory integer to the degree of $V^\natural$; it does not assert that the multiplicity of each zero is the dimension of a representation of the Monster. That additional identification is not equivalent to the existence of the coupled trace.

They fall outside the internal domain, without reopening any HMT theorem:

1. the identification of the dichotomy of analytic HMT publications with all arbitrary subsets of $\mathbb{R}$ of the ambient universe;

2. the macroscopic or thermodynamic realization of the finite HMT time crystal already constructed, including the preservation of coherence at large volume and its experimental testing;
3. the decimal hardening of spectral windows through a concrete execution of interval arithmetic;
4. an additional representation-theoretic identification between individual spectral multiplicities and irreducible Monster modules.

These four boundaries are external recognitions or comparisons, not gaps in the construction of the continuum, the cardinal closure, RH, or the intertwining of the double circle.

The terminal residue preserves, without permutation,

$$\begin{aligned}\mathrm{RH} &\longrightarrow \text{double circle and spectral field} \longrightarrow \text{Navier–Stokes}\\ &\longrightarrow \text{Yang–Mills} \longrightarrow \text{Hodge} \longrightarrow \text{BSD} \longrightarrow \text{falsifiers}.\end{aligned}$$

102.6 Provenance of the results and reproduction of the extension

The exposition starts from the APP–TRIT–TPK kernel and maintains its correlative construction of the continuum. Regional readouts, the native product and irreducible clocks precede their analytic realizations. Integration of centre, boundary and memory brings together results of the HMT–MD corpus with the compositions developed for the double circle. Provenance is recorded result by result, so that a consolidated formulation or an additional certificate does not retrospectively make the structure it uses new.

102.6.1 Dependencies brought together in the main text

The kernel comprises the common definitions and operations, together with its two figures. The definitions, statements and proofs of the five preceding developments are preserved in full.

The central chart, its lifted boundary and the transport signatures are developed in section 8.11. The distinction between the central point $(5, 5)$, the product signature 555555 and the sheets that its transport distinguishes is preserved in definition 8.64 and proposition 8.65. The capacity calendar and its two return levels are proved in theorems 8.69 and 8.70. The geometry of the chart is not identified with the complete history: its recovery uses the multiaffine law and the quotients preserved at the boundary.

Double-circle transport and memory moments are brought together in Section 97.10. The gamma-tail readouts of Section 97.11 reconstruct the columns with their domains and cross-products. Section 97.9 establishes the estimate on a complete window and its transport to subspaces with tails. Conservation equalities and positivity of a form are distinct statements: each result of this extension preserves the domain in which it is proved.

The formal antecedents necessary for these compositions are developed in the emitter construction 1.3.4, in the certificate of generation to arbitrary depth 8.55, in the joint connection 8.57 and in the transverse inversion of the record in section 11.4.9. The equations and proofs used thus remain set out together with their domains and representation data.

102.6.2 Reproduction order and scope of the checks

The edition preserves the antecedents, the five preceding developments and the focal checks accompanying their identities. Its compilation attests a legible material realization of the text; documentary preservation and computational checks do not thereby certify every result of a project. The extension's contribution consists of incorporating the following compositions with their proofs.

The folder accompanying the PDF preserves the LaTeX sources, the five developments in Markdown, the programs and JSON receipts. Reproduction follows the mathematical dependencies of the objects:

1. Construct the centre and boundary readouts while preserving residue and quotient, and check the partition of the 324 seeds under forward and half-turn transports.
2. Evaluate integer parts of the vacancy calendar through rational brackets. Bounds with remainders precede the digits and fix certification of each position.
3. Check seam balances, memory terminals and moment factorizations; preserve cross-terms when forming the joint matrices.
4. Evaluate local bounds for the gamma tail and Schur complement, with the domains of the estimates printed in their statements.
5. Compile the manuscript and compare common sources, transferred equations, references and page layout.

Rational and interval checks verify the finite identities and bounds they declare. Functional proofs establish the corresponding universal statements. File preservation and successful compilation are separate editorial checks; neither is presented as a substitute for a global proof.

Ordinary and optimized execution of the programs uses explicit conditions: disabling the interpreter's assertions does not alter the acceptance criterion. The delivery's instruction file specifies the commands and environment dependencies. Earlier originals are preserved separately and are not overwritten by this extension.

PART VI

Arithmetic-geometric coupling, conservation and recovery of information

Chapter 103

Refinement of histories and conservation of unity

103.1 Generation of emissions and realization domain

The construction starts from APP emissions and their enriched prolongations. An emission preserves the two sheets and their divisions

$$\delta^{\diamond} = \mathrm{res}^{\diamond} + 9\,\mathrm{quo}^{\diamond}, \qquad \diamond \in \{\Sigma, \Pi\}.$$

TRIT produces orientation and carry through

$$\Delta(\epsilon) = \mathrm{or}(\epsilon) + 3\kappa(\epsilon), \qquad \mathrm{or}(\epsilon) \in \{-1, 0, +1\}.$$

TPK transports the complete pair of sheets and updates memory through

$$U_{\epsilon_2\epsilon_1} = U_{\epsilon_2} U_{\epsilon_1}, \qquad \mathsf{U}_{\epsilon}(m) = \mathsf{C}_{\epsilon} m + \kappa(\epsilon), \qquad \kappa(\epsilon_2\epsilon_1) = \kappa(\epsilon_2) + \mathsf{C}_{\epsilon_2}\kappa(\epsilon_1).$$

The cocycle makes affine composition associative. The path boundary telescopes, but its ordered record is an ordered word, not the sum of its entries. The odometer increments vertical memory when the phase returns; return does not identify the complete states. The reduced catalogue transfer does not replace the action of emissions on the tree; the construction in section 6.4.1 y proposition 6.22 preserves this distinction.

The enriched state preserves the intermediate cells, both sheets, remainders, quotients, orientation, carry, clock, memory, boundary, path, and ordered record. An admissible emission jointly updates these fields. Truncation erases exactly its final contribution. A neutral prolongation gives a section of truncation but records a step: it is not an absence of history. This yields finiteness, nonemptiness, and surjectivity at every level, followed by total survival.

This development stops at the analytic realization of this system and its memory. No target numerical values or conventional constants enter as inputs. The following probabilistic coefficients arise solely from the number of effective outgoing emissions.

103.2 Refinement on the complete multisection

Fix an actual enriched prefix x of depth k. Write

$$H_n = \mathrm{Term}_{k,k+n}(x), \qquad \rho_n : H_{n+1} \longrightarrow H_n, \qquad \Omega_x = \varprojlim_{n}(H_n, \rho_n).$$

Each element of H_n is a complete prolongation up to that horizon, with its emission witnesses. For $h \in H_n$, the children are $h\epsilon$, for all emissions $\epsilon \in \mathrm{Out}(h)$. Operation multiplicities are preserved, even when reduced terminal data coincide. By section 6.4.2:

$$p_h(\epsilon) = \frac{1}{d(h)} > 0, \qquad d(h) = \#\,\mathrm{Out}(h), \qquad \mu_{n+1}(h\epsilon) = \mu_n(h)\,p_h(\epsilon).$$

Therefore,

$$\sum_{\epsilon \in \mathrm{Out}(h)} \mu_{n+1}(h\epsilon) = \mu_n(h), \qquad (\rho_n)_*\mu_{n+1} = \mu_n. \tag{103.1}$$

Proposition 6.4.2 constructs the unique probability measure μ_x on Ω_x with these cylinder masses; every nonempty cylinder has positive mass. The measure neither selects a history nor imposes a filter subsequent to the existence of the five constructions.

Proposition 103.1 (Refinement of observables is isometric and unital)**.** *Let* $\mathscr{L}_n = L^2(H_n, \mu_n)$ *and*

$$R_n : \mathscr{L}_n \longrightarrow \mathscr{L}_{n+1}, \qquad (R_n f)(h\epsilon) = f(h).$$

Then $R_n^* R_n = I$, $R_n 1 = 1$, *and its adjoint is*

$$(E_n g)(h) = \sum_{\epsilon \in \mathrm{Out}(h)} p_h(\epsilon) g(h\epsilon). \tag{103.2}$$

In particular, $E_n R_n = I$, $E_n 1 = 1$, *and* $R_n E_n$ *is the orthogonal projection onto the observables depending only on the prefix.*

Proof. Applying (103.1),

$$\|R_n f\|_{n+1}^2 = \sum_h \mu_n(h) |f(h)|^2 \sum_\epsilon p_h(\epsilon) = \|f\|_n^2.$$

The same grouping in the inner product gives (103.2). The statements concerning unity hold pointwise; the projection statement follows from $E_n = R_n^*$ and $E_n R_n = I$. Moreover, $R_n(fg) = R_n f \, R_n g$ and $R_n \bar{f} = \overline{R_n f}$: on finite observables, it is also a unital algebra homomorphism. □

Upon iteration, $R_{m,n} = R_{m-1} \cdots R_n$ coincides with pullback along the composed truncation. The cylindrical pullbacks $R_{\infty,n}$ realize the inductive limit of these Hilbert spaces in $L^2(\Omega_x, \mu_x)$. Their union is dense: cylinders form an algebra generating the sigma-algebra, and simple functions from that algebra are dense in L^2. Constructing the limit requires no choice of a trajectory.

103.2.1 The same isometry in the history basis

The unitary identification $W_n f(h) = \sqrt{\mu_n(h)} f(h)$ maps $\mathscr{L}_n$ to $\ell^2(H_n)$. Conjugating R_n gives

$$\widehat{R}_n \delta_h = \sum_{\epsilon \in \mathrm{Out}(h)} \sqrt{p_h(\epsilon)} \, \delta_{h\epsilon}. \tag{103.3}$$

The vectors on the right have disjoint supports for distinct parents, because $\rho_n(h\epsilon) = h$. Each column has norm one by normalization. This directly proves isometry on the already generated enriched histories, without imposing that a numerical projection preserve all memory. The unit vector is transformed into

$$\Omega_n = \sum_{h \in H_n} \sqrt{\mu_n(h)} \, \delta_h, \qquad \widehat{R}_n \Omega_n = \Omega_{n+1}.$$

No artificial copy of h is appended to a result in order to recover it: $h\epsilon$ is precisely the prolongation already produced by the APP–TRIT–TPK domain.

103.3 Correlative prolongation of the five operations

The construction in section 6.4.9 defines a single record $\mathfrak{e}_\epsilon$ for each emission. Its spectral, solenoidal, gauge, cohomological, and determinantal operations depend on this same emission, with the same source, target, orientation, carry, boundary, path, and ordered record. The cellular action satisfies

$$\partial \operatorname{Cell}(\epsilon) = \operatorname{Cell}(\epsilon)\partial, \qquad \operatorname{Cell}(\epsilon_2\epsilon_1) = \operatorname{Cell}(\epsilon_2)\operatorname{Cell}(\epsilon_1).$$

The complex and its determinant line belong to the same object; the constructed filling satisfies $\partial h_* = z_- - z_+$. Totality of the constructor does not require a specialized trivialization to be acyclic or invertible. Joint existence is thus preserved before any specialized reader.

The naturality in propositions 6.28 y 6.29 is expressed jointly as

$$u_{(\ell,N'),(k,N)}\mathfrak{D}_{\ell,N'}(\widehat{x}_\ell) = \mathfrak{D}_{k,N}(\tau_{\ell,k}\widehat{x}_\ell). \tag{103.4}$$

Its proof does not identify an isolated fine edge with a fictitious coarse edge: it restricts the emission history and preserves the actions of its entries. Transport composes over the same cylinder probabilities; balances use conditional expectation and its corrector; incidence and ports use their cellular maps; homology and determinant use the same map of complexes. These are not five limits of separately selected histories.

Two directions must be distinguished. State and coefficient maps run from fine to coarse. The pullbacks R_n of Proposition 103.1 run from coarse observables to fine observables. Expectation E_n returns in the reduction direction. This distinction makes it possible to realize (103.4) analytically without reversing its domains.

The terminal construction of theorem 6.25 y sections 6.4.7 y 6.4.8 prolongs the complete terminals and simultaneously preserves polar telescoping, Gram and losses, incidence with measure, return cone and Smith–Bockstein data. Promoting one of these actions to a bounded operator requires the corresponding norm and bound (see the passage to the limit proved at the end of this section). A compatible finite family does not become a bounded operator on the limit merely by its name.

103.4 Memory fibres: Gram criterion and conservation of unity

For a nonscalar realization, assign to each prefix h a Hilbert fibre $\mathscr{M}_h$, and to its emission a typed linear transport $I_\epsilon : \mathscr{M}_h \to \mathscr{M}_{h\epsilon}$. This linear operator is not identified with the affine update U_ϵ without specifying the representation realizing it.

On $\mathscr{H}_n = \bigoplus_{h\in H_n} \mathscr{M}_h$, define

$$(V_n\xi)_{h\epsilon} = \sqrt{p_h(\epsilon)}I_\epsilon\xi_h.$$

Disjointness of the children proves the exact identity of proposition 6.24:

$$V_n^*V_n\big|_{\mathscr{M}_h} = \sum_{\epsilon\in\operatorname{Out}(h)} p_h(\epsilon)I_\epsilon^*I_\epsilon. \tag{103.5}$$

The necessary and sufficient criterion for V_n to be isometric is that the sum of (103.5) be I at each parent. Each I_ϵ being isometric is sufficient. It is also necessary if all I_ϵ are already contractions: then each $I - I_\epsilon^*I_\epsilon$ is positive, and a sum with strictly positive weights can vanish only if each summand vanishes. The Gram criterion characterizes isometry of the total map; isometry of each transport constitutes a sufficient condition, which is also necessary within the class of contractions.

For the scalar histories of (103.3), $I_\epsilon = 1$, so the condition has been proved. In additional analytic fibres, (103.5) is retained and the precise assumption allowing passage to isometry is identified.

If the fibres have distinguished unit vectors u_h and $I_\epsilon u_h = u_{h\epsilon}$, then

$$V_n\Big(\bigoplus_h \sqrt{\mu_n(h)}u_h\Big) = \bigoplus_{h\epsilon} \sqrt{\mu_{n+1}(h\epsilon)}u_{h\epsilon}. \tag{103.6}$$

Isometry alone does not assert (103.6): preserving the norm and preserving a distinguished unit vector are distinct properties.

103.5 Symmetries and readers on the common domain

A coherent reversible symmetry of the tree transports all emissions and their multiplicities. Invariance of multiplicities in section 6.4.2 proves that it preserves degrees and cylinder probabilities. It may map Ω_x to Ω_{gx}; only when it fixes the prefix does it act within the same prolongation fibre.

Therefore

$$(K_g f)(g\omega) = f(\omega)$$

defines a unitary map $L^2(\Omega_x, \mu_x) \to L^2(\Omega_{gx}, \mu_{gx})$. Naturality of truncation implies $K_{g,n+1}R_n = R'_n K_{g,n}$, and the corresponding identity for expectations follows by taking adjoints. In memory fibres, one additionally requires the square

$$S_{g,h\epsilon} I_\epsilon = I_{g\epsilon} S_{g,h}$$

with $S_{g,h}$ unitary. This is the intertwiner that turns a tree symmetry into a symmetry of this memory representation; it is not attributed merely by name to every subsequent exceptional group.

For the double readout, take the initial gauge and its prefix transport specified in section 21.11.1 y proposition 21.55. Work on a common multisection Ω_x where the readers are defined; for the Archimedean reader, this includes the nested compact intervals and diameter contraction specified in (10.49). This is a premise concerning the reader realization, rather than a new existence criterion for the joint constructor. The finite identities are

$$r_{n,m}Q_n = Q_m\rho_{n,m}, \qquad a_{n,m}R_n^{\mathrm{arq}} = R_m^{\mathrm{arq}}\rho_{n,m}. \tag{103.7}$$

They determine the joint readout at the limit. If $L = (\mathrm{ev}_{\mathrm{arq}}, Q_\infty)$ and $\nu = L_*\mu_x$, then

$$C_L : L^2(Y, \nu) \longrightarrow L^2(\Omega_x, \mu_x), \qquad C_L f = f \circ L,$$

is an isometry, since equality of norms is the definition of pushforward measure. It preserves the unit and its ranges are the observables measurable with respect to the information published by L. For compatible finite readers, (103.7) also implies consistency of the pushforward measures.

This isometry does not imply that the reader distinguishes every state. The construction in proposition 21.55 distinguishes the fact that the same visible stream with different hidden memory may have the same incidence. The adjoint of C_L is expectation with respect to the reader; $C_L C_L^*$ preserves exactly this observable part. If an enlarged realization (L, M) is injective and Borel, with a measurable inverse on its image—for example, a continuous injection from the compact history space into an appropriate Hausdorff space—its pullback does identify the whole of L^2. The required memory is the memory already preserved in the state, not a new retrospective selection.

103.6 Passage-to-the-limit theorem for the observable/memory charge

This section specifies the types in the connection with a memory conservation identity. Canonical refinement of observables supplies the required isometric maps. An additional realization in memory fibres uses the Gram criterion of (103.5).

Let $(\mathscr{H}_n, R_n)$ and $(\mathscr{K}_n, S_n)$ be two inductive systems of Hilbert spaces with isometric inclusions. For each n, let

$$J_n : \mathscr{H}_n \to \mathscr{K}_n \text{ isometric}, \quad P_n = J_n J_n^*, \quad U_n \text{ unitary on } \mathscr{K}_n,$$

and let $\widetilde{A}_n$ be bounded and self-adjoint, with $\sup_n \|\widetilde{A}_n\| < \infty$. Define

$$A_n = J_n^* \widetilde{A}_n J_n, \quad T_n = J_n^* U_n J_n, \quad \eta_n = (I - P_n) U_n J_n.$$

Assume conservation and separation at every level,

$$U_n^* \widetilde{A}_n U_n = \widetilde{A}_n, \qquad [\widetilde{A}_n, P_n] = 0, \tag{103.8}$$

and the following refinement squares:

$$J_{n+1} R_n = S_n J_n, \qquad P_{n+1} S_n = S_n P_n, \tag{103.9}$$

$$U_{n+1} S_n = S_n U_n, \qquad \widetilde{A}_{n+1} S_n = S_n \widetilde{A}_n. \tag{103.10}$$

Theorem 103.2. *These families induce bounded operators on the inductive limits, with J_∞ isometric and U_∞ unitary, and preserve*

$$A_\infty = T_\infty^* A_\infty T_\infty + \eta_\infty^* \widetilde{A}_\infty \eta_\infty. \tag{103.11}$$

The same identity holds at every finite depth. If $\widetilde{A}_n \geq 0$, the retained charge is positive. Without positivity, a self-adjoint form is preserved, rather than necessarily a positive energy.

Proof. Decompose $U_n J_n = J_n T_n + \eta_n$. The two terms belong to $P_n \mathscr{K}_n$ and $(I - P_n)\mathscr{K}_n$. Commutation in (103.8) makes the cross terms of the form $\widetilde{A}_n$ vanish. Applying the other identity in (103.8),

$$A_n = J_n^* U_n^* \widetilde{A}_n U_n J_n = T_n^* A_n T_n + \eta_n^* \widetilde{A}_n \eta_n.$$

The second equality in (103.9), together with the first, implies $J_{n+1}^* S_n = R_n J_n^*$: write $P_{n+1} S_n = S_n J_n J_n^* = J_{n+1} R_n J_n^*$ and multiply by J_{n+1}^*. By (103.9)–(103.10),

$$T_{n+1} R_n = R_n T_n, \qquad \eta_{n+1} R_n = S_n \eta_n, \qquad A_{n+1} R_n = R_n A_n.$$

The operators are thus defined on the algebraic unions of the systems. Isometries and the uniform bound allow extension by continuity to the completions. Compatibility of U_n^* also follows from compatibility of U_n, because both levels are unitary; the limit is therefore unitary, not merely isometric. The projections P_n induce a projection whose range is the closure of the union of the ranges of J_n; it is $J_\infty J_\infty^*$. All identities persist first on finite-level vectors and then by density. This proves (103.11). □

Compatibility of J_n alone does not replace the second equality in (103.9). A refinement preserving the observable inclusion while mixing its complement with it may alter the memory defect.

103.6.1 Explicit compatible nonadic realization

Suppose C_n is unitary on $\mathscr{H}_n$, natural with respect to R_n, and A_n is bounded and self-adjoint, uniformly bounded, natural, and satisfies $[A_n, C_n] = 0$. On $\mathscr{K}_n = \mathscr{H}_n^{\oplus 9}$, define

$$J_n v = \tfrac{1}{3}(v, \dots, v), \quad S_n = R_n^{\oplus 9}, \quad U_n(v_1, \dots, v_9) = (C_n v_9, v_1, \dots, v_8), \quad \widetilde{A}_n = I_9 \otimes A_n.$$

The factor $1/3$ normalizes the nine components. The formulas directly verify (103.8)–(103.10), including the projection. The compression is $T_n = (8I + C_n)/9$, and

$$\eta_n^* \widetilde{A}_n \eta_n = A_n - T_n^* A_n T_n = \frac{8}{81}(I - C_n)^* A_n (I - C_n). \tag{103.12}$$

The final equality uses $C_n^* A_n C_n = A_n$. By the theorem, (103.12) also holds at the limit. Nonadic refinement or complete history refinement transports the charge and its memory when C_n and A_n satisfy the indicated squares.

For $A = I$, finite telescoping gives

$$\|v\|^2 = \|T^N v\|^2 + \sum_{j=0}^{N-1} \|\eta T^j v\|^2.$$

Thus, $v \mapsto (\eta v, \eta T v, \dots, \eta T^{N-1} v, T^N v)$ is an isometry. The corresponding charge formula replaces the norms by the forms of A and $\widetilde{A}$. The terminal term is not removed without proving convergence to zero; depth compatibility alone does not prove this temporal stability.

If $D_{N,n}$ denotes this isometry at depth n and temporal horizon N, the preceding squares also prove

$$(S_n^{\oplus N} \oplus R_n) D_{N,n} = D_{N,n+1} R_n.$$

Indeed, each component satisfies $\eta_{n+1} T_{n+1}^j R_n = S_n \eta_n T_n^j$, and the terminal component satisfies $T_{n+1}^N R_n = R_n T_n^N$. Finite-horizon memory accumulation and resolution refinement commute. The same calculation proves equivariance for a symmetry represented by unitaries intertwining $J, U, P, \widetilde{A}$; it does not extend the action to symmetries for which these squares have not been constructed.

Chapter 104

Conservation of observables and the complete record

104.1 Balance of a conserved observable

Let $\mathcal{H}, \mathcal{K}$ be realizations of a readout space and its enriched extension. Let $J : \mathcal{H} \to \mathcal{K}$ be an isometry, $P = JJ^*$, $U : \mathcal{K} \to \mathcal{K}$ a bounded transport, and $\widetilde{A}$ a bounded self-adjoint observable. Suppose

$$U^*\widetilde{A}U = \widetilde{A}, \qquad [\widetilde{A}, P] = 0.$$

We define

$$A = J^*\widetilde{A}J, \qquad T = J^*UJ, \qquad \eta = (I - P)UJ.$$

Proposition 104.1. *The charge decomposes exactly between readout and complement:*

$$\boxed{A = T^*AT + \eta^*\widetilde{A}\eta.} \tag{104.1}$$

Proof. The identity $UJ = JT + \eta$ is an orthogonal decomposition. Expanding $J^*U^*\widetilde{A}UJ$, the cross terms vanish because $\widetilde{A}$ reduces the subspaces $P\mathcal{K}$ and $(I - P)\mathcal{K}$. The left-hand term is A; the two diagonal terms are those in (104.1). This also proves the identity of sesquilinear forms for two distinct states. If $\widetilde{A} \geq 0$, both summands are positive. For $\widetilde{A} = I$, the conservation hypothesis is $U^*U = I$. □

If the readout mixes sectors of the observable, the balance additionally retains

$$T^*J^*\widetilde{A}\eta + \eta^*\widetilde{A}JT.$$

These terms represent interference between the two spaces carrying the charge. The reducing condition stated above ensures their vanishing for the entire decomposition. In particular realizations, they may also vanish for other reasons, for example when $\eta = 0$.

104.2 Specialization to the nonadic connection

Let C be the unitary realization of memory transport on $\mathcal{H}$. On $\mathcal{H}^9$, transport of the nine phases and their uniform inclusion are

$$S_C(v_0, \dots, v_8) = (Cv_8, v_0, \dots, v_7), \qquad Jv = \tfrac{1}{3}(v, \dots, v).$$

The factor $1/3$ follows from normalization of nine copies. The compression and its complement are

$$T = \frac{8I + C}{9}, \qquad \eta v = \frac{1}{27}\big(8(C - I)v, -(C - I)v, \dots, -(C - I)v\big).$$

If $A = A^*$ is bounded and $[A, C] = 0$, the observable $\widetilde{A} = I_9 \otimes A$ satisfies the hypotheses of Proposition 104.1. Therefore,

$$\boxed{A = T^*AT + \frac{8}{81}(I - C)^*A(I - C).} \tag{104.2}$$

The coefficients arise from the distribution among the nine components: $8^2 + 8 = 72$, divided by 27^2, gives $8/81$. The identity is the sesquilinear balance already documented in the spectral article, expressed here for a general observable.

Telescopic iteration gives, for every $N \geq 1$,

$$A = T^{*N} A T^N + \sum_{j=0}^{N-1} T^{*j} \eta^* \widetilde{A} \eta T^j. \tag{104.3}$$

For $A = I$, the map

$$V_N v = (T^N v, \eta v, \eta T v, \dots, \eta T^{N-1} v)$$

is isometric. The step $N \to N+1$ decomposes only the terminal component $T^N v$ into its new readout and complement, retaining every preceding record. Conservation is thus verified at any depth.

Distinction of operations. One has $S_C^9 = I_9 \otimes C$. Iteration T^N describes successive compressions with storage of their complements. Enriched transport without intermediate compressions is S_C^N. Both operations have defined domains and different functions; the proof preserves this distinction.

104.3 Terminal sector and the unlimited-depth record

Let P_{fix} be the orthogonal projection onto $\ker(I - C)$.

Theorem 104.2. *For every unitary transport C, the nonadic compression satisfies*

$$\operatorname*{s-lim}_{N\to\infty} T^N = P_{\mathrm{fix}}, \qquad \boxed{I = P_{\mathrm{fix}} + \sum_{j=0}^{\infty} T^{*j} \eta^* \eta T^j.} \tag{104.4}$$

The series converges in the strong topology. For each bounded self-adjoint observable A commuting with C, one also obtains

$$\boxed{A = P_{\mathrm{fix}} A P_{\mathrm{fix}} + \sum_{j=0}^{\infty} T^{*j} \eta^* (I_9 \otimes A) \eta T^j.} \tag{104.5}$$

Proof. In the spectral representation of the unitary operator C, compression corresponds to $t(z) = (8+z)/9$. On the unit circle,

$$|t(z)|^2 = 1 - \frac{8}{81}|1 - z|^2.$$

Hence $t(z)^N \to 0$ for $z \neq 1$, while $t(1)^N = 1$. Dominated convergence with respect to each vector spectral measure proves $T^N \to P_{\mathrm{fix}}$ strongly. The same argument holds for T^{*N}. Since A is bounded, $T^{*N} A T^N \to P_{\mathrm{fix}} A P_{\mathrm{fix}}$ strongly. Taking the limit in (104.3) gives (104.5), and specializing to $A = I$ gives (104.4). □

In particular,

$$V_\infty v = (P_{\mathrm{fix}} v, \eta v, \eta T v, \eta T^2 v, \dots)$$

is an isometry. It preserves the complete inner product as well as the norm.

Corollary 104.3 (Bilateral memory)**.** *For the shift $C e_n = e_{n+1}$ on $\ell^2(\mathbb{Z})$, $P_{\mathrm{fix}} = 0$: a fixed sequence would be constant, and its only square-summable realization is zero. Consequently, the entire initial norm is distributed through the complement record. This specifies the unlimited behaviour of the bilateral memory realization present in the corpus.*

Corollary 104.4 (Finite calendar)**.** *On a cycle of d positions, the uniform sequence determines a one-dimensional fixed subspace. This sector remains as the terminal component, while the complement accumulates the remainder. The finite calendar and the bilateral record therefore have different terminal components.*

In the bilateral case, strong convergence may coexist with $\|T^N\| = 1$ for every N. The proof assumes no uniform contraction rate. It also distinguishes this compression from the mode $(5/9)C$, whose geometric contraction is uniform and is studied separately in the sources.

104.4 Preservation of symmetry and chart transport

Let R be unitary and define $C' = RCR^*$, $A' = RAR^*$. The explicit compression formula gives

$$T(C')R = RT(C), \qquad \eta(C')R = R^{\oplus 9}\eta(C). \tag{104.6}$$

Proof. The first equality follows by expanding $(8I + RCR^*)R/9$. The second follows from $(C' - I)R = R(C - I)$ in each of the nine components of η. □

Iteration of (104.6) intertwines the finite registers. Moreover, $P_{\mathrm{fix}}(C') = RP_{\mathrm{fix}}(C)R^*$, by transport of the kernel of $I - C$, so the unlimited register is also intertwined. Thus, the balance of observables is covariant when the chart, operator and observable are transported jointly. Symmetries commuting with C additionally act in the same fixed chart. This distinction allows exceptional transformations to be incorporated with their effectively transported frames, flags and orientations.

The composition in lemma 11.39, section 21.11.4 y proposition 21.60 uses the record's Hadamard matrix, $H_{12}^2 = 4I$, and the incidence $\mathcal{I}$ of the twelve positions in the 132 hexads:

$$J_H = H_{12}/2, \qquad \mathcal{I}^*\mathcal{I} = 36I + 30\mathbf{1}\mathbf{1}^*, \qquad U_W = \mathcal{I}/6\big|_{\mathbf{1}^\perp}.$$

Both normalized operators are isometric on the indicated domains. The composition $B = U_W J_H$ on $W = J_H(\mathbf{1}^\perp)$ preserves inner products and intertwines the transported representation of M_{12} with the action on the hexads. The integer record K additionally preserves the integral inversion $H_{12}/4$ on its congruence lattice; this inversion and isometric normalization have different functions. The proof, the APP–Witt–Leech prolongation, and their domains are developed here.

In this composition, incidence conservation has concrete operator content. Its extension through other transports uses (104.6) and the effective intertwiners from the sources, respecting their respective groups and domains.

104.4.1 Complete transport of the twelve coordinates of K

Separation of the centred subspace can be completed by also retaining its mean. Let $P_0 = I - \mathbf{1}\mathbf{1}^*/12$, $\mu(k) = \mathbf{1}^*k/12$, and

$$F(k) = \left(\mu(k), \frac{1}{6}\mathcal{I}P_0 k\right) \in \mathbb{R} \oplus E_{\mathrm{inc}}.$$

Equip the codomain with $\|(\mu, y)\|^2 = 12|\mu|^2 + \|y\|^2$. The incidence Gram operator proves

$$\|F(k)\|^2 = \|k\|^2, \qquad \boxed{F^{-1}(\mu, y) = \mu\mathbf{1} + \frac{1}{6}P_0\mathcal{I}^*y.} \tag{104.7}$$

Indeed, $\mathcal{I}^*\mathcal{I}P_0 = 36P_0$, so the inverse formula recovers P_0k, while the first term recovers its mean. The action of M_{12} is trivial on the mean and permutes the hexads; hence F is equivariant. Composing FJ_H transports the normalized signed coordinates. All twelve record coordinates are thereby preserved,

rather than only the centred part. The domain of this reconstruction is the dodecaphasic record; the complete history memory retains its other coordinates and its prolongation.

104.4.2 Specialization to the exceptional operator of order three

The exceptional construction produces the orthogonal operator g_c on the realization of the Leech neighbour, through the twelve APP–Witt fibres of type A_2, and proves $g_c^3 = I$ and $\ker(I - g_c) = 0$. Its construction, intertwining, and lattice preservation are located in section 21.11.11 y section 106.3.

We now construct, as an operator composition of that output with the nine-phase chart,

$$T_3 = \frac{8I + g_c}{9}, \qquad \eta_3 = (I - JJ^*)S_{g_c}J.$$

Corollary 104.5. *This composition satisfies*

$$\boxed{T_3^*T_3 = \frac{19}{27}I, \qquad \eta_3^*\eta_3 = \frac{8}{27}I, \qquad \|T_3^N v\|^2 = \left(\frac{19}{27}\right)^N \|v\|^2.} \tag{104.8}$$

Proof. The vector $(I + g_c + g_c^2)v$ is fixed by g_c; the absence of fixed vectors implies $I + g_c + g_c^2 = 0$. Since $g_c^* = g_c^2$, one has $g_c + g_c^* = -I$. Substitution gives

$$T_3^*T_3 = \frac{65I + 8(g_c + g_c^*)}{81} = \frac{57}{81}I = \frac{19}{27}I.$$

Balance (104.2) with $A = I$ gives the second coefficient. Repeated application of the norm identity gives the power for every N. □

The unlimited record is isometric, and its terminal component tends to zero at the explicit rate in (104.8). Here, the exceptional structure determines the two complementary coefficients; both arise from the polynomial relation of g_c and the nine phases. This is a mathematical composition developed in this research. Its definition neither identifies g_c with Γ_9 nor asserts that S_{g_c} is the canonical temporal operator of TPK: it preserves the distinction between exceptional prolongation and temporal holonomy while composing them explicitly.

104.5 History refinement and compatibility of balances

For enriched histories of depth n, let $p_h(\varepsilon)$ be the probability of a surviving extension, normalized by $\sum_\varepsilon p_h(\varepsilon) = 1$. Canonical refinement on the history bases is

$$R_n\delta_h = \sum_{\varepsilon \in \mathrm{Out}(h)} \sqrt{p_h(\varepsilon)}\, \delta_{h\varepsilon}.$$

Extensions of different histories have different prefixes and disjoint supports. Hence $R_n^*R_n = I$. This is the isometric realization of projective consistency of the measure: the coefficients arise from the survival weights already constructed.

To transport (104.1) between depths, inclusions, projections, transports, and observables are preserved jointly. With refinement isometries $R_n, \widetilde{R}_n$, the required squares are

$$J_{n+1}R_n = \widetilde{R}_nJ_n, \quad P_{n+1}\widetilde{R}_n = \widetilde{R}_nP_n, \quad U_{n+1}\widetilde{R}_n = \widetilde{R}_nU_n, \quad \widetilde{A}_{n+1}\widetilde{R}_n = \widetilde{R}_n\widetilde{A}_n.$$

These squares imply $T_{n+1}R_n = R_nT_n$ and $\eta_{n+1}R_n = \widetilde{R}_n\eta_n$. With uniform bounds, the identities pass to the inductive limit of the realizations. Histories, by contrast, form the projective system of prefixes; the opposite directions of the two types of maps remain distinguished. The measure, Gram, and passage-to-the-limit proofs are included.

104.6 Variational specialization: action and orientation

The elliptic action in section 24.3 y chapter 109 supplies a physical specialization of the principle, with parameters constructed at their HMT stages. In its canonical coordinates,

$$H_\eta(Q,P) = \frac{\omega}{2}\left(e^{-\eta}Q^2 + e^{\eta}P^2\right), \qquad I_\eta = H_\eta/\omega.$$

The canonical transformation $Q = e^{\eta/2}q$, $P = e^{-\eta/2}p$ turns I_η into $(q^2+p^2)/2$. Rotations of (q,p), transported to (Q,P), form a continuous symmetry. For the Lagrangian $L = P\dot{Q} - \omega I_\eta$, its Noether charge is I_η. On the source contour $I_\eta = \hbar$, the oriented action is $\oint P\,dQ = 2\pi\hbar = h$, with the orientation of the Hamiltonian orbit. The proof distinguishes the symplectic and antisymplectic transformations: they can preserve the same energy while acting with different signs on oriented action. The full variational proof is presented in chapter 109.

104.6.1 Updating the form and the connection term

The form matrix $M_\eta = \mathrm{diag}(e^{\eta/2}, e^{-\eta/2})$ allows development of transport between ellipses with different parameters. Fix $J_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $R(\theta) = \exp(-\theta J_2)$, the Hamiltonian rotation in the (q,p)-plane. The transport

$$z' = M_{\eta'} R(\delta\theta) M_\eta^{-1} z, \qquad z = (Q,P)^{\mathsf{T}},$$

is symplectic and satisfies exactly $I_{\eta'}(z') = I_\eta(z)$. The proof consists of moving both states to their normalized coordinates and using preservation of q^2+p^2 under rotation. It preserves action while changing the form.

For a differentiable realization $\eta(t)$, with angular advance $\dot{\theta} = \omega$, differentiation of this transport gives

$$\dot{Q} = \omega e^{\eta} P + \tfrac{1}{2}\dot{\eta} Q, \qquad \dot{P} = -\omega e^{-\eta} Q - \tfrac{1}{2}\dot{\eta} P.$$

Its Hamiltonian generator, obtained from these two equations, is

$$\boxed{H_{\mathrm{trans}} = \omega I_\eta + \frac{\dot{\eta}}{2} QP.} \tag{104.9}$$

The second summand is the connection term for the varying form. With the convention $\{f,g\} = \partial_Q f \partial_P g - \partial_P f \partial_Q g$,

$$\partial_t I_\eta = \frac{\dot{\eta}}{2}(-e^{-\eta}Q^2 + e^{\eta}P^2), \quad \left\{I_\eta, \frac{\dot{\eta}}{2}QP\right\} = \frac{\dot{\eta}}{2}(e^{-\eta}Q^2 - e^{\eta}P^2).$$

The two contributions cancel, and $dI_\eta/dt = 0$. For the prescribed transport, (104.9) is unique up to a function of time. The differentiable realization is a declared specialization of transport between forms; the preceding discrete result applies directly between two generated parameters. The specific TPK update retains its own rule for selecting these parameters and their times.

This gives a precise connection: an observable conserved by the complete dynamics is distributed between readout and memory through (104.1). When this observable is the generator of a continuous symmetry of the constructed action, the distributed quantity is a Noether charge. The norm, the symmetry charge, and the energy functional are related through their specific operators.

An effective bounded specialization is obtained from the 108-state calendar. Its realized Hamiltonian is $H_{\mathrm{clk}} = \hbar\omega_0 N_{108}$, with $N_{108} = \sum_{k=0}^{107} k P_k$ and P_k its Fourier projectors. The clock action has charge $\hbar\langle\psi, N_{108}\psi\rangle = E_{\mathrm{clk}}/\omega_0$. Transports and inclusions satisfying the hypotheses of (104.1) distribute this charge between readout and complement. All operators here are finite and bounded. The elliptic action of

(104.9) has been proved in its classical symplectic realization; a quantization with unbounded observables additionally retains its own domain conditions.

Chapter 105

Recovery of the state and its dynamics

105.1 Recoverable representation of transport

Let C be the unitary realization of memory transport on $\mathcal{H}$. The nine-phase chart, its uniform inclusion and its compression are

$$S_C(v_0,\dots,v_8) = (Cv_8, v_0, \dots, v_7), \qquad Jv = (v,\dots,v)/3, \qquad T = (8I + C)/9.$$

Let $\eta = (I - JJ^*)S_C J$. Its action is

$$\eta v = \frac{1}{27}\big(8(C-I)v, -(C-I)v, \dots, -(C-I)v\big).$$

Normalization of nine copies determines $1/3$; the distribution of the seam determines $8/81$ in

$$I - T^*T = \eta^*\eta = \frac{8}{81}(I-C)^*(I-C). \tag{105.1}$$

Write $P = \operatorname{proj}\ker(I-C)$. The preceding theorem proves strong convergence $T^N \to P$. Therefore,

$$\mathcal{V}v = (Pv, \eta v, \eta T v, \eta T^2 v, \dots) \quad \text{in} \quad \mathcal{R} = P\mathcal{H} \oplus \ell^2(\mathbb{N}_0; \mathcal{H}^9) \tag{105.2}$$

is an isometry. Denote its closed image by $\mathcal{M}$.

On the record space, define the block shift

$$\mathcal{B}(a, m_0, m_1, m_2, \dots) = (a, m_1, m_2, \dots). \tag{105.3}$$

The first component preserves the fixed sector; the remaining components are the complete vector records, including their correlations.

Theorem 105.1. *The original transport has the exact representation*

$$\boxed{\mathcal{V}C = (9\mathcal{B} - 8I)\mathcal{V}.} \tag{105.4}$$

The restriction $C = (9\mathcal{B} - 8I)|_{\mathcal{M}}$ is unitary on $\mathcal{M}$, and

$$C = \mathcal{V}^* C \mathcal{V}. \tag{105.5}$$

Proof. Since $PT = P$, definition (105.2) gives, componentwise,

$$\mathcal{V}Tv = (Pv, \eta T v, \eta T^2 v, \dots) = \mathcal{B}\mathcal{V}v.$$

The algebraic identity $C = 9T - 8I$ implies (105.4). The isometry $\mathcal{V} : \mathcal{H} \to \mathcal{M}$ is surjective by definition of its image. Equality (105.4) identifies the restriction with $\mathcal{V}C\mathcal{V}^{-1}$, which is unitary because C is unitary. This also proves $C\mathcal{M} = \mathcal{M}$ and (105.5). □

Restriction to the subspace of compatible registers is essential: $9\mathcal{B} - 8I$ on all of $\mathcal{R}$ is not unitary. The theorem characterizes transport on registers that actually arise from the same linear trajectory of the documented chart.

Corollary 105.2. *For $v, w \in \mathcal{H}$ and $k \in \mathbb{Z}$,*

$$\langle C^k v, w\rangle = \langle C^k \mathcal{V} v, \mathcal{V} w\rangle. \tag{105.6}$$

All cross moments of the realized dynamics are thus preserved. Negative powers belong to the inverse of C on $\mathcal{M}$, rather than to an inversion of the unilateral shift on the ambient space.

Corollary 105.3. *For every bounded observable A, its realization on the image is $\widehat{A} = \mathcal{V} A \mathcal{V}^*|_{\mathcal{M}}$. Products, adjoints, and commutators are preserved. In particular,*

$$[A, C] = 0 \quad \Longleftrightarrow \quad [\widehat{A}, C] = 0. \tag{105.7}$$

The proof uses $\mathcal{V}^*\mathcal{V} = I$ and the fact that $\mathcal{V}\mathcal{V}^*$ is the identity on $\mathcal{M}$. Symmetry conservation is expressed through complete transport of its operators, in addition to an equality of norms.

105.2 Explicit reconstruction and record depth

Let $m_j = \eta T^j v$. The telescopic identity gives, for each N,

$$\boxed{v = T^{*N} T^N v + \sum_{j=0}^{N-1} T^{*j} \eta^* m_j.} \tag{105.8}$$

Passing to the strong limit,

$$\boxed{v = P v + \sum_{j=0}^{\infty} T^{*j} \eta^* m_j.} \tag{105.9}$$

Partial reconstruction with fixed terminal component, $v_N = Pv + \sum_{j<N} T^{*j} \eta^* m_j$, has the exact error

$$v - v_N = T^{*N} T^N (I - P) v. \tag{105.10}$$

The series converges for every state. If the complete record has an error δr measured in the norm of $\mathcal{R}$, its reconstruction through $\mathcal{V}^*$ changes by at most $\|\delta r\|$ in norm, because $\|\mathcal{V}^*\| = 1$. This is uniform stability of the complete readout.

105.2.1 Difference between finite and unlimited depth

For the bilateral shift $C e_k = e_{k+1}$ on $\ell^2(\mathbb{Z})$, one has $P = 0$. Consider

$$v_L = L^{-1/2} \sum_{k=1}^{L} e_k.$$

Then $\|(I - C) v_L\|^2 = 2/L$. Commutation of T with $I - C$, contractivity of T, and (105.1) imply

$$\sum_{j=0}^{N-1} \|\eta T^j v_L\|^2 \le \frac{16 N}{81 L}. \tag{105.11}$$

For any fixed depth N, the right-hand side tends to zero as $L \to \infty$, although $\|v_L\| = 1$. The fixed-depth memory record, separated from its terminal component, has no uniform lower bound. By contrast, the unlimited record has norm exactly one for each v_L.

The difference corresponds to two distinct quantifiers: every state is preserved upon completion of its record; a prescribed depth does not uniformly recover every state without its terminal component. Conservation at arbitrary depth here has an exact functional expression.

105.2.2 Vector information and intensity

The theorem preserves m_j, not merely $\|m_j\|^2$. For example, in the bilateral realization, $v = e_0$ and $w = e_1$ have identical intensities at every depth because the shift commutes with T and transports η unitarily. Their vector records differ, and (105.9) recovers the two distinct states. Intensities serve the balance; records with their correlations additionally serve reconstruction.

105.3 Naturality of recovery under refinement

Let $\iota_n : \mathcal{H}_n \to \mathcal{H}_{n+1}$ be the refinement isometries obtained from the common emissions, and let C_n be unitary realizations with

$$C_{n+1}\iota_n = \iota_n C_n. \tag{105.12}$$

The relation also holds for adjoints: multiplication by C_{n+1}^* and C_n^* gives $C_{n+1}^*\iota_n = \iota_n C_n^*$. The images are therefore reducing. The polynomial formulas for T_n, η_n, and the strong limit of T_n^N give

$$T_{n+1}\iota_n = \iota_n T_n, \quad \eta_{n+1}\iota_n = \iota_n^{\oplus 9}\eta_n, \quad P_{n+1}\iota_n = \iota_n P_n. \tag{105.13}$$

Let $\mathfrak{I}_n$ be the refinement applying ι_n to the terminal component and $\iota_n^{\oplus 9}$ to every record. Then

$$\boxed{\mathcal{V}_{n+1}\iota_n = \mathfrak{I}_n\mathcal{V}_n, \qquad \mathcal{B}_{n+1}\mathfrak{I}_n = \mathfrak{I}_n\mathcal{B}_n.} \tag{105.14}$$

Proof. Each component of the first equality is an identity from (105.13), iterated to the corresponding power of T_n. The second equality states that refining every block commutes with shifting the block index, as verified directly. Both maps are bounded, so the equalities pass from finitely supported records to their completion. □

By (105.4) and (105.14), reconstruction of the dynamics also commutes with refinement. The genealogical-depth index n and the successive-compression index j remain distinct. The equality expresses their compatibility when they act through the documented squares, rather than identifying them by name.

105.4 Two exact regimes of memory distribution

For a unit state v with $Pv = 0$, define

$$a_N = \|T^N v\|^2, \qquad b_N = \|\eta T^N v\|^2 = a_N - a_{N+1}. \tag{105.15}$$

One has $a_0 = 1$, $a_N \to 0$, $b_N \geq 0$, and $\sum b_N = 1$. The weights b_N describe the distribution of the memory record across depths. This index counts compressions; identifying it with a physical duration would require application of the corresponding temporal reader.

105.4.1 Exceptional transport of order three

The fixed-point-free orthogonal operator g_c satisfies $g_c^2 + g_c + I = 0$. For the explicit composition $C = g_c$, the preceding development obtained

$$T^*T = \frac{19}{27}I, \qquad a_N = \left(\frac{19}{27}\right)^N, \qquad b_N = \frac{8}{27}\left(\frac{19}{27}\right)^N. \tag{105.16}$$

The mean depth, counting the first record as depth one, is

$$\sum_{N\geq 0}(N+1)b_N = \frac{27}{8}. \tag{105.17}$$

This is a result of that composition of the nonadic chart with the already constructed exceptional transport; it preserves the domain and does not identify g_c with the complete temporal holonomy on the basis of its order.

105.4.2 Bilateral record of revolutions

For $Ce_k = e_{k+1}$ and $v = e_0$, the binomial formula determines every term:

$$T^N e_0 = 9^{-N} \sum_{k=0}^{N} \binom{N}{k} 8^{N-k} e_k, \quad a_N = 81^{-N} \sum_{k=0}^{N} \binom{N}{k}^2 64^{N-k}. \tag{105.18}$$

This formula is exact at any depth. The subsequent circular representation gives

$$a_N = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left(\frac{65 + 16\cos\theta}{81} \right)^N \, d\theta. \tag{105.19}$$

Theorem 105.4. *In this bilateral realization,*

$$\boxed{a_N \sim \frac{9}{4\sqrt{2\pi}} N^{-1/2}, \qquad b_N \sim \frac{9}{8\sqrt{2\pi}} N^{-3/2}.} \tag{105.20}$$

Proof. Write $r(\theta) = (65 + 16\cos\theta)/81$ and $q = 8/81$. Near zero,

$$r(\theta) = 1 - q\theta^2 + O(\theta^4), \qquad \log r(\theta) = -q\theta^2 + O(\theta^4).$$

For a sufficiently small fixed neighbourhood, positive constants c_1, c_2 bound $-\log r(\theta)$ between $c_1\theta^2$ and $c_2\theta^2$. Outside this neighbourhood, $r \le \rho < 1$. The substitution $x = \sqrt{N}\theta$, the Gaussian bound, and dominated convergence give

$$\lim_{N\to\infty} \sqrt{N}\, a_N = \frac{1}{2\pi} \int_{\mathbb{R}} e^{-qx^2} \, dx = \frac{1}{2\sqrt{\pi q}} = \frac{9}{4\sqrt{2\pi}}.$$

For the second limit, apply the same procedure directly to

$$b_N = \frac{1}{2\pi} \int_{-\pi}^{\pi} r(\theta)^N (1 - r(\theta)) \, d\theta.$$

In the variable x, $N(1 - r(x/\sqrt{N})) \to qx^2$, locally dominated by a constant times x^2; outside the neighbourhood, the contribution is exponentially small even after multiplication by $N^{3/2}$. Therefore,

$$\lim_{N\to\infty} N^{3/2} b_N = \frac{q}{2\pi} \int_{\mathbb{R}} x^2 e^{-qx^2} \, dx = \frac{1}{4\sqrt{\pi q}} = \frac{9}{8\sqrt{2\pi}}.$$

This proof of the second limit uses its own integral, without differentiating an uncontrolled asymptotic equivalence. □

By Tonelli's theorem and the tail-sum identity for a positive sequence,

$$\sum_{N\ge 0} (N+1) b_N = \sum_{N\ge 0} a_N = +\infty. \tag{105.21}$$

The entire norm is preserved in memory, but its mean depth diverges for this bilateral state. The distribution law depends on the effective transport representation: the exceptional sector of order three has a geometric rate, whereas the bilateral record considered here has an algebraic rate.

105.5 Composition with Euler's identity and incidence

The extended Euler identity of Section 10.47 realizes the three regimes through the Coxeter element of A_2, a nilpotent transport and F_{av}^2, with their declared antecedents. Their normalized generators satisfy $J_\tau^2 = -\tau I$ and have trace zero. In their two-dimensional charts,

$$C_\tau(t) = \exp(tJ_\tau), \qquad \Omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad C_\tau(t)^{\mathsf{T}} \Omega C_\tau(t) = \Omega.$$

Zero trace gives $\det C_\tau(t) = 1$, and the two-dimensional identity $M^{\mathsf{T}} \Omega M = (\det M)\Omega$ proves the final equality. For

$$T_\tau = \frac{8I + C_\tau}{9}, \qquad D_\tau = \frac{\sqrt{8}}{9}(C_\tau - I),$$

one obtains a common oriented conservation law:

$$\boxed{\Omega = T_\tau^{\mathsf{T}} \Omega T_\tau + D_\tau^{\mathsf{T}} \Omega D_\tau.} \tag{105.22}$$

Proof. Expanding the two terms, the cross contributions of C_τ have opposite coefficients. The remaining terms are $72\Omega/81 + 9C_\tau^{\mathsf{T}} \Omega C_\tau/81 = \Omega$. □

This alternating form corresponds to oriented area in the canonical plane. Its preservation permits comparison of the three regimes while respecting their differences. For the concrete representatives given by the Coxeter operator C, $I + N$, and F_{av}^2, respectively,

$$(\det T, \det D) = \left(\frac{19}{27}, \frac{8}{27}\right), \qquad (1, 0), \qquad \left(\frac{89}{81}, -\frac{8}{81}\right). \tag{105.23}$$

The sum is one in all three cases. In the parabolic case, D has rank one and may preserve information although its area is zero. In the hyperbolic case, the complement has the opposite orientation; the balance concerns signed area. Theorem 105.1 uses a unitary, positive realization: the hypotheses of each result are expressly retained.

The development of action and variable form proves the version between different charts, its integration over closed curves and its compatibility with refinement. The incidence development composes reconstruction with $F(k) = (\mu(k), \mathcal{I} P_0 k/6)$, retaining the twelve coordinates of K; it also transports the operators and their local frames. Thus, the same conservation identity admits typed realizations of norm, incidence and oriented action.

Chapter 106

Exceptional incidence and transport of forms

106.1 Generation of the record and conservation of incidence

106.1.1 Dodecaphasic record of the enriched history

Section 11.4.2 defines

$$\mathcal{R}_{12}(x) = ((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m))_{m=1}^{12}.$$

It preserves the window, subpath, orientation, carry, and incidence ledger. Section 11.4.6 fixes

$$x_{\mathrm{term}} = (\mathcal{U}_{108} \cdots \mathcal{U}_1) x_{\mathrm{seed}}, \quad \mathcal{U}_t = \mathsf{Upd}_t \mathsf{Tra}_t \mathsf{Sel}_t,$$

$$R_{\mathrm{sgn}} = \Pi_H \mathcal{E}_{108}^{90,120} \mathcal{R}_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,mem}} \to \mathbb{Z}^{12}.$$

The following algebraic reconstruction begins with this typed output. It does not replace evaluation of the preceding events or obtain their coordinates by imposing K or alpha as a target.

106.1.2 Integral normalization and isometric normalizations

For the step-three orbits $(1, 4, 7, 10)$, $(2, 5, 8, 11)$, $(3, 6, 9, 12)$, Lemma 11.39 fixes the symmetric matrix $H = H_{12}$ and proves $H^2 = 4I$.

$$\mathcal{L}_H = \{u \in \mathbb{Z}^{12} : Hu \equiv 0 \pmod 4\}, \qquad \mathscr{K}(u) = \tfrac{1}{4} Hu, \qquad \mathscr{K}^{-1}(k) = Hk.$$

This is an integral isomorphism between the sublattice of signed records and $\mathbb{Z}^{12}$. The factor $1/4$ implements inversion, not a Euclidean isometry.

As an immediate consequence of the same identity, $J_H = H/2$ satisfies $J_H^* J_H = I$: this is the real isometric transport. If $u = Hk$, then $u/2 = J_H k$ and $\|u\|^2 = 4\|k\|^2$. Confusing $H/4$ with $H/2$ would change the balance by a factor of four.

In section 21.11.4 y proposition 21.60, the constructed design determines

$$I : \mathbb{R}^{12} \to \mathbb{R}^{132}, \qquad (Iv)(H') = \sum_{p \in H'} v_p, \qquad I^* I = 36 I_{12} + 30 J_{12}.$$

The coefficients arise from the incidences: each point belongs to 66 hexads, and each pair to 30. On $V = \mathbf{1}^{\perp}$, the term J_{12} vanishes, so $U_W = I/6 : V \to E_{\mathrm{inc}}$ is an isometry. The factor $1/6$ normalizes this screen; it is not the inverse map for K.

106.1.3 Prefix refinement and event partitions

Section 21.11.1 constructs causal frames $f_{j+1} = g_j(x) f_j$ and prefix encodings Q_n. It proves

$$r_{n,m} Q_n = Q_m p_{n,m}, \qquad \gamma_{A^f}(w f^{-1}) = \gamma_A(w)(f^{-1} \oplus f^{-1}).$$

The proof uses the fact that a prolongation preserves preceding words, transports, and frames. The inverse limit produces Q_∞. Recovery of the visible word follows from the first component of γ; the text expressly distinguishes this scope from recovery of all deep memory and passage to supports.

The additive and affine composition of the record, described in section 11.4.2 y proposition 6.22, proves a second conservation property: with compatible prospective contributions $(\delta w_t, \delta q_t)$, record

inversion is additive. Concatenating segments or subdividing the same list of events gives the same final record. The version with nontrivial transport uses the affine cocycle. Preserving the total under a change of partition does not assert that the record stops growing when new events are added.

106.2 K–Witt transport of norms, operators, and balances

A formalization of the recovered results is assembled here, together with the algebraic proof below. This assembly attributes no new priority to its starting identities.

Let $P_0 = I - J_{12}/12$, $V = P_0\mathbb{R}^{12}$, $W_H = J_H V$, and

$$B := U_W J_H|_{W_H} : W_H \longrightarrow E_{\mathrm{inc}}.$$

Since $J_H^2 = I$, this is an isometric isomorphism between eleven-dimensional spaces. For a record k, its normalized signed coordinate is $J_H k$. If $\widehat{P}_0 = J_H P_0 J_H$,

$$B\widehat{P}_0(J_H k) = U_W P_0 k,$$

$$\|\widehat{P}_0(J_H k)\|^2 = \|U_W P_0 k\|^2 = \sum_{p=1}^{12} k_p^2 - \frac{(\sum_p k_p)^2}{12}.$$

No constant value has been introduced to obtain this equality: it follows from H^2 and the incidence Gramian. The removed mean must be retained separately to recover the whole of k.

For $g \in \mathrm{Aut}(\mathcal{H})$, let $\rho_{12}(g)$ be its point permutation and $\rho_{\mathrm{hex}}(g)$ its hexad permutation. The action on signed coordinates is

$$\widehat{\rho}_H(g) = J_H \rho_{12}(g) J_H = \tfrac{1}{4} H \rho_{12}(g) H.$$

It is orthogonal, preserves W_H, and also preserves the sublattice $\mathcal{L}_H$: if $u = Hk$, its image is $H\rho_{12}(g)k$. The explicit intertwining in section 21.11.4 gives

$$B\widehat{\rho}_H(g) = \rho_{\mathrm{hex}}(g) B.$$

Proof. Substitute the definitions, cancel J_H^2, and apply $U_W \rho_{12}(g) = \rho_{\mathrm{hex}}(g) U_W$. The integral record, centred inner product, and incidence action are thus preserved, each on its own domain. □

For an operator A already constructed on W_H, one obtains $A_{\mathrm{inc}} = BAB^*$. By substitution,

$$BA = A_{\mathrm{inc}} B, \quad \langle z, Az\rangle = \langle Bz, A_{\mathrm{inc}} Bz\rangle.$$

Therefore, if a transport C on W_H preserves A, $C^*AC = A$, its transport $C_{\mathrm{inc}} = BCB^*$ preserves A_{inc}. The condition that a particular C be a publication of TPK dynamics remains in the causal composition producing it. Isometry does not by itself transform an incidence permutation into the nonadic cycle.

Commutation need not be imposed to compare transported charts. If R is unitary, $C' = RCR^*$ and $T(C) = (8I + C)/9$, then $T(C')R = RT(C)$ by substitution. Together with $A' = RAR^*$, the balance in one chart is conjugated to that in the other. Commutation $[R, C] = 0$ corresponds only to the additional problem of keeping that same seam C fixed. This distinction agrees with the lattice naturality of Section 106.3.

One available concrete finite action is the star selected by the flag:

$$\sigma_{B_K} = (1\ 3)(2\ 11)(5\ 7)(8\ 12).$$

Section 21.11.6 proves its construction and distinguishes it from the group generated by the 495 stars. The individual star gives C_2; the family gives M_{12}. Transporting the marking and origin gives covariance between frames. If a symmetry of a fixed frame is sought, the appropriate domain is its stabilizer, not automatically all of M_{12}. If it must additionally commute with C, the subgroup satisfying the specific equation $[\widehat{\rho}_H(g), C] = 0$ is used.

106.3 Order-three action on the lattice fibres

The construction in sections 21.11.11 y 21.11.12 produces twelve A_2 fibres labelled by $(i, \mu, \varepsilon) \in \mathbb{Z}/3\mathbb{Z} \times \{0,1\} \times \{0,1\}$. The alignment $\lambda(i,\mu,\varepsilon) = 4i + 2\mu + \varepsilon \pmod{12}$ is bijective. If C_{A_2} is the Coxeter operator and R the reflection satisfying $RC_{A_2}R = C_{A_2}^{-1}$, the trivializations and transported frames fix

$$g_b = \iota_b^{-1} P_b C_{A_2} P_b^{-1} \iota_b, \quad T_{i\mu\varepsilon} = \iota_{\lambda(i,\mu,\varepsilon)}^{-1} P_{\lambda(i,\mu,\varepsilon)} R^{\mu},$$

$$g_\lambda T_{i\mu\varepsilon} = T_{i\mu\varepsilon} C_{A_2}^{(-1)^{\mu}}.$$

The direct sum $T_\lambda : W_{\mathrm{APP}} \otimes \mathbb{C} \to \bigoplus_{b=1}^{12} (A_{2,b} \otimes \mathbb{C})$ is a C_3-equivariant isomorphism. The proof consists of conjugation and the bijection of the twelve labels: it preserves pair, sheet, and orbit. It is not a coincidence of dimensions.

The constructions in equation (21.147) y proposition 21.73 use $q^\star = (1,1,1,1,1,1)$ and its full-support word $c^\star = (q^\star, q^\star A_W)$ to orient the twelve blocks. The resulting g_c has order three, has no nonzero fixed vectors, and preserves the Niemeier gluing. For the incidence vector v of squared norm 54,

$$N_0 = \ker(\langle \cdot, v \rangle \bmod 3), \qquad N_v = N_0 + \mathbb{Z}\frac{v}{3},$$

$$y_* = (g_c v - v)/3 \in N_0, \qquad z_* = (g_c^{-1} v - v)/3 \in N_0.$$

The proof identifies their discriminant classes as $c^\star$ and $-c^\star$, and their pairings with v as -27. Hence $g_c N_0 = N_0$ and $g_c(v/3) = v/3 + y_*$, giving $g_c N_v = N_v$. The preserved structure includes the gluing, congruence kernel, and class generating the Leech neighbour.

Prolongation to the 24 full-support orientations and the lattice lift of a monomial code automorphism h are developed in Section 21.11.19. With all marks transported,

$$g_{hu} = \widetilde{h}\, g_u\, \widetilde{h}^{-1}.$$

This C_3 is an admissible group genuinely intertwined with the APP fibres and exceptional structure. It is not identified here with C_9 or its quotient by a mere relation of orders. Nor is the lattice lift replaced by the ternary matrix without its action on the A_2 fibres.

106.4 Refinement of energy and its differential

The energy operator of (128.1) has the form $D_{9,m}^{*} W_m D_{9,m}$, with U_a transporting orientation and carry. The domains in section 128.1 are

$$\mathcal{H}_m = \bigoplus_{v} H_v, \quad \mathcal{K}_m = \bigoplus_{a \in \mathcal{E}_m^{+}} H_{t(a)}, \quad (D_m f)_a = f_{t(a)} - U_a f_{s(a)}, \quad E_m = \langle D_m f, \mathsf{W}_m D_m f \rangle.$$

The fixed maps J_m and K_m satisfy, for the family C^1 considered,

$$D_{m+1}(t)J_m = K_m D_m(t), \qquad K_m^{*}\mathsf{W}_{m+1}(t)K_m = \mathsf{W}_m(t).$$

The result in theorem 128.5 proves $E_{m+1}(J_m f) = E_m(f)$ by substitution, and equality of differentials follows by differentiating both identities. For parameter-dependent refinement, the term $D_{m+1}\dot{J}_m f$ is also retained.

With $v_a = U_a f_s$ and $q = \mathsf{W}_m D_m f$, the response to $\dot{U}_a = A_a U_a$ is

$$\mathfrak{j}_m(A) = -2\,\mathrm{Re}\sum_a \langle q_a, A_a v_a\rangle, \quad \mathcal{J}_a = v_a q_a^{*} - q_a v_a^{*}.$$

The transport product $U_\gamma = U_N \cdots U_1$ satisfies

$$\dot{U}_\gamma U_\gamma^{-1} = \sum_{k=1}^{N} B_k A_k B_k^{-1}, \qquad B_k = U_N \cdots U_{k+1}.$$

This formula retains the order of each incidence and transports its covector contragrediently. Corollary 129.5 composes this differential with connection variations and proves, for compatible refinements of the action,

$$s_m = P_m^{\mathsf{T}} s_{m+1}, \qquad M_m \sigma_m = P_m^{\mathsf{T}} M_{m+1}\sigma_{m+1}.$$

Here, P_m carries connection variations, and M_m is the cellular pairing; they are neither the mean-zero projector nor the Hadamard matrix.

106.4.1 Assembly with incidence

In a realization of fibres W_H whose frame actions are $\widehat{\rho}_H(g_a)$, conjugation by B carries every transport, field, and weight to E_{inc}. By the intertwining proved in Section 106.2, the difference operators satisfy $D_{\mathrm{inc}}B_{\mathrm{vertices}} = B_{\mathrm{edges}}D_H$. Transporting J_m, K_m, and W_m as well, the two preceding refinement squares remain the same conjugated squares. By substitution, they preserve energy; for fixed B, they also preserve the differential and covectors.

The balance law and its covectors are transported to the exceptional representation while retaining compatibility with refinement. Each map uses the transports of the specified dynamics and the subspaces they preserve. The variation domain is defined in section 128.1.

Chapter 107

Incidence reconstruction and covariance

107.1 The complete isometry and its domain

Let $H = \mathbb{R}^{12}$, with the Euclidean inner product; let $P_0 = I - \mathbf{1}\mathbf{1}^*/12$, $\mu(k) = \mathbf{1}^* k/12$, and let $\mathcal{I} : H \to \mathbb{R}^{132}$ be the incidence matrix of section 21.11.4 y proposition 21.60. Write $E_{\mathrm{inc}} = \mathcal{I}(\mathbf{1}^{\perp})$ and

$$Y = \mathbb{R} \oplus E_{\mathrm{inc}}, \qquad \langle (\mu, y), (\nu, z) \rangle_Y = 12\mu\nu + \langle y, z \rangle.$$

The complete isometry constructed in Section 104 is

$$F : H \longrightarrow Y, \qquad Fk = (\mu(k), \mathcal{I} P_0 k/6),$$

$$F^{-1}(\mu, y) = \mu \mathbf{1} + P_0 \mathcal{I}^* y/6.$$

The Gram identity $\mathcal{I}^*\mathcal{I} = 36I + 30\mathbf{1}\mathbf{1}^*$ proves both inverse compositions and $F^*F = I_H$, $FF^* = I_Y$, with the indicated weighted inner product. Hence F is orthogonal between H and Y. It can be complexified without changing the proofs.

The codomain is the twelve-dimensional space Y, not the whole of $\mathbb{R} \oplus \mathbb{R}^{132}$. Extending an operator from Y to its complement in that ambient space requires an additional choice; this is not part of the uniquely transported dynamics. In normalized signed coordinates, one uses FJ_H, with $J_H = H_{12}/2$. Integral inversion remains $H_{12}/4$ on its sublattice, rather than an alternative metric normalizer.

107.2 Covariant lifting theorem on the image

Theorem 107.1. *For a bounded operator D on H, there exists a unique operator on Y satisfying $D_Y F = FD$. It is*

$$D_Y = FDF^{-1}.$$

The correspondence preserves sums, products, adjoints, norm, positivity, and identity. In particular, it maps unitaries to unitaries and self-adjoint observables to self-adjoint observables. For a unitary C and an observable A,

$$C^*AC = A \quad \Longleftrightarrow \quad C_Y^* A_Y C_Y = A_Y.$$

If R is a unitary chart change, $R_Y = FRF^{-1}$, then

$$F(RDR^{-1})F^{-1} = R_Y D_Y R_Y^{-1}.$$

Proof. The first formula follows by multiplying the intertwining relation by F^{-1}. Uniqueness follows from surjectivity onto Y. The product and adjoint identities follow from $F^{-1} = F^*$, and equality of norms follows from the surjective isometry. The final equality is an associative composition of these maps. No commutation hypothesis between R and D enters. □

For $g \in \mathrm{Aut}(\mathcal{H})$, Proposition 21.60 supplies

$$F\rho_{12}(g) = \big(1 \oplus \rho_{\mathrm{hex}}(g)\big)F.$$

Thus, the chart change has a specific combinatorial action on the hexads. By contrast, for a general unitary D, D_Y is an operator of the incidence representation, not necessarily a permutation of the design. Preserving the inner product of that representation does not turn all its unitaries into combinatorial automorphisms or elements of the Monster.

107.2.1 Covariance under a noncommuting chart change

Let C be the cyclic advance $Ce_p = e_{p+1}$ on the twelve positions, that is, the reverse direction of convention S in section 11.4. It is an operation of the window chart, not the complete temporal holonomy. Let R be the already constructed star

$$R = (1\ 3)(2\ 11)(5\ 7)(8\ 12).$$

Then $RCe_1 = e_{11}$, whereas $CRe_1 = e_4$. They do not commute. Nevertheless, for $C' = RCR^{-1}$, $T(C')R = RT(C)$ and $\eta(C')R = R^{\oplus 9}\eta(C)$ hold exactly, and likewise in Y through F. Chart covariance does work in an example where commutation in a fixed chart fails.

107.3 Explicit recovery from the incidence record of complements

Let C be unitary, $T = (8I + C)/9$, $\eta = (I - JJ^*)S_C J : H \to H^9$, and let P be the projection onto $\mathrm{Fix}(C)$, as in Section 104. Write $F_9 = F^{\oplus 9}$. The incidence version of the finite record is

$$\mathcal{W}_N k = \left(FT^N k, F_9\eta k, F_9\eta T k, \dots, F_9\eta T^{N-1}k\right).$$

Theorem 107.2. *This map is isometric and has the explicit left inverse*

$$\mathcal{W}_N^*(a, b_0, \dots, b_{N-1}) = T^{*N}F^{-1}a + \sum_{j=0}^{N-1} T^{*j}\eta^* F_9^{-1} b_j.$$

In particular, applying this formula to $\mathcal{W}_N k$ recovers k exactly. The infinite record

$$\mathcal{W}_\infty k = \left(FPk, (F_9\eta T^j k)_{j\ge 0}\right)$$

is also isometric, and its left inverse is

$$k = PF^{-1}a + \sum_{j\ge 0} T^{*j}\eta^* F_9^{-1} b_j \quad \text{for } (a, (b_j)) = \mathcal{W}_\infty k.$$

The series converges in norm. For arbitrary square-summable data, the same formula defines the bounded adjoint, although not every datum in the codomain belongs to the image of $\mathcal{W}_\infty$.

Proof. Applying F and F_9 to each component of V_N or V_∞ preserves the inner product. Taking the adjoint of this composition gives the formulas. The telescopic identity in Section 104 proves $\mathcal{W}_N^*\mathcal{W}_N = I$, and its strong limit proves $\mathcal{W}_\infty^*\mathcal{W}_\infty = I$. Convergence of the series follows by applying a bounded operator to truncations of a sequence in a Hilbert direct sum. □

This reconstruction does not preserve k as an intact first coordinate: the first component is the compressed terminal component or its fixed sector; the rest arises from successive complements. When $P = 0$, the incidence complements alone recover k. The contribution recovered from the first N blocks is

$$k_N = \sum_{j<N} T^{*j}\eta^* F_9^{-1} b_j = \left(I - T^{*N}T^N\right)k.$$

The remainder is $T^{*N}T^N k$, which tends to zero if $P = 0$. With a nonzero fixed sector, FPk must be retained; complement memory alone does not recover that sector. Reconstruction rates and dynamics on the block index are developed in Section 105.

If A is self-adjoint and $[A, C] = 0$, the observable form is also preserved:

$$\langle k, Ak\rangle = \langle FPk, A_Y FPk\rangle_Y + \sum_{j\ge 0}\langle F_9\eta T^j k, (I_9 \otimes A_Y)F_9\eta T^j k\rangle.$$

The scalar series converges absolutely because A is bounded and the sum of the squared norms of the components is finite. The hypothesis expresses preservation of A by C; it does not require C to commute with exceptional chart changes.

107.4 Natural lifting of refinement with local frames

The construction in sections 6.4.1 y 6.4.2 supplies sets Z_n of enriched cylindrical states, truncations, and projective measures with full support. For a descendant z' of z,

$$w_n(z'|z) = \sqrt{\mu_{n+1}(z')/\mu_n(z)}, \qquad \sum_{\tau z'=z} w_n(z'|z)^2 = 1.$$

The label z' preserves the ordered record, orientation, carry, boundary, memory, path, and terminal component. Refinement of a state does not identify distinct descendants.

Let $q(z)$ be the integer memory record, C a unitary on H, and R_z orthogonal changes of the fibre frame. For concrete incidence frames, one may use $R_z = \rho_{12}(g_z)$, with $g_z \in \mathrm{Aut}(\mathcal{H})$, transporting their marks. Define

$$G_z = R_z C^{q(z)}, \qquad U_{z',z} = G_{z'} G_z^* = R_{z'} C^{q(z')-q(z)} R_z^*.$$

This construction prolongs the explicit gauge equivalence of section 21.11.1. It does not require $[R_z, C] = 0$ and keeps the order of operations explicit.

On $\mathscr{H}_n = \ell^2(Z_n) \otimes H$,

$$\mathcal{U}_n(e_z \otimes v) = \sum_{\tau z'=z} w_n(z'|z) e_{z'} \otimes U_{z',z} v.$$

Define $\mathscr{F}_n = I_{\ell^2(Z_n)} \otimes F$, with codomain $\mathscr{Y}_n = \ell^2(Z_n) \otimes Y$.

Theorem 107.3. *The refinement is isometric and satisfies*

$$\mathcal{U}_n^Y \mathscr{F}_n = \mathscr{F}_{n+1}\mathcal{U}_n, \quad \mathcal{U}_n^Y = \mathscr{F}_{n+1}\mathcal{U}_n\mathscr{F}_n^{-1}.$$

The formula for each term is the preceding one with $U^Y_{z',z} = FU_{z',z}F^{-1}$. Systems at several depths preserve composition and admit a surjective isometry between their inductive limits. All fibre coefficients are preserved exactly with their labels z.

Proof. Descendants of distinct parents are orthogonal; each $U_{z',z}$ is unitary; and the weights have squared sum one. This proves isometry. Along a trajectory, the intermediate factors $G_z^* G_z$ cancel and the measure ratios telescope. The composition does not depend on the partition of the trajectory. The square with F is verified on $e_z \otimes v$, term by term. The maps and their inverses are compatible isometries, so they extend inversely to the inductive completions. □

107.4.1 Compatible observables and dynamics

If A_0 is a bounded fibre observable, let

$$(\mathscr{A}_n\psi)_z = G_z A_0 G_z^* \psi_z.$$

Then $\mathscr{A}_{n+1}\mathscr{U}_n = \mathscr{U}_n\mathscr{A}_n$, whence $\mathscr{U}_n^*\mathscr{A}_{n+1}\mathscr{U}_n = \mathscr{A}_n$. This is obtained by substituting $U_{z',z} = G_{z'}G_z^*$. This is conservation of a field of observables transported by refinement; it does not assert that A_0 commutes with C in a fixed chart.

The unitary dynamics at each level,

$$(\mathscr{C}_n\psi)_z = G_z C G_z^* \psi_z$$

satisfies $\mathscr{C}_{n+1}\mathscr{U}_n = \mathscr{U}_n\mathscr{C}_n$. Their adjoints are also intertwined: since both $\mathscr{C}$ are unitary, multiply the identity by their inverses. Thus, T, its nonadic complements, and its fixed projections are intertwined. The finite and infinite records of Section 107.3 are natural with respect to this refinement. Upon applying $\mathscr{F}_n$, the same squares hold in the incidence fibres. For $\mathscr{A}_n$ also to be conserved by these dynamics at a fixed level, the precise condition is $[A_0, C] = 0$; covariance between frames still does not require $[R_z, C] = 0$.

107.4.2 Bilateral-memory specialization with varying frames

In the reversible orbit of chapter 105, a coordinate publication can be represented by $\psi = (\psi_m)_{m\in\mathbb{Z}} \in \ell^2(\mathbb{Z}; H)$. Its advance is $(C_0\psi)_m = \psi_{m-1}$. F acts pointwise. For frames $R_m = \rho_{12}(g_m)$, the unitary change $(\mathscr{R}\psi)_m = R_m\psi_m$ produces

$$(C'\psi)_m = R_m R_{m-1}^* \psi_{m-1}.$$

The incidence operator has the same formula with $1 \oplus \rho_{\mathrm{hex}}(g_m g_{m-1}^{-1})$. Neither constant frames nor commutation with the shift is imposed. Since C' is conjugate to C_0, it has no nonzero fixed vectors in this square-summable space. Section 107.3 recovers the complete linear publication from its incidence complements. This concerns the orbit and represented coordinates: not an identification of all TPK histories with $\mathbb{Z}$.

107.5 Direct extension to the twelve A_2 fibres

The exceptional construction preserves twelve A_2 fibres and the order-three operator g_c developed in Section 106.3. Let $V_{A_2} = A_2 \otimes_{\mathbb{Z}} \mathbb{R}$ be their two-dimensional Euclidean realization. The same positional isometry can be tensored over $\mathbb{R}$ with this space:

$$F_{A_2} = F \otimes I_{V_{A_2}} : \mathbb{R}^{12} \otimes_{\mathbb{R}} V_{A_2} \longrightarrow Y \otimes_{\mathbb{R}} V_{A_2}.$$

Its first component is the vector mean, and its second consists of the centred incidence sums, now valued in V_{A_2}. The incidence Gram operator, tensored with the identity, again proves the complete isometry and inverse. Hence $g_c^Y = F_{A_2} g_c F_{A_2}^{-1}$ is orthogonal, of order three, and fixed-point-free. The nonadic composition of Section 104 can be read out and recovered on this V_{A_2}-valued screen through Sections 107.2 and 107.3. The twelve scalars of K are not confused with the twenty-four coordinates of the A_2 fibres, nor is the action turned into a hexad permutation when the lift also acts within the fibres.

107.6 Exact scope with respect to histories

Let $k : X \to H$ be the record reader on a history domain, and let $\ell = F \circ k$. Then

$$\ell(x) = \ell(y) \quad \Longleftrightarrow \quad k(x) = k(y).$$

The complete screen adds zero loss relative to K, but it does not change the fibres of this reader. A map $d : X \to X$ descends to dynamics on the values of K if and only if

$$k(x) = k(y) \Longrightarrow k(dx) = k(dy).$$

The same condition is necessary and sufficient for descent to the incidence image. The proof consists of defining $D(k(x)) = k(dx)$; the condition is equivalent to independence of the representative. If this D is linear and unitary in the stated realization, Section 107.2 applies. If it is nonlinear, F still conjugates it as a map but does not make it unitary.

The criterion distinguishes descent to K from the enriched dynamics. Section 11.4.6 establishes that the reader uses subpath, orientation, carry, and incidences; Section 21.55 distinguishes recovery of the visible word, support, and deep memory. On $\ell^2(Z_n) \otimes H$, Section 107.4 preserves enriched labels and transports the fibre representation. The equivalence acts on the previously generated history domain.

For an already constructed cut, naturality of the record in proposition 11.31 fixes $K_N = K_{108} \circ \tau_{N,108}$: F preserves this naturality exactly. A sequence of new events may update K; the additive or affine composition in section 11.4 preserves independence of partition, not constancy of the value when events are added.

Chapter 108

Affine holonomy and memory symmetries

108.1 Effective composition of memory

For an admissible emission ϵ, the construction in proposition 6.22 defines

$$\mathsf{U}_\epsilon(m) = C_\epsilon m + \kappa_\epsilon, \qquad \kappa_{\epsilon_2\epsilon_1} = \kappa_{\epsilon_2} + C_{\epsilon_2}\kappa_{\epsilon_1}. \tag{108.1}$$

The domain is the memory module at the source; the codomain is that of the next emission. The product preserves order. On a path γ of length r, one obtains

$$C_\gamma = C_r \cdots C_1, \qquad \kappa_\gamma = \sum_{j=1}^{r} C_r \cdots C_{j+1}\kappa_j, \qquad m_\gamma = C_\gamma m_0 + \kappa_\gamma. \tag{108.2}$$

The empty product in the sum is the identity. The proof is induction using (108.1): appending the next emission multiplies the preceding record by its linear transport and adds its increment. The positional boundary may cancel while the transported sum in (108.2) remains.

Proposition 108.1 (Memory class of a return)**.** *Let M be an abelian module, and consider a path closed in the base whose memory transport is $H(m) = Cm + \kappa$, with C an automorphism of M. Its return class is*

$$\mathfrak{m}(H) = [\kappa] \in M/(I - C)M. \tag{108.3}$$

A memory-coordinate change $m' = Rm + b$, with R invertible, transforms the return into

$$C' = RCR^{-1}, \qquad \kappa' = R\kappa + (I - C')b. \tag{108.4}$$

The map induced by R takes $[\kappa]$ to $[\kappa']$. The transport H has a fixed point exactly when its class (108.3) is zero.

Proof. Substituting $m = R^{-1}(m' - b)$ into H gives (108.4). Since $R(I - C) = (I - C')R$, the map R induces an isomorphism between the quotients. The term $(I - C')b$ represents zero in the target quotient. Finally, the fixed-point equation $Cm + \kappa = m$ is equivalent to $(I - C)m = \kappa$. This proves the final assertion. □

Formula (108.3) determines whether a change of origin removes the increment or merely redistributes it among coordinates. In particular, when $C = I$, the class is the vector κ itself. A nonzero translation remains nonzero under every invertible affine change.

Proposition 108.2 (Return symmetry versus a change of representation)**.** *An affine transformation $A(m) = Rm + b$ commutes with H exactly when*

$$RC = CR, \qquad (I - C)b = (I - R)\kappa. \tag{108.5}$$

Proof. The linear parts of AH and HA are RC and CR; their constant parts are $R\kappa + b$ and $Cb + \kappa$. Equating them gives (108.5). If H is merely transported through (108.4), commutation is not required: the same law is obtained in another representation. By contrast, a symmetry of the fixed return requires both equalities in (108.5). □

This precisely distinguishes covariance of the law from the stabilizer of a specific memory. The distinction is relevant to studying variations in state symmetry without modifying the composition laws.

108.2 Application to the effective record of the observable revolution

Section 125 defines two ordered counters: g counts orientation reversals, and s counts effective sheet changes. Their canonical count per 27-step block is

$$c_{27} = (1, 18).$$

The complete observable phase returns after four such blocks. In the path groupoid, the record module is $M = \mathbb{Z}^2$, and

$$c_{108} = (4, 72) = 4v, \qquad v = (1, 18), \qquad H(g, s) = (g + 4, s + 72). \tag{108.6}$$

Identity (108.6) is a corpus result used here; the verifier checks its consequences rather than recounting the original emissions. The symbol c_{108} denotes this two-counter increment. It differs from the dodecaphasic seal K and from the central cocycle of the Heisenberg representation.

Theorem 108.3 (Complete record invariants under full revolutions)**.** *The orbits of H and its inverse on $\mathbb{Z}^2$ are classified exactly by*

$$\boxed{\mathcal{I}(g, s) = s - 18g, \qquad \nu(g, s) = [g]_4.} \tag{108.7}$$

Consequently,

$$\mathbb{Z}^2/\mathbb{Z}(4, 72) \cong \mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}. \tag{108.8}$$

Proof. Adding $(4, 72)$ preserves both expressions in (108.7). If two records have the same invariants, then $g' - g = 4N$ for an integer N, and $s' - s = 18(g' - g) = 72N$; thus they differ by exactly $N(4, 72)$. The map in (108.7) is surjective: given an integer j and r modulo four, choose a representative g of r and set $s = j + 18g$. This proves (108.8). □

The description covers every orbit of this memory reader. Orbits of the complete enriched state additionally preserve their remaining coordinates. For a forward-directed prolongation, a later record is obtained when the preceding integer N is nonnegative; the bilateral equivalence in (108.8) belongs to the groupoid.

The quantity $\mathcal{I}$ is the unique primitive integer linear charge, up to sign, invariant under these translations. Indeed, for $L(g, s) = ag + bs$, invariance requires $4a + 72b = 0$, so $(a, b) = b(-18, 1)$. A revolution accumulates longitudinal memory and preserves a transverse relation determined by the increment.

The factor four has a precise origin here: it is $\gcd(4, 72)$ and, in the preceding count, the number of 27-step blocks completing the observable return. The class ν preserves the information lost when the increment is divided by four and only the primitive direction v is retained.

Corollary 108.4 (Joint block and phase record)**.** *Write the phase of these four blocks as $a \in \mathbb{Z}/4\mathbb{Z}$. The update*

$$(a, g, s) \longmapsto (a + 1, g + 1, s + 18)$$

preserves $(s - 18g, [g - a]_4)$. Both data classify its bilateral orbits: the difference $N = g' - g$ simultaneously satisfies $a' - a = [N]_4$ and $s' - s = 18N$. This brings together memory advance and phase return without replacing either by the other.

108.3 Parabolic generator determined by memory

The ordered pair of counters equips the module M with the unimodular alternating form

$$\Omega_M((g,s),(g',s')) = gs' - sg'.$$

Its domain is the record module. This form is not identified with a dimensional physical area or with the form on the APP torus, whose domain differs. The choice of order (g,s) fixes its orientation.

Theorem 108.5 (Unimodular stabilizer of the increment)**.** *Define, directly from the primitive vector v in (108.6),*

$$N_v m = v\,\Omega_M(v,m) = v\mathcal{I}(m), \qquad N_v = \begin{pmatrix} -18 & 1 \\ -324 & 18 \end{pmatrix}. \tag{108.9}$$

Then $N_v^2 = 0$, $N_v \neq 0$, and

$$\boxed{\mathrm{Stab}_{SL_2(\mathbb{Z})}(c_{108}) = \{I + nN_v : n \in \mathbb{Z}\}.} \tag{108.10}$$

Every transformation in (108.10) preserves Ω_M, the increment c_{108}, and the charge $\mathcal{I}$. For nonzero n, it is a nonidentity unipotent matrix of trace two, of parabolic type.

Proof. The identity $\Omega_M(v,v) = 0$ implies $N_v^2 m = v\Omega_M(v,v)\Omega_M(v,m) = 0$. Its upper-right entry is one, so it is nonzero. The matrix

$$B = \begin{pmatrix} 1 & 0 \\ 18 & 1 \end{pmatrix}$$

has determinant one, maps the first basis vector to v, and satisfies

$$N_v = BNB^{-1}, \qquad N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}. \tag{108.11}$$

An integer automorphism fixes $4v$ exactly when it fixes v, because M is torsion-free. A determinant-one matrix fixing the first basis vector necessarily has the form $\begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}$. Conjugation by B proves (108.10). The rest follows from this expression or directly from (108.9). □

Formula (108.9) makes the construction independent of the second vector chosen to complete v to an oriented unimodular basis: any other complement differs by an integer multiple of v and produces the same N_v. Under an oriented transformation $R \in SL_2(\mathbb{Z})$, one has $N_{Rv} = RN_vR^{-1}$.

The action can be written particularly clearly as

$$(I + nN_v)m = m + n\mathcal{I}(m)v. \tag{108.12}$$

The transverse charge determines how far this symmetry shifts along the memory direction. Summing revolutions produces the displacement $4Nv$; stabilizing symmetries preserve this advance law.

On the quotient (108.8), the transformation $I + nN_v$ acts as $(\mathcal{I}, [g]_4) \mapsto (\mathcal{I}, [g + n\mathcal{I}]_4)$. It therefore preserves the family of orbits and may permute its residue classes; ν is an invariant of the return H, not of every stabilizing transformation. This difference follows directly from (108.12).

Conjugation (108.11) supplies an explicit algebraic map from the parabolic TRIT model, defined in proposition 10.47, to the record module extended to real scalars. One also obtains $\exp(tN_v) = I + tN_v$ and $B\exp(tN) = \exp(tN_v)B$. This intertwining concerns operators: the particular motion selected by

TPK also uses its emissions and calendar. The complete arithmetic group in (108.10) fixes this reader; the admissible symmetry group of the total state is obtained by intersecting it with the actions preserving the remaining data and relations.

In the translated system (108.6), affine changes $m \mapsto Rm + b$, with R in (108.10) and arbitrary b, commute with H. Those additionally preserving the fixed initial record must satisfy $Rm_0 + b = m_0$. Distinguishing the two conditions separates symmetry of the law from symmetry of a marked trajectory.

Theorem 108.6 (Variational realization of the charge and stabilizer)**.** *The scalar extension of the record, $M_{\mathbb{R}} = M \otimes_{\mathbb{Z}} \mathbb{R}$, preserves the generated coordinates (g, s) and the form $\Omega_M = dg \wedge ds$. It is a subsequent realization of the integer module. With the convention $\iota_{X_H}\Omega_M = dH$, one has*

$$X_{\mathcal{I}} = v, \qquad X_{\frac{1}{2}\mathcal{I}^2} = \mathcal{I}v = N_v m. \tag{108.13}$$

Thus, the constructed translation and parabolic family admit explicit Hamiltonian generators. The flow of $\mathcal{I}$ is $m \mapsto m + uv$; at u equal to four it reproduces (108.6). The flow of $\mathcal{I}^2/2$ is $m \mapsto (I + uN_v)m$. The parameter u corresponds to this continuous realization; the discrete return step and intermediate emissions retain their own TPK calendar.

Proof. For a vector $X = (X_g, X_s)$, $\iota_X(dg \wedge ds) = X_g\, ds - X_s\, dg$. Since $d\mathcal{I} = ds - 18\, dg$, the first field is $(1, 18) = v$. The chain rule gives the second. The quantity $\mathcal{I}$ remains constant along both fields because $d\mathcal{I}(v) = 0$. The second flow therefore integrates $dm/du = \mathcal{I}(m_0)v$, equivalent to $\exp(uN_v) = I + uN_v$. Nondegeneracy of Ω_M implies that the Hamiltonian generating N_v is $\mathcal{I}^2/2$ plus an additive constant: its differential is fixed by $\iota_{N_v m}\Omega_M$. □

The mathematical action

$$\mathcal{A}[m] = \int_{u_0}^{u_1} \left[s\frac{dg}{du} - \frac{1}{2}(s - 18g)^2 \right] du \tag{108.14}$$

yields, by variation, the equations $dg/du = \mathcal{I}$, $ds/du = 18\mathcal{I}$. The translation $g \mapsto g + \varepsilon$, $s \mapsto s + 18\varepsilon$ preserves the Hamiltonian and changes the Lagrangian by the total derivative $d(18\varepsilon g)/du$, for constant ε. Its Noether charge is

$$\underbrace{s\,\delta g}_{s} - \underbrace{18g}_{\text{boundary term}} = s - 18g = \mathcal{I}. \tag{108.15}$$

The variation is interpreted per unit of ε. The equations directly verify $d\mathcal{I}/du = 18\mathcal{I} - 18\mathcal{I} = 0$. The discrete translation (108.6) itself is also realized by the Hamiltonian $H_{\mathrm{ret}} = 4\mathcal{I}$, whose flow at parameter one is H; the two Hamiltonians Poisson-commute. The stabilizer flow $I + uN_v$ and the return $m + 4v$ are distinct commuting actions: on the line $\mathcal{I} = 0$, the former fixes every point, while the latter continues to accumulate memory.

More generally, every C^1 Hamiltonian on this plane invariant under translations $m \mapsto m + uv$ has the form $F(\mathcal{I})$. To prove this, the global coordinates $(g, \mathcal{I})$ express the symmetry as translation in g; invariance removes dependence on g from H. Its field is $F'(\mathcal{I})v$. This classification makes explicit both the common conservation law and the additional choice of specific dynamics.

Action (108.14) is dimensionless and belongs to the realized record plane. Its proof supplies an exact variational relation between memory, charge, and stabilizer. Conversion to physical action and dimensional time is performed through the corresponding action and clock readers; these units are not assigned to the counter u.

108.4 APP curvature and conservation of the central phase

Section 4.3.4 works on $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$. The sheets are $S(x, y) = x + y$ and $P(x, y) = xy$. The mixed connections use differences of these potentials, not the potentials themselves as links:

$$F(S, P) = \Delta_x\Delta_y P - \Delta_y\Delta_x S = 1, \qquad F(P, S) = -1 \pmod 9. \tag{108.16}$$

The oriented sum of links around a rectangle is ab or $-ab$, depending on order. The alternating area is $\sigma(u, v) = ad - bc$ for $u = (a, b)$, $v = (c, d)$. Section 23.5.2.1 represents these transports through $D(u) = X^a Z^b$, $ZX = \omega XZ$, with ω the ninth root in the subsequent representation. Then

$$D(u)D(v) = \omega^{bc} D(u + v), \qquad D(u)D(v)D(u)^{-1}D(v)^{-1} = \omega^{-\sigma(u,v)} I. \tag{108.17}$$

The position resulting from the commutator returns. The central phase retains oriented area with the sign fixed in (108.17). This is retention modulo nine: an area divisible by nine has trivial central phase, although a lift with quotient and record may distinguish its paths. The phase does not replace that lift.

Proposition 108.7 (Exact covariance of central transport)**.** *Since two is invertible modulo nine, define*

$$W(a, b) = \omega^{ab/2} D(a, b), \qquad W(u)W(v) = \omega^{-\sigma(u,v)/2} W(u + v). \tag{108.18}$$

For $R \in SL_2(\mathbb{Z}/9\mathbb{Z})$, the map

$$\omega^z W(u) \longmapsto \omega^z W(Ru) \tag{108.19}$$

is an automorphism of the central extension. It preserves its products and commutation phases.

Proof. The phase in the product of the two W is $\frac{ab}{2} + \frac{cd}{2} + bc - \frac{(a+c)(b+d)}{2} = \frac{bc-ad}{2}$. This proves (108.18). The identity $\sigma(Ru, Rv) = \det(R)\sigma(u, v) = \sigma(u, v)$ shows that (108.19) preserves the law; invertibility of R supplies the inverse automorphism. If $\det R = -1$, the corresponding automorphism also changes $z \mapsto -z$; the area sign and centre are reversed jointly. □

The complete record and its central phase have different types. Covariance preserves the area law while the presentation changes; the affine class in (108.3) preserves memory content while its origin changes. Both properties act on typed path readers, and their maps must remain separate when composed with the exceptional readout of the complete state.

Proposition 108.8 (Persistence under local frames and subdivisions)**.** *Let γ be a loop based at x, with invertible links U_ϵ. The local change $U'_\epsilon = G_t U_\epsilon G_s^{-1}$ transforms its holonomy into $H'_\gamma = G_x H_\gamma G_x^{-1}$: frames at interior vertices cancel successively. If $H_\gamma = \omega^k I$, the central phase remains exactly the same. For refined links whose product reproduces the preceding link, subdivision likewise preserves H_γ, by associativity. On APP plaquettes, cancellation of interior edges realizes this property through finite Stokes.*

An elementary rectangle has additive Wilson value one and nontrivial central phase. This mixed transport therefore distinguishes actual holonomy from the identity that links of the form $G_t G_s^{-1}$ would produce. Conservation under subdivision concerns compatible loops and links: adding another area changes the transport.

The integer lift of holonomy distinguishes oriented area from its nonadic remainder: for a rectangle with sides four and seven, $28 = 1 + 9 \cdot 3$, whereas $-28 = 8 + 9(-4)$ corresponds to the reverse orientation. The residual phase coincides for areas one and twenty-eight, while their quotients distinguish the accumulations. This example exhibits the difference between finite phase and complete record; its area quotient and the temporal counter q_{mem} retain distinct domains.

108.5 Composition between the three regimes and continuity of the balance

The realizations in propositions 10.47 y 10.48 construct generators $J_k^2 = -\tau_k I$ on their own fibres, of real dimension two. Take effectively specified links $B_k : V_k \to V_{k+1}$ preserving the alternating forms, $B_k^* \Omega_{k+1} B_k = \Omega_k$. The symbol $*$ in this section means transpose/bilinear pullback. The operators $E_k = \exp(t_k J_k)$ preserve Ω_k: in dimension two, zero trace of the generator implies $J_k^* \Omega_k + \Omega_k J_k = 0$. The symplectic identity is the hypothesis that would be retained in extending the lemma to higher dimensions.

For the nonadic compression and its recorded complement,

$$T_k = B_k(8I + E_k)/9, \qquad D_k = B_k\sqrt{8}(E_k - I)/9,$$

algebraic expansion gives

$$\Omega_k = T_k^* \Omega_{k+1} T_k + D_k^* \Omega_{k+1} D_k. \tag{108.20}$$

Indeed, the cross terms cancel, and the numerator is $72\Omega_k + 9E_k^* \Omega_k E_k = 81\Omega_k$. For $P_0 = I$, $P_{k+1} = T_k P_k$, successive substitution in path order gives

$$\boxed{\Omega_0 = P_N^* \Omega_N P_N + \sum_{k=0}^{N-1} (D_k P_k)^* \Omega_{k+1} (D_k P_k).} \tag{108.21}$$

The terminal component and every complement remain present. The identity is oriented and bilinear; positivity results apply in the positive profiles proved in the preceding sections. The conserved form does not require a link between distinct regimes to intertwine their generators: if $BJ_\tau = J_{\tau'} B$, squaring with invertible B would impose $\tau = \tau'$. Conservation of a common structure allows the three regimes to remain distinct.

The complete transport $U_N = (B_{N-1}E_{N-1}) \cdots (B_0 E_0)$ maps V_0 to V_N. Matrix monodromy requires a typed closure $K : V_N \to V_0$; only then is KU_N an endomorphism whose trace can be computed. Compatible basis changes preserve this trace by conjugation. Phase return, fibre closure, and return of the vector remain different conditions.

If the links have exclusively the form $B_{yx} = G_y G_x^{-1}$, their product along a path is $G_{\text{final}} G_{\text{inicial}}^{-1}$. Closing with the same frame gives the identity. The holonomy in (108.17) and the increment in (108.6) exhibit concrete mechanisms that this mere substitution of frames cannot represent by itself.

108.6 Compatibility with refinement and arbitrary extent

The memory action is compatible with a restriction homomorphism of modules $p : M' \to M$ when

$$pC' = Cp, \qquad p\kappa' = \kappa. \tag{108.22}$$

Then $pH' = Hp$, and p induces a quotient map

$$M'/(I - C')M' \longrightarrow M/(I - C)M, \qquad [\kappa'] \longmapsto [\kappa]. \tag{108.23}$$

Proof. The first equality in (108.22) maps $(I - C')M'$ into $(I - C)M$; the second fixes the image of the increment. Compatibility of H follows by substitution. Concatenations and refinements compose the same squares by virtue of law (108.1). □

A nonzero return class appearing at a preserved level remains nonzero in every compatible lift: a zero class would project to zero. This statement applies to the system of memories and restrictions satisfying (108.22); the joint constructor and the maps of its inverse system are preserved in section 6.4.

In the register of (108.6), for each integer N we have $H^N(m) = m + N(4, 72)$. The proof is algebraic for arbitrary N, not an inference from a finite number of iterations. In forward prolongation, each prefix preserves its finite register; the complete history is described by the compatible family of these registers, without replacing its counters with an "infinite" integer quantity.

If complete dynamics has the reader q_{mem} with $q_{\mathrm{mem}}(\Gamma_9 x) = q_{\mathrm{mem}}(x) + 1$, it likewise cannot have a periodic state of positive period N on that domain: applying the reader would yield $q_{\mathrm{mem}}(x) = q_{\mathrm{mem}}(x)+N$. This corollary uses the complete integer degree; its residual quotients may have finite periods, as appropriate to the observable calendar in the corpus.

108.7 Foundational consequence and scope of the composition

The specific connection obtained is

$$\text{return increment } 4v \;\longrightarrow\; \mathcal{I}(m) = \Omega_M(v, m) \;\longrightarrow\; N_v m = v\mathcal{I}(m) \;\longrightarrow\; I + nN_v. \tag{108.24}$$

The accumulated register determines a conserved charge and a parabolic family stabilizing its direction. Evolution and conservation belong to the same action: g and s change, their relation $s - 18g$ remains, and the increment preserves an explicit stabilizer. This makes precise part of the link between memory and symmetry that motivated the investigation.

Equality (108.21) connects this research with the preceding balances: an evolution may redistribute the form between readout and complements while preserving the total. The APP identities (108.16)–(108.19) show, in another concrete reader of the same origin, how transport order produces a central datum even when position returns.

The charge (108.7) is an algebraic invariant of transport and, through the explicit action (108.14), a Noether charge of the record realization. Theorem 108.6 and its variational development construct this relation, its symmetry, and its boundary term. The preceding physical action and current developments retain their domains and units; transporting them to this realization requires preservation of their dimensional maps.

Composition with dimensional readers must transport the pair (v, Ω_M) and the charge $\mathcal{I}$, preserving their units and the variational current. Every subsequent relation with π, ϕ, e, α and K must arise from this composition; the present formulas specify the information to be preserved.

Chapter 109

Variational conservation and oriented action

109.1 Symmetry of the elliptic action and Noether charge

Fix a positive action section $\hbar$, the angular pair A, C^* in a common unit, $A \neq 0$, $|C^*/A| < 1$, and

$$\eta = \operatorname{artanh}(C^*/A).$$

The realized plane $\mathcal{P}_\eta$ has coordinates (Q, P), both with the dimension of the square root of action, with

$$\lambda = P\,dQ, \qquad \Omega = dQ \wedge dP = -d\lambda.$$

The construction in section 24.3 gives

$$\mathcal{I}_\eta(Q,P) = \frac{1}{2}(e^{-\eta}Q^2 + e^{\eta}P^2), \qquad H_\eta = \omega \mathcal{I}_\eta, \qquad \omega > 0. \tag{109.1}$$

The HMT ellipse is $\mathcal{I}_\eta = \hbar$. Its area is $2\pi\hbar$; $\mathcal{I}_\eta$ has the dimension of action and H_η that of energy. Define the already realized matrices

$$M_\eta = \operatorname{diag}(e^{\eta/2}, e^{-\eta/2}), \quad J_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad R_\eta(\varepsilon) = M_\eta e^{-\varepsilon J_2} M_\eta^{-1}. \tag{109.2}$$

Proposition 109.1. *The group R_η is a canonical symmetry of the action*

$$\mathcal{S}_\eta[z] = \int_{t_a}^{t_b} \left(P\dot{Q} - \omega \mathcal{I}_\eta(Q,P)\right) dt \tag{109.3}$$

and its Noether charge is $\mathcal{I}_\eta$.

Proof. The determinant of M_η is one, and $M_\eta^{\mathsf{T}} J_2 M_\eta = J_2$. Moreover, $\mathcal{I}_\eta(M_\eta y) = \|y\|^2/2$, which is invariant under $e^{-\varepsilon J_2}$. The generator

$$X_\eta = e^{\eta} P\,\partial_Q - e^{-\eta} Q\,\partial_P$$

satisfies $\iota_{X_\eta}\Omega = d\mathcal{I}_\eta$. By Cartan's formula,

$$\mathcal{L}_{X_\eta}\lambda = dF_\eta, \qquad F_\eta = \lambda(X_\eta) - \mathcal{I}_\eta = e^{\eta}P^2 - \mathcal{I}_\eta.$$

Since $X_\eta H_\eta = 0$, the variation of the action density is dF_η/dt. Its charge is

$$\frac{\partial L}{\partial \dot{Q}} X_\eta Q - F_\eta = P e^{\eta} P - F_\eta = \mathcal{I}_\eta.$$

The equations $\dot{Q} = \omega e^{\eta} P$, $\dot{P} = -\omega e^{-\eta} Q$ directly verify $d\mathcal{I}_\eta/dt = 0$. □

The positive parametrization of the ellipse is $Q = a_S \cos\theta$, $P = b_S \sin\theta$. These equations assign it $\dot{\theta} = -\omega$. Thus, over a turn traversed according to the dynamical flow, $\oint P\,dQ = 2\pi\mathcal{I}_\eta$; with increasing θ, the integral is $-2\pi\mathcal{I}_\eta$. This is the orientation distinction established in section 24.3.2. On the radial contour, the magnitude is $h = 2\pi\hbar$.

109.2 Change of form: determined transport and connection

For two already published forms η, η' and a phase advance ϑ, define

$$\mathcal{T}^{\vartheta}_{\eta',\eta} : \mathcal{P}_\eta \to \mathcal{P}_{\eta'}, \qquad \mathcal{T}^{\vartheta}_{\eta',\eta} = M_{\eta'} e^{-\vartheta J_2} M_\eta^{-1}. \tag{109.4}$$

Proposition 109.2. *This transport is symplectic and satisfies*

$$\mathcal{I}_{\eta'}(\mathcal{T}^{\vartheta}_{\eta',\eta} z) = \mathcal{I}_\eta(z), \qquad \mathcal{T}^{\vartheta_2}_{\eta'',\eta'} \mathcal{T}^{\vartheta_1}_{\eta',\eta} = \mathcal{T}^{\vartheta_1+\vartheta_2}_{\eta'',\eta}. \tag{109.5}$$

Proof. All factors are symplectic. The first equality reduces to invariance of $\|y\|^2/2$ under rotation. In the second, the adjacent matrices $M_{\eta'}^{-1} M_{\eta'}$ cancel and the phases add. □

The formula receives the forms and advances from the reader; it does not select their values. The complete list of transitions can be retained alongside the composite transport: two lists yielding the same composite map are not identified as histories.

Proposition 109.3. *A differentiable realization $\eta(t), \vartheta(t) \in C^1$, with $\dot\vartheta = \omega(t)$, of the transport (109.4) has generator*

$$\boxed{H_{\mathrm{tr}}(Q,P,t) = \omega(t)\mathcal{I}_{\eta(t)}(Q,P) + \frac{\dot\eta(t)}{2} QP.} \tag{109.6}$$

This generator preserves $\mathcal{I}_{\eta(t)}(z(t))$.

Proof. Differentiating $z(t) = M_{\eta(t)} e^{-\vartheta(t) J_2} y_0$ gives

$$\dot Q = \omega e^{\eta} P + \frac{\dot\eta}{2} Q, \qquad \dot P = -\omega e^{-\eta} Q - \frac{\dot\eta}{2} P.$$

These are Hamilton's equations for (109.6). The connection term realizes exactly $\dot M_\eta M_\eta^{-1} z$, and its Hamiltonian is determined up to a function of t alone. Indeed,

$$\begin{aligned} \frac{d\mathcal{I}_\eta}{dt} &= \frac{\dot\eta}{2}(-e^{-\eta}Q^2 + e^{\eta}P^2) + \left\{ \mathcal{I}_\eta, \frac{\dot\eta}{2} QP \right\} \\ &= \frac{\dot\eta}{2}(-e^{-\eta}Q^2 + e^{\eta}P^2) + \frac{\dot\eta}{2}(e^{-\eta}Q^2 - e^{\eta}P^2) = 0. \end{aligned} \tag{109.7}$$

Equivalently, $Q = e^{\eta/2} q$, $P = e^{-\eta/2} p$ give

$$P\dot Q - H_{\mathrm{tr}} = p\dot q - \frac{\omega(t)}{2}(q^2 + p^2). \tag{109.8}$$

The rotational symmetry and its charge are transported exactly. □

Here the connection term has been derived from transport, not from an external force. The fixed-form LC Hamiltonian preserves $\mathcal{I}_\eta$. During a deformation, omitting the second term of (109.6) leaves the first term of (109.7) uncancelled. Variational conservation also requires transporting the canonical form.

The proposition determines the generator of the declared interpolation; it does not assign a unique physical interpolation to every TPK history. The discrete identity (109.4)–(109.5) works without interpolation.

109.3 Orientation and boundary of the action

The transformations in section 24.3.3 distinguish $S(Q,P) = (P,Q)$ and $J_2(Q,P) = (-P,Q)$. Both exchange the form $\eta \leftrightarrow -\eta$, but

$$S^*\Omega = -\Omega, \quad J_2^*\Omega = \Omega, \qquad S^*\lambda = -\lambda + d(PQ), \quad J_2^*\lambda = \lambda - d(PQ). \tag{109.9}$$

Likewise,

$$SR_\eta(\varepsilon)S^{-1} = R_{-\eta}(-\varepsilon), \qquad J_2R_\eta(\varepsilon)J_2^{-1} = R_{-\eta}(\varepsilon). \tag{109.10}$$

These are verified using $SM_\eta = M_{-\eta}S$, $J_2M_\eta = M_{-\eta}J_2$, $SJ_2S^{-1} = -J_2$. For an oriented open curve $z : [a,b] \to \mathcal{P}_\eta$,

$$\int_{J_2 z} \lambda = \int_z \lambda - [PQ]_a^b, \qquad \int_{Sz} \lambda = -\int_z \lambda + [PQ]_a^b. \tag{109.11}$$

The boundary terms vanish on a cycle and cancel when compatible endpoints are concatenated. Quadratic energy alone does not determine these signs or these terms.

Nonadic monodromy records phase return and $q_{\mathrm{mem}} \mapsto q_{\mathrm{mem}} + 1$. Constancy of a charge does not require the counter to remain fixed. In the elliptic realization, a turn preserves $\mathcal{I}_\eta$ while increasing the accumulated oriented integral by $2\pi\mathcal{I}_\eta$. Charge, integrated action, phase, and register have distinct types. An angular turn is not identified here with an arbitrary TPK cycle without specifying its reader.

109.4 Variational clock charge and balance between reading and memory

109.4.1 An explicit action charge of the clock

The calendar is realized on $\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^{108}$, with Fourier projectors $P_k = |\widetilde{k}\rangle\langle\widetilde{k}|$, and determines

$$N_{108} = \sum_{k=0}^{107} kP_k, \quad H_{\mathrm{clk}} = \hbar\omega_0 N_{108}, \quad \omega_0 = \frac{2\pi}{108 t_0}. \tag{109.12}$$

Its propagator over t_0 is the shift by one cell. The clock action is

$$\mathcal{S}[\psi] = \int \left[\frac{i\hbar}{2}(\langle\psi,\dot\psi\rangle - \langle\dot\psi,\psi\rangle) - \langle\psi, H_{\mathrm{clk}}\psi\rangle\right] dt. \tag{109.13}$$

The inner product is antilinear in the first variable. The equation is $i\hbar\dot\psi = H_{\mathrm{clk}}\psi$.

Proposition 109.4. *For $B = B^*$ with $[B, H_{\mathrm{clk}}] = 0$, the symmetry $\psi \mapsto e^{-i\varepsilon B}\psi$ has charge*

$$Q_B(\psi) = \hbar\langle\psi, B\psi\rangle. \tag{109.14}$$

Proof. Localizing the parameter, $\delta\psi = -i\varepsilon(t)B\psi$, gives $\delta L = \hbar\dot\varepsilon\langle\psi, B\psi\rangle$. Integration by parts in the variational equations gives $dQ_B/dt = 0$. Directly,

$$\frac{d}{dt}\langle\psi, B\psi\rangle = \frac{i}{\hbar}\langle\psi, [H_{\mathrm{clk}}, B]\psi\rangle = 0.$$

With $B = I$, norm is conserved; with $B = N_{108}$, the charge is the action $E_{\mathrm{clk}}/\omega_0$. □

The symplectic form of the underlying real space is $\Omega_{\mathrm{clk}}(u,v) = 2\hbar\,\mathrm{Im}\langle u, v\rangle$; its one-form is $\Theta_\psi(v) = -\hbar\,\mathrm{Im}\langle\psi, v\rangle$, with $\Omega_{\mathrm{clk}} = -d\Theta$.

109.4.2 Exact charge balance

Let $\mathcal{H}, \mathcal{K}$ be finite-dimensional Hermitian spaces, $J : \mathcal{H} \to \mathcal{K}$ an isometry, U unitary on $\mathcal{K}$, and

$$\Pi = JJ^*, \quad T = J^*UJ, \quad \eta_{\mathrm{mem}} = (I - \Pi)UJ. \tag{109.15}$$

The operator η_{mem} is distinct from the scalar parameter η.

Proposition 109.5. *If*

$$\widetilde{B} = \widetilde{B}^*, \quad U^*\widetilde{B}U = \widetilde{B}, \quad [\widetilde{B}, \Pi] = 0, \quad B = J^*\widetilde{B}J, \tag{109.16}$$

then

$$B = T^*BT + \eta_{\mathrm{mem}}^*\widetilde{B}\eta_{\mathrm{mem}}, \qquad Q_B(\psi) = Q_B(T\psi) + Q_{\widetilde{B}}(\eta_{\mathrm{mem}}\psi). \tag{109.17}$$

Proof. Expand $UJ\psi = JT\psi + \eta_{\mathrm{mem}}\psi$ in $J^*U^*\widetilde{B}UJ = J^*\widetilde{B}J$. Commutation with Π cancels the cross terms. Evaluating the operator identity and multiplying by $\hbar$ gives the action balance. □

By iteration,

$$Q_B(\psi) = Q_B(T^n\psi) + \sum_{j=0}^{n-1} Q_{\widetilde{B}}(\eta_{\mathrm{mem}}T^j\psi). \tag{109.18}$$

This sum records successive complements of the compressed dynamics. The complete dynamics has another exact formula, with $z_n = U^nJ\psi$:

$$Q_B(\psi) = Q_B(J^*z_n) + Q_{\widetilde{B}}((I - \Pi)z_n). \tag{109.19}$$

Without an additional property, T^n is not identified with J^*U^nJ: the complete state can reabsorb memory. If $B, \widetilde{B} \geq 0$, all summands in (109.18) are nonnegative; for signed charges, the equality remains, without this positivity interpretation.

If U is the propagator of an action such as (109.13), commutation of $\widetilde{B}$ with its Hamiltonian supplies Noether conservation. The reduction condition involving Π specifies the readings that separate charge without interference terms.

Without imposing (109.16), the general identity preserves the additional terms:

$$\begin{aligned} &Q_B(T\psi) + Q_{\widetilde{B}}(\eta_{\mathrm{mem}}\psi) + 2\hbar\,\mathrm{Re}\langle JT\psi, \widetilde{B}\eta_{\mathrm{mem}}\psi\rangle \\ &= Q_B(\psi) + \hbar\langle\psi, J^*(U^*\widetilde{B}U - \widetilde{B})J\psi\rangle. \end{aligned} \tag{109.20}$$

The physical charge uses its reader, for example N_{108}; a norm identity corresponds to $B = I$. The sections $\hbar_{\mathrm{pre}}$ and $\hbar_{\mathrm{ret}}$ preserve the return reader of section 14.6.3 y equation (14.72); their difference and the memory complement have their respective domains of definition.

109.5 Covariant balance of the total tensor

The variational elimination of contorsion and the Noether identity of the covariant action, developed in Proposition 131.6, provide

$$\mathcal{T}_{\mu\nu} = T_{\mu\nu}^{\mathrm{phys,LC}} + U_{\mu\nu}^{\mathrm{phys,spin}}, \qquad \mathring{\nabla}^\mu\mathcal{T}_{\mu\nu} = 0. \tag{109.21}$$

Its domain is the realized HMT–MD chart, with the couplings held constant during the variation. For a Killing field ξ,

$$j^{\mu}_{\xi} = \mathcal{T}^{\mu\nu}\xi_{\nu}, \qquad \mathring{\nabla}_{\mu} j^{\mu}_{\xi} = 0. \tag{109.22}$$

The proof uses (109.21), the symmetry of $\mathcal{T}$, and the antisymmetry of $\mathring{\nabla}_{\mu}\xi_{\nu}$. Upon integration, the difference between the charges of the hypersurfaces is the flux through the lateral boundary.

Conservation belongs to the total tensor; each component may exchange charge. Theorem 136.3 explicitly determines $\mathcal{J}^{\mathrm{tr}}_{\nu} = \partial_{\nu}\,\mathrm{tr}_{g}(T^{\mathrm{res}})/4$ and the opposite balances of the trace and traceless part. This is recovered as a covariant instance of the joint-balance criterion, not as a new gravitational equation.

Chapter 110

Conservation of action forms and oriented area in the tritic regimes

110.1 Balance between two action forms

The angular outputs A, C^*, in a common unit, determine the form $\eta = \operatorname{artanh}(C^*/A)$ on the domain $A \neq 0$, $|C^*/A| < 1$. Given two successive forms η_n, η_{n+1}, define

$$M_n = \operatorname{diag}(e^{\eta_n/2}, e^{-\eta_n/2}), \qquad G_n = M_n^{-\mathsf{T}} M_n^{-1}, \qquad I_n(z) = \tfrac{1}{2} z^{\mathsf{T}} G_n z.$$

Here $z = (Q, P)^{\mathsf{T}}$, with both coordinates having the dimension of the square root of action. The scale $\hbar$, when it fixes the contour $I_n = \hbar$, is the previously constructed action output; it does not serve as a fitting target.

Let R_n be the canonical rotation of angular advance θ_n. The transport without angular advance and the transport with that advance are, respectively,

$$B_n = M_{n+1} M_n^{-1}, \qquad C_n = M_{n+1} R_n M_n^{-1}. \tag{110.1}$$

Both go from chart n to chart $n+1$. Define the compressed reading and its normalized complementary register:

$$T_n = \frac{8B_n + C_n}{9}, \qquad D_n = \frac{\sqrt{8}}{9}(C_n - B_n). \tag{110.2}$$

The operator D_n is an isometrically normalized realization of the unique pattern of differences among the nine phases. The nine-component register is $(8z, -z, \dots, -z)/27$, with $z = (C_n - B_n)v$; the sum of its inner products gives the same factor $8/81$. The nine-phase register is retained when the individual labels enter into other readers.

Theorem 110.1. *Action is conserved between reading and memory:*

$$\boxed{G_n = T_n^{\mathsf{T}} G_{n+1} T_n + D_n^{\mathsf{T}} G_{n+1} D_n.} \tag{110.3}$$

Proof. Normalization of the charts gives $B_n^{\mathsf{T}} G_{n+1} B_n = G_n = C_n^{\mathsf{T}} G_{n+1} C_n$. On expanding (110.2), the cross contributions have coefficients +8 and −8. The remaining diagonal coefficients are 72 for B_n and 9 for C_n, divided by 81. The sum is G_n. □

With $z_{n+1} = T_n z_n$, $m_n = D_n z_n$, the scalar form is

$$\boxed{I_n(z_n) = I_{n+1}(z_{n+1}) + I_{n+1}(m_n).} \tag{110.4}$$

The telescoping sum, retaining each memory in the chart where it was emitted, gives

$$I_0(z_0) = I_N(z_N) + \sum_{n=0}^{N-1} I_{n+1}(m_n). \tag{110.5}$$

The transport B_n is an effective part of this composition: replacing it by the identity when the forms differ changes the domains and may invalidate (110.3).

110.2 Exact accumulation law with variable phase

In normalized coordinates $y_n = M_n^{-1} z_n$, the reading is $y_{n+1} = (8I + R_n)y_n/9$. For a planar rotation,

$$\left(\frac{8I + R_n}{9}\right)^{\mathsf{T}} \left(\frac{8I + R_n}{9}\right) = r_n I, \qquad r_n = 1 - \frac{32}{81}\sin^2(\theta_n/2). \tag{110.6}$$

Therefore,

$$I_N(z_N) = I_0(z_0) \prod_{n=0}^{N-1} r_n. \tag{110.7}$$

Theorem 110.2. *For $I_0(z_0) > 0$, the terminal component tends to zero exactly when*

$$\sum_{n\geq 0} \sin^2(\theta_n/2) = +\infty. \tag{110.8}$$

Proof. Let $c = 32/81$ and $u_n = \sin^2(\theta_n/2) \in [0, 1]$. We have $cu_n \leq -\log(1 - cu_n) \leq cu_n/(1 - c)$, by integrating $1/(1 - s)$ between zero and cu_n. The sum of these logarithms diverges exactly when $\sum u_n$ diverges. Applying the logarithm to the product in (110.7) gives the equivalence. □

Equation (110.5) is preserved in both cases. A sequence of angular advances may leave a positive terminal component or transfer all action to the register, depending on the sum in (110.8). Change of form alone preserves action; angular dispersion determines its allocation in this realization. The phases θ_n must come from the specific reader of the trajectory: the proof does not retrospectively select a sequence to impose a result.

110.3 Extended Euler and common oriented area

The generators of the three quadratic regimes are

$$J_{+1} = (2C_{A_2} + I)/\sqrt{3}, \qquad J_0 = N, \qquad J_{-1} = (2F_{\mathrm{av}}^2 - 3I)/\sqrt{5}.$$

In their two-dimensional charts they have trace zero and satisfy $J_\tau^2 = -\tau I$. The Coxeter element comes from the APP antecedent, the nilpotent from threshold transport and F_{av} from the descent of TPK modes. The exponential functions constitute the subsequent analytic realization:

$$E_\tau(t) = \exp(tJ_\tau) = c_\tau(t)I + s_\tau(t)J_\tau,$$

where (c_τ, s_τ) are $(\cos, \sin)$, $(1, t)$, and $(\cosh, \sinh)$, respectively. Zero trace gives determinant one. With

$$\Omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

we obtain $E_\tau^{\mathsf{T}} \Omega E_\tau = \Omega$. In variable charts we take $C_n = M_{n+1} E_{\tau_n}(t_n) M_n^{-1}$ and the same B_n as in (110.1).

Theorem 110.3. *The three regimes satisfy*

$$\boxed{\Omega = T_n^{\mathsf{T}} \Omega T_n + D_n^{\mathsf{T}} \Omega D_n,} \tag{110.9}$$

with T_n, D_n from (110.2).

Proof. In dimension two, $L^{\mathsf{T}}\Omega L = (\det L)\Omega$. The determinants of M_n, B_n, and C_n are one. The expansion used in (110.3), applied to the alternating form, proves (110.9). □

In a fixed chart, the two determinants are

$$\det T_\tau = \frac{65 + 16c_\tau(t)}{81}, \qquad \det D_\tau = \frac{16(1 - c_\tau(t))}{81}. \tag{110.10}$$

This follows from $\det(aI + C) = a^2 + a\,\mathrm{tr}\,C + \det C$ and $\mathrm{tr}\,E_\tau = 2c_\tau$. Their sum is one. For the representatives C_{A_2}, $I + N$, F_{av}^2, the pairs are $(19/27, 8/27)$, $(1, 0)$, $(89/81, -8/81)$.

The parabolic regime may produce a nonzero rank-one memory with zero area. The hyperbolic regime preserves oriented area through a complement of opposite sign. The elliptic regime additionally permits a positive action balance between the forms of the two fibres. The common alternating form and the metric forms of each regime retain their respective types.

110.3.1 Integrated action and orientation

Let γ be a closed piecewise C^1 curve in the canonical plane. For any real matrix L of order two,

$$\oint_{L\gamma} P\,dQ = (\det L) \oint_{\gamma} P\,dQ.$$

Indeed, writing $Q' = aQ + bP$, $P' = cQ + dP$, the integrals of $Q\,dQ$ and $P\,dP$ are zero, and $\oint Q\,dP = -\oint P\,dQ$. The coefficient $ad - bc$ remains. Applying (110.10),

$$\boxed{\oint_{\gamma} P\,dQ = \oint_{T_n\gamma} P\,dQ + \oint_{D_n\gamma} P\,dQ.} \tag{110.11}$$

The signs are those of the transported curves. The identity is preserved for the three regimes and for changes of form with determinant one.

110.4 The common factor of the exponential reader

The radional reader in section 24.3 y proposition 10.48 also contains $e^{-x}\exp(-yJ_\tau)$. This factor is retained when it acts in the reader. Let

$$C_n = e^{-x_n} M_{n+1} E_{\tau_n}(t_n) M_n^{-1}.$$

Now $C_n^{\mathsf{T}}\Omega C_n = e^{-2x_n}\Omega$. The same expansion gives

$$T_n^{\mathsf{T}}\Omega T_n + D_n^{\mathsf{T}}\Omega D_n = \frac{8 + e^{-2x_n}}{9}\Omega. \tag{110.12}$$

For $x_n \geq 0$, define a complementary scale register

$$D_{\mathrm{esc},n} = \frac{\sqrt{1 - e^{-2x_n}}}{3} B_n.$$

The complete identity is then

$$\Omega = T_n^{\mathsf{T}}\Omega T_n + D_n^{\mathsf{T}}\Omega D_n + D_{\mathrm{esc},n}^{\mathsf{T}}\Omega D_{\mathrm{esc},n}. \tag{110.13}$$

This is a composition defined here to represent explicitly the reader's scale defect. Its coefficient comes from (110.12). The name of this register does not identify it with another physical sector of the corpus; the map is retained so that this comparison can be made with their respective operators and domains.

110.5 Action refinement over the complete emissions

For each enriched prefix h, let M_h be its chart and $G_h = M_h^{-\mathsf{T}} M_h^{-1}$. For each surviving emission ϵ, let R_ϵ be a realized rotation and

$$U_\epsilon = M_{h\epsilon} R_\epsilon M_h^{-1}, \qquad (\mathscr{U} z)_{h\epsilon} = \sqrt{p_h(\epsilon)}\, U_\epsilon z_h.$$

The weights come from the emission measure of the common construction; $\sum_\epsilon p_h(\epsilon) = 1$, with multiplicities preserved. From $U_\epsilon^{\mathsf{T}} G_{h\epsilon} U_\epsilon = G_h$ it follows that

$$\sum_{h,\epsilon} I_{h\epsilon}((\mathscr{U} z)_{h\epsilon}) = \sum_h I_h(z_h). \tag{110.14}$$

The proof first sums the weights of a parent's descendants. Along a trajectory, the intermediate factors $M_h^{-1} M_h$ cancel, and rotations compose in the recorded order. This preserves labels and memory without mixing children of different parents. The alternating form on the direct sum satisfies the same transport identity for the three symplectic regimes, replacing R_ϵ with $E_{\tau_\epsilon}(t_\epsilon)$.

The metric completions are taken with $\sum_h z_h^{\mathsf{T}} G_h z_h$, so these maps are isometric. Further identifying this norm with a fixed Euclidean direct sum requires uniform bounds on M_h and M_h^{-1}; that additional identification is not used in (110.14).

Chapter 111

Explicit reconstruction from complete returns

111.1 State domain and bilateral extension

A chart of the surviving domain generated by APP–TRIT–TPK is considered. A state of this chart preserves the operator sheets, the tritic orientation, the residue, the quotient, the carry, the route, the boundary, the memory register and the calendar origin. The update acts on this complete state.

Let X_0 be a nonempty compact Hausdorff space and $F : X_0 \to X_0$ a continuous surjective update. These are the hypotheses of the result in the chart considered. The bilateral extension of the update is

$$\mathscr{X}_F = \big\{(x_k)_{k\in\mathbb{Z}} \in X_0^{\mathbb{Z}} : F(x_k) = x_{k+1} \text{ for every } k \in \mathbb{Z}\big\}, \tag{111.1}$$

with the topology induced by the product.

Lemma 111.1 (Existence and bilateral transport)**.** *The space $\mathscr{X}_F$ is compact, Hausdorff, and nonempty. Every coordinate projection $\mathscr{X}_F \to X_0$ is surjective. The shift*

$$\sigma((x_k)_{k\in\mathbb{Z}}) = (x_{k+1})_{k\in\mathbb{Z}}$$

is a homeomorphism of $\mathscr{X}_F$.

Proof. Each condition $F(x_k) = x_{k+1}$ defines a closed subset of the compact Hausdorff product $X_0^{\mathbb{Z}}$. With an index k_0 and a state $z \in X_0$ fixed, any finite family of these conditions, together with $x_{k_0} = z$, admits a solution: they are completed forward through F and backward through preimages, which exist by surjectivity. The conditions therefore have the finite intersection property. Compactness produces a bilateral history with $x_{k_0} = z$.

The shifts σ and $\sigma^{-1}((x_k)) = (x_{k-1})$ preserve the relations in (111.1); both are continuous by their coordinate action. □

111.2 Tritic sampling and complete reconstruction of evolution

With the schedule origin fixed, the typed return times are

$$\mathscr{T}_+ = \{k \in \mathbb{Z} : 1 + (k \bmod 9) \in \{1, 4, 7\}\} = 3\mathbb{Z}.$$

The complete state x_k is preserved at each such time. Define the space of return records by

$$\mathscr{Y}_+ = \big\{(y_j)_{j\in\mathbb{Z}} \in X_0^{\mathbb{Z}} : F^3(y_j) = y_{j+1} \text{ for every } j \in \mathbb{Z}\big\}. \tag{111.2}$$

Theorem 111.2 (Recovery from complete returns)**.** *The map*

$$r = \mathrm{Ret}_+ : \mathscr{X}_F \longrightarrow \mathscr{Y}_+, \qquad r(x)_j = x_{3j},$$

is a homeomorphism. Its inverse is given explicitly by

$$\boxed{\big(r^{-1}(y)\big)_{3j+s} = F^s(y_j), \qquad j \in \mathbb{Z}, \quad s \in \{0, 1, 2\}.} \tag{111.3}$$

Proof. For $x \in \mathscr{X}_F$, $F^3(x_{3j}) = x_{3j+3}$, so $r(x) \in \mathscr{Y}_+$. Conversely, every integer k has a unique expression $k = 3j + s$, with $j \in \mathbb{Z}$ and $0 \le s < 3$, including when $k < 0$. Formula (111.3) therefore defines every coordinate of a sequence x.

If $s = 0$ or $s = 1$, then $F(x_{3j+s}) = F^{s+1}(y_j) = x_{3j+s+1}$. At the boundary between two blocks,

$$F(x_{3j+2}) = F^3(y_j) = y_{j+1} = x_{3j+3}.$$

Thus $x \in \mathcal{X}_F$. Reading its coordinates indexed by $3j$ returns y_j. In the reverse direction, the relations in (111.1) give $x_{3j+s} = F^s(x_{3j})$, so reconstruction from $r(x)$ returns x in full.

The map r is continuous because it selects coordinates. Each coordinate of its inverse is the composition of a coordinate projection with one of the continuous maps I, F, F^2. The inverse is therefore continuous. □

An additional discrete coordinate, for example the index $m \in \mathbb{Z}$ of a realization chart, is preserved through

$$\widetilde{r} : \mathbb{Z} \times \mathcal{X}_F \longrightarrow \mathbb{Z} \times \mathcal{Y}_+, \qquad \widetilde{r}(m, x) = (m, r(x)).$$

Its inverse is $(m, y) \mapsto (m, r^{-1}(y))$. The same result holds for a fixed schedule origin a: replace x_{3j} and x_{3j+s} with x_{a+3j} and x_{a+3j+s}.

111.3 Conjugation of transport and preservation of readouts

Let $\sigma_+(y)_j = y_{j+1}$ be the shift of records. The preceding reconstruction gives

$$r\sigma^3 = \sigma_+ r, \qquad (r\sigma r^{-1}(y))_j = F(y_j). \tag{111.4}$$

The map in the second equality is reversible on $\mathcal{Y}_+$; its inverse is

$$y \longmapsto \big(F^2(y_{j-1})\big)_{j \in \mathbb{Z}}.$$

Indeed, both compositions reduce to $F^3(y_{j-1}) = y_j$. Reversibility of the bilateral history is thus preserved even when the update F on an isolated state is not injective. If the nonadic revolution is realized as $\Gamma_9 = \sigma^9$, then

$$r\Gamma_9 = \sigma_+^3 r. \tag{111.5}$$

Corollary 111.3 (Joint readouts and recovered transport)**.** *Let $a : \mathcal{X}_F \to \mathcal{R}$ and $q : \mathcal{X}_F \to \mathcal{E}$ be two continuous readers of the same state, and let $d : \mathcal{X}_F \to \mathcal{X}_F$ be a homeomorphism of the calibrated domain. Then*

$$a_+ = a \circ r^{-1}, \qquad q_+ = q \circ r^{-1}, \qquad d_+ = r \circ d \circ r^{-1}$$

are continuous, d_+ is a homeomorphism, and

$$(a, q) = (a_+, q_+) \circ r, \qquad rd = d_+ r. \tag{111.6}$$

For every integer $N > 0$,

$$d^N x = x \quad \Longleftrightarrow \quad d_+^N r(x) = r(x).$$

Proof. Compose the maps with the homeomorphism of theorem 111.2. The inverse of d_+ is $rd^{-1}r^{-1}$. The identity $d_+^N r = rd^N$, together with injectivity of r, proves the last equivalence. □

Application to the double readout takes $\mathcal{R} = R_{\mathrm{HMT}}$ and the incidence codomain constructed in section 21.11.1 y proposition 21.55. The result establishes a recoverable presentation of the same histories, their readers, and their transport. Its object is this dynamical equivalence of presentations.

Chapter 112

Observable return and persistence of the register

112.1 Joint recovery from complete returns

Let X be the domain of complete calibrated histories of equation (111.1), including the calendar origin and, when used, the discrete chart index. The states preserve the transitions and memory register. We write $r = \mathrm{Ret}_+ : X \to Y_+$ for sampling at complete returns, with $Y_+ = r(X)$.

The result in theorem 111.2 provides its explicit inverse: $x_{3j+s} = F^s(y_j)$, for $s = 0, 1, 2$. Reconstruction uses the complete state preserved at each return and the effective update; (111.4) also preserves transport.

Let $a : X \to R_{\mathrm{HMT}}$ be numerical evaluation by cylinders and $q : X \to E_\infty$ incidence with its gauge, according to section 10.5, section 21.11.1 y proposition 21.55. Let $d : X \to X$ be a reversible continuous transport, with the gauge transported. On Y_+, define

$$a_+ = a \circ r^{-1}, \qquad q_+ = q \circ r^{-1}, \qquad d_+ = r \circ d \circ r^{-1}.$$

Then

$$\boxed{(a, q) = (a_+, q_+) \circ r, \qquad rd = d_+ r.} \tag{112.1}$$

Proof. This is corollary 111.3: the compositions with r and r^{-1} cancel, and the inverse of d_+ is $rd^{-1}r^{-1}$. Both readers are transported from the same complete state. □

In particular, for $N \in \mathbb{Z}_{>0}$, $d^N x = x$ if and only if $d_+^N r(x) = r(x)$. Conjugation preserves periodicity or aperiodicity of the complete state. The dynamics of a partial reader is determined through its own transport factor.

112.2 Explicit subsequent representation of transport

On the already generated set of histories, consider the subsequent realization $H = \ell^2(X)$, with orthonormal basis $(\delta_x)_{x \in X}$ and counting measure. Every vector has at most countable support. Reversible transport determines

$$C\delta_x = \delta_{dx}, \qquad C^{-1}\delta_x = \delta_{d^{-1}x}.$$

The bijection d proves that C is unitary. This representation preserves the complete labels of the histories. The space X and its transport precede this linear realization.

The nonadic chart of chapter 104 determines

$$T = \frac{8I + C}{9}, \qquad \eta v = \frac{1}{27}(8(C - I)v, -(C - I)v, \ldots, -(C - I)v),$$

$$I - T^*T = \eta^*\eta = \frac{8}{81}(I - C)^*(I - C).$$

Let P be the orthogonal projection onto $\ker(I - C)$. The spectral proof in chapters 104 y 105 gives $T^N \to P$ strongly. Telescoping provides the isometry

$$\mathcal{V}v = (Pv, \eta v, \eta T v, \eta T^2 v, \ldots), \qquad \mathcal{M} = \mathrm{Im}\,\mathcal{V}.$$

The register shift B preserves the first component and removes the first memory block. On the compatible image,

$$\boxed{\widehat{C} = \mathcal{V} C \mathcal{V}^{-1} = (9B - 8I)|_{\mathcal{M}}.} \tag{112.2}$$

The inverse of the representation is given by

$$v = Pv + \sum_{j \geq 0} T^{*j} \eta^* (\eta T^j v). \tag{112.3}$$

Proof. The defect identity telescopes up to N; its limit preserves the norm exactly. The identities $\mathcal{V}T = B\mathcal{V}$ and $C = 9T - 8I$ give (112.2). The isometry $\mathcal{V}$ is surjective onto $\mathcal{M}$; taking its adjoint gives (112.3), with norm convergence of the series. Unitarity of the recovered transport is established on $\mathcal{M}$. □

For $A \in \mathcal{B}(H)$, let $\widehat{A} = \mathcal{V} A \mathcal{V}^{-1}$ on $\mathcal{M}$. This correspondence preserves norm, products, adjoints, and commutators, since $\mathcal{V}^{-1} = \mathcal{V}^*|_{\mathcal{M}}$. It jointly represents the numerical observables, the incidence observables, and their relations with C.

112.3 Numerical convergence and correlations with incidence

The cylinders of (10.49) provide, in the chart of integer index $m(x)$, six trits per block. We write

$$\xi_n(x) = \sum_{k=1}^{6n} d_k(x) 3^{-k}, \qquad \xi(x) = a(x) - m(x), \qquad 0 \leq \xi(x) - \xi_n(x) \leq 3^{-6n}.$$

Here $d_k \in \{0, 1, 2\}$ is the subsequent ternary reading of the trit; its balanced orientation retains its own typing. The chart retains m separately, including the endpoint convention, and reconstructs $a = m + \xi$. At endpoints with a double representation, ξ is interpreted in that chart.

Let M_f denote multiplication by f on $\ell^2(X)$. The normalization $0 \leq \xi_n \leq \xi \leq 1$ makes M_ξ and M_{ξ_n} contractions. For a set B in the finite incidence codomain of q_j, define $E_{j,B} = M_{\mathbf{1}_{q_j^{-1}(B)}}$. This is the projector onto the histories satisfying that incidence.

Theorem 112.1 (Simultaneous conservation of precision and transport)**.** *For every $t \in \mathbb{Z}$,*

$$\boxed{\left\| \widehat{C}^{-t} \widehat{M}_\xi \widehat{C}^t - \widehat{C}^{-t} \widehat{M}_{\xi_n} \widehat{C}^t \right\| = \|M_\xi - M_{\xi_n}\| \leq 729^{-n}.} \tag{112.4}$$

The relations among the incidence projectors, their products, and their transport are preserved exactly. For an ordered product of contractions containing r numerical observables M_ξ, evaluated at arbitrary integer times, and any finite number of exact incidence or unitary factors, replacing those r factors by M_{ξ_n} changes the product in norm by at most

$$\boxed{r\, 729^{-n}.} \tag{112.5}$$

The same bound holds for any matrix element between unit vectors. The factors may be noncommutative; their order is preserved.

Proof. The norm of a multiplication operator on $\ell^2(X)$ is $\sup_{x \in X} |f(x)|$; the ternary tail proves the first bound. Conjugation by C^t and by $\mathcal{V}$ preserves the norm. For products $A_1 \cdots A_s$ and $B_1 \cdots B_s$, use

$$\prod_{i=1}^{s} A_i - \prod_{i=1}^{s} B_i = \sum_{j=1}^{s} B_1 \cdots B_{j-1} (A_j - B_j) A_{j+1} \cdots A_s.$$

The exact factors give zero difference; each of the remaining r contributes norm at most 729^{-n}. Submultiplicativity and the bound one for the other factors prove (112.5). Cauchy–Schwarz gives the assertion about matrix elements. □

This uniformity preserves precision when the complete approximate observable is transported. The operator C and incidence remain exact in (112.4). The index n measures cylinder depth; t measures iterations of the transport d; j in (112.3) measures compression iterations.

112.4 Covariance of the memory operator under return

Restrict X and its atomic representation to the graded reversible sector $X_{\mathrm{rev,grad}}$ of the clock in (10.53). The integer memory degree q_{mem} is preserved in each history. For $d = \Gamma_9$, its update is $q_{\mathrm{mem}}(dx) = q_{\mathrm{mem}}(x)+1$. The memory operator D is multiplication by q_{mem}, with domain

$$\operatorname{Dom} D = \{v : \sum_{x\in X} |q_{\mathrm{mem}}(x)|^2 |v_x|^2 < \infty\}.$$

The index change $x \mapsto dx$ and the inequalities $(q \pm 1)^2 \le 2q^2 + 2$ prove that C and C^{-1} preserve this domain. On it,

$$C^* D C = D + I, \qquad \widehat{C}^* \widehat{D} \widehat{C} = \widehat{D} + I_{\mathcal{M}}, \qquad \operatorname{Dom} \widehat{D} = \mathcal{V} \operatorname{Dom} D. \tag{112.6}$$

Proof. On δ_x, the left-hand side equals $q_{\mathrm{mem}}(dx)\delta_x = (q_{\mathrm{mem}}(x) + 1)\delta_x$. The identity extends to the indicated domain by truncating the support in the graph norm of D. The second equality is obtained by unitary conjugation to $\mathcal{M}$. □

By induction, $q_{\mathrm{mem}}(d^N x) = q_{\mathrm{mem}}(x) + N$. Every integer $N > 0$ changes the complete state. Every orbit of d is infinite; a square-summable function constant on each of these orbits is zero. In this bilateral realization, $P = 0$. Formula (112.3) then reconstructs the complete linear state from its memory complements. This conclusion uses the effective grading of the clock.

Phase return coexists with the memory increment in (112.6). Sturmian aperiodicity and its complexity belong to the symbolic factor in section 10.5; the present result preserves the graded dynamics of the complete state.

112.5 Incidence, refinement, and three regimes

The register K also has the complete realization in chapter 107, $\mathcal{F}k = (\mu(k), IP_0k/6)$. Its inverse preserves the twelve coordinates, including the mean. Applying $\mathcal{F}$ to the corresponding fibres and retaining the history labels transports this representation. The map $\mathcal{F} \circ K$ preserves exactly the fibres of the reader K; recovery of complete histories comes from r or from their effective labels.

The isometric refinement systems in chapters 103, 105 y 107 preserve $\mathcal{V}$ and C through their intertwining squares. The proof uses the levelwise realizations constructed there. The atomic representation $\ell^2(X)$ and the projective-measure realizations L^2 retain their corresponding domains and measures.

The link with folding and unfolding is developed in propositions 10.47 y 10.48: Coxeter element, nilpotent transport and action of F_{av}^2. For each two-dimensional realization E preserving the alternating form Ω, the nonadic chart satisfies

$$\Omega = T_E^* \Omega T_E + D_E^* \Omega D_E, \qquad T_E = (8I + E)/9, \quad D_E = \sqrt{8}(E - I)/9. \tag{112.7}$$

The algebraic expansion cancels the cross terms and uses $E^*\Omega E = \Omega$. In the real realization, $*$ means transpose. The oriented law brings together the three regimes through the forms and transports of chapters 109 y 110. Its realization as action also uses the normalizations and connections specified there.

The relation to connection dynamics is formulated through the constructions in chapters 108 a 110. The identities (112.2)–(112.7) preserve their representation, the precision of the observables, and the transported forms.

Chapter 113

Reversible coupling and nonstationary transport

113.1 Reversible extension of the balance between two forms

Let $B, C : V \to V'$ be isomorphisms preserving a nondegenerate form b between two realizations:

$$B^{*} b' B = C^{*} b' C = b.$$

The form may be a positive metric or an alternating form. In real spaces, $*$ denotes transposition with respect to the chosen coordinates; the equality expresses transport of the form between the specified realizations. In Hilbert spaces, the operators and their inverses are bounded.

With $s = \sqrt{8}$ and $Q_V = \frac{1}{3}\left(\begin{smallmatrix} sI & -I \\ I & sI \end{smallmatrix}\right)$, define

$$\boxed{\mathcal{U}(B,C) = Q_{V'}^{*} \operatorname{diag}(B,C) Q_V = \frac{1}{9}\begin{pmatrix} 8B + C & \sqrt{8}(C-B) \\ \sqrt{8}(C-B) & B + 8C \end{pmatrix}.} \tag{113.1}$$

We write $T = (8B + C)/9$, $D = \sqrt{8}(C - B)/9$ and $R = (B + 8C)/9$. The complete update is

$$\begin{pmatrix} x' \\ m' \end{pmatrix} = \begin{pmatrix} T & D \\ D & R \end{pmatrix} \begin{pmatrix} x \\ m \end{pmatrix}. \tag{113.2}$$

Theorem 113.1. *The map* (113.1) *is reversible and preserves the form $b \oplus b$:*

$$\mathcal{U}(B,C)^{*} (b' \oplus b') \mathcal{U}(B,C) = b \oplus b, \quad \mathcal{U}(B,C)^{-1} = \mathcal{U}(B^{-1}, C^{-1}). \tag{113.3}$$

Proof. We have $Q^{*}Q = I$ by $8 + 1 = 9$. Its scalar blocks make Q preserve $b \oplus b$ for any form b. The diagonal map preserves the forms by hypothesis. Composition proves (113.3), and inversion of the three factors gives the stated inverse. □

For incoming memory $m = 0$, the balance $b = T^{*} b' T + D^{*} b' D$ is recovered. The second column determines the response to arbitrary incoming memory. Conservation of positive norms and conservation of oriented area are the respective specializations of (113.3).

113.1.1 Collective realization in the nine copies

On V^{9}, let $W_E = \operatorname{diag}(I, \dots, I, E)$, with E in the ninth position. Let $A(a, b) = (a/\sqrt{8}, \dots, a/\sqrt{8}, b)$ and $L = AQ$. Then $L(x, 0) = Jx$ and

$$W_E L = L \mathcal{U}(I, E). \tag{113.4}$$

Proof. $W_E A = A \operatorname{diag}(I, E)$; multiplying by Q and using $AQ = L$ gives (113.4). Orthogonality of the mean of the first eight positions to their seven differences also shows that the complement remains fixed under W_E. □

The original cyclic step is $S_E = P_{\mathrm{cyc}} W_E$. Hence $S_E L = (P_{\mathrm{cyc}} L) U(I, E)$, with distinct input and output charts. Collective reduction preserves the corresponding pattern: $S_E^{9} = I_9 \otimes E$, whereas $W_E^{9} = \operatorname{diag}(I_8, E^{9})$. When a reader uses the nine individual labels, they are preserved in their original representation.

113.2 Exact composition and memory re-entry

For $B_1, C_1 : V_0 \to V_1$ and $B_2, C_2 : V_1 \to V_2$,

$$\boxed{\mathcal{U}(B_2, C_2)\mathcal{U}(B_1, C_1) = \mathcal{U}(B_2B_1, C_2C_1).} \tag{113.5}$$

Proof. In (113.1), the factors $Q_{V_1}Q_{V_1}^*$ cancel, and the two diagonal blocks multiply in the indicated order. Induction extends the formula to any finite number of transports, preserving their order. □

The reading block contains the identity

$$\boxed{T_2T_1 + D_2D_1 = \frac{8B_2B_1 + C_2C_1}{9}.} \tag{113.6}$$

From $(x, 0)$, the first stage produces (T_1x, D_1x). The second reading is $T_2T_1x + D_2D_1x$. The second term is exactly the contribution of the reintroduced memory. Storing D_1x outside the next coupling and continuing only with T_1x yields the separate-register procedure, whose reading is T_2T_1x. The equality (113.6) makes the difference between the two procedures precise.

The realization U preserves the coupling state and the ordered products $B_N \cdots B_1$, $C_N \cdots C_1$. Preservation of all prefixes also includes the HMT emission register, which retains each factor together with its order.

113.2.1 Covariant increment equation

For the separate register $x_{n+1} = T_nx_n$, $m_n = D_nx_n$, we have

$$x_{n+1} - B_nx_n = m_n/\sqrt{8}. \tag{113.7}$$

With $G_0 = I$ and $G_{n+1} = B_nG_n$, telescoping gives

$$x_0 = G_N^{-1}x_N - \frac{1}{\sqrt{8}} \sum_{n<N} G_{n+1}^{-1}m_n. \tag{113.8}$$

Memory is the increment relative to transport between forms B_n, with the declared normalization. The equality (113.8) is a finite algebraic reconstruction; its passage to an infinite series requires convergence. The following theorem constructs the stable inverse through the limit of positive operators.

113.3 Memory of a nonstationary sequence

In a Hilbert realization H, let C_n be unitaries, with their declared composition order. We write

$$T_n = (8I + C_n)/9, \quad D_n = \sqrt{8}(C_n - I)/9, \quad P_0 = I, \quad P_{n+1} = T_nP_n, \quad A_N = P_N^*P_N.$$

The index N counts compressions with separate storage, unlike complete transport with reentry. For variable metrics with B_n isometric isomorphisms, conjugation by G_n takes the transports to a fixed Hilbert space and produces this same case, with $\widetilde{C}_n = G_{n+1}^{-1}C_nG_n$. The assertion uses the fiber metrics and the declared isometries between them.

Theorem 113.2 (Positive terminal and nonstationary recovery)**.** *There exists a positive operator* $0 \le A_\infty \le I$*, the strong limit of* A_N*, and*

$$\boxed{I = A_\infty + \sum_{n\ge 0} P_n^*D_n^*D_nP_n.} \tag{113.9}$$

The map

$$\boxed{\mathcal{V}v = (A_\infty^{1/2}v, (D_nP_nv)_{n\geq 0})} \tag{113.10}$$

is isometric and has a stable left inverse

$$\mathcal{V}^*(a,(m_n)) = A_\infty^{1/2}a + \sum_{n\geq 0} P_n^*D_n^*m_n, \qquad \|\mathcal{V}^*\| = 1. \tag{113.11}$$

Proof. The local identity $T_n^*T_n + D_n^*D_n = I$ gives $A_N - A_{N+1} = P_N^*D_N^*D_NP_N \geq 0$. The quadratic forms of the decreasing positive sequence converge to that of a positive operator A_∞. For $B_N = A_N - A_\infty$, the inequality $0 \leq B_N^2 \leq B_N$ makes that convergence strong. Finite telescoping and the limit prove (113.9). Evaluation on v proves (113.10). Its adjoint is (113.11); the series converges in norm because the truncations of a square-summable register converge and the adjoint is bounded. □

Reconstruction with the limit terminal and N registers has exact error $(A_N - A_\infty)v$. The vector $A_\infty^{1/2}v$ is the canonical positive realization of the norm terminal. Its existence follows from the Gram limit, independently of vector convergence of P_Nv.

113.4 Three different properties: exhaustion, distinction and stability

Let $Mv = (D_nP_nv)_n$. From (113.9), $M^*M = I - A_\infty$. Therefore:

1. All the norm of v passes to the register exactly when $A_\infty v = 0$.
2. The register distinguishes each state exactly when $\ker(I - A_\infty) = \{0\}$.
3. Recovery from memory alone has a bounded inverse exactly when $I - A_\infty \geq \varepsilon I$ for some $\varepsilon > 0$. In that case a left inverse is $(I - A_\infty)^{-1}M^*$.

Moreover,

$$\boxed{\ker M = \bigcap_{n\geq 0} \mathrm{Fix}(C_n).} \tag{113.12}$$

Proof. If $Mv = 0$, then $D_0v = 0$, whence $C_0v = v$ and $P_1v = v$. Inductively, $D_nP_nv = 0$ gives $C_nv = v$ and $P_{n+1}v = v$. The converse is immediate. The three equivalences follow from the Gram matrix M^*M and the characterization of operators bounded below. □

113.4.1 Exact example separating the three properties

In the algebraic example $C_0 = -I$ and $C_n = I$ for $n \geq 1$,

$$A_\infty = \frac{49}{81}I, \qquad M^*M = \frac{32}{81}I, \qquad m_0 = -\frac{2\sqrt{8}}{9}v, \qquad v = -\frac{9}{2\sqrt{8}}m_0. \tag{113.13}$$

The memory contains $32/81$ of the squared norm and allows the complete vector to be recovered. The terminal retains $49/81$ and is a positive operator distinct from a projector. Recoverability depends on the kernel and conditioning of the reader. Reading and memory constitute correlated components of an isometry.

This example separates the three logical consequences of the theorem. Application to a physical trajectory also preserves the selection and effective provenance of its C_n through TPK.

113.5 Quantitative criterion for complete transfer

For $P_{j,n} = T_{j-1}\cdots T_n$ and $P_{n,n} = I$, a window of length L has Gram matrix

$$G_{n,L} = \sum_{j=n}^{n+L-1} P_{j,n}^{*} D_j^{*} D_j P_{j,n} = I - P_{n+L,n}^{*} P_{n+L,n}.$$

If $G_{n,L} \geq \kappa I$, with $\kappa > 0$, in each consecutive block of length L, then

$$\|P_N\|^2 \leq (1-\kappa)^{\lfloor N/L \rfloor}, \qquad A_\infty = 0. \tag{113.14}$$

Each block contracts the squared norm by $1-\kappa$; composition and contractivity of the remaining steps prove (113.14).

A sufficient criterion preceding the products is

$$\sum_{j=n}^{n+L-1} D_j^{*} D_j \geq \alpha I \quad \Longrightarrow \quad G_{n,L} \geq \frac{\alpha}{[1+2(L-1)/9]^2} I. \tag{113.15}$$

Proof. For $y_j = P_{j,n} v$, we have $y_{j+1} - y_j = D_j y_j/\sqrt{8}$ and $\|D_j\| \leq 2\sqrt{8}/9$. Hence

$$\|D_j v\| \leq \|D_j y_j\| + \frac{2}{9} \sum_{i=n}^{j-1} \|D_i y_i\|.$$

The triangular matrix of partial sums has norm at most $L-1$. Applying the window's ℓ^2 norm and the Gram hypothesis proves (113.15).

□

The absence of a common fixed vector gives distinguishability, whereas (113.15) adds a quantitative uniform separation. Neither condition is presumed merely by mentioning symmetries: each applies to the effective transports of the sequence.

113.6 Complete incidence realization and changes of regime

Section 107.1 constructs, for the twelve-coordinate register, $Fk = (\mu(k), \mathcal{I} P_0 k/6)$, with an inverse and weighted inner product on $Y = \mathbb{R} \oplus \mathcal{I}(\mathbf{1}^{\perp})$. The transformation $F \oplus F$ takes the complete coupling to

$$\mathcal{U}_Y = (F' \oplus F')\mathcal{U}(B,C)(F^{-1} \oplus F^{-1}) = \mathcal{U}(F'BF^{-1}, F'CF^{-1}). \tag{113.16}$$

This identity preserves the second column, re-entry, and composition. For variable forms, the form is also transported through F. In the real realization of the twelve A_2 fibres, use $F \otimes \mathrm{id}_{V_{A_2}}$, with $V_{A_2} = A_2 \otimes_{\mathbb{Z}} \mathbb{R}$. Its domain is the real space of fibres; preservation of the integer lattice corresponds to the lattice transport already proved. The map F recovers K and retains the remaining genealogical labels in the complete state.

The positive version of (113.9)–(113.15) uses unitary transports in the declared metrics. The alternating-form version of (113.1)–(113.8) admits the three Euler regimes. With $E = F_{\mathrm{av}}^2 = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, we obtain $\det T = 89/81$, $\det D = -8/81$. The finite oriented sums telescope, and the area terminal components grow as $(89/81)^N$. The positive Hilbert limit uses the specific unitary hypotheses of Theorem 113.2.

The balance brings together forms and domains, reversible evolution with re-entry, and unlimited recovery in the positive realizations. The subsequent physical applications preserve the readers, connections, and scales of this operator composition.

Chapter 114

Dimensional reconstruction and exterior conservation

114.1 Two memories recover the centred register

114.1.1 Register-reading operators

In the ordered chart of the register K of section 11.4 y theorem 11.43, let $V = \mathbb{R}^{12}$ be its subsequent linear realization and let S be the permutation $(Sx)_i = x_{i+1}$, with indices modulo 12. The readers $I - S^3$ and $I - S^4$ are those of the transverse extractor of theorem 11.43. The nonadic compression of chapter 113 provides, for $j = 3, 4$,

$$T_j = \frac{8I + S^j}{9}, \qquad D_j = \frac{\sqrt{8}}{9}(S^j - I), \qquad T_j^* T_j + D_j^* D_j = I. \tag{114.1}$$

The partition 8 + 1 and normalization 9 come from the nine positions and their collective contrast. Consider the following explicit composition of readers, applied to the generated register:

$$m_0 = D_3 K, \qquad m_1 = D_4 T_3 K, \qquad MK = (m_0, m_1). \tag{114.2}$$

The second memory acts on the reading produced by the first stage. The complements are archived separately. The complete evolution with re-entry corresponds to the reversible coupling in chapter 113.

114.1.2 Inversa exacta

Since $(S^3)^4 = I$,

$$T_3^{-1} = \frac{512I - 64S^3 + 8S^6 - S^9}{455}. \tag{114.3}$$

Indeed, $(8I + S^3)(512I - 64S^3 + 8S^6 - S^9) = 4095I$ and $4095 = 9 \cdot 455$. Hence the memories provide

$$b = -\frac{9}{\sqrt{8}} m_0 = (I - S^3)K, \quad c = -\frac{9}{\sqrt{8}} T_3^{-1} m_1 = (I - S^4)K. \tag{114.4}$$

Commutation of T_3 with S^4 justifies the second equality. Define

$$w_i = c_i - b_{i+1}, \quad B_0 = 0, \quad B_i = \sum_{j<i} w_j.$$

The identity $w_i = K_i - K_{i+1}$ proves that $B_i = K_0 - K_i$. If $q = \sum_{i=0}^{11} K_i$, we recover exactly

$$K_i = \frac{q + \sum_{j=0}^{11} B_j}{12} - B_i. \tag{114.5}$$

This is the inverse (11.112), now composed with compression and memory. With $q = 0$, the formula returns $P_{11}K$, where

$$P_{11} = I - \frac{1}{12}\mathbf{1}\mathbf{1}^*.$$

The two memories recover the eleven zero-mean components. The uniform charge is recovered through q. The kernel of M is precisely the uniform line: vanishing of both differences implies fixation by S^3 and S^4; since $S = S^4(S^3)^{-1}$, it implies fixation by S.

114.1.3 Optimal stability bound

The Gram matrix of the procedure is

$$G = M^{*}M = D_3^{*}D_3 + T_3^{*}D_4^{*}D_4T_3 = I - (T_4T_3)^{*}(T_4T_3). \tag{114.6}$$

In mode k of S, the eigenvalue of $T_j^{*}T_j$ is

$$\frac{65 + 16\cos(2\pi jk/12)}{81}.$$

Substituting it into the preceding Gram matrix gives, with multiplicities,

$$\operatorname{Spec} G = \left\{0^{[1]},\ (16/81)^{[2]},\ (8/27)^{[2]},\ (32/81)^{[1]}, (952/2187)^{[4]},\ (1256/2187)^{[2]}\right\}. \tag{114.7}$$

The zero mode is the mean. Let L be the least-squares inverse of M on $\mathbf{1}^{\perp}$, extended to the register space by

$$L = (G|_{\mathbf{1}^{\perp}})^{-1}M^{*}.$$

Then

$$LM = P_{11}, \qquad \|L\| = \frac{9}{4}. \tag{114.8}$$

The bound is optimal because modes $k = 3, 9$ attain $16/81$. For perturbed data and reconstruction with L,

$$\|\delta K\|^2 \le \frac{|\delta q|^2}{12} + \frac{81}{16}\big(\|\delta m_0\|^2 + \|\delta m_1\|^2\big). \tag{114.9}$$

The uniform and centred components are orthogonal. Formula (114.5) is an exact inverse on compatible data; (114.8) specifies the stable extension used for noisy data, which need not satisfy the compatibility conditions of (114.5).

114.1.4 Example with the generated dodecaphasic register

The register in (11.107) is

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601). \tag{114.10}$$

It is an output of the preceding generator, used as an application case. The coefficients and readers are fixed before this register is evaluated. To store the memories using rational arithmetic, write $z_i = m_i/\sqrt{8}$. The two effective registers are

$$9z_0 = (495, 116, 684, -108, -601, 90, 173, 88, -313, -560, 397, -461),$$

$$81z_1 = (2729, 2503, 3818, -5843, 2583, -920, -4051, 4338, -5312, -1583, 233, 1505). \tag{114.11}$$

Substituting these registers into the reconstruction formulas, with $q = 6263$, reproduces the twelve components of K. With $q = 0$, it reproduces $K - (6263/12)\mathbf{1}$. The supplementary certificate first reconstructs the register from the memories and then compares it with (11.107).

Adding a third memory $D_3T_4T_3K$ raises the smallest positive eigenvalue of the Gram matrix to $8/27$. The optimal amplification decreases from $9/4$ to $\sqrt{27/8}$. A third memory $D_4T_4T_3K$ retains $16/81$. The choice between repeating step 3 or step 4 has a stability effect calculable before evaluating the register.

114.2 Reconstruction of the dimensional projector from two memories

114.2.1 Composition with the incidence already constructed

The exceptional chart of section 21.11.5 defines the orthogonal representation of A_5 on the twelve classes of A_5/C_5, with explicit representatives and character. Its three-dimensional isotypic projector is (21.137):

$$P_3 = \frac{3}{60}\sum_{a\in A_5} \chi_3(a^{-1})\rho(a), \qquad P_3P_{11} = P_3, \qquad P_3\mathbf{1} = 0. \tag{114.12}$$

The generated register precedes this representation. The result in lemma 21.62, together with (21.139) and (21.140), establishes

$$u_K = P_3P_{11}K, \qquad \|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0,$$

$$P_{10}(K) = P_{11} - \frac{u_K u_K^{*}}{\|u_K\|^2}. \tag{114.13}$$

The new composition of (114.8), (114.12), and (114.13) is

$$\boxed{u_K = P_3L(m_0, m_1), \qquad P_{10}(K) = P_{11} - \frac{P_3L(m)\,[P_3L(m)]^{*}}{\|P_3L(m)\|^2}.} \tag{114.14}$$

Proof. The identities $LM = P_{11}$ and $P_3P_{11} = P_3$ give $P_3LMK = P_3K = u_K$. Nonvanishing is evaluated in (21.139). The rank-one quotient therefore coincides with that of (21.140). The composition recovers the complete rank-ten orthogonal projector from the two memories, independently of the charge q and terminal reading T_4T_3K. □

The reduction $12 \to 11$ removes the uniform direction, and the reduction $11 \to 10$ uses the vector selected by K. The composition recovers the full projector matrix on the linear incidence carrier. Its dimensional realizations retain the maps of proposition 21.64.

114.2.2 Projector error

Let ε be the joint norm of the error in the two memories, and let $\widehat{u} = P_3L(m+\delta m)$. Then $\|\widehat{u} - u_K\| \le 9\varepsilon/4$. If $9\varepsilon/4 < \|u_K\|$, the vector $\widehat{u}$ is nonzero and

$$\boxed{\|\widehat{P}_{10} - P_{10}\| \le \frac{9\varepsilon}{4\|u_K\|}.} \tag{114.15}$$

Proof. The operator-norm distance between two orthogonal projectors onto lines is the sine of the angle between them. The distance from u_K to the line of $\widehat{u}$ is at most $\|u_K - \widehat{u}\|$. Division by $\|u_K\|$ proves the bound. Here $\|u_K\| \approx 765{,}733$, and the coefficient is approximately $0{,}00293836$. □

For registers close to $\ker P_3$, stability of the direction depends on $\|u_K\|$. The bound $9/4$ for the centred register remains valid.

114.2.3 A scalar descriptor of K, with explicit invariances

The register K, its scalar readings, and its invariants are distinguished. For $K \notin \mathbb{R}\mathbf{1}$, define

$$\eta_K = \frac{\|P_3 P_{11} K\|^2}{\|P_{11} K\|^2}. \tag{114.16}$$

For the register (11.107), $\sum_i K_i^2 = 4251257$ and $\|P_{11}K\|^2 = 11789915/12$. Thus,

$$\eta_K = \frac{3(6638585 + 2275584\sqrt{5})}{5 \cdot 11789915} = \frac{13089003 + 13653504\varphi_{\mathrm{HMT}}}{58949575} \approx 0,5967954228259091. \tag{114.17}$$

The second expression uses the subsequent quadratic recognition of φ_{HMT}. We have $0 \le \eta_K \le 1$. The quotient is invariant under $K \mapsto aK + b\mathbf{1}$, with $a \neq 0$, and under simultaneous orthogonal changes of K, P_{11}, P_3. In the fixed chart it is invariant under $\rho(A_5)$, since both projectors commute with that representation. It is recoverable from the memories because both norms defining it are recoverable. It measures the quadratic fraction of the centered register lying in the chosen isotypic sector. The complete register also preserves the information that this scalar descriptor identifies. The provenance of this additional formalization is documented in the supplement; the affine invariances proved here belong to the linear realization.

114.3 Application to an effective vector of the exceptional construction

The construction of section 21.11.13 y proposition 21.73 uses twelve fibers A_2, their gluing and the lattice neighbor. The tritic word is $c^\star = (1, 1, 1, 1, 1, 1, 2, 1, 1, 1, 1, 1)$. Its blocks act by C^{-1} when the component is 1 and by C when it is 2, in the charts specified by equations (21.147) y (21.148). The resulting operator g satisfies $g^3 = I$, $g^2 + g + I = 0$, and is orthogonal for the sum of the metrics A_2. Descent to the gluing and neighbor is proved in proposition 21.73. The following calculations act on its real carrier of dimension 24.

In each fibre,

$$C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}.$$

On the sum of the twelve fibres, define

$$T = \frac{8I + g}{9}, \qquad D = \frac{\sqrt{8}}{9}(g - I).$$

With the adjoint relative to that metric, $g^* = g^{-1} = -g - I$, and we obtain

$$T^*T = \frac{19}{27}I, \qquad D^*D = \frac{8}{27}I, \qquad D^{-1} = -\frac{3}{\sqrt{8}}(g + 2I). \tag{114.18}$$

The inverse comes from $(g - I)(g + 2I) = -3I$. The neighbour construction fixes the vector in (21.142), $v = 4\rho_1 + \rho_2 + \cdots + \rho_{12}$, with a root ρ_b of squared norm 2 in each fibre. Therefore,

$$\|v\|^2 = 54, \qquad \|Tv\|^2 = 38, \qquad \|Dv\|^2 = 16, \qquad v = -\frac{3}{\sqrt{8}}(g + 2I)Dv. \tag{114.19}$$

A single complement recovers this complete vector. The reading preserves 38 units of squared norm and the register contains 16; their sum is 54. The result uses the vector in (21.142) and its lattice fibres.

114.4 Conservation law in every exterior degree

114.4.1 Statement and proof

Let $P_0 = I$, $P_n = T_{n-1} \cdots T_0$, and

$$\mathcal{J}_N v = (P_N v, D_0 P_0 v, \ldots, D_{N-1} P_{N-1} v).$$

The law in chapters 110 y 113 preserves the form G_0 through the orthogonal sum of the corresponding forms: $\mathcal{J}_N^* G_{\mathrm{sal}} \mathcal{J}_N = G_0$. For each admissible finite exterior degree p, it follows that

$$\boxed{(\Lambda^p \mathcal{J}_N)^* (\Lambda^p G_{\mathrm{sal}})(\Lambda^p \mathcal{J}_N) = \Lambda^p G_0.} \tag{114.20}$$

The induced form is defined by

$$\langle x_1 \wedge \cdots \wedge x_p, y_1 \wedge \cdots \wedge y_p \rangle_{\Lambda^p G} = \det(\langle x_i, y_j \rangle_G)_{i,j=1}^{p}.$$

Proof. Substitute the degree-one balance into each entry of this determinant. The equality holds on decomposable vectors and extends bilinearly because these span the exterior power. □

The relevant decomposition is

$$\Lambda^p \Big(\bigoplus_a H_a \Big) \simeq \bigoplus_{\sum n_a = p} \bigotimes_a \Lambda^{n_a} H_a.$$

In the positive case, if $\mathcal{J}_{p,\mathbf{n}}$ denotes the components of that map,

$$\boxed{\|\xi\|^2 = \sum_{\sum n_a = p} \|\mathcal{J}_{p,\mathbf{n}} \xi\|^2.} \tag{114.21}$$

The purely visible, purely registered, and mixed components are preserved. For $p = 2$ and $p = 3$, the squared area and volume norms, respectively, are preserved. For an alternating or indefinite form, the exterior identity retains its bilinear interpretation.

114.4.2 Exact distribution among the exterior sectors

In the preceding Coxeter realization, $a = 19/27$ and $b = 8/27$. Normalizing T and D gives two isometries, so the component with k directions in memory has squared norm

$$\boxed{\|\mathcal{J}_{p,k} \xi\|^2 = \binom{p}{k} a^{p-k} b^k \|\xi\|^2.} \tag{114.22}$$

This is proved by exterior expansion of $x \mapsto (\sqrt{a}\, x, \sqrt{b}\, x)$. Components with distinct memory positions are orthogonal; the normalized isometries T and D preserve their norms.

For a unit-norm bivector,

Sector	Squared norm
Two directions in the reading	361/729
One direction in the reading and one in memory	304/729
Two directions in memory	64/729

The sum is one. The mixed sector contains exactly 304/729, approximately 41,7%, of the squared-area identity. In degree three, the four components are $(6859, 8664, 3648, 512)/19683$; the mixed components sum to $12312/19683$.

The law applies to $0 \le p \le 24$ on the carrier of the twelve A_2 fibres, and functorially to other generated carriers. Exterior degree, refinement resolution, the scale of a metric, and physical dimension have distinct typings. The change $G \mapsto s^2 G$, with $s > 0$, multiplies the squared norm of degree p by s^{2p}; both sides of the exterior identity transform in the same way. The realization of dimensions 10 and 11 preserves the previously specified dimensional maps.

114.4.3 Naturality and arbitrary depth

The generated refinement of histories preserves measure through

$$R\delta_h = \sum_{\epsilon \in \mathrm{Out}(h)} \sqrt{p_h(\epsilon)}\, \delta_{h\epsilon}.$$

The probabilities come from the multiplicities and normalization of the APP–TRIT–TPK emissions in section 6.4.2 y chapter 103. The register identifies the preceding state of each emission. If the transport square is $\mathcal{J}_N' R = (\bigoplus_a R_a)\mathcal{J}_N$, then

$$(\Lambda^p J_N')(\Lambda^p R) = \Lambda^p(\bigoplus R_a)(\Lambda^p J_N). \tag{114.23}$$

Apply $\Lambda^p(AB) = \Lambda^p(A)\Lambda^p(B)$. The squares of the five correlative operations and their common limit are those of propositions 6.28 y 6.29 y section 6.4.9; all act within the same construction of the continuum.

In the nonstationary positive case, chapter 113 proves $P_N^* P_N \downarrow A_\infty$ strongly, and

$$\mathcal{J} v = (A_\infty^{1/2} v, (D_n P_n v)_{n \ge 0}), \qquad \mathcal{J}^* \mathcal{J} = I.$$

By density, $\Lambda^p \mathcal{J}$ is isometric for each finite degree p. The exterior sum extends to finitely supported multi-indices over the countable Hilbert direct sum; Parseval justifies passage to the limit. The terminal component $A_\infty^{1/2}$ and the memories jointly preserve the initial form at arbitrary depth.

114.4.4 Precision of area and volume reconstruction

For the reader M, order the eleven positive eigenvalues of G, with multiplicity, as $\lambda_1 \le \cdots \le \lambda_{11}$. In degrees $1 \le p \le 11$ of $\mathbf{1}^\perp$, the singular-value decomposition induces

$$\|(\Lambda^p M)^\dagger\| = (\lambda_1 \cdots \lambda_p)^{-1/2}. \tag{114.24}$$

The exterior modes use p distinct directions. The computed spectrum gives the optimal constants $9/4$, $81/16$, $243\sqrt{6}/64$, and $2187/128$ for $p = 1, 2, 3, 4$. In degree twelve, $\Lambda^{12} M = 0$; recovery of the complete volume also incorporates the uniform charge. The tensor product of p independent readers on the zero-mean subspace has bound $(9/4)^p$. Tensoring the reader with an identity preserves the bound $9/4$. The complete register $\mathcal{J}$ has an inverse of norm one on its image in every degree.

114.5 Transport memory and relative holonomy

The reversible coupling in chapter 113 is

$$U(B, C) = \frac{1}{9} \begin{pmatrix} 8B + C & \sqrt{8}(C - B) \\ \sqrt{8}(C - B) & B + 8C \end{pmatrix} = Q^* \,\mathrm{diag}(B, C) Q,$$

with Q constant and orthogonal, fixed by the partition $8 + 1$. Hence $U(B_2, C_2)U(B_1, C_1) = U(B_2 B_1, C_2 C_1)$, preserving the order of factors. On a loop γ, let H_B, H_C be the ordered products of the two transports. The memory block of the complete evolution is

$$D_\gamma = \frac{\sqrt{8}}{9}(H_C - H_B).$$

We reconstruct exactly

$$\boxed{H_B^{-1}H_C = I + \frac{9}{\sqrt{8}}H_B^{-1}D_\gamma.} \tag{114.25}$$

The equality is operatorial: recording the response of the block on a basis recovers the complete relative holonomy. Its evaluation on a vector recovers the corresponding action. Under a chart change at the base point, both sides are conjugated. If $H_B = I$, the complement determines $H_C - I$. Memory and transport defect along a circuit are thus related; the differential realization additionally uses its connection and the limit of circuits.

114.5.1 An elliptic–parabolic loop produces hyperbolic self-scaling

The construction in proposition 10.47 contains the Coxeter operator C and the nilpotent

$$N_0 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$

on their respective carriers. Consider their realizations on a common oriented plane, using the indicated bases and the form

$$\Omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

The Coxeter element C and the transport $I + N_0$ have determinant one and preserve Ω. This chart allows them to be composed while preserving the distinction between the generators of their regimes and their own positive metrics.

Let

$$P = I + N_0 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

Since $N_0^2 = 0$, we have $P^n = I + nN_0$ for every $n \in \mathbb{Z}$. The ordered loop of four transports gives

$$H_n = C^{-1}P^{-n}CP^n = \begin{pmatrix} 1+n & n^2 \\ n & n^2 - n + 1 \end{pmatrix}. \tag{114.26}$$

For $n \neq 0$, its normalized difference is

$$F_n = \frac{H_n - I}{n} = \begin{pmatrix} 1 & n \\ 1 & n-1 \end{pmatrix}.$$

Multiplying these matrices yields, without introducing spectral values,

$$\boxed{F_n^2 = H_n, \qquad F_n^2 - nF_n - I = 0.} \tag{114.27}$$

With $H_B = I$, the memory is $D_{\gamma,n} = (\sqrt{8}/9)nF_n$. Consequently,

$$\boxed{H_n = \left(\frac{9}{n\sqrt{8}}D_{\gamma,n}\right)^2.} \tag{114.28}$$

The matrix memory response reconstructs the hyperbolic self-scale. For $n > 0$, subsequent spectral recognition identifies

$$\rho_n = \frac{n + \sqrt{n^2+4}}{2}, \quad \operatorname{Spec} F_n = \{\rho_n, -\rho_n^{-1}\}, \quad \operatorname{Spec} H_n = \{\rho_n^2, \rho_n^{-2}\}. \tag{114.29}$$

The case $n = 1$ produces the golden polynomial. The relation to the operator $F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$ generated by the calendar in (10.41) preserves the chart change:

$$F_1 = P F_{\mathrm{av}} P^{-1}, \qquad H_1 = P F_{\mathrm{av}}^2 P^{-1}. \tag{114.30}$$

The transport P, of determinant one, intertwines the two matrices and preserves Ω. The case $n = 2$ produces the spectral readings $1 + \sqrt{2}$ and $3 + 2\sqrt{2}$. The composition relates these realizations while preserving their respective genealogies; the selection of a four-factor word remains specified as part of the reader.

In the same example $n = 1$, the oriented balance is

$$D_\gamma^{\mathsf{T}} \Omega D_\gamma = -\frac{8}{81}\Omega, \qquad T_\gamma^{\mathsf{T}} \Omega T_\gamma = \frac{89}{81}\Omega. \tag{114.31}$$

The sum of the two contributions is Ω. The memory term has opposite orientation: the visible contribution $89/81$ is compensated by $-8/81$. This alternating balance and the positive allocation $19/27 + 8/27 = 1$ preserve their respective forms.

The expression for H_n holds for every $n \in \mathbb{Z}$. The definition of F_n and reconstruction through its square use $n \neq 0$; the preceding spectral parametrization uses $n > 0$. In general,

$$D_{\gamma,n}^{\mathsf{T}} \Omega D_{\gamma,n} = -\frac{8n^2}{81}\Omega, \qquad T_{\gamma,n}^{\mathsf{T}} \Omega T_{\gamma,n} = \left(1 + \frac{8n^2}{81}\right)\Omega.$$

The identities $N_0^2 = 0$ and $C^2 + C + I = 0$ prove the complete family; the supplementary program checks its exact specializations. The provenance of this additional formalization is documented in the supplement.

114.6 Symmetry, action, and conserved charge

Let $(E_n)_{n\in\mathbb{Z}}$ be finite-dimensional real vector spaces and $U_n : E_n \to E_{n+1}$ the invertible transports of the complete evolution. The cotangent lift acts on $q_n \in E_n$ and $p_n \in E_n^*$. In dual bases, define the auxiliary discrete Lagrangian

$$L_n(q_n, q_{n+1}, p_{n+1}) = p_{n+1}^{\mathsf{T}}(q_{n+1} - U_n q_n).$$

The action is used in a local sense: for each finitely supported variation, sum L_n over a finite interval containing all affected terms. The first variation is independent of any enlargement of that interval. Specifically,

$$\delta \mathcal{S} = \sum_{n\in\mathbb{Z}} \Big[\delta p_n^{\mathsf{T}}(q_n - U_{n-1} q_{n-1}) + \delta q_n^{\mathsf{T}}(p_n - U_n^{\mathsf{T}} p_{n+1}) \Big], \tag{114.32}$$

where the sum is finite for every admitted variation. Stationarity with respect to all these variations is equivalent to

$$q_{n+1} = U_n q_n, \qquad p_n = U_n^{\mathsf{T}} p_{n+1} \quad (n \in \mathbb{Z}).$$

The second equation is $p_{n+1} = U_n^{-\mathsf{T}} p_n$, that is, the cotangent lift of transport.

Proposition 114.1 (Variational charge of intertwined transport)**.** *Let $A_n \in \operatorname{End}(E_n)$ be a family satisfying*

$$A_{n+1} U_n = U_n A_n.$$

On the stationary solutions of (114.32)*, the charge*

$$\boxed{J_n = p_n^{\mathsf{T}} A_n q_n = J_{n+1}} \tag{114.33}$$

is constant.

Proof. The evolution equations and intertwining give

$$J_{n+1} = p_{n+1}^{\mathsf{T}} A_{n+1} U_n q_n = p_{n+1}^{\mathsf{T}} U_n A_n q_n = p_n^{\mathsf{T}} A_n q_n.$$

Conservation also has an explicit variational derivation. For constant parameter ε, the transformations

$$q_n \mapsto e^{\varepsilon A_n} q_n, \qquad p_n \mapsto e^{-\varepsilon A_n^{\mathsf{T}}} p_n$$

preserve every L_n, because $e^{\varepsilon A_{n+1}} U_n = U_n e^{\varepsilon A_n}$. If the parameter is replaced by a finitely supported sequence (ε_n), the first variation is

$$\delta L_n = (\varepsilon_{n+1} - \varepsilon_n) p_{n+1}^{\mathsf{T}} U_n A_n q_n.$$

On a solution, the last factor is J_n. Finite summation by parts gives

$$\delta \mathcal{S} = \sum_{n \in \mathbb{Z}} \varepsilon_n (J_{n-1} - J_n).$$

Stationarity for every finitely supported sequence produces (114.33). □

For the preceding cyclic readers, take

$$A_0 = S - S^{-1}, \qquad \mathcal{A} = \operatorname{diag}(A_0, A_0)$$

on the complete carrier $V \oplus V$. The matrix $\mathcal{A}$ commutes with $U(I, S^3)$ and $U(I, S^4)$, since its blocks are polynomials in S. Consequently, $p_n^{\mathsf{T}} \mathcal{A} q_n$ preserves an oriented correlation between neighbouring positions.

The construction specifies a Lagrangian, its symmetry, and the corresponding conserved charge, in the variational sense developed in chapter 109. Its domain is the cotangent realization of the readers. The physical action and its units retain the operators and normalizations of the corresponding constructions. The auxiliary Lagrangian is obtained after the transport U_n.

Chapter 115

Canonical realization of covariance

115.1 Canonical covariance and reciprocity of the action ellipse

The preceding construction determines two complementary invariants: the product of the semiaxes fixes the action area and their quotient preserves the anisotropy of the angular pair. We now specify the canonical realization in which these semiaxes are two standard deviations. The starting structure is the ellipse already obtained from the angular and action expressions of APP–TRIT–TPK; the operator realization is established after that construction.

In this subsection we write $\eta = \eta_{\mathrm{el}} = \operatorname{artanh}(C^*/A)$, with $|C^*/A| < 1$ and $\hbar > 0$. The angular quotient uses the same unit for both its components. In the balanced coordinates (Q, P), both of square-root-of-action dimension, we define

$$V_\eta := \frac{1}{4}\begin{pmatrix} a_S^2 & 0 \\ 0 & b_S^2 \end{pmatrix} = \frac{\hbar}{2}\begin{pmatrix} e^{\eta} & 0 \\ 0 & e^{-\eta} \end{pmatrix}. \tag{115.1}$$

This positive matrix has entries of action dimension. Its interpretation as a quantum covariance is specified by the following realization.

Proposition 115.1 (Gaussian realization of the action covariance)**.** *Consider the canonical representation on $L^2(\mathbb{R}, dQ)$, with $\widehat{Q}f(Q) = Qf(Q)$ and $\widehat{P}f(Q) = -i\hbar f'(Q)$, initially on the Schwartz space $\mathcal{S}(\mathbb{R})$. The normalized state*

$$\psi_\eta(Q) = \left(\pi\hbar e^{\eta}\right)^{-1/4} \exp\!\left(-\frac{Q^2}{2\hbar e^{\eta}}\right) \tag{115.2}$$

has zero means and covariance matrix V_η. In particular,

$$(\Delta Q)^2 = \frac{\hbar e^{\eta}}{2}, \qquad (\Delta P)^2 = \frac{\hbar e^{-\eta}}{2}, \qquad \operatorname{Cov}(Q, P) = 0, \qquad \det V_\eta = \frac{\hbar^2}{4}. \tag{115.3}$$

This realization saturates the Robertson–Schrödinger inequality.

Proof. The preceding operators are essentially self-adjoint on $\mathcal{S}(\mathbb{R})$, which is a common invariant core; on this space, $[\widehat{Q}, \widehat{P}] = i\hbar I$. For $\widehat{Y} = (\widehat{Q}, \widehat{P})$, the symmetric covariance is

$$V_{jk} = \frac{1}{2}\left\langle (\widehat{Y}_j - \langle \widehat{Y}_j \rangle)(\widehat{Y}_k - \langle \widehat{Y}_k \rangle) + (\widehat{Y}_k - \langle \widehat{Y}_k \rangle)(\widehat{Y}_j - \langle \widehat{Y}_j \rangle) \right\rangle.$$

With $s = \hbar e^{\eta} > 0$, let $I_s = \int_{\mathbb{R}} e^{-Q^2/s}\, dQ$. The product of two equal integrals, evaluated in polar coordinates, gives $I_s^2 = 2\pi \int_0^\infty r e^{-r^2/s}\, dr = \pi s$. Moreover, the integral of $\frac{d}{dQ}(Qe^{-Q^2/s})$ is zero, owing to decay at both endpoints; hence $\int_{\mathbb{R}} Q^2 e^{-Q^2/s}\, dQ = sI_s/2$. These identities and parity prove normalization, the zero mean and $\langle \widehat{Q}^2 \rangle = s/2$. Moreover, $\widehat{P}\psi_\eta = ie^{-\eta} Q\psi_\eta$. Therefore, $\langle \widehat{P} \rangle = 0$, $\|\widehat{P}\psi_\eta\|^2 = \hbar e^{-\eta}/2$ and $\operatorname{Re}\langle \widehat{Q}\psi_\eta, \widehat{P}\psi_\eta \rangle = 0$.

For any normalized state in that domain, Cauchy–Schwarz applied to $(\widehat{Q} - \langle \widehat{Q} \rangle)\psi$ and $(\widehat{P} - \langle \widehat{P} \rangle)\psi$ gives

$$(\Delta Q)^2 (\Delta P)^2 \geq \operatorname{Cov}(Q, P)^2 + \frac{1}{4}\left|\langle [\widehat{Q}, \widehat{P}] \rangle\right|^2 = \operatorname{Cov}(Q, P)^2 + \frac{\hbar^2}{4}.$$

The computed variances attain equality. Equivalently, the operator

$$a_\eta = \frac{e^{-\eta/2}\widehat{Q} + ie^{\eta/2}\widehat{P}}{\sqrt{2\hbar}}$$

satisfies $[a_\eta, a_\eta^\dagger] = I$ and $a_\eta \psi_\eta = 0$, by direct substitution. □

Proposition 115.2 (Area, dispersion, and reciprocal transport)**.** *The action ellipse is exactly the covariance sublevel set*

$$\mathcal{E}_\eta = \left\{ y = (Q,P)^{\mathsf{T}} : y^{\mathsf{T}} V_\eta^{-1} y \le 4 \right\} = \left\{ \frac{Q^2}{a_S^2} + \frac{P^2}{b_S^2} \le 1 \right\}. \tag{115.4}$$

Its area is $h = 2\pi\hbar$, its semiaxes are $a_S = 2\Delta Q$, $b_S = 2\Delta P$, and

$$\frac{\Delta P}{\Delta Q} = e^{-\eta} = \frac{b_S}{a_S} = R_{\mathrm{el}}^2. \tag{115.5}$$

The canonical rotation J_2 of Section 24.3 transports V_η to $V_{-\eta}$ and preserves the symplectic form.

Proof. Inverting the diagonal matrix (115.1) gives (115.4). Its semiaxes are the positive roots of four times its variances, and

$$\mathrm{Area}(\mathcal{E}_\eta) = 4\pi\sqrt{\det V_\eta} = 2\pi\hbar = h,$$

in agreement with the areal law (24.4). The ratio of the positive roots proves (115.5). If $M_\eta = \mathrm{diag}(e^{\eta/2}, e^{-\eta/2})$, then

$$V_\eta = M_\eta V_0 M_\eta^{\mathsf{T}}, \qquad M_\eta^{\mathsf{T}} J_2 M_\eta = J_2, \qquad J_2 V_\eta J_2^{\mathsf{T}} = V_{-\eta}.$$

These identities follow by multiplication. In operator terms, $(\widehat{Q}', \widehat{P}') = (-\widehat{P}, \widehat{Q})$ preserves $[\widehat{Q}', \widehat{P}'] = i\hbar I$. The permutation $S_2 : (Q,P) \mapsto (P,Q)$ also exchanges the variances but reverses the sign of the commutator and of the symplectic form. Thus covariance transport respects the distinction between canonical reciprocity and orientation reversal already established in Section 24.3. □

115.1.0.1 Position, momentum, and dimensional transduction.

Let $\lambda_{xp} > 0$ be a factor of the dimensional chart, with the dimension of momentum per unit length. The transformation

$$Q = \sqrt{\lambda_{xp}}\, x, \qquad P = \frac{p_x}{\sqrt{\lambda_{xp}}}$$

realizes the balanced pair as a position x and its conjugate momentum p_x; it preserves $dQ \wedge dP = dx \wedge dp_x$ and $[\widehat{x}, \widehat{p}_x] = i\hbar I$. By transformation of covariance,

$$V_\eta^{(x,p_x)} = \frac{\hbar}{2} \begin{pmatrix} e^\eta/\lambda_{xp} & 0 \\ 0 & \lambda_{xp} e^{-\eta} \end{pmatrix}, \qquad \Delta x\, \Delta p_x = \frac{\hbar}{2}, \qquad \frac{\Delta p_x}{\Delta x} = \lambda_{xp} e^{-\eta}. \tag{115.6}$$

The dispersion ratio acquires the dimension of momentum per length here. By contrast, (115.5) belongs to the balanced chart. For the inductive–capacitive realization already defined, (24.13) supplies the dimensionless identity $Z_\eta / Z_* = e^{-\eta} = \Delta P / \Delta Q$. Each reading uses its declared transduction and preserves the same action determinant.

115.1.0.2 Contour energy and mean energy of the state.

The inductive–capacitive realization has Hamiltonian

$$H_\eta(Q,P) = \frac{\omega}{2}\left(e^{-\eta} Q^2 + e^{\eta} P^2 \right), \qquad \omega > 0.$$

On $\partial\mathcal{E}_\eta$, its value is $H_\eta = \hbar\omega$, by the semiaxis equations. In the quantum realization of Proposition 115.1,

$$\langle \widehat{H}_\eta \rangle_{\psi_\eta} = \frac{\omega}{2}\left(e^{-\eta} \frac{\hbar e^{\eta}}{2} + e^{\eta} \frac{\hbar e^{-\eta}}{2} \right) = \frac{\hbar\omega}{2}. \tag{115.7}$$

The two-standard-deviation contour therefore has twice the mean energy of this Gaussian state. The areal law fixes action normalization; the angular pair fixes its distribution between the two coordinates; the canonical representation and explicit state realize that distribution as covariance. Saturation of uncertainty is thus established in the realization specified by its operators and its state.

Chapter 116

Sheet return, areal–volumetric incidence and constitutive orientation

The sheet structure enters before electromagnetic quantities are evaluated. Its function is to distinguish closure of a projection, restoration of an orientation and evolution of the transported register. These operations act on related objects of different types: a projected trajectory may have closed while its lift remains on the opposite sheet; orientation may have been restored while memory preserves the two windings performed. The constitutive construction must receive this information together with the structure determining it.

116.1 Projected return and restoration of the oriented cover

Let ℓ be a return loop of a surviving extension, and let $\varepsilon : \langle \ell \rangle \to \{+1, -1\}$ be the character of its lift, with $\varepsilon(\ell) = -1$. The associated interval bundle has the presentation

$$\mathcal{M} = ([0, 1] \times [-1, 1])/(0, u) \sim (1, -u). \tag{116.1}$$

The decisive datum is the sign of transport around the specified loop. The identification of endpoints geometrically realizes that character.

Proposition 116.1 (Two closure orders)**.** *One winding of the loop closes the base and reverses the fibre orientation. Two windings restore orientation. In the angular parametrization of the boundary readout, these returns correspond, respectively, to the areal closure 2π and the volumetric closure 4π of the oriented cover.*

Proof. The equivalence relation of (116.1) identifies the terminal fibre with the initial one by $u \mapsto -u$. Composing two transports gives $u \mapsto -(-u) = u$. Parametrizing one winding of the base by 2π assigns 4π to its square. The statement concerns this lift and this readout. □

TPK memory also preserves the trajectory traversed and the register updates. The square of the sign character is the identity, but it does not impose vanishing of these updates. The spinorial representation, when used, must transport this datum through its own map.

116.2 Descent of incidence from the tritic calendar

In the primitive block $(+1, -1, 0)$, the TPK updates the arithmetic mode through $+1 : m \mapsto \Sigma$, $-1 : m \mapsto \Pi$ and $0 : m \mapsto m$. Its cyclic orbit is (Σ, Π, Π). The sheet readout assigns Σ to the areal sheet and Π to the volumetric sheet. In the basis order $(e_{\mathrm{ar}}, e_{\mathrm{vol}})$, edge incidence is represented by

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{116.2}$$

The three consecutive pairs are $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$, each with multiplicity one. The calendars of lengths 9, 27 and 108 contain 3, 9 and 36 copies of the primitive block. Their incidence matrices are therefore these multiples of F_{av}.

This construction preserves the distinction between chronological frequency and the measure of the continuation space. The former assigns weights $(1/3, 2/3)$ to the mode cycle. The latter is defined on the minimal memory-one symbolic envelope admitting exactly the preceding pairs. Its adjacency matrix is F_{av}; trajectory counts belong to that envelope.

Proposition 116.2 (Return weights of the two sheets)**.** *Let* $F_0 = 0$*,* $F_1 = 1$ *and* $F_{n+1} = F_n + F_{n-1}$*. For* $n \geq 1$*,*

$$F_{\mathrm{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}. \tag{116.3}$$

The Parry measure of this envelope assigns the sheets weights proportional to $(1, \varphi^2)$*, and the ratio of diagonal counts converges to* φ^{-2}*.*

Proof. The power formula follows by induction using the recurrence. The square of F_{av} is strictly positive. Its positive Perron vector is $(1, \varphi)$, with eigenvalue φ, since $\varphi^2 = \varphi + 1$. As the matrix is symmetric, the Parry weights are proportional to the squares of that vector's components. The other root of the characteristic polynomial is $-\varphi^{-1}$; its modulus is strictly less than φ, giving the limit of the diagonal ratios. □

Spectral identification of this incidence follows its construction from the calendar. The regional coordinate φ retains its earlier coinductive genealogy: recognition of the eigenvalue does not select the calendar.

116.3 Boundary marking and areal–volumetric ratio

Let $\Pi_{\mathrm{HMT}}(X_\infty)$ be the value of the regional closure readout already constructed. With the diagonal sheet projectors, define

$$D_\pi = \Pi_{\mathrm{HMT}}(X_\infty) P_{\mathrm{ar}} + P_{\mathrm{vol}}, \qquad \Theta_n = \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}} \rangle}. \tag{116.4}$$

Volumetric normalization is unity; regional closure marks the areal return only once. Applying (116.3),

$$\Theta_n = \Pi_{\mathrm{HMT}}(X_\infty) \frac{F_{n-1}}{F_{n+1}} \longrightarrow \frac{\pi}{\varphi^2}. \tag{116.5}$$

The return ratio is determined by incidence, measure and marking. The quotient $2\pi/4\pi$, by contrast, describes the cover's two closure orders. Both relations participate in the sheet readout without replacing each other.

116.4 Transport of orientation to the constitutive channels

In a two-channel representation, let $\mathcal{R}$ be a self-adjoint involution and $\mathcal{S}$ a unitary interchange operator satisfying $\mathcal{S}\mathcal{R}\mathcal{S}^{-1} = -\mathcal{R}$. Write the angular coordinates already constructed as $x = A_{\mathrm{rad}}$ and $y = C_{\mathrm{rad}}^*$, with $x > |y|$. Then

$$B = xI + y\mathcal{R}, \qquad T = e^{-B}, \qquad \mathcal{S}T(y)\mathcal{S}^{-1} = T(-y). \tag{116.6}$$

Indeed, conjugation transforms $B(y)$ into $B(-y)$ and commutes with its convergent exponential series. The eigenvalues $q_\pm = e^{-x \mp y}$ are interchanged. To fix the response order, the chamber $x > y > 0$ is used, where $0 < q_+ < q_- < 1$. The map $(x, y) \mapsto (x, -y)$ transports it to the opposite chamber $x > -y > 0$, where $0 < q_- < q_+ < 1$. Both belong to the contractive domain $x > |y|$. On the boundary $y = 0$ the two channels coincide. Conjugation interchanges the chambers; it does not preserve the strict ordering of their labels. It acts on the projectors through $\mathcal{S}P_\pm\mathcal{S}^{-1} = P_\mp$, with $P_\pm = (I \pm \mathcal{R})/2$. This concrete map transmits orientation to the constitutive operator developed next.

Chapter 117

Discrete polarization and the tritic mode of arithmetic projections

Refinement and comparison between the APP sheets provide two complementary observations. The first follows the accumulated discrepancy between the number of transitions and the capacity acquired; the second preserves the mode of the tritic selector in the pairing of the additive and multiplicative fibres. Discrete polarization and the electronic prefactor are obtained from these respective operations. Their articulation with the vacuum requires preserving both the temporal information and the spaces on which the operators act.

117.1 Refinement discrepancy and endpoint convention

The cardinalities of the ternary block and its decimal representation fix

$$\rho = \log_{1000} 729 = \log_{10} 9, \qquad \delta = 1 - \rho = \log_{10}(10/9).$$

We have $0 < \delta < 1$. Moreover, δ is irrational: an equality $\delta = p/q$, with $q > 0$, would imply $10^{q-p} = 9^q$, which is incompatible with prime factorization. This mismatch already enters the encoding of refinement. Here its centred readout is made explicit, preserving the phase origin and the endpoint convention.

Definition 117.1 (Lower and upper encodings)**.** For $\theta \in \mathbb{R}$ and $n \in \mathbb{Z}$, define

$$z_n^{\downarrow}(\theta) = \lfloor (n+1)\delta + \theta \rfloor - \lfloor n\delta + \theta \rfloor, \tag{117.1}$$

$$z_n^{\uparrow}(\theta) = \lceil (n+1)\delta + \theta \rceil - \lceil n\delta + \theta \rceil. \tag{117.2}$$

Both take values in $\{0, 1\}$. The arrow distinguishes only the endpoint convention for the intervals; tritic orientation retains its earlier definition.

The lower encoding coincides with the one used in the development of refinement. The upper encoding recovers the formulation of polarization using the ceiling function. The two expressions are related by an exactly determined boundary term.

Proposition 117.2 (Change of convention and boundary term)**.** *Let* $b_n(\theta) = \mathbf{1}_{\mathbb{Z}}(n\delta + \theta)$. *Then*

$$z_n^{\uparrow}(\theta) - z_n^{\downarrow}(\theta) = b_n(\theta) - b_{n+1}(\theta). \tag{117.3}$$

In particular, for $N \geq 0$*,*

$$\sum_{n=0}^{N-1} (z_n^{\uparrow} - z_n^{\downarrow}) = b_0 - b_N.$$

Proof. For every real x, $\lceil x \rceil = \lfloor x \rfloor + 1 - \mathbf{1}_{\mathbb{Z}}(x)$. Applying this identity to both endpoints of each increment gives (117.3); its sum telescopes. The irrationality of δ implies that, for fixed θ, at most one integer index satisfies $n\delta + \theta \in \mathbb{Z}$. □

With $\theta = 0$, the first upper symbol is 1 and the lower one is 0; for $n \geq 1$ they coincide. The initial term belongs to the register and is preserved when the convention is changed. The densities and discrepancy bounds are transported with that term, without modifying the TPK update or restarting the history at each phase return.

117.2 Bounded polarization and exact temporal balance

Definition 117.3 (Centred discrete polarization)**.** The polarization of the upper encoding, relative to the density δ, is

$$P_N^{\uparrow}(\theta) = \sum_{n=0}^{N-1} \big(z_n^{\uparrow}(\theta) - \delta\big), \qquad P_0^{\uparrow} = 0. \tag{117.4}$$

Its temporal increment is

$$J_N^{\uparrow}(\theta) = P_{N+1}^{\uparrow}(\theta) - P_N^{\uparrow}(\theta) = z_N^{\uparrow}(\theta) - \delta. \tag{117.5}$$

Centring separates uniform growth of density δ from phase information. Thus, $P_N^{\uparrow}$ measures an accumulated imbalance, not the total number of vacancies. The increment $J_N^{\uparrow}$ preserves the local pulse and the background relative to which it is evaluated.

Theorem 117.4 (Uniform bound and discrete temporal continuity)**.** *For $N \geq 0$ and every phase θ,*

$$P_N^{\uparrow}(\theta) = \lceil N\delta + \theta \rceil - \lceil \theta \rceil - N\delta, \qquad |P_N^{\uparrow}(\theta)| < 1. \tag{117.6}$$

For any integers $0 \leq a < b$,

$$\sum_{n=a}^{b-1} J_n^{\uparrow}(\theta) = P_b^{\uparrow}(\theta) - P_a^{\uparrow}(\theta), \qquad \left| \sum_{n=a}^{b-1} J_n^{\uparrow}(\theta) \right| < 1. \tag{117.7}$$

The density of the vacancy sequence is δ.

Proof. Summing the ceiling increments in (117.2) yields the first identity. Writing $r(x) = \lceil x \rceil - x \in [0, 1)$ gives $P_N^{\uparrow} = r(N\delta + \theta) - r(\theta)$; its absolute value is less than one. On the interval $[a, b)$, one similarly obtains $r(b\delta + \theta) - r(a\delta + \theta)$, proving the second bound, which is sharper than the sum of two individual bounds. Finally, $N^{-1} \sum_{n=0}^{N-1} z_n^{\uparrow} = \delta + N^{-1} P_N^{\uparrow} \to \delta$. □

The lower encoding admits the same proofs with $r(x)$ replaced by $\lfloor x \rfloor - x \in (-1, 0]$. In particular, $P_N^{\uparrow} - P_N^{\downarrow} = b_0 - b_N$. The bounded discrepancy previously used in the Dirichlet readouts and the present polarization therefore preserve an explicit relationship of origin and endpoints. Nor does aperiodicity introduce secular drift in this imbalance: the history can extend indefinitely while the centred discrepancy remains uniformly bounded.

117.3 Realization on the charge and time lines

To realize the balance dimensionally, specify a charge line $\mathcal{L}_Q$ with a nonzero section u_Q and an increasing sequence of times t_N on an oriented time line. With $\Delta t_N = t_{N+1} - t_N > 0$, the centred charge and the mean current of each interval are defined by

$$Q_N = P_N^{\uparrow} u_Q, \qquad I_N = \frac{Q_{N+1} - Q_N}{\Delta t_N} = \frac{u_Q}{\Delta t_N} \big(z_N^{\uparrow} - \delta\big). \tag{117.8}$$

Thus, $Q_N \in \mathcal{L}_Q$ and $I_N \in \mathcal{L}_Q \otimes \mathcal{L}_T^{-1}$. The section u_Q and the time intervals are data of this realization; the preceding arithmetic construction has already determined $P_N^{\uparrow}$ and $J_N^{\uparrow}$.

Proposition 117.5 (Preservation of balance under dimensional realization)**.** *For $a < b$,*

$$Q_b - Q_a = \sum_{n=a}^{b-1} \Delta t_n I_n, \qquad \left| \frac{Q_b - Q_a}{u_Q} \right| < 1. \tag{117.9}$$

If all intervals have length t_0, the two possible currents are $-\delta u_Q / t_0$ and $(1 - \delta) u_Q / t_0$.

Proof. Multiplying each identity in (117.8) by Δt_n and summing telescopes the charges. The bound is (117.7); the two local values follow from $z_n^{\uparrow} \in \{0,1\}$. □

The continuity proved is temporal and refers to the centred charge. A spatial realization also incorporates the localization of charges, incidence between cells, and identification of boundary fluxes. In a constitutive description by channels, the coupling is specified through an excitation map $\iota : \mathcal{L}_Q \to \mathcal{H}_{\mathrm{ch}} \otimes \mathcal{L}_Q$ and an observation map $\ell : \mathcal{H}_{\mathrm{ch}} \otimes \mathcal{L}_Q \to \mathcal{L}_Q$, where $\mathcal{H}_{\mathrm{ch}}$ is a real realization of the channel space. If both are linear and independent of the time index, the response of a fixed operator $\mathcal{V}$ is transported by

$$Q_N^{\mathrm{resp}} = \ell(\mathcal{V} \otimes I_{\mathcal{L}_Q})\iota(Q_N), \qquad I_N^{\mathrm{resp}} = \frac{Q_{N+1}^{\mathrm{resp}} - Q_N^{\mathrm{resp}}}{\Delta t_N}.$$

Linearity preserves the telescoping balance. This composition makes explicit the data of a constitutive identification: the scalar sequence determines the pulse, while ι, $\mathcal{V}$, and ℓ determine its excitation, transport, and observation through channels. Identities (117.4)–(117.9) establish the first construction independently of that choice of realization. The vacuum operator is constructed in Section 118 on its own channels and projectors.

117.4 Pairing the additive and multiplicative fibres

The second observation comes from the three-dimensional realization of APP, $\mathcal{A}_3 = D_9^3$, with uniform measure and $D_9 = \{1, \dots, 9\}$. The observables preserved are

$$\Sigma(x) = \rho_9(x_1 + x_2 + x_3), \qquad \Pi(x) = \rho_9(x_1 x_2 x_3),$$

where $\rho_9(n) = 1 + [(n-1) \bmod 9]$ for $n > 0$. In $\ell^2(\mathcal{A}_3)$, let $P_{\Sigma,3}$ and $P_{\Pi,3}$ be the conditional expectations on their fibres. For example,

$$(P_{\Sigma,3} f)(x) = \frac{1}{|\Sigma^{-1}(\Sigma(x))|} \sum_{y:\, \Sigma(y) = \Sigma(x)} f(y).$$

They are orthogonal projections defined on the same support. The incidence matrix $N_{ab} = |\Sigma^{-1}(a) \cap \Pi^{-1}(b)|$ results from enumerating the 729 triples, adding and multiplying their coordinates before applying ρ_9:

$$N = 9 \begin{pmatrix} 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 1 & 0 & 2 & 0 & 1 & 2 & 0 & 0 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 0 & 2 & 1 & 0 & 2 & 0 & 1 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 1 & 2 & 0 & 0 & 2 & 1 & 0 & 3 \end{pmatrix}. \tag{117.10}$$

The rows sum to 81, and the column sums are

$$(m_1, \dots, m_9) = (36, 36, 108, 36, 36, 108, 36, 36, 297).$$

Therefore, the pairing of the normalized indicator functions of the fibres is $C_{ab} = N_{ab}/\sqrt{81 m_b}$. Normalization incorporates the multiplicities produced by APP, not a choice of singular values.

Proposition 117.6 (Singular mode of the tritic selector)**.** *In the canonical chart, the selector vector is* $m_{\mathrm{ph}} = (1, -1, 0)^3$. *We have*

$$Cm_{\mathrm{ph}} = C^{\mathsf{T}} m_{\mathrm{ph}} = -\tfrac{1}{2} m_{\mathrm{ph}}. \tag{117.11}$$

Thus, the corresponding singular value is $s = 1/2$.

Proof. In the six columns where m_{ph} is nonzero, $m_b = 36$ and $C_{ab} = N_{ab}/54$. Multiplying the rows of (117.10) by $(1, -1, 0)^3$ yields $-m_{\mathrm{ph}}/2$. For the transposed product, the signed sums of columns $3, 6, 9$ are zero; the other six give the same values $-m_{\mathrm{ph},b}/2$. This proves both identities and, by composition, $CC^{\mathsf{T}} m_{\mathrm{ph}} = m_{\mathrm{ph}}/4$. □

117.5 Commutator norm and electronic prefactor

Theorem 117.7 (Exact norm of arithmetic incompatibility)**.** *The two projections satisfy*

$$\left\| [P_{\Sigma,3}, P_{\Pi,3}] \right\| = \frac{\sqrt{3}}{4}. \tag{117.12}$$

The maximum is attained in the principal plane corresponding to the tritic mode of (117.11).

Proof. The rational matrix $M = CC^{\mathsf{T}}$ has entries $M_{ac} = \sum_b N_{ab} N_{cb}/(81 m_b)$. Its complete spectrum is verified through the following independent subspaces: the vectors $(1, \dots, 1)$, $(1, -1, 0)^3$, and $(1, 1, -2)^3$ have eigenvalues 1, $1/4$, and $7/132$, respectively; the subspace of vectors supported on $\{3, 6, 9\}$ whose sum is zero has dimension 2 and eigenvalue $1/18$; the zero-sum vectors supported on $\{1, 4, 7\}$ or $\{2, 5, 8\}$ form a kernel of dimension 4. Substitution into the matrix verifies these actions, and the dimensions sum to 9. Consequently,

$$\operatorname{spec} M = \{1, 1/4, 7/132, 1/18, 1/18, 0, 0, 0, 0\}.$$

For two orthogonal projections, a singular value $s \in (0, 1)$ of the pairing determines a principal plane in which their matrices are

$$P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad Q = \begin{pmatrix} s^2 & s\sqrt{1 - s^2} \\ s\sqrt{1 - s^2} & 1 - s^2 \end{pmatrix}.$$

This form is obtained by taking a unit vector u in the first image with $PQu = s^2 u$ and completing it with $(Qu - s^2 u)/(s\sqrt{1 - s^2})$. Their commutator is $s\sqrt{1 - s^2} \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. The sectors with singular value 0 or 1 contribute zero. Therefore, the total norm is the maximum of $\sqrt{\lambda(1 - \lambda)}$ over the spectrum of M. That maximum is $\sqrt{3/16}$, attained at $\lambda = 1/4$. □

The norm is the prefactor entering the electronic composition. Its derivation preserves the three-dimensional support, the fibres, and the selector mode; scalar evaluation does not replace that structure. In particular, knowing $\sqrt{3}/4$ gives the maximum magnitude of the incompatibility, while the projectors preserve the directions in which it acts.

117.6 Quadratic defect and response of the 90/120 sectors

The tritic mode simultaneously determines

$$1 - s^2 = \frac{3}{4} = \frac{90}{120}, \qquad s = \frac{1}{2}. \tag{117.13}$$

The first expression is the quadratic defect of the APP principal plane. The last preserves the lengths of the two calendar sectors. The constitutive response uses those sectors on another object: a contractive channel $q \in (0, 1)$. Its evaluation is

$$r(q) = \frac{1 - q^{90}}{1 - q^{120}}.$$

The relationship between the sector ratio and this response can be made precise without identifying their operators.

Proposition 117.8 (Limit of the response ratio)**.** *Para* $0 < q < 1$,

$$\frac{3}{4} < r(q) < 1, \qquad \lim_{q \uparrow 1} r(q) = \frac{3}{4} = 1 - s^2. \tag{117.14}$$

Proof. With $u = q^{30} \in (0, 1)$, factoring $1 - u^3$ and $1 - u^4$ gives $r(q) = (1 + u + u^2)/(1 + u + u^2 + u^3)$. The limit at $u = 1$ is $3/4$. Moreover, $4(1 + u + u^2) - 3(1 + u + u^2 + u^3) = (1 - u)(3u^2 + 2u + 1) > 0$, and the denominator exceeds the numerator by $u^3 > 0$. This yields both inequalities. □

The exact coincidence concerns the defect of the singular mode and the limit of the sector response. In the contractive interior, the response depends on q and is strictly greater than $3/4$. The constitutive development preserves its two channels $q_\pm$ and its projectors $P_\pm$; the projectors $P_{\Sigma,3}$ and $P_{\Pi,3}$, for their part, preserve the arithmetic fibres that determined the prefactor. An operator equivalence between the two realizations requires a map between their spaces that intertwines the corresponding actions. Equations (117.11), (117.12), and (117.14) specify the shared information and keep the data of each realization visible.

Chapter 118

Constitutive operator and reconstruction of the vacuum channels

The constitutive quantities are obtained by an operation on angular transport. The starting information comprises the channels, their projectors, and the orientation distinguishing them. This organization makes it possible to follow separately the construction of the operator, the evaluation of its spectral functions, and its subsequent dimensional realization.

118.1 Positive response on two sheets

In the oriented chamber $x > y > 0$ of Section 116, let $P_{\pm} = (I \pm \mathcal{R})/2$ and $T = q_{+}P_{+} + q_{-}P_{-}$, with $0 < q_{+} < q_{-} < 1$. The incidences constructed by the calendar fix the sectors 90 and 120. The constitutive response is

$$\mathcal{V} = (I - T^{90})(I - T^{120})^{-1}. \tag{118.1}$$

This definition receives the transport arising from the TPK and preserves the sheet assignments. The response rule and its domain are an explicit part of the construction.

The quotient arises from comparing the two calendar incidences on the same transport, not from fitting four quantities separately. If $S = T^{30}$ and $\Sigma_j(S) = I + S + \cdots + S^{j-1}$, factoring $I - S^j$ gives

$$\mathcal{V}\,\Sigma_4(S) = \Sigma_3(S), \qquad \mathcal{V} = \Sigma_3(S)\Sigma_4(S)^{-1}. \tag{118.2}$$

The factors Σ_3 and Σ_4 express, respectively, the sectors $90 = 3 \cdot 30$ and $120 = 4 \cdot 30$. Since the spectrum of S is contained in $(0, 1)$, $\Sigma_4(S)$ is invertible: the completion equation determines a unique response for the fixed transport. This uniqueness concerns the declared constitutive rule and its incidences. Electromagnetic identification adds the oriented assignment of sheets and the dimensional lines specified below.

Proposition 118.1 (Decomposition and positivity)**.** *The response is well-defined and*

$$\mathcal{V} = r_{+}P_{+} + r_{-}P_{-}, \qquad r_{\pm} = \frac{1 - q_{\pm}^{90}}{1 - q_{\pm}^{120}}. \tag{118.3}$$

Its eigenvalues satisfy $3/4 < r_{-} < r_{+} < 1$ *in this chamber.*

Proof. Each coefficient $1 - q_{\pm}^{120}$ is positive. The inverse of $I - T^{120}$ is the sum of the projectors divided by those coefficients, proving (118.3). With $s = q^{30}$, one obtains

$$f(s) = \frac{1 + s + s^2}{1 + s + s^2 + s^3}, \qquad f'(s) = -\frac{s^2(3 + 2s + s^2)}{(1 + s + s^2 + s^3)^2} < 0. \tag{118.4}$$

The limits at 0 and 1 are 1 and $3/4$, respectively. Monotonicity and the channel ordering complete the proof. □

118.2 Four coordinates of a common response

Define the normalized evaluations

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2, \qquad \widehat{Z} = \frac{r_-}{r_+}, \qquad \widehat{c} = \frac{1}{r_+ r_-}. \tag{118.5}$$

The first pair preserves the quadratic responses assigned to each sheet. The product captures the common mode; the quotient distinguishes their relative orientation. The following hold exactly:

$$\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}, \qquad \frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^2, \qquad r_+ = \frac{1}{\sqrt{\widehat{Z}}\widehat{c}}, \quad r_- = \sqrt{\frac{\widehat{Z}}{\widehat{c}}}. \tag{118.6}$$

The positive roots fix the inversion. Under sheet conjugation, read relative to the fixed markings $P_\pm$, $\widehat{\varepsilon}$ and $\widehat{\mu}$ are interchanged, $\widehat{Z}$ is inverted, and $\widehat{c}$ is preserved. The response is then transported to the chamber $x > -y > 0$: the formulas remain valid, with the orderings $q_- < q_+$ and $r_+ < r_-$ reversed. Consequently, common mode and orientation are data recoverable through complementary observables.

Proposition 118.2 (Determination of the quadratic evaluations)**.** *Let $W = r_+P_+ + r_-P_-$ be a positive response on the two sheets. With the product and quotient readouts fixed,*

$$\widehat{c}^{-1} = \det W = r_+ r_-, \qquad \widehat{Z} = r_-/r_+,$$

there exists a unique positive pair $(\widehat{\varepsilon}, \widehat{\mu})$ satisfying $\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}$ and $\widehat{\mu}/\widehat{\varepsilon} = \widehat{Z}^2$. It is precisely (r_+^2, r_-^2).

Proof. Positivity permits taking roots unambiguously:

$$\widehat{\mu} = \frac{\widehat{Z}}{\widehat{c}} = \frac{r_-}{r_+} r_+ r_- = r_-^2, \qquad \widehat{\varepsilon} = \frac{1}{\widehat{Z}\widehat{c}} = \frac{r_+}{r_-} r_+ r_- = r_+^2.$$

These expressions satisfy both relations and are their only positive roots. □

Thus the squares are not two independent choices added to the channels: they are determined by the multiplicative and oriented readouts once the constitutive relations are fixed. This proposition establishes uniqueness within that system of rules. Interpreting the rules as an electromagnetic response retains its additional physical-representation content.

The determinantal readout of transport and the constitutive response must also preserve their order. For $T = e^{-xI - y\mathcal{R}}$, one has $\det T = e^{-2x}$, whereas

$$\det \mathcal{V} = f(q_+^{30}) f(q_-^{30}) = \widehat{c}^{-1}.$$

Both arise from the same two-sheet operator but evaluate different functions of its spectrum. In general, applying the determinant first and then a rational function is not equivalent to taking the determinant of that function of the operator. Keeping both eigenvalues until the response is completed preserves orientation information that an isolated determinant no longer distinguishes.

118.3 Cubic inversion and angular recovery

Theorem 118.3 (Constitutive inversion in the contractive domain)**.** *For each $r \in (3/4, 1)$, there exists a unique $s \in (0, 1)$ such that $f(s) = r$. This s is the unique root in that interval of*

$$rs^3 + (r-1)(1 + s + s^2) = 0. \tag{118.7}$$

The labeled response reconstructs $s_\pm$, $q_\pm = s_\pm^{1/30}$, and

$$x = -\frac{1}{2}\log(q_+ q_-), \qquad y = \frac{1}{2}\log\frac{q_-}{q_+}. \tag{118.8}$$

Proof. The derivative and limits in (118.4) prove that f is a decreasing bijection between the stated intervals. Multiplying $f(s) = r$ by its denominator produces (118.7). The positive root of order 30 recovers the channel. Finally, adding and subtracting $\log q_\pm = -x \mp y$ gives (118.8). □

Reconstruction preserves the sheet labels. The complete operator $\mathcal{V}$ also preserves the projectors, and the inverse function is applied by spectral calculus. Recovering two angular coordinates is an operation defined on this representation; the complete historical TPK trace preserves additional data.

The interval $r \in (3/4, 1)$ and the inverse function of this theorem belong to the internal normalization of (118.5). If coordinates expressed in another units chart are available, this normalization is first recovered through the transformation in equation (118.11); cubic inversion is then applied.

118.4 Logarithmic coordinates and refinement

Let $\mathcal{E} = \log(r_+ r_-)$ and $\mathcal{B} = \log(r_-/r_+)$. Then

$$\log \mathcal{V} = \tfrac{1}{2}\mathcal{E} I - \tfrac{1}{2}\mathcal{B}\mathcal{R}. \tag{118.9}$$

This decomposition displays the invariant and oriented components. In the amplification $\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$, normalized partial expectations satisfy $E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m$. For every polynomial p, $p(\mathcal{V}_m) = p(\mathcal{V}) \otimes I_{9^m}$; hence $E_m(p(\mathcal{V}_{m+1})) = p(\mathcal{V}_m)$. Uniform continuity extends the identity to continuous functions on the spectrum. Thus projectors, powers, and the logarithm are preserved in the stated tower.

118.5 Dimensional types of the four evaluations

With the action, charge, and velocity lines, equipped with sections u_S, u_Q, u_C, the dimensional realization reads

$$Z_{\mathrm{vac}} = \widehat{Z} u_S u_Q^{-2}, \qquad c_{\mathrm{vac}} = \widehat{c} u_C, \tag{118.10}$$

$$\mu_{\mathrm{vac}} = \widehat{\mu} u_S u_C^{-1} u_Q^{-2}, \qquad \varepsilon_{\mathrm{vac}} = \widehat{\varepsilon} u_S^{-1} u_C^{-1} u_Q^{2}. \tag{118.11}$$

Multiplying and dividing these expressions preserves $\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}} = c_{\mathrm{vac}}^{-2}$ and $\mu_{\mathrm{vac}}/\varepsilon_{\mathrm{vac}} = Z_{\mathrm{vac}}^2$. The SI chart subsequently evaluates the sections. Physical comparison requires presenting their construction and normalization alongside the evaluation; the four normalized coordinates of (118.5) retain their dimensionless type.

118.6 Reconstruction of the action shape from the constitutive response

The constitutive response and the inductive–capacitive realization receive the same angular pair constructed from APP–TRIT–TPK. The former evaluates rational functions of the two channels; the latter uses the ratio of their exponents to determine the shape of the action ellipse. Cubic inversion allows the two readouts to be composed without identifying their numerical ratios.

Let $x = A_{\mathrm{rad}}$ and $y = C^{*}_{\mathrm{rad}}$, with $x > |y|$, be the lifted coordinates already constructed, and preserve their sheet labels. Write

$$q_{\pm} = e^{-(x\pm y)}, \qquad s_{\pm} = q_{\pm}^{30}, \qquad r_{\pm} = f(s_{\pm}), \qquad f(s) = \frac{1+s+s^2}{1+s+s^2+s^3}. \tag{118.12}$$

The contractive domain gives $s_{\pm} \in (0,1)$ and $r_{\pm} \in (3/4, 1)$. In the chamber $x > y > 0$, we have $s_{+} < s_{-}$ and $r_{+} > r_{-}$; sheet interchange transports this chamber to the opposite orientation.

The image of the two normalized constitutive coordinates is the domain

$$\mathcal{U} = \left\{(z,v) \in (0,\infty)^2 : (zv)^{-1/2} \in (3/4,1), \quad (z/v)^{1/2} \in (3/4,1)\right\}. \tag{118.13}$$

Here $(z,v) = (\widehat{Z}, \widehat{c})$. The restrictions express membership of the reconstructed channels in the domain of the inversion theorem; they do not constitute a subsequent choice of their values.

Proposition 118.4 (Constitutive composition of the shape and LC impedance)**.** *For $(\widehat{Z}, \widehat{c}) \in \mathcal{U}$, let $s_{\pm} \in (0,1)$ be the unique roots of*

$$r_{\pm} s_{\pm}^3 + (r_{\pm} - 1)(1 + s_{\pm} + s_{\pm}^2) = 0, \qquad r_{+} = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \quad r_{-} = \sqrt{\frac{\widehat{Z}}{\widehat{c}}}. \tag{118.14}$$

The angular ratio, the anisotropy of the action ellipse, and the relative LC impedance are reconstructed exactly by

$$\frac{y}{x} = \frac{\log s_{+} - \log s_{-}}{\log s_{+} + \log s_{-}}, \tag{118.15}$$

$$\eta_{\mathrm{el}} = \frac{1}{2} \log \frac{\log s_{+}}{\log s_{-}}, \tag{118.16}$$

$$\frac{Z_{\mathrm{LC}}}{Z_{*}} = e^{-\eta_{\mathrm{el}}} = \sqrt{\frac{\log s_{-}}{\log s_{+}}}. \tag{118.17}$$

In the last identity, $Z_{\mathrm{LC}} = Z_{\eta_{\mathrm{el}}}$ is the impedance of the LC chart of (24.12)*.*

Proof. The cubic inversion in (118.7) uniquely determines $s_{\pm}$, because f is a decreasing bijection from $(0,1)$ onto $(3/4,1)$. Their positive roots of order 30 recover $q_{\pm}$. The identities

$$\log s_{+} = -30(x+y), \qquad \log s_{-} = -30(x-y)$$

prove (118.15) by difference and sum. Both logarithms are negative; their ratio is positive and their sum is nonzero. Therefore,

$$\frac{1}{2} \log \frac{\log s_{+}}{\log s_{-}} = \frac{1}{2} \log \frac{x+y}{x-y} = \operatorname{artanh}(y/x) = \eta_{\mathrm{el}}.$$

The relation $Z_{\eta_{\mathrm{el}}}/Z_{*} = e^{-\eta_{\mathrm{el}}}$, proved in (24.13), gives (118.17). □

The composition preserves the information needed for each reconstruction. With $\hbar$, one recovers $a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}$ and $b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}$; with the chart (ω, Z_{*}), one recovers the inductance and capacitance

already defined. Action, clock and dimensional reference accompany the form as typed data. Inverting two dimensionless coordinates does not reconstruct their units or the entire memory of the state.

Normalization enters before solving the cubic equations. If Z_{vac} and c_{vac} are received in a dimensional chart, the relations (118.11) first determine

$$\widehat{Z} = \frac{Z_{\mathrm{vac}}}{u_S u_Q^{-2}}, \qquad \widehat{c} = \frac{c_{\mathrm{vac}}}{u_C}.$$

These are the coordinates to which (118.14) applies. The reference Z_* belongs to the LC realization and is explicitly preserved in (118.17).

The two ratios are related through the channels, but evaluate different functions:

$$\widehat{Z} = \frac{f(s_-)}{f(s_+)}, \qquad \frac{Z_{\mathrm{LC}}}{Z_*} = \sqrt{\frac{\log s_-}{\log s_+}}. \tag{118.18}$$

The preceding reconstruction provides the map between the two readouts. In particular, interchanging the sheets inverts both ratios, changes η_{el} to $-\eta_{\mathrm{el}}$, and preserves $\widehat{c}$. In the symmetric limit $y = 0$, the channels coincide and both ratios equal 1. Outside that case, a common origin does not impose equality of the two functions. The action shape is recoverable from the constitutive response while preserving orientation and normalization.

118.7 Constitutive speed and kinematic realization of the clock

The constitutive response and the kinematic reader realize the same velocity section. Their identification preserves the order of construction: the APP sheets, their TRIT orientation and the angular transport published by TPK precede the velocity readings and the choice of units. In the two-sheet representation of section 116, with $x > |y|$ and rank-one projectors $P_\pm$, the transport is

$$T = e^{-xI - y\mathcal{R}} = q_+ P_+ + q_- P_-, \qquad q_\pm = e^{-x \mp y}, \qquad 0 < q_\pm < 1.$$

Its temporal blocks of lengths 90 and 120 produce the response $\mathcal{V}$ in (118.1). The coordinates x, y and the channels are outputs of the preceding angular development; this composition applies its readouts to that already constructed transport.

The symmetric logarithmic readout of temporal transport is

$$\mathcal{E} = \log\big[(1 - q_+^{90})(1 - q_-^{90})\big] - \log\big[(1 - q_+^{120})(1 - q_-^{120})\big]. \tag{118.19}$$

On the dimensional velocity line, with positive section u_C, the kinematic reader publishes $c_{\mathrm{int}} = \exp(-\mathcal{E})u_C$. The constitutive response publishes $c_{\mathrm{vac}} = \widehat{c}\,u_C$ through (118.5).

Proposition 118.5 (Constitutive and kinematic identity)**.** *In the same dimensional chart, we have*

$$c_{\mathrm{int}} = c_{\mathrm{vac}} = \widehat{c}\,u_C, \qquad \widehat{c} = (r_+ r_-)^{-1} = \exp(-\mathcal{E}). \tag{118.20}$$

The identification preserves sheet interchange.

Proof. All factors in (118.19) are positive. The logarithm law and (118.3) give

$$\mathcal{E} = \log(r_+ r_-) = \log\det\mathcal{V}, \qquad e^{-\mathcal{E}} = (\det\mathcal{V})^{-1}.$$

The determinant corresponds to the rank-one two-sheet realization. The two definitions therefore publish the same section. Exchanging the sheets permutes r_+ and r_- and preserves their product. The determinant

$\det T = e^{-2x}$ corresponds to elementary transport, whereas $\det \mathcal{V} = r_+ r_-$ corresponds to its temporal response; (118.20) uses the latter. □

118.7.1 Path length and elementary duration

The positive dimensional frame (u_S, u_C, u_T, u_Q) induces the length basis $u_L = u_C u_T$. For an enriched path γ of $n = |\gamma|$ transitions and a constant channel, the additive readers are

$$T_{\mathrm{int}}(\gamma) = n u_T, \qquad L_{\mathrm{int}}(\gamma) = n \widehat{c}\, u_L. \tag{118.21}$$

Concatenation adds the numbers of transitions and their realizations. Enriched routes also preserve their orientation and memory.

Corollary 118.6 (Normalization of the elementary length)**.** *For $n > 0$, $L_{\mathrm{int}}(\gamma)/T_{\mathrm{int}}(\gamma) = c_{\mathrm{vac}}$. In the normalization $t_0 = u_T$,*

$$\ell_0 = c_{\mathrm{int}} t_0 = \widehat{c}\, u_L. \tag{118.22}$$

In a temporal chart $t_0 = \tau_0 u_T$, with $\tau_0 > 0$, we obtain $\ell_0 = \tau_0 \widehat{c}\, u_L$.

Proof. Dividing the two expressions in (118.21) cancels n and uses $u_L/u_T = u_C$. Multiplying the speed section by t_0 proves both elementary formulas. □

When the channel depends on the edge, the readout retains the additive form $L_{\mathrm{int}}(\gamma) = \sum_{e \in \gamma} \widehat{c}(e) u_L$. Its quotient by $n u_T$ is the mean of the speeds of those edges. The constant-channel expression is the homogeneous specialization of this readout.

118.7.2 Change of chart and adapted normalization

Proposition 118.7 (Covariance of the identification)**.** *Let $u'_C = d u_C$ and $u'_T = \eta u_T$, with $d, \eta > 0$. The coordinates of the same sections satisfy*

$$\widehat{c}' = d^{-1} \widehat{c}, \qquad \tau'_0 = \eta^{-1} \tau_0, \qquad u'_L = d\eta u_L. \tag{118.23}$$

If another publication writes $c' = \widehat{c}' u'_C$ with $u'_C = d u_C$, equality of sections is exactly equivalent to $d\widehat{c}' = \widehat{c}$.

Proof. Equality of each section in the two bases gives $\widehat{c}' u'_C = \widehat{c} u_C$ and $\tau'_0 u'_T = \tau_0 u_T$. In particular,

$$\tau'_0 \widehat{c}' u'_L = \frac{\tau_0}{\eta} \frac{\widehat{c}}{d} d\eta u_L = \tau_0 \widehat{c} u_L = \ell_0.$$

The final equivalence follows from the same substitution for speed. □

The adapted choice $d = \widehat{c}$ gives $u'_C = c_{\mathrm{vac}}$ and $\widehat{c}' = 1$: it expresses the constructed section in an adapted basis. The coefficient of the internal chart remains $(r_+ r_-)^{-1}$, and this is the normalization used by cubic inversion. Keeping the action and charge bases, (118.11) produces

$$\widehat{\mu}' = d\widehat{\mu}, \qquad \widehat{\varepsilon}' = d\widehat{\varepsilon}, \qquad \widehat{\mu}'\widehat{\varepsilon}' = (\widehat{c}')^{-2}.$$

In the adapted chart, we have $\widehat{\mu}' = r_-/r_+$ and $\widehat{\varepsilon}' = r_+/r_-$, by substitution of $\widehat{\mu} = r_-^2$ and $\widehat{\varepsilon} = r_+^2$.

118.7.3 Preservation of the readout under amplification

For the refinement $\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$, the normalized trace $\tau_m = \mathrm{Tr}/(2 \cdot 9^m)$ satisfies

$$\exp[-2\tau_m(\log \mathcal{V}_m)] = \exp[-\log r_+ - \log r_-] = \widehat{c}. \tag{118.24}$$

Indeed, each eigenvalue appears 9^m times; that multiplicity cancels against the denominator of the normalized trace. The ordinary amplified determinant is $(r_+ r_-)^{9^m}$. The two-sheet normalization, equivalently expressed by (118.24), preserves the constitutive readout during amplification. This realization preserves the enriched transport from which it originates.

Chapter 119

Charge section and electrical quantization relations

The constitutive response establishes a relation between the two sheets and a relative propagation scale. The charge section is obtained by composing this response with the fine-structure constant and the action, both constructed in the preceding chapters. This order has a precise consequence: charge does not retrospectively determine the dodecaphase record. It is the record, together with the action and the vacuum response, that determines the charge section on the corresponding line.

119.1 Positive determination of the charge section

Consider the positive sections $\hbar_a$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$, and $h_a = 2\pi\hbar_a$. The impedance Z_{vac} has already been constructed through (118.11). The quotient h_a/Z_{vac} belongs to the quadratic charge line. This dimensional compatibility allows the following definition to be formulated without yet choosing an SI chart.

Definition 119.1 (Positive charge section)**.** The charge section corresponding to action orientation a is

$$e_a = \left(\frac{2\alpha h_a}{Z_{\mathrm{vac}}}\right)^{1/2}. \tag{119.1}$$

The root is taken on the positive charge half-line. Its conjugate section is $-e_a$; the sign of the latter is not identified with the action return index.

Proposition 119.2 (Existence, uniqueness, and compatibility of the coupling)**.** *The equation $Z_{\mathrm{vac}} e_a^2 = 2\alpha h_a$ determines a unique positive section. In the constitutive realization, one also has*

$$\alpha = \frac{Z_{\mathrm{vac}} e_a^2}{2h_a} = \frac{e_a^2}{4\pi\varepsilon_{\mathrm{vac}}\hbar_a c_{\mathrm{vac}}}. \tag{119.2}$$

Proof. Positivity of α, h_a, and Z_{vac} guarantees a unique positive root. The constitutive identities give $\varepsilon_{\mathrm{vac}} c_{\mathrm{vac}} = Z_{\mathrm{vac}}^{-1}$. Substituting this equality and $h_a = 2\pi\hbar_a$ into the first expression of (119.2) yields the second. □

The last expression is the usual form of electromagnetic coupling in a physical chart. Here it appears as a subsequent identity of the constructed sections. The proof does not recalculate α from a measured charge: it establishes the algebraic consistency of the preceding result with the section just defined. Physical identification additionally requires retaining the chart of units and the coupling regime used in the comparison. An identity between quantities and an experimental comparison have different functions in that recognition.

119.2 Resistance, conductance, flux, and frequency

The following four quantities use the same section e_a. Their dependencies can be fully resolved before any decimal is evaluated.

Theorem 119.3 (Composition of the electrical quanta)**.** *The sections*

$$R_K = \frac{h_a}{e_a^2} = \frac{Z_{\mathrm{vac}}}{2\alpha}, \qquad G_0 = \frac{2e_a^2}{h_a} = \frac{4\alpha}{Z_{\mathrm{vac}}}, \tag{119.3}$$

$$\Phi_{0,a} = \frac{h_a}{2e_a} = \sqrt{\frac{h_a Z_{\mathrm{vac}}}{8\alpha}}, \qquad K_{J,a} = \frac{2e_a}{h_a} = \Phi_{0,a}^{-1} \tag{119.4}$$

satisfy exactly

$$R_K G_0 = 2, \qquad G_0 Z_{\mathrm{vac}} = 4\alpha, \qquad K_{J,a}\Phi_{0,a} = 1, \qquad K_{J,a}^2 R_K = \frac{4}{h_a}. \tag{119.5}$$

Proof. Substituting $e_a^2 = 2\alpha h_a / Z_{\mathrm{vac}}$ into the first two definitions cancels h_a and gives (119.3). Squaring the positive section $h_a/(2e_a)$ gives $h_a Z_{\mathrm{vac}}/(8\alpha)$; positivity fixes the root in (119.4). Its inverse is $2e_a/h_a$. The first three products in (119.5) reduce, respectively, to 2, 4α, and 1. Finally, $(4e_a^2/h_a^2)(h_a/e_a^2) = 4/h_a$. □

The physical realization recognizes in these sections the von Klitzing resistance, the conductance quantum, the flux quantum, and the Josephson constant. The factor 2 in the conductance belongs to the normalization of the quantity defined here; identifying it with a multiplicity of channels in a material system requires specifying that representation. The four equations do not constitute four independent generators: they share α, the action, and the vacuum response. Precisely this dependency produces the cross-identities and makes it possible to check an evaluation without altering the operations from which it arose.

119.3 Action return and transport of the sections

The quotient $R_{\mathrm{act}} = h_{\mathrm{pre}}/h_{\mathrm{ret}}$, obtained before the angular pair, preserves the distinction between the two action sections. It does not change the sheet assignments of the constitutive response. These are two distinct operations: action return and channel interchange.

Proposition 119.4 (Covariance under return)**.** *With common α and Z_{vac}, one has*

$$\frac{e_{\mathrm{pre}}}{e_{\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad R_K^{\mathrm{pre}} = R_K^{\mathrm{ret}}, \qquad G_0^{\mathrm{pre}} = G_0^{\mathrm{ret}}, \tag{119.6}$$

$$\frac{\Phi_{0,\mathrm{pre}}}{\Phi_{0,\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad \frac{K_{J,\mathrm{pre}}}{K_{J,\mathrm{ret}}} = R_{\mathrm{act}}^{-1/2}. \tag{119.7}$$

Proof. The first identity follows by dividing the two versions of (119.1) and taking the positive root. In (119.3), the action has already cancelled. The other two identities follow from the powers $h_a^{1/2}$ and $h_a^{-1/2}$ in (119.4). □

Resistance and conductance preserve the constitutive quotient, whereas flux and frequency also retain the action orientation. This separation gives a structural reading of their dependencies: some quantities are invariants of the sheet quotient, while others additionally measure the action section used. The metrological comparison must specify which section it evaluates; the numerical proximity of the two actions does not authorize their identification.

Chapter 120

Hexadic–octadic incidence and the Barbero–Immirzi functional

Let $H \hookrightarrow O$ be the marked inclusion of a hexad in an octad, $|H| = 6$, $|O| = 8$, constructed through the binary residue of Section 21.68. The hexad, dodecad and regional chart determining that inclusion are preserved. The incidence objects

$$\mathcal{F}_6 = H \times \binom{H}{2}, \qquad \mathcal{F}_8 = O \times \binom{H}{2}$$

have cardinalities 90 and 120. Their normalized difference gives

$$\frac{|\mathcal{F}_6| - |\mathcal{F}_8|}{24\binom{6}{2}} = -\frac{1}{12}.$$

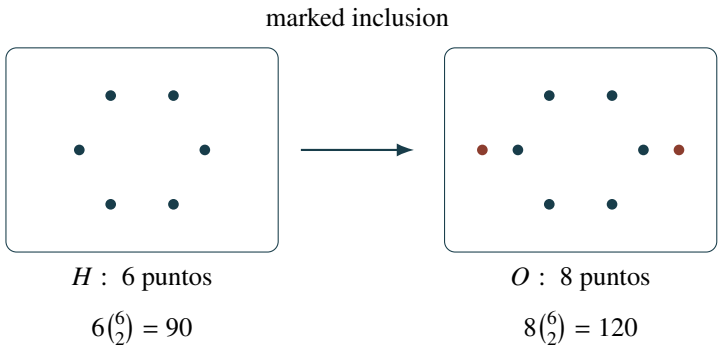

Figure 120.1: Marked incidence from six to eight points. The drawing represents the sets and inclusion; it does not attempt to turn the faces or vertices of a cube into Steiner blocks without their incidence map.

120.1 Dodecaphase fundamental chain and pole coefficient

In the free module of oriented events, fix the fundamental chain of the revolution

$$c_{12}^{+} = \sum_{j \in \mathbb{Z}/12\mathbb{Z}} [j, \mathcal{F}_6] - [\partial_{\mathrm{ret}}, \mathcal{F}_8].$$

Multiplicity twelve corresponds to the sectors and multiplicity one to the oriented seam. The involution reverses orientation of the complete chain. Let

$$S_m(q) = \frac{q^m}{1 - q^{3m}}, \qquad 0 < q < 1.$$

The linear reader assigns S_{90} to every sector and S_{120} to the seam; consequently,

$$\mathscr{R}(c_{12}^{+}) = 12 S_{90} - S_{120}.$$

Definition 120.1 (Oriented evaluation of hexadic–octadic incidence)**.** The parameter γ_{HMT} is the conjugate evaluation of the chain c_{12}^{+}, completed by its angular component. On the domain $0 < q_{\pm} < 1$, it is defined by

$$\gamma_{\mathrm{HMT}} = \frac{\pi A C^{*}}{180} + [\mathscr{R}(c_{12}^{+})](q_{-}) - [\mathscr{R}(c_{12}^{+})](q_{+}).$$

The marked incidence determines the event spaces; the oriented chain fixes the multiplicities, and the channels of Section 14.26 determine the evaluation.

Theorem 120.2 (Pole coefficient and conjugate evaluation)**.** *The image of the fundamental chain has coefficient* $1/24$ *relative to* $(1-q)^{-1}$ *and residue* $-1/24$ *relative to* $(q-1)^{-1}$*. Its evaluation on the previously generated channels determines*

$$\gamma_{\mathrm{HMT}} = \frac{\pi A C^{*}}{180} + 12\big[S_{90}(q_{-}) - S_{90}(q_{+})\big] - \big[S_{120}(q_{-}) - S_{120}(q_{+})\big]. \tag{120.1}$$

Proof. The factorization $1-q^{3m} = (1-q)\sum_{j=0}^{3m-1} q^{j}$ implies $\lim_{q\uparrow 1}(1-q)S_m(q) = 1/(3m)$. By linearity,

$$\frac{12}{270} - \frac{1}{360} = \frac{1}{24}.$$

The coordinate $q-1$ reverses the sign of the residue. The conjugate evaluation and the angular component of Definition 120.1 yield (120.1). □

The Diophantine certificate $4a-3b=45$ admits the pairs $(12+3t, 1+4t)$, $t \geq 0$; it certifies minimality of $(12,1)$ but does not replace the origin of multiplicities in the chain. The evaluation of (120.1) is

$$\gamma_{\mathrm{HMT}} = 0.27400767269445927474725526077398041940\ldots.$$

This numerical value is an output of the oriented functional, rather than an external value used to select A, C^{*}, or their coefficients.

120.2 Parity and structural sensitivity

Reversing C^{*} exchanges q_{+} and q_{-} and changes the sign of the angular component. Therefore

$$\gamma_{\mathrm{HMT}}(A, -C^{*}) = -\gamma_{\mathrm{HMT}}(A, C^{*}).$$

The functional preserves orientation, whereas other readers, such as $q_{+}q_{-}$, are even. This difference precedes its physical interpretation.

Chapter 121

Action, gravity, and thermal information

121.1 Dodecaphasic period and circular realization of action

The already constructed calendar determines $T_{108} = 108t_0$. The constitutive speed, duration and trajectory length are obtained through the identities of Proposition 118.5 and equations (118.21) and (118.22). In its circular realization,

$$\omega_{108} = \frac{2\pi}{108t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0, \qquad \ell_0 = c_{\mathrm{int}}t_0.$$

The unit ℓ_0 and the time and velocity charts remain explicit; the SI chart does not select the cycle. For each oriented action section $a \in \{\mathrm{pre}, \mathrm{ret}\}$,

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2}.$$

The reduced and full lengths are, respectively,

$$\frac{\hbar_a}{m_{108,a}c_{\mathrm{int}}} = R_{108}, \qquad \frac{h_a}{m_{108,a}c_{\mathrm{int}}} = 2\pi R_{108}.$$

The same action and duration enter into both readings.

Proposition 121.1 (Radius-coincidence selector)**.** *In the dimensional family*

$$G_a(\vartheta) = \vartheta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}, \qquad \vartheta > 0,$$

the circular-realization condition $G_a(\vartheta)m_{108,a}/c_{\mathrm{int}}^2 = R_{108}$ has the unique solution

$$\vartheta_{108}^{\circ} = (54/\pi)^2.$$

Proof. The first radius is $r_g(\vartheta) = \vartheta(\pi/54)\ell_0$. Comparing it with $(54/\pi)\ell_0$, with $\ell_0 > 0$, reduces the equality to a strictly increasing linear equation. □

The coincidence condition is an explicit part of this realization; the theorem solves for its coefficient without using a metrological value of G. The radius used here is Gm/c^2, so the factor two from the convention $2Gm/c^2$ is not inadvertently transferred.

Proposition 121.2 (Reciprocal action and gravity, conserved area)**.** *In the two preceding charts,*

$$\frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad \hbar_a G_a = \vartheta_{108}^{\circ} c_{\mathrm{int}}^5 t_0^2, \qquad \ell_P^2 = \frac{\hbar_a G_a}{c_{\mathrm{int}}^3} = \vartheta_{108}^{\circ}\ell_0^2.$$

Proof. The definition of G_a contains $\hbar_a^{-1}$ and the remaining factors are common to the two charts. Taking the quotient and the product gives the three equalities. □

This reciprocity explains why orientation information can vary without changing the area. A precise relation is thus available between the reciprocal action sections, the Planck scale and the areal operator of Section 122.

Chapter 122

Area operator and reconstruction of sectorial information

Regrouping six trits constructs a bijection between $(\mathbb{Z}/9\mathbb{Z})^3$ and $(\mathbb{Z}/27\mathbb{Z})^2$, both of cardinality 729. The bijection is not presented as an additive isomorphism. On a 9×9 boundary block, the source decomposes 36 links into two sets of 18, labeled by channels 90 and 120.

122.1 Tritic regrouping and boundary incidence

The correspondence preserves an ordered word, in addition to its cardinality. Write each coordinate $x_j \in \mathbb{Z}/9\mathbb{Z}$, for $j = 1, 2, 3$, through its unique positional representatives $x_j = r_{2j-1} + 3r_{2j}$, with $r_k \in \{0, 1, 2\}$. The map is

$$\beta_{729}(x_1, x_2, x_3) = \big(r_1 + 3r_2 + 9r_3,\ r_4 + 3r_5 + 9r_6\big) \in (\mathbb{Z}/27\mathbb{Z})^2. \tag{122.1}$$

Proposition 122.1 (Positional correspondence between interior and boundary)**.** *The map β_{729} is bijective and preserves the order of the six trits. Its inverse extracts the two triples of digits and regroups them into three pairs.*

Proof. The positional expansion of the representatives $0, \dots, 8$ and $0, \dots, 26$ is unique. Extracting the six digits, regrouping them, and extracting them again returns the same word. The inverse operation thus restores each of the three initial coordinates. □

Carry preserves its position in the enriched word. The additive operations of the two packagings have different boundaries: for example, $\beta_{729}(0, 2, 0) = (18, 0)$ and $\beta_{729}(0, 1, 0) = (9, 0)$, whose sum in the order-twenty-seven torus is $(0, 0)$, whereas $\beta_{729}(0, 3, 0) = (0, 1)$. This distinction allows the positional correspondence to be reused while keeping the operations typed.

In the torus $(\mathbb{Z}/27\mathbb{Z})^2$, the block $B_\partial = \{0, \dots, 8\}^2$ has the oriented link sets

$$\partial B_{90} = \{((-1, j), (0, j)),\ ((8, j), (9, j)) : 0 \le j \le 8\}, \tag{122.2}$$

$$\partial B_{120} = \{((i, -1), (i, 0)),\ ((i, 8), (i, 9)) : 0 \le i \le 8\}. \tag{122.3}$$

All coordinates are read modulo twenty-seven. Each system contains eighteen links and the two systems are disjoint. Their labels preserve the incidence channels; the cardinality of the links is $18 + 18$.

Theorem 122.2 (Minimum capacity of the cubic cut)**.** *In the cubic graph with vertices $\{0, \dots, N-1\}^3$, with $N \ge 2$, links between neighbors, and unit capacity per link, the minimum cut between two opposite faces has capacity N^2. For $N = 9$, a maximally mixed product state on the trits of a minimum layer has information*

$$\mathrm{cap}_{\min} = 81, \qquad s_{\mathrm{corte}} = 81 \log 3. \tag{122.4}$$

Proof. The N^2 lines parallel to the normal of the faces form edge-disjoint paths. Every separating cut intercepts each path, so it contains at least N^2 links. The links crossing a transverse layer constitute a cut of that cardinality. Each uniform trit contributes $\log 3$ nats; entropy is additive for the product state of the eighty-one trits of the layer. □

The capacity of the cubic cut and the state of the thirty-six links in (122.3) belong to observables defined on different cuts. The genealogy preserves both domains and their measures.

122.2 Transport of the collective incidence modes

The spaces $\mathcal{F}_6$ and $\mathcal{F}_8$ of Section 120 provide the uniform vectors

$$u_{90} = \frac{1}{\sqrt{90}} \sum_{f \in \mathcal{F}_6} (\delta_f, 0), \qquad u_{120} = \frac{1}{\sqrt{120}} \sum_{f \in \mathcal{F}_8} (0, \delta_f)$$

in $\ell^2(\mathcal{F}_6) \oplus \ell^2(\mathcal{F}_8)$. In $\ell^2(\partial B_{90}) \oplus \ell^2(\partial B_{120})$, construct

$$v_{90} = \frac{1}{\sqrt{18}} \sum_{e \in \partial B_{90}} (\delta_e, 0), \qquad v_{120} = \frac{1}{\sqrt{18}} \sum_{e \in \partial B_{120}} (0, \delta_e).$$

The two pairs are orthonormal. Denote their respective spanned planes by $\mathscr{H}_{\mathrm{inc}}^{\mathrm{coll}}$ and $\mathscr{H}_{\partial}^{\mathrm{coll}}$.

Theorem 122.3 (Collective intertwining of the sectorial labels)**.** *There is a unique surjective linear isometry between these planes such that*

$$\mathcal{J}_{6\to 8} u_m = v_m \quad (m = 90, 120). \tag{122.5}$$

For the operators

$$D_{\mathrm{inc}} = 90|u_{90}\rangle\langle u_{90}| + 120|u_{120}\rangle\langle u_{120}|,$$
$$D_{\partial} = 90|v_{90}\rangle\langle v_{90}| + 120|v_{120}\rangle\langle v_{120}|,$$

we have

$$\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\partial} \mathcal{J}_{6\to 8}. \tag{122.6}$$

The sectorial projectors and their oriented combination with coefficients $12 : -1$ *are also transported.*

Proof. The image of a basis fixes the unique linear map. Norms and inner products are preserved because both bases are orthonormal. Identity (122.6) holds on each vector u_m, since its two sides are $m v_m$. The projectors are expressed as $(120I - D)/30$ and $(D - 90I)/30$; their linear functional calculus and any combination of the two preserve intertwining. □

This transport acts on the two uniform modes and their spectral labels. Individual incidences and fluctuations within each sector remain in their complete spaces. The link preserves exactly the collective datum that the areal weighting will use.

122.3 Angular character and area operator

Let $N_e = \mathrm{diag}(0, 1, 2)$ on each link, and let N_{90}, N_{120} be the sector sums. With the scale

$$\theta_{\mathrm{clk}} = \frac{C^*}{6} \frac{\pi}{180}, \qquad a_0 = \frac{1 + 2\cos(10^\circ)}{3} \theta_{\mathrm{clk}},$$

fixed, the angular factor is the normalized real character of the triplet

$$\chi_{10} = \frac{1}{3} \operatorname{Tr} \mathrm{diag}(1, e^{i\pi/18}, e^{-i\pi/18}) = \frac{1 + 2\cos(10^\circ)}{3}, \qquad a_0 = \chi_{10} \theta_{\mathrm{clk}}. \tag{122.7}$$

The sum of the conjugate phases proves the equality. On the positive branch considered, $\theta_{\mathrm{clk}} > 0$, $\chi_{10} > 0$, and $\gamma_{\mathrm{HMT}} > 0$; hence a_0 and the areal scale are positive. The angular triplet and its normalization precede the entropic distribution on the links. With these quantities, the normalized area operator is

$$\widehat{\mathcal{A}}/\ell_P^2 = \gamma_{\mathrm{HMT}} a_0 (N_{90} + N_{120}).$$

Its spectrum has values $n\gamma_{\mathrm{HMT}}a_0$, $0 \le n \le 72$, with multiplicities given by $(1 + z + z^2)^{36}$. The proof consists in summing the eigenvalues $0, 1, 2$ of the 36 tensor factors.

Theorem 122.4 (Recovery of the boundary sectors)**.** *Let*

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}.$$

Then

$$N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N. \tag{122.8}$$

Thus the total and the weighted reader jointly recover the two occupations.

Proof. La matriz $\left(\begin{smallmatrix} 1 & 1 \\ 90 & 120 \end{smallmatrix}\right)$ has determinant 30. Its inversion gives (122.8). On the domain of integer occupations, the image satisfies $D \in 30\mathbb{Z}$ and $90N \le D \le 120N$. □

The modular Hamiltonian of the source is $K_A = -\log \rho_A = cI + \Delta_{\mathrm{mod}} D$. For $\Delta_{\mathrm{mod}} \neq 0$ and known normalization, $D = (K_A - cI)/\Delta_{\mathrm{mod}}$ publishes the second observable. This operator describes the spectral structure of the reduced state; it is not identified by notation with the generator of time evolution. The area preserves the total occupation and the pair adds the provenance. For example, $(N_{90}, N_{120}) = (1, 0)$ and $(0, 1)$ share $N = 1$, but have $D = 90$ and $D = 120$.

122.4 State normalization and the meaning of the modular Hamiltonian

The second observable is made explicit through the state that defines it. The preceding tensor decomposition is retained: eighteen qutrits per sector, each with number operator $\mathrm{diag}(0, 1, 2)$; N_m is the sum of these operators and the sectors act on distinct factors. Let

$$z_m = 1 + e^{-m\Delta_{\mathrm{mod}}} + e^{-2m\Delta_{\mathrm{mod}}}, \qquad m \in \{90, 120\}.$$

The family of source states has the product realization

$$\rho_A = Z^{-1} e^{-\Delta_{\mathrm{mod}}(90N_{90} + 120N_{120})}, \qquad Z = z_{90}^{18} z_{120}^{18}.$$

Commutativity of the number operators and tensor factorization prove the expression for Z. The state has full rank for real, finite Δ_{mod}, and its spectral logarithm gives

$$K_A = -\log \rho_A = (\log Z) I + \Delta_{\mathrm{mod}} D.$$

For $\Delta_{\mathrm{mod}} \neq 0$, K_A weights the excitations of the two sectors differently. Joint reading with N recovers the two occupations by equation (122.8).

The need for joint reading is seen in two complementary examples. The occupation states $(1, 0)$ and $(0, 1)$ have the same total $N = 1$ and different modular weights. Conversely, $(4, 0)$ and $(0, 3)$ have the same $D = 360$ and different totals. The pair (N, D) distinguishes both cases. This recovery concerns sectoral occupations, not each microscopic vector within a degeneracy of those occupations.

When $\Delta_{\mathrm{mod}} = 0$, the state is proportional to the identity and K_A is scalar: that reading ceases to distinguish the sectors. For $\Delta_{\mathrm{mod}} \neq 0$, the known normalization allows one to recover D and compose it with the area. The role of the modular Hamiltonian is thereby defined: it characterizes the reduced state and its information distribution. Its inclusion in the article is motivated by that mathematical function, whereas the evolution Hamiltonian belongs to the dynamical development of the action.

122.5 Reduced state, Schmidt decomposition, and entanglement entropy

If $\rho_A = \sum_\nu p_\nu |\nu\rangle\langle\nu|$, the purification

$$|\Psi\rangle = \sum_\nu \sqrt{p_\nu}\, |\nu\rangle_A |\nu\rangle_B$$

satisfies $\mathrm{Tr}_B\, |\Psi\rangle\langle\Psi| = \rho_A$. Thus $-\mathrm{Tr}(\rho_A \log \rho_A)$ is the entanglement entropy of this particular pure bipartition. The enlarged state declares which system carries that interpretation.

For a two-sheet involution with one eigenvector of each sign,

$$\rho_y = \frac{e^{-yR}}{2\cosh y}, \qquad R^2 = I,$$

diagonalization gives

$$S(\rho_y) = \log(2\cosh y) - y\tanh y, \qquad D(\rho_y \| \rho_{-y}) = 2y\tanh y.$$

Entropy is even in y; the distance explicitly compares the two orientations. This two-level entropy is not identified with the capacity $81\log 3$ of the triadic cut.

Chapter 123

Genealogical memory, informational reduction and thermal transduction

The thermal construction uses two publications of the same APP–TRIT–TPK development. The first preserves the states, admissible routes and register information; the second provides the oriented action and the duration of the return. Their composition determines an energy per tritic decision. The temperature and energy coordinates are subsequently introduced through explicit dimensional maps. This sequence allows one to identify what information is preserved, what information a reader publishes and what quantity converts that information into dimensional entropy.

123.1 Reader, memory, and state recovery

Fix a finite level of the development and denote by Ω the set of admissible enriched states. The register preserves sheet, orientation, residue, quotient, carry, route, phase and memory in the domains where each coordinate enters. Let

$$q : \Omega \longrightarrow Y, \qquad M : \Omega \longrightarrow \mathcal{M}$$

be the visible publication and the retained memory, respectively. For a distribution p over Ω, we write $\mathsf{H}(p) = -\sum_x p_x \log p_x$, with $0 \log 0 = 0$. The logarithm is applied to dimensionless probabilities.

Definition 123.1 (Genealogical recovery of a publication)**.** The pair $\widehat{q} = (q, M)$ is a recoverable reader on the support Ω_p when there exists

$$d : \widehat{q}(\Omega_p) \longrightarrow \Omega_p, \qquad d \circ \widehat{q} = \mathrm{id}_{\Omega_p}.$$

The fibre information of q is $\mathsf{H}_{\mathrm{fib}}(q; p) = \mathsf{H}(X \mid q(X))$, where X has law p.

Proposition 123.2 (Recovery identity and cost of reduction)**.** *For a recoverable reader,*

$$\mathsf{H}(X \mid q(X), M(X)) = 0, \tag{123.1}$$

$$\mathsf{H}(X) = \mathsf{H}(q(X)) + \mathsf{H}(X \mid q(X)), \tag{123.2}$$

$$\mathsf{H}(X \mid q(X)) = \mathsf{H}(M(X) \mid q(X)). \tag{123.3}$$

Proof. The map d recovers X from the pair $(q(X), M(X))$, so the first conditional entropy is zero. Since q is a function of X, the chain rule gives the second equality. For the third, expand $\mathsf{H}(X, M(X) \mid q(X))$ in two ways. One gives $\mathsf{H}(X \mid q(X))$, since M is a function of X; the other gives $\mathsf{H}(M(X) \mid q(X)) + \mathsf{H}(X \mid q(X), M(X))$. □

Euclidean division on the APP sheets displays the elementary arithmetic mechanism. With $i, j \in \{1, \dots, 9\}$, one preserves

$$i + j = 9q^{+}_{ij} + R^{+}_{ij}, \qquad ij = 9q^{\times}_{ij} + R^{\times}_{ij}, \qquad 1 \le R^{\sigma}_{ij} \le 9 \quad (\sigma \in \{+, \times\}).$$

The residue–quotient pair recovers the integer value of the operation. Summing the differences over the eighty-one positions gives

$$2025 - 810 = 54 + 9 \cdot 129.$$

Quotient memory restores the contribution not published by residual reduction. Recoverability of the complete state additionally requires preserving the relevant position and route coordinates; the residue–quotient pair identifies the result of the operation here.

123.2 Reversible update, tritic decision and erasure

Let $U : \Omega \to \Omega$ be the TPK update on a domain where enriched transport has an inverse. The transported law is $p'_y = p_{U^{-1}y}$. The bijection preserves the multiset of probabilities and therefore

$$\mathsf{H}(U(X)) = \mathsf{H}(X), \qquad \mathsf{H}(X \mid U(X)) = 0. \tag{123.4}$$

If the observed output is $q(U(X))$, the unpublished information is quantified by $\mathsf{H}(X \mid q(U(X)))$. The complete state, its publication and the resetting of a register are thus three distinct maps.

For the three oriented TRIT states, let $p = (p_{-1}, p_0, p_{+1})$ be a normalized distribution. Its information is

$$I_{\mathrm{TRIT}}(p) = -\sum_{a=-1}^{1} p_a \log p_a, \qquad 0 \le I_{\mathrm{TRIT}}(p) \le \log 3. \tag{123.5}$$

The upper bound corresponds to $p_a = 1/3$. Indeed,

$$D(p\|(1/3, 1/3, 1/3)) = \sum_a p_a \log(3p_a) = \log 3 - I_{\mathrm{TRIT}}(p) \ge 0;$$

the inequality follows from the convexity of $t \log t$, and equality characterizes the uniform distribution. The lower bound corresponds to a distribution concentrated on one state.

The ideal Landauer realization uses a memory with energetically degenerate logical states, an isothermal environment at temperature Θ and a balance that preserves the output of the logical map and accounts for auxiliary registers. In that model, the decrease in logical entropy is $k_B[\mathsf{H}(X) - \mathsf{H}(F(X))] = k_B\mathsf{H}(X \mid F(X))$ for a deterministic map F. The entropic balance requires transferring at least that amount to the environment; its energy expression is $Q \ge k_B\Theta\mathsf{H}(X \mid F(X))$. The distinction between reversible logical evolution and physical erasure corresponds to the Landauer–Bennett realization [168]. The invertible update (123.4) has zero logical contribution; resetting a uniform triple requires transferring $\log 3$ nats to the environment and satisfies $Q \ge k_B\Theta \log 3$. The control energy and dissipation of a specific physical realization belong to its additional thermodynamic balance.

123.3 Action, frequency, and decision energy

Let $\mathcal{L}_{\mathrm{act}}$ and $\mathcal{L}_T$ be the dimensional lines of action and duration; the energy line is $\mathcal{L}_E = \mathcal{L}_{\mathrm{act}} \otimes \mathcal{L}_T^*$. The preceding development provides the positive sections $\hbar_a \in \mathcal{L}_{\mathrm{act}}$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$, and the elementary duration $t_0 \in \mathcal{L}_T$. The complete calendar provides

$$T_{108} = 108t_0, \qquad \omega_{108} = \frac{2\pi}{T_{108}}, \qquad h_a = 2\pi\hbar_a.$$

The dimensional contraction between action and frequency defines

$$\epsilon_a := \hbar_a\omega_{108} = \frac{h_a}{108t_0} = \frac{\hbar_a}{t_P}, \qquad t_P = \frac{54}{\pi}t_0. \tag{123.6}$$

The final expression uses the same reduced circular period as the gravitational section. The three expressions correspond to a single energy section, with an orientation a maintained in all the factors. The normalized information of a uniform decision produces the energy section per nat

$$\varepsilon_a := \frac{\epsilon_a}{\log 3} \in \mathcal{L}_E^+. \tag{123.7}$$

The previously constructed action determines the energy scale once the duration is fixed; the cardinality of the TRIT alternatives determines its informational normalization. The value of $\log 3$ enters through the count and measure declared in (123.5).

123.4 Dimensional definition of Boltzmann and selection of coordinates

Let $\mathcal{L}_\Theta$ be the oriented temperature line. The dimensional entropy space is $\mathcal{L}_{\mathrm{ent}} = \mathcal{L}_E \otimes \mathcal{L}_\Theta^*$. A positive linear map $k_B : \mathcal{L}_\Theta \to \mathcal{L}_E$ is, equivalently, a positive element of $\mathcal{L}_{\mathrm{ent}}$. Thus the same object can act on a temperature or multiply dimensionless information.

Definition 123.3 (Thermal normalization of the tritic decision)**.** A thermal pair compatible with the oriented section a consists of a positive transducer k_B and a positive section $\Theta_{\mathrm{clk},a} \in \mathcal{L}_\Theta$ such that

$$k_B(\Theta_{\mathrm{clk},a}) = \varepsilon_a, \qquad k_B\Theta_{\mathrm{clk},a} \log 3 = \epsilon_a. \tag{123.8}$$

The Boltzmann constant serves as the energy–temperature transducer of tritic information in this realization.

Theorem 123.4 (Uniqueness relative to the thermal section and dimensional covariance)**.** *Given a positive section $\Theta_{\mathrm{clk},a}$, there exists a unique positive linear map satisfying* (123.8)*. For positive bases u_E, u_Θ, if*

$$\epsilon_a = \epsilon_a^{\mathrm{num}} u_E, \quad \Theta_{\mathrm{clk},a} = \theta_a u_\Theta, \quad k_B(u_\Theta) = b\, u_E,$$

its coordinate is

$$b = \frac{\epsilon_a^{\mathrm{num}}}{\theta_a \log 3}. \tag{123.9}$$

Under $u'_E = s_E u_E$, $u'_\Theta = s_\Theta u_\Theta$, with $s_E, s_\Theta > 0$, one has

$$b' = \frac{s_\Theta}{s_E} b, \qquad \theta'_a = \frac{\theta_a}{s_\Theta}, \qquad (\epsilon_a^{\mathrm{num}})' = \frac{\epsilon_a^{\mathrm{num}}}{s_E}.$$

Proof. A nonzero section generates a line. Prescribing its image determines the unique linear map; the positivity of both sections proves its positivity. Substituting the coordinates into (123.8) gives $b\theta_a \log 3 = \epsilon_a^{\mathrm{num}}$. The three transformation laws are obtained by expressing the same sections and the same map in the new bases. □

The same Boltzmann constant must act in both orientations. Since t_P is common, simultaneous compatibility is equivalent to

$$\frac{\Theta_{\mathrm{clk,pre}}}{\Theta_{\mathrm{clk,ret}}} = \frac{\epsilon_{\mathrm{pre}}}{\epsilon_{\mathrm{ret}}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}}. \tag{123.10}$$

Indeed, an isomorphism of lines preserves quotients of sections. Conversely, if the preceding equality holds, the isomorphism determined in one orientation also satisfies the normalization of the other. Thus, return changes the thermal section of the cycle in the same proportion as the energy, while the transducer remains common to both readings.

The preceding equation makes explicit the choice required to publish an individual value. If the thermal section has not yet been selected by an independent reader, for each $\lambda > 0$ the pair

$$(k_B, \Theta_{\mathrm{clk},a}) \longmapsto (\lambda k_B, \lambda^{-1}\Theta_{\mathrm{clk},a})$$

preserves ϵ_a. Consequently, presenting an internally selected individual coordinate requires specifying the reader of $\Theta_{\mathrm{clk},a}$, the bases and their dimensional transport. The action and information equations remain determined before that specification. The subsequent identification of the bases with joule and kelvin belongs to the metrological publication of the result.

123.5 Dimensional entropy and information of the reduced state

For a distribution of admitted routes p, or for a reduced state with density matrix ρ, let

$$s(p) = -\sum_x p_x \log p_x, \qquad s(\rho) = -\operatorname{Tr}(\rho \log \rho).$$

Their dimensional publications are

$$S(p) = k_B s(p), \qquad S(\rho) = k_B s(\rho) \quad \text{in } \mathcal{L}_{\text{ent}}. \tag{123.11}$$

Evaluation at Θ produces an energy $\Theta S = k_B \Theta\, s$. For the uniform triple at the cycle temperature, (123.8) gives exactly

$$S_{\text{TRIT}} = k_B \log 3, \qquad \Theta_{\text{clk},a} S_{\text{TRIT}} = \epsilon_a.$$

If ρ_A is the reduction of the bipartite purification constructed in the areal section, $s(\rho_A)$ measures the entanglement of that bipartition. Unit transport preserves its eigenvalues, its orientation and the sectoral occupations. The areal scale $\gamma a_0 \ell_P^2$ converts occupations into area; the transducer k_B converts information into dimensional entropy. Both readings use the same register through distinct operators.

123.6 Spectral normalization of thermal histories

Let $\mathcal{G}$ be an already constructed finite graph of admissible extensions, with adjacency matrix A. Each edge e preserves its route coordinates and receives a dimensionless action increment $a_*(e) > 0$ from the corresponding reader. Having chosen the energy section ϵ_*, set $t = \beta\epsilon_*$, where $\beta = (k_B\Theta)^{-1}$. The thermal operator is

$$(L_t f)(y) = \sum_{e : x \to y} \exp[-t a_*(e)]\, f(x). \tag{123.12}$$

All its exponents are dimensionless. The condition $\rho(L_t) = 1$ normalizes the weighted growth of histories.

Proposition 123.5 (Existence and uniqueness of normalized pressure)**.** *Suppose that A is irreducible, $\rho(A) > 1$, and that $0 < m \le a_*(e) \le M$ for all edges. There exists a unique $t_* > 0$ such that $\rho(L_{t_*}) = 1$, and*

$$\frac{\log \rho(A)}{M} \le t_* \le \frac{\log \rho(A)}{m}. \tag{123.13}$$

Proof. Entrywise comparison gives $e^{-tM}A \le L_t \le e^{-tm}A$ for $t \ge 0$. Monotonicity of the spectral radius of nonnegative matrices implies the corresponding bounds for $\rho(L_t)$. The spectral radius is continuous, equals $\rho(A) > 1$ at zero and tends to zero at infinity. For $s > 0$, moreover, $L_{t+s} \le e^{-sm}L_t$, so that $\rho(L_{t+s}) \le e^{-sm}\rho(L_t) < \rho(L_t)$. Continuity and strict decrease prove existence and uniqueness. Substituting the value one into the initial bounds proves (123.13). □

The local realization of three equally weighted alternatives, represented by a vertex with three loops and $a_*(e) = 1$, satisfies $\rho(L_t) = 3e^{-t}$. Its normalization gives $t_* = \log 3$. With $\epsilon_* = \epsilon_a$, we obtain $\beta_{\mathrm{clk}} = \log 3/\epsilon_a$, precisely the relation (123.8). This calculation identifies the local tritic confluence. For a graph of histories with additional restrictions, confluence with the same clock requires checking

$$\rho\big(L_{(\log 3/\epsilon_a)\epsilon_*}\big) = 1$$

with its effective increments. The local normalization and the pressure of the complete system thus retain their respective domains.

The resulting relation brings together structure, value and meaning. The register determines the recoverable information; probabilities over continuations determine its entropic reading; action and period determine ϵ_a; the energy–temperature transducer publishes dimensional entropy. Area and entanglement are related through the reduced state and its boundary operators, keeping visible which datum produces each quantity.

Chapter 124

Oriented incidence and gravitational tensor representation

The exceptional publication of the state preserves the incidence accompanying its arithmetic reading. The ternary matrix A_W of (21.126) provides a precise material antecedent here. Its balanced lift $C = \mathrm{bal}(A_W)$, with representatives $0, 1, -1$, satisfies

$$C = C^{\mathsf{T}}, \qquad C^2 = 5I_6, \qquad \operatorname{Tr} C = 0.$$

The six positions have the order $(\infty, 0, 1, 2, 3, 4)$. This incidence first produces a three-dimensional space; its quadratic reading then produces the five-component space on which the gravitational coupling acts.

124.1 Signed covering and calendar transport

We define

$$E_C = \frac{1}{2}(I_6 + C/\sqrt{5}), \quad \mathcal{H}_C = \operatorname{im} E_C, \quad v_{u,\sigma} = \sigma\sqrt{2}E_C e_u, \quad \sigma \in \{1, -1\}.$$

Proposition 124.1 (Twelve oriented positions)**.** *The vectors $v_{u,\sigma}$ are twelve distinct unit vectors in a three-dimensional space. Their incidence is determined by $\langle v_{u,\sigma}, v_{v,\tau}\rangle = 1/\sqrt{5}$. Orientation reversal acts by antipodality.*

Proof. The quadratic identity for C implies $E_C^2 = E_C = E_C^*$; its trace is three. Since the diagonal of C is zero,

$$\langle v_{u,\sigma}, v_{v,\tau}\rangle = \begin{cases} \sigma\tau, & u = v, \\ \sigma\tau C_{uv}/\sqrt{5}, & u \neq v. \end{cases}$$

This proves normalization, distinction of the twelve vectors and incidence. Changing σ to $-\sigma$ changes the sign of the vector. □

An explicit Euclidean expression is obtained by setting $\nu = \sqrt{1+\varphi^2}$ and

$$B = \frac{1}{\nu}\begin{pmatrix} 0 & -1 & -\varphi & 0 & \varphi & 1 \\ -1 & -\varphi & 0 & 1 & 0 & -\varphi \\ -\varphi & 0 & -1 & -\varphi & -1 & 0 \end{pmatrix}.$$

The relation $\varphi^2 = \varphi + 1$, for the coordinate already generated, gives $B^*B = 2E_C$. Consequently $B/\sqrt{2}|_{\mathcal{H}_C}$ is an isometry and takes $v_{u,\sigma}$ to $\sigma B e_u$. The image is

$$\mathcal{V} = \frac{1}{\nu}\big(\{0\}\times\{\pm1\}\times\{\pm\varphi\} \;\cup\; \{\pm1\}\times\{\pm\varphi\}\times\{0\} \;\cup\; \{\pm\varphi\}\times\{0\}\times\{\pm1\}\big).$$

The internal coordinate, the incidence and its twelve geometric representatives are thus related.

The calendar coordinate is written $(b, r) \in \mathbb{Z}/12\mathbb{Z} \times \{0, \dots, 8\}$. A route of length n induces

$$k(r,n) = \left\lfloor \frac{r+n}{9} \right\rfloor, \qquad (b,r) \longmapsto \big(b + k(r,n) \bmod 12,\ (r+n) \bmod 9\big).$$

The explicit alignment of its positions $p = b + 1$ with the signed chart is

p	1	2	3	4	5	6	7	8	9	10	11	12
u	∞	0	0	∞	1	3	3	1	2	4	4	2
σ	+	−	+	−	−	+	−	+	−	+	−	+

This table fixes a trivialization of the carrier. Each change of position jointly transports the vectors and their incidence matrix.

Proposition 124.2 (Covariance of the frame under return)**.** *If $Se_p = e_{p+1 \bmod 12}$, the matrix representation of an operator P of the carrier is transported as $P_k = S^k P S^{-k}$. This transport preserves inner products, incidences and route composition. After twelve returns the chart returns, preserving the memory accumulated in the source state.*

Proof. S is orthogonal and $S^{12} = I$; the metric properties and periodicity of the chart follow. For composition, with $r' = (r + n) \bmod 9$, Euclidean division gives $k(r, n + m) = k(r, n) + k(r', m)$. The exponents of S are added exactly with the carry. The operation acts on the calendar coordinate; the route's memory updates remain present in its enriched domain. □

124.2 Quadratic reading and five-component space

Let $\mathbb{R}^{\mathcal{V}}$ be the space of the twelve coordinates, $\mathsf{A}e_v = e_{-v}$ its antipodal involution and $\mathsf{J} = \mathbf{1}\mathbf{1}^{\mathsf{T}}$. We define

$$P_5 = \frac{1}{2}(I + \mathsf{A}) - \frac{1}{12}\mathsf{J}, \qquad Q_v = vv^{\mathsf{T}} - \frac{1}{3}I_3, \qquad \Gamma_0 x = \sum_{v \in \mathcal{V}} x_v Q_v.$$

Theorem 124.3 (Five-component projector and tensor isometry)**.** *P_5 is the rank-five orthogonal projector onto the space of coordinates even under antipodality and of zero sum. Moreover,*

$$\Gamma_0^* \Gamma_0 = \frac{8}{5} P_5, \qquad \Gamma_0 \Gamma_0^* = \frac{8}{5} I_{\mathrm{Sym}_0^2(\mathbb{R}^3)}.$$

Therefore

$$\Gamma_5 = \sqrt{\frac{5}{8}}\, \Gamma_0|_{\operatorname{im} P_5}$$

is an isometry onto the space of traceless symmetric tensors.

Proof. The even space has one coordinate for each antipodal pair, so its dimension is six. The constant vector belongs to it; subtracting its rank-one projector gives P_5, of rank five.

Since $\langle Q_v, Q_w \rangle_F = (v^{\mathsf{T}} w)^2 - 1/3$, the entries of $\Gamma_0^* \Gamma_0$ equal $2/3$ for $w = \pm v$ and $-2/15$ in the other ten positions of each row. These are exactly the entries of $(8/5)P_5$.

The identity can also be checked in tensor space without resorting to a classification of representations. The list of vertices gives

$$\sum_v v_i^4 = \frac{12}{5}, \qquad \sum_v v_i^2 v_j^2 = \frac{4}{5} \quad (i \neq j),$$

and moments with any odd power vanish by sign changes. Indeed, $(1 + \varphi^2)^2 = 5\varphi^2$ and $1 + \varphi^4 = 3\varphi^2$. For a symmetric tensor Q, these sums give

$$\sum_v (v^{\mathsf{T}} Q v)\, vv^{\mathsf{T}} = \frac{8}{5} Q + \frac{4}{5} (\operatorname{tr} Q) I.$$

With $\operatorname{tr} Q = 0$, and using $\sum_v v^{\mathsf{T}} Q v = 4 \operatorname{tr} Q = 0$, we obtain $\Gamma_0 \Gamma_0^* Q = (8/5)Q$. The two identities prove the normalized isometry and its surjectivity. □

The gravitational section in 121 determines the operator $G_a P_5$. Its spectrum has G_a with multiplicity five and zero with multiplicity seven. Orientation is preserved in the carrier and its transport; G_a fixes the common coupling.

124.3 Transverse projection and helicities

For $n \in S^2$, set $\Pi = I - nn^{\mathsf{T}}$ and

$$\Lambda_n Q = \Pi Q \Pi - \frac{1}{2}\operatorname{tr}(\Pi Q \Pi)\Pi.$$

Proposition 124.4 (Rank-two transverse reduction)**.** *Λ_n is the orthogonal projector onto $\{Q \in \operatorname{Sym}_0^2(\mathbb{R}^3) : Qn = 0\}$, of dimension two.*

Proof. $\Pi n = 0$ gives transversality and $\operatorname{tr}\Pi = 2$ gives zero trace. A transverse traceless tensor remains fixed. The formula is self-adjoint for the Frobenius inner product. In a frame (e_1, e_2, n), the image has orthonormal basis

$$E_+ = \frac{e_1 e_1^{\mathsf{T}} - e_2 e_2^{\mathsf{T}}}{\sqrt{2}}, \qquad E_\times = \frac{e_1 e_2^{\mathsf{T}} + e_2 e_1^{\mathsf{T}}}{\sqrt{2}}.$$

□

The other three vectors of an orthonormal basis of the carrier are

$$E_1 = \frac{e_1 n^{\mathsf{T}} + n e_1^{\mathsf{T}}}{\sqrt{2}}, \quad E_2 = \frac{e_2 n^{\mathsf{T}} + n e_2^{\mathsf{T}}}{\sqrt{2}}, \quad E_0 = \frac{2nn^{\mathsf{T}} - e_1 e_1^{\mathsf{T}} - e_2 e_2^{\mathsf{T}}}{\sqrt{6}}.$$

When the transverse frame is rotated by an angle θ, the pairs $(E_+, E_\times)$ and (E_1, E_2) rotate by 2θ and θ, respectively, while E_0 remains fixed. The complexification thus has weights $2, -2, 1, -1, 0$. Λ_n preserves the first two and annihilates the rest. The chain is established

$$\mathbb{R}^{12} \xrightarrow{P_5} \operatorname{im} P_5 \xrightarrow{\Gamma_5} \operatorname{Sym}_0^2(\mathbb{R}^3) \xrightarrow{\Lambda_n} \mathcal{H}_{\mathrm{TT}}(n), \qquad 12 \longrightarrow 5 \longrightarrow 5 \longrightarrow 2.$$

The five-component representation and its reduction are algebraic results preceding the choice of field equations. In the massless gravitational realization, the gauge constraints select the transverse image. This distinction preserves both the five structural coordinates and the two radiative helicities.

Chapter 125

Phase return and representation of accumulated memory

The chronology of enriched routes distinguishes position return, orientation return and phase return. The observable publication identifies certain arrival states, while the cumulative register preserves the sequence traversed. The geometric representation must transport both data jointly.

125.1 Inversion cocycle and change of sheet

Let F_{obs} be the chronological publication of TPK transport. Its canonical blocks have the hierarchy

27	positional return with orientation reversal,
54	positional and orientational return,
108	complete return of the observable phase.

The register counts orientation inversions $g(a)$ and effective changes of sheet $s(a)$. For a route,

$$c(\gamma) = \sum_{a \subset \gamma} (g(a), s(a)), \qquad c(\gamma_2\gamma_1) = c(\gamma_2) + c(\gamma_1). \tag{125.1}$$

The canonical computation of the block of length 27 publishes $c_{27} = (1, 18)$. Composition preserves those increments in the four blocks that complete the observable period. On forward-oriented routes the register is cumulative; its extension to the route groupoid uses $\mathbb{Z}^2$ and $c(\bar{\gamma}) = -c(\gamma)$.

Proposition 125.1 (Memory of the complete observable turn)**.** *Writing $\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}$, the lift to the register, for $x \in O_{108}$ and $z \in \mathbb{Z}^2$, satisfies*

$$\widetilde{\mathcal{K}}_{27}(x, z) = (\mathcal{K}_{27}x, z + (1, 18)), \qquad \widetilde{\mathcal{K}}_{27}^{4}(x, z) = (x, z + (4, 72)).$$

After N complete turns, the increment is $N(4, 72)$.

Proof. The observable projection of $\mathcal{K}_{27}$ has order four. The preceding canonical computation fixes $c_{27} = (1, 18)$ as a constant over that observable orbit. The additivity of (125.1) sums the four increments and gives $c_{108} = 4(1, 18) = (4, 72)$. Repetition applies the same concatenation law and produces Nc_{108}. The return of the first coordinate preserves the increment of the second. □

125.2 Affine representation of the cocycle

The discrete realization uses an element R_4 of order four in $\mathrm{Spin}^+(1, 3)$, a unit temporal vector u fixed by its vector action and a unit of length $\ell_0 > 0$. The scale ℓ_0 retains its provenance in the dimensional section. We define

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma) = \left(R_4^{c_g(\gamma)},\ \ell_0 c_s(\gamma) u\right) \in \mathrm{Spin}^+(1, 3) \ltimes \mathbb{R}^{1,3}. \tag{125.2}$$

The power acts on the vector through the associated vector representation of the spin group.

Theorem 125.2 (Composition and translational amplitude of return)**.** *The map $\rho_{\mathrm{C}}^{\mathrm{disc}}$ preserves the identity, concatenation and inversion. At complete returns,*

$$\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}) = (I, 72\ell_0 u), \qquad \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_{108}^{N}) = (I, 72N\ell_0 u). \tag{125.3}$$

Inversion changes the sign of the translation.

Proof. The semidirect product is $(R,a)(S,b)=(RS,a+Rb)$. Since $R_4u=u$,

$$\begin{aligned}\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2)\rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_1) &= \left(R_4^{c_g(\gamma_2)+c_g(\gamma_1)},\, \ell_0(c_s(\gamma_2)+c_s(\gamma_1))u\right)\\ &= \rho_{\mathrm{C}}^{\mathrm{disc}}(\gamma_2\gamma_1).\end{aligned}$$

The identity cocycle is zero and that of the inverse is its opposite. For the complete turn, substitute $c_{108}=(4,72)$ and $R_4^4=I$. Concatenating N turns keeps the rotational part equal to the identity and sums their translations. □

The amplitude $72\ell_0$ is a length associated with a finite route. A realization through a co-tetrad and a connection transports it to its affine holonomy. The local contribution to the gravitational equations is subsequently obtained through the curvature of that connection, the variation of the matter action and the normalization of its density. The representation thus preserves the exact cumulative content that must enter that realization.

Chapter 126

Boundary soldering and energy response

The cubic realization of transport preserves six oriented incidences. Its geometric quotient, the Lorentzian form and the energy response are obtained from the same incidence matrix. Transport proceeds from the enriched APP–TRIT–TPK route: the face, sign, carry and memory accompany each edge. This section develops the linear operation acting on that boundary publication.

126.1 Cubic incidence and the rank-four quotient

Let $H_F = \mathbb{R}^F$, with $F = \{(i,\epsilon) : 1 \le i \le 3,\ \epsilon \in \{-1,1\}\}$, its Euclidean inner product, and its basis $e_{i,\epsilon}$. Face opposition is the orthogonal involution $Re_{i,\epsilon} = e_{i,-\epsilon}$. Define

$$u = \sum_{i,\epsilon} e_{i,\epsilon}, \qquad P_u = \frac{uu^{\mathsf{T}}}{6}, \qquad P_- = \frac{I-R}{2}, \qquad P_0 = \frac{I+R}{2} - P_u, \qquad P_\square = P_u + P_-.$$

The vertices are $V = \{-1,1\}^3$. The incidence matrix $M : \mathbb{R}^V \longrightarrow H_F$ is determined by

$$M_{(i,\epsilon),\nu} = \mathbf{1}_{\{\nu_i = \epsilon\}}.$$

Proposition 126.1 (Incidence decomposition)**.** *We have*

$$MM^{\mathsf{T}} = 12P_u + 4P_-, \qquad \ker M^{\mathsf{T}} = P_0 H_F.$$

Consequently, the quotient $Q = H_F/P_0H_F$, orthogonally identified with $P_\square H_F$, has dimension four.

Proof. A face contains four vertices. Two opposite faces have no common vertices and two faces on different axes have two common vertices. Writing $\mathbf{J} = uu^{\mathsf{T}}$, we obtain

$$MM^{\mathsf{T}} = 4I + 2(\mathbf{J} - I - R) = 2(I-R) + 2\mathbf{J} = 4P_- + 12P_u.$$

The three projectors P_u, P_-, P_0 are orthogonal and sum to I; their ranks are one, three and two, respectively. The identity $\|M^{\mathsf{T}}x\|^2 = \langle x, MM^{\mathsf{T}}x\rangle$ identifies the stated kernel. The complementary rank is four. □

On Q, the form

$$B = P_- - P_u$$

has signature $(3,1)$. The time orientation is fixed by u. With

$$t = \frac{u}{\sqrt{6}}, \qquad d_i = \frac{e_{i,+} - e_{i,-}}{\sqrt{2}}, \qquad W = \sqrt{6}P_u + \sqrt{2}P_-,$$

we have $We_{i,\epsilon} = t + \epsilon d_i$. These six vectors are null for B, whereas

$$3t + \nu_1 d_1 + \nu_2 d_2 + \nu_3 d_3$$

has squared norm -6. The same incidence satisfies $MM^{\mathsf{T}} = 2W^*W$ on Q. The proper rotations of the cube commute with the projectors, preserve both forms and fix t. These identities determine the metric of the cubic publication.

126.2 Cellular soldering and memory transport

For each oriented edge a, the route publication provides the face $\lambda(\underline{a})$, the sign $\sigma(a)$, the source and target fibres and the transport $U(a) : Q_{s(a)} \longrightarrow Q_{t(a)}$. Inversion satisfies $U(\bar{a}) = U(a)^{-1}$. The boundary half-edges retain their formal inversion and their incidence at the boundary. With $\ell_m = \ell_0\, 9^{-m} > 0$, the soldering is

$$\beta_m(a) = \ell_m \sigma_m(a) n^{s(a)}_{\lambda(\underline{a})}, \qquad n_{i,\epsilon} = t + \epsilon d_i. \tag{126.1}$$

The face and sign are transported together with the route memory. The inversion convention requires

$$\beta_m(\bar{a}) = -U_m(a)\beta_m(a). \tag{126.2}$$

Applying this relation twice recovers $\beta_m(a)$; the carry register separately preserves the ordered composition.

Proposition 126.2 (Naturality of soldering under refinement)**.** *Let $a = a_1 \cdots a_9$ be a compatible refinement of an edge. Suppose that the nine child incidences, transported to the parent fibre, preserve the face and sign, and that $\ell_{m+1} = \ell_m/9$. Let $\mathcal{U}_j : Q_{m,s(a)} \longrightarrow Q_{m+1,s(a_j)}$ be the accumulated transport that includes the refinement identification and the path to the origin of child j. Then*

$$\beta_m(a) = \sum_{j=1}^{9} \mathcal{U}_j^{-1} \beta_{m+1}(a_j).$$

The equality is compatible with inversion and with concatenation of the memory register.

Proof. Each summand, expressed in the fibre at the origin of the parent, is $(\ell_m/9)\sigma_m(a)n_{\lambda(\underline{a})}$. The sum of nine terms reproduces the parent soldering. Inversion reverses the order of the transports and replaces each one with its inverse; the relation (126.2) provides the overall sign. Memory is concatenated in that same order, so refinement preserves both the vector publication and its enriched register. □

126.3 Positive response, uniqueness, and minimal extension

The linear screen soldering is $\bar{\beta}_m = \ell_m W|_Q$. It is invertible, with

$$\bar{\beta}_m^{-1} = \ell_m^{-1} \left(\frac{1}{\sqrt{6}} P_u + \frac{1}{\sqrt{2}} P_- \right).$$

The eigenvalue $5/9$ of the antisymmetric sector of the normalized block $B_c/9$, constructed in Section 4.3.4, determines the compression coefficient $q_{\mathrm{vis}} = 5/9$. We reserve this notation to distinguish it from the Euclidean quotient $q_9(n)$ of the arithmetic kernel. Its realization on the screen uses an isometry $V_9 : Q \longrightarrow \mathcal{K}$. The visible contribution $C_9 = q_{\mathrm{vis}} V_9$ and its complement $D_9 = \sqrt{1 - q_{\mathrm{vis}}^2}\, V_9$ satisfy

$$C_9^* C_9 + D_9^* D_9 = I_Q, \qquad D_9^* D_9 = \frac{56}{81} I_Q.$$

The coefficient 56 is $9^2 - 5^2$; it belongs to the quadratic defect of that compression reader.

Theorem 126.3 (Energy response determined by soldering)**.** *There is a unique operator $\Lambda_m : Q \longrightarrow Q$ such that $\bar{\beta}_m^* \Lambda_m \bar{\beta}_m = D_9^* D_9$. It is positive definite and*

$$\Lambda_m = \frac{28}{243 \ell_m^2} (P_u + 3P_-) = \frac{112}{81 \ell_m^2} (M M^{\mathsf{T}}|_Q)^{-1}. \tag{126.3}$$

On H_F, the corresponding identity has right-hand side $(56/81)P_{\square}$.

Proof. Congruence by the invertible soldering necessarily determines

$$\Lambda_m = \bar{\beta}_m^{-*} \frac{56}{81} I_Q \bar{\beta}_m^{-1}.$$

Substituting the inverse, the coefficient of P_u is $56/(486\ell_m^2) = 28/(243\ell_m^2)$; that of P_- is $28/(81\ell_m^2)$. Both are positive. By Proposition 126.1, $(MM^{\mathsf{T}}|_Q)^{-1} = P_u/12 + P_-/4$, which gives the second expression. Extension to six faces annihilates $P_0 H_F$; the identity therefore extends through $P_\square$. □

Proposition 126.4 (Characterization by minimal extension)**.** *For every $b \in Q$,*

$$\langle b, \Lambda_m b \rangle = \frac{112}{81\ell_m^2} \min_{Mx=b} \|x\|^2.$$

The minimizing extension is unique: $x_{\min} = M^{\mathsf{T}}(MM^{\mathsf{T}}|_Q)^{-1} b$.

Proof. The stated vector satisfies $Mx_{\min} = b$ and belongs to $\operatorname{im} M^{\mathsf{T}} = (\ker M)^\perp$. Every other solution is $x_{\min} + z$, with $z \in \ker M$; by orthogonality, its squared norm is $\|x_{\min}\|^2 + \|z\|^2$. Moreover,

$$\|x_{\min}\|^2 = \langle b, (MM^{\mathsf{T}}|_Q)^{-1} b \rangle.$$

The formula for Λ_m completes the proof. □

The operator $MM^{\mathsf{T}}|_Q$ realizes the Dirichlet–to–Neumann response of this incidence formulation; its inverse is the Neumann–to–Dirichlet response. The preceding energy corresponds to the latter, with the normalization of the soldering and the compression defect. The Schur complement of $\left(\begin{smallmatrix} I & M^{\mathsf{T}} \\ M & 0 \end{smallmatrix}\right)$ is $-MM^{\mathsf{T}}$, which offers the same variational elimination.

126.4 Preservation of density by refinement

Consider the sector of cubic transports, orthogonal for the energy inner product and compatible with the form B. We fix a common label space Q^{lab}, identified isometrically with the parent's screen. The solderings have types $\bar{\beta}_m : Q^{\mathrm{lab}} \longrightarrow Q_m$ and $\bar{\beta}_{m+1,j} : Q^{\mathrm{lab}} \longrightarrow Q_{m+1,j}$; the operators Λ act in their respective target fibers. If $U_j : Q_j \longrightarrow Q$ transports the child fiber to the parent's, then

$$\bar{\beta}_{m+1,j} = \frac{1}{9} U_j^{-1} \bar{\beta}_m, \qquad \Lambda_{m+1,j} = 81 U_j^{-1} \Lambda_m U_j.$$

The factor 81 comes from $\ell_{m+1}^{-2} = 81\ell_m^{-2}$.

Theorem 126.5 (Invariance of the normalized density)**.** *Each child preserves the parent's quadratic response:*

$$\bar{\beta}_{m+1,j}^{*} \Lambda_{m+1,j} \bar{\beta}_{m+1,j} = \frac{56}{81} I_{Q^{\mathrm{lab}}}.$$

For r refinements, the joint response, expressed in the parent's fibers, is

$$E_{m+r} = \frac{56}{81} I_{Q^{\mathrm{lab}}} \otimes I_{9^r}.$$

The expectation with normalized trace $\tau_{9^r}(A) = 9^{-r} \operatorname{Tr}(A)$ satisfies

$$(\mathrm{id} \otimes \tau_{9^r})(E_{m+r}) = \frac{56}{81} I_{Q^{\mathrm{lab}}}$$

at every finite depth.

Proof. The congruence of a child contains the factors $1/9, 81, 1/9$; their product is one. Orthogonality cancels the intermediate transports. The direct sum of nine equal responses identifies the first refinement with $(56/81)I_Q \otimes I_9$. Iteration produces the tensor with I_{9^r}. Finally $\tau_{9^r}(I_{9^r}) = 1$. The expectations compose through the identity $\tau_{9^{r+s}} = \tau_{9^r} \otimes \tau_{9^s}$. □

The unital inclusions $A \mapsto A \otimes I_9$ are compatible with that family of traces. In the inductive limit of the matrix algebras, the response is the central element $(56/81)I_Q \otimes \mathbf{1}$. The unnormalized extensive sum produces, in contrast, $9^r(56/81)I_Q$. This distinction specifies which quantity is preserved: the quadratic screen density.

126.5 Variational realization of the response

The material realization uses an isometry $J_{\mathrm{scr}} : Q \longrightarrow \mathcal{H}_\partial$ compatible with the spin action and with refinement. The boundary co-tetrad is $e = J_{\mathrm{scr}}\bar{\beta}_m$. Let Λ_{CE} be the boundary response obtained by second variation of the material and geometric action, with its boundary conditions and elimination of the interior variables. The compatibility defect is

$$\mathcal{R}_{\mathrm{grav}} = \bar{\beta}_m^*(J_{\mathrm{scr}}^*\Lambda_{\mathrm{CE}}J_{\mathrm{scr}} - \Lambda_m)\bar{\beta}_m = e^*\Lambda_{\mathrm{CE}}e - D_9^*D_9. \tag{126.4}$$

By the invertibility of $\bar{\beta}_m$,

$$\mathcal{R}_{\mathrm{grav}} = 0 \quad \Longleftrightarrow \quad J_{\mathrm{scr}}^*\Lambda_{\mathrm{CE}}J_{\mathrm{scr}} = \Lambda_m.$$

The isometry J_{scr} transports the boundary states; the variational spin current is a degree-three form with values in bivectors. Each enters with its own domain in the realization of the response.

The construction determines a positive energy form, its minimizing interior extension and the density preserved by refinement. The amplitude of a concrete material contribution is obtained by evaluating the current of that realization in its variational quadratic form. This differentiates the operator fixing the response, the current on which it acts and the gravitational observable published by the evaluation.

Chapter 127

Geometric realization of transport and soldering

The discrete representation of return and screen soldering determine two aspects of transport: the accumulation of memory along routes and the comparison of their fibres. Their geometric realization preserves both operations. This section fixes the target space, the dimensional normalization of the connection and the identities that its variation will use.

127.1 Screen, co-tetrad and connection

The screen quotient $Q_{\square}$, its Lorentzian form, and the soldering β_m come from 126. In each cell, a screen realization $J_{\mathrm{scr},m}$ transports the form and soldering to the corresponding geometric fibre. Its cellular image is

$$e_m = J_{\mathrm{scr},m}\beta_m.$$

The scale ℓ_m remains within the soldering. Changes of frame act jointly on $J_{\mathrm{scr},m}$, the connection and the transport of the cells.

A smooth realization of those data on an oriented manifold $\mathcal{U}$ of dimension four consists of a nondegenerate co-tetrad $e = (e^I)$, a Lorentz connection $\omega = (\omega^I{}_J)$ and a realization of routes $\mathfrak{R}_{\mathrm{C}}$ satisfying

$$\mathrm{Hol}_{\mathcal{A}_{\ell_0}}(\mathfrak{R}_{\mathrm{C}}(\gamma)) = \rho_{\mathrm{C}}(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)). \tag{127.1}$$

In this matrix equality, the representation is normalized by

$$N_{\ell_0}(R,a) = (\Lambda(R), a/\ell_0), \qquad \rho_{\mathrm{C}} = N_{\ell_0} \circ \rho_{\mathrm{C}}^{\mathrm{disc}},$$

where $\Lambda : \mathrm{Spin}^+(3,1) \to SO^+(3,1)$ is the vector representation. The map N_{ℓ_0} preserves the semidirect product: dividing the translation $a + \Lambda(R)b$ by ℓ_0 is equivalent to composing the two normalized translations. The complete turn therefore publishes $72u$ in the normalized connection and $72\ell_0 u$ in the dimensional chart. The spin lift separately preserves $R_4^{c_g(\gamma)}$; the vector representation has the central kernel $\{1,-1\}$, so that lift is retained when using spinor fields. Identity, concatenation, inversion and subdivision are maintained in the corresponding realization. The screen pairing and the holonomy condition specify the data of the realization used in the field equations.

With $\eta = \mathrm{diag}(-1,1,1,1)$, define $g = \eta_{IJ} e^I \otimes e^J$. For a positive elementary scale ℓ_0, constant in the chart, the affine connection is

$$\mathcal{A}_{\ell_0} = \begin{pmatrix} \omega & \ell_0^{-1} e \\ 0 & 0 \end{pmatrix}. \tag{127.2}$$

The co-tetrad has the dimension of length; the factor ℓ_0^{-1} makes its translational component dimensionally homogeneous.

Proposition 127.1 (Curvature and torsion of the realized connection)**.** *The curvature of* (127.2) *is*

$$\mathcal{F}_{\ell_0} = \mathrm{d}\mathcal{A}_{\ell_0} + \mathcal{A}_{\ell_0} \wedge \mathcal{A}_{\ell_0} = \begin{pmatrix} F_\omega & \ell_0^{-1} T \\ 0 & 0 \end{pmatrix}, \quad F_\omega = \mathrm{d}\omega + \omega \wedge \omega, \quad T = \mathrm{d}e + \omega \wedge e. \tag{127.3}$$

Proof. The product of matrices of forms produces $\omega \wedge \omega$ in the diagonal block and $\ell_0^{-1}\omega \wedge e$ in the translational block. The exterior derivative contributes $\mathrm{d}\omega$ and $\ell_0^{-1}\mathrm{d}e$, since ℓ_0 is constant. Their sum proves the equality. □

Curvature describes the frame-transport defect and torsion that of the co-tetrad. Both belong to the same realized connection; their components retain distinct tensorial domains.

Proposition 127.2 (Covariance and Bianchi identities)**.** *Under a change of frame* $g_L : \mathcal{U} \to SO^+(3,1)$*,*

$$e' = g_L e, \qquad \omega' = g_L \omega g_L^{-1} - \mathrm{d}g_L\, g_L^{-1},$$

we have $T' = g_L T$ *and* $F_{\omega'} = g_L F_\omega g_L^{-1}$*. Furthermore,*

$$D_\omega T = F_\omega \wedge e, \qquad D_\omega F_\omega = 0. \tag{127.4}$$

Proof. In $\mathrm{d}(g_L e) + \omega' \wedge g_L e$, the terms containing $\mathrm{d}g_L \wedge e$ cancel. The same substitution into the curvature gives its transformation by conjugation. For the first Bianchi identity, expand

$$D_\omega(\mathrm{d}e + \omega \wedge e) = (\mathrm{d}\omega + \omega \wedge \omega) \wedge e.$$

In $\mathrm{d}F_\omega + \omega \wedge F_\omega - F_\omega \wedge \omega$, the terms containing $\mathrm{d}\omega$ and the cubic products cancel in pairs. This proves the second identity. □

127.2 The three quadratic realizations of curvature

The TRIT sheet $\tau \in \{+1, 0, -1\}$ is represented in the Cartan algebra by generators $J_{ab} = -J_{ba}$ and $P_a^{(\tau)}$, with relations

$$\begin{aligned} [J_{ab}, J_{cd}] &= \eta_{bc} J_{ad} - \eta_{ac} J_{bd} - \eta_{bd} J_{ac} + \eta_{ad} J_{bc}, \\ [J_{ab}, P_c^{(\tau)}] &= \eta_{bc} P_a^{(\tau)} - \eta_{ac} P_b^{(\tau)}, \\ [P_a^{(\tau)}, P_b^{(\tau)}] &= -\tau J_{ab}. \end{aligned}$$

For constant $\ell > 0$, write

$$\mathcal{A}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}\omega^{ab} J_{ab} + \ell^{-1} e^a P_a^{(\tau)}.$$

Proposition 127.3 (Curvature of the tritified realization)**.** *With the preceding relations,*

$$\mathcal{F}_\tau^{\mathrm{Cart}} = \tfrac{1}{2}(F_\omega^{ab} - \tau \ell^{-2} e^a \wedge e^b) J_{ab} + \ell^{-1} T^a P_a^{(\tau)}. \tag{127.5}$$

Proof. Expand $\mathrm{d}\mathcal{A} + \frac{1}{2}[\mathcal{A}, \mathcal{A}]$. The bracket of the Lorentz sector produces F_ω, the mixed bracket produces $D_\omega e$, and the translational bracket contributes $-\frac{1}{2}\tau \ell^{-2} e^a \wedge e^b J_{ab}$. □

On the central sheet the affine connection is recovered; the extreme sheets preserve the two signs of the constant-curvature term. The representation thus retains the tritic regime of the route before applying the variational equations. The holonomy equality (127.1) corresponds to the central sheet. On each extreme sheet, the representation $\rho_{\mathrm{C},\tau}$ in its Cartan group and its respective holonomy condition are used. The current and the metric tensor use the fields and representation of the same realization.

Chapter 128

Variational response of memory energy

The transport of a route identifies the fibers at its endpoints and preserves the orientation and memory entering that identification. The associated energy compares the final field with the transported initial field. Its differential quantifies how that comparison responds to a variation of transport. This section obtains the response directly from the discrete functional and develops its composition, covariance and inversion.

128.1 Discrete functional and space of variations

At a finite level m, let $\mathcal{V}_m$ be the vertices of the route publication and $\mathcal{E}_m^+$ an orientation of each edge. Each vertex carries a finite-dimensional Hermitian fiber H_v. We define

$$\mathcal{H}_m = \bigoplus_{v\in\mathcal{V}_m} H_v, \qquad \mathcal{K}_m = \bigoplus_{a\in\mathcal{E}_m^+} H_{t(a)}.$$

The Hermitian inner product is antilinear in the first variable. For unitary $U_a : H_{s(a)} \to H_{t(a)}$, the difference operator is

$$(D_m f)_a = f_{t(a)} - U_a f_{s(a)}, \qquad E_m(f,U) = \langle D_m f, \mathsf{W}_m D_m f\rangle, \qquad \mathsf{W}_m = \mathsf{W}_m^* > 0. \tag{128.1}$$

This is the energy of the term $D_m^* \mathsf{W}_m D_m$ in the discrete generator. The weight W_m may couple different edges. The soldering operator W of Section 126 and this energy weight have different domains and roles.

The transport U is a publication of the enriched state. The field f and the weight W_m remain explicit as arguments of the functional; each material application preserves the rules that determine them. Differentiable families of the unitary realizations of transport are considered,

$$\dot U_a = A_a U_a, \qquad A_a^* = -A_a.$$

The variations used physically form the subspace preserving the conditions of the corresponding realization. The differential is calculated first in the unitary tangent space and then restricted to that subspace.

Proposition 128.1 (Transport-response covector)**.** *Write*

$$v_a = U_a f_{s(a)}, \qquad r = D_m f, \qquad q = \mathsf{W}_m r.$$

At fixed field and weight, the energy differential is

$$\mathfrak{j}_m(A) = -2\,\mathrm{Re}\sum_{a\in\mathcal{E}_m^+} \langle q_a, A_a v_a\rangle. \tag{128.2}$$

Its representative for the real Hilbert–Schmidt inner product is

$$\mathcal{J}_a = v_a q_a^* - q_a v_a^*, \qquad \mathcal{J}_a^* = -\mathcal{J}_a, \qquad \mathfrak{j}_m(A) = \sum_a \mathrm{Re}\,\mathrm{Tr}(\mathcal{J}_a^* A_a). \tag{128.3}$$

For simultaneous variations of field, transport and weight we have

$$\dot E_m = 2\,\mathrm{Re}\sum_a \left\langle q_a, \dot f_{t(a)} - U_a \dot f_{s(a)} - A_a v_a\right\rangle + \langle r, \dot{\mathsf{W}}_m r\rangle. \tag{128.4}$$

Proof. The first-order update, written in the algebra of dual numbers with $\epsilon^2 = 0$, gives

$$r + \epsilon \dot r, \qquad \dot r_a = \dot f_{t(a)} - U_a \dot f_{s(a)} - A_a v_a.$$

The coefficient of ϵ in the energy is

$$\langle \dot r, \mathsf{W}_m r\rangle + \langle r, \mathsf{W}_m \dot r\rangle + \langle r, \dot{\mathsf{W}}_m r\rangle.$$

Self-adjointness of the weight yields (128.4). Fixing field and weight leaves (128.2). Moreover,

$$\operatorname{Tr}(\mathcal{J}_a^{*} A_a) = v_a^{*} A_a q_a - q_a^{*} A_a v_a.$$

Anti-Hermiticity of A_a implies $v_a^{*} A_a q_a = -\overline{q_a^{*} A_a v_a}$, giving the stated representative. □

The response is thus evaluated: on each edge the field is transported, its difference from the final field is calculated and the energy weight is applied. The antisymmetrized product of those two vectors determines $\mathcal{J}_a \in \mathfrak{u}(H_{t(a)})$. This operator represents, through the real Hilbert–Schmidt inner product, the response covector on the unitary variations of the target fiber.

128.2 Composition and transport of the response

Proposition 128.2 (Composition rule along a route)**.** *For a route formed by N transports, let $U_\gamma = U_N \cdots U_1$ and $B_k = U_N \cdots U_{k+1}$, with $B_N = I$. If $\dot U_k = A_k U_k$, then*

$$\dot U_\gamma U_\gamma^{-1} = \sum_{k=1}^{N} B_k A_k B_k^{-1}. \tag{128.5}$$

Thus a representative $\mathcal{J}_\gamma$ in the final fibre induces in factor k the contribution $B_k^{*}\mathcal{J}_\gamma B_k$. When a factor belongs to several routes in the functional, its contributions are summed with the incidences used by that functional.

Proof. The product rule gives

$$\dot U_\gamma = \sum_{k} U_N \cdots U_{k+1} A_k U_k \cdots U_1.$$

Multiplication by U_γ^{-1} eliminates the factors to the right of A_k and yields (128.5). By unitarity and cyclicity of the trace,

$$\operatorname{Re}\operatorname{Tr}(\mathcal{J}_\gamma^{*} B_k A_k B_k^{-1}) = \operatorname{Re}\operatorname{Tr}((B_k^{*}\mathcal{J}_\gamma B_k)^{*} A_k).$$

Linearity of the differential proves the sum of contributions. □

This formula preserves the position of each operation within the route. Transport following an incidence determines how its contribution is represented in the final fiber; the local response is recovered by transporting it to the fiber of that incidence.

Proposition 128.3 (Covariance under unitary frame changes)**.** *Let g_v be unitary frame changes independent of the variation parameter, and $G_{\mathcal{E}} = \bigoplus_a g_{t(a)}$. Under the transformations*

$$f_v' = g_v f_v, \quad U_a' = g_{t(a)} U_a g_{s(a)}^{-1}, \quad \mathsf{W}_m' = G_{\mathcal{E}} \mathsf{W}_m G_{\mathcal{E}}^{-1}, \quad A_a' = g_{t(a)} A_a g_{t(a)}^{-1},$$

we have

$$\mathcal{J}_a' = g_{t(a)} \mathcal{J}_a g_{t(a)}^{-1}, \qquad \mathfrak{j}_m'(A') = \mathfrak{j}_m(A). \tag{128.6}$$

Proof. We obtain $r' = G_{\mathcal{E}} r$, $q' = G_{\mathcal{E}} q$ and $v_a' = g_{t(a)} v_a$. Substitution into (128.3) proves the first identity. Invariance of the Hermitian inner product, or cyclicity of the trace, proves the second. □

When frame changes depend on the parameter, their derivatives also act on the field and weight. The corresponding covariant expression is then the complete differential (128.4).

128.3 Oriented inversion and transport of the weight

Inversion can be seen explicitly in the case of a local energy per edge, $\mathsf{W}_m = \bigoplus_a W_a$. For $a : s \to t$, its inverse carries

$$U_{\bar{a}} = U_a^{-1}, \qquad r_{\bar{a}} = -U_a^{-1} r_a, \qquad W_{\bar{a}} = U_a^{-1} W_a U_a.$$

These rules preserve the edge energy exactly.

Proposition 128.4 (Differential compatibility with inversion)**.** *If W_a and the fields at both endpoints remain fixed, then*

$$A_{\bar{a}} = -U_a^{-1} A_a U_a, \qquad \dot{W}_{\bar{a}} = U_a^{-1} [W_a, A_a] U_a.$$

The complete variation of the reversed edge's energy coincides with the original. In particular, if $[W_a, A_a] = 0$, the partial transport covector satisfies

$$\mathfrak{j}_{\bar{a}}(U_a^{-1} A_a U_a) = -\mathfrak{j}_a(A_a). \tag{128.7}$$

Proof. The derivative of U_a^{-1} is $-U_a^{-1} A_a$, from which the two formulas result. Writing $v_a = U_a f_s$ and $f_t = r_a + v_a$, the part due exclusively to reversed transport equals

$$\mathfrak{j}_{\bar{a}}(A_{\bar{a}}) = -2 \operatorname{Re}\langle r_a, W_a A_a f_t \rangle = \mathfrak{j}_a(A_a) - 2 \operatorname{Re}\langle r_a, W_a A_a r_a \rangle.$$

Variation of the weight contributes

$$\langle r_{\bar{a}}, \dot{W}_{\bar{a}} r_{\bar{a}} \rangle = \langle r_a, [W_a, A_a] r_a \rangle = 2 \operatorname{Re}\langle r_a, W_a A_a r_a \rangle.$$

The two terms compensate each other. If the commutator is zero, that contribution disappears; linearity in A_a gives (128.7). □

Energy is summed over one orientation per edge. A sum over both orientations carries the factor $1/2$. This convention preserves the same functional and hence the same response.

128.4 Compatibility with refinement

Theorem 128.5 (Transport of the differential by refinement)**.** *Let $J_m : \mathcal{H}_m \to \mathcal{H}_{m+1}$ and $K_m : \mathcal{K}_m \to \mathcal{K}_{m+1}$ be fixed maps. For a family C^1, suppose the refinement identities*

$$D_{m+1}(t) J_m = K_m D_m(t), \qquad K_m^* \mathsf{W}_{m+1}(t) K_m = \mathsf{W}_m(t). \tag{128.8}$$

Then $E_{m+1}(J_m f) = E_m(f)$. The transport covectors agree on variations linked by the first identity. When the weights vary, their contributions to the differential also agree.

Proof. By substitution,

$$\langle D_{m+1} J_m f, \mathsf{W}_{m+1} D_{m+1} J_m f \rangle = \langle D_m f, K_m^* \mathsf{W}_{m+1} K_m D_m f \rangle = E_m(f).$$

Differentiating the first identity of (128.8) gives $\dot{D}_{m+1} J_m = K_m \dot{D}_m$. Consequently,

$$2 \operatorname{Re}\langle D_{m+1} J_m f, \mathsf{W}_{m+1} \dot{D}_{m+1} J_m f \rangle = 2 \operatorname{Re}\langle D_m f, \mathsf{W}_m \dot{D}_m f \rangle.$$

The derivative of the second identity is $K_m^* \dot{\mathsf{W}}_{m+1} K_m = \dot{\mathsf{W}}_m$, proving agreement of the weight-variation terms. □

The statement uses compatibility of the transport family. If J_m depends on the parameter, the chain rule also preserves the term

$$2\,\mathrm{Re}\langle D_{m+1}J_m f, \mathsf{W}_{m+1}D_{m+1}\dot{J}_m f\rangle.$$

The resulting naturality jointly transports the functional, its incidences and its differential.

128.5 Material realization of the response

The result of this section is the explicit covector $\mathfrak{j}_m$, with its representative $\mathcal{J}_a$. The material realization composes that covector with the variation of transport induced by the connection and with the normalization of the action. If $\mathcal{L}_m$ denotes that differential map, the covector on connection variations is $\mathcal{L}_m^{*}\mathfrak{j}_m$. The composition rule (128.5) evaluates its part corresponding to finite products of transports.

In section 131, the current σ_{IJ} is a three-form defined by variation of the material action. Identification between the two realizations preserves the field, representation, weight, dimensional normalization and passage to the limit used by that action. These data allow evaluation of the contraction entering the torsional density. The present development provides the discrete differential composed in that calculation.

Chapter 129

Realization of the current in connection coordinates

Memory energy assigns each route a response preserving its incidences and the order of transports. Inserting it into a geometric action requires its components with respect to connection variations. This step is obtained by differentiating the transport that already realizes the route: the connection current is the composition of that differential with the energy covector of the preceding section.

The elliptic, parabolic and hyperbolic regimes of TRIT require preserving the complete differential before restricting it to a particular representation. Unitary rotations constitute a domain of that construction. The following extension also preserves the dilation and transport directions admitted by the geometric realization used.

129.1 Differential on invertible transports

The fibers, fields and weight of (128.1) are retained. We now consider invertible transports and differentiable families with $\dot U_a = A_a U_a$, where A_a belongs to the tangent space of the chosen representation. We write

$$v_a = U_a f_{s(a)}, \qquad r_a = f_{t(a)} - v_a, \qquad q = \mathsf{W}_m r, \qquad E_m = \langle r, \mathsf{W}_m r\rangle.$$

Proposition 129.1 (Complete representative of the differential)**.** *At fixed field and weight, the following holds*

$$\mathrm{d}_U E_m(A) = -2\,\mathrm{Re}\sum_a \langle q_a, A_a v_a\rangle = \sum_a \mathrm{Re}\,\mathrm{Tr}(\mathcal{G}_a^* A_a), \qquad \mathcal{G}_a = -2 q_a v_a^*. \tag{129.1}$$

The anti-Hermitian and Hermitian projections of this representative are

$$\frac{\mathcal{G}_a - \mathcal{G}_a^*}{2} = v_a q_a^* - q_a v_a^* = \mathcal{J}_a, \qquad \frac{\mathcal{G}_a + \mathcal{G}_a^*}{2} = -(q_a v_a^* + v_a q_a^*). \tag{129.2}$$

Restriction to anti-Hermitian generators recovers exactly (128.3)*.*

Proof. The identity $\dot r_a = -A_a v_a$ and self-adjointness of the weight give $\dot E_m = 2\,\mathrm{Re}\langle q, \dot r\rangle$. Moreover,

$$\mathrm{Tr}(\mathcal{G}_a^* A_a) = -2\,\mathrm{Tr}(v_a q_a^* A_a) = -2 q_a^* A_a v_a.$$

The two projections are obtained by taking the adjoint. For the real Hilbert–Schmidt inner product, the Hermitian and anti-Hermitian subspaces are orthogonal; therefore the Hermitian part has zero contraction with an anti-Hermitian generator. □

The formula allows weights coupling edges: their action is calculated in $q = \mathsf{W}_m r$ before separating the contributions of each incidence. If field or weight vary, the complete expression (128.4) is retained, also valid for the invertible transports considered here.

129.2 Quadratic representations of TRIT

In a two-dimensional matrix realization of $\mathbb{A}_\tau$, one may take

$$J_+ = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad J_- = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad J_0 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Direct multiplication gives

$$J_+^2 = -I, \qquad J_-^2 = I, \qquad J_0^2 = 0.$$

Their exponentials realize, respectively, the elliptic, hyperbolic and parabolic regimes. The first is orthogonal for the fixed positive inner product. The second preserves the form $B = \operatorname{diag}(-1, 1)$, since $J_-^{\mathsf{T}} B + B J_- = 0$. The third represents the algebra of dual numbers. These representations fix examples of the quadratic types; their use on a screen of another dimension preserves the corresponding representation map.

A calculation distinguishes the components of the differential. On an edge, take $U = I$, $f_s = (1, 1)^{\mathsf{T}}$, $f_t = 2 f_s$ and $\mathsf{W} = I$. Then $q = v = f_s$, $\mathcal{J} = 0$, whereas

$$\mathrm{d}E(J_-) = -4, \qquad \mathrm{d}E(J_0) = -2. \tag{129.3}$$

The complete representative preserves both responses. The distinction identifies the space of variations before performing the material contraction.

129.3 Composition of routes and oriented inversion

Proposition 129.2 (Contragredient transport of the differential)**.** *For $U_\gamma = U_N \cdots U_1$, let $B_k = U_N \cdots U_{k+1}$ and $B_N = I$. We have*

$$\dot U_\gamma U_\gamma^{-1} = \sum_k B_k A_k B_k^{-1}.$$

The representative $\mathcal{G}_\gamma$ in the final fiber induces at incidence k

$$\mathcal{G}_k = B_k^{*} \mathcal{G}_\gamma (B_k^{-1})^{*}. \tag{129.4}$$

Proof. The product rule, followed by multiplication by U_γ^{-1}, proves the first equality. Cyclicity of the trace gives

$$\operatorname{Re}\operatorname{Tr}(\mathcal{G}_\gamma^{*} B_k A_k B_k^{-1}) = \operatorname{Re}\operatorname{Tr}((B_k^{*} \mathcal{G}_\gamma (B_k^{-1})^{*})^{*} A_k).$$

For unitary B_k, the conjugation of 128.2 is recovered. □

Proposition 129.3 (Inversion by energy congruence)**.** *For a local energy per edge, inversion is represented by*

$$U_{\bar a} = U_a^{-1}, \qquad r_{\bar a} = -U_a^{-1} r_a, \qquad W_{\bar a} = U_a^{*} W_a U_a. \tag{129.5}$$

It preserves energy. If W_a remains fixed,

$$A_{\bar a} = -U_a^{-1} A_a U_a, \qquad \dot W_{\bar a} = U_a^{*}(A_a^{*} W_a + W_a A_a) U_a.$$

The complete variation of the inverted energy coincides with the original.

Proof. Substitution into $r_{\bar a}^{*} W_{\bar a} r_{\bar a}$ produces $r_a^{*} W_a r_a$. The derivative of the inverse is $\dot U_a^{-1} = -U_a^{-1} A_a$; that of the weight is obtained by the product rule. Equality of energies holds for the entire family, so their derivatives coincide, including the term $\langle r_{\bar a}, \dot W_{\bar a} r_{\bar a} \rangle$. □

Congruence preserves positivity for every invertible transport. In the unitary representation it reduces to the inversion rule of 128.4. The sum uses one orientation per edge, or half the sum over both orientations.

129.4 Evaluation of current components

Let $\theta = (\theta_b)$ be a real variation of the connection coordinates of the realization used. The effective differential of transport defines the operators

$$A_a(\theta) = \dot{U}_a U_a^{-1} = \sum_b B_{ab}\theta_b. \tag{129.6}$$

For a finite composition, their contributions are obtained through (129.4). The operators B_{ab} are the derivatives of the connection representation that realizes the route.

Theorem 129.4 (Connection current of the memory action)**.** *For a material term $S_{\mathrm{mem}} = \mathfrak{a}_m E_m$, with $\mathfrak{a}_m$ its normalization on the action line, at fixed field, weight and normalization we have*

$$\delta S_{\mathrm{mem}} = -\frac{1}{2}\sum_b \theta_b s_b, \qquad s_b = 4\mathfrak{a}_m \operatorname{Re}\sum_a \langle q_a, B_{ab} v_a\rangle. \tag{129.7}$$

If the cellular pairing between the connection and current bases is an invertible matrix M, defined by $\delta S_{\mathrm{mem}} = -\frac{1}{2}\theta^{\mathsf{T}} M\sigma$, the current coordinates are

$$\sigma = M^{-1}s. \tag{129.8}$$

Proof. Substitute (129.6) into (129.1), multiply by $\mathfrak{a}_m$, and collect the coefficients of θ_b. The variational convention $-1/2$ fixes the factor 4. Comparing both expressions for every variation θ gives $M\sigma = s$; invertibility of the pairing proves existence and uniqueness of these coordinates. □

The formula explicitly realizes the composition mentioned in 128.5. To evaluate each component, the field is transported, the residual is calculated, the weight is applied and the result is contracted with the connection variation of the same realization. The pairing M preserves the orientation and volume of cells. A diagonal pairing gives the corresponding division by their volumes; other bases preserve the complete matrix.

If the connection also enters f, W_m or $\mathfrak{a}_m$, we apply (128.4) and add $E_m\delta\mathfrak{a}_m$. Contributions from all material terms are summed before composing the Cartan response.

Corollary 129.5 (Compatibility of the current with refinement)**.** *For the compatible families of 128.5, let P_m be the fixed map taking connection variations from level m to level $m+1$. If the memory actions coincide on those refined fields and transports, their covectors satisfy*

$$s_m = P_m^{\mathsf{T}} s_{m+1}, \qquad M_m\sigma_m = P_m^{\mathsf{T}} M_{m+1}\sigma_{m+1}.$$

Proof. Differentiating the equality of actions in the direction $P_m\theta$ gives $-\frac{1}{2}\theta^{\mathsf{T}} s_m = -\frac{1}{2}\theta^{\mathsf{T}} P_m^{\mathsf{T}} s_{m+1}$. The arbitrariness of θ and the cellular representations of both covectors prove the two identities. Composition of these maps iterates the equality to any finite number of refinements. □

129.5 Insertion into the Cartan equation

Section 131 normalizes the material three-form through $\delta_\omega S_m = -\frac{1}{2}\int \delta\omega^{IJ}\wedge\sigma_{IJ}$. The preceding theorem provides its cellular components for the declared memory action and pairing. The Cartan response uses that current together with the co-tetrad, the Barbero–Immirzi parameter and the gravitational coupling of the same realization.

The dependence of matter on contorsion determines how this equation is solved. For affine matter, the current is independent of contorsion, and the linear inversion and quadratic elimination proved in the next section apply. For a holonomy action, the differential is evaluated at the current connection, and that

dependence is retained when solving the equation. For example, an edge with $f_s = f_t = 1$, unit weight, and $U(t) = e^{it}$ has

$$E(t) = 2 - 2\cos t, \qquad E'(t) = 2\sin t.$$

Here the current depends on t. The complete formula retains that dependence instead of replacing it by its value at a particular connection.

Finally, the gravitational density is obtained from the metric variation of the effective action, with its field and normalization. The representation of the current, the contortion it produces and the resulting density are the successive operations of that composition. The subsequent dilution law transports the amplitude thus evaluated in the corresponding material section.

Chapter 130

Differential of the minimal boundary extension

The cubic incidence simultaneously determines the minimal-extension field and the weight of its response. For a boundary datum, both are calculated through the inverse of the incidence Gramian. We now develop the differential of this same operation, preserving the variations of the boundary, transport and normalization scale. In this way, the field involved in the response is selected by the screen variational problem.

130.1 Minimizing field and response weight

Let H and Q be finite-dimensional Hermitian spaces, with fixed inner products antilinear in the first variable. The real case is obtained by replacing adjoints with transposes. On an open set of real parameters Ω, consider families of class C^1

$$\mathsf{C}(\theta) : H \longrightarrow Q, \qquad b(\theta) \in Q, \qquad \chi(\theta) > 0, \qquad \operatorname{Ran} \mathsf{C}(\theta) = Q.$$

Surjectivity is equivalent to full row rank in orthonormal bases. We define the Gramian, the conjugate potential and the extension

$$\mathsf{L} = \mathsf{C}\mathsf{C}^*, \qquad y = \mathsf{L}^{-1} b, \qquad f_{\min} = \mathsf{C}^* y, \qquad \Lambda = \chi \mathsf{L}^{-1}. \tag{130.1}$$

The incidence C and the cellular pairing M of (129.8) are different operators.

Proposition 130.1 (Variational selection of the extension)**.** *The extension $f_{\min}$ is the unique norm minimizer among the fields $f \in H$ satisfying $\mathsf{C} f = b$. Its energy is*

$$E(\theta) = \chi \min_{\mathsf{C} f = b} \|f\|^2 = \chi \langle b, \mathsf{L}^{-1} b \rangle = \langle b, \Lambda b \rangle. \tag{130.2}$$

The field $f_{\min}$, potential y, and energy E depend C^1-smoothly on the parameters.

Proof. Surjectivity of C makes C^* injective, so $\langle z, \mathsf{L} z \rangle = \|\mathsf{C}^* z\|^2 > 0$ for $z \neq 0$. Thus L is invertible and $\mathsf{C} f_{\min} = \mathsf{L} y = b$. Every solution is $f_{\min} + z$, with $z \in \ker \mathsf{C}$. Since $f_{\min} \in \operatorname{Ran} \mathsf{C}^* = (\ker \mathsf{C})^{\perp}$,

$$\|f_{\min} + z\|^2 = \|f_{\min}\|^2 + \|z\|^2, \qquad \|f_{\min}\|^2 = \langle y, \mathsf{L} y \rangle = \langle b, \mathsf{L}^{-1} b \rangle.$$

These identities prove the minimum, its uniqueness and its value. Inversion is a differentiable operation on the open set of invertible matrices; the expressions in (130.1) provide the asserted regularity. □

The cubic realization of 126.1 corresponds to $H = \mathbb{R}^{\{-1,1\}^3}$, the screen quotient $Q = P_{\square} \mathbb{R}^6$ and the incidence $\mathsf{C} = M : H \to Q$. Its Gramian and normalization are

$$\mathsf{L}_{\square} = 12 P_u + 4 P_-, \qquad \chi_m = \frac{112}{81 \ell_m^2}, \qquad \Lambda_m = \frac{28}{243 \ell_m^2} (P_u + 3 P_-). \tag{130.3}$$

The factor $112/81$ comes from the soldering and the quadratic compression defect of (126.3). If b has length dimension, so do y and $f_{\min}$, the incidence is dimensionless and E is dimensionless. Conversion to action uses the normalization in the action line specified below.

130.2 Full differential of the minimum

Theorem 130.2 (Response to the variation of incidence and boundary)**.** *For every real tangent direction $\delta\theta$, one has*

$$\delta E = \delta\chi\,\langle b, y\rangle + 2\chi\,\mathrm{Re}\langle y, \delta b - (\delta \mathsf{C})\, f_{\min}\rangle. \tag{130.4}$$

If $\chi = 112/(81\ell_m^2)$, with variable $\ell_m > 0$,

$$\delta E = -2E\,\frac{\delta \ell_m}{\ell_m} + 2\chi_m\,\mathrm{Re}\langle y, \delta b - (\delta \mathsf{C})\, f_{\min}\rangle. \tag{130.5}$$

Proof. Differentiating $\mathsf{L}\mathsf{L}^{-1} = I_Q$ gives

$$\delta \mathsf{L}^{-1} = -\mathsf{L}^{-1}(\delta \mathsf{L})\mathsf{L}^{-1}, \qquad \delta \mathsf{L} = (\delta \mathsf{C})\mathsf{C}^{*} + \mathsf{C}(\delta \mathsf{C})^{*}.$$

Applying the product rule to (130.2) and using the self-adjointness of L^{-1} yields

$$\delta E = \delta\chi\,\langle b, y\rangle + 2\chi\,\mathrm{Re}\langle y, \delta b\rangle - \chi\langle y, (\delta \mathsf{L})\, y\rangle.$$

The two terms of the last product are conjugate to each other and $\mathsf{C}^{*} y = f_{\min}$; therefore,

$$\langle y, (\delta \mathsf{L})\, y\rangle = 2\,\mathrm{Re}\langle y, (\delta \mathsf{C})\, f_{\min}\rangle.$$

One obtains (130.4). Finally, $\delta\chi_m = -2\chi_m \delta\ell_m/\ell_m$ produces (130.5). □

The formula incorporates the variation of the minimizing field through the equation that determines it. It is also checked directly: $\mathsf{C}\delta f_{\min} = \delta b - (\delta \mathsf{C})\, f_{\min}$ and $f_{\min} = \mathsf{C}^{*} y$ imply

$$\delta\|f_{\min}\|^2 = 2\,\mathrm{Re}\langle f_{\min}, \delta f_{\min}\rangle = 2\,\mathrm{Re}\langle y, \delta b - (\delta \mathsf{C})\, f_{\min}\rangle.$$

For example, if C is fixed and $b = \ell_m b_0$, with b_0 fixed, the two terms of (130.5) cancel and the energy remains constant. This check jointly preserves the boundary dimension and its normalization.

130.3 Fixed quotient and frame changes

The preceding derivatives are taken in fixed spaces H, Q and Hermitian inner products. In the six-face presentation, the inverse always acts on $Q = P_{\square} H_F$. For a family of quotients $Q(\theta)$, an isometric trivialization $V_Q(\theta) : Q \to Q(\theta)$ is fixed first, and likewise for the domain. The derivatives of those maps are included when differentiating the expressions transported to the fixed spaces. The formulas apply on each open set where rank is preserved. Changes in the energy inner product additionally require differentiating that product; a Lorentzian metric and the positive inner product used for minimization retain their distinct types here.

Proposition 130.3 (Covariance of the minimum)**.** *Let g_H, g_Q be unitary. Under*

$$\mathsf{C}' = g_Q \mathsf{C} g_H^{*}, \qquad b' = g_Q b, \qquad \chi' = \chi,$$

$y' = g_Q y$, $f'_{\min} = g_H f_{\min}$ and $E' = E$ hold. When the frame changes depend on the parameter, the full differential preserves this equality. In particular, a pure frame variation has $\delta E = 0$.

Proof. The transformed Gramian is $\mathsf{L}' = g_Q \mathsf{L} g_Q^{*}$, from which the transformations of y, $f_{\min}$ and equality of energies are obtained. For a pure frame variation, at a point with identity frames, let $A_Q^{*} = -A_Q$ and $A_H^{*} = -A_H$ be their generators. Then

$$\delta \mathsf{C} = A_Q \mathsf{C} - \mathsf{C} A_H, \qquad \delta b = A_Q b, \qquad \delta b - (\delta \mathsf{C})\, f_{\min} = \mathsf{C} A_H f_{\min}.$$

Its contribution to (130.4) is $2\chi\,\mathrm{Re}\langle f_{\min}, A_H f_{\min}\rangle = 0$. The proof thus includes the terms due to the moving frames. □

130.4 Transported incidence and connection components

The connection dependence is specified before performing the contraction. An explicit blockwise realization of the incidence is obtained as follows. Let $\mathcal{K}$ be a common Hermitian fibre, $F = \{(i,\epsilon) : 1 \le i \le 3,\ \epsilon = \pm 1\}$ and $V = \{-1,1\}^3$. For each incidence $\nu_i = \epsilon$, the realization used declares a route $\gamma_{i,\epsilon,\nu}$ from the vertex fibre to the face fibre, with transport $U_{i,\epsilon,\nu}$. The trivializations identify these fibres with $\mathcal{K}$. We define

$$\begin{aligned}(\mathsf{B}_U f)_{i,\epsilon} &= \sum_{\nu_i=\epsilon} U_{i,\epsilon,\nu} f_\nu,\\ \mathsf{C}_U = (q_\square \otimes I_{\mathcal{K}})\mathsf{B}_U &: \bigoplus_{\nu\in V} \mathcal{K} \longrightarrow Q\otimes\mathcal{K}, \qquad q_\square = P_\square : H_F \to Q.\end{aligned} \tag{130.6}$$

This is an explicit variational continuation of the cubic incidence in the declared route representation. For identity transports, $\mathsf{C}_U = M \otimes I_{\mathcal{K}}$ and one recovers (130.3), tensored with the fibre. The Gramian remains positive in a neighbourhood of that realization, since positive definiteness is an open condition. On each full-rank domain, the weight and field are fixed by (130.1). The routes realizing the incidences, their orientations and their memories are data of this realization of APP–TRIT–TPK transport and accompany the construction.

If $\omega = (\omega_j)$ are real connection coordinates, the derivative of C_U is calculated by substituting in each block

$$\partial_j U_\gamma = \sum_{k=1}^{N} U_N \cdots U_{k+1}(\partial_j U_k) U_{k-1}\cdots U_1, \qquad U_\gamma = U_N\cdots U_1. \tag{130.7}$$

Empty products are identities. The formula follows from the product rule and preserves the position of each operation in the route. Thus, $\mathsf{C}_j := \partial_j \mathsf{C}_U$ is obtained from a finite sum of known matrices in the chosen realization, followed by the projection $q_\square \otimes I$. If a moving quotient is used, its derivative is incorporated according to 130.3. The fixed integer cubic matrix corresponds to the case $\mathsf{C}_j = 0$; the response to the connection follows from the transport dependence actually declared in (130.6).

Theorem 130.4 (Variational components of the minimal extension)**.** *For the screen action $S_{\min} = \mathfrak{a}_m E$, where $\mathfrak{a}_m$ is its normalization in the action line, let us write*

$$b_j = \partial_j b, \qquad \chi_j = \partial_j \chi, \qquad a_j = \partial_j \mathfrak{a}_m.$$

With the convention $\delta S_{\min} = -\frac{1}{2}\sum_j s_j \delta\omega_j$, the components are

$$\begin{aligned} s_j = {} & 4\mathfrak{a}_m \chi \,\mathrm{Re}\langle y, \mathsf{C}_j f_{\min} - b_j\rangle \\ & - 2\mathfrak{a}_m \chi_j \langle b, y\rangle - 2a_j E. \end{aligned} \tag{130.8}$$

For the cubic normalization, the second term equals $4\mathfrak{a}_m E\,\partial_j \ell_m/\ell_m$. If the cellular pairing of this same action has invertible matrix $\mathsf{M}_{\mathrm{cel}}$, its current coordinates are $\sigma = \mathsf{M}_{\mathrm{cel}}^{-1} s$.

Proof. The product rule gives $\partial_j S_{\min} = a_j E + \mathfrak{a}_m \partial_j E$. Substituting (130.4) and multiplying by -2 proves (130.8). The derivative of χ_m produces the scale expression. Finally, comparing $\delta S_{\min} = -\frac{1}{2}\delta\omega^{\mathsf{T}} s$ with $-\frac{1}{2}\delta\omega^{\mathsf{T}}\mathsf{M}_{\mathrm{cel}}\sigma$ for every variation gives $\mathsf{M}_{\mathrm{cel}}\sigma = s$, and its inverse determines the coordinates. □

The construction recovers a field and a weight jointly selected by the incidence, and evaluates their response to variations of the same realization. The boundary datum b, the route family, the scale ℓ_m, the normalization $\mathfrak{a}_m$ and the cellular pairing retain their publication rules. Interpretation as a material current uses those objects and the complete action. The Cartan response and its subsequent metric density are composed with it in the corresponding matter domain, preserving any dependence of the current on the connection.

Chapter 131

Spin current and algebraic Cartan–Holst response

The realization of the enriched transport in Section 127 provides the cotetrad and the connection; the dimensional sections and the incidence parameter of Sections 120 and 121 fix their couplings. Their composition determines a first-order variational problem. The material current occupies a precise position in it: it is the derivative of the action with respect to the connection and determines the torsional response with the same normalization.

131.1 Geometric domain and current normalization

We work on a smooth oriented four-dimensional manifold M, with internal Lorentzian bundle E, metric $\eta = \mathrm{diag}(-1,1,1,1)$ and non-degenerate cotetrad $e \in \Omega^1(M;E)$. In a local frame we write e^I, with $I = 0,1,2,3$. The metric connection $\omega^{IJ} = -\omega^{JI}$ acts through D_ω. When the fields Ψ are spinorial, a spin structure and the corresponding material representation are preserved. We define

$$\Sigma^{IJ} = e^I \wedge e^J, \qquad F^{IJ} = \mathrm{d}\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}, \qquad T^I = D_\omega e^I. \tag{131.1}$$

The operator $\star$ acts on the internal bivector indices,

$$(\star X)^{IJ} = \tfrac{1}{2}\epsilon^{IJ}{}_{KL}X^{KL}, \qquad \star^2 = -I, \qquad \mathsf{P}_\gamma = \star + \gamma^{-1}I. \tag{131.2}$$

This distinguishes this duality from the exterior duality of forms on M. Internal indices are raised and contracted with η.

We fix a chart with $G_{\mathrm{int}} > 0$, $c_{\mathrm{int}} > 0$, $\gamma = \gamma_{\mathrm{HMT}} \in \mathbb{R} \setminus \{0\}$ and Λ_{int} constant on it. We abbreviate $\kappa = 8\pi G_{\mathrm{int}}/c_{\mathrm{int}}^4$ and $c = c_{\mathrm{int}}$. These sections remain fixed during variation. The action is

$$S[e,\omega,\Psi] = \frac{1}{2\kappa c}\int_M \Sigma_{IJ} \wedge (\mathsf{P}_\gamma F)^{IJ} - \frac{\Lambda_{\mathrm{int}}}{\kappa c}\int_M \mathrm{vol}_e + S_{\mathrm{m}}[e,\omega,\Psi]. \tag{131.3}$$

The volume and orientation convention is the one that gives $\Sigma_{IJ} \wedge (\star F)^{IJ} = R\,\mathrm{vol}_e$ in the Levi–Civita sector. The prior dimensional type makes each summand an action section.

For the variation of the connection, variations with compact support in the interior are used, or $\delta\omega|_{\partial M} = 0$ is fixed. A boundary completion whose variational problem cancels the same boundary term may also be used. At fixed cotetrad and material fields, the spin current is the degree-three form, valued in dual internal bivectors, determined by

$$\delta_\omega S_{\mathrm{m}} = -\tfrac{1}{2}\int_M \delta\omega^{IJ} \wedge \sigma_{IJ}. \tag{131.4}$$

Pairing with an arbitrary compactly supported variation fixes σ uniquely. This definition preserves the action unit of the current and the normalization factor involved in its geometric response.

131.2 Connection variation and Holst inversion

Theorem 131.1 (Variational Cartan–Holst equation)**.** *On the preceding domain, stationarity with respect to the connection is equivalent to*

$$D_\omega(\mathsf{P}_\gamma\Sigma)^{IJ} = \kappa c\,\sigma^{IJ}. \tag{131.5}$$

Proof. The variation of the curvature is $\delta F = D_\omega\delta\omega$. The internal duality is parallel and self-adjoint for the bivector contraction; since γ is constant, $D_\omega\mathsf{P}_\gamma = \mathsf{P}_\gamma D_\omega$. Setting $B_{IJ} = (\mathsf{P}_\gamma\Sigma)_{IJ}$ yields

$$B_{IJ}\wedge D_\omega\delta\omega^{IJ}=\mathrm{d}(B_{IJ}\wedge\delta\omega^{IJ})-D_\omega B_{IJ}\wedge\delta\omega^{IJ}.$$

The last form changes sign when its factors of degrees three and one are interchanged. The boundary conditions eliminate the integral of the exact term. The cosmological term is independent of ω. Therefore,

$$\delta_\omega S=\frac{1}{2\kappa c}\int_M\delta\omega^{IJ}\wedge\left[D_\omega B_{IJ}-\kappa c\,\sigma_{IJ}\right].$$

The arbitrariness of the variation proves the equation, including its sign and coefficient. □

Lemma 131.2 (Real inverse of the Holst operator)**.** *For $\gamma\in\mathbb{R}\setminus\{0\}$,*

$$\mathsf{P}_\gamma^{-1}=\frac{\gamma^2}{1+\gamma^2}(-\star+\gamma^{-1}I).\tag{131.6}$$

Proof. Both factors are polynomials in $\star$ and commute. Their product before normalization is

$$(\star+\gamma^{-1}I)(-\star+\gamma^{-1}I)=-\star^2+\gamma^{-2}I=(1+\gamma^{-2})I.$$

The denominator $1+\gamma^2$ is positive on the fixed real domain. Multiplication by $\gamma^2/(1+\gamma^2)$ gives the identity. □

The current thus determines the degree-three bivector-valued form

$$Y^{IJ}:=\kappa c\,\frac{\gamma^2}{1+\gamma^2}(-\star+\gamma^{-1}I)\sigma^{IJ},\qquad D_\omega\Sigma^{IJ}=Y^{IJ}.\tag{131.7}$$

131.3 Pointwise reconstruction of torsion and contorsion

The Leibniz rule gives

$$D_\omega\Sigma^{IJ}=T^I\wedge e^J-e^I\wedge T^J=:\mathsf{L}_e(T)^{IJ}.\tag{131.8}$$

At each point, L_e acts from $\Lambda^2T^*M\otimes E$ to $\Lambda^3T^*M\otimes\Lambda^2E$. Both spaces have dimension twenty-four. Let E_I be the dual frame of the cotetrad, so that $\iota_{E_I}e^J=\delta_I^J$.

Theorem 131.3 (Algebraic inversion of the torsional equation)**.** *For a nondegenerate co-tetrad, L_e is an isomorphism. Its inverse on the form Y is written*

$$B^I=\sum_J\iota_{E_J}Y^{IJ},\qquad b=\tfrac14\sum_I\iota_{E_I}B^I,\qquad T^I=B^I-e^I\wedge b.\tag{131.9}$$

Equation (131.5) *therefore determines torsion pointwise from e and the current appearing in it.*

Proof. First let $Y=\mathsf{L}_e(T)$ and set $t=\sum_J\iota_{E_J}T^J$. The contraction of (131.8), using that T^I has degree two and that the cotetrad has four elements, gives

$$\sum_J\iota_{E_J}(T^I\wedge e^J)=2T^I,\qquad\sum_J\iota_{E_J}(e^I\wedge T^J)=T^I-e^I\wedge t.$$

Hence $B^I=T^I+e^I\wedge t$. A second contraction produces

$$\sum_I\iota_{E_I}B^I=t+3t=4t.$$

One recovers $t=b$ and then $T^I=B^I-e^I\wedge b$. In particular, the kernel of L_e is zero. Equality of dimensions proves its surjectivity and makes the formula valid for every form Y in the codomain. □

The connection decomposes uniquely as

$$\omega^{IJ} = \mathring{\omega}^{IJ}(e) + K^{IJ}, \qquad K^{IJ} = -K^{JI}, \qquad T^I = K^I{}_J \wedge e^J, \tag{131.10}$$

where $\mathring{\omega}(e)$ is the Levi–Civita connection and K the contorsion. To make the inverse explicit, we write $K_{IJ} = K_{IJK}e^K$ and $T_I = \frac{1}{2}T_{IJK}e^J \wedge e^K$. Then

$$T_{IJK} = K_{IKJ} - K_{IJK}, \qquad K_{IJK} = \tfrac{1}{2}(T_{KIJ} - T_{IJK} - T_{JKI}). \tag{131.11}$$

The second equality is obtained by combining the first cyclically and using $K_{IJK} = -K_{JIK}$; substituting it recovers the components of T. Torsion and contorsion are therefore two equivalent presentations of the algebraic response at fixed cotetrad.

Corollary 131.4 (Current-free sector and minimal linear response)**.** *If $\sigma = 0$, one obtains $T = 0$ and $\omega = \mathring{\omega}(e)$. For a material coupling whose current $\sigma[e, \Psi]$ is independent of K, equations* (131.7)*,* (131.9) *and* (131.11) *provide a unique response $K_*(e, \Psi)$, linear in σ.*

Proof. The three reconstruction maps are linear with e, γ and κc fixed. The zero current produces $Y = 0$, then $T = 0$ and finally $K = 0$. □

In the minimal action, the connection equation contains this pointwise response. Its evolution is obtained by evolving e and Ψ: $K_* = K_*(e, \Psi)$ changes with them. If a material action preserves additional algebraic dependence on K, the Cartan equation retains its variational form and must be solved with that current; the preceding linear response corresponds to the specified minimal domain.

131.4 Elimination of contorsion and quadratic contribution

Now consider the minimal coupling affine in K, expressed by

$$S_{\mathrm{m}}[e, \mathring{\omega} + K, \Psi] = S_{\mathrm{m}}[e, \mathring{\omega}, \Psi] - \tfrac{1}{2}\int_M K^{IJ} \wedge \sigma_{IJ}[e, \Psi]. \tag{131.12}$$

This condition identifies the material action to which the quadratic elimination applies; the current remains the one defined by (131.4).

The curvature expansion is

$$F(\mathring{\omega} + K) = F(\mathring{\omega}) + D_{\mathring{\omega}}K + K \wedge K, \qquad (K \wedge K)^{IJ} = K^I{}_L \wedge K^{LJ}. \tag{131.13}$$

Since $D_{\mathring{\omega}}\Sigma = 0$, the linear term is the exterior derivative of $\Sigma_{IJ} \wedge (\mathsf{P}_\gamma K)^{IJ}$. The corresponding boundary contribution remains explicit:

$$S_\partial[e, K] = \frac{1}{2\kappa c}\int_{\partial M} \Sigma_{IJ} \wedge (\mathsf{P}_\gamma K)^{IJ}. \tag{131.14}$$

On an interior domain, or with the compatible boundary completion, the action density that depends on the contorsion is

$$\mathcal{Q}_{e,\gamma}(K) - \tfrac{1}{2}K^{IJ} \wedge \sigma_{IJ}, \qquad \mathcal{Q}_{e,\gamma}(K) = \frac{1}{2\kappa c}\Sigma_{IJ} \wedge \mathsf{P}_\gamma(K \wedge K)^{IJ}. \tag{131.15}$$

The density $\mathcal{Q}_{e,\gamma}$ is a degree-four differential form, homogeneous of degree two in K.

Theorem 131.5 (Effective response quadratic in the current)**.** *Under* (131.12)*, substituting the algebraic solution K_* produces the effective spin density*

$$\mathcal{L}^{\mathrm{eff}}_{\mathrm{spin}} = -\tfrac{1}{4}K_*^{IJ} \wedge \sigma_{IJ} = -\mathcal{Q}_{e,\gamma}(K_*). \tag{131.16}$$

At fixed cotetrad and couplings, it is homogeneous of degree two in the current. The effective action also preserves $S_\partial[e, K_*]$, or its declared boundary completion.

Proof. By Corollary 131.4, K_* is linear in σ. The connection equation is precisely the stationarity of (131.15). Since it is algebraic, the radial variation $\delta K = K_*$ is applied pointwise; it may also be multiplied by a compactly supported function. Euler's identity for a quadratic form gives

$$2\mathcal{Q}_{e,\gamma}(K_*) - \tfrac{1}{2} K_*^{IJ} \wedge \sigma_{IJ} = 0.$$

Substitution into the action density proves (131.16). If $\sigma \mapsto \lambda\sigma$, then $K_* \mapsto \lambda K_*$ and the effective density is multiplied by λ^2. The expansion (131.13) separately identifies the boundary term accompanying this elimination. □

The specific current, its Lorentzian contraction, the duality and the conventions of the material action determine the sign and coefficient of this contribution. The quadratic identity provides the composition rule that allows them to be evaluated once these data have been specified.

131.5 Effective metric source and covariant balance

The normalization of the metric source is fixed in the same action line. After eliminating K, we define

$$\delta_g S_{\mathrm{m}}[e, \mathring{\omega}, \Psi] = -\tfrac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} \, \delta g^{\mu\nu}, \tag{131.17}$$

$$\delta_g S^{\mathrm{eff}}_{\mathrm{spin}} = -\tfrac{1}{2} \int_M \mathrm{vol}_e \; \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu} \, \delta g^{\mu\nu}. \tag{131.18}$$

Here interior variations are considered, with boundary terms treated according to the fixed variational problem. For the affine coupling, the second source is the metric variation of (131.16). The variation includes the dependence of the material current on e and Ψ.

Proposition 131.6 (Metric equation and conservation of the total source)**.** *With the preceding conventions, the metric equations are*

$$G_{\mu\nu}[g] + \Lambda_{\mathrm{int}} g_{\mu\nu} = \kappa c \big(\mathcal{T}^{S,\mathrm{LC}}_{\mu\nu} + \mathcal{U}^{S,\mathrm{spin}}_{\mu\nu} \big) = \kappa \big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu} \big), \tag{131.19}$$

where $T^{\mathrm{phys,LC}} = c\mathcal{T}^{S,\mathrm{LC}}$ and $U^{\mathrm{phys,spin}} = c\mathcal{U}^{S,\mathrm{spin}}$ when the cotetrad takes values in the length line. Every solution satisfies

$$\mathring{\nabla}^\mu \big(T^{\mathrm{phys,LC}}_{\mu\nu} + U^{\mathrm{phys,spin}}_{\mu\nu} \big) = 0. \tag{131.20}$$

Proof. Eliminating K preserves the equations of the remaining variables: in the chain rule, the term multiplying δK_* vanishes by the connection equation. In the Levi–Civita sector, the first Bianchi identity cancels the term $\Sigma_{IJ} \wedge F^{IJ}$, and the gravitational part is written $(2\kappa c)^{-1} \int_M (R - 2\Lambda_{\mathrm{int}}) \, \mathrm{vol}_e$. Its interior variation is

$$\frac{1}{2\kappa c} \int_M \mathrm{vol}_e \; (G_{\mu\nu} + \Lambda_{\mathrm{int}} g_{\mu\nu}) \delta g^{\mu\nu}.$$

The sum with (131.18) gives (131.19). The contracted Bianchi identity for $\mathring{\nabla}$, metric compatibility and the constancy of κ and Λ_{int} in the chart produce (131.20). □

Before eliminating the connection, the geometric identities retain the form

$$D_\omega T^I = F^I{}_J \wedge e^J, \qquad D_\omega F^{IJ} = 0. \tag{131.21}$$

The first is $D_\omega^2 e = F \wedge e$; the second is obtained by expanding $D_\omega(\mathrm{d}\omega + \omega \wedge \omega)$ and cancelling the terms. In a covariant material action, the total metric balance coincides with the Noether identity on the material

equations. Geometry and matter thus preserve a joint source; the partition between its Levi–Civita contribution and its spin contribution is determined by the specialized action.

Chapter 132

Torsional elimination and metric response of the minimal extension

The minimal extension provides a field, a response weight and a current through a single variational operation. Its transported incidence depends on the connection through the route products of (130.7). That dependence is preserved when composing the current with the Cartan–Holst equation. Elimination of the connection is therefore performed on the complete action of that extension. The affine case of 131.5 is contained as an exact specialization of the following construction.

132.1 Variational composition at a cellular level

Let us fix a finite level, its routes, the transport representation and the cellular pairing of 130.4. Let p be real coordinates of the co-tetrad and the material fields in a declared local trivialization, and $k \in \mathbb{R}^d$ the coordinates of the contortion K. The family $p \mapsto e(p)$ preserves nondegeneracy of the co-tetrad. The connection acting on each route is

$$\omega(p,k) = \mathring{\omega}(e(p)) + K(k), \qquad F(p,k) = S_{\min}[e(p), \omega(p,k), \Psi(p)] = \mathfrak{a}(p,k)E(p,k). \tag{132.1}$$

The spaces and bases of this expression are transported to fixed spaces before differentiation. We work on an open set where the incidence $\mathsf{C}(p,k)$ is surjective and the families are C^2. This additional regularity allows the Hessian of the action to be examined. The couplings $G_{\mathrm{int}}, c_{\mathrm{int}}, \gamma_{\mathrm{HMT}}$ preserve the chart and the variation convention of 131.1.

Let $Q(p,k)$ be the integral, or the declared cellular realization, of the quadratic form (131.15). In real bases,

$$Q(p,k) = \tfrac{1}{2} k^{\mathsf{T}} \mathsf{A}(p) k, \qquad \mathsf{A}(p)^{\mathsf{T}} = \mathsf{A}(p). \tag{132.2}$$

The operator A comes from the gravitational action and its pairing, whereas the Gramian $\mathsf{C}\mathsf{C}^*$ comes from the extension problem. Positivity of the latter guarantees existence of the minimizing field; the gravitational form retains its own signature. Boundary terms are retained according to (131.14); the following interior formulas apply with admissible variations that annul their contribution, or with the corresponding boundary completion.

Define the response covector by

$$d_k F(p,k)[h] = -\tfrac{1}{2} h^{\mathsf{T}} s(p,k), \qquad s(p,k) = \mathsf{M}_{\mathrm{cel}}(p,k)\sigma(p,k). \tag{132.3}$$

Here s and σ preserve the distinct types of (130.8): the former contains the coefficients of the differential and the latter the coordinates of the current in the material pairing. If the basis in k changes, that pairing is also transported. When differentiating $s = \mathsf{M}_{\mathrm{cel}}\sigma$, the derivatives of both factors are included when the pairing depends on the parameter.

Proposition 132.1 (Composed equation of extension and contorsion)**.** *Interior stationarity of the action with respect to contorsion is*

$$\mathcal{R}(p,k) := \mathsf{A}(p)k - \tfrac{1}{2} s(p,k) = 0. \tag{132.4}$$

Each component of s is calculated from the same extension:

$$\begin{aligned} s_j = {} & 4\mathfrak{a}\chi \,\mathrm{Re}\langle y, (\partial_{k_j}\mathsf{C}) f_{\min} - \partial_{k_j} b\rangle \\ & - 2\mathfrak{a}(\partial_{k_j}\chi)\langle b, y\rangle - 2(\partial_{k_j}\mathfrak{a})E. \end{aligned} \tag{132.5}$$

When the cellular pairing realizes the connection equation of 131.1, this equation is equivalent to composing $\sigma(p,k)$ with the Holst inverse, the inverse of L_e and the contortion reconstruction:

$$K = \mathsf{C}_e^{\mathrm{tor}}\,\mathsf{L}_e^{-1}\big(\kappa c\,\mathsf{P}_\gamma^{-1}\sigma[e,\mathring{\omega}(e)+K,\Psi]\big). \tag{132.6}$$

The symbol $\mathsf{C}_e^{\mathrm{tor}}$ exclusively designates the map $T \mapsto K$ of (131.11), with fixed co-tetrad.

Proof. The differential of $Q+F$, in the arbitrary direction h, is

$$d_k(Q+F)[h] = h^{\mathsf{T}}\big(\mathsf{A}k - \tfrac{1}{2}s\big).$$

Its vanishing in every direction proves (132.4). Theorem 130.4, applied to ∂_{k_j}, gives (132.5). With p fixed, $\delta\omega = \delta K$. The Cartan equation is transformed successively through (131.6), (131.9) and (131.11); each of these operations is invertible on its domain. This proves equivalence with (132.6) when both expressions use the same material and cellular realization. □

The composition preserves the connection on both sides. Routes passing through several cells can couple the current components between them. The pointwise reconstruction of T from a given current and the joint solution of (132.4) are, in that case, successive operations. This finite formulation keeps explicit the route representation entering the functional.

132.2 Local existence of a stationary branch

Theorem 132.2 (Local continuation of the torsional solution)**.** *Suppose (p_0,k_0) belongs to the preceding open set, $\mathcal{R}(p_0,k_0)=0$, and the total Hessian*

$$\mathsf{H}_0 = \mathsf{A}(p_0) + \partial_k^2 F(p_0,k_0) = \mathsf{A}(p_0) - \tfrac{1}{2}\partial_k s(p_0,k_0) \tag{132.7}$$

is invertible. There exist neighborhoods of p_0 and k_0 in which a unique branch C^1, $k = k_*(p)$, satisfies (132.4) and passes through k_0. On that branch,

$$\partial_{p_i} k_* = -\big[\mathsf{A} + \partial_k^2 F\big]^{-1}\big[(\partial_{p_i}\mathsf{A})k_* + \partial_{p_i}\partial_k F\big]. \tag{132.8}$$

Proof. Inversion of the Gramian is C^2 on the full-rank open set. Hence F is C^2 and $\mathcal{R}$ is C^1. Its derivative with respect to k, at (p_0,k_0), is H_0. The implicit function theorem provides the branch, its regularity and its uniqueness in a neighborhood of the point. Existence can also be seen through the map

$$\mathcal{T}_p(k) = k - \mathsf{H}_0^{-1}\mathcal{R}(p,k).$$

Its derivative with respect to k vanishes at (p_0,k_0). On a sufficiently small ball it has norm at most $q<1$. Shrinking the neighborhood of p_0 yields $\|\mathcal{T}_p(k_0)-k_0\| < (1-q)r$, where r is the radius of the ball. Thus, $\mathcal{T}_p$ maps the closed ball into itself and is contractive. Its fixed point is the local solution. Differentiating $\mathcal{R}(p,k_*(p))=0$ and solving for $\partial_{p_i}k_*$ gives (132.8). □

The hypothesis is verified on the composite action: the Gramian's rank ensures the screen minimum and the total Hessian controls the torsional branch. The asserted uniqueness is local around the specified solution; other branches may coexist in the same full-rank domain.

132.3 Effective action and non-affine contribution

Theorem 132.3 (Exact elimination identity)**.** *Let $k_*(p)$ be a stationary branch. Suppose, moreover, that the segment $t \mapsto (p, tk_*)$, $0 \le t \le 1$, remains in the open set where F is defined. The action correction relative to the Levi–Civita realization is*

$$\begin{aligned} \Delta S(p) &:= Q(p,k_*) + F(p,k_*) - F(p,0) \\ &= \tfrac{1}{4} k_*^{\mathsf{T}} s(p,k_*) - \tfrac{1}{2} \int_0^1 k_*^{\mathsf{T}} s(p,tk_*)\, dt. \end{aligned} \tag{132.9}$$

Equivalently,

$$\Delta S = -\tfrac{1}{4} k_*^{\mathsf{T}} s(p,k_*) + \tfrac{1}{2} \int_0^1 k_*^{\mathsf{T}} \big[s(p,k_*) - s(p,tk_*) \big]\, dt. \tag{132.10}$$

These identities refer to the integrated or cellular action. In a realization with local density, they apply to the density with its corresponding pairing of forms. The effective action preserves the declared boundary term separately.

Proof. By the chain rule and (132.3),

$$\frac{d}{dt} F(p,tk_*) = -\tfrac{1}{2} k_*^{\mathsf{T}} s(p,tk_*).$$

Integrating between 0 and 1 gives the difference of material actions. The stationarity equation, evaluated in the direction k_*, and the quadratic homogeneity of Q give

$$2Q(p,k_*) = \tfrac{1}{2} k_*^{\mathsf{T}} s(p,k_*).$$

The sum of both identities proves (132.9); adding and subtracting $\frac{1}{2} k_*^{\mathsf{T}} s(p,k_*)$ provides (132.10). □

Corollary 132.4 (Affine specialization)**.** *If $s(p,k) = s(p)$, then*

$$\Delta S = -\tfrac{1}{4} k_*^{\mathsf{T}} s(p) = -Q(p,k_*).$$

This is the integrated realization of (131.16)*.*

Proof. The difference inside the integral of (132.10) vanishes. The second equality follows from the radial stationarity identity. □

132.4 Metric differential of the eliminated action

Theorem 132.5 (Response of the geometric variables)**.** *On the branch of Theorem 132.2,*

$$\partial_{p_i} \Delta S = \tfrac{1}{2} k_*^{\mathsf{T}} (\partial_{p_i} \mathsf{A}) k_* + (\partial_{p_i} F)(p,k_*) - (\partial_{p_i} F)(p,0), \tag{132.11}$$

where the partial derivatives keep the coordinates k fixed. In fixed Hermitian inner products, each material derivative is calculated by

$$\begin{aligned} \partial_{p_i} F = {} & (\partial_{p_i} \mathfrak{a}) E + \mathfrak{a} (\partial_{p_i} \chi) \langle b, y \rangle \\ & + 2\mathfrak{a}\chi\, \mathrm{Re} \langle y, \partial_{p_i} b - (\partial_{p_i} \mathsf{C}) f_{\min} \rangle. \end{aligned} \tag{132.12}$$

If p_i varies the co-tetrad, $\partial_{p_i} \mathsf{C}$ includes the variation of $\mathring{\omega}(e(p)) + K(k)$, of the realized routes and of the trivializations used, according to their declared dependencies.

Proof. The total derivative of $Q(p,k_*)+F(p,k_*)$ contains, in addition to its partial derivatives, the term

$$\big[\partial_k Q(p,k_*)+\partial_k F(p,k_*)\big]\partial_{p_i}k_*.$$

The bracket is zero by the connection equation. Subtracting the derivative of $F(p,0)$ proves (132.11). The product rule and (130.4) prove (132.12). The composition (132.1) requires differentiating the Levi–Civita connection when varying e with k fixed. □

When the positive extension inner product also varies, its contribution is preserved explicitly. In coordinates, let $\mathsf{h}(p,k)>0$ be its Hermitian matrix and consider the minimum of $f^*\mathsf{h}f$ under $\mathsf{C}f=b$. Then

$$\mathsf{L}=\mathsf{C}\mathsf{h}^{-1}\mathsf{C}^*,\quad y=\mathsf{L}^{-1}b,\quad f_{\min}=\mathsf{h}^{-1}\mathsf{C}^*y,\quad E=\chi b^*y. \tag{132.13}$$

Here y represents the constraint covector in fixed bases. The positive matrix h retains its energy role, distinct from that of the Lorentzian metric.

Lemma 132.6 (Variation of the extension inner product)**.** *With the preceding conventions,*

$$\delta E=(\delta\chi)b^*y+2\chi\,\mathrm{Re}\big[y^*(\delta b-\delta\mathsf{C}f_{\min})\big]+\chi f_{\min}^*(\delta\mathsf{h})f_{\min}. \tag{132.14}$$

Proof. The formula $\delta\mathsf{h}^{-1}=-\mathsf{h}^{-1}(\delta\mathsf{h})\mathsf{h}^{-1}$ gives

$$\delta\mathsf{L}=(\delta\mathsf{C})\mathsf{h}^{-1}\mathsf{C}^*+\mathsf{C}\mathsf{h}^{-1}(\delta\mathsf{C})^*-\mathsf{C}\mathsf{h}^{-1}(\delta\mathsf{h})\mathsf{h}^{-1}\mathsf{C}^*.$$

When differentiating $E=\chi b^*\mathsf{L}^{-1}b$, the term $-\chi y^*(\delta\mathsf{L})y$ produces the two terms with $\delta\mathsf{C}$ and the positive term with $\delta\mathsf{h}$. This proves the complete identity. □

In a covariant material realization whose variation admits the metric pairing of (131.18), the correction determines

$$\delta_g\Delta S=-\tfrac12\int_M \mathrm{vol}_e\ \mathcal{U}^{S,\min}_{\mu\nu}\,\delta g^{\mu\nu},\qquad U^{\mathrm{phys},\min}_{\mu\nu}=c\mathcal{U}^{S,\min}_{\mu\nu}. \tag{132.15}$$

Equations (132.11) and (132.12), supplemented by (132.14) where appropriate, evaluate their coefficients in the declared metric variations. The screen minimum, torsional solution and metric derivative are three consecutive operations on the same action. The reduced action preserves the possible couplings between cells present in the original routes.

The homogeneous specialization of 134 additionally uses the realization of the resulting tensor: its spatial symmetry, the sign of contraction with the observer and the scaling law. When that evaluation gives $\rho_{\mathrm{corr}}(a)=-s_0a^{-6}$, the amplitude is read in the reference state as $s_0=-a_{\mathrm{ref}}^6\rho_{\mathrm{corr}}(a_{\mathrm{ref}})$. This reading preserves the material state and its normalization; the elimination theorem provides the action to be contracted.

132.5 Exact non-affine checking model

The following finite model checks the coefficients and the non-affine dependence of the identities. Its parameters belong to the algebraic example and keep the problem of material realization of the routes separate.

Proposition 132.7 (Exact elimination of a rank-one extension)**.** *Let $H=\mathbb{R}^2$, $Q=\mathbb{R}$, $\mathsf{C}(k)=(1\ \ k)$, $b=1$, $\chi=1$, $\mathfrak{a}=\lambda>0$, and $Q_{\mathrm{ex}}(k)=k^2/2$. Then*

$$f_{\min}=\frac{(1,k)^{\mathsf{T}}}{1+k^2},\quad F(\lambda,k)=\frac{\lambda}{1+k^2},\quad s(\lambda,k)=\frac{4\lambda k}{(1+k^2)^2},\quad \mathcal{R}(\lambda,k)=k\left(1-\frac{2\lambda}{(1+k^2)^2}\right). \tag{132.16}$$

For $\lambda=25/2$, the stationary solutions are $0,2,-2$. At $k_*=2$,

$$\mathsf{H}_* = \frac{16}{5}, \quad s_* = 4, \quad Q_{\mathrm{ex}}(k_*) = 2, \quad F(\lambda, k_*) = \frac{5}{2}, \quad \Delta S = -8. \tag{132.17}$$

The affine expression $-k_* s_*/4 = -2$ differs from the exact correction. On the positive branch,

$$\partial_\lambda \Delta S = -\frac{4}{5}, \qquad \partial_\lambda k_* = \frac{1}{20} \quad \text{in } \lambda = 25/2. \tag{132.18}$$

Proof. The Gramian is $1 + k^2 > 0$, so the minimum has the indicated expressions. Differentiating F gives $s = -2\partial_k F$ and then $\mathcal{R} = k - s/2$. For $\lambda = 25/2$, the equation is $k[(1 + k^2)^2 - 25] = 0$; since $1 + k^2 > 0$, its roots are precisely $0, \pm 2$. The total Hessian is

$$1 - \frac{2\lambda(1 - 3k^2)}{(1 + k^2)^3},$$

which equals $16/5$ at both nonzero roots. The correction is $2 + 5/2 - 25/2 = -8$. In the radial identity,

$$\int_0^1 k_* s(\lambda, t k_*)\, dt = \int_0^1 \frac{200t}{(1 + 4t^2)^2}\, dt = 20,$$

since an antiderivative is $-25/(1 + 4t^2)$. Thus $\Delta S = 8/4 - 20/2 = -8$, including the non-affine term. For $\lambda > 1/2$, the positive branch satisfies $k_*^2 = \sqrt{2\lambda} - 1$ and $\Delta S = \sqrt{2\lambda} - 1/2 - \lambda$. Their derivatives give (132.18). The envelope formula gives the same result: $(\partial_\lambda F)(\lambda, k_*) - (\partial_\lambda F)(\lambda, 0) = 1/5 - 1 = -4/5$. □

Chapter 133

Spinorial current and torsional amplitude of the material state

The preceding development and the following spinorial realization articulate two variational problems with common geometric antecedents. The minimal extension action $S_{\min} = \mathfrak{a}_m E$, constructed in section 130, incorporates the dependence of the transported incidence and its minimum on the connection; its torsional elimination preserves that complete dependence in section 132. The spinorial action S_D of (133.3) couples the same connection to the fields of its representation and is affine in the contortion when the co-tetrad and fields are fixed. Each current is obtained by varying its own action. A minimizing preparation can determine the initial material state of the spinorial realization; substitution of connection-dependent fields additionally preserves the terms of the composite differential. This distinction places the following amplitude calculation in its specific action and variational domain.

The spinorial representation of transport and the algebraic response of Cartan–Holst allow torsional intensity to be calculated as a functional of the material state. Its evaluation preserves three data: the field representation, the second moment of its current and the volume relative to which density is defined. The coupling coefficient results from the action and its inversion; the initial state determines the material amplitude.

133.1 Spinorial representation and affine material action

We preserve the co-tetrad, orientation and couplings of section 131. The spinorial realization uses the four-dimensional complex module obtained by complexifying the real matrices

$$J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{133.1}$$
$$g^0 = J \otimes I_2, \qquad g^1 = R \otimes I_2, \qquad g^2 = Z \otimes R, \qquad g^3 = Z \otimes Z.$$

Multiplication gives $\{g^I, g^J\} = 2\eta^{IJ} I_4$, with $\eta = \operatorname{diag}(-1, 1, 1, 1)$. The matrices are distinguished from the scalar parameter γ of the Holst operator. Define

$$g_I = \eta_{IJ} g^J, \quad \mathbb{B}_{IJ} = \tfrac{1}{4}[g_I, g_J], \quad A_D = -i g^0, \quad \bar{\psi} = \psi^\dagger A_D, \quad \Omega = \tfrac{1}{2}\omega^{IJ}\mathbb{B}_{IJ}. \tag{133.2}$$

The Clifford product satisfies

$$[\mathbb{B}_{IJ}, g^K] = \delta^K_J g_I - \delta^K_I g_J.$$

Thus, the same metric connection acts on the fields through $D\psi = \mathrm{d}\psi + \Omega\psi$ and $D\bar{\psi} = \mathrm{d}\bar{\psi} - \bar{\psi}\Omega$. Transport along a route is obtained by integrating this connection in its spinorial representation; it preserves the connection and the route of the preceding geometric realization.

Let $\eta_I = \iota_{E_I} \operatorname{vol}_e$, so that $e^J \wedge \eta_I = \delta^J_I \operatorname{vol}_e$. For a field of dimensional type $[\psi] = L^{-3/2}$, we take the minimal material action

$$S_D = \int_M \left\{ \frac{\hbar}{2}\left[\bar{\psi} g^I D\psi - (D\bar{\psi}) g^I \psi\right] \wedge \eta_I - mc\,\bar{\psi}\psi \operatorname{vol}_e \right\}. \tag{133.3}$$

Here $\hbar = \hbar_{\text{int}}$, $c = c_{\text{int}}$ and the mass m is the reading of the material species in the chosen chart. These values are outputs preceding this realization. The matrix A_D is Hermitian and $A_D g^I$ is anti-Hermitian. Therefore the symmetric kinetic term has the real convention corresponding to (133.1). In this signature, the torsion-free equation has principal term $\hbar g^I D_I$; the equivalent notation $i\hbar\Gamma^I D_I$, with $\Gamma^I = -i g^I$, uses the Clifford relation of opposite signature. This specification jointly fixes the adjoint, signature and imaginary factor of the action.

The material fields and co-tetrad remain fixed in the variation of the connection. A preparation coming from the minimal extension of section 130 can determine the initial datum of the field or state. Each action preserves its own variation: if a connection-dependent minimizing field is substituted into an action, its composite differential is also applied, or the envelope theorem under its stationarity hypotheses. Action (133.3) here realizes a coupling affine in contortion.

Proposition 133.1 (Spinorial current with variational normalization)**.** *Let* $B^{IJK} = \bar\psi g^{[I} g^J g^{K]}\psi$*, where brackets denote normalized antisymmetrization. The current defined in* (131.4) *by action* (133.3) *is*

$$\sigma_{JK} = -\frac{\hbar}{2}\,\bar\psi\{g^I, \mathbb{B}_{JK}\}\psi\,\eta_I = -\frac{\hbar}{2}\,B^I{}_{JK}\eta_I. \tag{133.4}$$

It is independent of contortion when e *and* ψ *are fixed. The inversion of section 131.3 therefore applies to this current.*

Proof. The variation of Ω is $\delta\Omega = \frac{1}{2}\delta\omega^{JK}\mathbb{B}_{JK}$. The two kinetic terms give, respectively, the product with g^I on the left and on the right. Consequently,

$$\delta_\omega S_D = \frac{\hbar}{4}\int_M \delta\omega^{JK}\wedge\eta_I\,\bar\psi\{g^I, \mathbb{B}_{JK}\}\psi.$$

Comparison with (131.4) fixes the factor and sign of (133.4). Expanding the anticommutator and using the Clifford relation cancels the degree-one contractions, leaving $\{g^I, \mathbb{B}_{JK}\} = g^{[I}g_J g_{K]}$. The action is linear in Ω, proving the last statement. □

133.2 Effective contraction and second-moment coefficient

The Lorentzian quadratic form of the trivector is written

$$q(B) = \frac{1}{3!}B^{IJK}B_{IJK} = -(B^{012})^2 - (B^{013})^2 - (B^{023})^2 + (B^{123})^2. \tag{133.5}$$

This contraction preserves the signature of the spinorial module. Its second moment depends on the state and on the realization of field products.

Theorem 133.2 (Effective interaction of the spinorial current)**.** *With material action* (133.3)*, algebraic elimination of contortion gives*

$$\mathcal{L}^{\mathrm{eff}}_{\mathrm{spin}} = C_\gamma q(B)\,\mathrm{vol}_e, \qquad C_\gamma = \frac{3\kappa c\hbar^2}{16}\frac{\gamma^2}{1+\gamma^2}. \tag{133.6}$$

The coefficient is obtained from the current and the Holst inverse with the normalizations of the preceding action.

Proof. By (131.16), it suffices to evaluate $-\frac{1}{4}K_*^{IJ}\wedge\sigma_{IJ}$, with

$$Y^{IJ} = \kappa c\frac{\gamma^2}{1+\gamma^2}(-\star + \gamma^{-1}I)\sigma^{IJ}, \qquad K_* = \mathsf{C}_e(Y).$$

Here C_e is the explicit composition of (131.9) with (131.11). Linearity of those two inverses reduces the calculation to the parts $-\star$ and I. To give the complete contraction, we order the trivector components as $(012, 013, 023, 123)$, extract the factors $\kappa c\hbar^2\gamma^2/(1+\gamma^2)$, and substitute $\sigma_{JK} = -\frac{1}{2}B^I{}_{JK}\eta_I$. The two matrices of the remaining quadratic form are

$$\mathcal{B}_{-\star} = \frac{3}{16}\,\mathrm{diag}(-1,-1,-1,1), \qquad \mathcal{B}_I = 0_{4\times4}. \tag{133.7}$$

These matrices are obtained using only $e^I \wedge \eta_J = \delta^I_J \,\mathrm{vol}_e$: for each component B^{abc}, we form σ, calculate Y, then $T^I = \sum_J \iota_{E_J} Y^{IJ} - \frac{1}{4} e^I \wedge \sum_{L,J} \iota_{E_L}\iota_{E_J} Y^{LJ}$, and finally $K_{IJK} = (T_{KIJ} - T_{IJK} - T_{JKI})/2$. The contraction gives the four diagonal entries shown; the six polarizations between distinct components are zero for both operators. This calculates all coefficients of the two quadratic forms. The part $\gamma^{-1} I$ vanishes and the part $-\star$ produces exactly (133.5), with the coefficient of (133.6). □

133.3 Finite fermionic realization and second moment of the state

We fix a periodic comoving cell, an orthonormal frame adapted to its observer and the homogeneous spatial mode of the four spinorial components. This finite realization has state space $\mathcal{F} = \bigoplus_{n=0}^{4} \Lambda^n \mathbb{C}^4$. Let $a_r, a_r^\dagger$, $r = 1, \dots, 4$ be its canonical operators, with $\{a_r, a_s^\dagger\} = \delta_{rs}$ and $\{a_r, a_s\} = 0$. The occupation vacuum fixes normal ordering. For a matrix M, we write

$$\mathrm{d}\Gamma(M) = \sum_{r,s} a_r^\dagger M_{rs} a_s, \qquad \widehat{N} = \mathrm{d}\Gamma(I_4).$$

The letter Γ in this notation denotes second quantization; nonadic holonomy retains its own notation.

The four matrices of the bilinears are calculated directly:

abc	012	013	023	123
$M_{abc} = A_D g^a g^b g^c$	$iJ \otimes R$	$iJ \otimes Z$	$iI_2 \otimes J$	$iZ \otimes J$

(133.8)

All are Hermitian, have zero trace and satisfy $M_{abc}^2 = I_4$. The quartic observable corresponding to (133.5), in this declared normal ordering, is

$$\begin{aligned} \widehat{\mathcal{Q}}_{\mathrm{sp}} &= \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc} :\mathrm{d}\Gamma(M_{abc})^2: \\ &= \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc} \mathrm{d}\Gamma(M_{abc})^2 + 2\widehat{N}. \end{aligned} \tag{133.9}$$

Normal ordering is part of the specified finite realization; its definition makes explicit the subtraction of single-occupation contractions.

Proposition 133.3 (Evaluation by the canonical relations)**.** *The operator $\widehat{\mathcal{Q}}_{\mathrm{sp}}$ is self-adjoint, preserves each occupation sector and has restrictions*

$$\widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^0 \oplus \Lambda^1} = 0, \qquad \widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^3} = 4I_4, \qquad \widehat{\mathcal{Q}}_{\mathrm{sp}}|_{\Lambda^4} = 8I_1. \tag{133.10}$$

In the basis of $\Lambda^2\mathbb{C}^4$ whose occupation subsets are $(12, 13, 23, 14, 24, 34)$*, its matrix is*

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & -4 \\ 0 & 2 & 0 & 0 & 6 & 0 \\ 0 & 0 & 2 & -6 & 0 & 0 \\ 0 & 0 & -6 & 2 & 0 & 0 \\ 0 & 6 & 0 & 0 & 2 & 0 \\ -4 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{133.11}$$

Proof. The relation $a_s a_t^\dagger = \delta_{st} - a_t^\dagger a_s$ applied to $\mathrm{d}\Gamma(M)^2$ separates its single-occupation contraction and gives

$$:\mathrm{d}\Gamma(M)^2: = \mathrm{d}\Gamma(M)^2 - \mathrm{d}\Gamma(M^2).$$

Since the first three signs of (133.8) are negative and the last positive, the sum of contractions is $-2\widehat{N}$. This proves (133.9). Self-adjointness and preservation of occupation follow from those same expressions.

On Λ^0 all terms vanish. On Λ^1, $\mathrm{d}\Gamma(M) = M$, and the squares sum to $-2I_4$, which cancels with $2\widehat{N}$. On Λ^4, $\mathrm{d}\Gamma(M) = \operatorname{tr} M = 0$, leaving eight. Identification by complement between $\Lambda^3\mathbb{C}^4$ and the dual of $\mathbb{C}^4$ takes $\mathrm{d}\Gamma(M)$ to $(\operatorname{tr} M)I - M^{\mathsf{T}} = -M^{\mathsf{T}}$. Their squares again sum to $-2I_4$, while $2\widehat{N} = 6I_4$; therefore the restriction is $4I_4$. Finally, applying the four explicit matrices to the six exterior products of the indicated basis produces (133.11). The operator is thus evaluated in the sixteen dimensions of $\mathcal{F}$. □

For a state operator $\varrho \geq 0$, $\operatorname{Tr}\varrho = 1$, define $q_\varrho = \operatorname{Tr}(\varrho\widehat{\mathcal{Q}}_{\mathrm{sp}})$. Its dependence on second moments is explicit:

$$q_\varrho = \sum_{a<b<c} \eta_{aa}\eta_{bb}\eta_{cc} \left\{ \langle \widehat{B}_{abc} \rangle_\varrho^2 + \operatorname{Var}_\varrho(\widehat{B}_{abc}) - \langle \widehat{N} \rangle_\varrho \right\}, \qquad \widehat{B}_{abc} = \mathrm{d}\Gamma(M_{abc}). \tag{133.12}$$

Covariance and normal subtraction are preserved even when the mean currents vanish. In particular, if P_3 is the projection onto $\Lambda^3\mathbb{C}^4$,

$$\varrho_3 = \tfrac{1}{4}P_3, \qquad \langle \widehat{B}_{abc} \rangle_{\varrho_3} = 0, \qquad q_{\varrho_3} = 4 > 0. \tag{133.13}$$

It is a positive state of trace one and constitutes an explicit witness to the positive domain of the functional. The two-occupation sector also contains negative values; for example, the vector $(|12\rangle + |34\rangle)/\sqrt{2}$ has value -4. The sign of the intensity thus comes from the contraction and the state, and remains separate from the selection of cosmological conditions.

133.4 Density, pressure and preservation of the comoving amplitude

In the spatially homogeneous realization, fix

$$e^0 = N(t)c\,\mathrm{d}t, \qquad e^j = a(t)\,\mathrm{d}x^j, \qquad \mathcal{V}(t) = a(t)^3 V_c,$$

with lapse $N(t) > 0$, dimensionless scale factor $a(t) > 0$ and comoving volume $V_c > 0$. The frame and periodic mode of subsection 133.3 remain declared. The normalization of the homogeneous field is $\widehat{\psi} = \mathcal{V}^{-1/2}(a_1, a_2, a_3, a_4)^{\mathsf{T}}$. Each bilinear carries a factor $\mathcal{V}^{-1}$, and its normally ordered product carries $\mathcal{V}^{-2}$. The symmetric kinetic temporal form preserves this canonical normalization: terms arising from differentiating $\mathcal{V}^{-1/2}$ cancel between its two summands.

Theorem 133.4 (Torsional amplitude as a functional of the state)**.** *Keeping the canonical state and the realization of the product fixed during metric variations, the effective spin term has reduced action*

$$S_{\mathrm{spin}}^{\mathrm{hom}} = \int \mathrm{d}t\, N(t) \frac{cC_\gamma}{a(t)^3 V_c}\, q_\varrho. \tag{133.14}$$

Its energy density and isotropic pressure are

$$\rho_{\mathrm{spin}} = p_{\mathrm{spin}} = -\frac{cC_\gamma}{V_c^2}\, q_\varrho a^{-6}. \tag{133.15}$$

In any evolution preserving q_ϱ, the corresponding constant amplitude is

$$\boxed{s_0[\varrho, V_c] = \frac{3\kappa c^2\hbar^2}{16} \frac{\gamma^2}{1+\gamma^2} \frac{\operatorname{Tr}(\varrho\widehat{\mathcal{Q}}_{\mathrm{sp}})}{V_c^2}.} \tag{133.16}$$

Proof. Spatial integration of (133.6) multiplies the factor $\mathcal{V}^{-2}$ by $Nc\mathcal{V}\,\mathrm{d}t$, giving (133.14). In canonical variables, lapse variation defines energy through $\delta_N S_{\mathrm{m}} = -\int E\,\delta N\,\mathrm{d}t$. Therefore,

$$E_{\mathrm{spin}} = -\frac{cC_\gamma q_\varrho}{a^3 V_c}, \qquad \rho_{\mathrm{spin}} = \frac{E_{\mathrm{spin}}}{a^3 V_c}.$$

The isotropic spatial variation satisfies $\delta_a S_{\mathrm{m}} = \int 3Na^2 V_c p\, \delta a\, \mathrm{d}t$. Applied to (133.14), it gives

$$3Na^2 V_c p_{\mathrm{spin}} = -\frac{3NcC_\gamma q_\varrho}{a^4 V_c}.$$

This simultaneously proves the sign, pressure and density of (133.15). Since q_ϱ is preserved, the coefficient of $-a^{-6}$ is constant and we obtain (133.16). Dimensionality is consistent: $[cC_\gamma]$ = energy L^3, so s_0 has the dimension of energy density. □

Corollary 133.5 (Preserved domain of positive amplitude)**.** *Let there be a unitary evolution of $\mathcal{F}$ preserving $\Lambda^3\mathbb{C}^4$. For every initial state of trace one supported on that sector, $q_{\varrho(t)} = 4$ holds, and*

$$s_0 = \frac{3\kappa c^2\hbar^2}{4V_c^2}\frac{\gamma^2}{1+\gamma^2} > 0. \tag{133.17}$$

Proof. Invariance of the sector preserves the support of the state; on it, (133.10) gives $\widehat{\mathcal{Q}}_{\mathrm{sp}} = 4I$. Preservation of the trace then fixes its expectation at four, independently of the internal evolution of its coherences. Positivity of the couplings, $V_c > 0$ and $\gamma \neq 0$ proves the formula and its sign. □

For general states, preservation of $\langle \widehat{N} \rangle$ determines dilution of the occupation density, $n(t) = \langle \widehat{N} \rangle / (a^3 V_c)$. Preservation of the quartic moment is checked separately. If $i\hbar\dot{\varrho} = [H(t), \varrho]$, then

$$\frac{\mathrm{d}q_\varrho}{\mathrm{d}t} = \frac{i}{\hbar}\,\mathrm{Tr}\big(\varrho[H(t), \widehat{\mathcal{Q}}_{\mathrm{sp}}]\big). \tag{133.18}$$

Commutation, invariance of a sector where the observable is scalar, or a conservation proved for the specific state provide the relevant conditions. If the moment evolves, (133.15) preserves its instantaneous evaluation; its balance includes

$$\dot{\rho}_{\mathrm{spin}} + 6H\rho_{\mathrm{spin}} = -\frac{cC_\gamma}{V_c^2}\, a^{-6}\dot{q}_\varrho, \qquad H = \dot{a}/a$$

in proper time. This term records exchange with the remaining material degrees of freedom.

The composition is determined: spinorial representation of transport, material action, variational current, Cartan–Holst inversion, second moment and normalized density. The domain $s_0 > 0$ of section 134 thus has an evaluable functional and explicit witness states. Its use in cosmological dynamics additionally preserves the material, geometric and conservation conditions stated in that section.

Chapter 134

Memory dilution and persistence of the bounce

The evolution of memory and spatial expansion are two readings of the same sequence of states. The refinement index can be eliminated between them; that elimination determines the dilution exponent transmitted by the cosmological realization to its torsional contribution. The initial amplitude depends on evaluation of the concrete material current in its variational response. The scaling law and bounce theorem that follow preserve that dependence.

Theorem 133.4 determines that amplitude as a functional of the material state and comoving volume. Corollary 133.5 provides an explicit domain of states with positive, conserved amplitude. In that domain, evaluation of s_0 precedes the cosmological integration developed below. The ordinary density $\rho_0 > 0$ and its barotropic law are additionally specified in section 134.2: the witness to positivity of the amplitude does not in itself evaluate that material density.

134.1 The a^{-6} dilution law

Proposition 134.1 (Elimination of the memory index)**.** *Let $a_{\mathrm{ref}} > 0$, $\varphi > 1$, and let the route readers be*

$$\frac{a_n}{a_{\mathrm{ref}}} = \varphi^{n/3}, \qquad M_n = \varphi^{-2n}.$$

Then

$$M_n = \left(\frac{a_n}{a_{\mathrm{ref}}}\right)^{-6}$$

for every index of the sequence. If the realization of the quadratic density is $s_n^2 = s_*^2 M_n$, with $s_*^2 > 0$, we obtain

$$s_n^2 = s_*^2 \left(\frac{a_n}{a_{\mathrm{ref}}}\right)^{-6}.$$

Proof. Raising the first equality to the power -6 gives φ^{-2n}, which is exactly the second reader. Multiplying by the initial amplitude reproduces the second statement. The exponent is determined by the quotient of the exponents of the two readers; the amplitude is the evaluation of the reference state. □

In the continuous homogeneous realization, this constitutive law is preserved: the torsional density is written $s_0 a^{-6}$, where the normalization of the factor a, the material coefficient and the reference amplitude have been absorbed into s_0. The scaling law and evaluation of s_0 are successive operations of the construction.

134.2 Homogeneous threshold and transversality

Consider the homogeneous, spatially flat chart, in units $c = 1$, with constant $G > 0$, positive densities ρ_0, s_0 and constant barotropic parameter $w < 1$. The specified realization satisfies $\Lambda_{\mathrm{eff}} = 0$ and the equations

$$\rho_{\mathrm{m}}(a) = \rho_0 a^{-3(1+w)}, \qquad \rho_{\mathrm{s}}(a) = s_0 a^{-6}, \tag{134.1}$$

$$H^2 = \frac{8\pi G}{3}\big(\rho_{\mathrm{m}} - \rho_{\mathrm{s}}\big) =: F_0(a), \qquad \dot{H} = -4\pi G\big((1+w)\rho_{\mathrm{m}} - 2\rho_{\mathrm{s}}\big). \tag{134.2}$$

The couplings belong to the dimensional section already constructed. The expression for ρ_{s} incorporates the sign of its contribution in this gravitational realization.

Theorem 134.2 (Existence and uniqueness of the transverse threshold)**.** *There exists a unique $a_{\mathrm{b}} > 0$ with $F_0(a_{\mathrm{b}}) = 0$:*

$$a_{\mathrm{b}}^{3(1-w)} = \frac{s_0}{\rho_0}.$$

The region allowed by $H^2 \geq 0$ is $a \geq a_{\mathrm{b}}$. At the threshold, with $\rho_{\mathrm{b}} = \rho_{\mathrm{m}}(a_{\mathrm{b}}) = \rho_{\mathrm{s}}(a_{\mathrm{b}}) > 0$,

$$\dot{H}_{\mathrm{b}} = 4\pi G(1-w)\rho_{\mathrm{b}} > 0.$$

The solution crossing $H = 0$ has a strict minimum of a, with local expansion

$$a(t) = a_{\mathrm{b}}\left[1 + 2\pi G(1-w)\rho_{\mathrm{b}}(t-t_{\mathrm{b}})^2 + O((t-t_{\mathrm{b}})^3)\right].$$

Proof. The factorization

$$F_0(a) = \frac{8\pi G}{3}a^{-6}\left(\rho_0 a^{3(1-w)} - s_0\right)$$

reduces its zeros to that of a strictly increasing function of $(0,\infty)$ on $(-s_0,\infty)$. This proves existence, uniqueness and the sign of F_0 on both sides of the threshold. The second equation of (134.2), evaluated at equality of densities, gives the formula for $\dot{H}_{\mathrm{b}}$. Since $\dot{a} = aH$, at the threshold $\ddot{a}_{\mathrm{b}} = a_{\mathrm{b}}\dot{H}_{\mathrm{b}} > 0$. The equations are smooth for $a > 0$, so their Taylor expansion gives the indicated expansion. The sign change of H is transverse: it passes from contraction to expansion. □

For $w = 1$, both terms have the same exponent and equality of amplitudes determines a degenerate case. For $w > 1$, the sign of $\dot{H}$ at a coincidence of densities is negative. The domain $w < 1$ of the theorem expresses exactly the order between the two dilution exponents.

134.3 Local persistence under controlled perturbations

Persistence of the threshold uses two independent estimates: control of the sign at the endpoints and of the derivative on the interval. Let $I = [a_-, a_+] \subset (0,\infty)$, with $a_- < a_{\mathrm{b}} < a_+$, be chosen so that

$$F_0(a_-) < 0 < F_0(a_+), \qquad m_I := \inf_{a\in I} F_0'(a) > 0.$$

Such an interval exists because

$$F_0'(a_{\mathrm{b}}) = \frac{8\pi G}{a_{\mathrm{b}}}(1-w)\rho_{\mathrm{b}} > 0.$$

Define $\delta_I = \min\{-F_0(a_-), F_0(a_+)\} > 0$.

Theorem 134.3 (Local persistence of the transverse bounce)**.** *Let $R \in C^1(I)$ be a perturbation satisfying*

$$\|R\|_{\infty,I} < \delta_I, \qquad \|R'\|_{\infty,I} < m_I.$$

Then $F_R = F_0 + R$ has a unique zero $a_R \in (a_-, a_+)$, and $F_R'(a_R) > 0$. The realization $H^2 = F_R(a)$ admits a local transverse bounce, with

$$\dot{H}_R = \frac{a_R}{2}F_R'(a_R) > 0$$

at the threshold. If $R(a,\eta)$ is jointly C^1, the persistent zeros depend locally in a C^1 manner on the parameter η.

Proof. The first bound preserves $F_R(a_-) < 0 < F_R(a_+)$; the intermediate value theorem provides an interior zero. The second gives $F_R'(a) \geq m_I - \|R'\|_{\infty,I} > 0$ on I, so the zero is unique and simple.

At $a > a_R$ near the zero, $F_R(a) = F_R'(a_R)(a - a_R) + o(a - a_R)$. The integral

$$t - t_{\mathrm{b}} = \int_{a_R}^{a} \frac{d\xi}{\xi\sqrt{F_R(\xi)}}$$

is finite and strictly increasing. Its inverse defines the expanding branch; time reflection defines the contracting branch. The two join with $\dot{a}(t_{\mathrm{b}}) = 0$ and

$$a(t) - a_R = \frac{a_R^2 F_R'(a_R)}{4}(t - t_{\mathrm{b}})^2 + o((t - t_{\mathrm{b}})^2).$$

Away from the threshold, differentiating $H^2 = F_R(a)$ gives $\dot{H} = aF_R'(a)/2$; its continuous limit gives the positive expression at a_R. The C^1 regularity of F_R guarantees continuity of acceleration at this junction. Finally, $\partial_a F_R(a_R) > 0$ allows application of the implicit function theorem when the perturbation depends jointly on (a, η). □

The first bound controls existence; the second ensures local uniqueness and transversality. The proved stability corresponds to that threshold in the selected interval. The torsional amplitude enters its location, while the relation between exponents determines the temporal orientation of the crossing.

Chapter 135

Explicit homogeneous solution and causal completeness

Determination of the amplitude allows a complete realization of the bounce to be developed, in addition to the local argument. The spatially flat chart of (134.2) is retained, in units $c = 1$, with $\rho_0, s_0, G > 0$, and the material sector is specialized to dust, $w = 0$, with $\Lambda_{\mathrm{eff}} = 0$. The coefficient s_0 is that obtained from the material state in the corresponding realization; the following integration uses that coefficient and preserves its domain.

Theorem 135.1 (Exact integration of the dust bounce)**.** *Set*

$$a_{\mathrm{b}}^3 = \frac{s_0}{\rho_0}, \qquad \tau^2 = \frac{s_0}{6\pi G \rho_0^2}, \qquad u = t - t_{\mathrm{b}}.$$

The solution of the homogeneous system with $a(t_{\mathrm{b}}) = a_{\mathrm{b}}$ and $H(t_{\mathrm{b}}) = 0$ is, for every $t \in \mathbb{R}$,

$$a(t) = a_{\mathrm{b}} \left(1 + \frac{u^2}{\tau^2}\right)^{1/3}, \qquad H(t) = \frac{2u}{3(\tau^2 + u^2)}, \qquad \dot{H}(t) = \frac{2(\tau^2 - u^2)}{3(\tau^2 + u^2)^2}. \tag{135.1}$$

It has a unique minimum, at t_{b}; it contracts before and expands afterward. The evolution is smooth and satisfies $a(t) \geq a_{\mathrm{b}} > 0$.

Proof. Let $y = a^3$. The Friedmann equation gives

$$\dot{y}^{\,2} = 24\pi G(\rho_0 y - s_0).$$

The function $y = s_0/\rho_0 + 6\pi G \rho_0 u^2$ satisfies that identity and the initial conditions. Its derivatives give the three expressions of (135.1). To check the evolution equation as well, let us write

$$\rho_{\mathrm{b}} = \frac{\rho_0^2}{s_0}, \qquad x = \frac{u}{\tau}.$$

Then

$$\rho_{\mathrm{m}} = \frac{\rho_{\mathrm{b}}}{1 + x^2}, \qquad \rho_{\mathrm{s}} = \frac{\rho_{\mathrm{b}}}{(1 + x^2)^2}, \qquad 4\pi G \rho_{\mathrm{b}} = \frac{2}{3\tau^2}.$$

Substituting into $\dot{H} = -4\pi G(\rho_{\mathrm{m}} - 2\rho_{\mathrm{s}})$ gives exactly the third formula. Thus the complete system $(\dot{a}, \dot{H})$ is satisfied, whose field is smooth for $a > 0$. Its local uniqueness, continued along the explicit solution, fixes the evolution through those initial conditions. The denominator is positive for every t, and the statements about the minimum and the sign follow from H. □

135.1 Finite curvature and extension of geodesics

The metric realized in this chart is $g = -dt^2 + a(t)^2\, d\mathbf{x}^2$ on $\mathbb{R} \times \mathbb{R}^3$. With the convention in which the flat curvature scalar is $R = 6(\dot{H} + 2H^2)$, the solution gives

$$R(t) = \frac{4\tau^2 + \frac{4}{3}u^2}{(\tau^2 + u^2)^2}.$$

In particular, $R(t_{\mathrm{b}}) = 4/\tau^2$ is finite. In an orthonormal frame, the Riemann components depend on H^2 and on $\dot{H} + H^2$, which are bounded functions on $\mathbb{R}$. The same holds for polynomial contractions of those components; for example,

$$R_{\mu\nu\rho\sigma} R^{\mu\nu\rho\sigma} = 12\big[(\dot{H} + H^2)^2 + H^4\big].$$

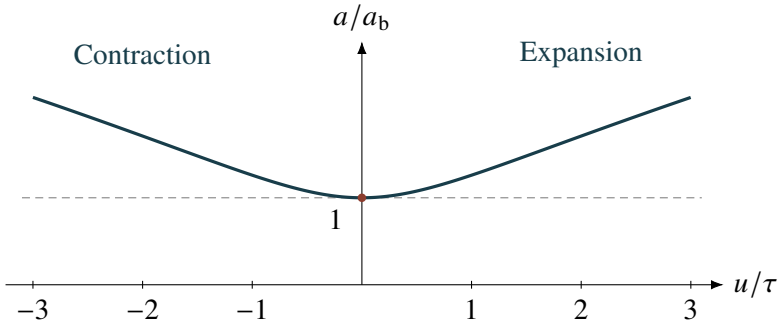

Figure 135.1: Dimensionless profile of the proved solution: $a/a_{\mathrm{b}} = (1 + (u/\tau)^2)^{1/3}$. The parameters a_{b} and τ are calculated from ρ_0, s_0, G; the drawing represents the entire rescaled family.

Proposition 135.2 (Completeness of causal geodesics)**.** *The preceding metric realization is geodesically complete for the timelike and null geodesics of its Levi–Civita connection, in both directions.*

Proof. Spatial translations provide the constants $p_i = a^2\, dx^i/d\lambda$. Causal normalization gives

$$\left|\frac{dt}{d\lambda}\right| = \sqrt{\epsilon + \frac{|\mathbf{p}|^2}{a(t)^2}}, \qquad \epsilon = 1 \text{ in the timelike case}, \quad \epsilon = 0 \text{ in the null case}.$$

A nonconstant null geodesic has $|\mathbf{p}| > 0$. Since $a \geq a_{\mathrm{b}}$, in the timelike case

$$\left|\frac{d\lambda}{dt}\right| \geq \left(1 + \frac{|\mathbf{p}|^2}{a_{\mathrm{b}}^2}\right)^{-1/2} > 0,$$

and in the null case $|d\lambda/dt| = a/|\mathbf{p}| \geq a_{\mathrm{b}}/|\mathbf{p}| > 0$. Thus, reaching $t = \pm\infty$ requires infinite affine length. On a compact time interval, a and its derivatives are smooth and a is bounded away from zero. The preceding explicit equations and $dx^i/d\lambda = p_i/a^2$ allow the geodesic to be continued through its finite endpoints. Both possibilities of continuation are covered. □

The completeness result belongs to this homogeneous dust realization, with its spatial, matter and amplitude conditions. Its local persistence under perturbations of the threshold preserves the bounds of theorem 134.3; that local property and the global completeness of the explicit solution are distinct conclusions. The minimum scale comes from the relation between material density and torsional response. Memory thus enters a verifiable geometric evolution, with a regular realization of contraction and expansion.

Chapter 136

Residual tensor, trace decomposition, and covariant balance

The geometric realization of the enriched state provides a metric, while the material transducer publishes the source to which the reading refers. The residual tensor preserves the difference between the two publications in the same tensor space. Its decomposition distinguishes the sector proportional to the metric from the traceless sector, and determines the exchange current corresponding to that partition.

136.1 Chart data and construction of the residual tensor

Let us fix an HMT state x and a connected chart $\mathcal{U}$ of its geometric realization. On $\mathcal{U}$, the nondegenerate co-tetrad of section 127 determines a smooth metric $g = g_x$ of signature $(-+++)$. We denote by $\mathring{\nabla}$ its Levi–Civita connection and write

$$\mathsf{G}_{\mu\nu}[g] := \mathrm{Ric}_{\mu\nu}[g] - \tfrac{1}{2}R[g]g_{\mu\nu}.$$

This distinguishes the Einstein tensor $\mathsf{G}[g]$ from the gravitational coupling G_{int}. The derivative used in the balances of this section is $\mathring{\nabla}$, consistently with the effective metric equation of Section 131.5.

We work in the dimensional chart $c_{\mathrm{int}} = 1$. We assume $G_{\mathrm{int}}(x) > 0$ and $\Lambda_{\mathrm{ref}}(x)$ constant on $\mathcal{U}$, and put $\kappa_x = 8\pi G_{\mathrm{int}}(x)$. The symbol x identifies the state supplying those readers; covariant differentiation acts on the points of $\mathcal{U}$. The genealogy of the couplings remains in section 121.

Let T_b be the smooth symmetric tensor published by the chart's material transducer; in the baryonic reading, it is its baryonic source. We define

$$\mathcal{E}^{\mathrm{ref}}_{\mu\nu} := \kappa_x^{-1}\big(\mathsf{G}_{\mu\nu}[g] + \Lambda_{\mathrm{ref}}g_{\mu\nu}\big), \qquad T^{\mathrm{res}}_{\mu\nu} := \mathcal{E}^{\mathrm{ref}}_{\mu\nu} - T_{b,\mu\nu}. \tag{136.1}$$

The tensor T^{res} is the effective residual tensor, also denoted T_{osc} when interpreting the geometric sector remaining to be published relative to T_b. The construction preserves $g_x, G_{\mathrm{int}}, \Lambda_{\mathrm{ref}}$ and T_b as effective arguments.

Theorem 136.1 (Uniqueness of the residual and balance with the material source)**.** *For the preceding data there exists a unique symmetric tensor T^{res} satisfying $\mathcal{E}^{\mathrm{ref}} = T_b + T^{\mathrm{res}}$. Its divergence is*

$$\mathring{\nabla}^{\mu}T^{\mathrm{res}}_{\mu\nu} = -\mathring{\nabla}^{\mu}T_{b,\mu\nu}. \tag{136.2}$$

In particular, if the material source is conserved separately, $\mathring{\nabla}^{\mu}T_{b,\mu\nu} = 0$, then T^{res} is also conserved.

Proof. The difference of two tensors satisfying the stated equation is zero; expression (136.1) provides its existence. The contracted Bianchi identity and Levi–Civita metric compatibility give

$$\mathring{\nabla}^{\mu}\mathsf{G}_{\mu\nu} = 0, \qquad \mathring{\nabla}g = 0.$$

Since κ_x and Λ_{ref} are constant on the chart, $\mathring{\nabla}^{\mu}\mathcal{E}^{\mathrm{ref}}_{\mu\nu} = 0$. Differentiating the difference defining T^{res} proves (136.2), including the statement under separate material conservation. □

The spatial and temporal constancy of the couplings in the chart fixes the domain of this balance. A family of states may publish different couplings in different charts; each preceding identity applies to the chart and state specifying it.

136.2 Canonical decomposition and exchange current

Define the trace function and the two tensors

$$\theta := g^{\mu\nu}T^{\mathrm{res}}_{\mu\nu}, \qquad T^{\Lambda}_{\mu\nu} := \tfrac{1}{4}\theta g_{\mu\nu}, \qquad T^{0}_{\mu\nu} := T^{\mathrm{res}}_{\mu\nu} - T^{\Lambda}_{\mu\nu}. \tag{136.3}$$

The superscript Λ identifies the component proportional to the metric; Λ_{ref} is the reference parameter of (136.1). Their functions are distinct.

Proposition 136.2 (Trace projectors and uniqueness of the decomposition)**.** *On symmetric covariant tensors of order two, the maps*

$$P_{\mathrm{tr}}(S) = \tfrac{1}{4}\,\mathrm{tr}_g(S)g, \qquad P_0(S) = S - P_{\mathrm{tr}}(S)$$

satisfy

$$P_{\mathrm{tr}}^2 = P_{\mathrm{tr}}, \quad P_0^2 = P_0, \quad P_{\mathrm{tr}}P_0 = P_0P_{\mathrm{tr}} = 0, \quad P_{\mathrm{tr}} + P_0 = I. \tag{136.4}$$

In particular, $T^{\mathrm{res}} = T^{\Lambda} + T^{0}$, $\mathrm{tr}_g\, T^{0} = 0$*, and this decomposition is unique.*

Proof. In dimension four, $g^{\mu\nu}g_{\mu\nu} = 4$. Therefore, $\mathrm{tr}_g(P_{\mathrm{tr}}S) = \mathrm{tr}_g\, S$, which proves idempotence of P_{tr}, vanishing of the trace of P_0S and, by expansion, the other identities. If $S = fg + Q$ with $\mathrm{tr}_g\, Q = 0$, taking the trace gives $f = \mathrm{tr}_g\, S/4$. This also determines $Q = S - fg$, and with it uniqueness. □

Theorem 136.3 (Covariant exchange between the two sectors)**.** *On the domain of* (136.1)*, let* $b_\nu := \mathring{\nabla}^{\mu}T_{b,\mu\nu}$*. The trace-exchange current is the one-form*

$$\mathcal{J}^{\mathrm{tr}}_{\nu} := \tfrac{1}{4}\partial_\nu\theta = \mathring{\nabla}^{\mu}T^{\Lambda}_{\mu\nu}. \tag{136.5}$$

The complete balances are

$$\mathring{\nabla}^{\mu}T^{0}_{\mu\nu} = -b_\nu - \mathcal{J}^{\mathrm{tr}}_{\nu}, \qquad \mathring{\nabla}^{\mu}(T^{\Lambda} + T^{0})_{\mu\nu} = -b_\nu. \tag{136.6}$$

If $b = 0$*, the two sectors exchange exactly opposite currents. In that case they are conserved separately if and only if* θ *is constant in the connected chart.*

Proof. Metric compatibility allows the calculation

$$\mathring{\nabla}^{\mu}\big(\tfrac{1}{4}\theta g_{\mu\nu}\big) = \tfrac{1}{4}g^{\mu\alpha}(\partial_\alpha\theta)g_{\mu\nu} = \tfrac{1}{4}\partial_\nu\theta.$$

Subtracting this equality from (136.2) produces (136.6). With $b = 0$, separate conservation is equivalent to $\mathrm{d}\theta = 0$; a smooth function with zero differential is constant on each connected component. □

The one-form $\mathcal{J}^{\mathrm{tr}}$ measures the exchange of the tensor partition. It retains a type distinct from the transport covector of section 128 and from the spin current $\sigma_{IJ} \in \Omega^3(\mathcal{U}; \Lambda^2E^*)$ of (131.4).

136.3 Link to the effective Cartan–Holst source

On a solution of (131.19), in the same units $c = 1$, the residual has expression

$$T^{\mathrm{res}} = T^{\mathrm{phys,LC}} + U^{\mathrm{phys,spin}} - T_b + \frac{\Lambda_{\mathrm{ref}} - \Lambda_{\mathrm{int}}}{\kappa_x}\, g. \tag{136.7}$$

Indeed, substituting $\mathsf{G} + \Lambda_{\mathrm{int}}g = \kappa_x(T^{\mathrm{phys,LC}} + U^{\mathrm{phys,spin}})$ into (136.1) gives equality term by term. When the material transducer publishes precisely $T_b = T^{\mathrm{phys,LC}}$ and $\Lambda_{\mathrm{ref}} = \Lambda_{\mathrm{int}}$, we obtain $T^{\mathrm{res}} = U^{\mathrm{phys,spin}}$. The separate conservation condition of T_b in theorem 136.1 retains its own function: (131.20) establishes the balance of the total source, and the partition among its components depends on the material action used.

136.4 Trace sector and acceleration of the selected charts

The TRIT reader of state x publishes $s = \tau(x) \in \{+1, 0, -1\}$, and its positive clock publishes

$$H_* = \frac{2\pi}{108 t_0(x)} > 0. \tag{136.8}$$

Let h_s be a three-dimensional metric of constant sectional curvature s. The three charts of the selected realization are written

$$g_s = -\mathrm{d}t^2 + a_s(t)^2 h_s, \qquad a_+(t) = H_*^{-1}\cosh(H_* t), \quad a_0(t) = \exp(H_* t), \quad a_-(t) = H_*^{-1}\sinh(H_* t). \tag{136.9}$$

The closed and flat charts are considered for $t \in \mathbb{R}$; the open chart, for $t > 0$. The sign s and the clock H_* retain their antecedents in the state selecting the realization.

Lemma 136.4 (Curvature of the three charts of the same clock)**.** *For the functions in* (136.9)*,*

$$\frac{\ddot{a}_s}{a_s} = H_*^2, \qquad \left(\frac{\dot{a}_s}{a_s}\right)^2 + \frac{s}{a_s^2} = H_*^2, \qquad \mathrm{Ric}[g_s] = 3H_*^2 g_s. \tag{136.10}$$

Consequently, $R[g_s] = 12H_*^2$ *and* $\mathsf{G}[g_s] = -3H_*^2 g_s$*.*

Proof. The first two equalities are obtained by differentiating the three functions: in the closed and open charts we use $\cosh^2 z - \sinh^2 z = 1$, and in the flat chart $\dot{a}_0 = H_* a_0$. To verify the tensor identification, the connection coefficients involving the time coordinate are

$$\Gamma^0{}_{ij} = a_s \dot{a}_s (h_s)_{ij}, \qquad \Gamma^i{}_{0j} = (\dot{a}_s/a_s)\delta^i_j,$$

and the purely spatial ones coincide with those of h_s. Contraction of the curvature gives

$$\mathrm{Ric}_{00} = -3\ddot{a}_s/a_s, \qquad \mathrm{Ric}_{0i} = 0, \qquad \mathrm{Ric}_{ij} = (a_s\ddot{a}_s + 2\dot{a}_s^2 + 2s)(h_s)_{ij}.$$

Substituting the first two identities of (136.10) produces $\mathrm{Ric}_{00} = -3H_*^2$ and $\mathrm{Ric}_{ij} = 3H_*^2 a_s^2 (h_s)_{ij}$. Taking the trace and forming the Einstein tensor proves the other statements, with the curvature convention of (131.19). □

Theorem 136.5 (Density, pressure, and sign of the selected acceleration)**.** *In the preceding charts, for* $\Lambda_{\mathrm{ref}} = 0$ *and* $T_b = 0$*, the residual tensor is*

$$T^{\mathrm{res}} = -\rho_* g_s, \qquad \rho_* := \frac{3H_*^2}{8\pi G_{\mathrm{int}}} > 0, \qquad T^\Lambda = T^{\mathrm{res}}, \quad T^0 = 0. \tag{136.11}$$

For a unit comoving observer $u = \partial_t$*, the density and isotropic pressure are* ρ_* *and* $p_* = -\rho_*$*. The acceleration equation evaluates to*

$$\frac{\ddot{a}_s}{a_s} = -\frac{4\pi G_{\mathrm{int}}}{3}(\rho_* + 3p_*) = H_*^2 > 0. \tag{136.12}$$

Proof. The preceding lemma and (136.1) give $T^{\mathrm{res}} = -(3H_*^2/\kappa_x) g_s$. Since $g_s(u,u) = -1$, $T^{\mathrm{res}}_{\mu\nu} u^\mu u^\nu = \rho_*$. The spatial projector $q^{\mu\nu} = g_s^{\mu\nu} + u^\mu u^\nu$ satisfies $q^{\mu\nu}(g_s)_{\mu\nu} = 3$, and therefore

$$p_* := \tfrac{1}{3} q^{\mu\nu} T^{\mathrm{res}}_{\mu\nu} = -\rho_*.$$

The trace equals $-4\rho_*$, so (136.3) produces the two sectors of (136.11). Finally, $\rho_* + 3p_* = -2\rho_*$, and substitution into the right-hand side of (136.12) gives $\kappa_x \rho_*/3 = H_*^2$, equal to the geometric value already calculated. Positivity uses exactly $G_{\mathrm{int}} > 0$ and $H_* > 0$. □

In this realization, the trace sector publishes a constant density and an opposite pressure, and the internal clock fixes positive acceleration. In a general chart, T^{Λ} describes the pointwise isotropic component, while T^0 preserves the traceless residual and both obey the exchange of (136.6). Identification of these sectors with observational dark sources requires a single realization to reproduce expansion, lensing, rotation, structure growth and the cosmic background jointly. The present construction fixes the tensor, its balances and the acceleration of the selected charts entering that comparison.

Chapter 137

Pure bipartite states, reduced entropy and horizon area laws

The enriched state preserves routes and their records during evolution; a subsystem reading determines which part of that information remains accessible. The construction of this section uses the angular channels of section 14.7, the incidence and the area operator of section 122, and the action, area and temperature units of sections 121 and 123. These are prior publications of the same APP–TRIT–TPK construction. Each here transmits its domain, orientation, normalization and realization conditions.

Three spaces are distinguished: the binary sheet record, the tritic factors of sectorial incidence, and the geometric realization of the exterior regions of a horizon. Purification, transport of observables, and dimensional conversion specify their relationships. This distinction preserves the structure accompanying each entropic value.

137.1 Sheet record and bipartite quantum purification

Write $a = A_{\mathrm{rad}}$ and $y = C^{*}_{\mathrm{rad}}$ for the angular coordinates already constructed. The channels and their probabilities are

$$\mathfrak{q}_{\pm} = e^{-a\mp y}, \qquad p_{\pm} = \frac{\mathfrak{q}_{\pm}}{\mathfrak{q}_{+}+\mathfrak{q}_{-}} = \frac{e^{\mp y}}{2\cosh y}. \tag{137.1}$$

The signs index these two channels. On $\mathcal{H}_{\mathrm{h}} = \mathrm{span}\{|+\rangle, |-\rangle\}$, define

$$\rho_{\mathrm{h}}(y) = p_{+}|+\rangle\langle+| + p_{-}|-\rangle\langle-|.$$

The auxiliary space $\mathcal{H}_{\mathrm{ar}} = \mathrm{span}\{|\mathrm{adv}\rangle, |\mathrm{ret}\rangle\}$ carries two orthonormal labels. With a phase χ_0 fixed, the joint state is

$$|\Psi_{\mathrm{ar}}\rangle = \sqrt{p_{+}}|+\rangle \otimes |\mathrm{adv}\rangle + e^{i\chi_0}\sqrt{p_{-}}|-\rangle \otimes |\mathrm{ret}\rangle. \tag{137.2}$$

Proposition 137.1 (Accessible information in the sheet record)**.** *The vector* (137.2) *is normalized, and its partial trace over* $\mathcal{H}_{\mathrm{ar}}$ *is* $\rho_{\mathrm{h}}(y)$*. Its entanglement entropy, expressed in nats, is*

$$s_{\mathrm{h}}(y) = \log(2\cosh y) - y\tanh y. \tag{137.3}$$

Exchange of the labels $+$ *and* $-$ *conjugates* $\rho_{\mathrm{h}}(y)$ *to* $\rho_{\mathrm{h}}(-y)$ *and preserves* s_{h}*.*

Proof. The squared norm is $p_{+} + p_{-} = 1$. Orthogonality of the auxiliary labels eliminates the cross terms in the partial trace. The squared Schmidt coefficients are precisely $p_{\pm}$. By (137.1), $p_{+} - p_{-} = -\tanh y$; substituting $\log p_{\pm} = \mp y - \log(2\cosh y)$ into $-\sum_{\pm} p_{\pm}\log p_{\pm}$ proves the formula. Exchange of signs permutes the two eigenvalues and preserves entropy. □

The common factor e^{-a} cancels upon normalization of the binary record. The relative phase χ_0 remains in the joint state even though this diagonal reduction does not express it. Logical reversibility concerns transport of the complete record, with its labels and correlations; phase return preserves the memory advance described in Section 125. A thermal implementation additionally has its own energy and dissipation law. In particular, s_{h} measures this binary subsystem and its concrete bipartition.

137.2 Quantum purification of the incidence sectors

The boundary incidence constructed earlier distinguishes two sets of eighteen links, with sectorial labels $m = 90, 120$. Each link carries $\mathbb{C}^3$, with basis $|0\rangle, |1\rangle, |2\rangle$ and occupation operator $\mathrm{diag}(0, 1, 2)$. Let N_m be their sectorial sums, and

$$\mathsf{N} = \mathsf{N}_{90} + \mathsf{N}_{120}, \qquad \mathsf{D}_\partial = 90\mathsf{N}_{90} + 120\mathsf{N}_{120}. \tag{137.4}$$

In the positive branch, γ_{BI} denotes the Barbero–Immirzi parameter already obtained, and $a_0 > 0$ its angular areal factor. This notation distinguishes the parameter from the connection and its holonomies. Area is published as

$$\widehat{\mathcal{A}}_m = \ell_P^2 \gamma_{\mathrm{BI}} a_0 \mathsf{N}_m, \qquad \widehat{\mathcal{A}} = \widehat{\mathcal{A}}_{90} + \widehat{\mathcal{A}}_{120}. \tag{137.5}$$

For the finite parameter $\Delta = \Delta_{\mathrm{mod}} \in \mathbb{R}$ of the reduced state, set

$$x_m = e^{-m\Delta}, \qquad z_m = 1 + x_m + x_m^2, \qquad Z(\Delta) = z_{90}^{18} z_{120}^{18}, \tag{137.6}$$

$$\rho_\partial(\Delta) = Z(\Delta)^{-1} e^{-\Delta \mathsf{D}_\partial}. \tag{137.7}$$

The trace in this section is the ordinary matrix trace, and the states have trace one. The parameter Δ preserves the selection and normalization of the antecedent state.

Proposition 137.2 (Tensor purification of the boundary)**.** *For a finite real weight w, let*

$$|\,\mathrm{TFD}(w)\rangle = \frac{|0\rangle|0\rangle + e^{-w/2}|1\rangle|1\rangle + e^{-w}|2\rangle|2\rangle}{\sqrt{1 + e^{-w} + e^{-2w}}}. \tag{137.8}$$

The product

$$|\Psi_\Delta\rangle = |\,\mathrm{TFD}(90\Delta)\rangle^{\otimes 18} \otimes |\,\mathrm{TFD}(120\Delta)\rangle^{\otimes 18} \tag{137.9}$$

is a normalized purification of $\rho_\partial(\Delta)$.

Proof. At each link, the sum of the squares of the three coefficients is one. The partial trace eliminates terms with different indices and returns $\mathrm{diag}(1, e^{-w}, e^{-2w})/(1 + e^{-w} + e^{-2w})$. Partial trace commutes with the tensor product. Multiplying the thirty-six reductions gives the exponential and partition function of (137.7). □

137.3 Informational equation and areal fluctuations

The occupation means and variances per link are

$$f_m = \frac{x_m + 2x_m^2}{z_m}, \qquad v_m = \frac{x_m + 4x_m^2}{z_m} - f_m^2. \tag{137.10}$$

Write $s(\rho) = -\mathrm{Tr}(\rho \log \rho)$, with $0 \log 0 = 0$. In the preceding purification, $s(\rho_\partial)$ is its entanglement entropy.

Proposition 137.3 (Mean area, entropy, and sectorial response)**.** *For real finite Δ, one has*

$$\langle \mathsf{N} \rangle_\Delta = 18(f_{90} + f_{120}), \tag{137.11}$$

$$\langle \mathsf{D}_\partial \rangle_\Delta = 18(90 f_{90} + 120 f_{120}), \tag{137.12}$$

$$\langle \widehat{\mathcal{A}} \rangle_\Delta = 18 \ell_P^2 \gamma_{\mathrm{BI}} a_0 (f_{90} + f_{120}), \tag{137.13}$$

$$s(\Delta) = \log Z(\Delta) + \Delta \langle \mathsf{D}_\partial \rangle_\Delta, \tag{137.14}$$

$$\frac{\mathrm{d}\langle \mathsf{D}_\partial \rangle_\Delta}{\mathrm{d}\Delta} = -\,\mathrm{Var}_\Delta(\mathsf{D}_\partial) = -18(90^2 v_{90} + 120^2 v_{120}), \tag{137.15}$$

$$\frac{\mathrm{d}s}{\mathrm{d}\Delta} = -\Delta\,\mathrm{Var}_\Delta(\mathsf{D}_\partial), \tag{137.16}$$

$$\frac{\mathrm{d}\langle\widehat{\mathcal{A}}\rangle_\Delta}{\mathrm{d}\Delta} = -18\ell_P^2\gamma_{\mathrm{BI}}a_0(90v_{90}+120v_{120}). \tag{137.17}$$

Proof. The local weights are $(1, x_m, x_m^2)/z_m$, whose first two moments give f_m and v_m. Additivity of occupation operators and factorization of the state give the first three formulas. Taking the trace of $-\rho_\partial\log\rho_\partial = \rho_\partial(\log Z + \Delta\mathsf{D}_\partial)$ gives the entropy. Differentiation of the finite sums yields $\partial_\Delta\log Z = -\langle\mathsf{D}_\partial\rangle_\Delta$ and $\partial_\Delta^2\log Z = \mathrm{Var}_\Delta(\mathsf{D}_\partial)$. Independent factors add their variances. In the derivative of (137.14), the two first-moment terms cancel. Finally, $\partial_\Delta f_m = -mv_m$ gives the area response. □

Loss of uniformity is quantified in dimension $d_\partial = 3^{36}$:

$$I_\partial(\Delta) = 36\log 3 - s(\Delta) = \mathcal{D}\big(\rho_\partial(\Delta)\|I/d_\partial\big) \geq 0. \tag{137.18}$$

Here $\mathcal{D}$ denotes relative entropy, defined and justified below. Substituting $\log(I/d_\partial) = -36\log 3\, I$ proves the identity. Convexity of $t\log t$ gives positivity; equality corresponds to the uniform distribution, which in this family occurs exactly at $\Delta = 0$. The deficit measures dimensionless information; the scale $\gamma_{\mathrm{BI}}a_0\ell_P^2$ measures area per occupation.

Theorem 137.4 (Occupation inversion and complementary area)**.** *Let $\mathcal{R}_\partial$ be the involution exchanging $|0\rangle$ and $|2\rangle$ and fixing $|1\rangle$ in each factor. Then*

$$\mathcal{R}_\partial\mathsf{N}\mathcal{R}_\partial^* = 72I - \mathsf{N}, \tag{137.19}$$

$$\mathcal{R}_\partial\mathsf{D}_\partial\mathcal{R}_\partial^* = 7560I - \mathsf{D}_\partial, \tag{137.20}$$

$$\rho_\partial(-\Delta) = \mathcal{R}_\partial\rho_\partial(\Delta)\mathcal{R}_\partial^*, \tag{137.21}$$

$$s(-\Delta) = s(\Delta), \tag{137.22}$$

$$\langle\widehat{\mathcal{A}}\rangle_{-\Delta} + \langle\widehat{\mathcal{A}}\rangle_\Delta = 72\gamma_{\mathrm{BI}}a_0\ell_P^2, \tag{137.23}$$

$$\mathcal{D}\big(\rho_\partial(\Delta)\|\rho_\partial(-\Delta)\big) = \Delta\big(7560 - 2\langle\mathsf{D}_\partial\rangle_\Delta\big). \tag{137.24}$$

Proof. Each occupation transforms by $n \mapsto 2-n$. In each sector, $\mathsf{N}_m \mapsto 36I - \mathsf{N}_m$, so the constant term of the weighted reader is $36(90+120) = 7560$. Moreover, $z_m(-\Delta) = e^{2m\Delta}z_m(\Delta)$ and $Z(-\Delta) = e^{7560\Delta}Z(\Delta)$. Substitution into the normalized state proves conjugation. Its spectrum preserves entropy; the transformation of N gives complementary area. Subtracting the logarithms of the two states and taking the expectation in $\rho_\partial(\Delta)$ gives the final equality. □

At $\Delta = 0$, $s = 36\log 3$. As $\Delta \to +\infty$, zero occupation concentrates the state and entropy tends to zero; inversion carries that limit to maximal occupation. For $\Delta > 0$, entropy decreases strictly because the weighted reader has more than one eigenvalue and the state has full rank. The complete configuration, area, and entropy thus preserve differentiated roles.

137.4 Modular law and finite area variations

Fix $\rho_0 = \rho_\partial(\Delta_0)$, with real finite Δ_0, and hold $\Delta_0, \gamma_{\mathrm{BI}}, a_0, \ell_P$ constant. The normalized areas $\mathcal{A}_m^{\mathrm{n}} = \gamma_{\mathrm{BI}}a_0\mathsf{N}_m$ express the modular operator as

$$\mathsf{K}_0 = -\log\rho_0 = c_0 I + \sum_{m=90,120}\beta_m\mathcal{A}_m^{\mathrm{n}}, \quad \beta_m = \frac{m\Delta_0}{\gamma_{\mathrm{BI}}a_0}, \quad c_0 = \log Z(\Delta_0). \tag{137.25}$$

One has $\beta_{120} = \frac{4}{3}\beta_{90}$, including when both are zero. The ratio is $4/3$ when $\Delta_0 \neq 0$. K_0 is the logarithm of this reference state; its type distinguishes it from temporal transport and the gravitational connection.

Theorem 137.5 (First modular law and finite correction)**.** *For any normalized state σ on the same space, let $\Delta_\sigma\langle B\rangle = \mathrm{Tr}[(\sigma-\rho_0)B]$. Then*

$$s(\sigma)-s(\rho_0)=\sum_{m=90,120}\beta_m\Delta_\sigma\langle\mathcal{A}^{\mathrm{n}}_m\rangle-\mathcal{D}(\sigma\|\rho_0), \tag{137.26}$$

where $\mathcal{D}(\sigma\|\rho_0)=\mathrm{Tr}[\sigma(\log\sigma-\log\rho_0)]$ is finite and nonnegative. If $\sigma(\varepsilon)$ is differentiable, normalized, and $\sigma(0)=\rho_0$, one obtains

$$\left.\frac{\mathrm{d}s(\sigma(\varepsilon))}{\mathrm{d}\varepsilon}\right|_0=\sum_{m=90,120}\beta_m\left.\frac{\mathrm{d}\langle\mathcal{A}^{\mathrm{n}}_m\rangle_{\sigma(\varepsilon)}}{\mathrm{d}\varepsilon}\right|_0. \tag{137.27}$$

Proof. By definition, $\mathcal{D}(\sigma\|\rho_0)=-s(\sigma)+\mathrm{Tr}(\sigma\mathsf{K}_0)$, whereas $s(\rho_0)=\mathrm{Tr}(\rho_0\mathsf{K}_0)$. Subtraction and (137.25) prove the finite identity, since normalization cancels the term $c_0 I$.

For positivity, diagonalize σ with eigenvalues p_i and vectors u_i, and ρ_0 with eigenvalues $q_j>0$ and vectors v_j. If $r_i=\langle u_i,\rho_0 u_i\rangle>0$, concavity of the logarithm gives

$$\sum_j|\langle u_i,v_j\rangle|^2\log q_j\le\log r_i.$$

Consequently, $\mathcal{D}(\sigma\|\rho_0)\ge\sum_i p_i\log(p_i/r_i)\ge 0$. The final inequality is convexity of $t\log t$ with weights r_i, whose sum is one. Faithfulness of ρ_0 keeps its logarithms finite; zero eigenvalues of σ are interpreted through $0\log 0=0$.

For the infinitesimal formula, in a neighbourhood of the faithful state ρ_0, the derivative of the trace of $-\sigma\log\sigma$ is $-\mathrm{Tr}[\dot\sigma(\log\rho_0+I)]$. This identity follows from the spectral derivative of the trace. The condition $\mathrm{Tr}\,\dot\sigma=0$ leaves $\mathrm{Tr}(\dot\sigma\mathsf{K}_0)$, and substitution of (137.25) completes the proof. □

For physical areas, the coefficients are β_m/ℓ_P^2. Applying the common transducer k_B gives $S=k_B s$ and preserves the term $k_B\mathcal{D}$ in full. The derivative in (137.17) varies Δ; law (137.27) holds Δ_0 fixed and varies the state around the reference. These are different operations.

137.5 Action, decision energy, and areal unit

We fix the same oriented action section and its gravitational and thermal sections, on the positive branch. The antecedents provide

$$\begin{aligned}\ell_P^2&=\frac{\hbar G}{c^3},&\qquad t_P&=\frac{\ell_P}{c},\\ T_{108}&=2\pi t_P,&\qquad h&=2\pi\hbar,\\ E_P&=\frac{\hbar}{t_P}=k_B\Theta_{\mathrm{clk}}\log 3.\end{aligned} \tag{137.28}$$

The thermal equality preserves the previously constructed pair and normalization; changing its dimensional basis transports k_B and Θ_{clk} jointly. The elementary area increment is $\delta\mathcal{A}=\gamma_{\mathrm{BI}}a_0\ell_P^2$.

Proposition 137.6 (Conversion coefficient between decision and area)**.** *The ratio of decision energy to the areal increment satisfies*

$$\begin{aligned}\mathcal{T}_{I/A}:=\frac{E_P}{\delta\mathcal{A}}&=\frac{k_B\Theta_{\mathrm{clk}}\log 3}{\gamma_{\mathrm{BI}}a_0\ell_P^2}\\ &=\frac{c^3}{\gamma_{\mathrm{BI}}a_0 G t_P}=\frac{c^4}{\gamma_{\mathrm{BI}}a_0 G\ell_P}.\end{aligned} \tag{137.29}$$

Its dimension is energy per area.

Proof. Substitution of $E_P = \hbar/t_P$ and $\ell_P^2 = \hbar G/c^3$ cancels the common action section. The identity $\ell_P = ct_P$ gives the final expression. Positivity of the factors ensures that all quotients are defined. □

The capacity 81 of the cubic cut and the bipartition of the thirty- six sectoral links correspond to different domains. In the cubic graph $\{0, \dots, N-1\}^3$, the N^2 parallel lines between two opposite faces are edge-disjoint: every cut intercepts the N^2, and a transverse layer attains that bound. For $N = 9$, the uniform product state of the trits of that layer has $s_{\mathrm{corte}} = 81 \log 3$. Assigning a decision of the same cycle to each link publishes

$$S_{\mathrm{corte}}^{\mathrm{fis}} = 81 k_B \log 3, \qquad E_{\mathrm{corte}}^{(1)} = 81 E_P = \Theta_{\mathrm{clk}} S_{\mathrm{corte}}^{\mathrm{fis}}. \tag{137.30}$$

The proof combines the minimum cut, additivity of product-state entropy, and (137.28). In the sectorial state, the relevant finite equation remains (137.26), with its relative entropy.

137.6 Cosmological normalization of the horizon

For an areal radius $R > 0$, the cosmological realization considered uses the triad

$$E_\Lambda(R) = \frac{c^4 R}{2G}, \qquad S_{\mathrm{H}}(R) = \frac{k_B \pi R^2}{\ell_P^2}, \qquad T_{\cos}(R) = \frac{\hbar c}{2\pi k_B R}. \tag{137.31}$$

The factor 2π belongs to this temperature normalization. The area $\mathcal{A}_{\mathrm{H}} = 4\pi R^2$ expresses the same entropy as $S_{\mathrm{H}}/k_B = \mathcal{A}_{\mathrm{H}}/(4\ell_P^2)$.

Theorem 137.7 (Gravitational half-action cell)**.** *In* (137.31)*,*

$$T_{\cos}(R) S_{\mathrm{H}}(R) = E_\Lambda(R), \tag{137.32}$$

$$T_{\cos}(\ell_P) S_{\mathrm{H}}(\ell_P) = \frac{E_P}{2} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2}, \tag{137.33}$$

$$E_\Lambda(\ell_P) t_P = \frac{\hbar}{2}, \qquad E_\Lambda(\ell_P) T_{108} = \frac{h}{2}. \tag{137.34}$$

Keeping the chart constants fixed and varying R,

$$T_{\cos}\, \mathrm{d}S_{\mathrm{H}} = 2\, \mathrm{d}E_\Lambda, \qquad S_{\mathrm{H}}\, \mathrm{d}T_{\cos} = -\mathrm{d}E_\Lambda. \tag{137.35}$$

Proof. Multiplying temperature and entropy gives $\hbar c R/(2\ell_P^2) = c^4 R/(2G)$. At $R = \ell_P$, the result is $\hbar/(2t_P) = E_P/2$. The two durations in (137.28) give the action relations. For the differentials, $\mathrm{d}E_\Lambda = c^4 \mathrm{d}R/(2G)$, $\mathrm{d}S_{\mathrm{H}} = 2\pi k_B R \mathrm{d}R/\ell_P^2$, and $\mathrm{d}T_{\cos} = -T_{\cos} \mathrm{d}R/R$. Substitution proves both identities. □

The product $E_\Lambda = T_{\cos} S_{\mathrm{H}}$ expresses a state identity. Its radial variations preserve both terms of (137.35); a complete thermodynamic interpretation additionally specifies the corresponding time generator, work and material realization. In this chart, action and gravitation fix the unit ℓ_P^2, while Boltzmann converts information into dimensional entropy. Transport of sections with $G\hbar$ fixed preserves that unit when the section c is kept fixed, and preserves S_{H}/k_B at fixed radius.

In the cell $R = \ell_P$, $S_{\mathrm{H}}/k_B = \pi$, so the effective multiplicity is $\Omega_{\mathrm{eff}} = e^\pi$. For the tritic hyperbolic involution H_{trit}, with spectrum $\{1, -1\}$, diagonalization gives $\mathrm{spec}(e^{\pi H_{\mathrm{trit}}}) = \{e^\pi, e^{-\pi}\}$. This spectral relation specifies the expansive value; a microscopic identification of both spaces additionally preserves their realization map and the state.

137.7 Kruskal chart and exchange of the exteriors

Let us fix a published state x, its radius $R = R(x) > 0$ and the positive sections c, G. In the following chart, x, R, c, G are fixed parameters; t, r are the spacetime coordinates. The exterior realization of the two sheets is specified by

$$f(r) = 1 - \frac{R}{r}, \qquad \mathrm{d}s^2 = -f(r)c^2\mathrm{d}t^2 + f(r)^{-1}\mathrm{d}r^2 + r^2\mathrm{d}\Omega_2^2, \qquad r > R. \tag{137.36}$$

For the sheet reader $\sigma \in \{+1, -1\}$, define

$$r_* = r + R\log\left(\frac{r}{R} - 1\right), \tag{137.37}$$

$$\mathcal{U} = -\sigma\exp\left(-\frac{ct - r_*}{2R}\right), \qquad \mathcal{V} = \sigma\exp\left(\frac{ct + r_*}{2R}\right). \tag{137.38}$$

The symbols $\mathcal{U}, \mathcal{V}$ are coordinates and are distinguished from route-transport operators.

Theorem 137.8 (Geometric realization and sheet involution)**.** *Chart* (137.38) *realizes the two sheets as the two exteriors $\mathcal{U}\mathcal{V} < 0$ of the Kruskal extension. We have*

$$-\mathcal{U}\mathcal{V} = \left(\frac{r}{R} - 1\right)e^{r/R}, \qquad \mathrm{d}s^2 = -\frac{4R^3}{r}e^{-r/R}\,\mathrm{d}\mathcal{U}\,\mathrm{d}\mathcal{V} + r^2\mathrm{d}\Omega_2^2. \tag{137.39}$$

The involution

$$C_{\mathrm{H}} : (\sigma, \mathcal{U}, \mathcal{V}) \longmapsto (-\sigma, -\mathcal{U}, -\mathcal{V}) \tag{137.40}$$

is isometric, fixes the areal radius, exchanges the exterior regions, and preserves the horizon set $\mathcal{U}\mathcal{V} = 0$. The metric is regular at $r = R$ and satisfies the vacuum equations on the regular domain $r > 0$.

Proof. Multiplying the coordinates gives the first identity. Since $\mathrm{d}r_*/\mathrm{d}r = f^{-1}$,

$$\mathrm{d}\mathcal{U} = \frac{\mathcal{U}}{2R}(-c\,\mathrm{d}t + f^{-1}\mathrm{d}r), \qquad \mathrm{d}\mathcal{V} = \frac{\mathcal{V}}{2R}(c\,\mathrm{d}t + f^{-1}\mathrm{d}r).$$

Their product reproduces the radial and temporal part of the metric. The function $z \mapsto (z-1)e^z$ has derivative $ze^z > 0$ for $z > 0$, determining r from the product. In the exterior region one recovers $\sigma = \operatorname{sign}\mathcal{V}$ and $t = (R/c)\log(-\mathcal{V}/\mathcal{U})$. At $r = R$, the radial coefficient of the extended metric is $-4R^2/e$, finite and nonzero. Inversion preserves the product, radius, and $\mathrm{d}\mathcal{U}\mathrm{d}\mathcal{V}$, and exchanges the two sign choices.

To check the vacuum in the exterior chart, the independent mixed components of the Einstein tensor reduce to

$$\mathsf{G}^t{}_t = \mathsf{G}^r{}_r = \frac{rf' + f - 1}{r^2}, \qquad \mathsf{G}^\theta{}_\theta = \mathsf{G}^\phi{}_\phi = \frac{f'}{r} + \frac{f''}{2}.$$

With $f' = R/r^2$ and $f'' = -2R/r^3$, all vanish. The regular expression (137.39) prolongs the result through the horizons on the domain $r > 0$. □

This realization preserves $E_{\mathrm{H}} = c^4R/(2G)$ and $S_{\mathrm{H}} = k_B\pi R^2/\ell_P^2$, which depend on the areal radius. The temperature $T_{\cos}$ of (137.31) belongs to the cosmological realization declared there. The exterior chart (137.36) preserves its own temporal normalization. The geometric map establishes the exchange of exteriors; comparison with formation by collapse, radiation spectra or quasinormal modes additionally uses their respective physical conditions.

137.8 Transport of states, observables, and refinements

Let F_x denote the chart of the two exteriors just constructed. In each regular angular chart, its temporal and radial Jacobian is

$$\left|\frac{\partial(\mathcal{U},\mathcal{V})}{\partial(t,r)}\right| = \frac{cr}{2R^3}e^{r/R} > 0. \tag{137.41}$$

The identity follows from the two differentials of the preceding proof. The remaining state records are transported as fiber coordinates; the chart preserves its identity and memory.

Proposition 137.9 (Unitary equivalence of sheet and exterior readings)**.** *Let μ be a sheet measure and $\nu = (F_x)_*\mu$ its transported measure. Change of variables defines a unitary map*

$$W_{\mathrm{H}} : L^2(\mu) \longrightarrow L^2(\nu), \qquad (W_{\mathrm{H}}\psi)(z) = \psi(F_x^{-1}z). \tag{137.42}$$

With densities relative to fixed coordinate measures, the same map incorporates the corresponding Jacobian factor. Conjugation

$$\mathfrak{I}_{\mathrm{H}}(B) = W_{\mathrm{H}}BW_{\mathrm{H}}^* \tag{137.43}$$

is a unital completely positive $*$-isomorphism. It transports the state, its expectations, and its modular functional calculus. For the symmetric measure of the two sheets, it also intertwines their involutions.

Proof. The definition of pushforward measure gives $\int |\psi \circ F_x^{-1}|^2 \,\mathrm{d}\nu = \int |\psi|^2 \,\mathrm{d}\mu$. The chart is invertible in the exteriors, so the isometry is surjective. Unitary conjugation preserves product, adjoint and identity; in each matrix amplification it conjugates by $I_n \otimes W_{\mathrm{H}}$, proving complete positivity. For a state ρ, cyclicity of the trace gives $\mathrm{Tr}(W_{\mathrm{H}}\rho W_{\mathrm{H}}^* \,\mathfrak{I}_{\mathrm{H}}(B)) = \mathrm{Tr}(\rho B)$. Functional calculus implies $g(W_{\mathrm{H}}\rho W_{\mathrm{H}}^*) = W_{\mathrm{H}}g(\rho)W_{\mathrm{H}}^*$ on its domain, in particular for the logarithm and modular flow of a state faithful on its support. The equality $F_x \circ C_{\mathrm{hoja}} = C_{\mathrm{H}} \circ F_x$ proves the intertwining of involutions; the symmetric measure realizes them unitarily. □

If the refinements preserve (σ, t, r, R) and use the same isometry on the fiber registers, the inclusions j_m^{hoja} and j_m^{ext} satisfy

$$W_{\mathrm{H},m+1} j_m^{\mathrm{hoja}} = j_m^{\mathrm{ext}} W_{\mathrm{H},m}. \tag{137.44}$$

Indeed, change of variables acts on the preserved geometric coordinates and inclusion on the same fibre coordinates; evaluating both compositions gives the same function and the same transported density. The equality extends the map to the refined system without resetting the records.

For a bipartition $\mathcal{H}_A \otimes \mathcal{H}_B$, a factorized transport $U_A \otimes U_B$ satisfies

$$\rho'_A = U_A \rho_A U_A^*, \qquad s(\rho'_A) = s(\rho_A).$$

The first identity follows from partial trace and the second from the spectrum. For a general unitary, the equivalent formulation also transports the subsystem algebra: $\mathcal{B}(\mathcal{H}_A) \otimes I \mapsto U(\mathcal{B}(\mathcal{H}_A) \otimes I)U^*$. This preserves the same operational question concerning accessible information. Entropy equalities apply to states with the relevant finite entropies.

The relation between information and gravitation is expressed through distinct composable operations: the state and bipartition fix accessible information; incidence and Barbero–Immirzi fix areal resolution; action and gravitation construct the unit ℓ_P^2; Boltzmann realizes entropy dimensionally; the horizon chart transports geometry and its observables. The finite laws preserve relative entropy, and the geometric realizations preserve their measures, temporal normalization and domains.

Chapter 138

Observer, memory, and relational response

The reading operation acts on the transport published by the APP–TRIT–TPK enriched state. Its domain preserves route, sheet, orientation, carry and memory; the result accessible to the observer is a map of that domain. This distinction allows three operations to be described together: choosing an oriented representative of transport, inscribing its record in an apparatus and the local response induced by the global boundary. Each operation transmits different information. The following construction specifies their maps and the conditions allowing them to be composed.

138.1 Boundary transport and intrinsic reading

The finite publication of transport provides an oriented cycle C_n, with $n \geq 1$, vertices $0, \dots, n-1$ and edges $e_j : j \longrightarrow j+1 \pmod n$. We fix the lattice realization L of the record, its vector space $W = L \otimes_{\mathbb{Z}} \mathbb{R}$, a positive inner product and the nonzero primitive representative $v \in L$ of the distinguished residual class, in the declared chamber. The APP sum and product sheets provide the transport polarizations; TRIT orientation and TPK updating precede this linear publication. The cycle, the lattice realization and the residual class are the data this section receives from the transport constructed previously.

A 0-cochain is a function on the vertices with values in W; a 1-cochain assigns a vector to each oriented edge. The coboundary acts by

$$(d\Phi)(e_j) = \Phi(j+1) - \Phi(j).$$

We denote by $\mathbf{1}_E$ the constant scalar cochain on the edges. For a transport $\omega \in C^1(C_n; W)$, its accumulated publication Γ_ω is obtained through partial sums and affine interpolation; its closure defect is

$$B(\omega) = \Gamma_\omega(1) - \Gamma_\omega(0) = \sum_{j=0}^{n-1} \omega(e_j). \tag{138.1}$$

Theorem 138.1 (Exact decomposition and harmonic mode of the cycle)**.** *Every transport has a unique decomposition*

$$\omega = d\Phi + u\mathbf{1}_E, \qquad \Phi(0) = 0, \qquad u = \frac{1}{n}\sum_j \omega(e_j).$$

In particular, $B(d\Phi) = 0$ *and* $B(\omega) = nu$.

Proof. Let $y_j = \omega(e_j) - u$. The sum of the y_j is zero. We define $\Phi(k) = \sum_{j=0}^{k-1} y_j$; the value for $k = n$ coincides with $\Phi(0) = 0$, so the function is well defined on the cycle, including its final edge. We have $d\Phi(e_j) = y_j$. If $d\Phi + u\mathbf{1}_E = d\Psi + w\mathbf{1}_E$, the sum over edges gives $nu = nw$. Then $d(\Phi - \Psi) = 0$; connectivity of the cycle and normalization at the initial vertex imply $\Phi = \Psi$. The identity $\sum_j (\Phi(j+1) - \Phi(j)) = 0$ directly proves telescopic cancellation. □

Definition 138.2 (Admissible transport and normalized reading)**.** Transport is admissible when its harmonic mode belongs to $\mathbb{R}v$. On the space $\mathcal{T}_{\mathrm{adm}}$ of those transports we define the global reading and its density per phase:

$$\mathfrak{a}_v(\omega) = \frac{\langle B(\omega), v\rangle}{\langle v, v\rangle}, \qquad \mu_v(\omega) = \frac{\mathfrak{a}_v(\omega)}{n}. \tag{138.2}$$

We have $B(\omega) = \mathfrak{a}_v(\omega)v$.

Theorem 138.3 (Determination of the intrinsic reading)**.** *The quotient* $\mathcal{T}_{\mathrm{adm}}/dC^0(C_n; W)$ *is one-dimensional, generated by the class of* $v\mathbf{1}_E$*. The map* μ_v *is the unique linear functional on* $\mathcal{T}_{\mathrm{adm}}$ *satisfying*

$$F(\omega + d\Phi) = F(\omega), \qquad F(v\mathbf{1}_E) = 1.$$

Proof. The preceding decomposition writes each admissible transport as $d\Phi + \lambda v\mathbf{1}_E$. Its class modulo exact cochains is determined by λ. The class of $v\mathbf{1}_E$ is nonzero because its sum is $nv \neq 0$. By linearity and invariance, every functional with the indicated characteristics equals $F(\omega) = \lambda F(v\mathbf{1}_E) = \lambda$. The formula (138.2) gives precisely $\mu_v = \lambda$. The global reading is $\mathfrak{a}_v = n\mu_v$. □

Definition 138.4 (Edge Observer)**.** Given the polarization of the published transport, a boundary observer is a pair $O = (\varepsilon, \Psi)$, where $\varepsilon \in \{+1, -1\}$ and $\Psi \in C^0(C_n; W)$. Its reading action is

$$\omega^O = \varepsilon\omega + d\Psi. \tag{138.3}$$

The sign fixes the orientation and the cochain fixes the trivialization. Two polarization choices are compared through their published transport; the relation (138.3) describes exactly the representatives differing by orientation and coboundary.

Proposition 138.5 (Covariance of the reading)**.** *The action preserves admissibility and satisfies*

$$B(\omega^O) = \varepsilon B(\omega), \quad \mathfrak{a}_v(\omega^O) = \varepsilon\mathfrak{a}_v(\omega), \quad \mu_v(\omega^O) = \varepsilon\mu_v(\omega).$$

Trivializations with the same orientation publish the same closure.

Proof. The sum of the coboundary $d\Psi$ is zero. Therefore, the harmonic mode transforms into εu, which still belongs to $\mathbb{R}v$, and the defect transforms into εB. The two scalar equalities are obtained by normalized projection. □

The unit of this reading is the residual representative v, with its internal normalization. Trivialization freedom acts on the cochain representative; closure information resides in its class. The description allows observers to be compared while keeping genealogical transport, its linear publication and the scalar evaluating the residual class separate.

138.2 Boundary identity and cellular interior

Let K be a finite oriented two-dimensional cell complex, equipped with a fundamental 2-chain c_K such that $\partial c_K = [C_n]$. This condition expresses that interior incidences cancel with their multiplicities and orientations. Let $\Omega \in C^1(K; W)$ be an extension of ω and $F_\Omega = d\Omega$ its additive discrete curvature.

Theorem 138.6 (Cellular holographic identity of the reading)**.** *With the preceding data,*

$$B(\omega) = \langle \Omega, \partial c_K \rangle = \langle d\Omega, c_K \rangle, \qquad \mathfrak{a}_v(\omega) = \frac{\langle \langle d\Omega, c_K \rangle, v \rangle}{\langle v, v \rangle}. \tag{138.4}$$

In particular, $F_\Omega = 0$ implies $\mathfrak{a}_v(\omega) = 0$. If closure is nonzero, every extension of transport on that complex has nonzero discrete curvature.

Proof. The pairing between chains and cochains satisfies $\langle d\Omega, c_K \rangle = \langle \Omega, \partial c_K \rangle$. When it is expanded, each interior edge appears with the sum of the incidence numbers of the adjoining cells; the condition on ∂c_K leaves exactly the oriented boundary cycle. The restriction of Ω to that cycle is ω, whose sum is $B(\omega)$. Projection onto v gives the second formula and the flatness implication. □

The equality compares two evaluations of the same extended cochain: the accumulated boundary defect and the coboundary integrated over the interior. Its curvature takes values in W and uses the additive cellular coboundary. Realization by a geometric connection additionally preserves its own coefficient space and transport law.

138.3 Isometric inscription of the record in the apparatus

Let $\mathfrak{M}_n$ be a nonempty finite set of records published at level n, with result, route, carry, sheet and memory. Its record space is $\mathcal{H}_n = \ell^2(\mathfrak{M}_n)$, with basis $|m\rangle$. The visible update F_n has a record lift

$$\widehat{F}_n(m) = (F_n(m), m).$$

We take as records of the next level a set containing those pairs. The second coordinate preserves the antecedent and makes the lift injective. This construction specifies the memory retained by inscription, including when the visible update merges values.

In a finite apparatus space $\mathcal{K}_{A,n}$, we fix an orthonormal family $(|a_m\rangle)_{m\in\mathfrak{M}_n}$ and define

$$\iota_n : \mathcal{H}_n \longrightarrow \mathcal{K}_{A,n}, \quad \iota_n|m\rangle = |a_m\rangle, \qquad V_n : \mathcal{H}_n \longrightarrow \mathcal{H}_{n+1}, \quad V_n|m\rangle = |\widehat{F}_n(m)\rangle.$$

Let $\mathcal{P}_n = \iota_n\mathcal{H}_n$ be the pointer subspace.

Theorem 138.7 (Compatibility between updating and inscription)**.** *The maps ι_n and V_n are isometries. There exists a unique isometry $W_n^0 : \mathcal{P}_n \longrightarrow \mathcal{K}_{A,n+1}$ satisfying*

$$W_n^0\iota_n = \iota_{n+1}V_n. \tag{138.5}$$

If $\dim\mathcal{K}_{A,n+1} \geq \dim\mathcal{K}_{A,n}$, it extends to an isometry of all of $\mathcal{K}_{A,n}$. Through auxiliary complements equalizing dimensions, a unitary extension between the enlarged spaces is obtained.

Proof. The basis images under ι_n are orthonormal; the images under V_n are also orthonormal by injectivity of $\widehat{F}_n$. For $z = \iota_n\psi$ we define $W_n^0 z = \iota_{n+1}V_n\psi$. The representation of z is unique, and the three maps preserve its norm. The formula determines the map on a basis of $\mathcal{P}_n$ and proves the square. If the target dimension is sufficient, the orthogonal complement of $W_n^0\mathcal{P}_n$ contains an orthonormal family of the size of $\mathcal{P}_n^{\perp}$; sending a basis of the latter to that family constructs the extension. Finally both spaces are enlarged to the same dimension and the two prescribed families are completed to orthonormal bases. The map between those bases is unitary. □

When the record includes labels of a finite instrument, this same inscription realizes its environment: if the operators $K_{y,a} : \mathcal{H}_S \to \mathcal{H}'_S$ satisfy $\sum_{y,a} K_{y,a}^* K_{y,a} = I$, the map

$$V_{\mathrm{inst}}\psi = \sum_{y,a} K_{y,a}\psi \otimes |y, a\rangle$$

is isometric, since its squared norm is $\sum_{y,a}\langle\psi, K_{y,a}^* K_{y,a}\psi\rangle = \|\psi\|^2$. The inscription ι transports each label to its corresponding pointer. The model thus fixes the premeasurement record; a material device additionally requires its interaction and calibration.

138.4 Outcome map and record conditioning

The preceding inscription is composed with the apparatus reader on the complete genealogical state. Coupling preserves the operation that produces the correlation; the output map publishes the result; conditioning restricts the prolongations compatible with that register.

Let (Ω_S, Σ_S) and (Ω_M, Σ_M) be the measurable spaces of genealogical states of the system and apparatus, obtained from their compatible cylinders and records. A measurement context is written $\mathfrak{M}_a = (U_a, q_a, C_a, m_0)$: m_0 is the apparatus preparation, C_a specifies compatibilities and the extension horizon, and

$$U_a : \Omega_S \times \Omega_M \longrightarrow \Omega_S \times \Omega_M, \qquad q_a : \Omega_M \longrightarrow Y_a$$

are, respectively, the measurable coupling and the measurable readout into the outcome space (Y_a, Σ_{Y_a}). In a reversible regime, U_a is bijective and bimeasurable; the corresponding unitarity is also required in the Hilbert-space realization. The individual outcome is the composition

$$\mathrm{Out}_a(x) = q_a\big(\mathrm{pr}_M\, U_a(x, m_0)\big). \tag{138.6}$$

It is determined by the complete state, apparatus preparation, and context. The statistical description of a preparation is another readout of the set of compatible states.

Proposition 138.8 (Outcome measure and restriction to a fibre)**.** *Let $\Omega_a \in \Sigma_S$ be the set of states compatible with the preparation and context, endowed with a probability measure μ_a on $(\Omega_a, \Sigma_S|_{\Omega_a})$. The map $\mathrm{Out}_a|_{\Omega_a}$ is measurable and induces the outcome probability measure*

$$\nu_a(B) = \mu_a\big(\mathrm{Out}_a^{-1}(B) \cap \Omega_a\big), \qquad B \in \Sigma_{Y_a}. \tag{138.7}$$

For an outcome y whose singleton is measurable, the fibre $\Omega_{a,y} = \{x \in \Omega_a : \mathrm{Out}_a(x) = y\}$ is measurable. Whenever $\mu_a(\Omega_{a,y}) > 0$,

$$\mu_{a,y}(E) = \frac{\mu_a(E \cap \Omega_{a,y})}{\mu_a(\Omega_{a,y})} \tag{138.8}$$

for $E \in \Sigma_S|_{\Omega_a}$ defines a probability measure concentrated on that fibre.

Proof. The inclusion $x \mapsto (x, m_0)$, coupling, apparatus projection, and readout are measurable; their composition is therefore measurable. Preimages preserve disjoint unions and the whole space, so (138.7) is countably additive with total mass one. The fibre is the preimage of the singleton $\{y\}$ within Ω_a. Restricting μ_a to that fibre gives a positive, countably additive measure; division by its positive mass normalizes it. □

For a prefix s of depth n, the extensions following the record form

$$\mathrm{Fut}_{a,y}(s) = \{x \in \Omega_{a,y} : x|_n = s\}.$$

The restriction preserves the prefix already traversed and the coupling register; it modifies the family of admitted prolongations. The output (138.6) acts on complete states; the outcome law (138.7) is obtained by transporting the preparation measure through that map. Representation by a density matrix expresses the statistical level of the quantum realization and retains its conditions of correspondence with the genealogical fibers.

138.5 Accessible algebra and pointer complement

Define $P_m = |a_m\rangle\langle a_m|$, $P = \sum_m P_m$, and $P_\perp = I - P$. The algebra of the pointer subspace is $P\mathcal{B}(\mathcal{K}_{A,n})P$, whose unit is P. On it, the diagonal reader is

$$\mathcal{D}_P(A) = \sum_m P_m A P_m.$$

Proposition 138.9 (Record expectation and unital extension)**.** *The map $\mathcal{D}_P$ is a completely positive, trace-preserving and idempotent conditional expectation onto the pointer algebra, with $\mathcal{D}_P(P) = P$. Its image is $\bigoplus_m \mathbb{C}P_m$. On the algebra of the complete apparatus, the map*

$$\mathcal{E}_P(A) = \sum_m P_m A P_m + P_\perp A P_\perp \tag{138.9}$$

is a unital, completely positive, trace-preserving conditional expectation. Its image is

$$\left(\bigoplus_m \mathbb{C}P_m\right) \oplus \mathcal{B}(\mathcal{P}_n^{\perp}).$$

Both maps are orthogonal projections for the Hilbert–Schmidt inner product. Their spectra are contained in $\{0,1\}$. *When eliminated components exist, the separation between the fixed subspace and the kernel is one.*

Proof. The projectors P_m are mutually orthogonal. In the complete apparatus, the family that adds $P_\perp$ sums to I. Each term $A \mapsto P_m A P_m$ is completely positive: after any matrix amplification it acts by congruence with $I \otimes P_m$. The same holds for $P_\perp$. The sum preserves that property. Cyclicity of the trace and the sum of the projectors prove trace preservation on each domain. Orthogonality annihilates the cross terms when the map is iterated, so it is idempotent. Its fixed elements are precisely the stated blocks and the map is bimodular with respect to that subalgebra. Moreover, $\operatorname{Tr}(A^* P_m B P_m) = \operatorname{Tr}((P_m A P_m)^* B)$, from which self-adjointness for Hilbert–Schmidt follows. A self-adjoint projection has only the spectral values zero and one when both subspaces are nonzero. If only the fixed subspace remains, the map is the identity. □

The sum $\sum_m P_m A P_m$, applied without the complement to the entire apparatus, sends I to P. Its natural unit belongs to the pointer algebra. The formula (138.9) also preserves the auxiliary block; an orthonormal resolution of that block provides, when desired, diagonalization of the entire apparatus.

If U is a unitary transformation of the apparatus and $P'_m = U P_m U^*$, then

$$\mathcal{E}_{P'}(UAU^*) = U \mathcal{E}_P(A) U^*.$$

The equality is obtained by substituting each projector into the sum. Likewise, for $A \in \mathcal{B}(\mathcal{P}_n)$, the square (138.5) implies

$$\mathcal{D}_{P_{n+1}}(W_n^0 A (W_n^0)^*) = W_n^0 \mathcal{D}_{P_n}(A)(W_n^0)^*.$$

Indeed, each matrix unit $|a_m\rangle\langle a_{m'}|$ is transported to the unit corresponding to the distinct records $\widehat{F}_n(m), \widehat{F}_n(m')$; the diagonal reader preserves exactly the terms with $m = m'$.

138.6 Factorization of the response through the effective boundary

Let $\mathcal{X}_\infty^{\mathrm{enr}}$ be the domain of compatible enriched states and let $b : \mathcal{X}_\infty^{\mathrm{enr}} \longrightarrow B_\infty$ be its global boundary trace. We denote by $B_{\mathrm{ef}} = \operatorname{im} b$ the effectively published boundary. For a response space $\mathcal{V}_\nu$, we consider $I_\nu : \mathcal{X}_\infty^{\mathrm{enr}} \longrightarrow \mathcal{V}_\nu$.

Theorem 138.10 (Relational response criterion)**.** *There exists a unique map* $\overline{I}_\nu : B_{\mathrm{ef}} \to \mathcal{V}_\nu$ *such that* $I_\nu = \overline{I}_\nu \circ b$ *if and only if*

$$b(x) = b(x') \quad \Longrightarrow \quad I_\nu(x) = I_\nu(x'). \tag{138.10}$$

Uniqueness extends to all of B_∞ *when* b *is surjective.*

Proof. A composition through b is constant on each fiber. Conversely, for $\beta \in B_{\mathrm{ef}}$, we define $\overline{I}_\nu(\beta) = I_\nu(x)$ with $b(x) = \beta$. Condition (138.10) guarantees independence of the representative; every value of $\overline{I}_\nu$ is determined by some state of that fiber. If b is surjective, $B_{\mathrm{ef}} = B_\infty$. Otherwise, the composition equation determines only the values on B_{ef}. □

This criterion is set-theoretic. For a continuous factorization, the topologies and the quotient-map condition of $b : \mathcal{X}_\infty^{\mathrm{enr}} \to B_{\mathrm{ef}}$ are also preserved; with it, continuity of I_ν is equivalent to that of its factor. This specification separates determination of a reading from its regularity properties.

Let $\ell_v : \mathcal{X}_\infty^{\mathrm{enr}} \to \mathcal{L}_v$ be the restriction accessible to a local neighborhood. The effective global character is verified through two states satisfying

$$\ell_v(x) = \ell_v(x'), \qquad I_v(x) \neq I_v(x'). \tag{138.11}$$

If I_v factors through b, these two states have distinct boundaries. Moreover, the response cannot be written as a function of ℓ_v, since that function would assign the same value to both states. The difference of boundaries thus acquires a verifiable operator effect.

138.7 Ambivalence weights and self-inertial response

For the general formula we consider positive readers A_∂, V_∂ and an energy reader Q defined on the declared effective boundary domain. A realization on $B_{\mathrm{av}} \subseteq B_{\mathrm{ef}}$ is made explicit below. Memory remains as a boundary coordinate $\mathsf{M}_\partial(\beta)$. The ambivalence hinge provides the two orientations

$$r_{\mathrm{av}} = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2}, \qquad r_{\mathrm{av}}^J = \frac{\varphi_{\mathrm{HMT}}}{\pi_{\mathrm{HMT}}^2}.$$

The superscript J expresses interchange of the generating pair.

138.7.0.1 Normalized realization of the boundary readers.

The APP–TRIT–TPK modal incidence, developed in the regional construction, provides the path envelope with matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

The positive vector $v = (1, \varphi_{\mathrm{HMT}})^{\mathsf{T}}$ satisfies $F_{\mathrm{av}} v = \varphi_{\mathrm{HMT}} v$. Its normalized transition and stationary weights are

$$P_{ij} = \frac{(F_{\mathrm{av}})_{ij} v_j}{\varphi_{\mathrm{HMT}} v_i}, \qquad P = \begin{pmatrix} 0 & 1 \\ \varphi_{\mathrm{HMT}}^{-2} & \varphi_{\mathrm{HMT}}^{-1} \end{pmatrix}, \qquad (\mu_{\mathrm{ar}}, \mu_{\mathrm{vol}}) = \frac{(1, \varphi_{\mathrm{HMT}}^2)}{1 + \varphi_{\mathrm{HMT}}^2}. \tag{138.12}$$

The rows of P sum to one by $\varphi^{-2} + \varphi^{-1} = 1$; the stationary equation $\mu_{\mathrm{ar}} = \mu_{\mathrm{vol}} \varphi^{-2}$, together with normalization, determines the stated weights. This Parry measure weights the paths of the envelope; the chronological frequency $(1/3, 2/3)$ counts the instants of the modal calendar and retains its distinct function.

The common memory-amplitude realization is defined on the sector $\mathcal{X}_{\mathrm{av}} \subset \mathcal{X}_\infty^{\mathrm{enr}}$ in which the readers of the two sheets have the factorization

$$\mathcal{L}_{\mathrm{vol}}(x) = \mu_{\mathrm{vol}} \mathcal{M}(x), \qquad \mathcal{L}_{\mathrm{ar}}(x) = \pi_{\mathrm{HMT}} \mu_{\mathrm{ar}} \mathcal{M}(x), \qquad \mathcal{M}(x) > 0. \tag{138.13}$$

Both values belong to the same positive memory-amplitude line. The areal publication carries the regional mark π_{HMT} of the return. The dimensionless reading is obtained by dividing both sections by $\mathcal{L}_{\mathrm{vol}}(x)$. Thus the sums of the weights are performed between quantities of the same type; a possible realization as physical areas and volumes is then composed with their respective dimensional transducers.

Proposition 138.11 (Descent of the normalized readers and the energy clock)**.** *On $B_{\mathrm{av}} = b(\mathcal{X}_{\mathrm{av}})$, the rules*

$$A_\partial(b(x)) = \frac{\mathcal{L}_{\mathrm{ar}}(x)}{\mathcal{L}_{\mathrm{vol}}(x)} = r_{\mathrm{av}}, \qquad V_\partial(b(x)) = 1 \tag{138.14}$$

define two positive readers independent of the representative. Given an orientation a of the action section, the decision energy of (123.6) *determines on states*

$$q_a(x) = \frac{h_a(x)}{108 t_0(x)} = \frac{\hbar_a(x)}{t_P(x)} \in \mathcal{L}_E^+, \qquad t_P = \frac{54}{\pi_{\mathrm{HMT}}} t_0. \tag{138.15}$$

We write

$$b_{\mathrm{av}} := b|_{\mathcal{X}_{\mathrm{av}}} : \mathcal{X}_{\mathrm{av}} \longrightarrow B_{\mathrm{av}}.$$

There exists a unique reader $Q : B_{\mathrm{av}} \to \mathcal{L}_E^+$ such that $q_a|_{\mathcal{X}_{\mathrm{av}}} = Q \circ b_{\mathrm{av}}$ if and only if, for any $x, x' \in \mathcal{X}_{\mathrm{av}}$,

$$b(x) = b(x') \implies \frac{h_a(x)}{t_0(x)} = \frac{h_a(x')}{t_0(x')}. \tag{138.16}$$

In particular, a chart of fixed action and duration satisfies this condition and publishes $Q = h_a/(108 t_0)$.

Proof. The quotient of (138.13) cancels the common amplitude and equals $\pi_{\mathrm{HMT}} \mu_{\mathrm{ar}}/\mu_{\mathrm{vol}} = \pi_{\mathrm{HMT}}/\varphi_{\mathrm{HMT}}^2$. The result is the same for all representatives of a fiber of b_{av} within $\mathcal{X}_{\mathrm{av}}$ and is positive. Dividing both readers by the same positive factor preserves the weighted quotients in which they enter. For the clock, the factorization criterion of theorem 138.10, applied to q_a, is exactly equivalent to (138.16). Fixed sections satisfy it; so do variable sections whose quotient descends through b_{av}. Uniqueness follows from the definition of B_{av} as the effective image. □

The value of the reader Q belongs to the energy line $\mathcal{L}_E = \mathcal{L}_{\mathrm{act}} \otimes \mathcal{L}_T^*$. With E_1, E_2 on that same line, $E_1 E_2/Q^2$ is dimensionless and independent of the positive energy basis. The symbol Q in this section exclusively designates that clock energy; the quantity of heat in the Landauer realization belongs to the corresponding thermal balance. Common-amplitude factorization specifies a concrete realization of the general readers. Every other domain preserves its boundary maps and its own verification of descent. Complete memory remains in the enriched history and in its boundary publication, even though it cancels in the normalized quotient.

We define

$$w_A(\beta) = \frac{A_\partial(\beta) r_{\mathrm{av}}}{A_\partial(\beta) r_{\mathrm{av}} + V_\partial(\beta) r_{\mathrm{av}}^J}, \qquad w_V(\beta) = 1 - w_A(\beta).$$

In realization (138.14), the weights admit the exact evaluation

$$w_A = \frac{r_{\mathrm{av}}^2}{r_{\mathrm{av}}^2 + r_{\mathrm{av}}^J} = \frac{\pi_{\mathrm{HMT}}^4}{\pi_{\mathrm{HMT}}^4 + \varphi_{\mathrm{HMT}}^5}, \qquad w_V = \frac{\varphi_{\mathrm{HMT}}^5}{\pi_{\mathrm{HMT}}^4 + \varphi_{\mathrm{HMT}}^5}. \tag{138.17}$$

Substitution preserves both factors of the definition: the normalized areal reader and its subsequent weighting by r_{av}. Generation and regional marking of the return are performed once. Multiplying numerator and denominator by $\varphi_{\mathrm{HMT}}^4 \pi_{\mathrm{HMT}}^2$ gives the last expression. These weights remain constant in the common-amplitude sector. With fixed projectors and energies, a variation of the response may come from the reader Q; the witness to global dependence additionally requires the states with equal local restriction and different response of (138.11).

Let P_A, P_V be complementary orthogonal projections of a response space $\mathcal{H}_v$, and let $E_1, E_2 > 0$ be two internal energies fixed for comparison. The response is

$$\overline{I}_v(\beta) = \frac{E_1 E_2}{Q(\beta)^2} \big(w_A(\beta) P_A + w_V(\beta) P_V \big), \qquad I_v = \overline{I}_v \circ b. \tag{138.18}$$

Energies that are explicit readers of β are also admitted; in that case they are preserved as such in the formula.

Proposition 138.12 (Positivity and covariance of the response)**.** *The response* (138.18) *is self-adjoint, positive definite and constant on the fibers of b. Its eigenvalues in the nonzero sectors are*

$$\lambda_A = E_1 E_2 Q^{-2} w_A, \qquad \lambda_V = E_1 E_2 Q^{-2} w_V.$$

The complete exchange $(A_\partial, r_{\mathrm{av}}, P_A) \leftrightarrow (V_\partial, r^J_{\mathrm{av}}, P_V)$ *permutes the two summands and preserves the operator. A unitary transport of the response space conjugates that operator and preserves its spectrum with multiplicities.*

Proof. Positivity of the readers gives $0 < w_A, w_V < 1$. For $z = z_A + z_V$, with $z_A = P_A z$, $z_V = P_V z$,

$$\langle z, \bar{I}_v z\rangle = \frac{E_1 E_2}{Q^2}(w_A\|z_A\|^2 + w_V\|z_V\|^2) > 0$$

if $z \neq 0$. The orthogonal decomposition proves the spectral expressions. Exclusive dependence on β gives constancy on the fibers and factorization. Exchanging the triples exchanges numerators, weights and projectors at once, so it preserves the sum. For a unitary transport U, substitution $P_A \mapsto UP_AU^*$, $P_V \mapsto UP_VU^*$ produces $U\bar{I}_vU^*$, with the same spectrum. □

An exchange implemented within the same space by a unitary sending P_A to P_V requires the two sectors to have equal dimension. Exchanging the two triples as labels of the formula is valid with each sector's own dimension.

Condition (138.11) requires comparing the responses. For example, simultaneously multiplying A_∂, V_∂ by the same positive factor preserves both weights; if E_1, E_2, Q are also preserved, the response remains identical. In contrast, with equal weights and energies, replacing Q by qQ, $q > 0$, multiplies the response by q^{-2}. If two states with equal local restriction realize that change with $q \neq 1$, they provide the global witness. These are operator separation conditions; existence of the states is checked in the boundary domain being realized.

138.8 Connection of the joint state and acceleration reading

In a differentiable realization of the joint state $\Gamma = (x, O, m)$, let N be its realization space, ∇^{tot} its connection and $\pi_S : N \to N_S$ a differentiable projection onto the subsystem, equipped with connection ∇^S. The connection and projection preserve the provenance of the transports and readers they realize. The observed frame is obtained through

$$\mathfrak{F}_O(\Gamma) = \mathrm{Res}_O(\Gamma, \nabla^{\mathrm{tot}}).$$

For a twice-differentiable trajectory $\Gamma(t)$, write $\gamma_S = \pi_S \circ \Gamma$.

Definition 138.13 (Self-inertia and projection defect)**.** A trajectory is self-inertial with respect to the declared connection when $\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma = 0$. The defect of its projection is

$$\mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma) = \nabla^S_{\dot\gamma_S}\dot\gamma_S - d\pi_S\big(\nabla^{\mathrm{tot}}_{\dot\Gamma}\dot\Gamma\big). \tag{138.19}$$

Proposition 138.14 (Subsystem acceleration)**.** *For a self-inertial trajectory,*

$$a_S = \nabla^S_{\dot\gamma_S}\dot\gamma_S = \mathcal{K}_{\pi_S}(\dot\Gamma, \dot\Gamma).$$

In coordinates x^B *on* N *and* y^a *on* N_S*, the defect is quadratic in velocity, with components*

$$(\mathcal{K}_{\pi_S})^a{}_{BC} = \partial_B\partial_C\pi^a_S + (\Gamma^S)^a{}_{bc}\,\partial_B\pi^b_S\partial_C\pi^c_S - \partial_D\pi^a_S(\Gamma^{\mathrm{tot}})^D{}_{BC}. \tag{138.20}$$

Proof. The chain rule gives $\ddot\gamma^a_S = \partial_B\pi^a_S\ddot\Gamma^B + \partial_B\partial_C\pi^a_S\dot\Gamma^B\dot\Gamma^C$. Adding the contribution of ∇^S and subtracting the image of the total acceleration, the terms containing $\ddot\Gamma$ cancel. The remaining ones are (138.20) contracted with $\dot\Gamma^B\dot\Gamma^C$. When total acceleration vanishes, the stated equality results. □

The geometric response factors through b when the connection, projection and kinematic datum used in evaluation are determined by $\beta = b(x)$, or when those kinematic data are kept fixed in the comparison.

Under those conditions, (138.20) gives the same result for any representatives of a fiber; theorem 138.10 constructs its unique factor on B_{ef}. If the kinematic datum varies, it forms part of the domain of the response being compared.

The self-inertial formulation describes a geodesic trajectory of the joint state and an effective acceleration of its subsystem due to the projection defect. The gravitational realization then identifies that connection, the frame and the response with their physical observables. Observer covariance, memory inscription and factorization through the boundary thus retain complementary functions: the first determines the reading class, the second retains the genealogy and the third specifies the relational dependence of the response.

Chapter 139

Bidirectional propagation and absorption condition at the boundary

APP–TRIT–TPK transport preserves the route orientation and memory distinguishing its outward journey from its return. On that antecedent, three successive operations are constructed: the action of an enriched history, propagation of a source through the realized transports and imposition of a common condition at the boundary. Inscription of the record in an apparatus space, established in section 138.3, allows those operations to be expressed through linear maps without confusing the observable publication with the state preserving its antecedents.

Temporal direction, sheet conjugation and spatial reflection have distinct domains. Their relations are first fixed on the record; the intertwinings used by a dynamical realization are then specified. This order determines which information remains in the propagators and which condition is introduced by choosing an absorbing boundary.

139.1 Route action and record involutions

A finite route contains its positions, cardinal directions $(d_1, \dots, d_N)$, sheets $(\mu_1, \dots, \mu_N)$, with $\mu_t \in \{\Sigma, \Pi\}$, and the increments of its enriched record. For $\lambda \geq 0$, we define

$$\mathcal{A}_\lambda(\gamma) = \sum_{t=2}^{N} \big(1 - \delta_{d_t, d_{t-1}} + \lambda(1 - \delta_{\mu_t, \mu_{t-1}})\big). \tag{139.1}$$

The first term counts changes of direction; the second counts sheet changes with the declared weight. For $N \leq 1$, the sum is zero. The sector's general action additionally preserves its boundary and memory terms:

$$\mathcal{S}[\gamma] = \sum_{a \subset \gamma} \mathcal{L}_a + \mathcal{B}_{\mathrm{in}}(\partial_- \gamma) + \mathcal{B}_{\mathrm{out}}(\partial_+ \gamma) + \mathcal{M}(\gamma). \tag{139.2}$$

The terms of this expression specify a variational class with typed endpoints and preserved memory. The sector's dynamics determines $\mathcal{L}_a$, the admissible conditions and the term $\mathcal{M}$.

On the records we define C_{r} as the global exchange of sheets; $\mathcal{P}_{\mathrm{r}}$ as a reflection of the spatial chart and its directions; and $\mathcal{T}_{\mathrm{r}}$ as reversal of temporal order, replacement of each direction by its opposite and exchange of endpoints. Cardinal reflection is an involutive permutation. Inversion of the signed record is $C_M(a_1, \dots, a_N) = (-a_N, \dots, -a_1)$. The sheets, quotients and memory are transported with the complete route; the scalar reading of a word constitutes a subsequent operation.

Proposition 139.1 (Invariance of the local route action)**.** *On the preceding domain of records,*

$$\mathcal{A}_\lambda(\gamma) = \mathcal{A}_\lambda(C_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(\mathcal{P}_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(\mathcal{T}_{\mathrm{r}}\gamma) = \mathcal{A}_\lambda(C_{\mathrm{r}}\mathcal{P}_{\mathrm{r}}\mathcal{T}_{\mathrm{r}}\gamma).$$

Proof. A global permutation of the direction alphabet preserves equality between consecutive directions. Exchanging the two sheets preserves equality between consecutive sheets. Reversing the order establishes a bijection between adjacent pairs, and replacement by opposite directions also preserves their equalities. Each operation preserves the two counts of (139.1); their composition preserves them. □

The proposition determines the symmetry of the local functional. For a transformation also to act on a dynamical problem with fixed boundaries, it must transport its class of admissible prolongations and the other three terms of (139.2). In particular, two routes with the same final publication may retain distinct variational classes through their memory.

An interaction between two sections realized at a boundary B uses a coupling map

$$\mathcal{I}_B : E_B^{(1)} \otimes E_B^{(2)} \longrightarrow E_B^{(12)}$$

and a term $\mathcal{S}_{\mathrm{int}}$ in the same action. Its covariance is expressed by

$$\rho_{12}(g)\mathcal{I}_B = \mathcal{I}_B\big(\rho_1(g) \otimes \rho_2(g)\big).$$

When composing the histories, the shared boundary record is counted once; memories on both sides are transported to the composite section. The coupling and this covariance condition are data of the concrete interaction, distinct from the record involutions.

139.2 Reversal of the realized evolution

The realization of the record provides a real Hilbert space $\mathcal{H}_{\mathbb{R}}$, an orthogonal complex structure J_E, with $J_E^2 = -I$, and a self-adjoint Hamiltonian H. Its domain $\mathcal{D}(H)$ is invariant under J_E; we assume $HJ_E = J_E H$ on that domain. Let C be an orthogonal involution preserving $\mathcal{D}(H)$ and satisfying

$$CJ_EC^{-1} = -J_E, \qquad CHC^{-1} = H. \tag{139.3}$$

The internal action constant $\hbar_{\mathrm{int}} > 0$ retains its prior generation; here it normalizes the evolution group.

Theorem 139.2 (Temporal conjugation of the group)**.** *The generator $A = -J_E H/\hbar_{\mathrm{int}}$, with domain $\mathcal{D}(H)$, is skew-adjoint. Its orthogonal group, unitary with respect to J_E, satisfies*

$$U(t) = \exp(-J_E H t/\hbar_{\mathrm{int}}), \qquad CU(t)C^{-1} = U(-t). \tag{139.4}$$

Proof. Orthogonality and $J_E^2 = -I$ imply $J_E^* = -J_E$. Domain invariance and commutation with H allow H to be treated as a complex self-adjoint operator in the space defined by J_E. By functional calculus, $-J_E H/\hbar_{\mathrm{int}}$ is skew-adjoint and generates the stated group. In finite dimension, the same statements follow from the exponential series and from $A^* = -A$. The hypotheses on C give $CAC^{-1} = -A$. Conjugating the group, or its functional calculus, produces $\exp(-tA) = U(-t)$. □

The map realizing the signed involution C_M as C preserves temporal orientation and the preceding domain. Charge conjugation of a field representation additionally preserves its own characters and operators. The equality (139.4) fixes the time reversal of the group under the stated conditions.

139.3 Propagators of the chronological channel of a route

Isometric inscription of the record admits the unitary extensions of theorem 138.7. Let us fix a bilateral realization of a chronological channel with fibers $\mathcal{H}_n$, $n \in \mathbb{Z}$, and unitary transports $U_n : \mathcal{H}_n \to \mathcal{H}_{n+1}$. The choice includes auxiliary spaces when required; it preserves the route and its preceding records. We denote by $U(n,k)$ the transport from k to n, with

$$U(k,k) = I, \qquad U(n,k)U(k,l) = U(n,l), \qquad U(n,k)^* = U(k,n).$$

For $n > k$, it is the product $U_{n-1}\cdots U_k$; for $n < k$, it is the inverse of the transport from n to k.

The source space $\mathcal{J}_c$ contains finitely supported sections. The response space $\mathcal{F}$ contains all sections of those fibers. The route's quadratic action, in internal units of this realization, uses

$$(D\psi)_n = \psi_{n+1} - U_n\psi_n, \qquad E[\psi] = \sum_n \|(D\psi)_n\|^2$$

for finitely supported sections. The kinetic operator with the sign convention $L = -D^*D$ is

$$(L\psi)_n = U_n^*\psi_{n+1} - 2\psi_n + U_{n-1}\psi_{n-1}. \tag{139.5}$$

Indeed, $(D^*z)_n = z_{n-1} - U_n^* z_n$, and substitution produces that formula. The variation of E is $-2\,\mathrm{Re}\langle \delta\psi, L\psi\rangle$.

Theorem 139.3 (Exact Green operators of the covariant difference)**.** *Writing $x_+ = \max(x, 0)$, the maps*

$$(G_{\mathrm{ret}} j)_n = \sum_k (n-k)_+ U(n,k)\, j_k, \tag{139.6}$$

$$(G_{\mathrm{adv}} j)_n = \sum_k (k-n)_+ U(n,k)\, j_k \tag{139.7}$$

from $\mathcal{J}_c$ to $\mathcal{F}$ satisfy

$$L G_{\mathrm{ret}} j = L G_{\mathrm{adv}} j = j.$$

The retarded response vanishes before and at the first position of the source; the advanced one vanishes after and at the last. They are the unique solutions vanishing sufficiently far in the respective direction. For finitely supported ψ, we also have $G_{\mathrm{ret}} L\psi = G_{\mathrm{adv}} L\psi = \psi$. With respect to the pairing with finitely supported sources, $G_{\mathrm{adv}} = G_{\mathrm{ret}}^\dagger$.

Proof. Each sum has as many terms as source positions. Composition of transports reduces application of L to the scalar identity

$$(n+1-k)_+ - 2(n-k)_+ + (n-1-k)_+ = \delta_{nk}.$$

The function $(k-n)_+$ satisfies the same identity. This proves the two equations and the supports. For uniqueness, a homogeneous solution vanishing at two consecutive positions is determined as zero at the next by (139.5); the recurrence, using invertible transports, extends in both directions. The difference of two solutions with the same causal support vanishes sufficiently far away and is therefore zero. Applying this argument to ψ and to $G_{\mathrm{ret}} L\psi$, or to the advanced case, gives the right-hand identities on finite support. Finally, for two compactly supported sources, the double sum of the pairing is finite and

$$\big((k-n)_+ U(k,n)\big)^* = (k-n)_+ U(n,k).$$

Interchanging the indices proves the stated adjoint relation. □

The responses belong to $\mathcal{F}$; in general they grow linearly outside the source and do not belong to ℓ^2. The finite-support domain and its pairing specify the Green adjunction used here. The result constructs propagation of the chronological channel from its action; a realization of spatial fields additionally preserves its own operator, geometry and propagation domain.

Let C_0 be an isometric involution, linear or antilinear, of $\mathcal{H}_0$. Transport from the reference fiber constructs

$$C_n = U(-n, 0) C_0 U(0, n) : \mathcal{H}_n \longrightarrow \mathcal{H}_{-n}, \qquad (C\psi)_n = C_{-n}\psi_{-n}.$$

We have $C_{-n}C_n = I$ and $C_{n+1}U_n = U_{-n-1}^* C_n$, by composition. In particular, $C^2 = I$, and the change $(n,k) \mapsto (-n,-k)$ in the preceding sums proves

$$CL = LC, \qquad C G_{\mathrm{ret}} C^{-1} = G_{\mathrm{adv}}. \tag{139.8}$$

When C_0 is the declared realization of the record involution, these formulas transport that involution throughout the channel, without identifying phase return with a memory reset.

139.4 Causal interchange and decomposition of the response

In a field realization, let $L : \mathcal{D}(L) \subset \mathcal{H}_\Phi \to \mathcal{H}_J$ be an operator with unique retarded and advanced Green operators on the domains of admissible sources. We denote by $J^+(S)$ and $J^-(S)$ the future and past causal domains of a support S. The conditions are

$$\begin{aligned} LG_{\mathrm{ret}} = LG_{\mathrm{adv}} = I, \\ \operatorname{supp}(G_{\mathrm{ret}} j) \subset J^+(\operatorname{supp} j), \\ \operatorname{supp}(G_{\mathrm{adv}} j) \subset J^-(\operatorname{supp} j). \end{aligned}$$

Let C_Φ, C_J be isometric involutions, both linear or both antilinear, that transport these domains, reverse their causal orientations, and satisfy $LC_\Phi = C_J L$. A Green pairing is retained for which $G_{\mathrm{adv}} = G_{\mathrm{ret}}^\dagger$.

Proposition 139.4 (Conjugation of the Green operators and parities)**.** *Under the preceding conditions,*

$$C_\Phi G_{\mathrm{ret}} C_J^{-1} = G_{\mathrm{adv}}.$$

On the real space of response operators, define

$$\Theta(K) = C_\Phi K C_J^{-1}, \qquad \mathsf{P}_\pm(K) = \tfrac{1}{2}(K \pm \Theta(K)).$$

These are complementary projections for the involution Θ*, and*

$$G_{\mathrm{sym}} = \tfrac{1}{2}(G_{\mathrm{ret}} + G_{\mathrm{adv}}), \qquad G_{\mathrm{rad}} = \tfrac{1}{2}(G_{\mathrm{ret}} - G_{\mathrm{adv}}) \tag{139.9}$$

satisfy $\Theta(G_{\mathrm{sym}}) = G_{\mathrm{sym}}$, $\Theta(G_{\mathrm{rad}}) = -G_{\mathrm{rad}}$, $G_{\mathrm{sym}}^\dagger = G_{\mathrm{sym}}$, *and* $LG_{\mathrm{rad}} = 0$*. The support of the symmetric response is contained in the union of the two causal domains.*

Proof. The conjugated operator solves the source equation, since

$$LC_\Phi G_{\mathrm{ret}} C_J^{-1} = C_J L G_{\mathrm{ret}} C_J^{-1} = I.$$

Orientation reversal takes its support to the advanced domain; its uniqueness identifies it with G_{adv}. The involutions give $\Theta^2 = I$; expanding $(I \pm \Theta)^2$ and $(I + \Theta)(I - \Theta)$ proves the statements about projections. Green adjunction proves symmetry and the difference of the two source equations gives $LG_{\mathrm{rad}} = 0$. The sum of two responses has support contained in the union of their supports. □

If the involutions are antilinear, Θ is linear over real scalars; this is the operator space used in the proposition. Conjugation of the temporal group, the support condition, and the Green adjoint relation are three distinct properties, transmitted by the corresponding realization maps.

The causal reduction of the bilateral update, developed in the section on conservation and recovery, identifies another precise origin of retardation: elimination of a memory component that continues to participate in the joint evolution. Its discrete kernel preserves the order of interactions and the contribution of the initial memory. The Green operators constructed here instead solve a propagation equation with support conditions. The two constructions can be composed once the realization map identifying their domains and operators is specified; their respective causality conditions remain explicit.

139.5 Projection of absorbed currents and variation of the action

Let $\gamma_\partial : \mathcal{H}_\Phi \to \mathcal{H}_\partial$ be the boundary reading, distinct from the route γ. We define

$$\mathcal{A}_\partial = \gamma_\partial G_{\mathrm{rad}}.$$

The finite window fixes the source space and boundary reading; the Green operators preserve their response domain. At a finite level with fixed inner products, its Moore–Penrose inverse determines

$$P_{\mathrm{abs}} = I - \mathcal{A}_\partial^+ \mathcal{A}_\partial. \tag{139.10}$$

Theorem 139.5 (Absorption condition and boundary response)**.** *P_{abs} is the orthogonal projection onto* $\ker \mathcal{A}_\partial$*. For any source j, the source $j_{\mathrm{abs}} = P_{\mathrm{abs}} j$ satisfies*

$$\gamma_\partial G_{\mathrm{ret}} j_{\mathrm{abs}} = \gamma_\partial G_{\mathrm{adv}} j_{\mathrm{abs}}. \tag{139.11}$$

It is the absorbed source closest to j for the declared inner product. Nonzero absorbed sources exist exactly when $\operatorname{rank} \mathcal{A}_\partial < \dim \mathcal{H}_J$.

Proof. The orthogonal decomposition $\mathcal{H}_J = \ker \mathcal{A}_\partial \oplus \operatorname{im} \mathcal{A}_\partial^*$ shows that $\mathcal{A}_\partial^+ \mathcal{A}_\partial$ is the identity on the second summand and zero on the first. Its complement is the stated projector. By definition, $2\mathcal{A}_\partial j_{\mathrm{abs}} = \gamma_\partial (G_{\mathrm{ret}} - G_{\mathrm{adv}}) j_{\mathrm{abs}} = 0$. For $k \in \ker \mathcal{A}_\partial$, the orthogonal decomposition gives

$$\|j - k\|^2 = \|(I - P_{\mathrm{abs}}) j\|^2 + \|P_{\mathrm{abs}} j - k\|^2.$$

The unique minimum corresponds to $k = P_{\mathrm{abs}} j$. The final equivalence is the rank–nullity theorem. □

In the source-field pairing, the symmetric action is $\mathcal{S}[j] = \frac{1}{2}\langle j, G_{\mathrm{sym}} j\rangle$. The declared adjunction makes that quantity real. For real variations,

$$\mathrm{d}\mathcal{S}[j](h) = \mathrm{Re}\langle h, G_{\mathrm{sym}} j\rangle.$$

The action restricted to absorbed sources is written on the ambient space as

$$\mathcal{S}_{\mathrm{abs}}[j] = \tfrac{1}{2}\langle P_{\mathrm{abs}} j, G_{\mathrm{sym}} P_{\mathrm{abs}} j\rangle, \quad \mathrm{d}\mathcal{S}_{\mathrm{abs}}[j](h) = \mathrm{Re}\langle P_{\mathrm{abs}} h, G_{\mathrm{sym}} P_{\mathrm{abs}} j\rangle. \tag{139.12}$$

When the pairing identifies field and source through Riesz, the ambient gradient is $P_{\mathrm{abs}} G_{\mathrm{sym}} P_{\mathrm{abs}} j$. The field response remains $G_{\mathrm{sym}} j_{\mathrm{abs}}$; the gradient projector expresses restriction of the variations. The formulas are proved by expanding the quadratic term of $j + th$ and using self-adjointness. A material term $\mathcal{S}_{\mathrm{matter}}$ adds its own differential.

139.6 Explicit absorbing condition in a chronological window

The channel of subsection 139.3 allows that condition to be evaluated without introducing a target response. Let there be a source supported on $0, \dots, N$, with $N \geq 1$. Let us transport its components to the reference fiber:

$$\widehat{j}_k = U(0,k) j_k, \qquad M_0(j) = \sum_{k=0}^{N} \widehat{j}_k, \qquad M_1(j) = \sum_{k=0}^{N} k\, \widehat{j}_k.$$

The identity $(n-k)_+ - (k-n)_+ = n - k$ gives

$$(G_{\mathrm{ret}} - G_{\mathrm{adv}}) j\big|_n = U(n,0)\big(n M_0(j) - M_1(j)\big). \tag{139.13}$$

Proposition 139.6 (Absorption and two transported moments)**.** *If the trace evaluates the field at two distinct positions a, b, equality of the advanced and retarded traces is equivalent to $M_0(j) = M_1(j) = 0$. In a fibre of dimension d, the space of such sources has dimension $(N-1)d$. For $N \geq 2$, it contains the nonzero sources with transported components $(z, -2z, z, 0, \dots, 0)$, $z \neq 0$.*

Proof. Invertibility of $U(a,0)$ and $U(b,0)$ reduces the boundary condition to $aM_0 - M_1 = 0$ and $bM_0 - M_1 = 0$. Subtracting the equations gives $(a-b)M_0 = 0$, and then $M_1 = 0$. The two-moment map is surjective: for prescribed values (z_0, z_1), it suffices to take $\widehat{j_0} = z_0 - z_1$, $\widehat{j_1} = z_1$, and all other components zero. Its rank is $2d$; its nullity is $(N+1)d - 2d$. The indicated source has both moments zero. □

In the transported frame, write

$$B_N = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 0 & 1 & \cdots & N \end{pmatrix}.$$

The absorbing projector is evaluated by

$$P_N = \left[I - B_N^{\mathsf{T}} (B_N B_N^{\mathsf{T}})^{-1} B_N \right] \otimes I_{\mathcal{H}_0}. \tag{139.14}$$

The two rows of B_N are independent for $N \geq 1$, so the inverse exists. Unitary transport between frames takes this projector to the original fibers. For $N = 2$,

$$P_2 = \frac{1}{6} \begin{pmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{pmatrix} \otimes I_{\mathcal{H}_0}.$$

This construction produces a nonzero absorbed class and its projection operation in the chronological channel. Its amplitude and identification with a material current preserve the rules of the corresponding physical sector.

139.7 Refinement and continuity of the boundary condition

Let $R_m^{\Phi}, R_m^{J}, R_m^{\partial}$ be the refinement maps of fields, sources and boundaries. Suppose they intertwine the two Green operators and the trace. Composition gives

$$R_m^{\Phi} G_{\mathrm{sym},m} = G_{\mathrm{sym},m+1} R_m^{J}, \qquad R_m^{\partial} \mathcal{A}_{\partial,m} = \mathcal{A}_{\partial,m+1} R_m^{J}. \tag{139.15}$$

The second equality takes an absorbed source to another absorbed source. Naturality of the projectors additionally preserves the orthogonal structure of the realizations.

Proposition 139.7 (Naturality of the absorbing projection)**.** *For a source isometry $R = R_m^{J}$, we have $P_{\mathrm{abs},m+1} R = R P_{\mathrm{abs},m}$ exactly when*

$$R(\ker \mathcal{A}_{\partial,m}) \subset \ker \mathcal{A}_{\partial,m+1}, \qquad R((\ker \mathcal{A}_{\partial,m})^{\perp}) \subset (\ker \mathcal{A}_{\partial,m+1})^{\perp}.$$

With these conditions at every level, the projectors define an orthogonal projection in the completion of the isometric inductive limit of the source spaces.

Proof. Each source is decomposed into its components in the kernel and its orthogonal complement. The two inclusions imply that applying the projection before or after refinement respectively preserves the first component and annihilates the second. Conversely, equality of operators applied to each component gives the two inclusions. In the inductive limit, the equality allows an operator to be defined on the union of the levels without dependence on the representative. All projectors have norm at most one, so the operator extends to the completion. Its self-adjointness and idempotence identities, valid on the dense union, pass by continuity to the completion. □

To extend a Green response to a completion as well, its domains and corresponding continuity estimates are preserved. Finite-support chronological propagation and factorization of the response through the boundary image, proved in 138.10, thus retain their respective domains during refinement.

The physical realization of emission and absorption composes these operators with the material currents, action and causal conditions of the sector. The intertwining must preserve the route involution, the source-field pairing, the transported action and the boundary conditions at each level. The preceding construction provides reversal of the group, the Green operators of the chronological channel, temporal decomposition and an explicit absorbing projection; spatial realizations use their own maps and causality conditions.

Chapter 140

Action realization and metrological comparison

140.1 Comparison of the reduced Planck constant

The International System in force since 20 May 2019 fixes $h = 6.62607015 \times 10^{-34}\,\mathrm{J\,s}$ exactly [162]. Its reduced constant is therefore

$$\hbar_{\mathrm{SI}} = \frac{6.62607015}{2\pi}\,10^{-34}\,\mathrm{J\,s} = 1.0545718176461563912\ldots \times 10^{-34}\,\mathrm{J\,s}.$$

The ellipsis corresponds to the expansion of an exact expression, not to an experimental uncertainty of h in the current SI. This reference value is used here after evaluation of the HMT readers; its function is comparative.

The two return coordinates of the article are

$$H_5 = 1.0545718176461544696\ldots,$$
$$\eta_{\mathrm{ret}} = 1.0545718169150390611\ldots.$$

In identifying $\mathcal{U}_S$ with J s, the relative difference of the preceding section with respect to $\hbar_{\mathrm{SI}}$ is approximately -1.82×10^{-15}. That of the subsequent section is approximately -6.93×10^{-10}. The second difference contains the effect of the return used by the electronic corrector; it is not equivalent to the evaluation error of the first section.

The precision of these comparisons allows the quantitative proximity of the construction of H_5 to be recognized while distinguishing proximity from exact identity. In this manuscript the displayed expressions do not provide an exact equality with $h/(2\pi)$. The proved result concerning Σ_H is its decade -34; the analytic result concerning H_5 is evaluation of the declared character. Physical identification is examined in this chart and with the explicit differences just given. The SI value does not enter into the definition of the determinantal norm or the regional recurrence.

Chapter 141

Covariance, normal form, and Gaussian spectrum

The positive action section $\hbar_a$ and the preceding canonical realization determine the normalization used here. The correspondence between covariance, spectrum, purity and entropy is proved for a finite number of modes; Fock space retains all its occupations. Symplectic reduction and Gaussian formulas are established results reproduced to make their application to memory transport self-contained.

141.1 Canonical coordinates and characteristic function

On $L^2(\mathbb{R}^d)$, let $\widehat{q}_j = \widehat{Q}_j/\sqrt{\hbar_a}$, $\widehat{p}_j = \widehat{P}_j/\sqrt{\hbar_a}$, and $\widehat{z} = (\widehat{q}_1, \widehat{p}_1, \dots, \widehat{q}_d, \widehat{p}_d)$. On Schwartz space,

$$[\widehat{z}_j, \widehat{z}_k] = i J_{jk} I, \qquad J = \bigoplus_{j=1}^{d} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

This convention fixes the sign of the canonical form. The Weyl operators $\mathcal{W}(\xi) = \exp(i\xi^{\mathsf{T}}\widehat{z})$ are defined through the self-adjoint closures of the indicated linear combinations. For a centred state ρ with finite second moments, the normalized covariance and its characteristic function are

$$W_{jk} = \operatorname{Tr}\rho(\widehat{z}_j\widehat{z}_k + \widehat{z}_k\widehat{z}_j), \qquad \chi_\rho(\xi) = \operatorname{Tr}(\rho\mathcal{W}(\xi)), \qquad V = \frac{\hbar_a}{2} W.$$

The state is centred Gaussian when

$$\chi_\rho(\xi) = \exp(-\xi^{\mathsf{T}} W \xi/4). \tag{141.1}$$

The expectation of $(c^{\mathsf{T}}\widehat{z})^\dagger(c^{\mathsf{T}}\widehat{z})$ is $c^\dagger(W + iJ)c/2$; thus $W + iJ \geq 0$. Moreover $W > 0$: if v is real and $v^{\mathsf{T}}Wv = 0$, positivity implies $(W + iJ)v = 0$, hence $Jv = 0$ and $v = 0$.

Lemma 141.1 (Uniqueness of the characteristic function)**.** *Two trace-class operators with the same characteristic function are equal.*

Proof. Regrouping positions and momenta as $\xi = (u, v)$,

$$(\mathcal{W}(u, v)f)(x) = e^{iu\cdot(x+v/2)} f(x + v).$$

For a finite-rank operator with Schwartz vectors and kernel K_A,

$$\operatorname{Tr}(A\mathcal{W}(u, v)) = \int K_A(x + v/2, x - v/2) e^{iu\cdot x}\, dx.$$

Plancherel and the change of variables with absolute Jacobian one give

$$\|A\|_{\mathrm{HS}}^2 = (2\pi)^{-d} \int_{\mathbb{R}^{2d}} |\operatorname{Tr}(A\mathcal{W}(\xi))|^2\, d\xi.$$

The preceding operators are dense in the trace class. Convergence in that norm implies Hilbert–Schmidt convergence and uniform convergence of the characteristic functions, because their difference is bounded by $\|A - B\|_1$. The equality extends in L^2. Applying it to the difference of the operators proves the assertion. □

141.2 Symplectic reduction of the positive form

Theorem 141.2 (Williamson normal form)**.** *For a real symmetric matrix $W > 0$ of order $2d$, there exist $S \in \mathrm{Sp}(2d, \mathbb{R})$ and $\nu_j > 0$ such that*

$$W = SDS^{\mathsf{T}}, \qquad D = \bigoplus_j \nu_j I_2.$$

The eigenvalues of JW are $\pm i\nu_j$. The condition $W + iJ \geq 0$ is equivalent to $\nu_j \geq 1$ for every j.

Proof. The matrix $B = W^{1/2} J W^{1/2}$ is skew-symmetric and invertible. If $-B^2 u = \nu^2 u$ and $\|u\| = 1$, the vector $v = -Bu/\nu$ is a unit vector orthogonal to u; it satisfies $Bu = -\nu v$, $Bv = \nu u$. The complement of this pair is invariant. Iteration produces an orthogonal matrix O with $O^{\mathsf{T}} B O = JD$. Defining $S = W^{1/2} O D^{-1/2}$,

$$S^{\mathsf{T}} J S = J, \qquad SDS^{\mathsf{T}} = W.$$

The similarity $W^{1/2}(JW)W^{-1/2} = B$ determines the values ν_j, with multiplicity. Congruence by S^{-1} transforms $W + iJ$ into $D + iJ$; each block has eigenvalues $\nu_j + 1$ and $\nu_j - 1$. □

Lemma 141.3 (Unitary implementation in a finite number of modes)**.** *Every symplectic matrix S admits a unitary U_S satisfying $U_S^\dagger \mathcal{W}(\xi) U_S = \mathcal{W}(S^{\mathsf{T}}\xi)$. The conjugation $\rho \mapsto U_S \rho U_S^\dagger$ transports covariance by $W \mapsto SWS^{\mathsf{T}}$.*

Proof. In the polar decomposition $S = OP$, the identity $J^{-1}(S^{\mathsf{T}}S)J = (S^{\mathsf{T}}S)^{-1}$, applied by spectral calculus to the positive root, proves $PJP = J$. Then O is orthogonal symplectic. The eigenspaces of P are paired through J with eigenvalues λ, λ^{-1}; that of eigenvalue one is J-invariant. Hence an orthogonal symplectic matrix K reduces P to $\bigoplus_j \mathrm{diag}(e^{r_j}, e^{-r_j})$.

Dilation is implemented by

$$(\mathcal{D}_r f)(x) = e^{-\frac{1}{2}\sum_j r_j} f(e^{-r_1} x_1, \dots, e^{-r_d} x_d).$$

A change of variables proves its unitarity and the conjugation of $(\widehat{q}_j, \widehat{p}_j)$ to $(e^{r_j}\widehat{q}_j, e^{-r_j}\widehat{p}_j)$. An orthogonal symplectic transformation commutes with J and corresponds to a matrix $u \in U(d)$ on $a_j = (\widehat{q}_j + i\widehat{p}_j)/\sqrt{2}$. Its second quantization $\Gamma(u) = \bigoplus_{n\geq 0} u^{\otimes_s n}$ is unitary on $\mathcal{F}_s(\mathbb{C}^d)$, and the identity on finite symmetric products gives the transformation of the a_j.

The Hermite basis identifies this space with $L^2(\mathbb{R}^d)$. To justify its completeness, if f is orthogonal to all polynomials multiplied by $e^{-|x|^2/2}$, the entire function $F(z) = \int f(x) e^{-|x|^2/2} e^{z\cdot x}\, dx$ has all its derivatives at zero equal to zero. Thus $F = 0$; restricting to $z = i\xi$, Fourier uniqueness gives $f = 0$. Normalizations and orthogonality follow from creation and annihilation. Composition of the preceding implementations produces U_S. The Weyl equality implies $\chi_{U_S \rho U_S^\dagger}(\xi) = \chi_\rho(S^{\mathsf{T}}\xi)$, which proves the covariance law. □

141.3 Calculation of the spectrum of the isotropic density

In one mode, the normalized coherent states are

$$|z\rangle = e^{-|z|^2/2} \sum_{n\geq 0} \frac{z^n}{\sqrt{n!}} |n\rangle.$$

Its position function, $\pi^{-1/4} \exp[-(x - q_0)^2/2 + i p_0 (x - q_0/2)]$, where $q_0 = \sqrt{2}\,\Re z$, $p_0 = \sqrt{2}\,\Im z$, gives by integration

$$\langle z | \mathcal{W}(u, v) | z \rangle = e^{-(u^2+v^2)/4} e^{i(u q_0 + v p_0)}.$$

For $s > 0$, the integral

$$\rho^{(s)} = \frac{1}{\pi s}\int_{\mathbb{C}} e^{-|z|^2/s}|z\rangle\langle z|\, d^2z$$

converges in the trace class, is positive and has trace one. Angular integration annuls its entries off the occupation diagonal; radial integration gives

$$\langle n|\rho^{(s)}|n\rangle = \frac{s^n}{(1+s)^{n+1}}, \qquad \chi_{\rho^{(s)}}(u,v) = e^{-(2s+1)(u^2+v^2)/4}.$$

With $\nu = 2s+1$, the unique Gaussian state of covariance νI_2 is, by Lemma 141.1,

$$\rho_\nu = (1-t)\sum_{n\ge 0} t^n |n\rangle\langle n|, \qquad t = \frac{\nu-1}{\nu+1}. \tag{141.2}$$

The case $\nu = 1$ is the projector onto the vacuum.

Theorem 141.4 (Spectrum, purity, and entropy)**.** *A centred Gaussian state with covariance W and symplectic eigenvalues $\nu_1,\dots,\nu_d$ is unitarily equivalent to $\bigotimes_j \rho_{\nu_j}$. Its eigenvalues are*

$$\lambda_{\boldsymbol{n}} = \prod_j (1-t_j)t_j^{n_j}, \qquad t_j = \frac{\nu_j-1}{\nu_j+1}, \quad \boldsymbol{n}\in\mathbb{N}^d.$$

Con $0\log 0 = 0$*,*

$$\operatorname{Tr}\rho^2 = \prod_j \nu_j^{-1} = (\det W)^{-1/2}, \tag{141.3}$$

$$-\operatorname{Tr}(\rho\log\rho) = \sum_j \left[\frac{\nu_j+1}{2}\log\frac{\nu_j+1}{2} - \frac{\nu_j-1}{2}\log\frac{\nu_j-1}{2}\right]. \tag{141.4}$$

Proof. Williamson gives $W = SDS^{\mathsf T}$. The product of the isotropic densities has characteristic function $e^{-\xi^{\mathsf T}D\xi/4}$. Unitary implementation and Weyl uniqueness prove the equivalence and spectral formula. In one mode,

$$\sum_{n\ge0}(1-t)^2t^{2n} = \frac{1-t}{1+t} = \nu^{-1},$$

and

$$-\sum_{n\ge0}(1-t)t^n\log((1-t)t^n) = -\log(1-t) - \frac{t}{1-t}\log t.$$

Substitution of $t = (\nu-1)/(\nu+1)$ proves the formulas; the limit at $t=0$ is zero. In the finite product, Tonelli justifies summing the nonnegative entropy terms, and $\det W = \prod_j \nu_j^2$ gives the determinantal expression. □

If the state is the reduction of a pure bipartite vector, its eigenvalues are the squares of the Schmidt coefficients. The singular value decomposition of the Hilbert–Schmidt operator defined by that vector proves equality of the nonzero spectra of both reductions. The calculated entropy is then the entanglement entropy.

141.4 Preparation and transport of the two covariances

The subsequent application uses two identical pure Gaussian inputs. In general, for $M \in \mathrm{Sp}(2d, \mathbb{R})$, their covariance is $V_0 = (\hbar_a/2)MM^{\mathsf{T}}$, and the joint input has covariance $V_0 \oplus V_0$. Physical transport is obtained by conjugating U_H by $M \oplus M$. In the balanced chart, the normalized input covariance is I_{4d}; with

$$T = \frac{8I + H}{9}, \qquad D = \frac{\sqrt{8}(H - I)}{9},$$

the first reduction has

$$W = TT^{\mathsf{T}} + DD^{\mathsf{T}} = \frac{8I + HH^{\mathsf{T}}}{9}.$$

Its characteristic function is obtained by setting the arguments of the second group of modes to zero. It therefore remains Gaussian and the preceding theorems calculate its entire spectrum, without truncating the occupation register.

Chapter 142

Physical actions and the spectrum of reduced memory

142.1 Genealogy of the dimensional sections

The coordinates π, φ, e, α are realizations of the correlated outputs constructed in Sections 11.6 and 16.2. This section uses $\alpha = \alpha_A$, with the orientation and periodization of Definition 11.59:

$$\alpha = \pi + e - \varphi - 4 - \kappa_{\mathrm{per}}, \qquad \kappa_{\mathrm{per}} = \frac{N_K}{1000^{12} - 1}, \quad N_K = 234543140729659824621058914794146601. \tag{142.1}$$

Identity (11.126) follows from the recurrence with compatible carry and its telescoping, proved in Proposition 11.57. Period twelve corresponds to the register: a window of twelve blocks with a zero boundary condition and a compatible infinite section are different objects. Equality (142.1) uses the latter. The ordered register K preserves its incidences in addition to admitting the scalar reading κ_{per}.

The action reader, constructed in Section 14.6, determines

$$\begin{aligned} H_5 &= \tfrac{1}{2}\sqrt{1000\alpha/\varphi} - \alpha + \tfrac{9}{16}\alpha^2 - \tfrac{5}{9}\alpha^3 + \tfrac{7}{48}\alpha^4 - \tfrac{1}{54}\alpha^5, \\ D_A &= \exp(-100\pi\alpha/9), \\ C_\pi &= 169\alpha^6 + \frac{D_A\alpha^7}{1 - D_A\alpha}, \\ \eta_{\mathrm{ret}} &= H_5 - \frac{90}{\pi}C_\pi, \\ \hbar_{\mathrm{pre}} &= H_5\mathcal{A}_0, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\mathcal{A}_0, \qquad R_{\mathrm{act}} = H_5/\eta_{\mathrm{ret}}, \end{aligned} \tag{142.2}$$

Here $\mathcal{A}_0 = 10^{-34}\mathcal{U}_S$. The decade comes from the determinantal reader of $\varphi\alpha^{16}$, whose construction and bounds appear in Theorem 14.19; H_5 and η_{ret} are the mantissas of the two positive sections of reduced action. In each section $a \in \{\mathrm{pre}, \mathrm{ret}\}$, we have $h_a = 2\pi\hbar_a$.

The construction of the central electron, developed in Section 16.2, determines the coordinate

$$\begin{aligned} \Delta_4 &= \frac{\pi - e\log\pi}{270}\left(1 + \frac{\pi}{729}\right), \\ B_e &= \frac{\sqrt{3}}{4}\left[\exp(\varphi/\pi^2) - 22\alpha^3\right](1 + 15\Delta_4), \\ \kappa_e &= 80 - 54\alpha + 6\Delta_4, \qquad \varepsilon_e^\beta = B_e R_{\mathrm{act}}^{\kappa_e}. \end{aligned} \tag{142.3}$$

The prefactor $\sqrt{3}/4$ comes from the norm of the commutator of the sum and product projectors on the fibers specified in (16.12). The central route and its registers determine the return coefficients of (16.43) and (16.44). The dimensional realization is $E_e^\beta = \varepsilon_e^\beta\mathcal{U}_E$, $m_e^\beta = E_e^\beta/c^2$, with the energy chart of (16.47).

The dodecaphasic clock determines the energy basis of (16.48):

$$\omega_{108} = \frac{2\pi}{108 t_0}, \quad E_{\mathrm{clk}} = \hbar_{\mathrm{ret}}\omega_{108}, \quad b_e = B_e\frac{\mathcal{U}_E}{E_{\mathrm{clk}}}.$$

Substitution of (142.3), preserving the same physical energy, proves

$$\boxed{\frac{m_e^\beta c^2}{\hbar_{\mathrm{ret}}} = b_e R_{\mathrm{act}}^{\kappa_e}\omega_{108}, \qquad \frac{m_e^\beta c^2}{\hbar_{\mathrm{pre}}} = b_e R_{\mathrm{act}}^{\kappa_e - 1}\omega_{108}.} \tag{142.4}$$

Division by h_a, rather than $\hbar_a$, converts angular frequency into cyclic frequency. The conversion $\mathcal{U}_E/E_{\mathrm{clk}}$ remains explicit: a coordinate expressed in MeV changes when its energy basis is replaced by the clock quantum.

142.2 Normalization of the Maxwell–Dirac action

The constitutive response in Section 118 produces the speed c, impedance Z, permittivity ε, and permeability μ, all positive, with $\varepsilon c = Z^{-1}$ and $\mu c = Z$. The positive charge section in (119.1) satisfies

$$e_a^2 = \frac{2\alpha h_a}{Z} = 4\pi\alpha\varepsilon\hbar_a c. \tag{142.5}$$

Here $e_a > 0$ denotes the elementary charge of Section a; e in (142.1)–(142.3) denotes the Euler coordinate. We fix a homogeneous chart with positive constants $c, Z, \varepsilon, \mu, \hbar_a, e_a$, the mass $m = m_e^{\beta} > 0$ and the charge $q \in \{-e_a, e_a\}$; then $\sigma = q/e_a \in \{-1, 1\}$. In the Minkowski realization of signature $(+,-,-,-)$, with $x^0 = ct$, the Maxwell–Dirac action is

$$\mathcal{I} = \int d^4x \left[-\frac{F_{\mu\nu}F^{\mu\nu}}{4\mu c} + \bar{\psi}\left(i\hbar_a\gamma^\mu(\partial_\mu + iqA_\mu/\hbar_a) - mc\right)\psi \right]. \tag{142.6}$$

The component A_0 is the scalar potential divided by c, and $F = dA$. The spinor representation is fixed by the matrices g^I of (133.1), which satisfy $\{g^I, g^J\} = 2\eta^{IJ} I_4$ for $\eta = \mathrm{diag}(-1,1,1,1)$. Define $\Gamma^I = -ig^I$, so that $\{\Gamma^I, \Gamma^J\} = -2\eta^{IJ} I_4$, and, in this flat chart, $\gamma^\mu = \delta^\mu_I \Gamma^I$, $\bar{\psi} = \psi^\dagger \Gamma^0$. Signature, adjoint and imaginary factor are thus fixed jointly; the matrices γ^μ are distinguished from the scalar Holst parameter used later. Smooth fields and compactly supported variations are considered, or boundary conditions that annul boundary terms. The action realizes the already generated coefficients and the material representation of Section 133.1.

We define

$$\ell_a = \frac{\hbar_a}{mc}, \quad X = x/\ell_a, \quad \Psi = \ell_a^{3/2}\psi, \quad \mathsf{a}_\mu = \frac{e_a \ell_a}{\hbar_a} A_\mu, \quad \mathsf{f} = d\mathsf{a}.$$

Then

$$\boxed{\frac{\mathcal{I}}{\hbar_a} = \int d^4X \left[-\frac{\mathsf{f}_{\mu\nu}\mathsf{f}^{\mu\nu}}{16\pi\alpha} + \bar{\Psi}\big(i\gamma^\mu(\partial_\mu + i\sigma\mathsf{a}_\mu) - 1\big)\Psi \right].} \tag{142.7}$$

Proof. The volume change contributes ℓ_a^4, each derivative contributes ℓ_a^{-1}, and the product of fermionic fields contributes ℓ_a^{-3}. The coefficient of the mass term is $mc\ell_a/\hbar_a = 1$. The electromagnetic term contributes $\hbar_a/(4\mu c e_a^2)$. Since $\mu c = Z$ and $Ze_a^2 = 4\pi\alpha\hbar_a$, this coefficient is $1/(16\pi\alpha)$. Both terms and their normalizations are thereby determined. □

Variation with respect to a_ν, followed by substitution of (142.1), gives

$$\partial_\mu \mathsf{f}^{\mu\nu} = 4\pi\left(\pi + e - \varphi - 4 - \kappa_{\mathrm{per}}\right)\sigma\bar{\Psi}\gamma^\nu\Psi. \tag{142.8}$$

The cancellation composes the action sections, electronic construction, and constitutive response; the regional and dodecaphasic reader determines the remaining coupling. Mass persists in the length ℓ_a, and action in the dimensional conversion. Compton normalization is a subsequent realization of these outputs. In the Coulomb realization of the same electron, the Bohr length is ℓ_a/α: substituting $e_a^2 = 4\pi\alpha\varepsilon\hbar_a c$ into $4\pi\varepsilon\hbar_a^2/(me_a^2)$ gives exactly this expression.

The deduction uses fixed homogeneous coefficients. For spacetime-dependent coefficients, the product rule introduces derivatives of the scales and coupling into the transformed equations. Variation of an action with variable parameters must preserve these terms.

142.3 Areal scale of gravitational action and entropy

The circular realization of the cycle of 108 steps, constructed in Section 121, determines

$$t_P = \frac{54}{\pi} t_0, \qquad G_a = \frac{c^5 t_P^2}{\hbar_a}, \qquad \ell_P^2 = \frac{\hbar_a G_a}{c^3} = c^2 t_P^2. \tag{142.9}$$

The condition for coincidence of radii in that realization is $G_a m_{108,a}/c^2 = R_{108}$, with $m_{108,a} = \hbar_a \omega_{108}/c^2$. Its unique solution fixes the factor $(54/\pi)^2$; the radius used is $G_a m/c^2$. The reciprocity $G_{\mathrm{pre}}/G_{\mathrm{ret}} = R_{\mathrm{act}}^{-1}$ preserves ℓ_P^2 between the two sections.

Section 127 constructs the cotetrad and connection from the transport already realized. In the action of Section 131, fix a nondegenerate cotetrad e^I, the orientation, signature $\eta = \mathrm{diag}(-1, 1, 1, 1)$, and a metric connection ω, with curvature $F^{IJ} = d\omega^{IJ} + \omega^I{}_K \wedge \omega^{KJ}$. Take $\gamma \in \mathbb{R} \setminus \{0\}$ and hold $\gamma, \Lambda, c, G_a, \hbar_a$ constant during variation. Put $\Sigma^{IJ} = e^I \wedge e^J$ and $\mathsf{P}_\gamma = \star + \gamma^{-1} I$; internal Lorentzian duality satisfies $\star^2 = -I$ on bivectors. Variations have compact support or boundary conditions that cancel the surface term. Substitution of (142.9) into (131.3) gives

$$\boxed{\frac{\mathcal{I}_{\mathrm{grav}}}{\hbar_a} = \frac{1}{16\pi\ell_P^2}\left[\int \Sigma_{IJ} \wedge (\mathsf{P}_\gamma F)^{IJ} - 2\Lambda \int \mathrm{vol}_e\right].} \tag{142.10}$$

With the cotetrad and material fields fixed during variation of the connection, let σ_{IJ} be the material current defined by $\delta_\omega \mathcal{I}_m = -\frac{1}{2}\int \delta\omega^{IJ} \wedge \sigma_{IJ}$, according to (131.4). The same substitution in Theorem 131.1 produces

$$D_\omega(\mathsf{P}_\gamma \Sigma) = 8\pi\ell_P^2 \frac{\sigma}{\hbar_a}. \tag{142.11}$$

Proof. In section a, the original coefficient is $1/(2\kappa_a c)$, with $\kappa_a = 8\pi G_a/c^4$. Division by $\hbar_a$ converts it into $1/(16\pi\ell_P^2)$; the cosmological term retains its factor two. In the connection equation, $\kappa_a c \hbar_a = 8\pi\ell_P^2$ holds. Both identities use the same dimensional section. □

The Barbero functional of Section 120 retains its complete expression. Its channels are $q_\pm = e^{-x \mp y}$, with $x = \pi A/180$, $y = \pi C^*/180$, where A and C^* are the angular coordinates expressed in degrees. The domain $x > |y|$ ensures $0 < q_\pm < 1$:

$$\gamma = \frac{180}{\pi} xy + 12[S_{90}(q_-) - S_{90}(q_+)] - [S_{120}(q_-) - S_{120}(q_+)], \qquad S_m(q) = \frac{q^m}{1 - q^{3m}}. \tag{142.12}$$

Hexadic and octadic incidence fixes the multiplicities 90 and 120, and the oriented chain fixes the coefficients 12 and -1, as proved by (120.1). The areal construction of Section 122 additionally gives

$$a_0 = \frac{1 + 2\cos(\pi/18)}{3} \frac{y}{6}, \qquad \widehat{\mathcal{A}} = \gamma a_0 \ell_P^2 (N_{90} + N_{120}). \tag{142.13}$$

The inversion $y \mapsto -y$ changes the signs of γ and a_0; their product is even. The operator P_γ, by contrast, retains its orientation dependence. Invariance of the areal product is thus distinguished from invariance of each operator coefficient. The areal spectrum is realized in the positive section $\gamma a_0 > 0$, with the occupation operators $N_{90}, N_{120} \geq 0$ constructed in Section 122.

For the spherical cosmological horizon in (137.31), of radius $R > 0$ and area $\mathcal{A}_H = 4\pi R^2$, fix a section a and abbreviate $\hbar = \hbar_a$, $G = G_a$ during this calculation and the following bounce calculation. Then

$$\frac{S_H}{k_B} = \frac{\mathcal{A}_H}{4\ell_P^2}, \qquad T_{\cos} = \frac{\hbar c}{2\pi k_B R}, \qquad E_\Lambda = \frac{c^4 R}{2G}, \qquad T_{\cos} S_H = E_\Lambda. \tag{142.14}$$

The areal scale of (142.10), (142.11) and (142.14) is the same. The temperature corresponds to the spherical cosmological horizon; normalization of the Schwarzschild horizon constitutes another realization. On varying R while holding $c, G, \hbar, k_B$ fixed, differentiation of (142.14) preserves both terms: $T_{\cos}\, dS_H = 2\, dE_\Lambda$ and $S_H\, dT_{\cos} = -\, dE_\Lambda$, as in (137.35). What is obtained is the differential of an identity between states of that family, not a replacement of the dynamic balance with other variable parameters.

142.3.1 An explicit dynamical application

Theorem 133.4 determines the following amplitude for a spinor state with conserved second moment $q_\varrho > 0$. Conservation is expressed through (133.18); Corollary 133.5 provides a concrete realization in the three-occupation sector:

$$s_0 = \frac{3\pi G\hbar^2}{2c^2 V_c^2} \frac{\gamma^2}{1+\gamma^2} q_\varrho. \tag{142.15}$$

In the spatially flat realization with pressureless matter and $\Lambda = 0$, the constant $\rho_0 > 0$ is an energy density, $V_c > 0$ is the reference comoving volume, and $E_0 = \rho_0 V_c > 0$. The solution of Theorem 135.1 is

$$a_b^3 = s_0/\rho_0, \qquad \tau^2 = \frac{s_0 c^2}{6\pi G \rho_0^2}, \qquad a(t) = a_b \left(1 + \frac{(t-t_b)^2}{\tau^2}\right)^{1/3}.$$

Restoring c in (134.2) uses the coefficient $8\pi G/(3c^2)$ when the density is an energy density. In particular, $(\dot a/a)^2 = (8\pi G/(3c^2))(\rho_0 a^{-3} - s_0 a^{-6})$. Substitution of (142.15) into the solution parameters proves

$$\boxed{\left(\frac{\tau E_0}{\hbar}\right)^2 = \frac{q_\varrho}{4}\frac{\gamma^2}{1+\gamma^2}, \qquad \mathcal{V}_b = \frac{3\pi}{2} q_\varrho \frac{\gamma^2}{1+\gamma^2} \ell_P^2 \frac{\hbar c}{E_0}.} \tag{142.16}$$

Here $\mathcal{V}_b = V_c a_b^3$ is the physical volume at the bounce. The quantities G and V_c cancel in the first equality; E_0 remains as material energy. In the conserved sector $\Lambda^3\mathbb{C}^4$, Proposition 133.3 proves $\widehat{\mathcal{Q}}_{\mathrm{sp}} = 4I$, so $q_\varrho = 4$ for every normalized state supported in that sector, and $\tau E_0/\hbar = |\gamma|/\sqrt{1+\gamma^2}$. This yields a dynamical scale for the specified spinor state and cosmological realization.

142.4 Prolongation of memory transport: quantum realization

The quantum realization uses the reversible coupling of Section 113. We first consider a real canonical plane with alternating matrix $\Omega = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. The nonadic partition determines

$$Q = \frac{1}{3}\begin{pmatrix} \sqrt{8}I & -I \\ I & \sqrt{8}I \end{pmatrix}, \qquad U_H = Q^{\mathsf{T}} \operatorname{diag}(I, H) Q = \frac{1}{9}\begin{pmatrix} 8I + H & \sqrt{8}(H - I) \\ \sqrt{8}(H - I) & I + 8H \end{pmatrix}. \tag{142.17}$$

The operator $H \in \mathrm{Sp}(2, \mathbb{R})$ transports that plane. The matrix Q preserves the Euclidean product and the form $\Omega \oplus \Omega$; thus U_H is symplectic. The first component defines the observed system and the second the memory register; the complete transformation acts on both.

The ordered loop constructed in Section 114 is

$$C=\begin{pmatrix}0 & -1\\ 1 & -1\end{pmatrix},\quad P=\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix},\quad H_n=C^{-1}P^{-n}CP^n=\begin{pmatrix}1+n & n^2\\ n & n^2-n+1\end{pmatrix}. \tag{142.18}$$

For each $n\in\mathbb{Z}$, $\det H_n=1$ holds. In particular, for $n=1$,

$$H_1=\begin{pmatrix}2 & 1\\ 1 & 1\end{pmatrix}=F_1^2,\quad F_1=\begin{pmatrix}1 & 1\\ 1 & 0\end{pmatrix}=PF_{\mathrm{av}}P^{-1}. \tag{142.19}$$

Its spectrum is $\{\varphi^2,\varphi^{-2}\}$, by subsequent recognition of the already generated golden mode. The integer n specifies the oriented number of iterations in the chosen loop. The family of transports is determined algebraically; its realization as a physical protocol also preserves the corresponding preparation and evolution data.

142.4.1 Initial state, transport and reading

Proposition 115.1 constructs the Gaussian realization of the action ellipse. In the positive section $\hbar_a>0$, with $A>0$ and $|C^*/A|<1$, its covariance is

$$V_\eta=\frac{\hbar_a}{2}M_\eta M_\eta^{\mathsf{T}},\qquad M_\eta=\mathrm{diag}(e^{\eta/2},e^{-\eta/2}),\qquad \eta=\operatorname{artanh}(C^*/A). \tag{142.20}$$

In the Schrödinger representation on $L^2(\mathbb{R},dQ)$, with $\widehat{Q}$ multiplication by Q and $\widehat{P}=-i\hbar_a\,d/dQ$, the relation $[\widehat{Q},\widehat{P}]=i\hbar_a I$ holds on Schwartz space. The normalized pure state is

$$\psi_\eta(Q)=(\pi\hbar_a e^{\eta})^{-1/4}\exp[-Q^2/(2\hbar_a e^{\eta})].$$

The preparation is the product $\psi_\eta\otimes\psi_\eta$. The transport of (142.17) is expressed in the same covariance chart by

$$\widetilde{U}=(M_\eta\oplus M_\eta)U_H(M_\eta^{-1}\oplus M_\eta^{-1}). \tag{142.21}$$

Lemma 141.3 provides a unitary implementation of this symplectic matrix in two modes. Implementations that differ by a global phase produce the same conjugation of the state. The covariance transforms by $V\mapsto\widetilde{U}V\widetilde{U}^{\mathsf{T}}$; the joint state remains pure and its partial trace over the second mode determines the visible reading, according to the construction in Section 141.

Theorem 142.1 (Reduced mixing through relative deformation)**.** *The covariance of the visible reading is*

$$\boxed{V_{\mathrm{vis}}=\frac{\hbar_a}{2}M_\eta\frac{8I+HH^{\mathsf{T}}}{9}M_\eta^{\mathsf{T}}.} \tag{142.22}$$

Its normalized symplectic eigenvalue is

$$\boxed{\nu(H):=\frac{2\sqrt{\det V_{\mathrm{vis}}}}{\hbar_a}=\sqrt{1+\frac{8}{81}\left[\mathrm{tr}(HH^{\mathsf{T}})-2\right]}.} \tag{142.23}$$

Proof. Let $T=(8I+H)/9$ and $D=\sqrt{8}(H-I)/9$. The two initial modes are independent and have the same covariance. In the balanced chart of the initial state, the normalized visible covariance is $TT^{\mathsf{T}}+DD^{\mathsf{T}}$. Expansion gives

$$TT^{\mathsf{T}} + DD^{\mathsf{T}} = \frac{64I + 8(H + H^{\mathsf{T}}) + HH^{\mathsf{T}} + 8[HH^{\mathsf{T}} - H - H^{\mathsf{T}} + I]}{81}$$
$$= \frac{8I + HH^{\mathsf{T}}}{9}.$$

This proves (142.22). Since $\det M_\eta = 1$ and $\det(HH^{\mathsf{T}}) = 1$, $\det(8I + HH^{\mathsf{T}}) = 65 + 8\,\mathrm{tr}(HH^{\mathsf{T}})$. Division by 81 proves (142.23). The two positive eigenvalues of HH^{T} are reciprocal; their sum is at least two. Consequently, $\nu \geq 1$, with equality exactly when $HH^{\mathsf{T}} = I$. □

The scale $\hbar_a$ and deformation η are retained until the determinant is taken. Their cancellation is covariant because state and operator are transported jointly. The expression HH^{T} uses the Euclidean product of the balanced chart of the initial state; a chart change also transports that metric product.

An orthogonal and symplectic transport H can have $D \neq 0$ while preserving the isotropic Gaussian product, with $\nu = 1$. The operatorial complement and state entanglement therefore have different criteria. In this preparation, the non-isometric relative deformation characterizes exactly the case $\nu > 1$.

142.4.2 Exact evaluation of the golden loop

For (142.18),

$$\mathrm{tr}(H_n H_n^{\mathsf{T}}) - 2 = n^2(2n^2 - 2n + 5), \qquad \nu_n^2 = 1 + \frac{8}{81}n^2(2n^2 - 2n + 5). \tag{142.24}$$

The identity follows by summing the squares of the four entries. For $n = 1$, the sum is seven and

$$\boxed{\nu_1 = \frac{11}{9}, \quad \mathrm{Tr}\,\rho_{\mathrm{vis}}^2 = \frac{9}{11}, \quad \bar{n}_{\mathrm{W}} = \frac{1}{9}, \quad \frac{S_{\mathrm{vis}}}{k_B} = \frac{10}{9}\log 10 - \log 9.} \tag{142.25}$$

Theorem 141.4 proves that the centred one-mode Gaussian state with symplectic value ν is unitarily equivalent to the geometric density of (141.2), whose mean occupation is $\bar{n}_{\mathrm{W}} = (\nu - 1)/2$. For $\nu = 11/9$, its eigenvalues are

$$\lambda_j = \frac{9}{10}\,10^{-j}, \qquad j = 0, 1, 2, \ldots. \tag{142.26}$$

The series sums to one. Its square sums to $(9/10)^2/(1 - 10^{-2}) = 9/11$. Finally,

$$-\sum_j \lambda_j \log \lambda_j = -\log(9/10) + \log 10 \sum_j j\lambda_j = \frac{10}{9}\log 10 - \log 9.$$

The Gaussian reduction and its spectrum are proved in Section 141; the two preceding series evaluate the purity and entropy of this realization exactly. Since the joint state is pure, S_{vis}/k_B is also its dimensionless entanglement entropy. The global transformation is unitary, while the restriction to the first mode has positive entropy.

The result corresponds to the specified preparation and transport. Its identification with a vacuum measurement requires the experimental realization of that protocol. The entropy of a reduction and the transferred heat remain distinct quantities.

142.4.3 Composition with the thermal transducer

In the Williamson normal representation, choose a frequency $\omega > 0$ and define the energy reader $\widehat{H}_{\mathrm{W}} = \hbar_a\omega(\widehat{N} + \frac{1}{2})$. The frequency is part of this energy realization; covariance determines the populations. With this choice, (142.26) is a Gibbs state whose population ratio satisfies

$$e^{-\hbar_a\omega/(k_B T_{\mathrm{W}})} = \frac{1}{10}, \qquad T_{\mathrm{W}} = \frac{\hbar_a\omega}{k_B \log 10}.$$

If the clock frequency of the same section is taken, $\omega = 1/t_P = 2\pi/T_{108}$, the thermal-transducer identity (123.8), $\hbar_a/t_P = k_B\Theta_{\mathrm{clk},a}\log 3$, gives

$$\boxed{\frac{T_{\mathrm{W}}}{\Theta_{\mathrm{clk},a}} = \frac{\log 3}{\log 10}.} \tag{142.27}$$

The action section and thermal transducer cancel in the ratio. The index a of $\Theta_{\mathrm{clk},a}$ preserves compatibility with the section $\hbar_a$, as in (123.10). The temperature T_{W} is the Gibbs-equivalent temperature for the declared Hamiltonian; the isolated unitary evolution retains its reversible character. This spectral identification determines a thermal ratio and does not postulate thermalization dynamics.

142.5 Extension to arbitrary finite canonical dimension

Let $H \in \mathrm{Sp}(2d,\mathbb{R})$, with $d \geq 1$ finite. Two pure, centered and identical Gaussian states are prepared, each of d modes, with covariance $V_0 = (\hbar_a/2)MM^{\mathsf{T}}$, where $M \in \mathrm{Sp}(2d,\mathbb{R})$. Section 141 specifies this preparation and the joint chart transport by $M \oplus M$. In the balanced chart, the same coupling U_H produces $W = (8I + HH^{\mathsf{T}})/9$. The product $A = HH^{\mathsf{T}}$ is positive, symmetric and symplectic.

There exists an orthonormal symplectic basis in which

$$A = \mathrm{diag}(e^{2r_1}, e^{-2r_1}, \ldots, e^{2r_d}, e^{-2r_d}), \qquad r_j \geq 0.$$

The identity $A\Omega A = \Omega$, with $\Omega = \bigoplus_{j=1}^{d} \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, implies that Ω takes the eigenspace of λ to that of λ^{-1}. Paired orthonormal bases are chosen in these spaces. The eigenspace of $\lambda = 1$ is Ω-invariant and admits orthonormal canonical pairs. Their union constructs the required basis.

The matrix W is diagonal in that basis. The products of each pair determine its symplectic eigenvalues:

$$\boxed{\nu_j^2 = \frac{(8 + e^{2r_j})(8 + e^{-2r_j})}{81} = 1 + \frac{32}{81}\sinh^2 r_j.} \tag{142.28}$$

Theorem 141.4 composes partial-trace reduction with these symplectic eigenvalues:

$$\boxed{\mathrm{Tr}\,\rho_{\mathrm{vis}}^2 = \prod_{j=1}^{d} \nu_j^{-1}, \qquad \frac{S_{\mathrm{vis}}}{k_B} = \sum_{j=1}^{d} \left[\frac{\nu_j + 1}{2} \log \frac{\nu_j + 1}{2} - \frac{\nu_j - 1}{2} \log \frac{\nu_j - 1}{2} \right].} \tag{142.29}$$

Adopt $0 \log 0 = 0$ by continuity. The proof of Theorem 141.4 unitarily transforms the state into a product of d geometric density operators: the purity of the product is the product of the purities, and its entropy is the sum of the entropies. The result holds for every finite d and every transport H in the domain, retaining all occupations of Fock space.

For the loop (142.19), $r = 2\log\varphi$ and $\sinh^2 r = 5/4$, reproducing (142.25). Thus the transport spectrum and nonadic partition $8 + 1$ determine the spectrum of the reduced reading; the action sections fix its dimensional realization.

The dimension of an exceptional realization and its transport come from the corresponding constructor. Equation (142.28) determines the spectral law after realizing its canonical modes and the specified Gaussian preparation.

142.5.1 Operator identity between memory and complex structure

In the balanced canonical chart, let $J = \Omega$, with $J^2 = -I$ and $J^{\mathsf{T}} = -J$. This matrix realizes the canonical complex structure of phase space, and $D = \sqrt{8}(H - I)/9$ is the memory block. For the same preparation and the same chart transport of Section 141, we have

$$\boxed{-(JW)^2 = I + [D, J]\,[D, J]^{\mathsf{T}}, \qquad W = \frac{2}{\hbar_a} M^{-1} V_{\mathrm{vis}} M^{-\mathsf{T}}.} \tag{142.30}$$

Proof. The symplectic identities $HJH^{\mathsf{T}} = J$ and $H^{\mathsf{T}}JH = J$, together with $A = HH^{\mathsf{T}}$, give $JAJ^{\mathsf{T}} = A^{-1}$. If $C = HJ - JH$, multiplication of the four summands produces

$$CC^{\mathsf{T}} = A + JAJ^{\mathsf{T}} - HJH^{\mathsf{T}}J^{\mathsf{T}} - JHJ^{\mathsf{T}}H^{\mathsf{T}} = A + A^{-1} - 2I.$$

On the other hand,

$$-(JW)^2 = \frac{(8I + A^{-1})(8I + A)}{81} = I + \frac{8}{81}(A + A^{-1} - 2I).$$

Since $[D, J] = \sqrt{8}\,C/9$, we obtain (142.30). The identity holds in every finite canonical dimension and for every H in the domain, including transports that mix the modes. □

The eigenvalues of this operator are the ν_j^2, each with multiplicity two. Formula (141.3) then expresses purity directly in terms of the memory block:

$$\boxed{\operatorname{Tr}\rho_{\mathrm{vis}}^2 = \det\Big(I + [D, J]\,[D, J]^{\mathsf{T}}\Big)^{-1/4}.} \tag{142.31}$$

In one mode,

$$\nu^2 = 1 + \frac{1}{2}\|[D, J]\|_F^2. \tag{142.32}$$

In this protocol, D commutes with J exactly when the reduced reading preserves purity. For the loop H_1, $\|[D, J]\|_F^2 = 80/81$, and (142.32) gives $\nu^2 = 121/81$, yielding the purity $9/11$.

The commutator uses the complex structure compatible with the initial covariance and its metric product. A canonical change jointly transports the three data; the transpose of (142.30) refers to the balanced chart. The prior construction of the imaginary element in the formal kernel precedes this representation, which specifies its canonical action.

The joint evolution preserves purity through its unitary implementation; the commutator determines the loss of purity of the partial reading. The information of the joint state remains in the two factors and their correlations. The formula determines the purity of the reduction, which is a nonlinear functional of its density operator.

The real decomposition relative to J distinguishes its complex-linear and complex-antilinear components:

$$D_{\mathrm{lin}} = \frac{D - JDJ}{2}, \qquad D_{\mathrm{anti}} = \frac{D + JDJ}{2}.$$

The first component commutes with J and the second anticommutes with J. The identities $[D, J] = 2D_{\mathrm{anti}}J$ and $JJ^{\mathsf{T}} = I$ imply

$$\boxed{-(JW)^2 = I + 4D_{\mathrm{anti}}D_{\mathrm{anti}}^{\mathsf{T}}, \qquad \operatorname{Tr}\rho_{\mathrm{vis}}^2 = \det(I + 4D_{\mathrm{anti}}D_{\mathrm{anti}}^{\mathsf{T}})^{-1/4}.} \tag{142.33}$$

The complex-antilinear component of the memory block, defined relative to the complex structure of the initial state, determines exactly the purity and mixedness spectrum of this protocol. The complex-linear component can transport memory while preserving purity. The distinction concerns linearity relative to J; combinatorial complexity and the arithmetic classification of constants are properties of other objects.

Chapter 143

Conclusions on conservation, recovery and physical realization

The generating structure preserves operations and history before its numerical realization. In realized transport, this conservation is formulated as an identity of forms. A partial reading distributes charge between the visible component and the complement; including both defines a recoverable transformation. Refinement prolongs the same identity without identifying different depths or replacing the register by its intensity.

143.1 Conservation, reconstruction, and dimension

The equality $\mathcal{U}^{*}(b' \oplus b')\mathcal{U} = b \oplus b$ brings reading and memory together in a reversible operation. For compressions with a separate register, telescoping preserves the positive terminal component and the complete series of complements. For a fixed unitary holonomy, the terminal component is the projection onto its fixed-vector space; for a variable sequence, it is determined by the strong limit of the Gram operators.

Dodecaphasic memory allows the centred register to be recovered through two specified observations, with inverse norm $9/4$. Incidence transports this recovery to the dimensional projector. Its exterior prolongation preserves each degree through Gram determinants and requires the inclusion of mixed components. Thus the relations between length, area, and volume are expressed through maps defined on the same register, with their respective invariants.

143.2 Action and physical consequences

Action, clock, and energy basis retain their types throughout composition. The electronic ratio $m_e c^2/\hbar$ is expressed through the clock frequency and electronic character, preserving the basis-conversion factor. Maxwell–Dirac normalization removes the chosen dimensional scales and leaves the dimensionless coupling. Gravitational transport preserves the areal scale $\hbar G/c^3$; the homogeneous bounce solution retains its conditions on matter, torsion, and cosmological constant.

The Noether relation is manifested when the transported observable is a charge of the declared action. Change of form adds a connection term to the Hamiltonian generator and preserves oriented action exactly. The holonomy of a return also preserves the information distinguishing phase return from return of the complete state.

143.3 Memory and quantum spectrum

Identity (142.30) determines the symplectic spectrum of the reduced covariance through the antilinear component of the memory operator. For the loop

$$H_1 = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}, \qquad W_1 = \frac{1}{9}\begin{pmatrix} 13 & 3 \\ 3 & 10 \end{pmatrix},$$

we obtain $\det W_1 = 121/81$, symplectic eigenvalue $11/9$, and purity $9/11$. The spectrum of the reduced density operator is

$$\lambda_j = \frac{9}{10}\,10^{-j}, \qquad j = 0, 1, 2, \dots,$$

and its entropy satisfies

$$\frac{S}{k_B} = \frac{10}{9}\log 10 - \log 9.$$

These figures come from the transport and state fixed in the theorem. Spectral equivalence with a Gibbs density operator assigns a temperature to the chosen Hamiltonian; that equivalence retains its distinction from a dynamical thermalization process.

143.4 Contenido fundacional

The articulation between number, incidence, and dynamics resides in the conservation of a common antecedent and in the operations relating its realizations. The article makes this articulation explicit through reconstructions, bounds, spectra, and actions. Generation of values and transport of symmetries retain the same provenance; their observable consequences are calculated subsequently with the reader and state that actually participate. This order provides a precise mathematical formulation of dynamical memory and its physical realizations.

Chapter 144

The holographic arithmetic-geometric coupling constant

The dodecaphasic register links two realizations of the same state: the positional reading that enters into arithmetic closure and the reading that preserves incidence, orientation, and direction. The following development determines the operations made possible by the register already produced, the information retained by its memories, and the errors under which its relations can be recovered. Its reference function admits a precise formulation: the phase orbit of the register is a complete basis of its carrier, and isometric memory preserves exactly the Gram matrix of that basis.

The starting point remains the composition

$$\text{APP} \longrightarrow \text{TRIT} \longrightarrow \text{TPK} \longrightarrow \text{enriched state} \longrightarrow \text{joint discrete structure of the continuum.}$$

APP provides the sheets and their residues and quotients; TRIT preserves regime and orientation; TPK selects, transports and updates while preserving carry, route, boundary, survival and memory. The five constructions of the continuum belong to that joint production, developed in the preceding body. Here the work takes place after it, on its dodecaphasic integer publication and its typed readers. Neither the subsequent linear carrier nor the candidate set of a decoder replaces the domain of generated histories.

144.1 Definition of the register and realization of its coupling coordinate

Definition 11.30 fixes the generated object and its readers. We now develop its reversible encoding, its capacity for operator identification, and the stability of its incidence realizations.

The name expresses a constitutive function of the object, not an automatic identification with a physical interaction coefficient. Canonicity refers to the declared profile, origin and orientation. A chart transformation and an update incorporating new events are not the same operation. Nor is it asserted that the same numerical vector must be a necessary invariant of every system.

The calendar of one hundred and eight positions consists of twelve nonadic windows. The extension

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0$$

preserves phase carry; its non-splitting and the distinction between phase return and state return are proved in proposition 11.31. In each window, the register of a history retains the subroute, its orientation, the carry, and the incidence register. The causal order of extraction is

$$x_{\mathrm{term}} \longmapsto \mathcal{R}_{12}(x_{\mathrm{term}}) \longmapsto (b^{90}, b^{120}, Q_{\mathrm{TPK}}) \longmapsto U_{\mathrm{sgn}} \longmapsto K. \tag{144.1}$$

The regional coordinates and the signed register are two readings of the same terminal state; it is not postulated that the visible ternary matrix alone determines the signed coordinate.

To specify the final composition explicitly, the channels produced are

$$b^{90} = (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461),$$
$$b^{120} = (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \qquad Q_{\mathrm{TPK}} = 6263.$$

Let $B_r = \sum_{j=0}^{3} b^{120}_{r+3j}$ and $d_{r,j} = b^{90}_{r+3j}$, for $r = 1, 2, 3$. The harmonic reader gives

$$s_1 = \frac{Q_{\mathrm{TPK}} + 2B_1 + B_2}{3}, \qquad s_2 = s_1 - B_1, \qquad s_3 = s_2 - B_2,$$

$$U^{(r)} = (s_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}).$$

In this compatible output, $(B_1, B_2, B_3) = (972, -1073, 101)$, $(s_1, s_2, s_3) = (2378, 1406, 2479)$, and

$$\begin{aligned} U^{(1)} &= (2378, -452, -668, -322), \\ U^{(2)} &= (1406, 998, -204, -28), \\ U^{(3)} &= (2479, -551, -371, -997). \end{aligned}$$

Division by three belongs to the reader's three orbits, and the subsequent division by four to the Hadamard inverse; these are not coefficients fitted to a physical output. On the orbits $(1, 4, 7, 10)$, $(2, 5, 8, 11)$, $(3, 6, 9, 12)$, we apply

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad H_4^2 = 4I.$$

The products $H_4 U^{(r)}$ are, respectively,

$$(936, 2916, 2484, 3176), \quad (2172, 2636, 232, 584), \quad (560, 3296, 3656, 2404).$$

Their divisibility by four verifies membership in the Hadamard sublattice. After dividing and restoring the natural order, we obtain

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601), \qquad \mathbf{1}^* K = 6263. \tag{144.2}$$

The inversion and its congruences, including the index 4096 of the signed image, are proved in lemma 11.39 y proposition 11.41. Reconstruction is unique because $H_4^{-1} = H_4/4$, not because a register close to a known value of alpha was sought.

To avoid a collision of symbols, we shall write $\Delta_j = I - S^j$ for the antecedent integer extractors, with $(Sx)_i = x_{i+1}$ and indices modulo twelve. Then

$$\Delta_3 K = b^{90}, \qquad \Delta_4 K = b^{120}, \qquad Q(K) = 6263.$$

The extractor (Δ_3, Δ_4, Q) is injective, with invariant factors $1, \dots, 1, 12$, according to proposition 11.42. Its integral-image conditions and accumulation law remain those of the antecedent register. The normalized memory complements to be denoted by D_j are different operators, derived from those shifts and with a declared metric codomain.

144.2 Periodic encoding, closure, and exact inversion

Fix $B = 1000$, twelve positions, and

$$N(k) = \sum_{j=1}^{12} k_j B^{12-j}, \qquad d_B = B^{12} - 1, \qquad \kappa(k) = \frac{N(k)}{d_B}.$$

In the canonical chart,

$$\begin{aligned} \kappa_{\mathrm{ag}} &= \frac{234543140729659824621058914794146601}{10^{36} - 1}, \\ \alpha_A &= A_{reg} - \kappa_{\mathrm{ag}}, \qquad A_{reg} = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4. \end{aligned} \tag{144.3}$$

The three regional coordinates are published before acting in this reader; their common origin with the dodecaphasic closure does not require confusing the order of evaluation of the correlated coordinates.

The equality is a subsequent reader of the generated state. Solving it once its outputs are known is a legitimate inverse operation, distinct from using a target value to produce the register.

Proposition 144.1 (Reversibility and radius of the encoding)**.** *On the domain* $\{0,\dots,999\}^{12}$*, the fraction* $\kappa(k)$*, with declared base and length, determines* k *exactly. The same holds for the exact pair* (A_{reg},α_A) *when it satisfies* (144.3)*. If*

$$|\widetilde{\kappa}-\kappa(k)|<\frac{1}{2d_B},$$

rounding $d_B\widetilde{\kappa}$ *to the nearest integer recovers* $N(k)$ *without error. If the two terms of the closure are approximated separately, it suffices that the sum of their absolute errors be less than* $1/(2d_B)$*.*

Proof. Multiplication by d_B recovers the integer $N(k)$. Twelve Euclidean divisions by B, retaining the remainders and the number of positions, recover its blocks, including leading zero blocks. The error hypothesis places the true integer at a distance strictly less than half a unit. For the closure, the triangle inequality is applied to the error in the difference. Two consecutive integers show that the radius cannot be increased uniformly over the entire code domain: their midpoint is ambiguous. □

If a reduced fraction p/q is received, $N=d_Bp/q$ is calculated and integrality and $0\le N\le d_B$ are checked. The reduced denominator does not replace the base, length and chart metadata. The code contains 10^{36} words and requires $\lceil\log_2(10^{36})\rceil=120$ bits in a fixed-length binary representation. Twelve ten-bit blocks also occupy 120 bits: no additional compression, authentication or cryptographic integrity has been demonstrated. An exact fraction or the integer N avoids losing the precision required for this inversion.

The periodic reading is not to be confused with the truncation N/B^{12}. If $\kappa_j=\kappa(S^jK)$, positional division gives

$$\kappa_{j+1}=1000\kappa_j-K_{j+1},\qquad K_{j+1}=1000\kappa_j-\kappa_{j+1},\qquad \sum_{j=0}^{11}\kappa_j=\frac{6263}{999}. \tag{144.4}$$

Thus, the scalar orbit preserves all phase differences and allows $B_K=\{j+1:1000\kappa_j-\kappa_{j+1}\ge 729\}$ to be read. The reversibility of these publications does not imply that a scalar reconstructs the entire enriched history that produced the register.

144.3 Representation of the register through its complete orbit

In $V=\mathbb{R}^{12}$, with its canonical Euclidean inner product, consider

$$O_K=(K,SK,\dots,S^{11}K):\mathbb{R}^{12}\longrightarrow V.$$

The shift S acts on register positions. Periodicity alone does not identify it with the complete TPK evolution or with a subsequent exceptional symmetry.

Theorem 144.2 (Complete cyclic reference and exact Gram matrix)**.** *The matrix* O_K *is invertible. Its Gram matrix has the eigenvalues*

value	*multiplicity*
$39225169=6263^2$	1
$1248025-345420\sqrt{3}$	2
589609	2
1407529	2
1053157	2
$1248025+345420\sqrt{3}$	2
697225	1

and satisfies

$$589609\|c\|^2 \le \|O_K c\|^2 \le 39225169\|c\|^2, \quad \|O_K^{-1}\| = \frac{1}{\sqrt{589609}}, \quad \operatorname{cond}(O_K) = \frac{6263}{\sqrt{589609}}. \tag{144.5}$$

The orbit of the centered register has rank eleven.

Proof. The entries of the Gram matrix are the autocorrelations $\langle K, S^j K\rangle$. In order $j = 0, \dots, 11$ they are

$$(4251257, 2999323, 3163385, 3287920, 3216553, 3344743,$$
$$2950064, 3344743, 3216553, 3287920, 3163385, 2999323).$$

Since S is orthogonal, the Gram matrix is circulant. Substituting the twelve characters $\exp(2\pi i m/12)$ into that row gives the preceding real table. All values are positive. The smaller of the two values with $\sqrt{3}$ is greater than 589609, since $658416 > 345420\sqrt{3}$, an inequality checked by squaring its two positive sides. The other values in the table are greater than or equal to 589609. The uniform mode has value $(\sum K_i)^2 = 6263^2$; the triangle inequality for the Fourier transform, using $K_i \ge 0$, bounds all the others by that same value. The spectral theorem gives (144.5). Centering the register removes only the uniform mode; the remaining eleven retain the nonzero values in the table. □

The determinant, with the column order and orientation of S fixed here, is

$$\det O_K = 548311925921402018385039793000828362 5.$$

The absence of a proper period of the vector would not, by itself, prove invertibility: what is decisive is that none of its Fourier modes vanishes. The condition number is approximately 8.15643. If K is normalized to unit norm, the extrema of the Gram matrix are divided by $\|K\|^2 = 4251257$; the amplitude of its components must not be confused with an intrinsic improvement over every reference of equal norm.

Corollary 144.3 (Polar separation of form and orientation)**.** *Let*

$$G_K = O_K^* O_K, \qquad P_K = G_K^{1/2}, \qquad F_K = O_K G_K^{-1/2}.$$

Then P_K is positive definite, F_K is orthogonal and $O_K = F_K P_K$. An isometric realization $J : V \to \mathcal{Y}$ preserves G_K and P_K, and transports the isometric part to JF_K.

Proof. The positivity of the Gram matrix allows its root and inverse to be defined through the spectral theorem. The identity $F_K^* F_K = G_K^{-1/2} G_K G_K^{-1/2} = I$ proves the assertion. Moreover, $(JO_K)^*(JO_K) = O_K^* O_K$. □

This polar decomposition is defined from the complete Gram matrix: it is not obtained solely from the list of its eigenvalues or from the norm of K. The symbol P_K in this corollary is not the rank-ten dimensional projector to be constructed below. This separation is a consequence of the cyclic reference, not an identification of all its readers.

144.4 Operator identification and relative holonomy

Theorem 144.4 (Twelve general responses or one cyclic response)**.** *For any linear operator $H : V \to V$, its twelve responses $Y = (HK, HSK, \dots, HS^{11}K)$ determine*

$$H = YO_K^{-1}.$$

If $HS = SH$, a single complete vector response $y = HK$ determines

$$H = O_y O_K^{-1}, \qquad H = \sum_{j=0}^{11} h_j S^j, \qquad h = O_K^{-1} y. \tag{144.6}$$

With errors E in the response matrix or δy in the vector, respectively,

$$\|\widehat{H} - H\| \le \frac{\|E\|}{\sqrt{589609}}, \tag{144.7}$$

$$\|\widehat{h} - h\| \le \frac{\|\delta y\|}{\sqrt{589609}}, \qquad \|\widehat{H} - H\| \le \sqrt{\frac{12}{589609}}\,\|\delta y\|. \tag{144.8}$$

Proof. The first equality is $Y = HO_K$. If H commutes with S, then $HS^jK = S^j y$, so that $Y = O_y$. Commutation with the cycle determines all columns of H from one of them; the twelve powers $I, S, \dots, S^{11}$ are independent and span that operator space. Therefore $y = O_K h$, which gives the second formula. The first two bounds use $\|O_K^{-1}\| = 1/\sqrt{589609}$. The last uses $\|O_{\delta y}\| \le \|O_{\delta y}\|_{\mathrm{F}} = \sqrt{12}\|\delta y\|$. □

A response here means a vector of twelve components, not a scalar measurement. As an example, if $H = 2I + 3S - S^5$, the response $y = HK$ returns exactly the coefficients $2, 3, -1$ in their positions through (144.6); the inverter requires y, K, S, not the filter coefficients. By contrast, the nonzero operator whose first row is $(543, -234, 0, \dots, 0)$ and whose remaining rows are zero annihilates K. A single response does not identify an arbitrary operator.

The reference function admits an exact generalization. In a cycle of n positions, $H \mapsto Hg$ identifies all operators that commute with the cycle if and only if $O_g = (g, Sg, \dots, S^{n-1}g)$ is invertible. Sufficiency is the preceding proof. If O_g is singular, a nonzero vector in its kernel gives a polynomial of degree less than n that annihilates g; the operator is nonzero because the powers of the cycle are independent. The unit impulse also has an orthonormal orbit and serves as a reference. The specific consequence for K is that the same object already used in closure and incidence satisfies that condition, without having been chosen anew to optimize the test. No identification of nonlinear dynamics or arbitrary hidden states follows; an application to a linearization requires that it have been defined and justified.

Corollary 144.5 (Recovery of relative holonomy from the complement)**.** *Let H_B be known and invertible, and let H_C be another transport of the same type. The complement*

$$D_\gamma = \frac{\sqrt{8}}{9}(H_C - H_B)$$

determines

$$H_B^{-1} H_C = I + \frac{9}{\sqrt{8}} H_B^{-1} D_\gamma.$$

If D_γ commutes with S, in particular if both transports do, $y = D_\gamma K$ suffices to recover

$$H_B^{-1} H_C = I + \frac{9}{\sqrt{8}} H_B^{-1} O_y O_K^{-1}. \tag{144.9}$$

The error in this reconstruction is bounded by

$$\frac{9}{\sqrt{8}}\|H_B^{-1}\|\sqrt{\frac{12}{589609}}\,\|\delta y\|.$$

Proof. We solve for H_C in the definition of the complement and apply theorem 144.4. The bound follows from submultiplicativity. □

For $H_B = S^3$ and $H_C = S^4$, the rational datum $y/\sqrt{8} = (S^4 - S^3)K/9$ allows the relative holonomy S to be reconstructed without providing H_C to the inverter. If H_B is unitary, the error factor is approximately 0.01435510. Without commutation, the twelve general responses are retained, not a fictitious symmetry hypothesis. The selection of a physical loop and its representation still belong to its generating dynamics; this protocol does not replace them.

144.5 Preservation of references and observables through the complete register

Let C_n be unitary operators on a Hilbert space H,

$$T_n = \frac{8I + C_n}{9}, \qquad D_n = \frac{\sqrt{8}(C_n - I)}{9}, \qquad R_0 = I, \quad R_{n+1} = T_n R_n.$$

This formulation includes nonstationary sequences. It does not require commutation between C_n at different stages.

Theorem 144.6 (Isometric register, terminal component, and transport)**.** *For every N,*

$$R_N^* R_N + \sum_{n=0}^{N-1} R_n^* D_n^* D_n R_n = I.$$

The positive strong limit $A_\infty = \lim_N R_N^* R_N$ exists, and

$$\mathcal{V}x = \big(A_\infty^{1/2}x, (D_n R_n x)_{n\ge 0}\big) \quad \textit{satisfies} \quad \mathcal{V}^*\mathcal{V} = I. \tag{144.10}$$

Its image $\mathcal{M}$ is closed, and the inverse on it is $\mathcal{V}^*$, of norm one. In the finite case, the first component is replaced by $R_N x$ and the N complements are retained. For any bounded operator A,

$$A^{\mathcal{V}} = \mathcal{V}A\mathcal{V}^*\big|_{\mathcal{M}}$$

preserves products, adjoints, norm, and spectrum on that image, and

$$\langle \mathcal{V}x, A^{\mathcal{V}}\mathcal{V}y\rangle = \langle x, Ay\rangle.$$

Proof. Expanding the two terms of one stage gives $T_n^*T_n + D_n^*D_n = I$. Hence $R_n^*R_n - R_{n+1}^*R_{n+1} = R_n^*D_n^*D_nR_n$, and the telescoping sum proves the finite identity. The sequence of positive operators $R_N^*R_N$ is decreasing and bounded below; its strong limit exists. Taking inner products with x, the sum of the squared norms of the complements is $\|x\|^2 - \langle x, A_\infty x\rangle$. This proves that the series belongs to the Hilbert direct sum and that $\mathcal{V}$ is an isometry. An isometry has closed image and an adjoint inverse on it. Inserting $\mathcal{V}^*\mathcal{V} = I$ into the compositions proves the transport properties. Neither convergence of $R_N x$ nor the assertion that A_∞ is a projector has been assumed. □

Applying this result to the carrier of the register,

$$(\mathcal{V}O_K)^*(\mathcal{V}O_K) = O_K^*O_K. \tag{144.11}$$

The twelve directions and all their correlations are preserved, with the same bounds as in theorem 144.2, at any depth of complete memory. It is not asserted that the entire continuum has dimension twelve: this

twelve-dimensional reference is preserved in its image. The correct operators there are $S^{\mathcal{V}} = \mathcal{V}S\mathcal{V}^*$ and $H^{\mathcal{V}} = \mathcal{V}H\mathcal{V}^*$. An ambient shift of storage slots is not presumed to be $S^{\mathcal{V}}$.

If $z = \mathcal{V}y + \delta z$, the estimate

$$\widehat{h} = O_K^{-1}\mathcal{V}^* z$$

retains the first bound of (144.8) with $\|\delta z\|$ in place of $\|\delta y\|$. Depth does not worsen this constant because the isometry and its terminal component are preserved. A partial selection of channels has a different Gram matrix and requires its own bounds. The exterior powers $\bigwedge^p \mathcal{V}$ preserve Gram determinants; finite-rank traces and spectral measures of the transported observables are also preserved. Squared norms are not thereby interpreted automatically as Born probabilities: that reading requires its subsequent realization.

144.6 Exceptional incidence and selected direction

Let $e = \mathbf{1}$, $\Pi = I - ee^*/12 = P_{11}$. In the already constructed icosahedral chart A_5/C_5, the orthogonal representation ρ and the three-dimensional character determine

$$P_3 = \frac{3}{60}\sum_{g\in A_5} \chi_3(g^{-1})\rho(g), \quad P_3^* = P_3 = P_3^2, \quad \operatorname{rank} P_3 = 3, \quad P_3 e = 0. \tag{144.12}$$

This projector is received together with its representation and markings; it is not chosen to fit a direction to the register. Put

$$k = \Pi K, \qquad u = P_3 k, \qquad E_u = \frac{uu^*}{\|u\|^2}, \qquad Q_K = \Pi - E_u = P_{10}(K).$$

The exact evaluations are

$$\|k\|^2 = \frac{11789915}{12}, \qquad \|u\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20}, \tag{144.13}$$

$$\eta_K := \frac{\|u\|^2}{\|k\|^2} = \frac{3(6638585 + 2275584\sqrt{5})}{5 \cdot 11789915} \simeq 0.5967954228259091. \tag{144.14}$$

In particular, $u \neq 0$. Since $u^*k = \|u\|^2$,

$$E_u k = u, \qquad Q_K k = k - u, \qquad k = u + Q_K k, \qquad \|k\|^2 = \|u\|^2 + \|Q_K k\|^2. \tag{144.15}$$

The reduction $12 \to 11 \to 10$ removes first the uniform direction and then a selected line. It does not remove all of $\operatorname{im} P_3$: in $\operatorname{im} Q_K$, the two directions of that subspace orthogonal to u remain. These dimensions are those of the algebraic spaces written above; identifying them with physical dimensions requires their realization maps.

Proposition 144.7 (Exact transport of direction and descriptor)**.** *For a complete isometry $\mathcal{V}$, let $\Pi^{\mathcal{V}} = \mathcal{V}\Pi\mathcal{V}^*$, $P_3^{\mathcal{V}} = \mathcal{V}P_3\mathcal{V}^*$, and $u^{\mathcal{V}} = \mathcal{V}u$. On $\mathcal{M}$,*

$$Q_K^{\mathcal{V}} = \mathcal{V}Q_K\mathcal{V}^* = \Pi^{\mathcal{V}} - \frac{u^{\mathcal{V}}(u^{\mathcal{V}})^*}{\|u^{\mathcal{V}}\|^2}, \quad \operatorname{rank} Q_K^{\mathcal{V}} = 10, \quad \eta_K^{\mathcal{V}} = \eta_K.$$

Moreover, $\mathcal{V}^*u^{\mathcal{V}} = u$ and $\mathcal{V}^*Q_K^{\mathcal{V}}\mathcal{V} = Q_K$.

Proof. Substitute the definitions and $\mathcal{V}^*\mathcal{V} = I$. Norms and rank are preserved by the isometry. The identity on the image is $\mathcal{V}\mathcal{V}^*$, not the identity of a larger ambient storage space. Extension by zero outside the image adds no physical directions. □

The complete incidence screen provides another exact realization. If $\mathcal{I}$ is the incidence operator already constructed and $E_{\mathrm{inc}} = \mathcal{I}(e^{\perp})$, then

$$F : V \longrightarrow Y = \mathbb{R} \oplus E_{\mathrm{inc}}, \quad Fx = \left(\mu(x), \frac{\mathcal{I}\Pi x}{6}\right), \quad \mu(x) = \frac{\mathbf{1}^* x}{12}, \qquad \langle (\mu, y), (\nu, z)\rangle_Y = 12\mu\nu + \langle y, z\rangle \tag{144.16}$$

is a surjective isometry, since $\Pi\mathcal{I}^*\mathcal{I}\Pi = 36\Pi$. For the raw incidence of the 132 hexads, the complete identity is $\mathcal{I}^*\mathcal{I} = 36I + 30\mathbf{11}^*$; centring removes exactly its uniform component. The incidence image has dimension eleven; Y is not all of $\mathbb{R} \oplus \mathbb{R}^{132}$. Applying F term by term to memory preserves both the Gram matrix and the preceding operators and their domains. This composition introduces no Monster action on K.

144.7 Continuous stability and the need to preserve correlations

Theorem 144.8 (Direction error from complete memory)**.** *Let $z = \mathcal{V}K + \delta$, $\|\delta\| \le \varepsilon$, and reconstruct $\widehat{K} = \mathcal{V}^* z$, $\widehat{k} = \Pi\widehat{K}$, $\widehat{u} = P_3\widehat{k}$. All three errors are less than or equal to ε. If $\varepsilon < \|u\|$,*

$$\|Q_{\widehat{K}} - Q_K\| \le \frac{\varepsilon}{\|u\|}.$$

Si $\varepsilon < \|k\|$,

$$|\eta_{\widehat{K}} - \eta_K| \le \frac{\varepsilon}{\|k\|}.$$

Proof. The adjoint of the isometry and the projectors have norm one. Noise orthogonal to $\mathcal{M}$ disappears upon applying $\mathcal{V}^*$. For two nonzero lines, the norm of the difference of their projectors is the sine of the angle between them. The distance from u to the line of $\widehat{u}$ does not exceed $\|u - \widehat{u}\|$, so this sine is less than or equal to $\varepsilon/\|u\|$. The hypothesis prevents $\widehat{u} = 0$.

For the second assertion, normalize k and $\widehat{k}$. The difference of their rank-one projectors has eigenvalues $\pm\sin\theta$ in their plane. When paired with $0 \le P_3 \le I$, its absolute value does not exceed $\sin\theta$: in an eigenvector basis one obtains $\sin\theta(a - b)$, with $a, b \in [0, 1]$. The same distance argument gives $\sin\theta \le \varepsilon/\|k\|$. If the lines coincide, the difference of the ratios is zero. □

Here $\|u\| \simeq 765.733$, so the factor for the projector is approximately 0.00130594. In the reader with only two memories, the inverse has norm $9/4$ and the corresponding factor is $9/(4\|u\|) \simeq 0.00293836$. These are different observed data; the difference is not a cost-free improvement of the same channel. The integer correction in theorem 145.5 will allow the register to be recovered first without error within its radius, instead of propagating a continuous error to the projector.

Proposition 144.9 (Cross blocks are part of the observable)**.** *Write $\mathcal{V}x = (W_a x)_a$, including the terminal component. Then the (a, b) block of $A^{\mathcal{V}}$ is*

$$(A^{\mathcal{V}})_{ab} = W_a A W_b^*.$$

Its quadratic form is computed as a limit of finite truncations

$$\langle y, A^{\mathcal{V}} y\rangle = \lim_{F} \sum_{a,b\in F} \langle y_a, W_a A W_b^* y_b\rangle.$$

General conservation is not obtained by discarding all terms $a \neq b$.

Proof. The block formula follows from multiplying $\mathcal{V}A\mathcal{V}^*$. The truncation projectors converge strongly to the identity and $A^{\mathcal{V}}$ is bounded, proving the limit without asserting absolute convergence of an arbitrary

double series. For a counterexample, take $H = \mathbb{R}$, $C = -I$, $T = 7/9$, $D = -2\sqrt{8}/9$, $\mathcal{V}x = (Tx, Dx)$, and $A = I$. The diagonal part, evaluated at $\mathcal{V}x$, equals

$$(T^4 + D^4)x^2 = \frac{3425}{6561}x^2.$$

The cross terms contribute $3136x^2/6561$, and the sum is x^2, as required by the isometry. □

144.8 Discrete correction before incidence selection

The canonical two-memory readers are

$$T_j = \frac{8I + S^j}{9}, \qquad D_j = \frac{\sqrt{8}(S^j - I)}{9}, \qquad Mx = (D_3x, D_4T_3x).$$

The second memory acts after the first compression; the first complement is not reinjected in this protocol. The general theorem in theorem 145.5 will prove, without using the register as a target, the strict radii

$$r_0 = \frac{2\sqrt{146}}{81}, \qquad r_q = \frac{4\sqrt{73}}{81}.$$

The first radius recovers ΠK from MK, modulo uniform integer translation. The second recovers K in full when $q = \mathbf{1}^*K$ is also preserved. If a real-valued charge is observed with error less than $1/2$, rounding first recovers its integer charge channel. None of these procedures requires the terminal component T_4T_3K.

The high-block selection in the marked chart is

$$B_K = \{i : K_i \geq 729\} = \{4, 6, 9, 10\}. \tag{144.17}$$

The fourth component is exactly at the threshold. This circumstance separates continuous stability from discrete stability.

Proposition 144.10 (Zero continuous margin and integer restoration)**.** *The direct selector in* (144.17)*, applied to the real-valued reconstruction of the memories, has no positive Euclidean stability radius at MK, even with exact charge. By contrast, prior integer decoding with error less than r_q restores B_K exactly without changing the threshold.*

Proof. Let L be the least-squares inverse, satisfying $LM = \Pi$. For $t > 0$, put

$$e_t = -tM\Pi e_4, \qquad \widetilde{K}_t = \frac{q}{12}\mathbf{1} + L(MK + e_t) = K - t\Pi e_4.$$

We have $\|e_t\| \to 0$, but the fourth component is $729 - 11t/12 < 729$. For small t, only this membership changes. The second assertion follows by first recovering K exactly through theorem 145.5 and then applying the same selector. □

If the remaining marked data $P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}$ are kept exact or transported according to their law, uniqueness of the exceptional construction returns the same flag $B_K \subset H_\alpha^-$ and the same marked origin. Correcting the register is not equivalent to correcting independent errors in these markings. The witness

$$K' = K - e_4 + e_6, \qquad Q(K') = 6263, \qquad B_{K'} = \{6, 9, 10\}$$

also belongs to $\{0, \dots, 999\}^{12}$ and satisfies $\|MK' - MK\|^2 = 4672/6561$. The midpoint of the two memories is at distance r_q from each. This proves that the strict radius is uniformly optimal on the fixed-charge algebraic domain, not that K' has a constructed HMT terminal history.

Without charge, $M(K-\mathbf{1}) = MK$ and the high-block selections differ. The two memories can recover Q_K and η_K exactly, since these ignore the mean, without recovering that absolute selector. The condition $P_3\Pi K \neq 0$ remains necessary for the projector; integer correction does not remove this defining condition. A concrete finite test uses $z = MK/\sqrt{8}$ and adds $1/10$ to its first component. The error in the norm of M is $\sqrt{8}/10 < r_q$. The floor-and-ceiling algorithm in proposition 145.6 leaves 924 candidates of charge 6263 and recovers K and B_K exactly.

Applying the isometry (144.16) gives $M_{\mathrm{inc}} = (F \oplus F)M$. All distances between words and all noise norms are preserved, so the same radii and decoders apply in $Y \oplus Y$. This is the quantitative connection between memory and incidence; it does not depend on attributing an additional exceptional symmetry to the shift S.

144.9 Covariance, refinement, and variational charge

If G is orthogonal and $K' = GK$, $\Pi' = G\Pi G^*$, and $P_3' = GP_3G^*$ are transported jointly, then

$$u' = Gu, \qquad Q'_{K'} = GQ_KG^*, \qquad \eta'_{K'} = \eta_K.$$

In a fixed chart, $K \mapsto aK + b\mathbf{1}$, $a \neq 0$, leaves Q_K and η_K invariant; it does not leave the entire object invariant. For example, $\kappa(K+\mathbf{1}) - \kappa(K) = 1/999$, and the reading α_A would change by $-1/999$ if the regions were kept fixed. This is an algebraic counterexample to identifying the descriptor with the entire register, not an assertion of admissibility of that update as an HMT history.

Nor can one move only the register and arbitrarily keep the projector fixed. The finite formula (144.12) gives exactly

$$\|P_3S^3K\|^2 = \frac{369035}{4} - \frac{281861\sqrt{5}}{10}, \qquad \|P_3S^4K\|^2 = \frac{1327717}{4} + \frac{694618\sqrt{5}}{5}.$$

These differ from (144.13); in particular, $[P_3, S^3]$ and $[P_3, S^4]$ do not vanish. Transporting P_3 by the same conjugation does preserve η_K.

Decoding is also covariant. For a permutation R,

$$S' = RSR^{-1}, \qquad M' = (R \oplus R)MR^{-1}, \qquad M'R = (R \oplus R)M.$$

The lattice, charge and distances are preserved. In the uniqueness regime, the decoder output transforms by R; outside it, the set of minimizers is transported, without breaking a tie arbitrarily. A general orthogonal frame requires also transporting $\mathbb{Z}^{12}$ to $R\mathbb{Z}^{12}$ and the uniform direction to $R\mathbf{1}$. Rounding in the old lattice after changing the chart does not represent the same problem.

Proposition 144.11 (Naturality under refinement with local frames)**.** *Let z be a cylinder with children z', compatible positive weights $\sum_{\tau z'=z} \mu(z') = \mu(z)$, and orthogonal frames G_z. The refinement*

$$\mathcal{R}_n(e_z \otimes x) = \sum_{\tau z'=z} \sqrt{\frac{\mu(z')}{\mu(z)}}\, e_{z'} \otimes G_{z'}G_z^*x$$

is isometric. For the projector field $Q_z = G_zQ_KG_z^*$ and its block operator Q_n,

$$Q_{n+1}\mathcal{R}_n = \mathcal{R}_nQ_n, \qquad \mathcal{R}_n^*Q_{n+1}\mathcal{R}_n = Q_n.$$

The identities compose between levels and pass to the inductive limit.

Proof. The children have orthogonal supports and the weights sum to one; the frame changes are orthogonal. In each child, $Q_{z'}G_{z'}G_z^* = G_{z'}G_z^*Q_z$, which proves the first square. Multiplying by the

adjoint of the refinement gives the second. Compatibility by composition defines the operator in the limit of the isometric inclusions. The same argument holds for E_u. □

The statement preserves the publication of a prefix under compatible refinements. New events can produce another register; no temporal constancy of K follows. The ranks of fields over tensor fibers are those of these fibers, not a count of physical dimensions.

Proposition 144.12 (A transport charge with an explicit action)**.** *Let $U_n : E_n \to E_{n+1}$ be invertible transports. The auxiliary discrete action with cotangent variables is*

$$\mathcal{A}(q,p) = \sum_n p_{n+1}^*(q_{n+1} - U_n q_n).$$

Finitely supported variations give $q_{n+1} = U_n q_n$ and $p_n = U_n^* p_{n+1}$. If $G_0 = I$, $G_{n+1} = U_n G_n$, $A_0 = Q_K$, and $A_n = G_n A_0 G_n^{-1}$, the quantity

$$J_n = p_n^* A_n q_n$$

is independent of n. The action is invariant under the continuous group $q_n \mapsto \exp(tA_n)q_n$, $p_n \mapsto \exp(-tA_n^*)p_n$.

Proof. The indicated equations follow by varying p_{n+1} and q_n. The definition of A_n implies $A_{n+1}U_n = U_n A_n$. Hence

$$p_{n+1}^* A_{n+1} q_{n+1} = p_{n+1}^* U_n A_n q_n = p_n^* A_n q_n.$$

The same intertwining holds for the exponentials and makes every term of the action invariant. It is not required that A_n be antisymmetric: the covector transformation is contragredient. □

For orthogonal transports one may choose $p_n = q_n$; then $J_n = \|A_n q_n\|^2$, and the complement provides the remaining charge. In a symplectic realization without a positive form, the pairing written above is preserved and is not called positive energy. If the fibres are archived through isometries $\mathcal{V}_n$, the definitions

$$\widehat{U}_n = \mathcal{V}_{n+1} U_n \mathcal{V}_n^*, \qquad \widehat{A}_n = \mathcal{V}_n A_n \mathcal{V}_n^*, \qquad \widehat{q}_n = \mathcal{V}_n q_n,$$

with $\widehat{p}_n(y) = p_n(\mathcal{V}_n^* y)$ preserve the intertwining and the same charge on the images. This composition provides a concrete continuous action and symmetry for a conservation law; it attributes no automatic Noether currents to a finite group, nor does it identify the auxiliary action with every physical action.

144.10 Encoding, operator identification, and incidence stability

The contribution assembled here is an operational chain: the generated register has a reversible encoding; its orbit is a complete reference; terminal component and complements preserve this reference and the transported observables; the integer separation of two memories allows incidence and direction to be restored even when the real-valued selector has zero margin. The proofs concerning linearity, projection, and lattices are used as the language of subsequent realization, without changing the production of the object.

Each hypothesis has a witness that prevents it from being inadvertently extended. An isolated response does not identify an operator that does not commute with the cycle; only the complete memory automatically preserves the original Gram matrix; cross terms cannot be omitted; absolute selection requires charge; the projector requires a nonzero direction; noise bounds depend on normalization; a chart transformation requires transporting the form, lattice and readers. A reading perturbation does not become an admissible history by decree. These delimitations preserve the functions of K, without reducing it to twelve disconnected numbers or promoting a canonical property to universal invariance.

Chapter 145

Ternary algebraic norm and optimal recovery radii

The recovery radius of the two memories contains the factor $\sqrt{73}$. Its origin can be traced without introducing a target magnitude: it comes from the Gram matrix of the nonadic reader and, in another realization of the ternary cycle already constructed, is the scale factor of a similitude. Its square, 73, is the index of the rank-two lattice inclusion. These occurrences are brought together through explicit operations; they are not identified through a decimal resemblance to alpha. The subsequent comparison with $10^4\alpha_A$ will be treated as an inverse problem, with its data, permitted transformations, and exact conclusions.

The raw material preserves its APP–TRIT–TPK production and the subsequent cut described in section 144.1. The integer register, the orientation of shifts, the charge and the readers are received before distances are calculated. The canonical case uses $8+1$ and the denominator nine. The parameter $a>0$ introduced below is a subsequent algebraic family, not a new seed or a physical parameter selected by alpha. Errors belong to the reading channel; they are not identified with admissible events or histories.

145.1 Parametric double-memory operators and Gram matrix

In $V=\mathbb{R}^{12}$, let $(Sx)_i=x_{i+1}$, with indices modulo twelve. For $a>0$ and $j=3,4$, define

$$T_{j,a}=\frac{aI+S^j}{a+1},\qquad D_{j,a}=\frac{\sqrt{a}(S^j-I)}{a+1},\qquad M_a x=(D_{3,a}x,D_{4,a}T_{3,a}x). \tag{145.1}$$

The second memory is produced after the first compression. Archiving both is not equivalent to reinjecting the first complement into a reversible two-channel evolution. Let

$$p(a)=a^2+a+1,\quad A(a)=a(a^2+1),\quad B(a)=a^2,\qquad \Pi=I-\frac{\mathbf{1}\mathbf{1}^*}{12},\quad P_u=I-\Pi.$$

Proposition 145.1 (Balance and difference form)**.** *For every $a>0$,*

$$T_{j,a}^*T_{j,a}+D_{j,a}^*D_{j,a}=I,\qquad G_a:=M_a^*M_a=I-(T_{4,a}T_{3,a})^*(T_{4,a}T_{3,a}),$$

and

$$\begin{aligned}(a+1)^4G_a&=4ap(a)I-A(a)(S^3+S^4+S^8+S^9)\\&\quad-B(a)(S+S^5+S^7+S^{11}).\end{aligned} \tag{145.2}$$

Equivalently,

$$\begin{aligned}(a+1)^4\|M_ah\|^2&=A(a)\sum_i\big((h_i-h_{i+3})^2+(h_i-h_{i+4})^2\big)\\&\quad+B(a)\sum_i\big((h_i-h_{i+1})^2+(h_i-h_{i+5})^2\big).\end{aligned} \tag{145.3}$$

Proof. Orthogonality of S gives

$$T_{j,a}^*T_{j,a}=\frac{(a^2+1)I+a(S^j+S^{-j})}{(a+1)^2},\qquad D_{j,a}^*D_{j,a}=\frac{a(2I-S^j-S^{-j})}{(a+1)^2}.$$

Their sum is I; applying the identity to the two stages cancels the intermediate term $T_{3,a}^*T_{3,a}$. Since all operators are polynomials in S, the product of the two individual Gram matrices has diagonal $(a^2+1)^2$, single

terms of weight $a(a^2+1)$, and cross terms of weight a^2. The identity $(a+1)^4-(a^2+1)^2=4a(a^2+a+1)$ gives (145.2). Expanding the squared differences gives (145.3); each unoriented edge of each step appears exactly once, and the weighted degree is $4A+4B=4ap(a)$. □

At $a=8$ we obtain

$$\begin{aligned}6561G_8 = 2336I &- 520(S^3+S^4+S^8+S^9)\\ &- 64(S+S^5+S^7+S^{11}),\end{aligned} \tag{145.4}$$

whose first row is $(2336,-64,0,-520,-520,-64,0,-64,-520,-520,0,-64)/6561$. Also,

$$T_{4,8}T_{3,8}=\frac{64I+8S^3+8S^4+S^7}{81}.$$

The four distinct shifts produce the diagonal contribution

$$1-\frac{64^2+8^2+8^2+1}{81^2}=\frac{2336}{6561}=\frac{32(8^2+8+1)}{9^4}.$$

Theorem 145.2 (Kernel, spectrum, and complete inverse)**.** *For every $a>0$,* $\ker M_a=\mathbb{R}\mathbf{1}$. *The eigenvalues of G_a, indexed by the twelfth-root modes m, are*

m	$\lambda_m(G_a)$	*multiplicity*
0	0	1
$3,9$	$2a/(a+1)^2$	2
$4,8$	$3a/(a+1)^2$	2
6	$4a/(a+1)^2$	1
$1,5,7,11$	$a(5a^2+4a+5)/(a+1)^4$	4
$2,10$	$a(7a^2+2a+7)/(a+1)^4$	2

In particular,

$$L_a^{\mathrm{rec}}=(G_a+P_u)^{-1}M_a^*,\qquad L_a^{\mathrm{rec}}M_a=\Pi,\qquad \|L_a^{\mathrm{rec}}\|=\frac{a+1}{\sqrt{2a}}. \tag{145.5}$$

Proof. If $M_ah=0$, the first memory implies $S^3h=h$, hence $T_{3,a}h=h$; the second implies $S^4h=h$. Since $S=S^4(S^3)^{-1}$, the vector is uniform. The converse is immediate. In mode m, the balance gives

$$\lambda_m(G_a)=1-\frac{[a^2+1+2a\cos(\pi m/2)][a^2+1+2a\cos(2\pi m/3)]}{(a+1)^4}.$$

The twelve cosine pairs give the table. Relative to $2a/(a+1)^2$, the differences of the last two values are

$$\frac{3a(a^2+1)}{(a+1)^4}>0,\qquad \frac{a(5a^2-2a+5)}{(a+1)^4}>0.$$

The other positive values are larger multiples. Hence the minimum on $\mathbf{1}^\perp$ is $2a/(a+1)^2$. The operator G_a+P_u equals one on the uniform direction and is positive and invertible on its complement. The formula displayed is the least-squares inverse, and its norm is the reciprocal of the smallest nonzero singular value of M_a. □

At $a=1$, $T_{3,1}=(I+S^3)/2$ is singular, but (145.5) remains valid. Singularity of an individual compression does not eliminate recovery through its two memories. At $a=8$, the norm of the inverse is $9/4$.

145.2 Minimum distance in the domain of integer registers

The algebraic decoding domains are

$$C_0(a) = M_a\mathbb{Z}^{12}, \qquad \Lambda_q = \{k \in \mathbb{Z}^{12} : \mathbf{1}^* k = q\}, \qquad C_q(a) = M_a\Lambda_q.$$

The first image is identified with the lattice $\Pi\mathbb{Z}^{12}$ or with classes modulo $\mathbb{Z}\mathbf{1}$; the second preserves a fixed integer charge. These are domains containing the integer publications of the indicated type. Their use does not assert that each candidate corresponds to a produced HMT history.

Lemma 145.3 (Minimum cut of the memory graph)**.** *Every nonempty proper cut of the twelve positions has at least four edges of steps* $1, 5$ *and at least four of steps* $3, 4$*. Its weight in* (145.3) *is therefore at least* $4A(a) + 4B(a) = 4ap(a)$*; a cut consisting of one position attains this bound.*

Proof. Each step 1 and 5 forms a connected cycle of twelve positions; each cycle crosses a nontrivial cut at least twice. For the steps $3, 4$, if the set is invariant under neither, each family contributes at least two edges. If it is invariant under S^3, it is a union of classes modulo three; each of the four triangles of S^4 crosses it twice, giving eight edges. If it is invariant under S^4, it is a union of classes modulo four; each of the three length-four cycles of S^3 crosses it at least twice, giving at least six. Simultaneous invariance would force invariance under S, impossible for a nonempty proper set. All weights are positive; the cut of a single position has exactly four edges of each weight. □

Theorem 145.4 (Exact distances and fixed-charge minimizers)**.** *For every* $a > 0$ *and every integer charge* q*,*

$$d_0(a)^2 = \min_{h \notin \mathbb{Z}\mathbf{1}} \|M_a h\|^2 = \frac{4ap(a)}{(a+1)^4}, \qquad d_q(a)^2 = \frac{8ap(a)}{(a+1)^4}. \tag{145.6}$$

In the first minimum, h *ranges over* $\mathbb{Z}^{12}$*; the second is the minimum distance between distinct words of* $C_q(a)$*. The differences attaining the second minimum are exactly* $e_i - e_j$ *with* $j - i \equiv 2, 6, 10 \pmod{12}$*.*

Proof. For a nonconstant integer vector h, $(h_i - h_j)^2 \geq |h_i - h_j|$. Each absolute difference decomposes as a sum of cuts of the level sets $\{i : h_i > t\}$. There is at least one nontrivial level; by lemma 145.3, the weighted energy is at least $4ap(a)$. The vector e_i attains this energy. Division by $(a+1)^4$ proves the first minimum over all integer vectors, not only over indicators of subsets.

For fixed charge, the difference $h \neq 0$ is integral and has zero sum. Its squared norm is even because $h_i^2 \equiv h_i \pmod 2$. If $\|h\|^2 \geq 4$, the spectral minimum gives

$$\|M_a h\|^2 \geq \frac{8a}{(a+1)^2} > \frac{8ap(a)}{(a+1)^4},$$

since $(a+1)^2 - p(a) = a > 0$. Only $\|h\|^2 = 2$ remains, that is, $h = e_i - e_j$. Its energy is $2((G_a)_{ii} - (G_a)_{ij})$. The off-diagonal entries are zero at separations $2, 6, 10$, negative with weight $B(a)/(a+1)^4$ at $1, 5, 7, 11$, and negative with weight $A(a)/(a+1)^4$ at $3, 4, 8, 9$. The diagonal is $4ap(a)/(a+1)^4$; this proves the minimum and the exhaustive classification over the entire half-line $a > 0$. □

Theorem 145.5 (Strict correction radii of the memories)**.** *For a datum* $y = M_a k + e$*, with error measured in the joint norm of the two memories, the optimal uniform radii are*

$$r_0(a) = \frac{\sqrt{ap(a)}}{(a+1)^2}, \qquad r_q(a) = \frac{\sqrt{2ap(a)}}{(a+1)^2}. \tag{145.7}$$

If $\|e\| < r_0(a)$*, the nearest neighbour in* $C_0(a)$ *recovers* Πk *exactly. With known charge* q *and* $\|e\| < r_q(a)$*, the nearest neighbour in* $C_q(a)$ *recovers* k *exactly.*

Proof. The lattice $\Pi\mathbb{Z}^{12} \subset (1/12)\mathbb{Z}^{12}$ is discrete, and M_a is bounded below on $\mathbf{1}^{\perp}$. Its images are discrete and admit a nearest neighbour. If c' is another codeword and d is the corresponding minimum distance, $\|y - c'\| \geq d - \|e\| > \|e\|$ when $\|e\| < d/2$. The minimum is unique, and the preimage is unique in each indicated domain. The midpoint of two words at minimum distance lies at $d/2$ from both: no decoder can uniformly distinguish both inputs from that same datum. Optimality refers to the complete algebraic domains, not to an additional subset of histories that might have greater separation. □

In the canonical case,

$$r_0(8) = \frac{2\sqrt{146}}{81} \simeq 0.298346814162829, \qquad r_q(8) = \frac{4\sqrt{73}}{81} \simeq 0.421926110879878. \tag{145.8}$$

The 4 comes from $\sqrt{2 \cdot 8}$ when taking half the distance between fixed-charge registers; $73 = 8^2 + 8 + 1$ comes from the Gram matrix; $81 = 9^2$ comes from the two nonadic normalizations. The same product 9×9 counts the APP cells, but these two roles are not identified without their typed map. Nor does the factor four alone prove an assertion about spatial directions.

If the memories are stored as $z = M_a k/\sqrt{a}$, the noise norm changes. At $a = 8$, the radii for this rational datum are $r_0/\sqrt{8} = \sqrt{73}/81$ and $r_q/\sqrt{8} = \sqrt{146}/81$. Using the radii in (145.8) without this conversion changes the problem. The application to Q_K, η_K, B_K, and the incidence screen has been proved in section 144.8; in particular, the exact threshold $K_4 = 729$ does not prevent its discrete restoration.

145.3 Finite decoder and parameter duality

Proposition 145.6 (Floor and ceiling without a target table)**.** *With known charge, below radius $r_q(a)$, it suffices to examine at most $2^{12} = 4096$ integer candidates. Without charge, below $r_0(a)$, it suffices to examine at most $12 \cdot 2^{12} = 49152$ candidates distributed among twelve charge residues. The residual minimum returns k or its uniform class, respectively.*

Proof. With charge q, form $\widetilde{k} = L_a^{\mathrm{rec}} y + (q/12)\mathbf{1}$. Then

$$\|\widetilde{k} - k\| < \|L_a^{\mathrm{rec}}\| r_q(a) = \frac{\sqrt{p(a)}}{a+1} < 1.$$

Each true integer coordinate belongs to $\{\lfloor \widetilde{k}_i \rfloor, \lceil \widetilde{k}_i \rceil\}$. These products are enumerated, those whose sum differs from q are removed, and $\|M_a k' - y\|$ is minimized. The correct candidate is present, and theorem 145.5 ensures its uniqueness. Coordinates that are already integers reduce the number of candidates.

Without charge, write $\rho \in \{0, \dots, 11\}$ for the charge residue. Each class modulo $\mathbb{Z}\mathbf{1}$ has a unique representative whose sum is ρ, obtained by subtracting $\lfloor q/12 \rfloor \mathbf{1}$. For each ρ, form $\widetilde{k}_\rho = L_a^{\mathrm{rec}} y + (\rho/12)\mathbf{1}$. At the correct residue,

$$\|\widetilde{k}_\rho - k_\rho\| < \|L_a^{\mathrm{rec}}\| r_0(a) = \frac{\sqrt{p(a)}}{\sqrt{2}(a+1)} < 1.$$

Apply floor and ceiling, retain the sum ρ, and minimize the residual across the twelve groups. Uniqueness of the code class gives a unique centred output. These procedures use the reader and integrality; they do not receive K as a comparison table. □

For rational a, rational arithmetic can be retained by writing $R_a = M_a/\sqrt{a}$, $z = y/\sqrt{a}$. The centred reconstruction is

$$(R_a^* R_a + P_u)^{-1} R_a^* z = L_a^{\mathrm{rec}} y.$$

The residual can be compared through its rational squares. These guarantees concern twelve coordinates: they assert neither polynomial complexity for arbitrary dimension, cryptographic authentication, nor quantum advantage. The perturbed example in section 144.8 illustrates the canonical algorithm.

Proposition 145.7 (Reciprocal duality and maximum radius)**.** *The substitution $a \mapsto 1/a$ preserves the Gram matrix, distances, radii, and norm of the inverse. We have*

$$D_{j,1/a} = D_{j,a}, \qquad T_{j,1/a} = S^j T_{j,a}^{*}.$$

The maximum radii of this family are attained only at $a = 1$:

$$r_q(a) \le \frac{\sqrt{6}}{4}, \qquad r_0(a) \le \frac{\sqrt{3}}{4}.$$

Proof. The two operator identities follow by multiplying numerator and denominator by a. The individual Gram matrices and formula (145.1) are invariant under reciprocity. Put $t = a/(a+1)^2 \in (0, 1/4]$. Then

$$r_q(a)^2 = 2t(1-t), \qquad r_0(a)^2 = t(1-t).$$

Both expressions increase for $0 < t \le 1/4$, and $t = 1/4$ is equivalent to $a = 1$. Reciprocity leaves t fixed. As a tends to zero or infinity, t and the radii tend to zero. □

Equality of Gram matrices does not mean that $M_a = M_{1/a}$: the second complement includes a different compression. The endpoints $a = 0$ and $a = \infty$ do not belong to the domain of the theorem. Optimizing the family at $a = 1$, or using the reciprocal representative $1/8$, does not retroactively change the canonical origin $a = 8$.

145.4 The norm on the ternary augmentation module

The cycle $r \mapsto 4r \pmod 9$, with orbits $(1, 4, 7)$ and $(2, 8, 5)$, provides the augmentation module whose chart and form are

$$C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad C^2 + C + I = 0, \qquad C^T G_{A_2} C = G_{A_2}.$$

The action and its contragredient orientation belong to the antecedent ternary fibres. On this already constructed module, we compose

$$Q_-(a) = aI - C, \qquad Q_+(a) = (a+1)I + C.$$

Proposition 145.8 (Ternary similitude and integer index)**.** *For $a > 0$,*

$$Q_- Q_+ = p(a) I, \qquad Q_-^{\dagger_{G_{A_2}}} = Q_+, \qquad Q_-^T G_{A_2} Q_- = p(a) G_{A_2}, \qquad \det Q_- = p(a).$$

At $a = 8$, both conjugate charts are

$$Q_- = \begin{pmatrix} 8 & 1 \\ -1 & 9 \end{pmatrix}, \qquad Q_+ = \begin{pmatrix} 9 & -1 \\ 1 & 8 \end{pmatrix}, \qquad Q_- Q_+ = 73 I.$$

Each integer quotient is cyclic of order 73. On the quotient of Q_-, C acts by 8; on that of Q_+, by $-9 \equiv 64 \equiv 8^{-1} \pmod{73}$.

Proof. Expanding the product and substituting $C^2 = -C - I$ gives $p(a)I$. Invariance of the form implies $C^{\dagger_{G_{A_2}}} = C^{-1} = C^2 = -I - C$, from which the adjoint follows. Composing product and adjoint gives the

similitude. The determinant of $\left(\begin{smallmatrix} a & 1 \\ -1 & a+1 \end{smallmatrix}\right)$ is $p(a)$. At $a = 8$, the greatest common divisor of the entries of each matrix is one and its determinant is 73; the Smith normal form is $\operatorname{diag}(1, 73)$. The relation $8I - C = 0$ in the first quotient and $9I + C = 0$ in the second gives the indicated actions. Since $8^3 \equiv 1 \pmod{73}$ and $8 \not\equiv 1$, both actions have order three and opposite orientations. □

Thus $\sqrt{73}$ is a similitude scale factor in the inherited ternary metric, not merely a number inside a radius. Its subsequent complex recognition is $|8 - \omega|^2 = 73$, with $\omega^2 + \omega + 1 = 0$. The complex unit describes the realization of the operator; it was not used to select the register. These equalities do not identify the operator Q_- with K, with the entire TPK dynamics, or with the cokernel of the action-scale reader.

145.5 Invariant contribution of the complete cycle

On the twelve positions, let $U = S^4$. There are now four cycles of length three. Their projectors are

$$P_0 = \frac{I + U + U^2}{3}, \qquad P = I - P_0.$$

The rank of P_0 is four and that of P is eight. In particular, $P_0 \neq P_u$, since the latter preserves only the global uniform direction; nor is P to be confused with the exceptional projector P_3. We shall now use $Q_{-,a} = aI - U$ and $Q_{+,a} = (a + 1)I + U$ for the operators of the complete cycle.

Theorem 145.9 (Ternary Gram matrix with a fixed sector)**.** *We have*

$$Q_{-,a}^* Q_{-,a} = (a - 1)^2 P_0 + p(a)P = p(a)I - 3aP_0. \tag{145.9}$$

For $v \neq 0$, let

$$w(v) = \frac{\|P_0 v\|^2}{\|v\|^2}, \qquad s_{-,a}(v) = \frac{\|Q_{-,a} v\|^2}{\|v\|^2}.$$

Then $s_{-,a}(v) = p(a) - 3aw(v)$. In the canonical case,

$$Q_-^* Q_- = 49P_0 + 73P = 73I - 24P_0, \qquad s(v) = 73 - 24w(v) \in [49, 73]. \tag{145.10}$$

Proof. From $U^3 = I$ and $U^* = U^2$ it follows that P_0 is the orthogonal projector onto $\ker(U - I)$. Expanding the Gram matrix,

$$Q_{-,a}^* Q_{-,a} = (a^2 + 1)I - a(U + U^2).$$

The relation $U + U^2 = 3P_0 - I$ gives (145.9). Evaluating on v and dividing by its squared norm proves the remaining identities. □

The term 24 is exactly $3 \cdot 8$: it is the difference $p(8) - (8 - 1)^2$ between the augmentation reading and the fixed reading. It already appears in a single cycle of three positions. For m cycles, the fixed rank is m, the dimension is $3m$, and

$$\operatorname{tr}(Q_{-,a}^* Q_{-,a}) = 3m(a^2 + 1).$$

At $m = 4, a = 8$, the trace is 780 and the total trace correction is $24 \cdot 4 = 96$. The numerical equality $24 = 2 \cdot 12$ is not the operator origin of the coefficient.

The two complete charts also distinguish their determinants. In a single cycle,

$$\det(8I - U) = 8^3 - 1 = 511 = 7 \cdot 73, \qquad \det(9I + U) = 9^3 + 1 = 730 = 10 \cdot 73.$$

The fixed factor is 7 and 10, respectively; the augmentation module contributes 73. On the twelve positions, $\det(8I - U) = 511^4 = 68184176641$. The identity

$$73 = 8^2 + 8 + 1 = 9^2 - 9 + 1 = \frac{9^3 + 1}{9 + 1} = \frac{729 + 1}{10}. \tag{145.11}$$

is preserved. Its interpretation as an index and determinant factor precedes any subsequent completion or refinement reading.

145.6 Six received states and conservation of the complete reading

We again fix $a = 8$ and omit that subscript in the readers. The six objects being compared are

$$K, \quad k = \Pi K, \quad m_0 = D_3 K, \quad m_1 = D_4 T_3 K, \quad u = P_3 k, \quad q_K = Q_K K = k - u.$$

None is selected from the target of the test. To give the evaluations without replacing them by decimals, write $a_v = \|v\|^2$, $b_v = \|P_0 v\|^2$. We obtain

v	a_v	b_v
K	4251257	10684363/3
k	11789915/12	1170761/4
m_0	15413392/81	16838032/243
m_1	1105759232/6561	0
u	$1327717/4 + (568896/5)\sqrt{5}$	$3029657/20 + (145120/3)\sqrt{5}$
q_K	$1951691/3 - (568896/5)\sqrt{5}$	$2292404/15 - (145120/3)\sqrt{5}$

(145.12)

The table is obtained by applying $P_0 = (I + S^4 + S^8)/3$, the formulas for D_3, D_4T_3, and the finite character projector (144.12) to (144.2). All its entries belong to $\mathbb{Q}(\sqrt{5})$; the first four are rational. In particular, the first three weights and readings are

$$w(K) = \frac{10684363}{12753771}, \qquad s(K) = \frac{224866857}{4251257},$$
$$w(k) = \frac{3512283}{11789915}, \qquad s(k) = \frac{776369003}{11789915},$$
$$w(m_0) = \frac{1052377}{2890011}, \qquad s(m_0) = \frac{61904585}{963337}.$$

For u and q_K, the exact expressions are $w = b_v/a_v$, $s = 73 - 24b_v/a_v$, with the numerators and denominators in (145.12). The subsequent evaluations are

v	$w(v)$, approximately	$s(v)$, approximately
K	0.8377414805	52.89420446705527
k	0.2979057101	65.85026295779062
m_0	0.3641429046	64.26057028848679
m_1	0	73 exact
u	0.4428244530591254	62.37221312658099
q_K	0.1127385160275117	70.29427561533972

The equality for the second memory is forced: $P_0 D_4 T_3 = \sqrt{8} P_0 (U - I) T_3 / 9 = 0$, while $\|m_1\|^2 > 0$. It is not an evaluational coincidence.

Proposition 145.10 (Complete memory does not alter the fixed weight)**.** *The map*

$$V_2 v = (t(v), m_0(v), m_1(v)) = (T_4 T_3 v, D_3 v, D_4 T_3 v)$$

is isometric and intertwines P_0 and $Q_- = 8I - U$ with their diagonal copies. It separately preserves $\|v\|^2$, $\|P_0 v\|^2$, and $\|Q_- v\|^2$. Hence the joint readings w and s do not change.

Proof. The two-stage balance gives $V_2^* V_2 = I$. Each channel is a polynomial in S, so it commutes with U, P_0, Q_-. Applying the isometry to v, $P_0 v$, and $Q_- v$ gives the three norm equalities. After division, the total reading is the average of the channel readings weighted by their squared norms, not their unweighted arithmetic mean. Zero channels do not contribute to the total ratio. □

The terminal component explicitly confirms this partition. For K,

$$\|t(K)\|^2 = \frac{25538253193}{6561}, \qquad \|P_0 t(K)\|^2 = \frac{848595371}{243},$$

$$w(t(K)) = \frac{22912075017}{25538253193}, \qquad s(t(K)) = \frac{1314402682681}{25538253193} \simeq 51.46799480558349.$$

The sum of the three squared norms is 4251257, and that of the fixed-sector norms is $(848595371 + 16838032)/243 = 10684363/3$. For $k = \Pi K$,

$$\|t(k)\|^2 = \frac{16367568169}{26244}, \qquad \|P_0 t(k)\|^2 = \frac{217142795}{972}.$$

The complements do not change under centring, and their sums recover the norms in the second row of (145.12). Discarding the terminal component or a complement alters the partial reading; retaining them introduces no hidden correction.

In a complete infinite memory, the same conclusion holds when the channels commute with U: the positive limit and its square root also commute with it. Without this commutation, the transport $\mathcal{V} P_0 \mathcal{V}^*$ is used on the image, in accordance with theorem 144.6, not an assumed diagonal copy.

145.7 Inversion, charts and bilateral balance

Proposition 145.11 (What inversion or a frame change preserves)**.** *Replacing U by U^{-1} exchanges each $Q_{\pm,a}$ with its adjoint and preserves P_0, their Gram matrices, singular values, determinants, and induced distances. For every $v \neq 0$, it preserves $w(v)$ and $s_{-,a}(v)$. This is not the same as inverting $Q_{-,a}$, whose inverse, for $a \neq 1$, is*

$$Q_{-,a}^{-1} = \frac{1}{a-1} P_0 + \frac{1}{p(a)} Q_{+,a} P. \tag{145.13}$$

For an invertible chart R, transporting $U' = RUR^{-1}$, $v' = Rv$ and $g' = (R^{-1})^* R^{-1}$ preserves these norm ratios in the metric g'.

Proof. Since $U^* = U^{-1} = U^2$, inversion produces the adjoints. The operators are normal polynomials in U; their Gram matrices depend on $U + U^2$, which does not change. The written inverse is verified by sectors: $Q_{-,a}$ acts by $a - 1$ on the fixed sector and the product with $Q_{+,a}$ equals $p(a) I$ on the augmentation. For the chart, $Q' v' = RQv$ and $R^* g' R = I$; numerator and denominator recover exactly their original values. The adjoint with respect to g' is also the transport of the original adjoint. □

Reversing the order of the twelve positions satisfies $RSR^{-1} = S^{-1}$ and preserves P_0. The translations S^j, including the antipodal translation S^6, commute with U; a global negation also leaves the norms unchanged. None of these operations alone turns 73 into a different reading.

With the Euclidean metric fixed, an orthogonal frame applied only to the state preserves $s_{-,a}(v)$ for all v if and only if $R^* P_0 R = P_0$, by (145.9) and polarization. The group of these transformations is $O(\operatorname{im} P_0) \times O(\operatorname{im} P) \cong O(4) \times O(8)$, larger than the commutant of U. By contrast, a state filter $c_0 P_0 + c_1 P$, when its output is nonzero, produces

$$w' = \frac{|c_0|^2 w}{|c_0|^2 w + |c_1|^2 (1 - w)}. \tag{145.14}$$

The reading may change. Choosing these coefficients from a target is a declared adjustment of the filter, not a chart change of the same reading.

Theorem 145.12 (Bilateral balance and explicit recovery)**.** *For every $a > 0$, the complete cycle satisfies*

$$\begin{aligned} Q_{+,a} - Q_{-,a}^* &= 3P_0, & Q_{+,a}Q_{-,a} &= p(a)I - 3P_0, \\ Q_{+,a}^* Q_{+,a} &= p(a)I + 3(a+1)P_0, \end{aligned} \tag{145.15}$$

and

$$(a+1)Q_{-,a}^* Q_{-,a} + aQ_{+,a}^* Q_{+,a} = (2a+1)p(a)I. \tag{145.16}$$

The map

$$W_a v = \frac{(\sqrt{a+1}\, Q_{-,a}v, \sqrt{a}\, Q_{+,a}v)}{\sqrt{(2a+1)p(a)}} \tag{145.17}$$

is isometric and is inverted on its image by W_a^*, of norm one. For the unnormalized channels $x = Q_{-,a}v$, $y = Q_{+,a}v$,

$$v = \frac{x+y}{2a+1}, \qquad Uv = \frac{ay - (a+1)x}{2a+1}. \tag{145.18}$$

A pair (x, y) belongs to this unnormalized image if and only if $Q_{+,a}x = Q_{-,a}y$.

Proof. The expression $Q_+ - Q_-^*$ contains $I + U + U^2 = 3P_0$. Expanding Q_+Q_-, $Q_+^*Q_+$, and using $U^2 = 3P_0 - I - U$ gives (145.15). The weighted combination cancels the P_0 terms in (145.9) and (145.15); this proves $W_a^*W_a = I$. Since $Q_- + Q_+ = (2a+1)I$, the sum of the channels gives v; their combination $ay - (a+1)x$ gives $(2a+1)Uv$.

The image condition is necessary because the two operators commute. If it holds, define $v = (x+y)/(2a+1)$. Then

$$Q_-v = \frac{Q_-x + Q_-y}{2a+1} = \frac{(Q_- + Q_+)x}{2a+1} = x,$$

and similarly $Q_+v = y$. The adjoint inverse formula is that of any isometry; for the raw pair, the linear inverse $(x, y) \mapsto (x+y)/(2a+1)$ has norm $\sqrt{2}/(2a+1)$ on the product space. □

At $a = 8$, the fixed and augmentation sectors have readings $(49, 100)$ and $(73, 73)$, respectively, and

$$9\|Q_-v\|^2 + 8\|Q_+v\|^2 = 17 \cdot 73\|v\|^2 = 1241\|v\|^2, \qquad v = \frac{Q_-v + Q_+v}{17}.$$

For $s_{+,a}(v) = \|Q_{+,a}v\|^2/\|v\|^2$,

$$s_{+,a} = p(a) + 3(a+1)w, \qquad (a+1)s_{-,a} + as_{+,a} = (2a+1)p(a).$$

Cancellation holds even with a fixed component. The bilateral composition is a formalization on antecedent operators, not an assertion that every TPK return is automatically this pair.

If $\mathcal{V} : H \to \mathcal{M}$ is a complete isometric memory, $U^{\mathcal{V}} = \mathcal{V}U\mathcal{V}^*$ satisfies $(U^{\mathcal{V}})^3 = \Pi_{\mathcal{M}}$, where $\Pi_{\mathcal{M}} = \mathcal{V}\mathcal{V}^*$ is the identity on the image. There the transported Gram matrix is

$$(Q_{-,a}^{\mathcal{V}})^* Q_{-,a}^{\mathcal{V}} = p(a)\Pi_{\mathcal{M}} - 3a\mathcal{V}P_0\mathcal{V}^*.$$

It preserves the readings and bilateral recovery. Using diagonal copies of U is legitimate only when the channels intertwine that action; otherwise transport by $\mathcal{V}$ is the correct definition on the image.

145.8 Fine-structure coordinate and integer iterations

The complete alpha reader, with carry, supplies the block prefix

$$(007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 662, 999, \ldots).$$

The zero-boundary window ending in 663 is a different object; it is not interchanged with the complete output. The inherited closed interval suffices for the test:

$$\frac{729735256928380099728510547238 0662}{10^{36}} \le \alpha_A \le \frac{729735256928380099728510547238 0663}{10^{36}}. \tag{145.19}$$

The constant is not identified with either of its rational endpoints. Put $s_\alpha = 10^4 \alpha_A$, so that

$$\begin{aligned} \ell \le s_\alpha \le h, \\ \ell := 72.973525692838009972851054723806 62, \\ h := 72.973525692838009972851054723806 63. \end{aligned} \tag{145.20}$$

The inverse condition for the fixed reader is exactly

$$s(v) = s_\alpha \quad \Longleftrightarrow \quad w(v) = \frac{73 - s_\alpha}{24} \simeq 0.00110309613175. \tag{145.21}$$

None of the six states in section 145.6 satisfies this condition. The second memory has $s = 73$, whereas the other five have $s < 72$. This last inequality is verified exactly as $24b_v > a_v$. In the three rational rows, multiplying integers suffices; for u and q_K, the differences are

$$24b_u - a_u = \frac{66073183}{20} + \frac{5235904}{5}\sqrt{5} > 0,$$

$$24b_{q_K} - a_{q_K} = \frac{45259241}{15} - \frac{5235904}{5}\sqrt{5} > 0.$$

For the second, $\sqrt{5} < 5/2$ already gives a positive lower bound. The exclusion concerns this reader and these states; it does not declare a global absence of relations with alpha.

Since $0 < s_\alpha < 73$, the radius

$$r_\alpha = \frac{4\sqrt{s_\alpha}}{81} < \frac{4\sqrt{73}}{81}$$

is a valid conservative guarantee, but it is not the optimal radius of the canonical reader. Any number between zero and 73 would likewise give a smaller guarantee. If $a^2 + a + 1 = s_\alpha$ were imposed by changing a, then $\sqrt{2a}$ and $(a+1)^2$ would also change; one cannot replace only 73 and retain 4 and 81 as though the operator had not changed.

Theorem 145.13 (Exact weight iteration and reading recurrence)**.** *Let $v_n = Q_{-,a}^n v_0$, $a > 0$, and $b = (a-1)^2$. When $v_n \neq 0$,*

$$w_n = \frac{b^n w_0}{b^n w_0 + p(a)^n (1 - w_0)}. \tag{145.22}$$

For $a \neq 1$ and $0 < w_0 < 1$,

$$\frac{w_n}{1 - w_n} = \left(\frac{b}{p(a)}\right)^n \frac{w_0}{1 - w_0}, \quad w_n \downarrow 0, \quad s_n \uparrow p(a),$$

and

$$s_{n+1} = p(a) + b - \frac{bp(a)}{s_n}, \qquad s_{n+1} - s_n = \frac{(s_n - b)(p(a) - s_n)}{s_n} > 0. \tag{145.23}$$

Proof. The operator and its adjoints preserve the two orthogonal sectors. By (145.9), the squared norm in the fixed sector is multiplied by b at each step, and that in the complementary sector by $p(a)$. This gives (145.22) and the weight ratio. Since $p(a) - b = 3a > 0$, monotonicity and the limit are strict in the mixed case. Finally, $s_n = \|v_{n+1}\|^2/\|v_n\|^2$; the sequence of norms is a combination of b^n and $p(a)^n$, satisfying $a_{n+2} = (p(a) + b)a_{n+1} - bp(a)a_n$. Division by a_{n+1} gives the recurrence, and factoring its difference gives (145.23). □

If $a = 1$, the fixed sector vanishes at the first step. When the complement is nonzero, the subsequent reading is exactly three; a purely fixed state is transformed into zero and its quotient ceases to be defined. For $a \neq 1$, the inverse iteration satisfies $s_{n-1} = bp(a)/(p(a) + b - s_n)$ and decreases the mixed reading. Reversing the orientation $U \mapsto U^{-1}$, by contrast, leaves the sequence of norms of the forward iterations unchanged. Powers of $Q_{+,a}$ multiply the weight ratio by $((a+2)^2/p(a))^n > 1$ and decrease $s_{-,a}$ in mixed states. These are actual filters of the state, not chart changes or a TPK temporal trajectory identified by definition.

Proposition 145.14 (Complete test of all integer iterations)**.** *For $a = 8$, no integer iteration $Q_-^n v$, $n \geq 0$, with $v = K, k, m_0$, satisfies $s = s_\alpha$. The only crossings of the target interval occur between indices* 21, 22*,* 14, 15*, and* 15, 16*, respectively. For $v = m_1$, the reading remains exactly 73 in every iteration.*

Proof. Define the rational endpoints of the target weight:

$$w_L = \frac{73 - h}{24} = \frac{2647430716199002714894527619337}{240000000000000000000000000000000},$$

$$w_H = \frac{73 - \ell}{24} = \frac{4412384526998337858157546032 23}{400000000000000000000000000000000}.$$

For $w_0 = A/(A + B)$, the exact formula is $w_n = A49^n/(A49^n + B73^n)$. The data and crossings are

v	A	B	N
K	10684363	2069408	21
k	3512283	8277632	14
m_0	1052377	1837634	15

and satisfy, in each row,

$$\frac{A49^N}{A49^N + B73^N} > w_H > w_L > \frac{A49^{N+1}}{A49^{N+1} + B73^{N+1}}.$$

These are integer inequalities: for example, if $w_H = p_H/q_H$, the first is equivalent to $(q_H - p_H)A49^N > p_H B73^N$, and the last is verified analogously with w_L. Substitution of the three rows and the displayed integers proves the strict crossings without rounding alpha. Strict monotonicity in theorem 145.13 excludes all preceding and subsequent indices; between N and $N + 1$ there is no other integer. For m_1, $w_0 = 0$ remains zero by (145.22). □

For numerical reference, the readings on either side of the crossings are

v	s_N	s_{N+1}
K	72.97136264842803	72.98077012438719
k	72.96167997982852	72.97426483341773
m_0	72.96527892867391	72.97668298511348

The proof covers all $n \geq 0$, not only a finite sample. The inverse orientation gives the same crossings; positive powers of Q_+ and inverse powers of Q_- decrease the initial readings, already less than 72, and

likewise do not reach the target in these three families. The mixed products $Q_-^n Q_+^m$ constitute another two-index class, with weight ratio $(49/73)^n(100/73)^m w_0/(1-w_0)$; they are not excluded by the preceding one-parameter proof, nor are indices chosen here to fit alpha.

145.9 Angular reciprocity and the existing regional correction

The chart changes of proposition 145.11 include the reciprocity and elliptic deformation already constructed. In a plane realized by M_η, the transported form is $M_\eta^{-T} M_\eta^{-1}$; similarity does not change the eigenvalues of the cycle. Retaining the previous Euclidean product after changing the chart would define another observable. The involution $q_+ \leftrightarrow q_-$ preserves A, reverses C^* and sends η_{el} to $-\eta_{\mathrm{el}}$. The polar relation of the ellipse $\tan\phi = e^{-\eta_{\mathrm{el}}}\tan\theta$ changes the parametrization of the curve, not the spectral phase of a similar transport. It does not add a small phase to S^4.

Incidence conjugation has a different type. Its block law preserves

$$z_m^{\dagger} = z_{\rho(m)} + 100\mathbf{1}_{\{c_{\rho(m)}\neq 0\}} - 20c_{\rho(m)}, \qquad c_m = [C_m]_{10},$$

with the boundary terms before decimal reduction. In general, it is not an isometry of the block vector. Applying it to the register requires its connection to the incidence register and its endpoints; it is not replaced by an invented angular correction.

Proposition 145.15 (Regional correction of the counter-angle)**.** *The antecedent action and angle coordinates satisfy*

$$A_{\mathrm{deg}} = 1000\alpha_A, \qquad C^*_{\mathrm{ret,deg}} = 2(\eta_{\mathrm{ret}} + \alpha_A), \qquad C^*_{\mathrm{pre,deg}} = 2(H_5 + \alpha_A),$$

$$\eta_{\mathrm{ret}} = H_5 - \frac{90}{\pi}C_\pi(\alpha_A), \quad C_\pi(\alpha_A) = 169\alpha_A^6 + \frac{D_A\alpha_A^7}{1-D_A\alpha_A}, \qquad D_A = \exp(-100\pi\alpha_A/9).$$

The difference in radians is exactly

$$\theta_{C,\mathrm{pre}} - \theta_{C,\mathrm{ret}} = C_\pi(\alpha_A).$$

Proof. The difference in degrees is $2(H_5 - \eta_{\mathrm{ret}}) = 180C_\pi/\pi$. Multiplication once by $\pi/180$ gives the result. □

Here π and α_A are the coordinates already generated; H_5 and the remaining readers retain their antecedent definitions, not a recalibration. The subsequent evaluations are

coordinate	radians, approximately
θ_A	0.127362829013
θ_C	0.0370662264658
$\theta_C/6$ in each antipodal pair	0.00617770441097
C_π	$2.55207421805 \cdot 10^{-11}$

The channels $q_\pm$ are positive real attenuations; their exponent does not automatically become a unitary phase through a factor i. No additional divisors are introduced to approximate the scales of the following test.

145.10 Angular inverse problem in the dodecaphasic register

For a general target $s \in [49, 81]$, the principal orientation of the pure sector is obtained from

$$|8 - e^{i\theta}|^2 = 65 - 16\cos\theta, \qquad \theta(s) = \arccos\frac{65 - s}{16} \in [0, \pi].$$

In particular, the subsequent datum s_α determines

$$\theta_\alpha = \theta(s_\alpha), \qquad \delta_\alpha = \frac{2\pi}{3} - \theta_\alpha.$$

This formula solves an inverse problem using an output already produced; it does not claim to produce alpha anew.

Lemma 145.16 (Angular structure of the ternary complement)**.** *The operator $J = (U - U^2)/\sqrt{3}$ satisfies*

$$J^* = -J, \quad J^2 = -P, \quad JP_0 = P_0J = 0, \quad JP = PJ = J, \qquad U = P_0 - \frac{1}{2}P + \frac{\sqrt{3}}{2}J.$$

Proof. The adjoint exchanges U, U^2. Moreover, $(U-U^2)^2 = U+U^2-2I = -3P$, and $(I+U+U^2)(U-U^2) = 0$. The remaining relations follow from $P = I - P_0$; adding $(U + U^2)/2$ and $(U - U^2)/2$ gives the final expression. □

Theorem 145.17 (Angular family and preserved properties)**.** *For $\theta \in \mathbb{R}$, define*

$$U_\theta = P_0 + \cos\theta\, P + \sin\theta\, J, \qquad Q_{-,\theta} = 8I - U_\theta.$$

One has

$$U_\theta^* U_\theta = I, \qquad U_\theta U_\varphi = U_{\theta+\varphi}, \qquad U_{2\pi/3} = U,$$
$$Q_{-,\theta}^* Q_{-,\theta} = 49P_0 + (65 - 16\cos\theta)P. \tag{145.24}$$

The readers $T_\theta = (8I + U_\theta)/9$, $D_\theta = \sqrt{8}(U_\theta - I)/9$ preserve $T_\theta^* T_\theta + D_\theta^* D_\theta = I$. By contrast,

$$U_\theta^3 = I \iff 3\theta \in 2\pi\mathbb{Z}, \qquad \det Q_{-,\theta} = 7^4(65 - 16\cos\theta)^4.$$

Proof. The relations in lemma 145.16 cancel the terms between sectors. On the complement, $J^2 = -I$, so that $U_\theta^* U_\theta = P_0 + (\cos^2\theta + \sin^2\theta)P = I$. Multiplying two expressions and using the addition formulas gives the composition law. The expression for U in the lemma gives the ternary value. Since $U_\theta + U_\theta^* = 2P_0 + 2\cos\theta P$, expanding the Gram matrix gives (145.24). The expansions

$$81T_\theta^* T_\theta = 65I + 8(U_\theta + U_\theta^*), \qquad 81D_\theta^* D_\theta = 16I - 8(U_\theta + U_\theta^*)$$

prove the balance. The composition law gives $U_\theta^3 = P_0 + \cos(3\theta)P + \sin(3\theta)J$, which is the identity exactly under the indicated condition.

For the determinant, $Q_{-,\theta}$ acts by 7 on the four fixed dimensions. On the complement, a unit vector e and Je form an orthonormal pair; their orthogonal complement is stable under J. Repeating this yields four planes, on each of which the determinant is $(8 - \cos\theta)^2 + \sin^2\theta = 65 - 16\cos\theta$. Multiplying the contributions proves the formula. □

Corollary 145.18 (Inverse solution and separation of corrections)**.** *On $\operatorname{im} P$, the reader Q_{-,θ_α} has quadratic ratio exactly s_α. The orientations $\pm\theta_\alpha$ give the same ratio, and*

$$73 - s_\alpha = 8(1 - \cos\delta_\alpha + \sqrt{3}\sin\delta_\alpha).$$

We have $U_{\theta_\alpha}^3 \neq I$, and $\delta_\alpha \neq C_\pi(\alpha_A)$.

Proof. The definition of the phase solves for the complementary coefficient in (145.24); cosine is even. Substituting $\theta_\alpha = 2\pi/3 - \delta_\alpha$ gives the stable identity for the difference. Since $72 < s_\alpha < 73$, $\pi/2 < \theta_\alpha < 2\pi/3$ and $0 < 3\delta_\alpha < \pi/2$; hence $3\theta_\alpha$ is not a multiple of 2π.

The separation of corrections can be proved without relying on approximate figures. The interval gives $73 - s_\alpha > 0.026$. If $\delta_\alpha \leq 10^{-3}$, the inequalities $1 - \cos t \leq t^2/2$, $\sin t \leq t$, and $\sqrt{3} < 2$ would give

$$73 - s_\alpha \leq 8(10^{-6}/2 + 2 \cdot 10^{-3}) = 0.016004,$$

a contradiction. Thus $\delta_\alpha > 10^{-3}$. On the other hand, $0 < \alpha_A < 10^{-2}$, $0 < D_A < 1$ imply

$$0 < C_\pi(\alpha_A) < 169 \cdot 10^{-12} + \frac{10^{-14}}{1 - 10^{-2}} < 170 \cdot 10^{-12} < 10^{-7}.$$

The two quantities are distinct. □

The diagnostic evaluation gives

$$\delta_\alpha \simeq 0.00190956706826 \text{ rad} \simeq 0.109410133709^\circ, \qquad \theta_\alpha \simeq 119.890589866291^\circ.$$

The regional correction is approximately $7.48 \cdot 10^7$ times smaller. The inverse family preserves orthogonality and balance, but loses order three at that phase and changes the original determinant. Its real chart does not by itself provide an integer matrix or the lattice quotient of index 73. Solving the prescribed datum does not prove $73 = 10^4 \alpha_A$.

Proposition 145.19 (Reachability with the state preserved)**.** *For $v \neq 0$, with $w = w(v)$ fixed,*

$$s_\theta(v) = 49w + (65 - 16\cos\theta)(1 - w).$$

If $w < 1$, its image is exactly $[49, 81 - 32w]$. Hence a phase attaining s_α exists if and only if

$$w \leq \frac{81 - s_\alpha}{32} \simeq 0.250827322099.$$

When it exists, its principal orientation is

$$\theta_v = \arccos\left[\frac{1}{16}\left(65 - \frac{s_\alpha - 49w}{1 - w}\right)\right].$$

If $w = 1$, the reading is always 49 and does not reach the target.

Proof. Evaluating (145.24) and dividing by $\|v\|^2$ gives the formula. Cosine ranges over $[-1, 1]$, so the complementary coefficient ranges over $[49, 81]$. Its combination with the fixed weight gives the entire interval, without gaps. Solving the equality and checking the domain of arccosine gives the condition and the phase. The case $w = 1$ is evaluated without dividing by $1 - w$. □

Corollary 145.20 (Four impossibilities and two possible phases)**.** *Keeping the state and the fixed sector, the angular family does not attain s_α on K, k, m_0, u. It does attain it on m_1 and q_K.*

Proof. From the exact table (145.12), we obtain

v	$32b_v - 9a_v$
K	$227115677/3$
k	$2094607/4$
m_0	$122655440/243$
u	$37201759/20 + (7859008/15)\sqrt{5}$

All entries are positive. Thus $w > 9/32$, and the maximum $81 - 32w$ is less than $72 < s_\alpha$. For m_1, $b_{m_1} = 0$ and $a_{m_1} > 0$, so the interval is $[49, 81]$. For q_K,

$$a_{q_K} - 4b_{q_K} = \frac{588839 + 1195712\sqrt{5}}{15} > 0.$$

Hence $w(q_K) < 1/4$ and its maximum is greater than $73 > s_\alpha$. In both cases, the target belongs to the reachable interval. □

The evaluations of the maxima and, where they exist, the phases are

v	$\max_\theta s_\theta(v)$	θ_v
K	54.1922726227	does not exist
k	71.4670172771	does not exist
m_0	69.3474270513	does not exist
u	66.8296175021	does not exist
m_1	81	119.8905898663°
q_K	77.3923674871	133.5296853010°

The phase of the pure sector cannot be used indiscriminately for a mixed state: its reading would be $49w + s_\alpha(1-w) = s_\alpha - (s_\alpha - 49)w$. The original readers of V_2 are polynomials in S, such as P_0, P, J, U_θ. They therefore also intertwine the angular family, and $s_\theta(V_2 v) = s_\theta(v)$. Archiving the complements preserves the joint reading, but does not remove the reachability restrictions.

145.11 Composition of readers and scope of inverse problems

The factor 73 has been determined by three compatible and distinct operations: the Gram matrix of two nonadic readers, the similarity of the ternary augmentation module and the integer determinants of the two conjugate charts. Bilateral balance preserves the complete state and admits explicit inversion; complete memory preserves the transported readings, while selecting a channel can change their weights. The correction radii are uniform over all integer registers in the algebraic domain and throughout the family $a > 0$, with cut and parity proofs that do not depend on sampling.

The inverse test adds verifiable conditions, not a hidden calibration. Orientation inversion and metric covariance do not change the reading. The specified integer iterations are resolved for all their indices by an exact crossing and monotonicity. Angular variation produces a family that realizes the target in the allowed states, but the datum s_α selects its phase and the original ternary index is lost. Its identification with a prior realization of Γ_9 would require a typed composition on the enriched state; this test neither provides such an identification nor declares its absence throughout the corpus.

The new formalizations assemble antecedent operators and questions; no claim of worldwide priority is made for encoding, the use of cyclic vectors, or polar decomposition. The decimal figures presented are subsequent evaluations of exact formulas. The conditions of nonvanishing, charge, metric, lattice, and normalization are part of the result, and their counterexamples remain alongside the proofs. The function of the holographic arithmetic-geometric coupling constant is thereby preserved: a produced object that articulates readers, memory, and incidence, without turning every numerical coincidence into a new physical law.

Chapter 146

Conservative refinement of unity and carry memory

Dimensional completion and the record of operations admit an explicit arithmetic composition. The APP–TRIT–TPK architecture first provides the enriched state, the oriented readings, and the completions of unity. From these outputs we construct an affine transport that preserves the normalized sum and permits recovery, by Euclidean division, of every finite word of canonical carries. Its limit has cylinders of controlled diameter; boundary marks distinguish the histories that a scalar evaluation identifies.

The central block, its concatenations, and the partition $1000 = 729 + 243 + 27 + 1$ are antecedents of this construction. The composition of these objects with the affine transport, the residue inverse, and its prolongation constitutes the formalization developed in this section. The map acts on a declared arithmetic domain. Each realization on a particular enriched history also retains the prospective rule that produces its carries.

146.1 Relation between quadratic norm and cubic completion

Let $b \geq 1$ be an integer and $B = b + 1 \geq 2$. Define

$$p_b = b^2 - b + 1, \qquad q_b = B^2 - p_b = 3b. \tag{146.1}$$

Proposition 146.1 (Transfer of the completion)**.** *The identities*

$$Bp_b = b^3 + 1, \qquad Bq_b + 1 = B^3 - b^3 \tag{146.2}$$

determine the transformation

$$(p_b, q_b) \longmapsto (Bp_b - 1, Bq_b + 1) = (b^3, B^3 - b^3). \tag{146.3}$$

The sum changes from B^2 to B^3, while the sum of the coordinates divided by their respective scales remains equal to one.

Proof. The factorization $b^3 + 1 = (b + 1)(b^2 - b + 1)$ yields the first identity. The second follows from $(b + 1)^3 - b^3 = 3b^2 + 3b + 1$. Adding them proves the change of scale and, after division by B^3, the conservation of normalized unity. □

Para $b = 9$,

$$(73, 27) \longmapsto (10 \cdot 73 - 1, 10 \cdot 27 + 1) = (729, 271). \tag{146.4}$$

The complement preserves the decomposition $271 = 243 + 27 + 1$. In the preceding completion, the last contribution corresponds to the added apex. The correction $(-1, +1)$ has zero sum, and multiplication by ten transforms the scale of one hundred into that of one thousand. For the complete family, the transport of proportions is

$$\left(\frac{p_b}{B^2}, \frac{q_b}{B^2}\right) \longmapsto \left(\frac{p_b}{B^2} - \frac{1}{B^3}, \frac{q_b}{B^2} + \frac{1}{B^3}\right). \tag{146.5}$$

The quantity preserved by this identity is a linear sum. Quadratic forms and physical quantities have their own readers, which will subsequently be composed with this transport.

146.2 Concatenations of the central block and restoration of unity

For $b \geq 2$, the digits $b-2$ and 2 belong to the alphabet of base $B = b+1$. Consider the algebraic family

$$B_c^{(b)} = \begin{pmatrix} b-2 & 2 \\ 2 & b-2 \end{pmatrix}, \qquad C_B(u,v) = Bu + v. \tag{146.6}$$

The case $b = 9$ recovers the documented central block $\left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$, with eigenvalues 9 and 5. Its concatenations satisfy $72 + 27 = 77 + 22 = 99$. Concatenation, spectrum, and central position are distinct readings of the same antecedent and retain their domains.

Applying the reader to the rows of (146.6) gives

$$C_B(b-2, 2) = B(b-2) + 2 = b(b-1) = p_b - 1, \tag{146.7}$$

$$C_B(2, b-2) = 2B + (b-2) = 3b = q_b. \tag{146.8}$$

The sum is $B^2 - 1$. Restoring one unit in the first coordinate and performing the subsequent transfer yields

$$(p_b - 1, 3b) \xrightarrow{+(1,0)} (p_b, 3b) \xrightarrow{L_1} (b^3, B^3 - b^3). \tag{146.9}$$

In particular,

$$(72, 27) \longmapsto (73, 27) \longmapsto (729, 271). \tag{146.10}$$

The first arrow increases the sum by one. The second changes the scale and redistributes one unit through a zero-sum correction. To represent the contribution explicitly before incorporating it, the triple $(p_b - 1, 3b, 1)$ already has sum B^2, and the map $(x, y, r) \mapsto (x + r, y, 0)$ preserves that sum. Its inversion requires retaining the datum $r = 1$: on arbitrary triples the map is not injective.

Restitution is thus recorded without attributing to it a closed conservation of the pair before incorporating the unit. The family in b algebraically extends the received central case; the selection of atlas states remains that established by APP–TRIT–TPK. The composition (146.9) determines a carry equal to one in that transition, leaving open the prospective specification of subsequent operations.

146.3 Affine transport and the positivity domain

Definition 146.2 (Transport with carry)**.** For an integer base $B \geq 2$ and $c \in \mathbb{Z}$, define

$$L_c(x, y) = (Bx - c, By + c). \tag{146.11}$$

The integer c specifies the oriented transfer between the two coordinates. A positive sign reduces the first relative to Bx and increases the second by the same amount.

Proposition 146.3 (Inverse and positivity)**.** *In the subsequent affine realization $\mathbb{R}^2$, with B, c fixed,*

$$L_c^{-1}(X, Y) = \left(\frac{X + c}{B}, \frac{Y - c}{B} \right), \qquad X + Y = B(x + y). \tag{146.12}$$

The preimage is integral exactly when $X + c$ and $Y - c$ are divisible by B. For $x, y \geq 0$, the image is nonnegative exactly when

$$-By \leq c \leq Bx. \tag{146.13}$$

Proof. Direct substitution proves both identities in (146.12) and the integrality criterion. The inequalities $Bx - c \geq 0$, $By + c \geq 0$ are equivalent to (146.13). □

For the canonical alphabet $c \in \{0, \dots, B-1\}$, all prolongations are admissible if $x \geq 1$, $y \geq 0$. At the boundary $x = 0$, nonnegativity permits only $c = 0$. The positive domain and the general integer domain are thus distinguished by an explicit condition.

146.4 Canonical recovery through the residue

Theorem 146.4 (Canonical inverse by residue)**.** *Let $M \geq 1$ be an integer and let $X, Y \geq 0$ be integers such that $X + Y = BM$. There is a unique admissible triple (x, y, c) satisfying*

$$x + y = M, \qquad 0 \leq c \leq B-1, \qquad L_c(x, y) = (X, Y).$$

It is obtained from

$$c = Y \bmod B = (-X) \bmod B, \qquad y = \frac{Y - c}{B}, \qquad x = \frac{X + c}{B}. \tag{146.14}$$

Proof. Every preimage satisfies $Y \equiv c \pmod{B}$. The representative in $\{0, \dots, B-1\}$ is unique. The congruence $X + Y \equiv 0 \pmod{B}$ implies the divisibility of $X + c$. Euclidean division of Y gives $y \geq 0$, and $X + c \geq 0$ gives $x \geq 0$. If $c > 0$, the case $x = 0$ would require $X = -c < 0$, so the resulting triple belongs to the admissible domain. Its sum is M, and substitution into (146.11) recovers (X, Y). Uniqueness of the residue and the two quotients proves uniqueness of the triple. □

The integer pair and its scale contain the last canonical carry. Its recovery follows from the residue and does not require retaining another independent copy of that carry. There are $M + 1$ triples with $c = 0$ and M triples in each of the remaining $B - 1$ classes: the total is $BM + 1$, equal to the number of nonnegative pairs with sum BM.

For a general integer carry, write $c = r + B\ell$, with $0 \leq r \leq B - 1$. The residue determines r, whereas complete reconstruction also uses the lift ℓ:

$$y = \frac{Y - r}{B} - \ell, \qquad x = \frac{X + r}{B} + \ell. \tag{146.15}$$

Retaining the lift distinguishes the signed carry from its residual reduction.

146.5 Variable iteration and complete finite memory

Fix $(x_0, y_0) \in \mathbb{Z}^2$, with sum $M_0 > 0$, and a sequence of operations $c_1, c_2, \dots$. Define

$$(x_n, y_n) = L_{c_n} \cdots L_{c_1}(x_0, y_0), \qquad C_n = \sum_{j=1}^{n} c_j B^{n-j}, \qquad C_0 = 0. \tag{146.16}$$

The carries are supplied by the corresponding operational rule; the limit value does not participate in their selection.

Theorem 146.5 (Exact accumulated record)**.** *For every $n \geq 0$,*

$$\begin{aligned} x_n &= B^n x_0 - C_n, & y_n &= B^n y_0 + C_n, \\ x_n + y_n &= B^n M_0, & C_{n+1} &= BC_n + c_{n+1}. \end{aligned} \tag{146.17}$$

Proof. For $n = 0$, the identities are immediate. If they hold at n, applying $L_{c_{n+1}}$ multiplies all previous contributions by B and adds c_{n+1} to the accumulated carry. This gives the recurrence and, by substitution, both coordinates of the next stage. Their sum eliminates C_n. □

When the carries are canonical,

$$0 \le C_n \le B^n - 1. \tag{146.18}$$

In particular, $x_0 \ge 1$, $y_0 \ge 0$ guarantee $x_n \ge B^n(x_0 - 1) + 1$ and $y_n \ge 0$ at every stage.

Corollary 146.6 (Recovery of the complete word)**.** *Given B, n and the final pair, a finite canonical history recovers its input and all its carries through*

$$C_n = y_n \bmod B^n, \qquad y_0 = \left\lfloor \frac{y_n}{B^n} \right\rfloor, \qquad x_0 = \frac{x_n + C_n}{B^n}, \tag{146.19}$$

$$c_j = \left\lfloor \frac{C_n}{B^{n-j}} \right\rfloor \bmod B, \qquad 1 \le j \le n. \tag{146.20}$$

Proof. The bound (146.18) makes $y_n = B^n y_0 + C_n$ a Euclidean division. Its quotient and residue give y_0, C_n; the first coordinate gives x_0. Successive divisions of C_n by powers of B recover the digits. Equivalently, apply (146.14) from the last step to the first. □

The depth retains the leading zeros of the word, even though they do not change the integer C_n. If M_0 is stored instead of n, the exact equality $(x_n + y_n)/M_0 = B^n$ recovers the depth. Normalizing the pair to sum to one removes that scale counter unless it is retained by another reading.

146.6 Block composition and compatibility with the partition

A block of n operations, with accumulated carry C, acts by

$$L_C^{[n]}(x, y) = (B^n x - C, B^n y + C). \tag{146.21}$$

The composition of two blocks satisfies

$$L_D^{[m]} \circ L_C^{[n]} = L_{B^m C + D}^{[n+m]}. \tag{146.22}$$

Indeed, substituting the first image into the second multiplies its accumulated carry by B^m and adds D. The law

$$(n, C), (m, D) \longmapsto (n + m, B^m C + D)$$

is associative by composition of maps. It expresses the contribution of the first block at the scale of the second and preserves the output when the same ordered events are regrouped. Adding new events changes the accumulated carry according to this same law.

146.7 Convergence and quantitative control of the reading

Write $M_n = B^n M_0$ and

$$f_n = \frac{x_n}{M_n}, \quad g_n = \frac{y_n}{M_n}, \quad \theta_n = \frac{C_n}{B^n} = \sum_{j=1}^{n} \frac{c_j}{B^j}. \tag{146.23}$$

The exact identities are

$$f_n = \frac{x_0}{M_0} - \frac{\theta_n}{M_0}, \qquad g_n = \frac{y_0}{M_0} + \frac{\theta_n}{M_0}, \qquad f_n + g_n = 1. \tag{146.24}$$

Theorem 146.7 (Convergence of bounded carries)**.** *If $|c_j| \le C$ for every j, the series $\theta = \sum_{j \ge 1} c_j B^{-j}$ converges absolutely. The readings f_n, g_n converge to f, g, with $f + g = 1$, and*

$$|f - f_n| = |g - g_n| \le \frac{C}{M_0 (B - 1) B^n}. \tag{146.25}$$

Proof. The absolute tail satisfies

$$\sum_{j>n} \frac{|c_j|}{B^j} \le C \sum_{j>n} B^{-j} = \frac{C}{(B-1)B^n}.$$

Convergence of the geometric series and (146.24) prove all the assertions. □

For carries of both signs, a sufficient condition for positivity at every stage is $x_0, y_0 \ge C/(B-1)$. For the canonical alphabet, $x_0 \ge 1, y_0 \ge 0$ suffices. In this second case, $0 \le \theta \le 1$, f_n decreases and g_n increases, and

$$0 \le f_n - f = g - g_n \le \frac{1}{M_0 B^n}. \tag{146.26}$$

The sum remains fixed while the individual proportions evolve. The finite history remains recoverable when the integer coordinates and the scale are retained.

146.8 Compatible cylinders and boundary multiplicity

Consider the full canonical alphabet and an input $x_0 \ge 1, y_0 \ge 0$. A prefix of depth n, with accumulated carry C_n, admits exactly the limit values

$$I_n(C_n) = \left[\frac{C_n}{B^n}, \frac{C_n + 1}{B^n}\right] \tag{146.27}$$

of the reading θ.

Theorem 146.8 (Nested cylinders and distinction of histories)**.** *The B child cylinders of $I_n(C_n)$ cover the parent and overlap only at endpoints. The cylinders of an infinite history have diameter B^{-n} and a single-point intersection. Two different canonical histories produce the same value if and only if, at their first differing position, their digits differ by one and the subsequent tails are, respectively, all $B-1$ for the smaller digit and all zero for the larger.*

Proof. The child associated with c has endpoints $(BC_n + c)/B^{n+1}$ and $(BC_n + c + 1)/B^{n+1}$. These expressions prove inclusion, coverage and overlap only at endpoints. The tail of an expansion ranges over the interval $[0, B^{-n}]$; successively choosing one of the children produces an expansion of each point in that interval. The nested closed intervals have diameters tending to zero, which proves existence and uniqueness of the intersection for each history.

Let k be the first differing position and let $d_k > c_k$. If the readings coincide,

$$\frac{d_k - c_k}{B^k} = \sum_{j>k} \frac{c_j - d_j}{B^j} \le \sum_{j>k} \frac{B-1}{B^j} = \frac{1}{B^k}.$$

The positive integer difference $d_k - c_k$ must equal one. Equality in the tail bound requires $c_j = B-1$, $d_j = 0$ for every $j > k$. Conversely, those tails differ by exactly B^{-k}, which compensates for the first digit. This proves the complete characterization. □

The image of the cylinder for f has diameter $1/(M_0 B^n)$, matching (146.26). The histories $(1, 0, 0, \ldots)$ and $(0, B-1, B-1, \ldots)$ both produce $\theta = 1/B$, while retaining distinct prefixes and finite integer states. A boundary mark retains both provenances. A convention excluding tails eventually constant at $B-1$ selects one expansion for $\theta < 1$; the endpoint $\theta = 1$ is retained separately, since in the fractional alphabet it corresponds to the constant tail $B-1$.

The history of operations, the cylinder system, and the limit value are objects related by these maps. The uniqueness of a history's reading coexists with multiplicity of histories at boundary values.

146.9 Signed carries and prospective specification

Allowing carries outside the canonical alphabet requires retaining their lifts. Already in two steps, the words

$$(c_1, c_2) = (1, -1), \qquad (d_1, d_2) = (0, B - 1)$$

produce $C_2 = B - 1$ and the same final pair. Both are bounded by $B - 1$ and can preserve positivity, for example starting from $(73, 27)$ in base ten. The signed word, or the lifts in (146.15), distinguishes that information. The convergence theorem remains valid for both words; the canonical inverse, however, has the domain specified in its statement.

The transition (146.4) fixes $c_1 = 1$. An additional rule imposing $c_j = 1$ for every j gives

$$\theta_n = \frac{1 - B^{-n}}{B - 1}, \qquad \theta = \frac{1}{B - 1}. \tag{146.28}$$

In base ten, starting from $(73, 27)$, the sequence is

$$(73, 27) \longmapsto (729, 271) \longmapsto (7289, 2711) \longmapsto (72889, 27111),$$

and the first fraction converges to

$$\frac{73}{100} - \frac{1}{900} = \frac{164}{225} = 0{,}728888\ldots. \tag{146.29}$$

The conclusion belongs to that additional constant-carry rule. With only $c_1 = 1$ and nonnegative canonical prolongations, the first-step cylinder yields exactly

$$\frac{b^3 - 1}{B^3} \le f \le \frac{b^3}{B^3}. \tag{146.30}$$

In base ten it is $[0{,}728, 0{,}729]$. Changing the sign or the alphabet changes this family and requires preserving the corresponding additional memory. The presence of 729 in the completion determines the written arithmetic transition; identification with another reader of constants also uses its effective generation rule and its intertwining.

146.10 Operator realization and transport amplitudes

The resulting procedure comprises updating through (146.11), local residue checking, reconstruction of every canonical word through (146.20), control of the limit reading through (146.25), and regrouping of events through (146.22). Each operation retains the order and scale counter used by its inverse.

Conservation of the sum and quadratic conservation have different forms. For a normalized transfer $\delta = c/(BM)$,

$$(f - \delta)^2 + (g + \delta)^2 - (f^2 + g^2) = 2\delta(g - f) + 2\delta^2. \tag{146.31}$$

This expression determines the quadratic variation and is generally nonzero. The connection with an isometry will be obtained on the amplitudes of the admissible labels, through the residue bijection of chapter 148. Arithmetic transport and its unitary realization are thus composed while retaining their respective quantities, rather than being identified through a scalar coincidence.

Chapter 147

Bilateral conservation and arithmetic-geometric transduction

The holographic arithmetic-geometric coupling constant denotes the generated register K, with its ordered windows, phase origin, orientation and incidences. Its production through the signed register and Hadamard inversion is developed in section 11.4. The rational reading κ, the orbital frame O_K and the operators transporting its realizations are different objects. This distinction allows their functions to be composed: generation of the register, arithmetic encoding, information transport and recovery of the geometric readings.

The regional coordinates and α are received from the APP–TRIT–TPK genealogy, from the same enriched state and its joint discrete structure of the continuum. The following constructions act on these subsequent realizations. Their additional content is a dimension-independent bilateral conservation, a reversible extension admitting incoming memory and an archiving policy with uniformly controlled recovery.

147.1 Bilateral law for two isometric transports

Let H, H' be Hilbert spaces and $\mathcal{B}, C : H \to H'$ linear isometries, so that $\mathcal{B}^*\mathcal{B} = C^*C = I_H$. The calligraphic typography distinguishes these transports from the arithmetic base of the refinement. For $a > 0$, we define

$$\begin{aligned} p &= a^2 + a + 1 = a(a+1) + 1, \\ N &= (2a+1)p = (a+1)^3 + a^3, \\ Q_- &= a\mathcal{B} - C, \qquad Q_+ = (a+1)\mathcal{B} + C. \end{aligned} \tag{147.1}$$

Theorem 147.1 (Balance of two isometric realizations)**.** *For the maps* (147.1)*,*

$$(a+1)Q_-^*Q_- + aQ_+^*Q_+ = NI_H. \tag{147.2}$$

The identity holds in every dimension, including infinite Hilbert spaces, and admits rectangular transports with common domain and codomain.

Proof. Write $X = \mathcal{B}^*C + C^*\mathcal{B}$. The isometry of both transports gives

$$\begin{aligned} Q_-^*Q_- &= (a^2+1)I - aX, \\ Q_+^*Q_+ &= ((a+1)^2+1)I + (a+1)X. \end{aligned}$$

The weights $a+1$ and a exactly cancel the terms of X. The remaining coefficient is

$$(a+1)(a^2+1) + a((a+1)^2+1) = 2a^3 + 3a^2 + 3a + 1 = N.$$

The compositions are of bounded operators and the calculation uses only their products and adjoints. The proof therefore also applies in infinite dimension. □

For $a = 8$, received from the preceding nonadic partition,

$$9\|Q_-v\|^2 + 8\|Q_+v\|^2 = (9^3 + 8^3)\|v\|^2 = 17 \cdot 73\,\|v\|^2. \tag{147.3}$$

The factor $73 = 8 \cdot 9 + 1$ normalizes this general identity. In the ternary module it is also realized as a determinant and similarity factor; each of these functions retains its own hypotheses. The balance (147.2) uses the isometries and admits both transports of finite order and transports without that property.

147.2 Factorization, recovery and compatibility of the channels

Define

$$E_a v = \frac{1}{\sqrt{p}} \begin{pmatrix} \sqrt{a(a+1)}\, \mathcal{B} v \\ C v \end{pmatrix}, \qquad R_a = \frac{1}{\sqrt{2a+1}} \begin{pmatrix} \sqrt{a} & -\sqrt{a+1} \\ \sqrt{a+1} & \sqrt{a} \end{pmatrix}. \tag{147.4}$$

The matrix R_a acts on the two channels and is understood to be tensored with $I_{H'}$. We check $E_a^* E_a = I_H$, $R_a^* R_a = I_{H' \oplus H'}$, and

$$W_a v = R_a E_a v = \frac{1}{\sqrt{N}} \begin{pmatrix} \sqrt{a+1}\, Q_- v \\ \sqrt{a}\, Q_+ v \end{pmatrix}, \qquad W_a^* W_a = I_H. \tag{147.5}$$

In the case $a = 8$, the first distribution has weights $72/73$ and $1/73$; the second operation is a rotation between the channels. This factorization expresses the role of $72 + 1$ within the total norm, distinguishing it from the linear restitution of (146.9).

Proposition 147.2 (Bilateral recovery)**.** *The unnormalized channels $x = Q_- v$, $y = Q_+ v$ determine*

$$\mathcal{B} v = \frac{x + y}{2a+1}, \qquad C v = \frac{a y - (a+1) x}{2a+1}, \qquad v = \mathcal{B}^* \frac{x+y}{2a+1}. \tag{147.6}$$

From the normalized channels we recover $v = W_a^* W_a v$, with $\|W_a^*\| = 1$ when $H \neq \{0\}$.

Proof. Adding the two definitions of $Q_\pm$ eliminates Cv. The combination $aQ_+ - (a+1)Q_-$ eliminates $\mathcal{B}v$. The first isometry has left inverse $\mathcal{B}^*$, which proves the formulas. The last assertion follows from (147.5): the adjoint of an isometry has norm one. □

The image $\operatorname{im} W_a$ is closed and its orthogonal projector is $W_a W_a^*$. A normalized pair is compatible with a unique input exactly when it belongs to this image; its orthogonal component quantifies the compatibility defect.

If $\mathcal{B} = I$ and $C = U$ is unitary, the two $Q_\pm$ are polynomials in the same operator. For the unnormalized channels, the criterion simplifies to

$$Q_+ x = Q_- y. \tag{147.7}$$

Indeed, the equality is equivalent to $U(x+y) = ay - (a+1)x$. Defining $v = (x+y)/(2a+1)$ yields by substitution $Q_- v = x$, $Q_+ v = y$. Necessity follows from the commutation of the two polynomials. This simplified form belongs to the indicated unitary domain; the image criterion covers general transports between different spaces.

147.3 Transformation of readers and relative symmetry

Theorem 147.3 (Common reader in both channels)**.** *For every bounded self-adjoint operator F on H',*

$$W_a^* \operatorname{diag}(F, F) W_a = \frac{a(a+1)\mathcal{B}^* F \mathcal{B} + C^* F C}{a(a+1)+1}. \tag{147.8}$$

If $\mathcal{B}$ is unitary and $C = \mathcal{B} R$, with R unitary, the expression, for $G = \mathcal{B}^* F \mathcal{B}$, is

$$\mathcal{T}_a(G) = \frac{a(a+1) G + R^* G R}{a(a+1)+1}. \tag{147.9}$$

We have $\mathcal{T}_a(G) = G$ if and only if $GR = RG$.

Proof. The expansion of $(a+1)Q_-^* F Q_- + a Q_+^* F Q_+$ cancels the terms $\mathcal{B}^* F C + C^* F \mathcal{B}$. The coefficients of the remaining terms are $a(a+1)(2a+1)$ for $\mathcal{B}^* F \mathcal{B}$ and $2a+1$ for $C^* F C$. Dividing by N proves

(147.8). Substituting $C = \mathcal{B}R$ produces (147.9). Equality with G is equivalent to $R^{*}GR = G$, and the unitarity of R makes it equivalent to $GR = RG$. □

The reader $F = I$ recovers the norm. For a general reader, the identity determines its transformation, and the coincidence $\mathcal{B}^{*}F\mathcal{B} = C^{*}FC = G$ guarantees its conservation in all states. In the canonical case,

$$\mathcal{T}_{8}(G) = \frac{72G + R^{*}GR}{73}. \tag{147.10}$$

This formula relates conservation and symmetry through a specific commutator. The observable that exactly transports an operator A from the domain to the complete image is $W_{a}AW_{a}^{*}$; its ambient identity is $W_{a}W_{a}^{*}$. The diagonal observable of (147.8) is another choice, whose difference is calculated by the same theorem.

147.4 Reversible update with incoming memory

Now let $\mathcal{B} = I$, $C = U$, with U unitary on the same space, and write

$$A = \frac{\sqrt{a+1}}{\sqrt{N}}Q_{-}, \qquad D = \frac{\sqrt{a}}{\sqrt{N}}Q_{+}. \tag{147.11}$$

The operators A, D are normal and commute with one another and with their adjoints, being polynomials in U and U^{*}.

Theorem 147.4 (Unitary extension)**.** *The update*

$$\mathscr{R}_{a} = \begin{pmatrix} A & -D^{*} \\ D & A^{*} \end{pmatrix} : H \oplus H \to H \oplus H \tag{147.12}$$

is unitary. Its first column is W_{a}, and an input (v, m) preserves $\|v\|^{2} + \|m\|^{2}$.

Proof. The balance gives $A^{*}A + D^{*}D = I$. Normality provides $AA^{*} + DD^{*} = I$. The cross products of $\mathscr{R}_{a}^{*}\mathscr{R}_{a}$ and $\mathscr{R}_{a}\mathscr{R}_{a}^{*}$ vanish by the preceding commutations; their two diagonals are the identity. The first column reproduces (147.5), and conservation of the joint norm is the unitary identity applied to (v, m). □

For data $z = (z_{1}, z_{2})$, the explicit inversion is

$$v_{\mathrm{rec}} = A^{*}z_{1} + D^{*}z_{2}, \qquad m_{\mathrm{rec}} = -Dz_{1} + Az_{2}. \tag{147.13}$$

The hypothesis of zero incoming memory is checked through $m_{\mathrm{rec}} = 0$. If e is a perturbation of the data, unitarity gives

$$\|e\|^{2} = \|e_{\mathrm{rec}}\|^{2} + \|e_{\mathrm{mem}}\|^{2}. \tag{147.14}$$

The second component detects the part incompatible with that input. An error belonging to $\operatorname{im} W_{a}$ has zero memory residual and alters the recovered input. Correction of the integer register also uses its discrete separation distances.

147.5 Causal reduction of the bilateral update

The preceding unitary update realizes the transport of the state and its memory in a common space. Observation of the first component admits an equivalent description that explicitly retains the contribution of the record. This description follows from the transport already constructed, with the same coefficients and orientation: memory removed from the list of variables reappears as dependence on earlier states.

Fix the operators A, D of (147.11) and a realization $H \oplus H$. For $n \geq 0$, let

$$v_{n+1} = Av_n - D^* m_n, \qquad m_{n+1} = Dv_n + A^* m_n. \tag{147.15}$$

The joint update is $\mathscr{R}_a$ and preserves $\|v_n\|^2 + \|m_n\|^2$.

Proposition 147.5 (Exact elimination of the auxiliary record)**.** *For every $n \geq 0$, interpreting the empty sum as zero,*

$$m_n = (A^*)^n m_0 + \sum_{k=0}^{n-1} (A^*)^{n-1-k} D v_k, \tag{147.16}$$

$$v_{n+1} = Av_n - D^*(A^*)^n m_0 + \sum_{k=0}^{n-1} \mathscr{K}_{n-1-k} v_k, \tag{147.17}$$

$$\mathscr{K}_j = -D^*(A^*)^j D \quad (j \geq 0). \tag{147.18}$$

The reduced equation, together with (147.16), is equivalent to the joint recurrence for the same data (v_0, m_0).

Proof. The first identity holds for $n = 0$. If it holds for n, the second equation in (147.15) gives

$$m_{n+1} = (A^*)^{n+1} m_0 + \sum_{k=0}^{n-1} (A^*)^{n-k} D v_k + D v_n,$$

which is the identity at $n + 1$. Substitution at depth n into the first equation proves (147.17). Conversely, if v_n satisfies the reduced equation and m_n is defined by (147.16), the same difference of sums proves $m_{n+1} = Dv_n + A^* m_n$; substitution recovers the other equation. □

The kernel $\mathscr{K}_j$ describes a transfer into the record, j updates within it, and re-entry into the observed component. The term $-D^*(A^*)^n m_0$ preserves the initial memory. Omitting it corresponds to the particular case $m_0 = 0$, rather than an identity of the general transport. Equation (147.17) involves only the current and earlier states. The causal character of this reduction follows from the order of the joint recurrence.

The normalization of the balance also provides an explicit estimate. Since $Q_- = aI - U$, we have $\|A\|^2 \leq r_a = (a+1)^3/((a+1)^3 + a^3) < 1$, whereas $D^* D \leq I$. Consequently,

$$\|\mathscr{K}_j\| \leq r_a^{j/2}, \qquad \sum_{j \geq 0} \|\mathscr{K}_j\| \leq \frac{1}{1 - \sqrt{r_a}}. \tag{147.19}$$

This bound controls the weight of memory in the reduced equation; the norm of the joint state remains conserved by the unitary update.

The proposition is the temporal realization of the Schur reduction in proposition 1.198. For the formal series $V(z) = \sum_{n \geq 0} v_n z^n$ and $M(z) = \sum_{n \geq 0} m_n z^n$, the recurrences yield $V = v_0 + zAV - zD^* M$ and $M = m_0 + zDV + zA^* M$. Eliminating M,

$$V(z) = \left[I - zA + z^2 D^*(I - zA^*)^{-1} D\right]^{-1} \left[v_0 - zD^*(I - zA^*)^{-1} m_0\right]. \tag{147.20}$$

The formal inverses exist because their constant terms are identities; the state series and the joint resolvent also converge for $|z| < 1$. The initial source and the effective operator transform together. A readout that also acts on m_n retains its contribution through (147.16), in accordance with (1.182).

Re-entry here updates an incoming record. By contrast, the archiving policy below retains each complement in a distinct coordinate. Each operation has its own conservation law. The kernel $\mathscr{K}_j$, Green propagators, and a dimensional force have different types: the first eliminates a state component, Green propagators solve source equations with support conditions, and the force adds a dynamical realization and its units.

147.6 Nonstationary register and uniform convergence of the terminal component to zero

At each stage let H_n, H_{n+1} be Hilbert spaces and $\mathcal{B}_n, C_n : H_n \to H_{n+1}$ isometries. The parameter $a > 0$ remains fixed. Let A_n, D_n be the normalized blocks of (147.5); we continue through the first and record the second:

$$R_0 = I, \qquad R_{n+1} = A_n R_n, \qquad m_n = D_n R_n v. \tag{147.21}$$

This policy has a domain distinct from the reintroduction of memory in (147.12); each preserves its update.

Lemma 147.6 (Uniform transfer)**.** *At every stage,*

$$\|A_n\|^2 \le r_a := \frac{(a+1)^3}{(a+1)^3 + a^3} < 1, \quad D_n^* D_n \ge (1 - r_a) I, \quad \|R_n\|^2 \le r_a^n. \tag{147.22}$$

Proof. The triangle inequality gives $\|a\mathcal{B}_n - C_n\| \le a + 1$. Its normalization provides the first bound. The difference $N - (a+1)^3 = a^3 > 0$ proves $r_a < 1$. The local balance implies $D_n^* D_n = I - A_n^* A_n$, and multiplying the bounds of the continued channels produces the estimate of R_n. □

Theorem 147.7 (Complete memory at arbitrary depth)**.** *The finite map*

$$Z_N v = (R_N v, D_0 v, D_1 R_1 v, \dots, D_{N-1} R_{N-1} v) \tag{147.23}$$

is isometric. The infinite archive

$$Z_\infty v = (D_n R_n v)_{n \ge 0} \tag{147.24}$$

belongs to the Hilbert direct sum of the output spaces and satisfies

$$\|v\|^2 = \sum_{n \ge 0} \|m_n\|^2, \qquad v = \sum_{n \ge 0} R_n^* D_n^* m_n, \qquad Z_\infty^* Z_\infty = I. \tag{147.25}$$

The inversion series converges in norm and the adjoint has norm one.

Proof. The identity $A_n^* A_n + D_n^* D_n = I$, conjugated by R_n, produces

$$R_n^* R_n - R_{n+1}^* R_{n+1} = R_n^* D_n^* D_n R_n.$$

Summing from zero to $N - 1$ gives

$$I = R_N^* R_N + \sum_{n < N} R_n^* D_n^* D_n R_n. \tag{147.26}$$

This is the Gram identity of Z_N. By (147.22), the first term tends to zero in operator norm. The limit identity proves the quadratic convergence of the archive and its isometry. The adjoint of that isometry is bounded; the truncations of every square-summable archive converge in the Hilbert direct sum, and

their image under the adjoint proves convergence of the series in (147.25). Applying it to the exact data recovers v. □

With only the first N complements, the truncated adjoint has exact residual

$$v - \sum_{n<N} R_n^* D_n^* m_n = R_N^* R_N v, \qquad \left\| v - \sum_{n<N} R_n^* D_n^* m_n \right\| \le r_a^N \|v\|. \tag{147.27}$$

If the joint data error is at most ε, the total bound is $\varepsilon + r_a^N \|v\|$. With Z_N, including its terminal, or with Z_∞, the adjoint recovers with error at most ε.

The preceding policy exhausts the terminal through the proved uniform bound. The preceding evolutions that have a positive terminal $A_\infty \neq 0$ preserve in their archive the component $A_\infty^{1/2} v$. Arbitrary depth and removal of the terminal are therefore different conclusions and retain their respective hypotheses.

Proposition 147.8 (Inverse of finite memories without a terminal)**.** *For $N \ge 1$, let $M_N v = (D_n R_n v)_{n<N}$. Then*

$$M_N^* M_N = I - R_N^* R_N \ge (1 - r_a^N) I, \tag{147.28}$$

and the least-squares inverse

$$L_N = (I - R_N^* R_N)^{-1} M_N^*, \qquad L_N M_N = I, \qquad \|L_N\| \le (1 - r_a^N)^{-1/2} \tag{147.29}$$

recovers the input exactly with exact data.

Proof. The Gram identity is (147.26); the bound follows from (147.22). The positive operator is invertible by its strict lower bound. Composition proves $L_N M_N = I$, and $L_N L_N^* = (M_N^* M_N)^{-1}$ proves the stated norm. □

This finite inverse removes the bias of (147.27); its noise amplification is specified by (147.29). The truncated adjoint, the finite inverse and the adjoint of the complete archive are thus three operators with distinct behaviors.

For $a = 8$, the general bound is $r_a = 729/1241$. In the case $\mathcal{B} = I$, $C = S^4$, with S the cycle of twelve positions, the fixed projector $P_0 = (I + S^4 + S^8)/3$ gives

$$A^* A = \frac{a+1}{(2a+1)p} \big((a-1)^2 P_0 + p(I - P_0) \big). \tag{147.30}$$

Since $p - (a-1)^2 = 3a > 0$, its norm is $(a+1)/(2a+1)$. At $a = 8$ we obtain $9/17$; the eigenvalue of the fixed sector is $441/1241$. These rates belong to the declared transports and policy.

If both channels are refined in a tree, each complete level is also isometric by composition. Summing the norms of all complete layers would repeatedly count the same initial norm. Conservation is formulated through the refinement maps between levels or through the archive of complements in (147.24).

147.7 Geometric forms and conservation of their transport

Let b, b' be nondegenerate forms, symmetric or alternating, on the corresponding spaces, and suppose $\mathcal{B}^* b' \mathcal{B} = C^* b' C = b$. The same bilinear expansion proves

$$(a+1) Q_-^* b' Q_- + a Q_+^* b' Q_+ = N b. \tag{147.31}$$

Indeed, the mixed terms $\mathcal{B}^* b' C + C^* b' \mathcal{B}$ cancel with the same weights; the pure terms sum to Nb. The transported form is thus preserved without requiring positivity. The contraction and noise bounds of the

preceding subsection use, by contrast, positive Hilbert norms. A Lorentzian or alternating form preserves (147.31), with its own geometric interpretations, and does not replace positivity in those inequalities.

147.8 Channel correlation and inverse reading problem

For $v \neq 0$, define

$$\chi(v) = \frac{\operatorname{Re}\langle \mathcal{B}v, Cv\rangle}{\|v\|^2}, \qquad -1 \le \chi(v) \le 1. \tag{147.32}$$

The bound is Cauchy–Schwarz applied to the two isometric images. The normalized readings are

$$s_- = a^2 + 1 - 2a\chi, \qquad s_+ = (a+1)^2 + 1 + 2(a+1)\chi. \tag{147.33}$$

For $a = 8$,

$$s_- = 65 - 16\chi, \qquad s_+ = 82 + 18\chi, \qquad 9s_- + 8s_+ = 1241. \tag{147.34}$$

The two individual norms contain a common real correlation. The balance is an exact relation between them, not two independent arithmetic determinations of a constant.

Using the prior output α_A in the inverse test $s_- = 10^4\alpha_A$ determines the complementary reading

$$s_+ = 73 + \frac{9}{8}(73 - 10^4\alpha_A) \simeq 73{,}029783595557. \tag{147.35}$$

The equality is obtained by substitution into (147.34). The weighted average $(9s_- + 8s_+)/17$ remains exactly equal to 73. The comparison preserves the prior genealogy of α_A: it is a condition of the inverse test, not another independent producer of that output. A unitary change can alter χ and the two readings while maintaining the balance, even if a particular relation of ternary order changes.

147.9 Cyclic frame and transport of responses

On the carrier of the generated register, let $H = \mathbb{R}^{12}$, $(Sx)_i = x_{i+1}$, with cyclic indices, and

$$O_K = (K, SK, \dots, S^{11}K), \qquad 589609I \le O_K^* O_K \le 39225169I. \tag{147.36}$$

The bounds are those of the cyclic frame of the canonical register, proved in theorem 144.2. Let Z be one of the complete isometries Z_N, Z_∞, or a composition with the preceding archives that preserves its terminals and complements.

Theorem 147.9 (Preservation of frame conditioning)**.** *If $x = O_K\beta$, the datum $z = Zx$ determines*

$$\beta = O_K^{-1} Z^* z, \qquad \|\delta\beta\| \le \frac{\|\delta z\|}{\sqrt{589609}}. \tag{147.37}$$

The twelve columns of ZO_K form a basis of its image, even when the archive has infinitely many coordinates.

Proof. The equality $Z^*Z = I$ gives $(ZO_K)^*(ZO_K) = O_K^* O_K$. The Gram bounds are preserved and O_K is invertible by the strict lower bound. Composing their inverses proves recovery, and the norm $\|O_K^{-1}\| \le 589609^{-1/2}$, together with $\|Z^*\| = 1$, gives stability. The number of columns and their independence determine the dimension of the image, without identifying it with the entire storage space. □

For an operator H_0 commuting with S, the complete vector response $y = H_0K$ determines

$$H_0 = O_y O_K^{-1}. \tag{147.38}$$

Indeed, commutation implies $H_0 O_K = (y, Sy, \dots, S^{11}y) = O_y$. If only $z = Zy + e$ is received, define $\widehat{y} = Z^* z$ and $\widehat{H}_0 = O_{\widehat{y}} O_K^{-1}$. Then

$$\|\widehat{H}_0 - H_0\| \le \sqrt{\frac{12}{589609}}\,\|e\|. \tag{147.39}$$

The orbital matrix of δy has twelve columns of norm $\|\delta y\|$, so its operator norm does not exceed $\sqrt{12}\|\delta y\|$. This and (147.36) prove (147.39). For a general operator the protocol requires the twelve responses $H_0 S^j K$; a response in the cyclic case means its twelve components, not a scalar measurement.

In the transported image, the shift is $S_Z = ZSZ^*$, and satisfies $S_Z^j Z = ZS^j$. This equality determines the phase advance in the archive; a translation of cells in the ambient space represents that advance only when it coincides with the transported operator.

147.10 Positional reading and scalar precision

Fix $B_0 = 1000$, $d = B_0^{12} - 1$, and the row

$$\ell = \frac{(B_0^{11}, B_0^{10}, \dots, 1)}{d}. \tag{147.40}$$

Its linear extension acts on H, and in the word domain $\kappa(K) = \ell K$. The representative of the transported reader is $Z\ell^*$, so that

$$\kappa(K) = \langle Z\ell^*, ZK\rangle, \qquad |\delta\kappa| \le \|\ell\|\,\|e\|. \tag{147.41}$$

The geometric sum provides

$$\|\ell\|^2 = \frac{B_0^{12} + 1}{(B_0^2 - 1)(B_0^{12} - 1)}. \tag{147.42}$$

Indeed, the numerator of the sum of squares is $(B_0^{24} - 1)/(B_0^2 - 1)$, which divided by $(B_0^{12} - 1)^2$ gives (147.42).

With only N complements and the truncated adjoint, an additional error of at most $\|\ell\| r_a^N \|K\|$ appears. The finite inverse (147.29) removes that bias and retains its explicit noise amplification bound.

In the domain $\{0, \dots, 999\}^{12}$, the exact reading recovers $N_K = d\kappa$ and its twelve blocks through successive Euclidean divisions. If

$$|\widetilde{\kappa} - \kappa| < \frac{1}{2d}, \tag{147.43}$$

rounding $d\widetilde{\kappa}$ to the nearest integer recovers N_K: its distance to the true integer is less than half a unit. The base, length, origin and orientation accompany that representation. The scalar threshold of (147.43) is distinct from the vector bounds of the memory registers.

147.11 Incidence, charge and exact restitution of the register

Let $\mathbf{1} = (1, \dots, 1)^T$ and $\Pi = I - \mathbf{1}\mathbf{1}^*/12$. The incidence isometry of section 107.1 is

$$Fv = (\mu(v), \mathcal{I}\Pi v/6), \qquad \mu(v) = \frac{\mathbf{1}^* v}{12}, \qquad \|(\mu, y)\|_Y^2 = 12\mu^2 + \|y\|^2. \tag{147.44}$$

Its codomain is its declared image. The Gram matrix $\mathcal{I}^*\mathcal{I} = 36I + 30\mathbf{1}\mathbf{1}^*$ gives $\|\mathcal{I}\Pi v\|^2 = 36\|\Pi v\|^2$, and $12\mu(v)^2 + \|\Pi v\|^2 = \|v\|^2$, whence $F^*F = I$. Thus, from $z = Zv + e$,

$$\widehat{Fv} = FZ^* z, \qquad \|FZ^* e\|_Y \le \|e\|. \tag{147.45}$$

The unnormalized incidence $\mathcal{I}\Pi v$ has error at most $6\|e\|$; the signed register $H_{12} v$, whose normalization satisfies $H_{12}^* H_{12} = 4I$, has error at most $2\|e\|$.

The direction $u = P_3 \Pi K$ and the projector $P_{10} = \Pi - uu^*/\|u\|^2$, with $u \neq 0$, are recovered with their prior readers and chart. The absolute selection $\{j : K_j \geq 729\}$ has a discontinuity at $K_4 = 729$. Integer restitution is carried out before applying that threshold.

Proposition 147.10 (Decoding after the complete archive)**.** *Let K be integer and $z = ZK + e$, with $Z^*Z = I$. If $\|e\| < 1/2$, rounding each coordinate of Z^*z recovers K exactly. Composition restores κ, the signatures and the geometric readers defined on that register.*

Proof. The contractivity of Z^* gives $\|Z^*z - K\| \leq \|e\| < 1/2$. Each coordinate error is bounded by the joint norm, so the unique integer coordinate at a distance less than half a unit is the original one. Once K is recovered, evaluating any of its exact readers restores its value. □

In particular, the support $\{4, 6, 9, 10\}$ is recovered, including its boundary component. The other marks involved in an exceptional flag are preserved through their own channels: restitution of K exactly corrects the information whose sufficient arguments lie in it.

147.12 Preservation of the conditioning of two memories

Retain the preceding readers

$$T_j = \frac{8I + S^j}{9}, \qquad D_j = \frac{\sqrt{8}}{9}(S^j - I), \qquad Mv = (D_3 v, D_4 T_3 v). \tag{147.46}$$

The D_j in this equation are the preceding complements; the second bilateral block D of (147.11) retains its own definition. We have $\ker M = \mathbb{R}\mathbf{1}$ and an inverse L_M of norm $9/4$ on the centered sector, as proved in chapter 114.

Let $E = W_a \oplus W_a$ be in the space of the two memories. Its isometry implies

$$(EM)^*(EM) = M^*M, \qquad \ker(EM) = \mathbb{R}\mathbf{1}. \tag{147.47}$$

For $z = EMv + e$ and exact charge $q = \mathbf{1}^*v$, the reconstruction is

$$\widehat{v} = \frac{q}{12}\mathbf{1} + L_M E^* z, \qquad \|\widehat{v} - v\| \leq \frac{9}{4}\|e\|. \tag{147.48}$$

The proof consists in applying $E^*E = I$, using $L_M M = \Pi$ and $\|E^*\| = 1$. If the charge has error δq, the uniform and centered sectors are orthogonal and

$$\|\widehat{v} - v\|^2 \leq \frac{|\delta q|^2}{12} + \frac{81}{16}\|e\|^2. \tag{147.49}$$

The distances of all words in the integer image are preserved exactly by E. Therefore, the restitution radii of theorem 145.5 remain

$$r_0 = \frac{2\sqrt{146}}{81} \quad \text{uncharged}, \qquad r_q = \frac{4\sqrt{73}}{81} \quad \text{with exact charge}. \tag{147.50}$$

Within the first radius, ΠK is recovered, and with it the direction and its projector when they are defined. Within the second, preserving q, we recover K and the absolute threshold selector. Subsequently composing another complete isometry, finite or infinite, maintains the same guarantees: its adjoint is applied before the decoder. The radius is always expressed in the joint norm of the data with the fixed normalization.

This composition redistributes the information of M without degrading its conditioning and without creating the uniform channel that M removes. Gram conservation distinguishes this property from a numerical improvement obtained by changing the reader or the noise scale.

147.13 Orbital norm and polar normalization of the frame

The preceding inversion satisfies $K = H_{12}U_{\mathrm{sgn}}/4$, $H_{12}^{*}H_{12} = 4I$. Therefore

$$\|K\|^2 = \frac{1}{4}\|U_{\mathrm{sgn}}\|^2 = 4251257, \qquad \|U_{\mathrm{sgn}}\|^2 = 17005028. \tag{147.51}$$

Each translation S^j is orthogonal and preserves $\nu = \sqrt{4251257}$. Hence

$$\mathrm{tr}(O_K^{*}O_K) = 12\nu^2 = 51015084. \tag{147.52}$$

Division by ν normalizes each orbital column to norm one and preserves its order. It is uniform over the orbit and under its isometric transports. Different registers retain their own norms, and the normalized columns continue to have a nonscalar Gram matrix: its eigenvalues are the preceding ones divided by 4251257.

Operator normalization uses the complete Gram matrix:

$$G_K = O_K^{*}O_K, \qquad F_K = O_K G_K^{-1/2}, \qquad F_K^{*}F_K = I. \tag{147.53}$$

The inverse root exists by (147.36). The equality is checked by multiplying the Gram matrix by $G_K^{-1/2}$ on both sides. Thus ZF_K is isometric at any depth. The full recovery of the frame is

$$O_K = F_K G_K^{1/2}. \tag{147.54}$$

The pair (F_K, G_K) preserves the complete information. The unitary factor preserves an oriented orthonormal frame in the fixed charts, while the amplitudes also reside in G_K. Multiplying K by a positive scalar preserves F_K and changes G_K; K and $-K$ share a Gram matrix and have opposite polar factors, with different linear reading κ. Each example shows why an isolated factor does not replace the pair.

Translation of the origin preserves ν, but in the fixed positional chart

$$\kappa(SK) = 1000\kappa(K) - K_1. \tag{147.55}$$

This is obtained by shifting the positional numerator and using $d = 1000^{12} - 1$. To preserve the same reading under a chart change, the row ℓ is also transported by the inverse of that change. A general unitary chart may leave the lattice of integer blocks; decoding by Euclidean divisions is performed in the recovered block chart.

147.14 Exact example of transduction and error correction

Take $a = 8$, $U = S^4$ and the canonical register

$$\begin{aligned} K = (&234, 543, 140, 729, 659, 824,\\ &621, 58, 914, 794, 146, 601). \end{aligned} \tag{147.56}$$

Denoting by $(v)_{1:6}$ and $(v)_{7:12}$ its two blocks of six coordinates, the unnormalized readings are

$$\begin{aligned} (Q_{-}K)_{1:6} &= (1213, 3520, 499, 5774, 4358, 5798),\\ (Q_{-}K)_{7:12} &= (4822, -137, 7078, 5809, 1028, 4079),\\ (Q_{+}K)_{1:6} &= (2765, 5711, 1881, 6619, 6845, 8210),\\ (Q_{+}K)_{7:12} &= (5735, 1123, 8460, 7689, 1454, 6138). \end{aligned} \tag{147.57}$$

Their sum, divided by 17, recovers all blocks of K. The matrix identity $9Q_{-}^{*}Q_{-} + 8Q_{+}^{*}Q_{+} = 1241I$ precedes its evaluation on the specific vector.

To introduce a controlled error, the two memories are rationalized as $z_0 = MK/\sqrt{8}$, and $1/10$ is added to the first coordinate. Each block of twelve components is then transported through the two bilateral channels. The inverse by summation recovers the perturbed memory data, and the charge decoder receives $q = 6263$ together with these data, without receiving the sought register. The error norm in the original memories is $\sqrt{8}/10 < r_q$. Isometric normalization preserves that norm; the unnormalized channels merely facilitate exact rational calculation.

In this instance, the candidates of the floor-and-ceiling reconstruction satisfying the charge are 924. The minimum rationalized squared distance is $1/100$, and the decoder recovers (147.56). Uniqueness follows from the strict radius (147.50), not from the mere size of the enumeration. The recovered arithmetic reading is

$$\kappa = \frac{2345431407296598246210589147941466 01}{99999999999999999999999999999999999999}, \tag{147.58}$$

and the incidence selection is again $\{4, 6, 9, 10\}$, with the same threshold 729. The example introduces noise before transport. The proofs of contractivity of the adjoint also cover arbitrary subsequent errors whose joint norm lies within the declared radius.

The combined operational capacity is to transport and recover a generated register, maintain the conditioning of its responses and restore its arithmetic and incidence readings before applying discontinuous selections. Its effective premises are the prior production of K, the invertible cyclic frame, bilateral balance, the discrete separation of memories and the archive theorem. The register of twelve components preserves the scope of its readers; the complete enriched history retains its other registers and dependencies.

Chapter 148

Unitary lift of refinement and transport of readers

The residue bijection of theorem 146.4 and the bilateral balance of theorem 147.1 admit an explicit composition. An admissible arithmetic triple, containing a pair and its carry, determines a refined pair. The linearization of this bijection on orthonormal bases provides a unitary transport; two transports of this type can act as the two realizations of the bilateral balance.

The realization is established after the objects generated by APP–TRIT–TPK. Its combinatorial domain comprises the pairs and carries satisfying the conditions written below. The norm preserved by its linearization is the sum of squared amplitudes over those labels; the arithmetic conservation of $L_c(x, y) = (Bx - c, By + c)$ remains the sum of the two coordinates after rescaling. The composition relates both conservations through a specific map.

148.1 Bijection of admissible arithmetic states

Let $B \geq 2$ and $M \geq 1$ be integers. We define

$$\mathcal{D}_{B,M} = \big\{(x, y, c) \in \mathbb{Z}_{\geq 0}^2 \times \{0, \dots, B-1\} : x + y = M,\ c \leq Bx\big\}, \tag{148.1}$$

$$\mathcal{E}_{BM} = \big\{(X, Y) \in \mathbb{Z}_{\geq 0}^2 : X + Y = BM\big\}. \tag{148.2}$$

The condition $c \leq Bx$ maintains the nonnegativity of the first output coordinate. For $x = 0$ it only admits $c = 0$; for $x \geq 1$ it admits the entire canonical alphabet.

Theorem 148.1 (Exact correspondence of labels)**.** *The map*

$$\ell_{B,M} : \mathcal{D}_{B,M} \longrightarrow \mathcal{E}_{BM}, \qquad (x, y, c) \longmapsto (Bx - c, By + c) \tag{148.3}$$

is bijective. Both sets have cardinality $BM + 1$. Its inverse is given by

$$c = Y \bmod B, \qquad y = \frac{Y - c}{B}, \qquad x = \frac{X + c}{B}. \tag{148.4}$$

Proof. The domain condition and the identity $Bx - c + By + c = BM$ ensure that the image belongs to $\mathcal{E}_{BM}$. Given a pair in that set, the residue c is the unique alphabet element satisfying $Y \equiv c \pmod B$. Since $X + Y$ is divisible by B, so is $X + c$. Euclidean division of Y gives $y \geq 0$, and $X + c \geq 0$ gives $x \geq 0$. If $c > 0$, $x = 0$ would require $X = -c < 0$, so admissibility is preserved. The sum of the preimages is M, and substitution verifies the original image. Uniqueness of the residue and quotients proves the bijection.

There are $M + 1$ labels with $c = 0$ and M with each positive carry; therefore the cardinality is $(M + 1) + (B - 1)M = BM + 1$, equal to that of the output. □

The proof makes explicit the boundary endpoint of the domain, a necessary condition for equality of cardinalities. The new carry label is a typed part of the input to refinement.

148.2 Unitarity on label amplitudes

Take the real or complex Hilbert spaces with counting measure

$$\mathscr{H}_D = \ell^2(\mathcal{D}_{B,M}), \qquad \mathscr{H}_E = \ell^2(\mathcal{E}_{BM}), \tag{148.5}$$

and their labeled orthonormal bases. Define linearly

$$J_{B,M}|x, y, c\rangle = |Bx - c, By + c\rangle. \tag{148.6}$$

We shall write J when the parameters are fixed.

Proposition 148.2 (Unitary lift)**.** *The operator $J : \mathscr{H}_D \to \mathscr{H}_E$ is unitary: $J^*J = I_D$, $JJ^* = I_E$. The adjoint recovers each label through* (148.4)*.*

Proof. theorem 148.1 ensures that J maps two complete orthonormal bases bijectively. For $\psi = \sum_{d\in\mathcal{D}} \psi_d |d\rangle$,

$$\|J\psi\|^2 = \sum_{e\in\mathcal{E}} |\psi_{\ell_{B,M}^{-1}(e)}|^2 = \sum_{d\in\mathcal{D}} |\psi_d|^2 = \|\psi\|^2.$$

Surjectivity proves the two unitary identities and the inverse bijection describes the adjoint on each basis vector. □

The label $|73, 27, 1\rangle$ has norm one; the integers $73, 27, 1$ describe its arithmetic values, not its amplitudes. The construction represents reversible processing of labels or amplitudes. A specific physical realization additionally preserves the protocol preparing and transporting those amplitudes.

148.3 Diagonal proportion and carry readers

For a real function h on a finite set, denote by M_h its diagonal operator: each basis vector is multiplied by the value of h at its label. The bijection satisfies

$$J^* M_h J = M_{h\circ\ell_{B,M}}. \tag{148.7}$$

This is proved by acting on all basis vectors.

Define on the output

$$f_E(X,Y) = \frac{X}{BM}, \quad g_E(X,Y) = \frac{Y}{BM}, \quad \gamma_E(X,Y) = Y \bmod B, \tag{148.8}$$

and on the input $f_D = x/M$, $g_D = y/M$, $\gamma_D = c$. The identity (148.7) provides

$$\begin{aligned} J^* M_{f_E} J &= M_{x/M - c/(BM)}, \\ J^* M_{g_E} J &= M_{y/M + c/(BM)}, \\ J^* M_{\gamma_E} J &= M_c. \end{aligned} \tag{148.9}$$

The first two readers transport the unit transfer. Since $f_E + g_E = 1$, their sum is I_E and their compression is I_D. The third reader exactly preserves the carry as an integer observable, with its residual representation in the output.

148.4 Complete routes at arbitrary depth

Let $\mathcal{P}_n(B, M)$ be the set of routes of length n starting from all nonnegative pairs with sum M and, at each stage, satisfying the conditions of (148.1) for the corresponding sum. A route preserves its initial pair and its n admissible carries. Let Φ_n be the map assigning each route its final pair.

Theorem 148.3 (Recovery of routes at every finite depth)**.** *For every $n \geq 0$,*

$$\Phi_n : \mathcal{P}_n(B,M) \longrightarrow \mathcal{E}_{B^n M} \quad \textit{is bijective}, \qquad |\mathcal{P}_n(B,M)| = B^n M + 1. \tag{148.10}$$

Its linearization

$$J_n : \ell^2(\mathcal{P}_n(B,M)) \longrightarrow \ell^2(\mathcal{E}_{B^n M}), \qquad J_n|\pi\rangle = |\Phi_n(\pi)\rangle \tag{148.11}$$

is unitary.

Proof. From a pair with sum $B^n M$, the residue of (148.4) recovers the last carry and a unique preceding pair with sum $B^{n-1}M$. Repeating n times produces a unique route whose input sums to M. The direct composition recovers the original endpoint, proving bijection and inverse. The count is also obtained from the inputs: the M pairs with $x_0 \geq 1$ admit B^n words each, whereas $(0, M)$ admits only the all-zero word. The total is $MB^n + 1$. The bijective transformation of orthonormal bases proves the unitarity of J_n. □

With the depth known, the readers on the final pair are

$$c_j = \left\lfloor \frac{Y}{B^{n-j}} \right\rfloor \bmod B, \quad y_0 = \left\lfloor \frac{Y}{B^n} \right\rfloor, \quad x_0 = M - y_0, \qquad 1 \leq j \leq n. \tag{148.12}$$

These functions are diagonal and recover the complete memory of the finite operations. Compatibility with prolongation is

$$\Phi_{n+1}(\pi, c) = L_c(\Phi_n(\pi)). \tag{148.13}$$

On passing from n to $n + 1$, the new admissible carry label is incorporated. The spaces increase in dimension and the boundary label admits only $c = 0$; therefore the domain of the next step preserves admissibility, instead of replacing it with an unrestricted product with B digits.

148.5 Fixed input and exact image

If an initial pair (x_0, y_0) is fixed, with $x_0 \geq 1$, there are B^n routes and their image is exactly

$$\left\{(B^n x_0 - C, B^n y_0 + C) : 0 \leq C \leq B^n - 1\right\}. \tag{148.14}$$

corollary 146.6 proves that the accumulated B^n are distinct and recover the respective words. The linearization is unitary onto the subspace spanned by this image. If $x_0 = 0$, the image consists of a single label.

The cylinders of theorem 146.8 correspond to a fixed input. The complete domain of (148.10) brings together all pairs with sum M. Both constructions have explicit inverses, but their images and cardinalities differ. Arbitrary depth expresses the validity of the proof for every n; the limit of the reading and its boundaries remain as established in section 146.7.

148.6 Bilateral coupling of refinement

Let R be a previously declared permutation of $\mathcal{D}_{B,M}$, unitarily linearized on $\mathscr{H}_D$. Define the two transports

$$\mathcal{B} = J, \qquad C = JR : \mathscr{H}_D \longrightarrow \mathscr{H}_E. \tag{148.15}$$

The permutation is part of the specification of the procedure and is fixed before evaluating an output reading. For $a > 0$, $p = a^2 + a + 1$, $N = (2a + 1)p$,

$$Q_- = J(aI - R), \qquad Q_+ = J((a + 1)I + R). \tag{148.16}$$

Proposition 148.4 (Distribution and recovery of refined amplitudes)**.** *The operators* (148.16) *satisfy*

$$(a + 1)Q_-^* Q_- + aQ_+^* Q_+ = NI_D, \tag{148.17}$$

and the map

$$W_a\psi = \frac{1}{\sqrt{N}}\left(\sqrt{a + 1}\, Q_-\psi, \sqrt{a}\, Q_+\psi\right) \tag{148.18}$$

is isometric. For the unnormalized channels $u = Q_-\psi$, $v = Q_+\psi$,

$$J\psi = \frac{u+v}{2a+1}, \qquad \psi = J^* \frac{u+v}{2a+1}. \tag{148.19}$$

Proof. The two maps $\mathcal{B}, C$ are unitary. The cross terms of the Gram matrices of Q_- and Q_+ have coefficients $-a$ and $a+1$, respectively. The balance weights cancel them, while the diagonal terms sum to N, as in theorem 147.1. Normalization proves isometry. The sum of the channels is $(2a+1)J\psi$, and the unitarity of J gives the inverse. □

From the normalized channels the input is recovered directly by W_a^*, with inversion norm one; this adjoint already incorporates J^*. The alternative formula (148.19) separates recovery of $J\psi$ by summation from application of J^*, whose action on labels is calculated through residues. Reversible arithmetic refinement and bilateral amplitude transport are thereby composed.

Proposition 148.5 (Compatibility in the refined space)**.** *An unnormalized pair (u, v) belongs to the image of $\psi \mapsto (Q_-\psi, Q_+\psi)$ if and only if*

$$\big[(a+1)I_E + JRJ^*\big]u = \big[aI_E - JRJ^*\big]v. \tag{148.20}$$

Proof. The equality is equivalent to $JRJ^*(u+v) = av - (a+1)u$. If it holds, define $\psi = J^*(u+v)/(2a+1)$. On substitution into (148.16), this identity gives $Q_-\psi = u$ and $Q_+\psi = v$. Necessity follows from inserting the true channels. All compositions act on $\mathcal{H}_E$, so their types are defined. □

148.7 Law of observables on the two channels

Theorem 148.6 (Bilateral compression of a refined reader)**.** *For $F = F^*$ on $\mathcal{H}_E$, write $F_J = J^*FJ$. Then*

$$W_a^* \operatorname{diag}(F, F) W_a = \frac{a(a+1)F_J + R^*F_JR}{p}. \tag{148.21}$$

The reader F_J is preserved exactly if and only if it commutes with R.

Proof. Expanding $(a+1)Q_-^*FQ_- + aQ_+^*FQ_+$ cancels the mixed terms. The coefficient of $\mathcal{B}^*F\mathcal{B}$ is $a(a+1)(2a+1)$; that of C^*FC is $2a+1$. Dividing by N, substituting $C = JR$ and using $F_J = J^*FJ$ proves the formula. Equality with F_J is equivalent to $R^*F_JR = F_J$, or to $[F_J, R] = 0$ by unitarity. □

In the case $a = 8$, the weights are $72/73$ and $1/73$. The identity reader recovers the norm. A nonconstant reader may change even when the norm is preserved; its variation is calculated by (148.21). The operator that exactly preserves an original reader A in the complete image is $W_aAW_a^*$, whose image identity is $W_aW_a^*$. Reading $\operatorname{diag}(F, F)$ corresponds to the specific compression of the theorem and does not automatically replace that transported observable.

148.8 Arithmetic example of dimension one thousand and one

Take $B = 10$, $M = 100$. The label spaces have dimension 1001, and

$$d_1 = (73, 27, 1) \longmapsto e_1 = (729, 271). \tag{148.22}$$

The diagonal readers give

$$f_E(e_1) = \frac{729}{1000} = \frac{73}{100} - \frac{1}{1000}, \qquad g_E(e_1) = \frac{271}{1000}, \qquad \gamma_E(e_1) = 1. \tag{148.23}$$

Declare R to be the transposition of the admissible labels $d_1 = (73, 27, 1)$ and $d_2 = (73, 27, 2)$, leaving the others fixed. The second image is $e_2 = (728, 272)$. The transposition rule has been fixed on the labels, before any comparison with a constant.

For $a = 8$ and $\psi = |d_1\rangle$,

$$Q_-\psi = 8|e_1\rangle - |e_2\rangle, \qquad Q_+\psi = 9|e_1\rangle + |e_2\rangle. \tag{148.24}$$

The squared norms are 65 and 82, and

$$9 \cdot 65 + 8 \cdot 82 = 585 + 656 = 1241 = 17 \cdot 73. \tag{148.25}$$

The sum of the channels is $17|e_1\rangle$. The inverse (148.19) and the residue recover $|d_1\rangle$, including the carry one.

If $F = M_{f_E}$ is evaluated diagonally in both normalized channels, theorem 148.6 gives

$$\begin{aligned}\langle W_8\psi, \operatorname{diag}(F,F)W_8\psi\rangle &= \frac{72 \cdot 729 + 728}{73 \cdot 1000} \\ &= \frac{729}{1000} - \frac{1}{73000}.\end{aligned} \tag{148.26}$$

The complementary reading is one minus this quantity. For the diagonal carry reader we obtain

$$\frac{72 \cdot 1 + 2}{73} = \frac{74}{73}. \tag{148.27}$$

The original carry remains exactly recoverable: the observable $W_8 M_c W_8^*$ has on $W_8|d_1\rangle$ the eigenvalue one. The value $74/73$ is the response of the diagonal reader applied to both channels, whose relative transport is specified by (148.21). The example distinguishes conservation of information from variation of a particular reading.

148.9 Articulation with the generated register and application domains

The unitary J acts on $BM + 1$ labels, whereas the realization of K has twelve coordinates. In the example, 1001 counts refined pairs with sum one thousand, and twelve counts windows of the produced register. Both dimensions retain their specific combinatorial origin.

A particular composition between these two carriers can be formulated through a material selector of twelve distinct routes, with its provenance and operators. If that selector provides an isometry $J_{12} : \mathbb{R}^{12} \to \ell^2(\mathcal{D}_{B,M})$, then JJ_{12} is isometric, and the intertwining of the readers is checked on it. This is the hypothesis of that additional composition, not an implicit identification through the number of coordinates. The bilateral maps already defined directly on K in chapter 147 retain their complete domains without using that additional selector.

The result of this section brings together an arithmetic bijection, its unitary, intertwined diagonal readers, route recovery at any finite depth and an explicit bilateral composition. The route domain is that defined in (148.10). Applications to histories filtered by TPK retain their survival and prolongation rules; the label correspondence here proves the declared transport, without replacing those operators with an unrestricted arithmetic domain.

Chapter 149

Dimensional unity, relative symmetry, and recovery of structure

The holographic extreme and mean ratio articulates conservation of unity under evolution with its arithmetic and dimensional realizations. The composition developed here makes this principle precise through conserved quantities, domains, and inverses. The enriched state generated by APP–TRIT–TPK precedes the numerical and geometric readouts; its operations preserve the orientation, carry, incidence, and memory used by each realization.

149.1 Arithmetic conservation, unitarity, and isometric decomposition

Arithmetic refinement preserves normalized unity:

$$(x, y, c) \longmapsto (Bx - c, By + c), \qquad \frac{Bx - c}{B(x + y)} + \frac{By + c}{B(x + y)} = 1. \tag{149.1}$$

The residue inverse recovers the canonical carry and the preceding pair. Block composition preserves the contributions of events with their scale, and successive divisions recover every finite history. The limiting readout is controlled by decreasing cylinders; boundary marks retain the distinction between histories sharing a scalar evaluation.

The lift on labels transforms that bijection into a unitary J. It preserves the norm of amplitudes and transports the fraction and carry readers through $J^* M_h J = M_{h\circ\ell}$. The quantity $x^2 + y^2$ and the norm of $|x, y, c\rangle$ belong to different realizations. The proof of unitarity establishes the precise link between arithmetic reversibility and preservation of amplitudes.

The third conservation law corresponds to two isometric realizations:

$$(a + 1)Q_-^* Q_- + aQ_+^* Q_+ = (2a + 1)(a^2 + a + 1)I. \tag{149.2}$$

Cancellation of the mixed terms allows bilateral distribution and its norm-one reconstruction. The law holds for the transports on the domain specified in theorem 147.1. Its specialization to the ternary cycle provides additional norm and index properties; the general law remains valid for isometries without that finite order.

The chain formed by the three maps is effective: the bijection produces J; a previously declared permutation produces the second transport JR; the two transports satisfy the balance, and their channels recover the input through (148.19). The example in section 148.8 shows the complete procedure with $(73, 27, 1)$, $(729, 271)$, and 1001 admissible labels. The numbers in that realization are not introduced as substitutes for the structure generating the register K.

149.2 Complete memory and the logical contribution to the Landauer bound

The vanishing logical contribution to the Landauer bound, established in (123.4), applies to the recoverable transports constructed in this article. The bijection of theorem 148.1 preserves the carry through (148.4); its prolongation preserves the path through theorem 148.3. The archives of theorem 147.7 preserve the amplitudes and correlations needed to invert the transport.

Corollary 149.1 (Recovery and spectral conservation of the archive)**.** *Let $Z : H \to \mathcal{K}$ be one of the complete archives Z_N, Z_∞ of theorem 147.7, or the unitary lift J_n of theorem 148.3, on its respective domain. For a finite-rank density operator ρ on H, the output $\rho_Z = Z\rho Z^*$ satisfies*

$$\operatorname{Tr}\rho_Z = 1, \qquad Z^*\rho_Z Z = \rho, \tag{149.3}$$

$$s(\rho_Z) = s(\rho), \qquad s(\rho) = -\operatorname{Tr}(\rho \log \rho), \tag{149.4}$$

with $0 \log 0 = 0$. *If X is a random variable on the finite paths of theorem 148.3, then*

$$\mathsf{H}(X \mid \Phi_n(X)) = 0. \tag{149.5}$$

Proof. Write the finite spectral decomposition $\rho = \sum_j p_j |v_j\rangle\langle v_j|$, with the v_j orthonormal, $p_j > 0$, and $\sum_j p_j = 1$. The identity $Z^*Z = I$ implies that the Zv_j are orthonormal. Thus, $\rho_Z = \sum_j p_j |Zv_j\rangle\langle Zv_j|$ has the same nonzero eigenvalues, proving the trace and entropy identities. Multiplication by Z^* and Z recovers ρ. Finally, Φ_n^{-1} recovers each path from its final pair; the conditional distribution is concentrated on a single path and its entropy is zero. □

Conservation pertains to the complete archive. A visible reading q, accompanied by memory M, recovers the state under the hypothesis of (123.3); information not published by q remains in $\mathsf{H}(M(X) \mid q(X))$. Discarding a necessary complement or terminal defines another operation, whose recoverability is determined on the information actually retained. The preceding spectral equality preserves the distinction between entropy of the complete state, entropy of a partial reduction and transferred heat.

In the thermal model of Section 123, with degenerate logical states, an isothermal environment, and accounting for auxiliary registers, the term associated with erasure is $k_B \Theta \, \mathsf{H}(X \mid F(X))$, for a deterministic logical map F. Its contribution vanishes for the preceding recoverable transports; resetting a uniform TRIT satisfies $Q_{\mathrm{reset}} \geq k_B \Theta \log 3$. Preparation, control, finite operating speed, and coupling to the environment retain their own physical balances. The total heat of an implementation requires combining these contributions with the logical operation.

149.3 Conservation of observables and relative symmetry

Norm balance is the identity case of a more informative operator law. When the transports are unitary, with relative operator R, the effective reader is

$$\mathcal{T}_a(G) = \frac{a(a+1)G + R^*GR}{a(a+1)+1}. \tag{149.6}$$

The observable remains fixed exactly when $[G, R] = 0$. In the canonical case,

$$\mathcal{T}_8(G) - G = \frac{R^*GR - G}{73}. \tag{149.7}$$

This identity determines both conservation and variation: the defect measures the difference between two realizations of the same reader, weighted by the split $72 + 1$.

Complete memory also transports the observable through $A \mapsto ZAZ^*$ on $\operatorname{im} Z$. Products, adjoints, and pairings are preserved on that image. The diagonal channel readout and the transported observable are different operations; the carry example shows the difference between $74/73$ for the former and eigenvalue one for the latter. The information remains recoverable even if a particular diagonal readout changes value.

The variational charges of proposition 114.1 retain their foundation in an explicit action and intertwining. For $A_{n+1}U_n = U_nA_n$, the transport action gives the charge $p_n^*A_nq_n$. Its conservation and the norm identity are compatible results with different hypotheses. Likewise, preservation of an alternating or Lorentzian form in (147.31) retains its geometric meaning; the noise and contraction estimates use the Hilbert positivity declared in their proofs.

149.4 Role of the register in transduction

The holographic arithmetic–geometric coupling constant has a role defined by its compositions. The register K is obtained beforehand by oriented and Hadamard extraction. Its readout κ is reversible with the base, length, and origin fixed. Its frame O_K identifies cyclic responses because its Gram matrix has a strictly positive lower bound. Incidence and geometric direction use their declared readers on the same register.

The archive isometry preserves the Gram matrix of that frame and therefore retains the recovery bounds at every depth. The complete register admits norm-one inversion; the two partial memories retain their factor $9/4$ and their uniform kernel. The additional charge distinguishes recovery of the absolute register from that of its centred component. Integer decoding subsequently recovers the incidence selection even at a threshold lying exactly on a coordinate.

This capacity is more specific than preserving a total quantity: it allows recovery of operations and relations acting on a generated object. Its guarantees rest on the Gram matrix, the distances in the integer image, and the proven inverses, not on retaining another copy of the input by definition. At the same time, the finite number of windows of K remains distinct from the complete enriched history; the other registers and accompanying marks retain their own transports.

The orbit and its isometric transports preserve the norm $\nu = \|K\|$. Normalizing its columns to norm one requires preserving ν to invert that operation. Polar normalization uses the pair (F_K, G_K). The formula $O_K = F_K G_K^{1/2}$ preserves orientation and amplitudes. The positional reader must travel with the chart change, since the common orbital norm does not make κ invariant under an isolated renumbering of its components.

149.5 Depth, dimensions, and physical realizations

The bilateral policy that continues one channel and archives the other has uniform exhaustion of the terminal. Its limit is an isometry into the sum of all memories, and its inverse is the convergent adjoint series in (147.25). A finite number of complements has two distinct reconstructions: the truncated adjoint retains an explicit bias, and the least-squares inverse eliminates it with the computed noise amplification. The preceding evolutions with a positive terminal retain that component in the complete archive.

The dimension of the label space, the rank of a projector, and the dimension of a physical realization are related through their concrete maps. The unitary on 1001 labels and the twelve-window register are two explicit realizations of different domains. The exterior conservation law of the preceding development extends the Gram products to every finite degree, including the mixed contributions between terminal and memories. The exceptional and physical realizations remain linked to their already constructed representations and operators; numerical ranks alone do not replace that link.

149.6 Conclusions on the evolutionary conservation of unity

The physical actions and the Gaussian protocol of the manuscript preserve the couplings, forms, units and preparations involved in their proofs. The bilateral balance added here extends the family of conservative transports and their readings; its application to a physical realization is established by composing the operators of that realization, without replacing them with a coincidence of normalization.

The unity of the development thus resides in a proven sequence: generation and completion, refinement with memory, unitary realization, relative symmetry of the reader, and recovery of structure. The holographic extreme and mean ratio thereby receives an exposition in which change of scale, incidence, conservation, and transduction have explicit operations and jointly retain the information needed to invert their readouts.

Arithmetic formalization of bilateral balance

The nonadic specialization of the bilateral law admits an independent arithmetic formalization. The point of application lies after the construction of its coefficients and transports: the base-ten partition fixes $a = 8$, and the two registers are $8x - y$ and $9x + y$. On that domain, Lean 4.21.0 verifies seven theorems with its library `Std`. The formal sources and execution procedure are provided as a supplement. This complement states their mathematical content and relates it to the operator proofs of the article.

Polynomial identity and conservation of the norm

For any $x, y \in \mathbb{Z}$, we have

$$9(8x - y)^2 + 8(9x + y)^2 = 17(72x^2 + y^2).$$

Expansion of the two squares cancels the cross products. When $y^2 = x^2$, the same equality gives

$$9(8x - y)^2 + 8(9x + y)^2 = 17 \cdot 73\, x^2.$$

These are the first two formalized theorems. The first expresses a balance for arbitrary integer inputs; the second applies the explicit hypothesis of norm conservation. The integer $73 = 72 + 1$ occupies exactly the place it has in theorem 147.1.

Arbitrary finite dimension

Let $n \in \mathbb{N}$ and $x, y : \mathbb{N} \to \mathbb{Z}$. Define

$$S_n(x) = \sum_{j<n} x_j^2, \qquad E_n(x, y) = \sum_{j<n} \bigl(9(8x_j - y_j)^2 + 8(9x_j + y_j)^2\bigr).$$

The next two theorems establish

$$E_n(x, y) = 17\bigl(72 S_n(x) + S_n(y)\bigr)$$

and, under the hypothesis $S_n(y) = S_n(x)$,

$$E_n(x, y) = 17 \cdot 73\, S_n(x).$$

The formal proof proceeds by induction on n. The initial case is the empty sum; the induction step adds a coordinate and applies the already proved polynomial identity. The universal quantifier over n includes all finite dimensions. The hypothesis uses the total sum of squares, so it admits redistributions between coordinates.

Exact inversion of the bilateral channels

Write $q_- = 8x - y$ and $q_+ = 9x + y$. The fifth and sixth theorems are the exact equalities

$$q_- + q_+ = 17x, \qquad 8q_+ - 9q_- = 17y.$$

In the image of the map $(x, y) \mapsto (q_-, q_+)$, both left-hand sides are multiples of 17. The divisions recover the two inputs. The seventh theorem states their injectivity consequence:

$$\left.\begin{aligned} 8x - y &= 8x' - y', \\ 9x + y &= 9x' + y' \end{aligned}\right\} \quad \Longrightarrow \quad x = x' \text{ and } y = y'.$$

Cancellation in $\mathbb{Z}$ justifies this conclusion. The formal content coincides with recovery of the pair of registers, before normalizing them as channels of a metric realization.

Correspondence between algebraic proof and formalization

The formalization uses arbitrary integer variables and mathematical induction. It therefore constitutes a proof of the preceding statements, distinct from checking a finite set of examples. The system accepts the proof terms without added axiomatic declarations or deferred proofs. The supplement also records the logical dependencies reported by the tool for each declaration.

The operator law in the body of the article has a broader domain: isometries between Hilbert spaces, archives of arbitrary depth and conjugated readers. Its proofs are found in theorem 147.1 y sections 149.3 y 149.5. The Lean proof incorporated here certifies the stated arithmetic specialization, with its quantifiers and initial structure. The provenance of the coefficients, generation of the register and exceptional realizations retain the preceding proofs on which they depend.

Part VII

Recoverable geometry and reciprocity of coupling

Positive deformation, lattice duality, polar structure and oriented recovery of action.

The function of the holographic arithmetic–geometric coupling constant becomes precise by studying the transformations determined by its register. Its positional reading preserves twelve ordered components; its incidence realization distinguishes a direction; the bilateral archive allows it to be reconstructed. Composing these operations leads to a family of geometries whose fundamental volume remains constant and whose inversion produces the dual lattice. The register therefore participates both in the constitution of the geometry and in its recovery.

This development maintains the generative order established in the article. The additive and multiplicative evaluations of APP, the orientation of TRIT and the selection, transport and memory operations of TPK produce the enriched state and its joint discrete structure of the continuum. The regional coordinates and exceptional incidence are readings of that state. The vector, lattice and hyperbolic realizations that follow receive these outputs with their charts and orientations. The genealogy is preserved when the representation changes.

The distinction between scale and shape acquires an exact expression here. A deformation can dilate certain directions and contract others while preserving the total product of its factors. In the action ellipse, the product of the semiaxes preserves the action section. In the twelve radii determined by K, compensation preserves the lattice covolume. In the mass operator, a decomposition separates the uniform factor from the relative transformation of determinant one. Each conservation has its own object and proof; the readers allow them to be related without confusing their domains.

Radial reciprocity articulates two complementary constructions. In the chart of the spectral double circle, inverting the radius is exactly equivalent to reflecting the complex coordinate across the line of real part $1/2$. In the modular chart of the ellipse, exchanging semiaxes inverts the radius and changes the sign of the Klein coordinate. Both correspondences admit inverse formulas. The orientation register distinguishes the conjugate reading from a modification of the physical action section.

Substituting the full expressions for the angular readers reveals a specific arithmetic cancellation: the linear term of the preceding action section is compensated by the corresponding term of the counterangle. The regional continuation remains intact. The angular contrast, radius and hyperbolic coordinate are then expressed through the same publications involved in α, with the coupling constant within its dodecaphasic closure. Conversely, the oriented radial coordinate recovers the return section and allows the complete electronic expression to be rewritten.

The spectral realization in turn distinguishes two kinds of information. Lattice duality imposes a functional equation; covolume fixes the poles and their residues; deformation modifies the entire part of the completed function. The archive recovers the direction determining that variation and provides explicit bounds for the reconstruction error. Conservation and reversibility are thus expressed through operations encompassing the register, geometry and their analytic readings.

Chapter 150

Positive deformation and lattice duality of the generated register

150.1 Coupling direction and unimodular flow

Extraction of the register, its rational reading and the incidence projectors have been constructed in the preceding sections. Base one thousand, the phase origin, carry boundary and chart of the twelve positions are preserved. In that chart,

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601), \qquad u = P_3 P_{11} K,$$

$$P_{11} = I - \frac{1}{12}\mathbf{1}\mathbf{1}^{\mathsf{T}}, \qquad u \perp \mathbf{1}, \qquad \|u\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0.$$

The finite definition of P_3, the order of its classes and the exact evaluation of this norm appear in Lemma 21.62. The following realization uses that generated object. We write

$$\rho = \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2} > 0, \qquad h_i = (\log \rho)\frac{u_i}{\|u\|}, \qquad r_i(t) = e^{t h_i}, \qquad g_t = \operatorname{diag}(r_i(t)). \tag{150.1}$$

The regional coordinates are evaluated before this composition. The parameter $t \in \mathbb{R}$ indexes a mathematical deformation; its definition does not identify it with the TPK clock or with a refinement depth.

Proposition 150.1 (Scale compensation)**.** *The flow satisfies*

$$g_t g_s = g_{t+s}, \qquad g_0 = I, \qquad g_t^{-1} = g_{-t}, \qquad \det g_t = \prod_i r_i(t) = 1.$$

Proof. Orthogonality to the uniform mode gives $\sum_i h_i = 0$. Multiplication of exponentials proves the group law and inversion. The determinant is $\exp(t \sum_i h_i) = 1$. Each diagonal factor is positive. □

Conservation is multiplicative and global: each radius may vary. In logarithmic coordinates the zero sum is preserved. This distinction will allow the transverse projector of rank ten to be interpreted geometrically.

150.2 Exact reciprocity of the double circle

Consider the complex chart and its inverse

$$z(s) = \frac{s-1}{s}, \qquad s(z) = \frac{1}{1-z}.$$

For $r > 0$, $z = re^{i\theta} \neq 1$, define $s(r,\theta) = (1 - re^{i\theta})^{-1}$.

Proposition 150.2 (Conjugation of the spectral mirror)**.** *The following hold*

$$s(r^{-1}, \theta) = 1 - \overline{s(r,\theta)}, \tag{150.2}$$

$$\Re s(r,\theta) - \frac{1}{2} = \frac{1 - r^2}{2|1 - re^{i\theta}|^2}. \tag{150.3}$$

The unit circle, except for the excluded point $z = 1$, corresponds to the line $\Re s = 1/2$.

Proof. Radial inversion at a fixed angle is $z' = 1/\overline{z}$. Therefore,

$$\frac{1}{1-z'} = \frac{\overline{z}}{\overline{z}-1} = 1 - \frac{1}{1-\overline{z}}.$$

Moreover, $(1-z)^{-1} = (1-\overline{z})/|1-z|^2$. Subtracting $1/2$ from its real part produces (150.3). □

The relation to the radii of (150.1) is explicit: $r_i(-t) = r_i(t)^{-1}$. Equality of products preserves volume, while the proposition identifies an involution between complex charts. Locating the zeros of a function requires the properties of that function; it is not a consequence of the unit product of radii.

Three circular realizations in the corpus should be distinguished. The spectral chart takes $s = 1/2 + i\gamma$ to $z_\gamma = (\gamma + i/2)/(\gamma - i/2)$. The dual circle of integer memory takes an integer n to the character z^n. Nonadic compression takes z to $(8+z)/9$, a circle with center $8/9$ and radius $1/9$, tangent to the unit circle at 1. The modal ratio $5/9$ belongs, by contrast, to the eigenvalues $9, 5$ of the APP block $\left(\begin{smallmatrix} 7 & 2 \\ 2 & 7 \end{smallmatrix}\right)$. Their functions remain distinct when composed.

150.3 Positroid strata and balanced invariants

Let X be a real matrix of rank k, with twelve columns, and let $\Delta_I(X)$ be its maximal minor with columns I. The right action satisfies

$$\Delta_I(Xg_t) = e^{t\sum_{i\in I} h_i}\Delta_I(X). \tag{150.4}$$

Diagonal positivity preserves all signs and all vanishing minors. Thus, for $1 \le k \le 11$, a trajectory starting in $\mathrm{Gr}_{\ge 0}(k,12)$ remains in the same positroid stratum. Stratification by minors is used here as a subsequent realization; see Postnikov's general construction [175].

Proposition 150.3 (Positive duality of complementary ranks)**.** *Let* $A_\pm = \mathrm{diag}(1,-1,1,-1,\dots)$ *and* $\mathfrak{D}(V) = V^\perp A_\pm$*, with the positive orientation of their complementary minors. Then*

$$\mathfrak{D}(Vg_t) = \mathfrak{D}(V)g_{-t}.$$

Proof. Since g_t is diagonal and self-adjoint, $(Vg_t)^\perp = V^\perp g_t^{-1}$. The matrix $A_\pm$ commutes with g_t. For the sign of the minors, the orthogonal complement introduces, up to a global sign, $(-1)^{\sum_{j\in J} j}$. Multiplication of the columns by $(-1)^{j-1}$ leaves a sign independent of J; it is removed by a single global orientation. The complementary minors are then nonnegative. □

If $\mathbf{1}_I + \mathbf{1}_J = \mathbf{1}_L + \mathbf{1}_M$ and the denominator is nonzero, coordinatewise cancellation of the exponents proves

$$\frac{\Delta_I(Xg_t)\Delta_J(Xg_t)}{\Delta_L(Xg_t)\Delta_M(Xg_t)} = \frac{\Delta_I(X)\Delta_J(X)}{\Delta_L(X)\Delta_M(X)}. \tag{150.5}$$

In rank two, the four-index quotients and their exchange relations are recovered. By contrast, the product of complementary minors of the two paired trajectories receives the same factor twice and may vary. Nor does the circulant frame O_K, invertible for recovery, acquire the property of being totally nonnegative through this action: its minors preserve the signs established in its own realization.

150.4 Covolume, dual lattice and ternary symmetry

Let Λ be the previously constructed marked Leech lattice, self-dual and of covolume one in the metric of its twelve orthogonal planes of type A_2. The marked isometry

$$\sigma = \bigoplus_{i=1}^{12} P_i \mathsf{C} P_i^{-1}, \qquad \mathsf{C}^2 + \mathsf{C} + I = 0,$$

preserves the gluing and Λ, has order three and has no nonzero fixed vectors. The P_i are frames of the planes, distinct from the projectors P_3, P_{11}. Define

$$G_t = \bigoplus_{i=1}^{12} r_i(t) I_{A_{2,i}}, \qquad \Lambda_t = G_t \Lambda. \tag{150.6}$$

Theorem 150.4 (Reciprocal lattice deformation)**.** *For every $t \in \mathbb{R}$,*

$$\operatorname{covol}(\Lambda_t) = 1, \qquad \Lambda_t^* = \Lambda_{-t}, \qquad \sigma\Lambda_t = \Lambda_t.$$

Every isometry of Λ commuting with G_t also preserves Λ_t.

Proof. Each radius acts on two coordinates; thus, $\det G_t = \prod_i r_i(t)^2 = 1$. For an invertible operator G, a vector y belongs to $(G\Lambda)^*$ exactly when $G^* y \in \Lambda^*$. Therefore $(G\Lambda)^* = G^{-*}\Lambda^*$. Applying self-duality, self-adjointness and inversion yields $\Lambda_t^* = G_{-t}\Lambda$. Finally, G_t is scalar on each plane and commutes with σ, whence $\sigma G_t \Lambda = G_t \sigma \Lambda = G_t \Lambda$. The same calculation applies to the other commuting isometries. The operator σ does not change, so it preserves its order and absence of fixed vectors. □

The point $t = 0$ recovers the original lattice with its integrality, parity, self-duality and exceptional realization. The complete family is a family of unimodular Euclidean lattices in the sense of covolume one; away from the original point, neither integrality nor a Moonshine realization is assumed. The theorem identifies exactly the ternary symmetry that does persist and the duality relating the two directions of deformation.

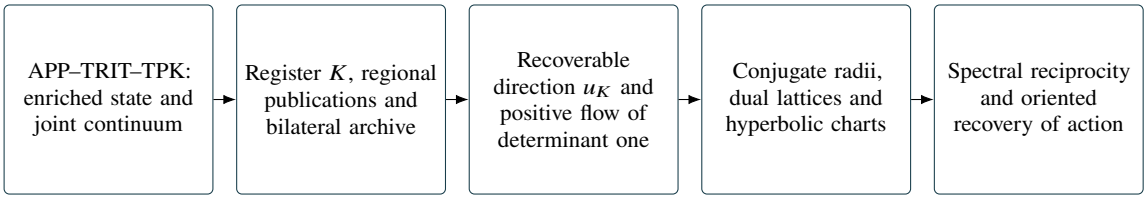

Figure 150.1: Dependencies of the extension. The arrows represent compositions specified in the proofs; recovery preserves the charts and orientation.

Chapter 151

Theta–Mellin reciprocity and conservation of the polar structure

151.1 Periodization of the generated lattice

The lattice Λ_t of Theorem 150.4 has an analytic reading that preserves its dependence on the register. For $x > 0$, define

$$\Theta_t(x) = \sum_{v \in \Lambda} \exp\Big(-\pi_{\mathrm{HMT}} x \|G_t v\|^2\Big). \tag{151.1}$$

In this realization, the previously generated coordinate π_{HMT} is identified with the circular normalization of Fourier analysis. That identification follows the construction of the lattice and the flow. To simplify the analytic notation, we shall use π with this meaning.

On every compact interval of t, the singular values of G_t are bounded above and below by positive constants. The lattice has $O(R^{24})$ points in a ball of radius R. Comparison over annuli with a Gaussian proves absolute and uniform convergence of (151.1) and its derivatives when x remains in a compact subset of $(0, \infty)$. The mode $v = 0$ contributes exactly one.

Theorem 151.1 (Reciprocity of the theta reading)**.** *For every $x > 0$ and $t \in \mathbb{R}$,*

$$\Theta_t(x) = x^{-12} \Theta_{-t}(1/x). \tag{151.2}$$

Proof. With the convention $\widehat{f}(\xi) = \int f(y) e^{-2\pi i \langle y, \xi \rangle}\, dy$, the Gaussian $f_x(y) = e^{-\pi x \|y\|^2}$ in dimension twenty-four has transform $\widehat{f_x}(\xi) = x^{-12} e^{-\pi \|\xi\|^2 / x}$. Periodize over Λ_t. Integrating the periodization over a fundamental domain shows that the Fourier coefficient indexed by $\xi \in \Lambda_t^*$ is $\widehat{f_x}(\xi)/\mathrm{covol}(\Lambda_t)$. Both Gaussian series converge absolutely; evaluating the expansion at the origin gives

$$\sum_{v \in \Lambda_t} f_x(v) = \mathrm{covol}(\Lambda_t)^{-1} \sum_{\xi \in \Lambda_t^*} \widehat{f_x}(\xi).$$

Substitute $\mathrm{covol}(\Lambda_t) = 1$ and $\Lambda_t^* = \Lambda_{-t}$. The proof retains the constant mode on both sides. □

The power x^{-12} comes from rank twenty-four. Inversion of the parameter follows from the dual lattice; it is not added as a symmetry independent of the reading.

151.2 Meromorphic continuation and functional equation

For $\Re s > 12$, let

$$\mathcal{E}_t(s) = \sum_{v \in \Lambda \setminus \{0\}} \|G_t v\|^{-2s}, \qquad \mathcal{L}_t(s) = \pi^{-s} \Gamma(s) \mathcal{E}_t(s). \tag{151.3}$$

The lattice-point count above proves absolute convergence in that half-plane. Applying the gamma integral term by term yields

$$\mathcal{L}_t(s) = \int_0^\infty (\Theta_t(x) - 1) x^{s-1}\, dx.$$

Theorem 151.2 (Polar decomposition and bilateral reciprocity)**.** *The function $\mathcal{L}_t$ extends meromorphically through*

$$\mathcal{L}_t(s) = \frac{1}{s - 12} - \frac{1}{s} + \int_1^\infty \Big[(\Theta_t(x) - 1) x^{s-1} + (\Theta_{-t}(x) - 1) x^{11 - s}\Big]\, dx. \tag{151.4}$$

Its only poles are simple, at $s = 0, 12$, with residues $-1, +1$, respectively. It satisfies

$$\mathcal{L}_t(s) = \mathcal{L}_{-t}(12 - s), \qquad \Xi_t(s) := s(s-12)\mathcal{L}_t(s) = \Xi_{-t}(12 - s), \tag{151.5}$$

and Ξ_t is entire.

Proof. Split the integral at $x = 1$. For $0 < x < 1$, theta reciprocity gives

$$\Theta_t(x) - 1 = x^{-12} - 1 + x^{-12}(\Theta_{-t}(1/x) - 1).$$

The first two terms integrate to $1/(s-12) - 1/s$. In the third, the change of variable $y = 1/x$ gives $\int_1^\infty (\Theta_{-t}(y) - 1)y^{11-s}\,dy$. The positive minimum length of the lattice ensures exponential decay of $\Theta_t(x) - 1$ as $x \to \infty$. On every compact set of s, that decay dominates every power of x and $\log x$; the integrals and their complex derivatives therefore converge uniformly and define entire functions. The residues are read from the rational part. Simultaneously replacing (t, s) by $(-t, 12 - s)$ exchanges the integrals and leaves the rational part invariant. Multiplication by $s(s-12)$ removes both poles. □

The center $s = 6$ results from the rank and exponent $-2s$ adopted in (151.3). The family is the Epstein completion of the deformed lattices. Its spectral variable and normalization remain distinct from those of the Riemann zeta function; the proved relation between the two constructions is the reciprocity of their circular and lattice realizations.

Corollary 151.3 (Polar conservation and antisymmetric component)**.** *The functions*

$$\mathcal{L}_t(s) - \mathcal{L}_0(s), \qquad \mathcal{A}_t(s) = \frac{\mathcal{L}_t(s) - \mathcal{L}_{-t}(s)}{2}$$

are entire. Moreover,

$$\mathcal{A}_t(12 - s) = -\mathcal{A}_t(s), \qquad \mathcal{A}_t(6) = 0.$$

Proof. The rational part of (151.4) is independent of t, so it cancels in both differences. The functional equation changes the sign of the second. Evaluation at its fixed point gives $2\mathcal{A}_t(6) = 0$. □

The deformation therefore resides in an entire difference and preserves the polar data exactly. The central zero belongs to the bilateral difference, without imposing a zero on each $\mathcal{L}_t$. The poles described are singularities of a Mellin transform; the physical connection with the mass operator is established later through the action section, with its own variable and reader.

151.3 Stable reconstruction from the bilateral archive

For the unitary cyclic shift S, the preceding recovery law provides

$$T_j = \frac{8I + S^j}{9}, \qquad D_j = \frac{\sqrt{8}(S^j - I)}{9}, \quad j = 3, 4,$$

$$m = (D_3K, D_4T_3K) = MK, \qquad LM = P_{11}, \qquad \|L\| = \frac{9}{4}. \tag{151.6}$$

Consequently,

$$u = P_3Lm. \tag{151.7}$$

With the incidence chart, marked lattice and regional ratio ρ fixed, this equality successively recovers $u/\|u\|$, g_t, G_t, Λ_t, Θ_t and $\mathcal{E}_t$. Reconstruction of this family requires neither the terminal T_4T_3K nor the uniform charge of the register. The geometric antecedents remain included among the fixed data.

Theorem 151.4 (Geometric and spectral stability of recovery)**.** *Suppose $m' = m + e$, $\|e\| \le \varepsilon$ and $9\varepsilon/4 < \|u\|$. Let $u' = P_3 L m'$, and reconstruct the flows with $u'/\|u'\|$, without varying ρ, P_3, L or the charts. If $a = |t \log \rho|$, then*

$$\|g_t' - g_t\|,\ \|G_t' - G_t\| \le \frac{9}{2}\, a e^a \frac{\varepsilon}{\|u\|}. \tag{151.8}$$

With $H_K = \operatorname{diag}(h_i)$, $b = |t|\|H_K' - H_K\|$, we have

$$b \le \frac{9a\varepsilon}{2\|u\|},$$

$$\Theta_t(e^{2b}x) \le \Theta_t'(x) \le \Theta_t(e^{-2b}x), \tag{151.9}$$

$$e^{-2\sigma b}\mathcal{E}_t(\sigma) \le \mathcal{E}_t'(\sigma) \le e^{2\sigma b}\mathcal{E}_t(\sigma), \qquad \sigma > 12. \tag{151.10}$$

Proof. The norm of the recovery operator gives $\|u' - u\| \le 9\varepsilon/4$, ensuring $u' \neq 0$. The triangle inequality and the reverse triangle inequality for norms imply

$$\left\| \frac{u'}{\|u'\|} - \frac{u}{\|u\|} \right\| \le \frac{2\|u' - u\|}{\|u\|}.$$

Every exponent lies between $-a$ and a. Applying the mean value theorem to the exponential and taking the diagonal operator norm proves (151.8); repeating each entry twice does not change that norm. The same estimate before exponentiation gives the bound on b.

Since the two generators are diagonal in the same chart,

$$e^{-2b}\|G_t v\|^2 \le \|G_t' v\|^2 \le e^{2b}\|G_t v\|^2.$$

Applying the decreasing exponential and summing proves (151.9). Raising to $-\sigma$ and summing within the domain of convergence proves (151.10). The bounds apply to all vectors, not to a finite truncation of the series. □

The error ε is measured in the normalized memories of (151.6). If the rational registers $z = m/\sqrt{8}$ are retained, their error is multiplied by $\sqrt{8}$ before applying the estimate. Independent errors in the regional ratio or in the charts require their own bounds. The result recovers a family of geometries and analytic readings, with quantitative control of the archive determining it.

Chapter 152

Hyperbolic geometry of the angular pair and recovery of action

152.1 Radion, action ellipse and marked charts

The oriented section of phase, action and memory called *radion* jointly preserves the angular increment $\theta = 1$, signed action $\sigma\hbar_{\mathrm{ret}}$, membership in the turn $2\pi_{\mathrm{HMT}}$, sheet, nonadic return and refinement cylinder. Its unity splice is expressed in the continuum chart by $1 = S_E - \Phi_T + \varepsilon_1$. The projection retaining only $\theta = 1$ produces the ordinary radian; the enriched section also preserves the register needed to transport and invert its other readings. In this section, *radius* will denote a positive shape coordinate, distinct from that enriched object.

To make the splice terms explicit, the dodecaphasic wheel has centers $30m - 10$ in its degree chart. The second phase contributes 50, and the publication $A = 1000\alpha$ determines

$$S_E = \frac{2\pi}{360}(50 + 1000\alpha).$$

The active sector of the tritic selector comprises $H_+ = \{1, 4, 7\}$ and $H_- = \{2, 5, 8\}$. The fifteen unordered pairs, read at the six active positions, produce $N_6 = 6\binom{6}{2} = 90$; their extension to eight positions produces $N_8 = 8\binom{6}{2} = 120$. The two sheets of the active sector, normalized by the ambient fibre of 729 elements, determine

$$\rho_{\mathrm{tw}} = \frac{2N_6}{729} = \frac{20}{81}, \qquad \Phi_T = \frac{20}{81}\Delta_4, \qquad S_T = 1 + \Phi_T, \qquad \varepsilon_1 = S_T - S_E,$$

where Δ_4 is the torsional coordinate in (153.1). The subtraction retains the preceding sections and directly proves $S_E - \Phi_T + \varepsilon_1 = S_E - \Phi_T + 1 + \Phi_T - S_E = 1$. The coefficient comes from the census and the two sheets, not from the value of the final difference.

The angular publications of the preceding sections satisfy, in the chart considered,

$$A > 0, \qquad |C^*| < A, \qquad \xi = \frac{C^*}{A}, \qquad \eta_{\mathrm{el}} = \operatorname{artanh}\xi.$$

The notation η_{el} distinguishes elliptic anisotropy from the return coefficient η_{ret}. For a positive action section $\hbar$, the semiaxes are

$$a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}, \qquad b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}, \qquad a_S b_S = 2\hbar. \tag{152.1}$$

The product fixes the action per revolution, whereas the ratio fixes the shape. Define

$$R_\star = \sqrt{b_S/a_S} = e^{-\eta_{\mathrm{el}}/2}, \qquad \tau_{\mathrm{el}} = iR_\star^2.$$

Theorem 152.1 (Compatibility of the radial, Poincaré and Klein charts)**.** *Let*

$$w = \frac{\tau_{\mathrm{el}} - i}{\tau_{\mathrm{el}} + i}, \qquad x_K = \frac{2w}{1 + w^2}.$$

On the real diameter of the Poincare disk and its image in the Klein disk,

$$w = \frac{R_\star^2 - 1}{R_\star^2 + 1} = -\tanh\frac{\eta_{\mathrm{el}}}{2}, \tag{152.2}$$

$$x_K = \frac{R_\star^4 - 1}{R_\star^4 + 1} = -\tanh\eta_{\mathrm{el}} = -\frac{C^*}{A}. \tag{152.3}$$

All these transformations are invertible on their domains; in particular, $R_\star^2 = (1+w)/(1-w)$.

Proof. Substitute $\tau = iR_\star^2$ into the fractional transformation. The simplified ratio has denominator $R_\star^2 + 1 > 0$ and $-1 < w < 1$. Substituting this ratio into $2w/(1+w^2)$ and multiplying numerator and denominator by $(R_\star^2+1)^2$ gives $(R_\star^4-1)/(R_\star^4+1)$. The identity $R_\star^4 = e^{-2\eta_{\mathrm{el}}}$ yields the hyperbolic tangent. Finally, $\tanh\eta_{\mathrm{el}} = \xi$. The recovery maps follow by solving the ratios. □

The sign of (152.3) corresponds to the orientation chosen for the diameter. The opposite orientation changes both signs. It is a hyperbolic coordinate of the marked rectangular chart: it preserves the marking and is not confused with a modular form or with a coordinate of the modular quotient devoid of orientation.

Exchanging the semiaxes acts by

$$(R_\star, \eta_{\mathrm{el}}, \tau_{\mathrm{el}}, w, x_K) \longmapsto (R_\star^{-1}, -\eta_{\mathrm{el}}, -1/\tau_{\mathrm{el}}, -w, -x_K). \tag{152.4}$$

On this diameter, the hyperbolic metrics of curvature -1 satisfy

$$\frac{|d\tau|^2}{(\Im\tau)^2} = \frac{4\,dw^2}{(1-w^2)^2} = \frac{dx_K^2}{(1-x_K^2)^2} = d\eta_{\mathrm{el}}^2 = 4\frac{dR_\star^2}{R_\star^2}. \tag{152.5}$$

These identities are verified by differentiating (152.2)–(152.3). In particular, $d(0,w) = |\eta_{\mathrm{el}}|$ and $d(w,-w) = 2|\eta_{\mathrm{el}}|$. The transformation $w \mapsto -w$ is a rotation by π on the entire disk and reflection about the centre on the generated diameter.

The normalization $(Q/a_S, P/b_S)$ of the ellipse's interior produces another realization of the Klein disk, with position coordinates. Its metric is

$$ds_K^2 = \frac{(1-r^2)(du^2+dv^2) + (u\,du + v\,dv)^2}{(1-r^2)^2}, \qquad r^2 = u^2+v^2 < 1.$$

This physical chart and the marked shape chart retain different domains. On the focal branch $\eta_{\mathrm{el}} \geq 0$, the eccentricity $e_f = \sqrt{1-e^{-2\eta_{\mathrm{el}}}}$ gives depth $u_f = \operatorname{artanh} e_f$, whence $\eta_{\mathrm{el}} = \log\cosh u_f$. Focal depth is not identified with anisotropy.

Shape chart: $w \mapsto -w$ Spectral chart: radial inversion

Figure 152.1: Two typed reciprocities. The first remains inside the disk and transports shape orientation; the second exchanges the interior and exterior of the unit circle. The plotted positions are schematic.

152.2 Structural substitution of the angular coordinates

The already constructed dodecaphasic closure publishes the same coordinate α through

$$\alpha = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{ag}}, \qquad \kappa_{\mathrm{ag}} = \frac{K_{\mathrm{int}}}{1000^{12} - 1}.$$

The compatible base, phase origin and carry boundary are retained. The complete analytic recurrence of the article represents that correlated coordinate; its publication is not replaced by a finite jet. Abbreviating the HMT subscripts, the action readers of (14.64)–(14.67) are

$$\begin{aligned} H_5 &= \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5, \\ D_A &= e^{-100\pi\alpha/9}, \qquad C_\pi = 169\alpha^6 + \frac{D_A\alpha^7}{1 - D_A\alpha}, \\ \eta_{\mathrm{ret}} &= H_5 - \frac{90}{\pi}C_\pi, \qquad A = 1000\alpha, \qquad C^* = 2(\eta_{\mathrm{ret}} + \alpha). \end{aligned} \tag{152.6}$$

The rational continuation retains every term of the regional recurrence. Its convergence follows without truncation: for $\alpha > 0$,

$$0 < \alpha e^{-100\pi\alpha/9} \le \frac{9}{100\pi e} < 1,$$

since xe^{-cx} attains its maximum $1/(ce)$ at $x = 1/c$.

Proposition 152.2 (Structural cancellation in the angular contrast)**.** *The generated ratio $\xi = C^*/A$ satisfies exactly*

$$\begin{aligned} \xi = {} & \frac{1}{\sqrt{1000\varphi\alpha}} + \frac{9\alpha}{8000} - \frac{\alpha^2}{900} + \frac{7\alpha^3}{24000} - \frac{\alpha^4}{27000} \\ & - \frac{9}{50\pi}\left(169\alpha^5 + \frac{D_A\alpha^6}{1 - D_A\alpha}\right). \end{aligned} \tag{152.7}$$

Proof. Start from $\xi = (\eta_{\mathrm{ret}} + \alpha)/(500\alpha)$. The term $-\alpha$ in H_5 cancels against the $+\alpha$ of the counter-angle. Dividing each remaining term by 500α yields the expression: the square root gives $1/\sqrt{1000\varphi\alpha}$, and $90/500 = 9/50$. The regional continuation retains its complete denominator. □

Therefore, $x_K = -\xi$ and $R_\star = ((1-\xi)/(1+\xi))^{1/4}$ are explicit expressions of the regional publications and the register. Substitution of the closure of α completes the dependence on $\pi, \varphi, e, \kappa_{\mathrm{ag}}$, without promoting metrological recognitions to generators.

152.3 Recovery of the Planck coordinate and preservation of orientation

Theorem 152.3 (Radial recovery map for the return section)**.** *In the positive chart, if $q = R_\star^4$, then*

$$\eta_{\mathrm{ret}} = \alpha\frac{499 - 501q}{1 + q}, \tag{152.8}$$

$$\hbar_{\mathrm{ret}} = \alpha\frac{499 - 501q}{1 + q}\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \tag{152.9}$$

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5(1+q)}{\alpha(499 - 501q)}. \tag{152.10}$$

The branch $\eta_{\mathrm{ret}} > 0$ is equivalent to $q < 499/501$, within $q > 0$.

Proof. The angular identities give $\eta_{\mathrm{ret}} = \alpha(500\xi - 1)$. Substitute $\xi = (1-q)/(1+q)$; the numerator is $499 - 501q$. Both the denominator and α are positive. The dimensional realization and the ratio are those of the action sections already constructed. The decade -34 and the unit $\mathcal{U}_S$ retain their preceding determinantal derivation. □

This formula makes the Planck section within the counter-angle explicit. In terms of the action quantities, the angular relation is

$$C^* = 2\left(\frac{\hbar_{\mathrm{ret}}}{10^{-34}\mathcal{U}_S} + \alpha\right).$$

Division by the dimensional basis extracts the dimensionless coefficient; it does not add an action quantity to a dimensionless constant.

For the angular orientation $\varepsilon \in \{-1, +1\}$, define

$$C^*_\varepsilon = 2\varepsilon(\eta_{\mathrm{ret}} + \alpha), \quad \xi_\varepsilon = C^*_\varepsilon/A, \quad q_\varepsilon = \frac{1-\xi_\varepsilon}{1+\xi_\varepsilon} > 0.$$

The recovery map on both charts is

$$\eta_{\mathrm{ret}} = \alpha\left(500\varepsilon\frac{1-q_\varepsilon}{1+q_\varepsilon} - 1\right). \tag{152.11}$$

Corollary 152.4 (Invariance of the conjugate recovery map)**.** *The transformation* $(\varepsilon, q) \mapsto (-\varepsilon, q^{-1})$ *preserves* η_{ret}, $\hbar_{\mathrm{ret}}$, *and* R_{act}.

Proof. The ratio $(1-q)/(1+q)$ changes sign when q is inverted. The product by ε remains invariant. We apply (152.11) and then the action publications. □

If orientation is discarded and $\varepsilon = +1$ is incorrectly held fixed, the same expression gives $\eta_{\mathrm{ret}}(q^{-1}) = -\eta_{\mathrm{ret}}(q) - 2\alpha$. The register therefore distinguishes two algebraically different operations. Nor is the angular orientation ε automatically identified with the symplectic sign σ: exchanging the axes is antisymplectic, whereas the rotation that exchanges them preserves the area form.

152.4 Intertwining phase and anisotropy

Let

$$S_\eta = \mathrm{diag}(e^{\eta/2}, e^{-\eta/2}), \quad J_0 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad J_\eta = S_\eta J_0 S_\eta^{-1} = \begin{pmatrix} 0 & -e^{\eta} \\ e^{-\eta} & 0 \end{pmatrix}.$$

Then $\det S_\eta = 1$, $J_\eta^2 = -I$, and $C_\eta(\theta) = e^{\theta J_\eta} = S_\eta e^{\theta J_0} S_\eta^{-1}$. The law $S_{\eta+\delta} = S_\delta S_\eta$ proves the exact intertwining identity

$$C_{\eta+\delta}(\theta) S_\delta = S_\delta C_\eta(\theta). \tag{152.12}$$

The transformation preserves $dQ \wedge dP$ and carries the phase evolution to the new ellipse. With the normalization of (152.1), the swept action is $\hbar\theta$, or $\sigma\hbar\theta$ on the oriented sheet. The phase θ, the anisotropy η_{el}, and the parameter t of the flow of K thus retain distinct functions, related by explicit operators.

152.5 Radial geodesic and differential realization of the direction of K

Each radius of (150.1) determines a rectangular chart and a hyperbolic coordinate:

$$\tau_i(t) = i r_i(t)^2, \qquad w_i(t) = \frac{r_i(t)^2 - 1}{r_i(t)^2 + 1} = \tanh(t h_i).$$

Theorem 152.5 (Geodesic of compensated radii)**.** *In the product of twelve hyperbolic diameters,*

$$d(w(s), w(t)) = 2|t - s|\,|\log \rho|, \qquad \sum_i \operatorname{artanh} w_i(t) = 0. \tag{152.13}$$

Composition of advances is given by

$$w_i(t + s) = \frac{w_i(t) + w_i(s)}{1 + w_i(t) w_i(s)}.$$

Proof. In coordinates $a_i = \log r_i$, the product metric is $4 \sum_i da_i^2$. The curve $a(t) = t h$ is a straight line, with speed $2\|h\| = 2|\log \rho|$, and $\sum_i a_i = 0$. Each diameter is totally geodesic. Distance in the product is the square root of the sum of squared distances in its factors, which are $2|t - s||h_i|$. The vanishing-sum identity and the composition law follow from $\operatorname{artanh} w_i = t h_i$ and the addition formula for the hyperbolic tangent. □

The regional ratio determines the speed of this realization; K determines its direction. If $\rho = 1$, the trajectory is constant. For $\rho \neq 1$, the space of radii with product one has dimension eleven, with tangent space $V_{11} = \mathbf{1}^{\perp}$, and the normal to the trajectory within it is

$$V_{10}(K) = V_{11} \cap u^{\perp}, \qquad P_{10}(K) = P_{11} - \frac{u u^{\mathsf{T}}}{\|u\|^2}.$$

The projector of Proposition 21.64 therefore acquires a differential realization: it removes the uniform scale and distinguishes the generated direction from its ten transverse variations. Its domain is this radial space, not the real twenty-four-dimensional space of all the disks.

With $D_t = \operatorname{diag}(\operatorname{sech}^2(t h_i))$, its expression in coordinates w is $D_t P_{10} D_t^{-1}$. Indeed, D_t is the differential of $a \mapsto \tanh a$, and transforms the metric $4I$ into $4 \operatorname{diag}((1 - w_i^2)^{-2})$. The transported projection is orthogonal for that metric.

152.6 Lattice lift and rectangular lift

The radii admit two realizations that should be retained explicitly. The operator $G_t = \bigoplus_i r_i I_2$ scales both axes of each A_2 plane simultaneously. It preserves the total covolume and commutes with the ternary isometry. The homothety of each plane preserves its internal complex modulus.

The chart $\tau_i = i r_i^2$ has another realization, of fixed area:

$$T_i = \operatorname{diag}(r_i^{-1}, r_i), \qquad (\omega_1, \omega_2) = (r_i^{-1}, i r_i), \qquad \omega_2/\omega_1 = i r_i^2.$$

This is the elliptic lift with $\eta = -2 \log r_i$. This convention transforms physical periods. The fractional linear action of the same matrix on i would give i/r_i^2; to obtain $i r_i^2$ under that other convention, one uses T_i^{-1}. Distinguishing the actions prevents an inadvertent inversion.

Both realizations are reconstructed from the same radii, but the ternary commutation of the homothety does not transfer to the anisotropic deformation. The state and its readers allow the two geometries to be compared without identifying their operators.

Chapter 153

Electron coordinate, operator scale, and reversibility of readings

153.1 Algebraic structure in the complete electronic expression

The expression in Section 16.2 is now composed with the radial recovery map, retaining its factors and dimensional realization. The electronic prefactor comes from the conditional projectors of addition and multiplication on $\ell^2(\{1,\dots,9\}^3)$. On the corresponding principal plane,

$$P=\begin{pmatrix}1&0\\0&0\end{pmatrix},\qquad Q=\begin{pmatrix}1/4&\sqrt{3}/4\\ \sqrt{3}/4&3/4\end{pmatrix},\qquad \|[P,Q]\|=\frac{\sqrt{3}}{4}.$$

The equality follows because $[P,Q]=(\sqrt{3}/4)\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$. Moreover,

$$S=2P-I,\qquad J=\frac{4}{\sqrt{3}}[P,Q],\qquad S^2=I,\quad J^2=-I,\quad SJ=-JS.$$

Hence $n_\pm=(S\pm J)/2$ satisfy $n_\pm^2=0$. The block retains hyperbolic, elliptic, and nilpotent generators within the algebraic realization already derived. The coefficient $\sqrt{3}/4$ and the normalization $4/\sqrt{3}$ serve distinct functions.

Using the previously constructed coordinates and regional integers, define

$$\begin{aligned}\Delta_4&=\frac{\pi-e\log\pi}{270}\left(1+\frac{\pi}{729}\right),\\ B_e&=\frac{\sqrt{3}}{4}\left[\exp\!\left(\frac{\varphi}{\pi^2}\right)-22\alpha^3\right](1+15\Delta_4),\qquad \kappa_e=80-54\alpha+6\Delta_4.\end{aligned}\tag{153.1}$$

Thus $\varepsilon_e^{\beta}=B_eR_{\mathrm{act}}^{\kappa_e}$. The pre-return action section and its return determine

$$\delta_{\mathrm{ret}}=H_5-\eta_{\mathrm{ret}}=\frac{90}{\pi}C_\pi,\qquad R_{\mathrm{act}}=1+\frac{\delta_{\mathrm{ret}}}{\eta_{\mathrm{ret}}}.$$

Corollary 153.1 (Radial realization of the electronic coordinate)**.** *On the branch $\alpha>0$, $\eta_{\mathrm{ret}}>0$, $|\xi|<1$,*

$$\begin{aligned}\varepsilon_e^{\beta}=\frac{\sqrt{3}}{4}&\left[\exp\!\left(\frac{\varphi}{\pi^2}\right)-22\alpha^3\right](1+15\Delta_4)\\ &\times\left[1+\frac{90C_\pi}{\pi\alpha}\,\frac{1+R_\star^4}{499-501R_\star^4}\right]^{80-54\alpha+6\Delta_4}.\end{aligned}\tag{153.2}$$

In the Klein coordinate of the marked chart,

$$R_{\mathrm{act}}=1+\frac{\delta_{\mathrm{ret}}}{\alpha(-500x_K-1)}.\tag{153.3}$$

The corresponding domains are

$$\frac{1}{500}<\xi<1,\qquad 0<R_\star^4<\frac{499}{501},\qquad -1<x_K<-\frac{1}{500}.$$

Proof. We substitute (152.8) into $R_{\mathrm{act}}=1+\delta_{\mathrm{ret}}/\eta_{\mathrm{ret}}$ and then into the complete electronic expression (16.7). The Klein chart gives $\xi=-x_K$. The intervals are obtained from $\eta_{\mathrm{ret}}=\alpha(500\xi-1)>0$ and the already proved monotone correspondences. □

The substitution preserves the regional deficit, torsional normalization, return character, and incompatibility norm. It expresses the same coordinate through a recoverable geometric reader. The radius and α remain correlated by their generation; they are not independent parameters fitted to a mass. The dimensional realization remains

$$E_e^{\beta} = \varepsilon_e^{\beta} \mathcal{U}_E, \qquad m_e^{\beta} = E_e^{\beta}/c_{\mathrm{int}}^2.$$

The action decade already incorporated into the Planck sections is not multiplied again onto a coordinate expressed in the energy chart.

A second exact form, useful for isolating the correction, is

$$\widehat{\delta}_{\mathrm{ret}} = \frac{90 C_\pi}{\pi H_5}, \qquad R_{\mathrm{act}} = (1 - \widehat{\delta}_{\mathrm{ret}})^{-1}, \qquad \varepsilon_e^{\beta} = B_e (1 - \widehat{\delta}_{\mathrm{ret}})^{-\kappa_e}.$$

Positivity of both sections ensures $1 - \widehat{\delta}_{\mathrm{ret}} > 0$. The three expressions are identities of the same return, not independent predictions.

153.2 Separation of scale and shape in a positive mass fibre

The operator law of return receives a finite positive fibre of routes together with its readers. To formulate its matrix consequence independently of species names, let $\mathcal{H}$ have dimension $d \geq 1$, let $B = B^*$ be the exponent operator, and let M^0 be positive definite. The return is the congruence

$$M^{\beta} = R_{\mathrm{act}}^{B/2} M^0 R_{\mathrm{act}}^{B/2}. \tag{153.4}$$

In the route basis of the diagonal reader, $Be_\gamma = \kappa_\gamma e_\gamma$ and $M^0 e_\gamma = m_e^{(0)} \chi_{\mathrm{ref}}(\sigma_\gamma - \sigma_e, \eta_\gamma - \eta_e) e_\gamma$. The signatures and character are those of the route construction; the following theorem applies to each positive fibre without replacing its selector.

Theorem 153.2 (Uniform and unimodular decomposition of return)**.** *If $R_{\mathrm{act}} > 0$, define*

$$\bar{\kappa} = \frac{\operatorname{tr} B}{d}, \qquad B_0 = B - \bar{\kappa} I, \qquad S_0 = R_{\mathrm{act}}^{B_0/2}.$$

Then

$$M^{\beta} = R_{\mathrm{act}}^{\bar{\kappa}} S_0 M^0 S_0, \qquad \det S_0 = 1, \tag{153.5}$$

$$\det M^{\beta} = R_{\mathrm{act}}^{\operatorname{tr} B} \det M^0. \tag{153.6}$$

With $\widehat{M} = M/(\det M)^{1/d}$,

$$\widehat{M}^{\beta} = S_0 \widehat{M}^0 S_0. \tag{153.7}$$

Proof. The scalar part of B commutes with B_0. Functional calculus gives $R_{\mathrm{act}}^{B/2} = R_{\mathrm{act}}^{\bar{\kappa}/2} S_0$. In an orthonormal eigenbasis of B,

$$\det S_0 = R_{\mathrm{act}}^{\frac{1}{2}\sum_\gamma (\kappa_\gamma - \bar{\kappa})} = 1.$$

Multiplication of determinants proves (153.6). Dividing (153.5) by the d-th root of that determinant cancels the scalar factor. The proof does not require B to commute with M^0; it does require positive definiteness for normalization by the determinant. □

In the joint diagonal basis of the source construction, the individual ratios are

$$q_\gamma = \frac{m_\gamma^{\beta}}{m_\gamma^{(0)}} R_{\mathrm{act}}^{-\bar{\kappa}} = R_{\mathrm{act}}^{\kappa_\gamma - \bar{\kappa}}, \qquad \prod_\gamma q_\gamma = 1.$$

The formal inversion $R_{\mathrm{act}} \mapsto R_{\mathrm{act}}^{-1}$ inverts each q_γ. It differs from oriented radial reciprocity, which preserves R_{act} by (152.11). The congruence preserves the normalized determinant, not the individual eigenvalues or the sum of masses. The null sector lies outside this positive normalization. For $d = 1$, $B_0 = 0$: the electron's return lies entirely in the uniform factor and remains in (153.2).

Substitution of (153.3) also acts on (153.4) through functional calculus. If

$$q(\xi) = 1 + \frac{\delta_{\mathrm{ret}}}{\alpha(500\xi - 1)} > 0,$$

then

$$M^\beta = e^{\frac{1}{2}(\log q(\xi))B}\, M^0\, e^{\frac{1}{2}(\log q(\xi))B}.$$

The genealogy of each exponent and each multisection is preserved. The structure shared with the flow of K consists of removing a uniform component and then applying a deformation of determinant one; B_0 is not identified with $\mathrm{diag}(u)$, nor R_{act} with ρ.

153.3 Circular compression and identification of transport

Theorem 153.3 (Bilateral recovery of a unitary operator)**.** *Let C be unitary on a Hilbert space, and let*

$$T = \frac{8I + C}{9}, \qquad D = \frac{\sqrt{8}(C - I)}{9}.$$

Then

$$T^*T + D^*D = I, \qquad v = Tv - \frac{Dv}{\sqrt{8}}, \qquad Cv = Tv + \sqrt{8}Dv. \tag{153.8}$$

Proof. Expansion gives

$$81T^*T = 65I + 8(C + C^*), \qquad 81D^*D = 16I - 8(C + C^*).$$

The sum is $81I$. The other identities follow by taking linear combinations of the two definitions. At a circular eigenvalue $|z| = 1$, the balance is $1 - |(8 + z)/9|^2 = (8/81)|1 - z|^2$. □

The archived pair recovers both the state and its image. For the invertible frame $O_K = (K, SK, \dots, S^{11}K)$ already constructed, the twelve responses form

$$Y = (CK, CSK, \dots, CS^{11}K), \qquad C = YO_K^{-1}.$$

If $CS = SC$, a single vector response $y = CK$ determines all the columns: $Y = (y, Sy, \dots, S^{11}y)$. The general case requires twelve vector trials. Recovery does not reduce that information to a single scalar.

The real diagonal generator $H_K = \mathrm{diag}(h_i)$ admits the unitary chart

$$C_K = (H_K + iI/2)(H_K - iI/2)^{-1}.$$

Each real eigenvalue is transformed into a number of modulus one. Moreover,

$$C_K - I = i(H_K - iI/2)^{-1}, \qquad H_K = \frac{i}{2}(C_K + I)(C_K - I)^{-1}.$$

Both inverses exist because H_K is self-adjoint and its spectrum is real. The archive of (153.8) therefore recovers this finite realization of the direction of K. Its dimension twelve and its domain remain distinct from those of a spectral operator for zeta.

153.4 Hierarchy of invariants and scope of the proofs

The completion $1000 = 729 + 271$, with normalized reading $1 = 729/1000 + 271/1000$, retains its generative function. The subsequent conservation laws are organized according to the object transported:

Realization	Invariant	Recovery or reciprocity
Archivo bilateral	Joint norm of reading and memory	State and image under the operator
Action ellipse	Product $a_S b_S = 2\hbar$	Radius and angular orientation
Flow of K	Product of twelve radii	Inversion $t \mapsto -t$
Deformed marked lattice	Covolume and ternary isometry	$\Lambda_t^* = \Lambda_{-t}$
Theta–Mellin reading	Poles and residues	Entire difference and functional equation
Positive mass fibre	Determinant after removing the common scale	Congruence by S_0

Conservation of volume does not imply conservation of each vector's norm. Polar conservation permits variation in the entire part. Recovery of action requires orientation to be retained. These distinctions express the operational content of evolutionary conservation: each transformation retains certain data, changes others, and preserves the register that allows the correspondence to be reconstructed.

The composition extends the function of K already proved in the article. The register participates in the reading of α; its direction is recovered from memory; that direction determines a radial geodesic and a reciprocal lattice deformation; the lattice family has a stable spectral reading. The action section provides the link to the electronic coordinate and to the positive congruence of the mass operator. This yields a chain of maps with explicit domains, inverses and invariants.

The supplement distinguishes written proofs from formalized ones. `FlujoReciproco.lean` contains ten theorems on diagonal flow, centering, determinants, inversion and lifting to twenty-four dimensions. `RadioKlein.lean` contains eleven rational theorems on charts, bounds, reciprocities and oriented recovery. The hyperbolic proofs, complete substitutions, separation of the mass operator and theta–Mellin argument appear in the text; their formalization is not attributed to compilation of those two files. Documentary receipts record provenance and reproduction, with a scope distinct from that of a mathematical proof.

Chapter 154

Carry and incidence registers and projective reconstruction of histories

The APP–TRIT–TPK construction fixes an enriched state before its numerical, incidence and operator realizations. The registers entering that construction are distinguished by the operation they allow to be inverted and by the relations they preserve. This section brings these distinctions together and composes recovery with refinement.

154.1 Carry, history, incidence and archive

The carry in Sections 146.4 and 146.5 is an integer arithmetic datum. Preserving it, together with depth and the final state, restores the antecedent through the explicit inverse (146.12). The transport history contains the ordered sequence of operations, sheets, orientations and returns. Within it, two stages with the same phase may have different accumulated registers. Holonomy acts on that history and on the frame in which its readings are performed.

The incidence register preserves the boundary relations used by the exceptional constructions. The ordered object K and its reading κ_{ag} enter with the normalizations and maps of Section 144.4. Sufficiency for recovering an operator is expressed there through the frame responses and the corresponding inversion. The archive memory of Section 147.6, in turn, is a sequence of components of a Hilbert space. The telescoping identity (147.26) preserves the norm between the remaining state and the archived components; the inverse (147.25) reconstructs the initial amplitude.

These four functions are composed while preserving their types. A carry integer, a transport word, an incidence and an archived amplitude constitute distinct data of the system. The recovery proofs specify which combination of them suffices for each reading. Figure 154.1 represents this functional hierarchy.

154.2 Refinement tree and local weights

Let H_k be the finite set of admissible prefixes of depth k, with truncations $p_{k+1,k}$, of the history system already constructed. An emission is counted with its multiplicity, and $d(\zeta) > 0$ denotes the number of emissions from ζ. The uniform seed distribution and the local weight $1/d(\zeta)$ define μ_k. The sum of the weights of the extensions of a prefix equals its weight: the measures are compatible and determine the cylinder measure μ. The propositions on fiber memory and naturality of the measure are proved below using these explicit definitions.

154.3 Enriched readers and fiber memory

The difference between history and value admits an operational criterion. At a finite level H_k, let $q_k : H_k \to Z_k$ be a reader and let $M_k : H_k \to \mathcal{M}_k$ be the preserved register. The enriched reader is $\widehat{q}_k = (q_k, M_k)$. Memory distinguishes states in the same reader fibre; its sufficiency is checked on the domain considered. This formulation incorporates into the article itself the complete development of the fibre information used below.

Proposition 154.1 (Recoverability at a finite level)**.** *An inverse of $\widehat{q}_k$ exists on its image if and only if $\widehat{q}_k$ is injective. For a random variable Z taking values in H_k with distribution μ_k, we have*

$$\mathsf{H}(Z) = \mathsf{H}(q_k(Z)) + \mathsf{H}(Z \mid q_k(Z)).$$

If $\widehat{q}_k$ is injective on the support of Z, then

$$\mathsf{H}(Z \mid q_k(Z), M_k(Z)) = 0.$$

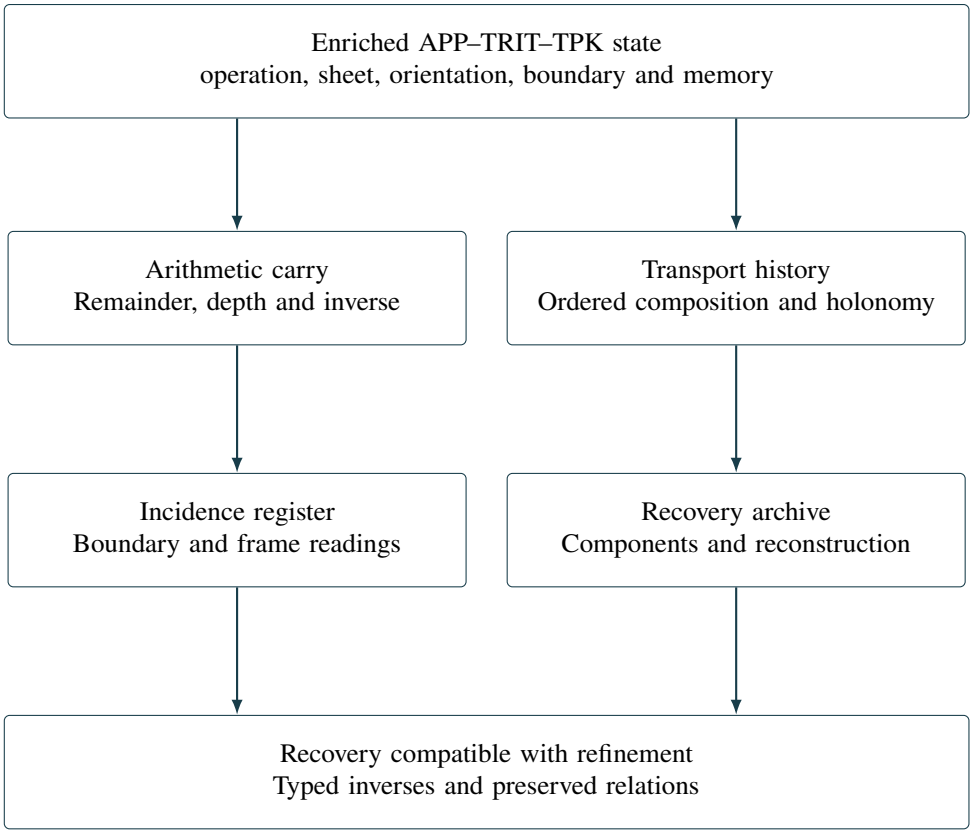

Figure 154.1: Organization of the registers by their role. The lower arrows indicate composition of recovery conditions, not identification of the four data types.

Here $\mathsf{H}(Z) = -\sum_z \Pr(Z = z) \log \Pr(Z = z)$, *with* $0 \log 0 = 0$, *is finite entropy in nats; conditional entropy is the average entropy of the conditional distributions.*

Proof. An inverse recovers a unique antecedent, which requires injectivity; conversely, injectivity allows each published pair to be assigned its unique antecedent. Since $q_k(Z)$ is a deterministic function of Z, grouping the sum defining $\mathsf{H}(Z)$ by fibres of q_k gives the chain rule. If the pair $(q_k(Z), M_k(Z))$ distinguishes the support, each corresponding conditional distribution is concentrated on a single state and its entropy is zero. □

Not publishing a coordinate and erasing the register that allows it to be recovered are distinct operations. This result does not identify entropy with the cardinality of the continuum or introduce a thermal interpretation: its domain, reader and distribution are those just fixed.

154.4 Equivariance of the measure under tree symmetries

Proposition 154.2 (Joint transport of the tree and its measure)**.** *Let* $g = (g_k)_{k \geq 0}$ *be a family of bijections* $g_k : H_k \to H_k$ *that commutes with truncations, fixes the root and bijectively transports the admissible emissions, preserving their multiplicities. Then*

$$d(g_k \zeta) = d(\zeta), \qquad (g_k)_* \mu_k = \mu_k, \qquad (g_\infty)_* \mu = \mu.$$

More generally, if μ_ζ *is the law of continuations of a history* $\zeta \in H_k$, *we have*

$$(g_\infty)_* \mu_\zeta = \mu_{g_k \zeta}.$$

Proof. The emission bijection preserves their number with multiplicities. The uniform seed distribution is also invariant. Each path and its image therefore receive the same product of local weights $1/d(\zeta)$. Equality of measures follows at each level and on each cylinder. Coherence with truncations defines g_∞, and uniqueness of the measure determined by cylinders proves equality in the limit. The same argument, starting at ζ, proves the assertion about continuations. □

This gives naturality of the tree and the measure: a coherent change of representation transports the weights and does not require choosing them anew. Preservation of emissions and multiplicities is an essential hypothesis of the proposition, not a datum added after the construction.

154.5 Recovery of histories and transport of membership

Proposition 154.3 (Compatibility of inverses and families)**.** *Let H_k be the preceding levels and $Y_k = \widehat{q}_k(H_k)$. Suppose that $\widehat{q}_k : H_k \to Y_k$ is bijective and that there exist truncations $s_{k+1,k}$ such that*

$$s_{k+1,k}\widehat{q}_{k+1} = \widehat{q}_k p_{k+1,k}.$$

Then the finite inverses induce a bijection

$$\widehat{q}_\infty : \varprojlim H_k \longrightarrow \varprojlim Y_k.$$

If $H = \varprojlim H_k$, $Y = \varprojlim Y_k$ and $\mathcal{T}(A) = \widehat{q}_\infty[A]$, the map $\mathcal{T} : \mathcal{P}(H) \to \mathcal{P}(Y)$ is bijective and preserves unions, intersections, relative complements and membership. Each restriction $A \to \mathcal{T}(A)$ is a bijection.

Proof. Composing the compatibility identity with the inverses gives

$$p_{k+1,k}\widehat{q}_{k+1}^{-1} = \widehat{q}_k^{-1} s_{k+1,k}.$$

Therefore, a compatible family $y = (y_k)$ determines the compatible family $x = (\widehat{q}_k^{-1}(y_k))$. The two coordinate maps are inverses. Direct image under a bijection has as its inverse direct image under the inverse bijection. For every family $(A_i)_{i\in I}$ of subsets of H,

$$\mathcal{T}\Big(\bigcup_i A_i\Big) = \bigcup_i \mathcal{T}(A_i),$$
$$\mathcal{T}\Big(\bigcap_i A_i\Big) = \bigcap_i \mathcal{T}(A_i),$$
$$\mathcal{T}(H \setminus A) = Y \setminus \mathcal{T}(A).$$

The first equality uses the definition of image. For the second and third, uniqueness of the antecedent allows the membership conditions to be transferred. Finally, $x \in A$ is equivalent to $\widehat{q}_\infty(x) \in \mathcal{T}(A)$, which also proves the assertion about restrictions. □

The route refinement theorem 148.3 provides a realization of this compatibility on arithmetic labels and their carries. The result distinguishes recovery of each state from preservation of operations on families. At the amplitude level, the unitary lift of 148.2 also transports the inner product. At the probabilistic level, Proposition 154.2 preserves the weights when emissions are transported with their multiplicities.

154.6 Connection with the genealogical closure of the continuum

Section 19.10 constructs a genealogical closure $\mathfrak{G}$ and establishes the cardinal identity $2^{\aleph_0} = \aleph_1$ over its internal power set. The closure, generator code and realized history form part of its definition; its set-theoretic representation is established after the genealogical construction through the operations and proofs included in that section.

The present articulation incorporates the proofs of memory, naturality and transport of families used by that relation to conservation. The proof chain is distinguished: inverses recover states; their compatibility recovers histories; the bijection transports membership operations; the genealogical closure of Section 19.10 fixes the domain of the cardinality statement. Thus, recovery and organization of families are integrated into the double projection with their respective objects, operations and conclusions.

Chapter 155

Census of residual-emitter signatures

This census specifies the finite fibers used in Section 4.3. Each initial condition is identified by

$$\nu = 4(9i + j) + d, \qquad 0 \le i, j \le 8, \quad d = 0, 1, 2, 3 \longleftrightarrow N, E, S, O.$$

Euclidean division recovers $d = [\nu]_4$, $j = [\lfloor \nu/4 \rfloor]_9$ and $i = \lfloor \nu/36 \rfloor$. Thus $0 \le \nu < 324$ enumerates each condition exactly once, and pairs of these identifiers enumerate the 104 976 conditions in Ω_{seed}.

Let $f_+(\nu)$ and $f_\times(\nu)$ be the six-component signatures obtained from the emission recurrence. At every active step the cell is read before the cursor advances; the direction vectors are

$$v_N = (-1, 0), \quad v_E = (0, 1), \quad v_S = (1, 0), \quad v_O = (0, -1).$$

Coordinates are reduced modulo nine and the vector is reversed after steps 27 and 54. Zero-phase steps do not move either cursor. Together with (4.30), these rules determine f_+ and $f_\times$ without a target-value catalog.

The table gives their complete images. The multiplicity m_σ counts identifiers in the fiber $f_\sigma^{-1}(a)$; $\nu_{\min}$ is its least element. Each word retains its initial zeros. The complete fiber is determined by

$$f_\sigma^{-1}(a) = \{\nu \in \{0, \dots, 323\} : f_\sigma(\nu) = a\}.$$

f_+	m_+	$\nu_{\min}$	$f_\times$	$m_\times$	$\nu_{\min}$
122564	18	17	000000	108	8
122898	18	24	177393	8	1
212645	18	5	177555	8	54
212988	18	0	177771	8	11
221456	18	29	339555	8	6
221889	18	12	339771	8	15
456221	18	28	339933	8	59
465898	18	21	393177	8	0
546988	18	9	393393	8	45
564122	18	16	393555	8	40
645212	18	4	555177	8	52
654889	18	33	555339	8	4
889221	18	13	555393	8	41
889654	18	32	555555	24	84
898122	18	25	555717	8	14
898465	18	20	555771	8	18
988212	18	1	555933	8	24
988546	18	8	717555	8	12
			717717	8	21
			717933	8	19
			771177	8	9
			771339	8	13
			771555	8	16
			933339	8	57
			933555	8	26
			933717	8	17

Evaluating the recurrence for the 324 identifiers gives the two partitions in the table: $18 \cdot 18 = 324$ and $24 \cdot 8 + 24 + 108 = 324$. Their fiber product yields 432 fibers of size 144, 18 of size 432, and 18 of size

1944, by injectivity of (4.31). Finally, applying (4.32) to that product of images gives 243 distinct words. This finite census belongs to the residual emitter; subsequent coinductive refinement retains its own law.

Chapter 156

Nonadic holonomy, reciprocity and recovery of geometric readers

The nonadic connection, areal–volumetric incidence and radial reciprocity enter different realizations of the same enriched state. The connection preserves the oriented sequence of nine phases and extends memory on return. Incidence records transitions between two reading modes. Radial reciprocity exchanges the two orientations of a geometric form of fixed area. Their composition is expressed through three precise results: invariance of a mark quotient at every depth, factorization of a determinant-one deformation and reconstruction of anisotropy from a normalized length and its orientation.

The construction order remains

$$\begin{gathered}\text{APP} \longrightarrow \text{TRIT} \longrightarrow \text{TPK} \longrightarrow \text{enriched state},\\ \text{enriched state} \longrightarrow \text{joint discrete structure of the continuum},\\ \text{joint discrete structure of the continuum} \longrightarrow \text{readers composed here}.\end{gathered}$$

The coordinates π, φ, e, α and register K appearing in the formulas are outputs of the preceding regional generation. The tritic calendar already determines consecutive pairs of additive and multiplicative modes. The language of matrices, hyperbolic functions and exterior minors then makes explicit the realizations of that generated structure.

156.1 Modal incidence and regional marks on finite returns

156.1.1 Enumeration of returns between sheets

The temporal block $(+, -, 0)$ induces the modal sequence (Σ, Π, Π). Its consecutive pairs, including the return link, are (Σ, Π), (Π, Π) and (Π, Σ). The primitive incidence, in areal–volumetric order, is therefore

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{156.1}$$

This matrix records the calendar pairs. The memory-one symbolic envelope it determines preserves that incidence; additional phase, orientation and register restrictions remain in the TPK state. The envelope count and survival of a complete enriched history are thus distinguished.

Let $f_0 = 0$, $f_1 = 1$ and $f_{n+1} = f_n + f_{n-1}$ for $n \geq 1$. These integers express here the counts produced by powers of the incidence. Conventional identification of this sequence remains subsequent to construction of the calendar.

Proposition 156.1 (Powers of incidence and diagonal returns)**.** *For every $n \geq 1$,*

$$F_{\mathrm{av}}^{n} = \begin{pmatrix} f_{n-1} & f_n \\ f_n & f_{n+1} \end{pmatrix}. \tag{156.2}$$

In particular, returns of length n to the areal and volumetric sheets have multiplicities f_{n-1} and f_{n+1}, respectively.

Proof. For $n = 1$, the formula is the definition of F_{av}, since $f_2 = 1$. Assuming validity for n, right multiplication gives

$$\begin{pmatrix} f_{n-1} & f_n \\ f_n & f_{n+1} \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} f_n & f_{n-1}+f_n \\ f_{n+1} & f_n + f_{n+1} \end{pmatrix} = \begin{pmatrix} f_n & f_{n+1} \\ f_{n+1} & f_{n+2} \end{pmatrix}.$$

Induction proves the identity. For an incidence matrix with entries zero or one, the multiplication rule sums sequences of compatible transitions between two positions. By induction on length, entry (i, j) of the power counts sequences of length n from i to j. The two diagonal entries count the stated returns. □

156.1.2 Regional marking of the return support

Let $e_{\mathrm{ar}} = (1, 0)^{\mathsf{T}}$ and $e_{\mathrm{vol}} = (0, 1)^{\mathsf{T}}$. For a positive coordinate c, produced before this evaluation, define the mark reader

$$D_c = c\, e_{\mathrm{ar}} e_{\mathrm{ar}}^{\mathsf{T}} + e_{\mathrm{vol}} e_{\mathrm{vol}}^{\mathsf{T}} = \mathrm{diag}(c, 1).$$

Diagonality preserves both sheets; the volumetric entry expresses its unit normalization. The areal mark c is applied once, after the return count. Its evaluation is

$$\Theta_{c,n} = \frac{\langle e_{\mathrm{ar}}, D_c F_{\mathrm{av}}^{n} e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^{n} e_{\mathrm{vol}} \rangle} = c\, \frac{f_{n-1}}{f_{n+1}}, \qquad n \geq 1. \tag{156.3}$$

The choice $c = \pi$ coincides with the boundary reader of the areal–volumetric return. The choice $c = e$ defines the complementary subsequent reader considered in this chapter. Both use the same return support and the regional coordinate already generated.

Theorem 156.2 (Depth-independent mark quotient)**.** *For any positive marks c, d and every $n \geq 2$,*

$$\frac{\Theta_{c,n}}{\Theta_{d,n}} = \frac{c}{d}. \tag{156.4}$$

In particular,

$$\frac{\Theta_{\pi,n}}{\Theta_{e,n}} = \frac{\pi}{e}, \qquad \lim_{n\to\infty} \Theta_{\pi,n} = \frac{\pi}{\varphi^2}, \qquad \lim_{n\to\infty} \Theta_{e,n} = \frac{e}{\varphi^2}. \tag{156.5}$$

Proof. The recurrence implies $f_j > 0$ for $j \geq 1$. For $n \geq 2$, the quotient $r_n = f_{n-1}/f_{n+1}$ is positive. By (156.3), the two evaluations are cr_n and dr_n, so division cancels exactly the same return factor. The preceding identification of the regional self-scaling coordinate with the stable ratio of this incidence gives $r_n \to \varphi^{-2}$. Multiplying by the constant marks π and e yields both limits. The finite quotient, by contrast, already has its exact value before passage to the limit. □

The first length has $f_0 = 0$: both evaluations vanish and their quotient lies outside the domain of (156.4). The restriction $n \geq 2$ expresses a property of the count and avoids extending a simplification to a zero denominator.

n	2	3	4	5	6
r_n	$1/2$	$1/3$	$2/5$	$3/8$	$5/13$
$\Theta_{\pi,n}$	$\pi/2$	$\pi/3$	$2\pi/5$	$3\pi/8$	$5\pi/13$
$\Theta_{e,n}$	$e/2$	$e/3$	$2e/5$	$3e/8$	$5e/13$

The table exhibits two simultaneous facts: each reader changes with depth, while their comparison remains fixed. Invariance pertains to a relationship between readers, not to immobility of the state supporting the reading.

156.1.3 Exact convergence bound to the stable ratio

The already established correspondence of the generated coordinate φ with the positive eigenvalue of F_{av} gives $\varphi^2 = \varphi + 1$ and $\varphi > 1$. The limit can be quantified without introducing a target decimal expansion.

Proposition 156.3 (Error of the return quotient)**.** *Setting $q = -\varphi^{-2}$, for $n \geq 1$ we have*

$$r_n = \varphi^{-2}\frac{1 - q^{n-1}}{1 - q^{n+1}}, \tag{156.6}$$

$$r_n - \varphi^{-2} = \varphi^{-2}\frac{q^{n-1}(q^2 - 1)}{1 - q^{n+1}}. \tag{156.7}$$

In particular,

$$|r_n - \varphi^{-2}| \leq \varphi^{-2}\frac{|q|^{n-1}(1 - q^2)}{1 - |q|^{n+1}}. \tag{156.8}$$

Proof. Let $\psi = -\varphi^{-1}$. From $\varphi^2 = \varphi + 1$ follows $\psi^2 = \psi + 1$. The sequence $b_n = (\varphi^n - \psi^n)/(\varphi - \psi)$ satisfies $b_0 = 0$, $b_1 = 1$ and the same recurrence as f_n. Induction gives $b_n = f_n$. Dividing the expression for f_{n-1} by that for f_{n+1}, and using $\psi/\varphi = q$, yields (156.6). Subtracting the limit produces (156.7). Finally, $|q| < 1$, $1 - q^2 > 0$ and $|1 - q^{n+1}| \geq 1 - |q|^{n+1} > 0$ give the bound. □

This formula is an exact reading of the convergence rate of the incidence already generated. The marks receive the error multiplied by c, but their quotient retains the exact cancellation of Theorem 156.2.

156.2 Multiplicative composition of the coupling flow

156.2.1 Generated direction and elimination of the uniform component

The dodecaphase register K, with its marking, produces the direction

$$u_K = P_3 P_{11} K, \qquad u_K \neq 0, \qquad \langle u_K, \mathbf{1} \rangle = 0.$$

The projectors are the operators already constructed in the corresponding realization of the register. This section fixes their result and writes

$$v = \frac{u_K}{\|u_K\|}, \qquad H_K = \operatorname{diag}(v_1, \ldots, v_{12}).$$

Then $\sum_i v_i = 0$, $\sum_i v_i^2 = 1$ and $\operatorname{tr} H_K = 0$. For a positive mark r and a real parameter t, define

$$g_{K,r}(t) = \exp\bigl(t \log(r) H_K\bigr) = \operatorname{diag}\bigl(r^{t v_1}, \ldots, r^{t v_{12}}\bigr). \tag{156.9}$$

The direction comes from the register; the mark determines the logarithmic scale of deformation. Parameter t parametrizes this geometric flow. Identification with a physical clock requires the corresponding temporal realization.

Theorem 156.4 (Mark homomorphism and determinant preservation)**.** *For $a, b > 0$ and $s, t \in \mathbb{R}$,*

$$g_{K,ab}(t) = g_{K,a}(t) g_{K,b}(t), \tag{156.10}$$

$$g_{K,a/b}(t) = g_{K,a}(t) g_{K,b}(t)^{-1}, \tag{156.11}$$

$$g_{K,r}(s + t) = g_{K,r}(s) g_{K,r}(t), \tag{156.12}$$

$$\det g_{K,r}(t) = 1. \tag{156.13}$$

Moreover, $g_{K,r}(t)^{-1} = g_{K,r}(-t) = g_{K,r^{-1}}(t)$.

Proof. All matrices are diagonal. Entry i of the first equality is $(ab)^{tv_i} = a^{tv_i}b^{tv_i}$, since $\log(ab) = \log a + \log b$ for positive bases. Every entry is strictly positive, so the matrix is invertible, and substitution $b \mapsto b^{-1}$ proves the second equality. The third follows from $r^{(s+t)v_i} = r^{sv_i}r^{tv_i}$. The determinant is the product of the twelve entries:

$$\prod_{i=1}^{12} r^{tv_i} = r^{t\sum_i v_i} = r^0 = 1.$$

The inverse formula again consists of inverting every entry. □

Corollary 156.5 (Composition of ambivalence and regional mirror)**.** *For every $n \geq 2$,*

$$g_{K,\Theta_{\pi,n}}(t)g_{K,\Theta_{e,n}}(t)^{-1} = g_{K,\pi/e}(t). \tag{156.14}$$

In the stable limit,

$$g_{K,\pi/\varphi^2}(t) = g_{K,\pi/e}(t)\, g_{K,e/\varphi^2}(t). \tag{156.15}$$

Proof. Both finite marks are positive for $n \geq 2$. Applying (156.11) and (156.4), their matrix quotient is the flow of mark π/e. For the second equality, it suffices to use $(\pi/e)(e/\varphi^2) = \pi/\varphi^2$ in (156.10). It also follows as the limit of the finite identity, since the exponential and logarithm are continuous on the domain of positive bases. □

The equality compares deformations with the same direction u_K. Internal mirror exchange of the regional channels retains its own domain on the enriched state; the ratio π/e is its subsequent scalar reading. The holonomy operator Γ_9 continues to act on phase and memory. These domains determine the meaning of the composition and preserve the register accompanying return.

156.2.2 Transport of minors and exterior invariants

Let X be a real matrix of rank k with twelve columns, and $\Delta_I(X)$ the column minor specified by a set I of k indices. Right action by $g_{K,r}(t)$ scales column i by r^{tv_i}.

Proposition 156.6 (Signs, strata and quotient invariants)**.** *We have*

$$\Delta_I\big(Xg_{K,r}(t)\big) = r^{t\sum_{i\in I} v_i}\Delta_I(X). \tag{156.16}$$

The signs and vanishing pattern of all minors are preserved. If I, J, P, Q satisfy $\mathbf{1}_I + \mathbf{1}_J = \mathbf{1}_P + \mathbf{1}_Q$, then, wherever $\Delta_P(X)\Delta_Q(X) \neq 0$, the quotient

$$\frac{\Delta_I\Delta_J}{\Delta_P\Delta_Q} \tag{156.17}$$

is invariant under the flow.

Proof. Multilinearity of the determinant multiplies the minor by the product of its column factors, proving (156.16). This product is positive and therefore preserves the minor's sign and vanishing. In (156.17), the total exponent is

$$t\sum_{i=1}^{12}(\mathbf{1}_I(i) + \mathbf{1}_J(i) - \mathbf{1}_P(i) - \mathbf{1}_Q(i))v_i = 0.$$

The denominator remains nonzero and cancellation is exact. □

For $k = 2$, a concrete application is

$$\frac{\Delta_{12}\Delta_{34}}{\Delta_{13}\Delta_{24}}.$$

Each of the four indices occurs once in the numerator and once in the denominator. In a configuration where the denominator minors are nonzero, this quantity remains fixed even though each individual minor changes. Exterior conservation thus possesses explicit observables in addition to the global determinant.

156.2.3 Lattice lifting and duality

The marked lattice realization of the preceding chapter uses the orthogonal sum of twelve planes. Write

$$G_{K,r}(t) = \bigoplus_{i=1}^{12} r^{t v_i} I_2.$$

If Λ is the reference self-dual Euclidean lattice already obtained, define $\Lambda_{r,t} = G_{K,r}(t)\Lambda$.

Proposition 156.7 (Covolume and reciprocity of deformed lattices)**.** *The covolume of $\Lambda_{r,t}$ equals that of Λ, and*

$$\Lambda_{r,t}^{*} = \Lambda_{r,-t}. \tag{156.18}$$

The factorization (156.15) *lifts to these twenty-four-dimensional operators.*

Proof. Each radius occurs twice in the determinant. Therefore,

$$\det G_{K,r}(t) = \prod_{i} r^{2 t v_i} = 1.$$

The linear change multiplies the covolume by the absolute value of the determinant, hence preserves it. For any invertible operator G, the condition $y \in (G\Lambda)^{*}$ is equivalent to $\langle y, Gx \rangle \in \mathbb{Z}$ for every $x \in \Lambda$. It is equivalent to $G^{\mathsf{T}} y \in \Lambda^{*}$, hence $(G\Lambda)^{*} = G^{-\mathsf{T}}\Lambda^{*}$. Here $\Lambda^{*} = \Lambda$, G is positive diagonal and $G^{-\mathsf{T}} = G_{K,r}(-t)$, proving (156.18). Factorization is verified on each two-dimensional block exactly as in (156.10). □

This conclusion preserves covolume and relates the deformation to its dual. Integrality of scalar products and evenness of norms are additional lattice properties. Theta–Mellin spectral reciprocity uses precisely the duality proved, together with Gaussian summability and the Poisson formula developed in their own chapter.

156.3 Normalized diagonal and restitution of radial orientation

156.3.1 Separation of scale and shape

The antecedent radial chart starts from the generated angular coordinates $A > 0$ and C^{*}, in the domain $|C^{*}| < A$. Define

$$\xi = \frac{C^{*}}{A}, \qquad \eta = \operatorname{artanh} \xi.$$

The variable η denotes shape anisotropy. Its meaning differs from that of the return mantissa η_{ret} entering the action section.

Let $s > 0$ be the areal scale produced by that section. In the action-ellipse realization, $s = 2\hbar$. The positive semiaxes are

$$a = \sqrt{s}\, e^{\eta/2}, \qquad b = \sqrt{s}\, e^{-\eta/2}, \qquad ab = s. \tag{156.19}$$

Reciprocity exchanges a and b. Its radial coordinate is $R_{*} = \sqrt{b/a} = e^{-\eta/2}$. The length considered below is the diagonal of the rectangle with sides a, b:

$$d = \sqrt{a^2 + b^2}, \qquad D = \frac{d}{\sqrt{ab}}.$$

Normalization removes the areal scale and preserves the rectangle's shape up to exchange of its sides.

Theorem 156.8 (Diagonal, anisotropy and reciprocity)**.** *In the preceding domain,*

$$D^2 = 2\cosh\eta = R_*^2 + R_*^{-2}, \qquad D = \frac{\sqrt{2}}{(1-\xi^2)^{1/4}}. \tag{156.20}$$

We have $D \geq \sqrt{2}$, and the following are equivalent

$$D = \sqrt{2}, \qquad \eta = 0, \qquad \xi = 0, \qquad R_* = 1, \qquad a = b.$$

For $D > \sqrt{2}$, the additional datum $\varepsilon = \operatorname{sgn}\eta \in \{-1, +1\}$ uniquely determines

$$\eta = \varepsilon\,\operatorname{arcosh}(D^2/2), \tag{156.21}$$

$$\xi = \varepsilon\sqrt{1 - 4/D^4}, \tag{156.22}$$

$$R_* = \exp\left[-\frac{\varepsilon}{2}\operatorname{arcosh}(D^2/2)\right]. \tag{156.23}$$

Proof. Dividing $a^2 + b^2$ by $ab = s$ in (156.19) yields

$$D^2 = e^{\eta} + e^{-\eta} = 2\cosh\eta.$$

Since $R_*^2 = e^{-\eta}$, the sum is also $R_*^2 + R_*^{-2}$. From $\xi = \tanh\eta$ and $1 - \tanh^2\eta = \cosh^{-2}\eta$, with $\cosh\eta > 0$, follows $\cosh\eta = (1-\xi^2)^{-1/2}$. The positive root supplies the second formula in (156.20).

The inequality $\cosh\eta \geq 1$, with equality only for $\eta = 0$, proves the bound and its equivalences through the definitions. For $D > \sqrt{2}$, cosh determines $|\eta| = \operatorname{arcosh}(D^2/2)$, and orientation ε determines its sign. Moreover,

$$\xi^2 = 1 - \cosh^{-2}\eta = 1 - \frac{4}{D^4}.$$

Monotonicity of tanh implies $\operatorname{sgn}\xi = \operatorname{sgn}\eta$, hence (156.22). Substitution of (156.21) into $R_* = e^{-\eta/2}$ proves the last formula. Every step is unambiguous in the stated domain. □

Corollary 156.9 (Exact recovery of the semiaxes)**.** *The data (s, D, ε), with $s > 0$ and $D > \sqrt{2}$, recover the ordered semiaxes through*

$$a^2 = \frac{s}{2}\left(D^2 + \varepsilon\sqrt{D^4 - 4}\right), \qquad b^2 = \frac{s}{2}\left(D^2 - \varepsilon\sqrt{D^4 - 4}\right). \tag{156.24}$$

If $D = \sqrt{2}$, recovery is $a = b = \sqrt{s}$.

Proof. The equations $a^2 + b^2 = sD^2$ and $a^2 b^2 = s^2$ determine a^2, b^2 as the positive roots of $z^2 - sD^2 z + s^2 = 0$. Its roots are the two quantities $s(D^2 \pm \sqrt{D^4 - 4})/2$. The sign of $a - b$ agrees with that of η, so ε assigns each root to its semiaxis. The roots are positive because $D^2 > \sqrt{D^4 - 4}$. Equality produces a double root s. □

156.3.2 Exact example of two reciprocal realizations

Take a test shape with $\xi = 3/5$. This example verifies the geometric reader; the concrete assignment of an HMT section is obtained from its own generated coordinates. We compute

$$\eta = \operatorname{artanh}(3/5) = \log 2, \qquad R_* = \frac{1}{\sqrt{2}}, \qquad D^2 = 2 + \frac{1}{2} = \frac{5}{2}.$$

For scale s, the semiaxes are $a = \sqrt{2s}$ and $b = \sqrt{s/2}$. The reciprocal shape has $\xi = -3/5$, $\eta = -\log 2$, $R_* = \sqrt{2}$ and exchanged semiaxes. Both have the same normalized diagonal $D = \sqrt{5/2}$ and the same product $ab = s$. The orientation datum distinguishes these two realizations exactly.

The diagonal therefore represents anisotropy intensity. The oriented register reconstructs the ordered shape. The areal scale, in turn, recovers its size. This separation specifies which datum each reader preserves and which datum the archive supplies.

156.3.3 Poincaré and Klein charts

The Poincaré chart of the radial diameter and its Klein chart are

$$w = \frac{R_*^2 - 1}{R_*^2 + 1} = -\tanh(\eta/2), \qquad x_{\mathrm{K}} = \frac{2w}{1 + w^2} = -\tanh \eta = -\xi. \tag{156.25}$$

The domains $R_* > 0$, $-1 < w < 1$ and $-1 < x_{\mathrm{K}} < 1$ correspond through these maps.

Proposition 156.10 (Radial reciprocity in both charts)**.** *Inversion $R_* \mapsto R_*^{-1}$ acts through*

$$\eta \mapsto -\eta, \qquad w \mapsto -w, \qquad x_{\mathrm{K}} \mapsto -x_{\mathrm{K}}.$$

The diagonal and areal scale remain invariant. The pair (D, ε) recovers both disk coordinates through (156.21) *and* (156.25)*.*

Proof. The identity $R_* = e^{-\eta/2}$ transforms inversion into a sign change of η. Both hyperbolic functions in (156.25) are odd, hence change sign. Formula $D^2 = R_*^2 + R_*^{-2}$ is invariant, and the product of the semiaxes remains s. The inverse formulas of Theorem 156.8 complete recovery. □

In the example $\xi = 3/5$, we obtain $w = -1/3$ and $x_{\mathrm{K}} = -3/5$. The reciprocal shape has $w = 1/3$ and $x_{\mathrm{K}} = 3/5$. Coincidence of the diagonal thus accompanies two opposite positions on the same diameter.

156.3.4 Radial inversion and reflection in the complex chart

The positive radius also enters the complex reciprocity chart. For $r > 0$ and an argument θ, let

$$z = re^{i\theta}, \qquad s(r, \theta) = \frac{1}{1 - z}, \qquad z \neq 1.$$

The domain excludes only the pole of this chart. Radial inversion preserves θ and replaces r by r^{-1}.

Proposition 156.11 (Reflection about the line of midpoint real part)**.** *In the preceding domain,*

$$s(r^{-1}, \theta) = 1 - \overline{s(r, \theta)}, \tag{156.26}$$

$$\operatorname{Re} s(r, \theta) - \frac{1}{2} = \frac{1 - r^2}{2|1 - re^{i\theta}|^2}. \tag{156.27}$$

Therefore, the circle $r = 1$, apart from the pole, maps to the line $\operatorname{Re} s = 1/2$*. Radial inversion is realized as reflection about that vertical line.*

Proof. The conjugate of $s(r, \theta)$ is $(1 - re^{-i\theta})^{-1}$. By direct calculation,

$$1 - \frac{1}{1 - re^{-i\theta}} = \frac{-re^{-i\theta}}{1 - re^{-i\theta}} = \frac{1}{1 - r^{-1}e^{i\theta}},$$

proving (156.26). For the second identity, multiply numerator and denominator of s by $1 - re^{-i\theta}$. Its real part is

$$\frac{1 - r\cos\theta}{1 - 2r\cos\theta + r^2}.$$

Subtracting $1/2$ reduces the numerator to $(1 - r^2)/2$. The denominator is positive on the domain. It follows that $\operatorname{Re} s = 1/2$ is equivalent to $r = 1$. Finally, if $s = x + iy$, then $1 - \overline{s} = (1 - x) + iy$, which is exactly reflection about the stated vertical line. □

For $\theta = \pi$, the radii $r = 2$ and $r = 1/2$ produce $s = 1/3$ and $s = 2/3$ respectively. The point $r = 1$ produces $s = 1/2$. This example makes reciprocity visible through three rational chart values.

The proved transformation belongs to the geometry of the complex chart. Applying it to a spectral operator requires preserving the operator and its domain as well as that chart. Likewise, the radial chart R_* preserves the angular section generating it. Equality of an inversion operation in two realizations supplies the stated correspondence; identification of their antecedent objects is maintained through the transports already constructed.

156.4 Recovery of the flow and compatibility of readers

Applying these readers to a flow direction requires preserving the generated direction as well as its scalar values. The reduced archive previously constructed has operators M and L with $LM = P_{11}$. If $m = MK$, then

$$u_K = P_3 L m. \tag{156.28}$$

This equality preserves the action of each operator and allows recovery to be composed with the flow.

Proposition 156.12 (Reconstruction of the flow from the reduced archive)**.** *With the preceding operators and marking, the archive m and a positive mark r determine*

$$g_{K,r}(t) = \operatorname{diag}\left(r^{\,t(P_3 L m)_1/\|P_3 L m\|}, \dots, r^{\,t(P_3 L m)_{12}/\|P_3 L m\|}\right).$$

All composition identities in (156.10)–(156.13) *are preserved.*

Proof. From $m = MK$ and $LM = P_{11}$ follows $P_3 L m = P_3 LMK = P_3 P_{11} K = u_K$. The direction is nonzero by the already proved property of the generated register. Normalization recovers v exactly, and its substitution into (156.9) recovers every flow entry. The identities depend only on this direction and positivity of marks, so remain valid. □

The archive identity recovers the direction of deformation. Regional readers supply their marks. The diagonal reader of the radial shape preserves its absolute anisotropy, and the oriented register recovers the sign. The resulting composition assigns invariance and reversibility to explicit data:

$$\begin{gathered}\text{sheet returns} \longrightarrow (\Theta_{\pi,n}, \Theta_{e,n}) \longrightarrow \pi/e,\\ \text{archive of } K \longrightarrow u_K \longrightarrow g_{K,r}(t) \longrightarrow \text{covolume and transported minors},\\ (s, D, \varepsilon) \longrightarrow (a, b) \longleftrightarrow (R_*, w, x_{\mathrm{K}}).\end{gathered}$$

The first line distinguishes the common support of two marks. The second expresses the register's operator function. The third specifies the geometric information needed for inversion. The enriched state preserves phase, turns, carries and incidences allowing these readers to be composed within their genealogy.

156.5 Temporal realization and domain of physical interpretation

Nonadic holonomy preserves its action on phase and memory; phase return increments the turn register. Counts of the modal envelope and mark ratios are evaluated on subsequent realizations. Radial reciprocity acts on a shape chart and its orientation. The proved articulation combines these operations through compatible readers, preserving the distinction between their parameters.

The relation π/φ^2 appears as a marked return ratio and as the scale of the conservative flow. The ratio π/e appears as a mark quotient on the same support. Both satisfy the exact factorization (156.15). Their involvement in a gravitational or cosmological realization preserves the conditions of the corresponding physical reader: clock identification, dimensional quantities, boundary response and geometric domain. This chapter's result concerns mathematical composition of the generated readers. Their physical applications subsequently use the corresponding realization.

Chapter 157

Positive geometry of refinement and conservation of canonical forms

Object and results

It is proved that reversible refinement with carry produced by the APP–TRIT–TPK architecture admits a stable canonical form: the sum of the forms of the refined cells coincides exactly with the form of the original cell, and all interior poles cancel. The identity extends exactly to the cuboidal product complex and preserves the iterated residues of the external boundary. The dodecaphase register K determines an invertible frame O_K, a Gram metric and an isometric archive preserving exterior volumes and allowing recovery of the history. An exhaustive calculation of minors shows that O_K is not totally nonnegative. The direction already constructed $u_K = P_3 P_{11} K$, combined with $\rho_A = \pi_{\mathrm{HMT}}/\varphi^2_{\mathrm{HMT}}$, defines a positive diagonal determinant-one flow preserving every Plücker sign and every positroid stratum. This separation permits formulation, under falsifiable conditions, of the intrinsic positroid atlas of the TPK, its cluster dynamics and its pushforward toward an amplituhedral section. The centrality of the electron is linked to the unique fixed point $(5, 5)$ of the APP atlas, without confusing it with the nonadic datum 111111 or the regional signature 555555.

157.1 Thesis and causal order

The starting object is not an externally chosen Grassmannian. The chain

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \widehat{x} \longrightarrow C^{\mathrm{disc}}_{\mathrm{cont}}$$

produces an enriched state preserving sheets, orientation, remainder, quotient, carry, route, boundary, survival, memory and return. The five constructions of the continuum emerge jointly. Positive geometry is an expression of their compatible refinement.

The article separates three assertions that must not be merged:

1. telescoping and the metric archive are exact results;
2. the moment curve, $D_K(s)$ and the centred flow $g_{K,\rho}(\tau)$ are exact new formalizations;
3. the intrinsic positroid atlas, cluster seed and equality with a complete amplituhedron require expressly declared additional maps.

This separation does not diminish the result: it identifies the proof of each arrow and avoids attributing positivity to a metric matrix that does not possess it.

157.2 Master theorem

157.3 Coinductive positive geometry of TPK refinement

The positive structure studied in this section is not introduced from a previously assumed Grassmannian. It arises from the same generating chain that constructs the enriched state:

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \widehat{x} \longrightarrow C^{\mathrm{disc}}_{\mathrm{cont}}.$$

APP simultaneously preserves both sheets, remainders and quotients; TRIT types the regime and orients each transition; TPK selects, transports and updates without losing carry, route, boundary, survival or memory. The five constructions of the continuum emerge jointly from that state. The following Grassmannian realization is a subsequent reader of its compatible refinement, not an input selecting the dynamics.

157.3.1 Carry, subdivision and ordered parameter

Fix an integer base $B \geq 2$. The elementary refinement operation with carry $c \in \{0, \dots, B-1\}$ is

$$L_c(x, y) = (Bx - c, By + c). \tag{157.1}$$

It preserves the rescaled sum, since

$$\frac{Bx - c}{B(x+y)} + \frac{By + c}{B(x+y)} = 1.$$

Its inverse recovers c through the declared residue class, then recovers (x, y) by Euclidean division. By composition, a carry word $c_1 \dots c_n$ determines a cell of depth n, and divisions in reverse order recover the complete word. Compatibility between truncations produces nested cylinders and preserves the history, not merely its limiting evaluation.

Let $M \geq 1$ be the number of intervals in the initial chart and

$$N_n = B^n M, \qquad t_{n,j} = \frac{j}{N_n}, \qquad 0 \leq j \leq N_n. \tag{157.2}$$

For $0 \leq j < N_n$, the subinterval of index c of point j has index

$$j' = Bj + c, \qquad t_{n+1,Bj+c} = t_{n,j} + \frac{c}{BN_n}. \tag{157.3}$$

The inequality $j < j' \Rightarrow t_{n,j} < t_{n,j'}$ makes visible the information required by positivity: carry does not merely refine; it inserts points while preserving the total order compatible with the linking maps.

157.3.2 Moment matrix and positive Grassmannian

Status. The following moment curve is a new formalization of the order already produced by refinement; it is not presented as an additional TPK operator or as an input to the generator.

For $1 \leq r \leq N_n + 1$, define the moment curve and its column matrix

$$v_r(t) = (1, t, \dots, t^{r-1})^{\mathsf{T}}, \qquad Z_n^{(r)} = (v_r(t_{n,0}) \ \cdots \ v_r(t_{n,N_n})).$$

Theorem 157.1 (Plücker positivity generated by carry)**.** *For every $I = \{j_1 < \cdots < j_r\}$,*

$$\Delta_I(Z_n^{(r)}) = \prod_{1 \leq a < b \leq r} (t_{n,j_b} - t_{n,j_a}) > 0. \tag{157.4}$$

Therefore, the row class of $Z_n^{(r)}$ belongs to $\mathrm{Gr}_{>0}(r, N_n + 1)$. Insertions (157.3) extend this system without altering the sign of any antecedent minor.

Proof. The minor is a Vandermonde determinant. Every factor of (157.4) is positive by the strict ordering of the points. An insertion maintains the order of the old columns and adds points within their intervals. Minors formed only from antecedent columns preserve their value exactly; those containing a new column are again products of positive differences. □

The weighted version preserves the same orientation. If $\lambda_{n,j} > 0$, put

$$C_{n;aj} = \lambda_{n,j} t_{n,j}^{a-1}.$$

Then

$$\Delta_I(C_n) = \left(\prod_{j \in I} \lambda_{n,j} \right) \Delta_I(Z_n^{(r)}) > 0. \tag{157.5}$$

Weights may receive a compatible cylindrical measure or the square root of a route multiplicity, provided they are declared before the external object is evaluated.

157.3.3 Survival masks and positroid realization

At every depth, the TPK preserves a survival mask $S_n \subseteq \{0, \dots, N_n\}$. To make it visible without changing the generator, allow

$$\lambda_{n,j} > 0 \quad (j \in S_n), \qquad \lambda_{n,j} = 0 \quad (j \notin S_n).$$

Status. Assigning a moment matrix to a survival mask is a *new formalization*: it uses data already generated by the TPK but is not presented as a theorem previously contained in the corpus. Its exact mathematical content is as follows.

Proposition 157.2 (Positroid realization of a mask)**.** *Suppose $|S_n| \geq r$. The weighted matrix satisfies*

$$\Delta_I(C_{n,S_n}) > 0 \iff I \subseteq S_n, \qquad \Delta_I(C_{n,S_n}) = 0 \iff I \not\subseteq S_n.$$

Its matroid is the uniform matroid of rank r on S_n, with the complementary positions as loops; in particular, it is a positroid. Realizations of two levels are compatible whenever their masks are compatible under the linking map and the old columns preserve their identification.

Proof. The factorization (157.5) shows that a minor vanishes exactly when it contains a zero weight. On S_n, all factors are positive and all subsets of cardinality r are bases. A uniform matroid realized by ordered points on the moment curve is positroidal; adding loops preserves this class. Compatibility follows because a refined mask inherits survivors and adds only the columns allowed by the compatibility hypothesis. □

The proposition certifies realization of each mask within the ordered-moment functor. It does not yet certify an intrinsic positroid atlas of the TPK or coverage of all cells of $\mathrm{Gr}_{\geq 0}(r, N_n + 1)$. That promotion requires a planar network or boundary measure derived from the TPK, together with its decorated permutation or Grassmann necklace, and naturality of those data under refinement. Absence of any of these components would falsify the global promotion, not the preceding proposition.

157.3.4 Plücker exchanges and cluster charts

For $r = 2$, write $z_j = \lambda_j(1, t_j)^{\mathsf{T}}$. If $a < b < c < d$, we have

$$\Delta_{ac}\Delta_{bd} = \Delta_{ab}\Delta_{cd} + \Delta_{ad}\Delta_{bc}. \tag{157.6}$$

Status. The following relation is exact for the ordered-moment realization. Reading it as a TPK cluster structure is a *new formalization*; it neither identifies carry with mutation nor claims that the corpus has already constructed a universal plabic graph.

Proposition 157.3 (Positive exchange in rank two)**.** *All coordinates of* (157.6) *are positive, and the mutation solving for either diagonal is subtraction-free. Insertion of a refined point through* (157.3) *commutes with evaluation of the Ptolemy relation. Triangulations of the ordered polygon and their flips therefore provide positive cluster charts for the ordered realization of each level.*

Proof. The identity follows by substituting $\Delta_{ij} = \lambda_i\lambda_j(t_j - t_i)$ and expanding. All its terms are positive. Insertion preserves the old coordinates and assigns the exact ordered parameter to the new column; evaluating the determinant first or the exchange relation first produces the same polynomial identity. □

In general rank, for $|I| = r - 2$ and $a < b < c < d$ outside I,

$$\Delta_{Iac}\Delta_{Ibd} = \Delta_{Iab}\Delta_{Icd} + \Delta_{Iad}\Delta_{Ibc}. \tag{157.7}$$

All terms are positive in the top cell and nonnegative in survival cells. Thus every short Plücker exchange is compatible with refinement within this realization. The correct assertion is that carry inserts data and mutations change charts on those data; a carry step is not identified with a flip. Intrinsic TPK cluster compatibility additionally requires deriving a seed, its quiver or plabic graph and the action of linking maps on mutations.

157.3.5 Canonical forms and cancellation of interior boundaries

For an oriented interval $I = [a, b]$, its canonical form is

$$\Omega_I = \frac{dt}{t-a} - \frac{dt}{t-b}. \tag{157.8}$$

If $a = c_0 < c_1 < \cdots < c_m = b$, then

$$\sum_{q=0}^{m-1} \Omega_{[c_q, c_{q+1}]} = \Omega_{[a,b]}. \tag{157.9}$$

Every interior pole occurs twice, with opposite residues.

The one-dimensional identity is exact and does not depend on an additional positroid interpretation. Its cubical extension is formulated below as an *exact new formalization*. Let $Q = \prod_{\ell=1}^{d} [a_\ell, b_\ell]$ with orientation $dx_1 \wedge \cdots \wedge dx_d$. Define

$$\Omega_Q = \bigwedge_{\ell=1}^{d} \left(\frac{dx_\ell}{x_\ell - a_\ell} - \frac{dx_\ell}{x_\ell - b_\ell} \right). \tag{157.10}$$

Theorem 157.4 (New formalization: multidimensional cubical telescoping)**.** *Subdivide each coordinate interval by the TPK refinement points, and denote the resulting cuboids, with induced orientation, by $Q_{\mathbf{j}}$. Then*

$$\boxed{\sum_{\mathbf{j}} \Omega_{Q_{\mathbf{j}}} = \Omega_Q.} \tag{157.11}$$

All interior-facet poles cancel. If $F_1 \supset F_2 \supset \cdots \supset F_s$ is a flag of oriented faces, then

$$\operatorname{Res}_{F_s} \cdots \operatorname{Res}_{F_1} \Omega_Q = \operatorname{sgn}(F_\bullet)\, \Omega_{F_s}. \tag{157.12}$$

In particular, the residue at each vertex has modulus one and the sign fixed by orientation.

Proof. The sum over the grid is the exterior product of the d one-dimensional sums. Applying (157.9) in each factor gives (157.11). An interior facet has two incident cells and opposite normal orientations, so their residues cancel. Taking a residue removes the corresponding normal factor and leaves the face's canonical form with its orientation sign. Iteration proves (157.12). □

Corollary 157.5 (Independence of refinement)**.** *The global form does not depend on how many carry levels have been inserted. Refining changes the triangulation or cubulation and preserves the sum of forms. TPK memory preserves which intermediate cells were traversed, even though the global form cancels their internal boundaries.*

Proposition 157.6 (General oriented cancellation criterion)**.** *Let $X = \bigcup_\sigma X_\sigma$ be a pure, oriented positive subdivision. Suppose each cell has a form Ω_σ and that, for every facet $F \subset \overline{X_\sigma}$,*

$$\operatorname{Res}_F \Omega_\sigma = [\sigma : F]\Omega_F.$$

For a chain $c = \sum_\sigma w_\sigma[\sigma]$,

$$\operatorname{Res}_F\left(\sum_\sigma w_\sigma \Omega_\sigma\right) = (\partial c)_F \Omega_F. \tag{157.13}$$

In particular, an interior facet cancels if and only if its coefficient in ∂c *is zero. Iterated residues on interior flags cancel by* $\partial^2 = 0$.

Proof. Linearity of the residue gives

$$\operatorname{Res}_F\left(\sum_\sigma w_\sigma \Omega_\sigma\right) = \sum_{\sigma \supset F} w_\sigma [\sigma : F]\Omega_F,$$

and the coefficient of Ω_F is precisely that of F in ∂c. Iteration identifies the sum of codimension-two incidences with the corresponding coefficient of $\partial^2 c$, which is zero. □

The proposition is an exact new formalization. Identifying the sum with the unique canonical form of X additionally requires excluding an ambiguous regular top form. The corpus already supplies the path-and-memory complex with $D^2 = 0$; positroid promotion requires constructing the morphism

$$\Omega_{\mathrm{TPK}} : C_\bullet^{\mathrm{TPK}} \longrightarrow \Omega^\bullet_{\log}, \qquad \operatorname{Res} \circ \Omega_{\mathrm{TPK}} = \Omega_{\mathrm{TPK}} \circ D.$$

On cylinders and products, this morphism is given by (157.8) and (157.10). For a general positroid atlas, strata, incidences, orientations, uniqueness and Plücker–cluster compatibility must be added. Nor can probabilistic history weights multiply the forms indiscriminately: a shared facet would retain a residue proportional to the weight difference. The factors $\sqrt{\mu}$ of a positive matrix belong to another operation.

157.3.6 The register K as a metric and archival frame

The dodecaphase register is produced by

$$x_{\mathrm{term}} \mapsto \mathcal{R}_{12} \mapsto (b^{90}, b^{120}, Q_{\mathrm{TPK}}) \mapsto U_{\mathrm{sgn}} \mapsto K$$

and equals

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601).$$

Let S be the cyclic shift of twelve positions and

$$O_K = (K, SK, \dots, S^{11}K), \qquad G_K = O_K^* O_K.$$

The reference development proves

$$\det O_K = 548311925921402018385039793000828362 5 > 0, \qquad 589609 I \le G_K \le 6263^2 I. \tag{157.14}$$

In particular, O_K is invertible and defines a quantitatively controlled frame. Since its determinant is positive, its polar decomposition can be written

$$O_K = F_K P_K, \qquad P_K = G_K^{1/2} > 0, \qquad F_K \in SO(12).$$

Proposition 157.7 (Exact covariance of Plücker data)**.** *Let* $X \in \mathrm{Mat}_{r\times 12}(\mathbb{R})$ *have rank* r *and* $Y = XO_K^{\mathsf{T}}$. *Then*

$$\Delta_I(Y) = \sum_{\substack{J \subseteq \{1,\dots,12\} \\ |J|=r}} \Delta_J(X) \det\big((O_K)_{I,J}\big). \tag{157.15}$$

Equivalently, the Plücker vector transforms by $\bigwedge^r O_K$. In rank twelve,

$$\Delta_{\{1,\dots,12\}}(XO_K^{\mathsf{T}}) = (\det O_K)\Delta_{\{1,\dots,12\}}(X).$$

Proof. Formula (157.15) is the Cauchy–Binet identity applied to every column set of Y. The exterior formulation and rank-twelve case are its functorial and maximal expressions, respectively. □

Plücker covariance does not amount to preserving standard total positivity. Indeed, O_K has minors of both signs. Two explicit witnesses are

$$\det\begin{pmatrix} 234 & 543 \\ 543 & 140 \end{pmatrix} = -262089, \qquad \det\begin{pmatrix} 234 & 140 \\ 543 & 729 \end{pmatrix} = 94566. \tag{157.16}$$

For example, the image under O_K of the positive coordinate plane generated by the first two canonical vectors already contains the first negative minor of (157.16). Therefore,

$$\left\{[XO_K^{\mathsf{T}}] : [X] \in \mathrm{Gr}_{\geq 0}(r,12)\right\} \not\subseteq \mathrm{Gr}_{\geq 0}(r,12) \quad \text{in general.} \tag{157.17}$$

Thus, O_K is an invertible metric and archival frame; it is neither a boundary-measurement matrix nor a generator of standard total positivity.

Positive chart adapted to K. The exact image

$$\mathrm{Gr}^K_{\geq 0}(r,12) := \left\{[XO_K^{\mathsf{T}}] : [X] \in \mathrm{Gr}_{\geq 0}(r,12)\right\} \tag{157.18}$$

defines a positive chart adapted to the frame. If $\Phi_K([X]) = [XO_K^{\mathsf{T}}]$, its adapted coordinates are

$$\Delta_I^K([Y]) := \Delta_I\Big(Y(O_K^{\mathsf{T}})^{-1}\Big) \geq 0. \tag{157.19}$$

This positivity is exact by transport of structure; it must not be confused with positivity of the minors of Y in the standard ambient basis. Likewise, a canonical form Ω in the original chart is transported as $(\Phi_K)_*\Omega$.

New formalization: positive diagonal action of K. Since all components K_i are strictly positive, define

$$D_K(s) := \mathrm{diag}\big(e^{s\log K_1}, \dots, e^{s\log K_{12}}\big), \qquad s \in \mathbb{R}, \tag{157.20}$$

so that $D_K(1) = \mathrm{diag}(K_1, \dots, K_{12})$. For every matrix $X \in \mathrm{Mat}_{r\times 12}$,

$$\Delta_I(XD_K(s)) = e^{\,s\sum_{i\in I}\log K_i}\Delta_I(X). \tag{157.21}$$

This action exactly preserves $\mathrm{Gr}_{\geq 0}(r,12)$ and its stratification by vanishing minors. The diagonal action is a new formalization constructed from the generated register K; it is neither attributed to the original reference development of O_K nor used to conceal the mixed signs of (157.16).

New formalization: centred flow determined by K. The corpus constructs

$$u_K = P_3P_{11}K, \qquad \|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0, \qquad u_K \perp \mathbf{1}. \tag{157.22}$$

Let $\widehat{u}_K = u_K/\|u_K\|$ and $\rho_A = \pi_{\mathrm{HMT}}/\varphi^2_{\mathrm{HMT}} > 0$. Then

$$g_{K,\rho}(\tau) = \operatorname{diag}\Big(\rho_A^{\tau\widehat{u}_{K,1}}, \dots, \rho_A^{\tau\widehat{u}_{K,12}}\Big) \in SL(12,\mathbb{R})_{>0}. \tag{157.23}$$

For every matrix X,

$$\Delta_I(X g_{K,\rho}(\tau)) = \rho_A^{\tau \sum_{i\in I} \widehat{u}_{K,i}} \Delta_I(X). \tag{157.24}$$

The flow therefore preserves signs and vanishing minors. The register K fixes the direction, and the generated ratio ρ_A normalizes the speed. The ratio ρ_A is evaluated here at a later stage: π_{HMT} and φ_{HMT} are two coordinates of the fourfold relation $(\pi, \varphi, e, \alpha)$ generated coinductively by the same APP–TRIT–TPK state. Neither their conventional values nor the already evaluated ratio select K, u_K or the refinement. Identifying τ with physical time requires a clock $\tau(t)$; extension to every depth requires a sectorial cocycle compatible with $j \mapsto Bj + c$.

The complete archive

$$\mathcal{V} v = \Big(A_\infty^{1/2} v, (D_j R_j v)_{j\ge 0}\Big), \qquad \mathcal{V}^*\mathcal{V} = I,$$

preserves this information in all degrees:

$$\left\langle \bigwedge^r \mathcal{V}\,\xi, \bigwedge^r \mathcal{V}\,\eta \right\rangle = \langle \xi, \eta\rangle, \qquad \| \wedge^r \mathcal{V}\,\xi\| = \|\xi\|. \tag{157.25}$$

It therefore preserves Gram determinants and Plücker norms. This isometry does not claim that $\mathcal{V}$ turns the minors of O_K into positive minors: it preserves the information archived in the space and orientation explicitly transported.

The rational reading

$$\kappa_{\mathrm{ag}} = \frac{234543140729659824621058914794146601}{10^{36} - 1}$$

is reversible once base, length and phase origin are fixed. The coupling function of K is therefore expressed in three distinct layers: its arithmetic reading κ_{ag}, its positive Gram form G_K and its incidence transport. All three are expressions of the generated register; none is used to choose the history retrospectively.

157.3.7 Areal–volumetric flow and marked ratio

The TPK calendar induces the primitive matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix},$$

whose powers obey the Fibonacci recurrence. The Parry measure of its symbolic envelope distinguishes the areal and volumetric modes and satisfies

$$\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi_{\mathrm{HMT}}^{-2}. \tag{157.26}$$

The regional reading marks this ratio once:

$$\Theta_n = \pi_{\mathrm{HMT}} \frac{F_{n-1}}{F_{n+1}} \longrightarrow \frac{\pi_{\mathrm{HMT}}}{\varphi_{\mathrm{HMT}}^2}. \tag{157.27}$$

The reciprocal reader $R(x, y) = x/y^2$, conjugated by $J(x, y) = (y, x)$, produces the orientation $\varphi_{\mathrm{HMT}}/\pi_{\mathrm{HMT}}^2$. These ratios are typed readers of the flow; they are not identified with κ_{ag}, although all participate in the same coupling architecture.

The complex's canonical form is stable under refinement, while (157.26) determines the stationary proportion of its two modes. This closes the circle: arithmetic refinement generates subdivision; the holographic ratio governs its asymptotic distribution; K preserves metric and orientation; and the canonical form retains only the external boundary after cancelling internal walls.

157.3.8 Electronic centre and material section

Normalize the atlas 9×9 by

$$\nu(r, s) = \left(\frac{r-1}{8}, \frac{s-1}{8} \right).$$

Cell inversion $\rho_c(r, s) = (10 - r, 10 - s)$ becomes $(u, v) \mapsto (1 - u, 1 - v)$. Its unique fixed point is

$$\nu(5, 5) = \left(\frac{1}{2}, \frac{1}{2} \right). \tag{157.28}$$

The 81 states are points of a grid whose elementary cubulation has 64 rectangles; they are not presented as 81 two-dimensional cells.

Theorem 157.8 (Uniqueness of the equivariant point section)**.** *In a stable fibre on which the coarse label remains fixed, every equivariant point selection for ρ_c must take the value* $(5, 5)$*. The level-zero electronic fibre contains that unique point; no other fibre admits such a selection.*

Proof. If $a(y)$ is equivariant and y is fixed, then $a(y) = a(\rho_c y) = \rho_c a(y)$. The unique solution of $\rho_c(r, s) = (r, s)$ is $r = s = 5$. The atlas census places this cell in the level-zero electronic fibre. □

The theorem explains why the electron is a central point section and the other species are presented through orbits or multisections. In particular, the following typed objects must be kept distinct:

1. the fixed cell $(5, 5)$, belonging to the atlas 9×9;
2. the datum 111111, belonging to the fifth nonadic boundary;
3. the transverse multiplicative signature $\mathcal{E}_\times = 555555$, belonging to the regional reader of π;
4. the sign block $(+1, +1, +1)$, appearing within the dodecaphase word

$$\tau_e = (+1, +1, +1, -1, -1, -1, +1, +1, +1, -1, -1, -1).$$

The central APP structure, distinct from these three registers, is

$$\mathcal{A}(5, 5) = ((1, 1), (7, 2)), \qquad 5 + 5 = 1 + 9 \cdot 1, \qquad 5 \cdot 5 = 7 + 9 \cdot 2.$$

Coincidence or repetition of digits does not constitute identification: $(5, 5)$, 111111 and 555555 have different domains, operations and causal functions.

Material positivity is subsequent. If $M_M^{(0)} \geq 0$ and $R_{\mathrm{act}} > 0$, then

$$M_M^{\beta, r} = R_{\mathrm{act}}^{B_M^r/2} M_M^{(0)} R_{\mathrm{act}}^{B_M^r/2} \geq 0. \tag{157.29}$$

Congruence preserves the positive cone and realizes on the mass branch the positivity previously structured; it does not turn observed mass into an atlas input.

157.3.9 Positive multimorphology of the enriched state

Multimorphology does not denote an informal superposition of figures. It is a system of typed morphisms with a common source:

$$\begin{aligned}\mathfrak{P}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow \mathrm{Gr}_{\geq 0}(k, N_n),\\ \mathfrak{R}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow C^{+}_{d,n},\\ \mathfrak{C}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow Q^{+}_{\mathrm{con,n}},\\ \mathfrak{M}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow \mathcal{L}^{+}_{M,n}.\end{aligned}$$

Their images are, respectively, Plücker, lattice, constitutive and mass-operator positivities. Each morphism preserves the coordinates needed by its reader and commutes with the refinement link of its codomain. The four codomains are neither identified nor used to select one another.

Proposition 157.9 (Multimorphological coherence)**.** *If each morphism commutes with truncation, boundary and residue, cancellation of interior faces is transported to the four realizations. If, in addition, a kinematic map*

$$\mathfrak{A}_{Z,n} : C \longmapsto CZ^{\mathsf{T}}$$

has degree one, preserves orientation and covers its image with compatible boundaries, the induced amplituhedral form is independent of representation depth.

Proof. Proposition 157.6 applies before each realization. Compatibility squares transport the incidence coefficient and residue. The degree-one condition avoids interior multiplicities in the kinematic pushforward. □

The moment-curve realization $\mathfrak{P}_n$ is exact as an ordered formalization; its promotion to an intrinsic positroid atlas retains the conditions already declared. The lattice and operator branches have previous HMT–MD reference developments. The constitutive branch must specify its positive form and reader in each application. Multimorphology combines these maps; it does not add a fifth positivity.

157.3.10 Positive constitutive realization and spectral naturality

The constitutive realization of Proposition 157.9 receives an operator already constructed from the two oriented TPK sheets. Section 39.8 determines its response and inverse; the present composition makes explicit the positive form and refinement link used by that realization.

Let $\widehat{\mathcal{X}}_{\mathrm{con}}$ be the domain of enriched states whose angular reading belongs to chamber $x > y > 0$. For $\xi \in \widehat{\mathcal{X}}_{\mathrm{con}}$, the reading produces a two-sheet space E_ξ, an orthogonal involution $\mathcal{R}_\xi$ and the transport

$$P_{\pm,\xi} = \frac{I \pm \mathcal{R}_\xi}{2}, \qquad T_\xi = q_{+,\xi} P_{+,\xi} + q_{-,\xi} P_{-,\xi}, \qquad 0 < q_{+,\xi} < q_{-,\xi} < 1.$$

The incidences 90 and 120 arise from the calendar and act on that same transport. The response is

$$V_\xi = (I - T_\xi^{90})(I - T_\xi^{120})^{-1}, \qquad W_{m,\xi} = V_\xi \otimes I_{9^m}.$$

Amplification preserves every position of the new nonadic fibre. On $E_{m,\xi} = E_\xi \otimes \mathbb{C}^{9^m}$, define the form

$$\mathfrak{C}_m(\xi)(v, w) := \langle W_{m,\xi} v, W_{m,\xi} w \rangle = \langle v, W_{m,\xi}^2 w \rangle. \tag{157.30}$$

This is a concrete realization in the cone of positive-definite Hermitian forms. Squaring preserves the quadratic responses of the two sheets expressing the coordinates $\widehat{\varepsilon}$ and $\widehat{\mu}$ of (39.44).

Proposition 157.10 (Coercivity, recovery and nonadic link)**.** *The form* (157.30) *satisfies, for every nonzero* $v \in E_{m,\xi}$,

$$\frac{9}{16}\|v\|^2 < \mathfrak{C}_m(\xi)(v,v) < \|v\|^2.$$

If $A_{m,\xi} = W_{m,\xi}^2$ *and* $\mathbb{E}_m$ *is the normalized partial expectation over the last nine-dimensional factor, then*

$$\mathbb{E}_m(A_{m+1,\xi}) = A_{m,\xi}.$$

The form, together with the oriented sheet labels, recovers V_ξ*, the two channels* $q_{\pm,\xi}$ *and their angular coordinates. If a unitary transport* $J : E_\xi \to E_{\xi'}$ *satisfies* $JT_\xi = T_{\xi'}J$*, then*

$$(J \otimes I)^* A_{m,\xi'}(J \otimes I) = A_{m,\xi}.$$

The identity holds for any continuous function of the spectrum applied to the response before amplification.

Proof. The sheet projectors are orthogonal and sum to the identity. The spectral calculus of (39.42) gives

$$V_\xi = r_{+,\xi}P_{+,\xi} + r_{-,\xi}P_{-,\xi}, \qquad r_{\pm,\xi} = f(q_{\pm,\xi}^{30}), \qquad f(s) = \frac{1+s+s^2}{1+s+s^2+s^3}.$$

In $0 < s < 1$, we have

$$4(1+s+s^2) - 3(1+s+s^2+s^3) = (1-s)(3s^2+2s+1) > 0,$$

and the denominator exceeds the numerator by $s^3 > 0$. Therefore $3/4 < r_{\pm,\xi} < 1$. Orthogonal decomposition and squaring these bounds prove coercivity, which remains identical under amplification.

Since $A_{m+1,\xi} = A_{m,\xi} \otimes I_9$ and the normalized trace of the last factor satisfies $\mathrm{tr}_9(I_9) = 1$,

$$\mathbb{E}_m(A_{m+1,\xi}) = (\mathrm{id} \otimes \mathrm{tr}_9)(A_{m,\xi} \otimes I_9) = A_{m,\xi}.$$

The same equality holds for each polynomial in $W_{m,\xi}$. Uniform approximation on the compact spectrum and continuity of the expectation extend it to every continuous function.

The positive root of $A_{0,\xi}$ recovers V_ξ. The oriented projectors identify its two eigenvalues. The function f is strictly decreasing on $(0,1)$ by (39.43); its inverse determines the unique roots of (39.46). The positive thirtieth root restores $q_{\pm,\xi}$, and (39.47) restores x and y.

Finally, $JT_\xi = T_{\xi'}J$ implies the same identity for all its powers. Invertibility of $I - T^{120}$ gives

$$J(I - T_\xi^{120})^{-1} = (I - T_{\xi'}^{120})^{-1}J.$$

This yields $JV_\xi = V_{\xi'}J$. Amplification, squaring and unitarity of J give the stated congruence. The polynomial argument and its uniform extension prove the last assertion. □

The link in this construction is the normalized expectation preserving the amplified operator. Compatibility with a geometric transport uses the intertwining $JT_\xi = T_{\xi'}J$ expressed in the statement. Transport of canonical forms and residues, in turn, maintains the boundary squares of Proposition 157.9. The operations at each level are thus specified: angular response, positive constitutive form, fibre amplification and incidence transport. Angular restitution recovers this reading; the enriched archive additionally preserves the history producing it.

157.3.11 Conditional amplituhedral formalization

Status. What follows is a *new conditional formalization*. The corpus supplies refinement, routes, survival and ordered data; identifying its image with an amplituhedron and promoting the cellular sum to a canonical form require the explicitly stated geometric hypotheses.

Fix $k, m \geq 1$ and $N = N_n + 1 \geq k + m$. Let $Z_n = Z_n^{(k+m)}$ be the positive external datum constructed by carry and let $C_n \in \mathrm{Gr}_{\geq 0}(k, N)$ be a matrix of surviving routes. On the locus where $\mathrm{rank}(C_n Z_n^{\mathsf{T}}) = k$, define

$$Y_n = C_n Z_n^{\mathsf{T}} \in \mathrm{Gr}(k, k+m). \tag{157.31}$$

Definition 157.11 (Candidate amplituhedral image)**.** Let $\mathfrak{C}_n^{\mathrm{TPK}}$ be the positive complex of routes and carries at depth n. Its image

$$\mathcal{A}_n^{\mathrm{HMT}}(k, m) = \{C Z_n^{\mathsf{T}} : C \in \mathfrak{C}_n^{\mathrm{TPK}}\}$$

is called the candidate amplituhedral image at level n. Denote by

$$\mathcal{F}_{\mathrm{kin},n} : \mathfrak{C}_n^{\mathrm{TPK}} \longrightarrow \mathrm{Gr}(k, k+m), \qquad [C] \longmapsto [C Z_n^{\mathsf{T}}]$$

its kinematic map.

Proposition 157.12 (Canonical pushforward under degree and boundary hypotheses)**.** *Suppose $\mathfrak{C}_n^{\mathrm{TPK}}$ is an oriented pure-dimensional complex, that $\mathcal{F}_{\mathrm{kin},n}$ is proper on its closure, generically finite of degree one on each component, preserves orientation, covers its image without undeclared interior overlaps and maps boundaries to boundaries compatibly with residues. Then*

$$\Omega_n^{\mathrm{HMT}} = (\mathcal{F}_{\mathrm{kin},n})_* \left(\sum_{\sigma \in \mathfrak{C}_n^{\mathrm{TPK}}} \Omega_\sigma \right) \tag{157.32}$$

is well defined, has logarithmic poles only on the external boundary of $\mathcal{A}_n^{\mathrm{HMT}}$ and is independent of every further compatible subdivision. Its residues are the canonical forms of the face images.

Proof. Theorem 157.4 cancels interior facets before pushforward. Degree one and absence of interior overlaps prevent spurious multiplicities; boundary–residue compatibility transports logarithmic poles and their residues. Compatible refinement changes the cellular decomposition but not its sum. □

The proposition determines a structural and recoverable form only when its hypotheses are verified. If, additionally, $\mathfrak{C}_n^{\mathrm{TPK}} = \mathrm{Gr}_{\geq 0}(k, N)$ is proved on the relevant domain and the map has the required coverage, then $\mathcal{A}_n^{\mathrm{HMT}}(k, m)$ coincides with the standard amplituhedron of those data and (157.32) is its complete canonical form. Without derivation of the complex, proof of the pushforward hypotheses and coverage, the object remains a candidate formalization; it is neither a theorem attributed to the corpus nor a surjectivity assertion.

157.3.12 Synthesis

The resulting structural multimorphology can be written as the composition

$$\begin{array}{c} \text{TPK history} \longmapsto \text{ordered cell} \\ \longmapsto \text{ordered positroidal realization} \\ \longmapsto \text{canonical form} \longmapsto \text{archive oriented by } K. \end{array}$$

Each arrow preserves different information: the TPK preserves genealogy; the Grassmannian preserves minors; the canonical form preserves the boundary after cancelling internal walls; K preserves the metric frame and recovery. The discrete structure of the continuum thus appears as a system simultaneously

admitting infinite refinement, finite positivity at every level and an archived limit without loss of the history generating it. The positroid realization, cluster charts, cubical extension and amplituhedral image are added formalizations with the precise statuses stated in each subsection; they are not projected retrospectively as theorems already proved by the corpus.

157.4 Stability under refinement and compatibility of sectorial readers

Theorem 157.13 (Unity and distribution of the contribution)**.** *The refinement-stability theorem has its primary location in the joint construction of the continuum. Its applications to the Weil form, the five terminal realizations, arithmetic–geometric coupling and the mass operator are typed corollaries. None of these applications can select refinement retrospectively or replace its proof.*

Proof. The canonical form and its cancellation are defined before any sectorial reader is applied. Every reader receives the same cellular sum and must commute with boundary and residue. The common property is proved once; each sector's specificity lies in its realization map. If a reader selected cells from its result, it would reverse the causal chain. □

157.5 Consecuencias estructurales

157.5.1 Multimorphology of the Grassmannian and amplituhedron

The term *multimorphology* here denotes a precise mathematical structure. Let $\widehat{\mathcal{X}}_{\mathrm{TPK}}$ be the enriched-state space and $p_{n+1,n}$ its truncation system. Positive multimorphological data consist of a system of typed realizations

$$\begin{aligned}
\mathfrak{P}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow \mathrm{Gr}_{\geq 0}(k, N_n),\\
\mathfrak{R}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow C^{+}_{d,n},\\
\mathfrak{C}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow Q^{+}_{\mathrm{con,n}},\\
\mathfrak{M}_n &: \widehat{\mathcal{X}}_{\mathrm{TPK,n}} \longrightarrow \mathcal{L}^{+}_{M,n},
\end{aligned}$$

where the codomains represent, respectively, Plücker, lattice, constitutive and mass-operator positivity. The four maps must commute with their refinement links and preserve the state coordinates used by each reading. The four codomains are not required to be equal, nor is one required to select the others.

The kinematic map

$$\mathfrak{A}_{Z,n} : C \longmapsto CZ^{\mathsf{T}}$$

composes with $\mathfrak{P}_n$ and produces amplituhedral morphology. Thus the Grassmannian organizes charts, strata and their mutations; the amplituhedron organizes kinematic images and their canonical forms. Multimorphology is the diagram maintaining these realizations simultaneously as images of the same enriched state.

Proposition 157.14 (Multimorphological coherence under refinement)**.** *If every realization commutes with truncation and its map on forms commutes with boundary and residue, cancellation of interior faces is transported to the four codomains and every degree-one amplituhedral image. The expressed forms are depth-independent, although their archives preserve refined routes.*

Proof. The source state's form is the oriented sum of its cells. Commutation with truncation identifies the two representations of each refinement; commutation with boundary and residue transports cancellation of opposite incidences. A degree-one kinematic map preserves the form's multiplicity in each interior. Therefore, only external boundaries survive in each realization. □

The existence of $\mathfrak{R}_n$ and $\mathfrak{M}_n$ rests on the lattice and material reference constructions already obtained. The moment-curve realization $\mathfrak{P}_n$ is exact as an ordered formalization; promotion to an intrinsic positroid

atlas requires boundary measurement. The amplituhedral realization additionally requires rank, degree and coverage. This is multimorphology's evidentiary boundary, not a restriction of its definition.

157.5.2 Continuum

Passage to the limit does not add disconnected points: it stabilizes compatible forms of the same refined structure. Internal walls disappear from the global form but remain in the memory of histories. This yields an exact distinction between geometric invariance and genealogical conservation.

157.5.3 Riemann–Weil

Telescoping makes realization of the arithmetic form independent of the nonadic mesh. Weil positivity continues to depend on the gamma, prime and polar channels and on the mixed-moment identity turning them into a Gram form. The new result does not replace that proof: it proves that no interior refinement pole can introduce a spurious negative direction.

157.5.4 Five terminal realizations

A terminal reader transports cancellation if it commutes with boundary and if the residue of the transported form coincides with the face's form. This condition unifies the gluing mechanism without disaggregating the continuum or turning the five problems into five generators.

157.5.5 Coupling and flow

The holographic constant of arithmetic–geometric coupling recovers K, and K determines O_K, G_K and the archive. The general action $D_K(s)$ opens a positive route. The centred direction $u_K = P_3 P_{11} K$, satisfying $u_K \perp \mathbf{1}$, refines it to

$$g_{K,\rho}(\tau) = \operatorname{diag}\big(\rho_A^{\tau \widehat{u}_{K,1}}, \dots, \rho_A^{\tau \widehat{u}_{K,12}}\big) \in SL(12,\mathbb{R})_{>0}.$$

The ratios φ^{-2}, π/φ^2 and φ/π^2 can parametrize different flow sections after being generated and typed as expressions of the coinductive fourfold relation $(\pi, \varphi, e, \alpha)$; none selects the TPK retrospectively or is confused with κ_{ag}.

157.5.6 Particles and masses

The congruence

$$M_M^{\beta,r} = R_{\mathrm{act}}^{B_M^r/2} M_M^{(0)} R_{\mathrm{act}}^{B_M^r/2}$$

preserves the positive cone. The electronic exception precedes this evaluation: it arises from the unique fixed point $(5,5)$. The boundary 111111 and signature 555555 remain distinct registers of the same genealogy.

157.6 Criterion for promotion to a positroid atlas and amplituhedron

Promotion is completed when the following are concretely constructed:

1. a planar network $\mathcal{N}_z$ for each cylinder, with positive weights derived from the TPK;
2. the boundary-measurement matrix and its LGV formula for all minors;
3. the decorated permutation or Grassmann necklace of each stratum;
4. a seed or plabic graph whose mutation commutes with refinement and memory;
5. the kinematic map $C \mapsto CZ^{\mathsf{T}}$, with rank, dimension, degree, coverage and boundary correspondence;
6. the canonical-form pushforward identity.

These conditions are not a sociological list: they are the falsifiers distinguishing a complete realization from a collection of positive points.

157.7 Theorem of closure of genealogical spiral correspondences

The central contribution is a law of geometric stability under refinement: depth adds memory and resolution, while the canonical form preserves the total boundary. The register K makes this process recoverable and metric; its centred direction organizes a determinant-one flow respecting Plücker signs. The electron occupies the unique equivariant centre of the material branch. With these components, passage to the positive Grassmannian ceases to be an analogy: it has an exact ordered realization and a promotion programme whose maps and falsifiers are fully specified.

Chapter 158

Conclusions on the generative construction and its realizations

The development establishes a constructive relationship between modular arithmetic, oriented dynamics, value generation, exceptional incidence and information recovery. The unity of this relationship resides in the enriched state produced by APP–TRIT–TPK. Each realization receives a determined part of its structure and preserves the data required by the next operation. Numerical evaluation, geometric form and the record of an execution are thus articulated through explicit maps.

The principal conclusions concern three inseparable mathematical questions: how a value is produced, what structure its production preserves and under which operations it can be recovered. The realizations of Dimensional Mechanics add a fourth determination: how that structure is expressed in observables with declared units and coupling conditions.

158.1 Arithmetic restitution and memory of operations

The initial APP construction fixes two levels: position on the grid and the arithmetic evaluation performed there. Nonadic reduction preserves the integer exactly when it retains remainder and quotient. Balanced ternary reduction has the same property with its oriented representative and extension quotient. The composition identities prove that both registers can be transported between the two decompositions.

In particular, restitution $n = \rho_9(n) + 9q_9(n)$ and compatibility $c_3(n) = c_3(\rho_9(n)) + 3q_9(n)$ allow integer information to be tracked through changes of representation. Addition carries and cross-terms of multiplication are computed on those coordinates. Recoverable information thus has, from this stage onward, a determined algebraic content 1.3, 1.22.

Composition of trajectories adds ordered memory. If a transition acts through $U_\varepsilon(m) = C_\varepsilon m + \kappa_\varepsilon$, concatenation satisfies

$$C_{\beta\alpha} = C_\beta C_\alpha, \qquad \kappa_{\beta\alpha} = C_\beta \kappa_\alpha + \kappa_\beta.$$

The second trajectory transports the accumulated memory before adding its increment. This cocycle law explains why the chronological register contains more information than an aggregated carry. Its proof fixes the operation that must be preserved when composing realizations 6.22.

The nonadic calendar supplies another exact distinction. The return of nine phases increments the turn coordinate. The extension $C_{12} \to C_{108} \to C_9$, with its carry, expresses compatibility between the visible phase and the dodecaphase register. The enriched continuation also preserves successive turns and incidences. Periodicity of a reading and evolution of its memory therefore constitute two simultaneous properties of the same transport.

Transfer between quadratic and cubic completions supplies another exact conservation identity. In the nonadic case,

$$(72, 27) \longmapsto (73, 27) \longmapsto (10 \cdot 73 - 1, 10 \cdot 27 + 1) = (729, 271).$$

The first operation incorporates the registered unit; the second changes the scale and redistributes one unit through a zero-sum correction. The normalized sum remains equal to one. This construction gives precise content to the holographic extreme and mean ratio and its conservative extension across scales 146.1.

158.2 Determination of the regions and the coinductive fourfold relation

Finite enumeration identifies the admissible configurations, emissions and words on which the lifts act. The chain $w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$ preserves prefixes and transport conditions when extending the regional realizations. Cylindrical compatibility and contraction provide the passage to arbitrary depth.

The regional outputs π_{HMT}, φ_{HMT} and e_{HMT} combine a positional expansion with an operator provenance. The classification of the five regions of π, the incidence of the φ axis, the joint continuations and the mirror involution preserve their distinctions in the limit. Subsequent analytic identifications certify properties of those outputs and allow their comparison in established mathematical languages.

The nonadic connection relates regional generation to return structure. Modal incidence arises from the tritic selector and its sequence of operations. Its powers generate recurrences; regional marks are then applied to the return support. This precedence distinguishes the regional emitter, the recurrence of a modal realization and the evaluation of a boundary ratio. Composition makes their relationships computable without identifying objects of different types.

The register K is determined from the regional bands. The first zero advance of the conversion clock locates the nonadic antecedent; oriented defects and the phase–charge reader produce the descriptor. The terminal repertoire, ternary cylinders and exceptional incidences delimit the candidates. The heterotypy condition selects the register in that finite domain. Subsequent inversion recovers its order, windows and signed realization. Uniqueness expressly preserves the candidate domain and selector conditions.

The integer fine-structure closure composes regional readings with the rational coordinate of K. Its compatible carry determines a unique infinite section, and the tail identity distinguishes the boundary of an isolated window from the restriction of the limit. In the notation of its development,

$$\alpha_{\mathrm{HMT}} = \pi_{\mathrm{HMT}} + e_{\mathrm{HMT}} - \varphi_{\mathrm{HMT}} - 4 - \kappa_{\mathrm{per}}.$$

The equality preserves the origin of all its terms and the complete decimal normalization (11.135).

The analytic representation develops that same pre-coordinate through a function defined in all degrees. If a is the generated pre-coordinate and $q = 1/729$, the linking coefficient

$$\lambda = -\frac{E_9(a)(1 - qa^3)}{a^{10}}$$

determines the geometric extension $E_\infty(X) = E_9(X) + \lambda X^{10}/(1 - X^3/729)$. Subsequent coefficients satisfy $b_{10+3n} = q^n\lambda$ and $b_{11+3n} = b_{12+3n} = 0$. Uniqueness is proved within this class of extensions, and the root is identified with the common coordinate. The second route contributes a correlated analytic representation with convergence control and projective compatibility 11.6.4.2.

158.3 Archimedean realization and exceptional incidence of the continuum

The truncation systems preserve admissible histories and their registers. The proved extendibility guarantees the existence of compatible sections. Cylindrical partitions provide an Archimedean evaluation; the incidence structure remains in the conjugate projection. Contraction determines the real value, while orientation, boundary and memory preserve the distinctions of the state.

This double projection jointly organizes spectral transport, solenoidal balance, gauge incidence, cohomological coherence and the determinant line. Naturality identities allow refinements and realizations to be carried out in compatible orders. The discrete continuum thus receives a common operational structure, on which its subsequent evaluations act.

Exceptional incidence is developed through a sequence of concrete constructions. Codes and markings determine lattice gluings; the Leech neighbour is proved positive, even, unimodular and rootless in the declared metric and chamber. Lattice identification uses these properties jointly. The construction of

oscillators and the twisted lattice algebra, followed by the orbifold parity sector, determines the realization of $V^\natural$ and its Monster action 21.71.

The significance of this sequence lies in the related genealogy of value and symmetry and their precise objects of action. Exceptional symmetry acts on the corresponding code, lattice or algebra. Dimensional reductions and duality realizations receive those carriers with their conditions. Numerical refinement and exceptional extension thus retain their linking maps within the common state.

158.4 Bilateral conservation and reversibility at arbitrary depth

The bilateral law supplies an operator conclusion independent of dimension. For two isometries $\mathcal{B}, C : H \to H'$ and $a > 0$, define $Q_- = a\mathcal{B} - C$ and $Q_+ = (a+1)\mathcal{B} + C$. The identity

$$(a+1)Q_-^*Q_- + aQ_+^*Q_+ = \big((a+1)^3 + a^3\big)I$$

follows by cancelling the cross-terms. Its validity includes infinite-dimensional Hilbert spaces and transports between distinct carriers with common domain and codomain.

In the nonadic specialization, $a = 8$, the normalization factors through the weights $72/73$ and $1/73$, followed by a rotation of the two channels. The resulting isometry has a left inverse of norm one. Recovery therefore maintains optimal control of the joint error in the declared norm. The factor $73 = 72 + 1$ enters into that identity; its other realizations as a norm or lattice index retain their own proofs.

The transport of observables specifies the content of conservation. For a reader G and a unitary relative transport R, the induced reading is

$$\mathcal{T}_a(G) = \frac{a(a+1)G + R^*GR}{a(a+1)+1}.$$

The equality $\mathcal{T}_a(G) = G$ is equivalent to commutation $GR = RG$. This yields a relative-symmetry criterion distinguishing invariant observables from those that change during transduction 147.3.

The recording policy at arbitrary depth preserves the continued component and its complement at each stage. The telescopic balance produces a finite isometry and, under the proved contraction bound, an infinite-record isometry. For $a = 8$, the uniform rate is $r_8 = 729/1241 < 1$. The first N complements recover the state with truncation error bounded by $r_8^N \|v\|$; a joint error ε adds exactly ε to that bound. The complete record admits the convergent inverse of Theorem 147.7.

The evolutionary conservation of unity is therefore expressed through local identities, isometric compositions and recovery in the limit. Modification of form or carrier is compatible with restitution of the state when the channels and incidences specified by the theorem are preserved.

158.5 Geometric reciprocity and exterior conservation

The coupling register produces a direction orthogonal to the uniform mode. Its positive diagonal flow has determinant one. The radii vary compensatorily; Plücker minors preserve sign and vanishing, and balanced quotients preserve their value. The same direction generates a unit-covolume deformation on the lattice planes.

The reciprocity of this deformation is expressed by $\Lambda_t^* = \Lambda_{-t}$. The commuting ternary symmetry persists along the flow, while integrality and exceptional realization retain the specific domain in which they were proved. Theorem 150.4 determines these properties simultaneously.

In the chart $s = (1-z)^{-1}$, radial inversion $z \mapsto 1/\overline{z}$ becomes $s \mapsto 1 - \overline{s}$. The unit circle corresponds to the line $\Re s = 1/2$, with the singular point excluded. Theta–Mellin reciprocity, polar structure and the Poincaré and Klein realizations preserve the analytic and geometric conditions of their own readers. Recorded orientation allows the radial reading to be inverted wherever the scalar reading combines conjugate realizations.

These identities broaden the meaning of the coupling constant: the arithmetic register determines a recoverable frame, a deformation direction and transports preserving exterior invariants. The correspondence between realizations is obtained by composing the constructed maps.

158.6 Action, angular geometry and material observables

The Dimensional Mechanics realization preserves an explicit precedence. The action scale receives the fine-structure coordinate and the regional reading of φ; the local norm of order sixteen fixes its decimal valuation. The forward and return Planck sections preserve their quotient R_{act}. The angular pair and its conjugate channels are then evaluated, with their orientation and units 14.11.3.

The marked inclusion of a hexad in an octad produces incidences of cardinalities 90 and 120. The dodecaphase chain determines the multiplicities of the Barbero–Immirzi functional and the pole coefficient $1/24$. Its evaluation uses the angle, counter-angle and previously constructed channels. Parity under angular inversion preserves the orientation of that reading 15.5.

Angular transport toward Witt incidence supplies an explicit composition with the mixing reader. Its left inverse and Gram identity preserve the transported angular information 20.14. The electric and magnetic constitutive structure likewise receives its modes, return ratios and scales; its identities allow the angular coordinates to be reconstructed in the specified domain.

The contragredient gravitational section of action satisfies

$$G_a = \frac{c_{\mathrm{int}}^3 R_{108}^2}{\hbar_a}, \qquad \frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = R_{108}^2.$$

The coincident-radii condition fixes this section within the declared class. Inversion of the action ratio compensates the gravitational ratio and preserves areal unity 80.3.8. The Boltzmann definition then relates energy per decision to the thermal section. For the clock of one hundred and eight events, $k_B \Theta_{\mathrm{clk},a} = h_a/(108 t_0 \log 3)$. Individualization of the transducer preserves the thermal section and unit bases it uses 48.5.2.

Material observables arise from the persistence of extensions and their route records. The electronic centre has a point selection determined by the atlas; the other classes use the operators of their fibres, orbits or multisections. The integer signature, character and towers transmit this information to the mass realization. Metrological comparison is carried out on the specified evaluations and couplings, preserving the distinction between operator, spectrum and individualized scalar.

158.7 Reconstruction and cardinal classification of the generated continuum

The cylinder construction proves coverage of values with recovery of registers. Cardinal closure adds a classification of those values in the genealogical closure $\mathfrak{G}$ determined by its term semantics and definability. Internal countability of the levels and the condensation lemma assign to each rational cut its first stage $\beta(r)$ and its first index $n(r)$ in that stage's enumeration.

The map

$$j_{\mathrm{HMT}}(r) = \omega\beta(r) + n(r)$$

is injective on the domain of the generated line $\mathbb{R}_{\mathrm{HMT}}^{\mathfrak{G}}$. Encoding countable well-orders constructs the injection of $\omega_1^{\mathfrak{G}}$ into that same line. Cantor–Bernstein concludes

$$\left|\mathbb{R}_{\mathrm{HMT}}^{\mathfrak{G}}\right| = \aleph_1^{\mathfrak{G}}, \qquad \mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) \models \mathrm{CH}.$$

This is the affirmative closure of the continuum hypothesis established in Theorem 19.27.

The conclusion encompasses every internal subset of that line: each is countable or has the cardinality of the generated continuum. The representation $\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) = L[h, m_\infty]$ identifies the construction's

domain after developing its genealogy. Transfers to a different set-theoretic domain retain as hypotheses the coverage and coincidence of the objects on which the injections act. The formulation thus keeps the cardinal result, its semantics and its quantifiers together.

The spectral, solenoidal, gauge, cohomological and determinantal terminal realizations are articulated through the same discrete structure. Their theorems specify the operator, positivity, coercivity or descent used by each realization, together with the corresponding naturality identities. The joint factorization of Chapter 95 preserves that origin and the domain of each conclusion.

158.8 Demonstrative content and scope of the integration

The demonstrative strength of the work arises from composition between results of different types. Symbolic identities prove equalities for their quantified domains. Exhaustive enumerations resolve finite selectors and censuses. Rational bounds control approximations and roots. Compatibility, convergence and naturality arguments justify extensions and passages to the limit.

Lean formalizations verify the specific declarations they contain, with their types, premises and dependencies. Executable calculations certify the instances or finite domains defined by their algorithms. Correspondence between mathematical statement and certificate assigns each check its precise scope. The physical realization also preserves the dimensional basis and the coupling rule with the observable.

The overall result is an operational genealogy: discrete arithmetic produces oriented states; their extensions determine constants and a continuum with incidence; their registers admit conservative transformations and recovery; their dimensional realizations provide structured observables. The unity of the development is expressed in these demonstrated relationships. Value, symmetry and recoverable information are linked by the construction producing them.

Appendix A

Algebraic and Combinatorial Certificates of Finite Objects

The finite objects used in the proofs admit a second channel of verification. This channel reconstructs catalogs, operators, and invariants from the declared seeds and checks them against exact identities or directed bounds; it complements the proofs but does not replace them.

A.1 Finite Catalogs and Certificates of Reproducibility

The following finite objects allow the verifications to be repeated without introducing production notation into the mathematical exposition. Each control preserves its corresponding domain, operation, invariant, and falsifier.

A.1.1 Finite catalogs of the common state

Finite object	Verifiable mathematical content
Catalog of length-six emissions	The 468 emissions U_6, their multiplicities, orientation, and additive and multiplicative signatures.
Spectral partition of the emissions	The twenty-six classes of size 18, together with the explicit map that reconstructs each emission from its class and its internal position.
Dodecaphasic Atlas of Routes	The 468 minimal routes with sheet, phase, carry, boundary, and memory.
Archimedean Reader Catalog	The five regions of π, the conjugate regions of e, and the self-scaling axis of φ, with their cylinders and multiplicities.
Hensel Flow of Twenty Blocks	The unimodular matrix, its integer inverse, the 3-adic states, and the residue–quotient recurrence that prolongs the three channels.
Nonadic monodromy record	The twenty blocks, their phases, ternary prefixes, and decimal prefixes; includes the 43 complete returns and the 387 pairs $(K, K+9)$ per channel.
Ventana of survival $K = 5, \ldots, 13$	The local candidates, the compatible branch, and the three outputs of the transition $9 \to 1$, without identifying phase return with state reset.
Initial Archimedean reading	The twelve decimal triples obtained from the first thirteen blocks of each channel, separated from the certificate of arbitrary precision.

A.1.2 Algebraic, Operatorial, and Spectral Identities of Finite Certificates

Withtrol	Identities and Forgers
Monodromy and generation of constants	It verifies $w_6 \to w_{30} \to R_{36} \to G_9$, the selection $3 \to 1$, the change of state after nine phases, the five regions of π, and the compatibility of truncations. It fails if a target digit is introduced before the reader.

Withtrol	Identities and Forgers
Conjugate angular coordinate	Verify the regional selector 169, the determinant recurrence, the analytic sum and its remainder bound, and the uniqueness of C^*. The test fails if an SI constant intervenes in the selection.
Quotient dynamics $468 = 18 \cdot 26$	It certifies the bijection between emissions and classes, the uniform return, the measure of the averaged shadow, the mode cocycles, and the microscopic lift. It distinguishes the chronological frequency from the Parry measure.
Integral channels of the constants	Verifies the identities $(729, 271, 315, 161)$, the set-theoretic realizations of $271/315$, the dihedral orbits, and the factorization of visible parity and carry parity.
Witt Incidence	Reconstruct the point–hexad incidence, the module E_{30}, the positive transport of P_3, the Witt star, and the equivariance obstructions.
Variational selector	It reconstructs the normalizer S_3, the Reynolds average, the polar factorization, and the chain of rank-three projectors; positivity is proved exactly in $\mathbb{Q}(\sqrt{5})$.
Elevation $W_{12} \to W_{24}$	It checks the four- and five-point incidences, the unique lift of hexads, and the typed correspondence with the five regions of π.
Realizaciones de $-1/12$	It constructs the rational projectors of the step-three and step-four shifts, verifies symmetry and idempotence, and obtains $(3-4)/12 = -1/12$ as the difference of normalized traces.
Schläfli Holonomy	Traverses the plaquettes, certifies $A^2 = 5I - 4A + 5J$, the configuration of the twenty-seven lines, their 45 triangles and the partition $729 = 27 + 270 + 432$.
Spectral functionals	Recomputes Catalan, Stieltjes, Apéry, Bendersky–Glaisher–Kinkelin, the two Euler–Kronecker extensions, and the directed bounds on prime products.
Vacancies and Criticality	It checks the separations $21/22$, the returns $6/7$, the finite harmonic part, and the dodecaphase approximants of the critical mode.

A.1.3 Typed Dictionary of the Catalogues

`Field`	Meaning and Codomain
`Esig sig`	Signature of the multiplicative channel; it identifies one of the twenty-six classes in the factorization of the emitter.
`hplus_type`	Additive channel orientation class for the two pairs of declared cardinal directions.
`diag_c`	Integer index of the diagonal class of the additive cursor.
`px_size`	Cardinal of the fiber of the corresponding additive class.
`colw`	Sextet of column weights of the emitted block; it belongs to $\mathbb{Z}^6_{\geq 0}$.

A.1.4 Reproducibility of Certificates and Exact Obstructions of Finite Constructions

The controls use integer or rational arithmetic whenever the object permits it. The analytical bounds use intervals with directed rounding and separate the symbolic proof from the decimal comparison. Each run reconstructs the objects from the declared seeds, verifies the incidence and naturality identities, and checks the outputs against an independent arithmetic implementation.

The native-product control rejects every dependence on a decimal evaluation, an external factorization, a sieve, a table of zeros, or a target constant. The nonadic control rejects identification of the ambient fiber of 729 elements with the cardinality of a space of histories. The phase control rejects $g(K + 9) = g(K)$ as proof of equality of states. The metrological control rejects every route selection performed after an observed magnitude has been consulted.

A discrepancy among an identity in the text, the finite catalog, and its independent control refutes the corresponding certification. This rule replaces no proof: it fixes a second verification channel for the finite objects that intervene in it.

A.2 Global compatibility among types, domains, morphisms, and certificates

The integral control checks the causal chain, repeats the mathematical identities on the finite objects, and compares the exact realizations with their independent formulations. A divergence between a definition, its mathematical table, and the declared invariant falsifies the corresponding control.

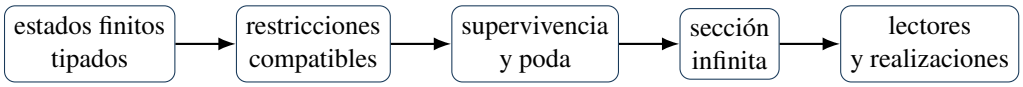
Appendix B

Exact Dependencies Between Generational Power, Reversible Information, and Gödel–Turing Obstruction

B.1 Logical Dependencies and Consistency Certificates

B.1.1 Causal chain of the certificates: finite states → restrictions → survival → infinite section → realizations

The logical chain of the integration does not begin from an Archimedean conclusion. It is organized in the following order:



A digit certificate verifies a restriction of the last arrow; it does not retrospectively create the states or replace the existence theorem for the limit.

B.1.2 Exact arithmetic identities of finite certificates

The censuses accompanying the nonadic filtration certificate satisfy

$$396 \cdot 6 = 2376, \qquad 43 \cdot 9 = 387, \qquad 432 + 4 \cdot 144 = 1008.$$

The first equality relates elementary boundary events and trits emitted per channel; the second counts the phase pairs $(K, K+9)$; the third reconstructs the total multiplicity of the five regions of π.

The two regional roles that cannot be permuted are

$$\begin{aligned} U_{\pi}^{\perp} &= (501, 614, 498, 169, 272, 272), \\ E_{\mathrm{sig}} &= 555555, \qquad \text{multiplicity } 432, \\ U_{\pi}^{--} &= (870, 923, 810, 418, 674, 521), \\ E_{\mathrm{sig}} &= 933717, \qquad \text{multiplicity } 144. \end{aligned}$$

B.1.3 Existence and uniqueness of the infinite branch in a finitely ramified tree of surviving prefixes

Lemma B.1 (Finitely branching tree)**.** *Let T be a tree with nonempty finite levels such that every surviving node has a surviving descendant. Then there is an infinite branch. If, moreover, each node of the selected subtower has exactly one compatible descendant, the branch is unique.*

Proof. Existence is König's lemma applied to the finitely branching tree. For uniqueness, two distinct branches would have a first level at which they diverge, yielding two compatible descendants of the same prefix, contrary to the hypothesis. □

Structural obstruction

An execution to depth N proves only what occurs in the truncated tree. The infinite claim requires the uniform law that preserves nonemptiness and compatibility at every level. The main text expressly separates the two statuses and, for the nonadic filtration, retains its certified uniform selector.

B.1.4 Closure and Full Power

For $A \subseteq X = \varprojlim X_n$, it has been proved

$$\overline{A} = \bigcap_n p_n^{-1}(p_n(A)).$$

The set of eventually null binary sequences is dense and proper in $2^{\mathbb{N}}$, yet it has all finite shadows. Therefore any algorithm that receives only $(p_n(A))_n$ cannot distinguish A from its closure. This example blocks the false identity

$$\varprojlim \mathcal{P}(X_n) = \mathcal{P}(\varprojlim X_n).$$

B.1.5 Typed compatibility of operators

The difference between the unital inclusion and the marked corner is verified directly:

$$\tau_{d+1}(a \otimes I_9) = \frac{\mathrm{Tr}(a)\,\mathrm{Tr}(I_9)}{9^{d+1}} = \tau_d(a),$$
$$\tau_{d+1}(a \otimes p_j) = \frac{\mathrm{Tr}(a)}{9^{d+1}} = \frac{1}{9}\tau_d(a).$$

The first branch is unital and tracial; the second preserves a marked corner and cannot be used to infer the factor II_1.

B.1.6 Cancellation of the Landauer cost in reversible state inversion

For a complete variable X and a projection $Y = q(X)$,

$$H(X) = H(Y) + H(X \mid Y).$$

If q is bijective, the fiber is a singleton and $H(X \mid Y) = 0$. If q is a reset of the uniform TRIT, the discarded information is $\log 3$ and the minimum cost is $k_B\Theta \log 3$. For the extension $\widehat{E}_N$ to L^1 of a normal trace-preserving conditional expectation E_N, and under the stated finiteness hypotheses,

$$S_\tau(\widehat{E}_N h) - S_\tau(h) = D_\tau(h \| \widehat{E}_N h) \geq 0.$$

The two formulas locate the same phenomenon in different domains: the cost belongs to the contraction of a fiber, not to the reversible evolution of the complete state.

B.1.7 Gödel–Turing Obstruction to a Uniform Projective Multiplicity Decider

Let T_e be the machine with index e. At level n, define

$$X_n^e = \{b_n\} \cup \{c_n : T_e \text{ did not halt before } n\}.$$

Each X_n^e is computable. The global fiber has two branches if T_e does not stop and one if it stops. Therefore

$$U_e : \quad \#q_\infty^{-1}(v) = 1 \quad \Longleftrightarrow \quad T_e \downarrow .$$

A uniform decider for U_e would decide HALT. A recursively axiomatizable theory that is sound and complete for every U_e would permit their decision by enumerating in parallel proofs of U_e and of its negation. This is the core of the *HMT theorem of uniform incompleteness for projective multiplicities*; its proof uses a Godel–Turing reduction. The uniform obstruction does not negate particular selectors constructed on calibrated HMT images.

Scope of the uniform incompleteness control

The Gödel–Turing reduction establishes the uniform obstruction for projective multiplicities. It does not negate the particular selectors constructed on calibrated HMT images, nor does it turn a global decision obstruction into indeterminacy of every concrete fiber.

B.2 Domain and Obstructions of Physical and Dimensional Realizations

The physical-dimensional realization is subject to ten families of control:

1. cylindrical concentration, unit mass, and finite moments;
2. spectra $(9, 5)$ of the APP block and $(7, 3)$ of the memory block;
3. identity $\tanh^2(2\log\varphi) = 5/9$;
4. antiunitarity in the stated finite model;
5. Poincare semidirect-product law;
6. constitutive identities of the vacuum;
7. split norm of the null modes and material closure;
8. selector $\theta_* = (54/\pi)^2$ and self-dual fixed point;
9. control CGLMP values;
10. invariants $(396, 729, 43, 387)$ of the nonadic filtration and domain $(81, 56, 13, 324)$, with separate null sector, of the General Law of Masses.

Exact scope of the controls

The ten families verify identities, finite domains, and reproducible examples. They do not replace complete functoriality of the four components, do not by themselves construct the common domain, do not prove the smooth Cartan prolongation, and do not promote open physical interfaces to internal theorems. The discrete realization retains its principal proof in section 62.2.1.

B.2.1 Functorial dependencies of the spectral, solenoidal, gauge, cohomological, and determinantal realizations

The preceding controls apply only after APP, TRIT, TPK, the common enriched state, the double projection, and the dimensional line have been constructed. The cylindrical concentration and finite spectrum prove properties of the realization; they do not retrospectively select the state. The periodicity of 108 phases, the atlas (81/56/13/324), the constitutive involution, and the cosmological programs retain separate domains and falsifiers.

The Dirac, von Neumann, CGLMP, Cartan, and Poincare identities are used as typed controls of the corresponding intertwiner. A numerical coincidence without the map specifying the domain, codomain, and action on generators does not constitute a physical realization.

Appendix C

Genealogical fidelity of the matrix bridge: domain, correspondence, and exact limits

C.1 Naturality, Positivity, and Compatibility Identities of the Genealogical–Matrix Bridge

The following controls are obtained by reconstructing the operators from their incidence data. Rational identities are calculated exactly; the floating-point comparisons state their error bound.

Verification	Status	Maximum error or identity
cuatro PVM qutrit	verified	4.72×10^{-16}
idempotency of the twelve projectors	verified	3.34×10^{-16}
solapamientos MUB	verified	$\lvert\mathrm{Tr}(PQ) - 1/3\rvert < 3.34 \times 10^{-16}$
QLS column obstruction	exact	minimum $1/3$
QMS aditivo $(9, 3)$	verified	exact rows and columns to tolerance
Three-context QMS $(9, 3)$	verified	numerical error $< 4.21 \times 10^{-16}$
noncommutativity of cells	verified	maximum norm $0.074074\ldots$
QMS atlas $(12, 3)$	verified	numerical error $< 4.24 \times 10^{-16}$
semiclassical decomposition	exact	zero reconstruction error
qutrit cube of order nine	verified	line error $< 4.21 \times 10^{-16}$
qutrit cube of order twelve	verified	line error $< 4.24 \times 10^{-16}$
$\mathbb{P}^1(\mathbb{Z}/9) \to \mathbb{P}^1(\mathbb{F}_3)$	exactly	$12 \to 4$ con fibras $(3, 3, 3, 3)$
truncation–compression	exact	conmutador cero
Direct reader $1/\pi$	exactly	unitary normalization
calibre MUB $3/\pi$	verified	probabilidad $1/\pi$, error $< 3.85 \times 10^{-16}$
Gram polynomial APP	exactly	$t^5(t-1)(t-5/7)(t-1/3)^2$
four Halmos intersections	exact sciences	$(64, 1, 5, 5)$
algebra C^* of APP in $d = 2$	exact	$\mathbb{C}^4 \oplus M_2 \oplus M_2$, dimension 12

The tolerance of the numerical controls is 2×10^{-10}. The rational assertions use no tolerance: they are obtained by exact fractions and Gaussian elimination over $\mathbb{Q}$.

C.2 Exact coefficients of the polynomial

The construction produces

$$\det(tI - CC^*) = t^9 - \frac{50}{21}t^8 + \frac{124}{63}t^7 - \frac{2}{3}t^6 + \frac{5}{63}t^5, \tag{GMC-A.1}$$

and coincides coefficient by coefficient with

$$t^5(t-1)(t-5/7)(t-1/3)^2. \tag{GMC-A.2}$$

The verification constructs CC^* from the exact cardinalities of the fibre intersections and applies Faddeev–LeVerrier over $\mathbb{Q}$; it does not depend on a numerical diagonalization.

C.3 Obstructions to the identification of undemonstrated equivalences in the matrix bridge

The finite certificate does not replace nonadic filtration to arbitrary depth, the General Mass Law, or the Planck derivations. Nor does it prove by itself APP–TRIT–TPK faithfulness of every cyclic QMS, complete equivariance of the calibration Ξ, identification of TPK memory with an auxiliary Stinespring system, infinite divisibility of an MPS channel, or categorical universality. Each of these assertions retains its principal residence and its own falsifiers.

Appendix D

Domain of seeds, emissions, and verifiable expansions

This block preserves the two levels supporting numerical publication: the exhaustive census of initial conditions and TPK emissions, and the extensive expansions produced by the rational readers. The complete catalog fixes the passage

$$104\,976 \longrightarrow 468 \longrightarrow 243,$$

whereas the ten-thousand-digit expansions document the effective prolongation of the sections of π, e, φ, and α_{HMT}.

The catalog of the (468) emissions and the (243) visible words is published in full below; the four expansions of ten thousand digits are published in full in the genealogy of constants. This terminal section links both developments without reducing their proofs, tables, or labels.

D.1 APP Seed Domain and Canonical Emission Catalogue

D.1.1 Exhaustive domain of initial conditions

Let

$$I_9 = \{0, 1, \ldots, 8\}, \qquad D = \{N, E, S, O\}, \qquad \mathcal{S} = I_9^2 \times D.$$

An element of $\mathcal{S}$ fixes the initial position and orientation of a cursor. The minimal emitter uses two cursors on the same APP support: one for additive evaluation and the other for multiplicative evaluation. Its complete domain is

$$\Omega_{\mathrm{seed}} = \mathcal{S}_+ \times \mathcal{S}_\times \cong \mathcal{S}^2, \qquad |\mathcal{S}| = 9^2 \cdot 4 = 324, \qquad |\Omega_{\mathrm{seed}}| = 324^2 = 104\,976.$$

Definition D.1 (Complete seed of the APP–TPK emitter)**.** A seed is an ordered pair.

$$\omega = (s_+, s_\times), \qquad s_+ = (i_+, j_+, d_+), \quad s_\times = (i_\times, j_\times, d_\times), \qquad s_+, s_\times \in \mathcal{S}.$$

The 104 976 seeds are exactly the elements of Ω_{seed}. The catalog rows are of emission type, and each represents a fiber of this seed domain.

The fifty-four-step recurrence defines the finite application.

$$T_{\min} : \Omega_{\mathrm{seed}} \longrightarrow \mathcal{U}_6^{\mathrm{cat}}, \qquad \omega \longmapsto U_6 = (U_1, \ldots, U_6).$$

Its image contains 468 distinct decimal sextets. The componentwise reduction then produces 243 distinct words in the ambient $\mathbb{F}_3^6$, of cardinal 729. Therefore, the three levels are typed as

$$\underbrace{104\,976}_{\text{seeds } \omega} \xrightarrow{T_{\min}} \underbrace{468}_{\text{emissions } U_6} \xrightarrow{\rho_3} \underbrace{243}_{\text{visible words}} \subset \underbrace{\mathbb{F}_3^6}_{\text{729 words}}.$$

Theorem D.2 (Census of the domain and of the image)**.** *The canonical catalog contains* 468 *distinct emissions* U_6*, and* $\#T_{\min}^{-1}(U_6)$ *is the cardinality of the fiber* $T_{\min}^{-1}(U_6)$*. Their multiplicities satisfy*

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976,$$

so that the sum of all fibers exactly recovers the domain Ω_{seed}*. The direct projection* $\rho_3(U_6)$ *has* 243 *distinct values.*

Proof of the exhaustive census $104\,976 \to 468 \to 243$ **and of the multiplicities of the fibres of** $T_{\min}$ The recurrence defining $T_{\min}$ resides in algorithm 8.25; the factorization of its image and the computation of the fibres reside in theorem 8.34 y corollary 8.35. This appendix does not introduce a second enumeration: it realizes, with all its fields, the canonical catalog produced by those results.

D.1.2 Complete Catalog of the 468 Emissions

The following table incorporates the ten fields of the exhaustive catalogue. The ordinal in the first column establishes a reading order, with a type distinct from that of the seeds and mathematical identifiers. The abbreviated columns preserve `diag_c`, `hplus_type`, `px_size`, `px_res_type`, `delta_diag_subset`, `delta_orbit`, `Esig`, and $\rho_3(U_6)$.

Table D.1: Complete canonical catalog of U6 emissions.

#	U_6 / $\rho_3(U_6)$	$\#T_{\min}^{-1}(U_6)$ / diagonal_c	hplus_kind / px_dimension / px_resolution kind_type	delta_diag_subset and delta_orbit	E-sign
1	252|109|252|903|850|850 / 010011	144 / 0	NW / 6 / A	0,1,4,5 / 0,1,4,5	3,9,3,1,7,7

The table is an enumeration of the image of $T_{\min}$. The specification of the domain remains in $\Omega_{\text{seed}} = \mathcal{S}^2$; to recover the individual initial conditions of an emission, one takes its fiber $T_{\min}^{-1}(U_6)$, whose cardinality is listed as $\#T_{\min}^{-1}(U_6)$.

D.2 Certification at depth 10^4 of the coinductive expansions of π, e and φ

Mathematical scope. The preceding uniform theorem quantifies over every positive integer N and constructs the infinite object as the inverse limit of its compatible cylinders. This chapter runs the case $N = 10^4$ as a particularly demanding finite certificate; 10^4 is not a bound on the generator, just as a million-digit run would be another instance of the same algorithm, not a modification of its law.

The present execution fixes a computational depth and checks that the resulting cylinder is contained in a single decimal cell of ten thousand positions. The smallest number of blocks compatible with the nonadic monodromy and with

$$3^{6B} > 10^{10000}$$

is

$$B = 3501 = 389 \cdot 9, \qquad 6B = 21006 \text{ trits}.$$

For each of the three channels, the 729 subcylinders are exhaustively traversed at every stage, and the unique subcylinder compatible with the reader's rational bracket is retained. The calculation yields

quantity calculated per channel	value
complete partitions $729 \to 1$	3501
transported trits	21006
pairs of equal phase $(K, K+9)$	3492
complete nonadic turns	388

and does not require an additional nonad. The first 396 blocks coincide exactly with the preceding thousand-digit witness.

The closure, propagation, and self-scaling readers are evaluated by means of exact rational inequalities. Computational acceleration reorganizes the sums through integer arithmetic and does not open libraries of constants or target decimal prefixes. Only after the outputs have been written is a second, independent computation performed. The following are verified, in this order: the rational generation of the three channels, the G9–T1 composition of α_{HMT}, and the agreement of all ten thousand digits with the reference expansions consulted only at the end. The three comparisons are exact at all ten thousand computed positions. This finite verification does not replace the uniform argument for prolongation to arbitrary depth.

The expanded proof also makes the meaning of return precise. Across the 3492 pairs per channel, the phase is preserved and the complete state always changes, since depth, prefix, and cylinder advance. A reduced local projection may recur in some pairs without the TPK state returning. This distinction replaces the stronger claim of local aperiodicity with the property actually proved: phase monodromy with memory of the enriched state.

The four complete expansions are printed in appendix E. The recurrences, rational intervals, and preceding counts determine the calculation; the printed expansions are its finite truncations and make it possible to compare each digit without becoming premises of the generator.

Appendix E

Arbitrary precision accuracy certificates and finite reproducible decimal samples

This appendix prints the complete outputs of the execution described in appendix D.2 y section 31.6. The line breaks are exclusively typographical. Each expansion constitutes a finite witness of the coinductive law of arbitrary precision proved in Part III; it neither defines the constant nor limits the depth of the generator.

E.1 Coinductive expansion of π and compatible truncation certificate

Appendix F

Formal Verified Formalization of the Algebraic Core and Certification of Finite Identities

The formalization checks the finite identities on matrices, algebras, and typed dodecaphase states. Its function is to isolate the algebraic obligations amenable to mechanical reduction and to keep the provenance of the data, finite enumeration, and formal proof separate.

F.1 Formal Verification of Finite Algebraic Identities

The following finite equalities are formalized in Lean and decided by reduction of the logical core, without additional external axioms. The theorems prove:

Theorem	Contents
`aw_symmetric`	symmetry of the Paley–Witt matrix A_W;
`aw_squared_minus_identity`	$A_W^2 = -I_6$ over $\mathbb{F}_3$;
`x_sq_add_one_has_no_root` criterion	irreducibility of $x^2 + 1$ over $\mathbb{F}_3$;
`dual_has_nonzero_nilpotent` record	existence of a nilpotent in the parabolic algebra;
`split_has_nontrivial_idempotent`	existence of a nontrivial idempotent in the hyperbolic algebra;
`canonical_charge`	$\sum_{m=1}^{12} K_m = 6263$;
identifier	The three Hadamard orbits produce the published
`hadamard_orbit_one/two/three`	dodecaphasic state.

The formalization takes the matrices and the dodecaphase vector as typed data and verifies their algebraic consequences. The construction of the signed state and the enumeration of the (104 976) seeds belong to the preceding combinatorial theorems and are not replaced by this formal reduction.

Appendix G

Correspondence between statements, proofs, certificates, and primary scientific sources

The following table identifies the principal mathematical residence of each result and the negative control that distinguishes its derivation from a mere coincidence. No row replaces the statement or the principal proof.

Table G.1: Results, reference proofs and reproducible controls.

Result	Reference proof	Control reproducible
Construction of APP, double evaluation, and spectral jump	APP chapters and genealogical arithmetic	Support, spectrum, and reconstruction identities of the two leaves
TRIT state, orientation, and three quadratic algebras	TRIT Chapter and Algebraic Classification	Conservation of residue, quotient, orientation, and carry
Complete operational inventory of the TPK	Chapters of transport, memory, and fundamental operators	Commutativity, naturality, and compatible prolongation
Extrema and Holographic Mean Ratio	Nonadic cubic completion	Identity $1000 = 729 + 243 + 27 + 1$ and conservation of the unit
Extendible generation of π, e, φ	Coinductive Biographies and Nonadic Monodromy	Nested cylinders, compatible truncations, and oracle falsifier
Two internal constructions of α_{HMT}	Dodecaphase wheel and reversible cards	Equivalence of outputs and separation of CODATA recognition
Dodecaphase projectors and defect $-1/12$	Hensel–Witt Kernel	Symmetry, idempotence, ranks $3/4$, and normalized trace
Archimedean and exceptional double projection	Cylinder reader and incidence reader	Same input state, typed codomains and non-identification of outputs
Leech lattice, VOA and Moonshine	Complete exceptional runner	Incidence Entanglers and Equivariant Obstructions
Genealogy of the Number and Spectral Functionals	Closure of the concept of number and spectral arithmetic	Euler Products, Characters, and Directed Bounds
Action line and decimal order -34	Bidirectional action and conjugate angular coordinates	Cokernel of order 16 and separation of the relative corrector
Barbero-Immirzi, area operator and spectrum	Hexad-octad transition and modular Hamiltonian	Channels $90/120$, area, first law, and relative entropy
CKM Angles and CP Violation	Chapter of Rational Mixing and Reflection	Unitarity, Jarlskog and caution regarding physical reflection
Bidirectional electron and refined mass	Definition of particle and first electronic implementation	Central fixed point, readers K_D/K_Ω, and rector beta value
Atlas $81/56/13/324$ and mass operators	General Mass Law and route-by-route atlas	Full coverage, null sector and prospective selection

Result	Reference proof	Control reproducible
Permittivity and permeability of the vacuum	Bilayer constitutive response	Separate reconstruction of Z, μ, ε, c
Variational and Hamiltonian Formulation of Gravity	Einstein–Cartan–Holst Gravity	Euler–Lagrange/Hamilton equivalence and torsional controls
Navier–Stokes and Yang–Mills	Terminal Closures of the Fluid and Caliber Realizations	PF84 matrix, coercivity, and transfer

The preceding reduced formulations do not govern the theorems of Part IV. The scope of each specialization is determined there by its object, its domain, its maps, and its comparison identities. In particular, a historical label cannot by itself declare a conclusion open or closed, just as a documentary classification does not replace the commutativity of a diagram. The finite constructions in the preceding table are preserved as antecedents; their prolongation is decided through the explicit comparators of each chapter.

Appendix H

Domains, charts and realization interfaces

This block separates the internal theorems, evaluation charts, physical interfaces, and extension programs. The separation permits each equality to be read in its precise domain and keeps visible which data, gauges, orientations, or boundary conditions enter a realization.

H.1 Domains, codomains, and hypotheses of the results

1. The census $104\,976 \to 468 \to 243$, the image of 42 triples, the factorization $468 = 26 \times 18$, the five regions, and the five cycles are exhaustive theorems of the finite transport system specified in this work.

2. The enriched catalogue produces, through finite fiber predicates and without decimal consultation, the unique closure orbit, the unique propagation orbit and the unique self-scaling orbit; the internal gauge orients the representatives 010211, 201101, 121200 within them. Their characters are constructed, respectively, by the five-region closure with unit return, the semigroup recurrence $(n+1)a_{n+1} = a_n$ and the unique positive ray of the incidence F_{av}. Archimedean evaluation then publishes the generated values and conventional recognition names them π, e, φ. For each depth N, TPK extension produces a unique prefix compatible with that of depth $N-1$; the inverse limit of these prefixes fixes the complete expansion. Thus words, characters and values are successive stages of an internal construction, not labels chosen through external tables.

3. The dodecaphase theorem has as its causal domain the enriched terminal state x_{term} produced by APP–TRIT–TPK. The signed chart publishes from it $x_{\mathrm{term}} \xrightarrow{R_{\mathrm{sgn}}} U_{12}^{\mathrm{sgn}}$, and integral inversion then publishes $U_{12}^{\mathrm{sgn}} \xrightarrow{\mathcal{H}_{12}^{-1}} K$. In this domain, the correspondences with (D_3K, D_4K, Q), the Hadamard representation and the dodecaphase closure are exact and reversible. Neither U nor K are generating inputs. The reduced trace of a positional trajectory and the complete bivariate system are distinct objects, as established in the section 4.1.

4. Equality with the 2018 central string is an external recognition. The internal mathematical word and its proof are independent of the subsequent metrological recommendations.

5. The finite instance of the double projection proves a common flag, W_{12} and M_{12}. In the lattice branch, the gluing of A_2^{12}, the radial chamber and the origin are fixed; the resulting 3-neighbor is certified even, unimodular and rootless, and is classically identified with Leech. The construction of $V^\natural$ and the Monster is a classical consequence. The arrow $W_{12} \to W_{24}$ is realized through the residual design of a dodecad and the unique lift of its hexads, relative to a choice (D, ℓ); the identifications are made through maps, not through cardinality equalities. The projective compatibility of these data and their double realization on the common enriched state are proved in the theorems 17.8 y 17.9.

6. The cylinder theorem produces a unique real for each history in its domain. The extension law coherently covers each compact set and the directed exhaustion covers the entire line, as proved by the theorems 18.3 y 18.9 y proposition 18.5. Therefore, evaluation is surjective and its Archimedean quotient is $\mathbb{R}$; coverage is a conclusion of the HMT generator, not an additional premise.

7. The native product is proved in the canonical sector of words. The monoidal extension to the complete space of histories and the intertwining with the survival filtrations are formulated as distinct maps in the chapter 27.

H.2 Causal Invariance of Interfaces with Respect to External References

H.2.1 Criterion of causal independence with respect to external references: directed acyclic graph and prior fixation of the output

Let P be the internal primitives, R the declared rules, readers, gauges, and normalizations, G a generator, $o = G(\mathsf{P}, \mathsf{R})$ its output, and y an external reference.

Definition H.1 (Prospectively independent interface)**.** The interface is prospectively independent of y if:

1. $y \notin \mathrm{Anc}(o)$;
2. $\mathsf{P}, \mathsf{R}, G$ and the negative controls are fixed before y is opened;
3. the execution has no direct or indirect access to y;
4. o and its trace are sealed before computing a comparison $\mathrm{cmp}(o, y)$.

Definition H.2 (Selection independence)**.** The blindness of each execution is not enough if, after producing candidates $G_j(\mathsf{P}, \mathsf{R}_j)$, one publishes

$$j_*(y) = \arg\min_j \mathrm{cmp}\big(G_j(\mathsf{P}, \mathsf{R}_j), y\big)\,.$$

Selection independence prohibits this operation from determining the published output.

Definition H.3 (Multivalued prediction)**.** If the non-metrological physical descriptors and the internal constraints admit several multisections, the prospective output is the complete set

$$\widehat{\mathfrak{R}}(d) = \{\mathcal{M} : \mathcal{M} \text{ satisfies all the constraints preregistered for } d\}.$$

Nonuniqueness is an output of the procedure. Subsequently choosing an element by proximity to a magnitude is prohibited.

H.2.2 No-Interference Theorem

Definition H.4 (Directed Acyclic Faithful and Complete Causal Graph)**.** A directed acyclic graph D is faithful if every node represents the same function and the same inputs as the cited construction. It is complete for an output if every causally relevant dependency appears as an edge or a declared root. Faithfulness and completeness are semantic hypotheses; the acyclicity of the dataset does not prove them.

Theorem H.5 (Prospective independence conditional on the causal graph)**.** *Let a deterministic system of structural equations be represented by a finite directed acyclic graph D that is faithful and complete for o. If $y \notin \mathrm{Anc}_D(o)$, all ancestral roots of o remain frozen and the execution has no hidden access to y, then for any y_0, y_1,*

$$o_{\mathrm{do}(y=y_0)} = o_{\mathrm{do}(y=y_1)}.$$

Proof. The predecessors of o are topologically ordered. Their roots are internal and remain fixed. By induction on the order, each node receives the same arguments under both interventions and, by determinism, returns the same value. Equality propagates to o. The cryptographic digest does not create the independence; it merely makes a subsequent alteration detectable. □

Corollary H.6 (Permutation of the external comparison)**.** *If names, rows, or external values are permuted after sealing, the internal output does not change, although its score may change:*

$$o_{\mathrm{do}(y=\sigma y_0)} = o_{\mathrm{do}(y=y_0)}, \qquad \mathrm{cmp}(o, \sigma y_0) \neq \mathrm{cmp}(o, y_0).$$

Proposition H.7 (Calibrated branch separation)**.** *If an external reference intervened in a historical selection, the dependence does not contaminate internal objects that do not descend from that selection. The branch can be isolated and subjected to a new prospective protocol without modifying the kernel.*

Proof. To be a predecessor is a local property of the graph. The branches

$$Z_0 \longrightarrow p = 5 \longrightarrow \text{electronic scale}, \qquad \{\text{masses}\} \longrightarrow \{\text{calibrated signatures}\} \longrightarrow \text{table}$$

remain outside the protected subgraph. The towers, the formal character, the atlas, and the center $(5, 5)$ receive no edges from those references. □

H.2.3 Counterfactual Invariance on the Directed Causal Graph and Scope of the Conclusion

The published causal graph contains 71 nodes, 89 edges, 16 interfaces, and 29 protected outputs. The causal check establishes acyclicity, counts, declared routes, existence of the registered sources, absence of external references among the recorded ancestors, and counterfactual invariance of the symbolic model. The result is

$$\#\{\text{external predecessors of protected outputs}\} = 0.$$

The certificate does not by itself prove that no edge is missing, nor does it audit every data reading of each scientific program. Its strength is therefore PROVED FROM EXPLICIT STARTING STRUCTURE: the conclusion is obtained on the expressly declared directed acyclic graph and remains conditional on its fidelity and completeness.

Simultaneously replacing the CODATA, Planck, Barbero–Immirzi, CKM, mass, gravity and time-crystal references can alter comparisons and calibrated branches. Within the declared graph, it does not alter the catalogue of 468 emissions, the five regions of π, the correlated coinductive generation, α_{12}, C^*, the decade -34, the towers, the atlas, the electronic center, the double projection or the exceptional corridor.

H.2.4 Multivalued trial without access to the target value and identification criterion

Algorithm H.8 (Future assignment without magnitudes)**.** The physical interface is executed in four irreversible phases:

1. *Freezing*: authority, atlas, involutions, restrictions, code, priority, and negative controls are sealed.
2. *Permitted input*: only sector, generation, charge, color, conjugation, spin/statistics, composition, and metrological type are received; masses, refined signatures, residues, angles, and units are excluded.
3. *Output*: all compatible multisections are enumerated; for each extension of each multisection, the observable route, record, signature, χ_{form}, specialization, and observable are computed. In composite objects, the extensions and records are spliced first. The complete multiset is sealed.
4. *Opening*: a distinct custodian opens the magnitudes and computes residuals, uncertainties, and covariances without modifying any candidate.

The enriched multisection, rather than a point extension selected retrospectively, is the output of the physical matching. The subsequent evaluation may be performed fiber by fiber. The preceding algorithm is a falsifiable specification; it is not presented as an already executed multiset prediction.

Comparison Criterion H.9 (Failure of the blind protocol)**.** The protocol fails if the code can read a magnitude, if a calibrated historical signature reappears as an input, if a candidate is discarded after opening the reference, if positive mass is confused with exactly zero mass, or if the sealed multiset changes when the external catalog is permuted.

H.2.5 Formal character and reconstructive completeness

For $v = (n_A, s_C, k, b_{120}, b_\zeta) \in \mathbb{Z}^5$, the formal character prior to any specialization is

$$\chi_{\mathrm{form}}(v; x_A, x_C, x_\Delta, x_{120}, x_{270}) = \exp\bigl(n_A x_A + s_C x_C + k x_\Delta + b_{120} x_{120} + b_\zeta x_{270}\bigr)\,.$$

The declared specialization

$$\Theta_0 = \left(A_{\mathrm{rad}}, \frac{C^*_{\mathrm{rad}}}{6}, \Delta_4, s_{120}, \zeta_{270}\right), \qquad \zeta_{270} = 135\Delta_4^2,$$

produces $\chi_0(v) = \chi_{\mathrm{form}}(v; \Theta_0)$. The raw signature, the formal character, its central specialization, the global refinement $\eta \in \mathcal{E}_{\mathfrak{S}}$, and a calibrated table are five different objects.

Theorem H.10 (Positive reconstructive completeness)**.** *Let*

$$\mathcal{N} = \langle 90, 120\rangle_{>0}$$

and let $(n_j)_{j\ge1}$ be its increasing enumeration. Given $0 < q_+ < q_- < 1$, define

$$a_j = q_-^{n_j} - q_+^{n_j} > 0.$$

Then $a_j \to 0$ and $\sum_j a_j < \infty$. Having fixed a deterministic rule for resolving half-integer ties, for every $r \in \mathbb{R}$ the recurrence

$$r_0 = r, \qquad \nu_j = \mathrm{nint}\left(\frac{r_{j-1}}{a_j}\right), \qquad r_j = r_{j-1} - \nu_j a_j$$

satisfies

$$|r_j| \le \frac{a_j}{2} \longrightarrow 0, \qquad r = \sum_{j\ge1} \nu_j a_j, \qquad \sum_{j\ge1} |\nu_j a_j| < \infty.$$

Therefore every $R > 0$, with $r = \log R$, is represented exactly in the completion by $\exp(\sum_j \nu_j a_j)$.

Proof. The indices of $\mathcal{N}$ are 90, 120 and all multiples of 30 from 180 onward. Consequently,

$$\sum_{n\in\mathcal{N}} q_-^n = q_-^{90} + q_-^{120} + \frac{q_-^{180}}{1 - q_-^{30}} < \infty.$$

As $0 < a_j < q_-^{n_j}$, the sequence is sumable and converge to zero. The definition of integer mas proximo implica $|r_j| \le a_j/2$. By telescopado, $\sum_{i=1}^{N} \nu_i a_i = r - r_N \to r$. For $j \ge 2$,

$$|\nu_j a_j| = |r_{j-1} - r_j| \le \frac{a_{j-1} + a_j}{2},$$

and the summability of (a_j) proves absolute convergence. □

The theorem establishes completeness of the dictionary on $\mathbb{R}_{>0}$. If the coefficients ν_j are obtained from the residue of a known mass, their use is CALIBRATED RECONSTRUCTION; it does not provide prospective selection. Nor does it represent exactly zero mass. The photon, gluon, or a prospective spin-two mode require exact symmetry protection in the physical representation.

H.2.6 Prospective invariance protocols for constant families

Barbero–Immirzi. S_{90}, S_{120}, the weights $(12, -1)$, and their normalization are frozen before a physical reference is opened. The evaluation of $\Gamma_{6\to 8}$ is blind to that reference, but the prior uniqueness of the series and weights and the intertwiner with the area operator are distinct problems.

CKM and CP. The four equations, their coefficients, and the angular convention are sealed; the four parameters, $|V|$ and J, are published simultaneously. The comparison uses a covariance fixed in advance.

Constitutive. The dimensionless identities precede Z_{ref} and c_{ref}. A change of chart transforms the realization, not the identities, and does not create four independent predictions.

Gravity and inertia. The ratios $G_{\mathrm{tor}}/I_{\mathrm{tor}} = 1$ and $G_{\mathrm{av}}/I_{\mathrm{av}} = \pi/\varphi^2$ belong to different layers. Their physical interpretation requires a morphism and a prospective contrast; a cosmological phenomenon does not select the ratio.

H.2.7 Evidentiary stratification: internal identities, deductions, calibrated reconstructions, and interfaces subject to mathematical closure

Table H.1: Levels that causal independence does not allow to collapse.

Level	Example	Allowed Statement
Certified internal generator	Regions, α_{12}, C^*, -34, atlas	Output obtained in the declared domain.
Blind conditional evaluation	$\Gamma_{6\to 8}$, fixed CKM, $\chi_0(v)$	Do not consult the white, but it depends on the functional or signature.
Blind protocol not executed	Multivalued specification	There exists a falsifiable procedure; not a sealed output.
Calibrated Reconstruction	Historical signatures and refinement from $r = \log R$	Exact evaluation conditioned on a reference.
Pending physical interface	Particle–antiparticle, area, zero mass, gravity	Domain defined; lack of representation or contrast.

Appendix I

Reproducibility of the atlas and comparison of mass realizations

The theory of masses is generated over the complete domain of 81 positions, 56 route families, 13 multisections, 324 oriented routes, and the null sector. The structural phase computes

$$\begin{aligned}\text{position or fibre} &\longrightarrow \text{family} \longrightarrow \text{oriented route}\\ &\longrightarrow \text{record} \longrightarrow \text{nominal signature} \longrightarrow \text{character and tower},\end{aligned}$$

and, when the fiber possesses the corresponding operator reader, adds the refinement branch

$$\text{record} \longrightarrow (K_D, K_\Omega) \longrightarrow \text{fiber spectrum}.$$

The second branch refines the first and does not replace it: in particular, W, Z, and H preserve their CT–108 routes, their angular signatures, and their scalar characters even though they do not belong to the operatorial atlas of thirteen multisections. These invariants are fixed before the external comparison; a metrological reference does not intervene in the selection of route, position, signature, or coefficient.

I.1 Finite invariants of classification

- complete atlas of 81 cells with their readers;
- 56 route families with their spectra;
- 13 multisection operators;
- 324 oriented routes with ledger and character;
- complete inventories of masses and widths;
- chart comparativa posterior to the selection genealogica.

I.2 Conditions of accuracy, stability, and reproducibility of the certificates

The integral control requires the coverage $81/56/13/324$, the null sector, the 14 profiles of K_D, the 9 profiles of K_Ω, the 40 joint pairs, and the 18 reader coincidences. It further verifies that the refined electron mass is evaluated from a single expression, that the null sectors retain κ as not applicable, that an operator row does not publish a scalar residual, that the twelve nominal routes $e, \mu, \tau, u, d, s, c, b, t, W, Z, H$ retain their scalar character, and that the physical realization preserves the proper codomain of each output. The absence of a K_D/K_Ω pair in a sector cannot degrade or erase its native scalar reader.

The reproduced electronic output is

$$m_e^{\beta} = m_e^{(0)} R_{\mathrm{act}}^{80-54\alpha_{\mathrm{HMT}}+6\Delta_4} = 0.510998950690000808608257165\ldots\ \mathrm{MeV}/c^2.$$

Higher-rank fibers publish their operator pair, their spectra, and the corresponding realization morphism. Eigenvalue selection is determined by that morphism before external comparison.

I.3 Scientific domain of classification

The mass domain is the preceding complete atlas. The construction receives exclusively positions, families, multisections, routes, records, and typed operators; provenance data remain separate from the scientific load.

Appendix J

Complementary Proofs of the Algebraic, Spectral, Modular, and Electroweak Identities

This appendix gathers the proofs that can be verified without reconstructing the entire narration. The hypotheses appear in each statement. The classical results used to interpret an operator that has already been constructed are distinguished from the internal identities.

J.1 Positivity of the vacuum operator

Lemma J.1. *If $T = T^*$ and $\mathrm{Spec}(T) \subset (0,1)$, then $I - T^n > 0$ for every $n \geq 1$, $I - T^{120}$ is invertible and*

$$\mathcal{V} = (I - T^{90})(I - T^{120})^{-1} > 0.$$

Proof. For $t \in (0,1)$, $1 - t^n > 0$. By functional calculus, $I - T^n$ is positive. Since the spectrum of $I - T^{120}$ is separated from zero in finite dimension, it has a positive inverse. Both factors are functions of T, commute, and their product is positive. □

Lemma J.2 (Monotonicity of the completion)**.** *The function*

$$r(q) = \frac{1 - q^{90}}{1 - q^{120}}$$

is strictly decreasing in $(0,1)$.

Proof. With $s = q^{30}$,

$$r(s) = \frac{1 + s + s^2}{1 + s + s^2 + s^3}.$$

A derivation yields

$$\frac{dr}{ds} = -\frac{s^2(3 + 2s + s^2)}{(1 + s + s^2 + s^3)^2} < 0.$$

As $ds/dq = 30q^{29} > 0$, also $dr/dq < 0$. □

J.2 Traces that recover the constituent characters

From $\log \mathcal{V} = (\log r_+)P_+ + (\log r_-)P_-$ and $\tau(P_\pm) = 1/2$,

$$2\tau(\log \mathcal{V}) = \log r_+ + \log r_- = \log(r_+ r_-).$$

Moreover, $RP_+ = P_+$, $RP_- = -P_-$; hence

$$-2\tau(R \log \mathcal{V}) = -\log r_+ + \log r_- = \log(r_-/r_+).$$

Exponentiating yields $\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}$. There is no approximation in this step.

J.3 UHF Tower Compatibility

Be $\mathcal{A}_m = M_2 \otimes M_{9^m}$ and the inclusion $\iota_m(x) = x \otimes I_9$. The expectativa

$$E_m = \mathrm{id}_{M_2} \otimes \mathrm{id}_{M_{9^m}} \otimes \tau_9$$

satisfies $E_m \iota_m = \mathrm{id}$. Therefore,

$$E_m(\mathcal{V} \otimes I_{9^{m+1}}) = \mathcal{V} \otimes I_{9^m}.$$

The same equality holds for every continuous function of $\mathcal{V}$, in particular $\log \mathcal{V}$. The normalized trace is compatible, and the characters do not change under refinement.

J.4 Coefficients of the analytic criticality profile

Let

$$b_m = \frac{2(3m-1)}{\sqrt{899}}.$$

The expansion $1 - \cos(b_m x) = b_m^2 x^2/2 - b_m^4 x^4/24 + O(x^6)$ gives

$$u_0(x) = \frac{1}{24} \sum_{m=1}^{12} b_m^2 x^2 - \frac{1}{288} \sum_{m=1}^{12} b_m^4 x^4 + O(x^6).$$

Consequently,

$$\sum b_m^2 = \frac{4}{899} \sum (3m-1)^2 = 24,$$

whence the quadratic coefficient is one. The integer calculation of the fourth moment reduces the coefficient to

$$-\frac{715769}{2424603}.$$

This fraction provides an algebraic control more informative than its decimal value.

J.5 Closed trigonometric sum

The identity

$$\sum_{m=1}^{M} \cos(a + (m-1)d) = \frac{\sin(Md/2)}{\sin(d/2)} \cos\!\left(a + \frac{M-1}{2} d\right)$$

with $M = 12$, $a = 4y$, $d = 6y$ produces

$$\sum_{m=1}^{12} \cos(2(3m-1)y) = \frac{\sin 36y}{\sin 3y} \cos 37y.$$

Dividing by 12 proves the first form of equation (45.6); $2 \sin 36y \cos 37y = \sin 73y - \sin y$ proves the second.

J.6 Schwarziano negativo

For $x \in (0,1]$, each $b_m x \in (0,\pi)$. Therefore

$$u_0'(x) = \frac{1}{12}\sum b_m \sin(b_m x) > 0,$$

$$u_0'''(x) = -\frac{1}{12}\sum b_m^3 \sin(b_m x) < 0.$$

Since $f_\lambda' = -\lambda u_0'$, the factors $-\lambda$ cancel in the Schwarzian quotients, and

$$S(f_\lambda) = \frac{u_0'''}{u_0'} - \frac{3}{2}(u_0''/u_0')^2 < 0.$$

Parity extends the conclusion to $[-1,0)$. The origin is critical quadratic by $u_0(x) = x^2 + O(x^4)$.

J.7 Levy integral

The dominated convergence allows

$$\begin{aligned} -\int_0^1 \log x \, d\mu_G(x) &= \frac{1}{\log 2}\int_0^1 \frac{-\log x}{1+x}\,dx \\ &= \frac{1}{\log 2}\sum_{n=0}^{\infty}(-1)^n \int_0^1 x^n(-\log x)\,dx \\ &= \frac{1}{\log 2}\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n^2} \\ &= \frac{\eta(2)}{\log 2} = \frac{\pi^2}{12\log 2}. \end{aligned}$$

J.8 Values of the dodecaphase character

The product $\chi_{12} = \chi_{-3}\chi_{-4}$ vanishes if $\gcd(n,12) > 1$. In the four unit classes, multiplication yields $(+,-,-,+)$. The series

$$L(s,\chi_{12}) = \sum_{k\ge 0}\left[\frac{1}{(12k+1)^s} - \frac{1}{(12k+5)^s} - \frac{1}{(12k+7)^s} + \frac{1}{(12k+11)^s}\right]$$

can be evaluated at $s=1$ by means of Euler products or the field-unit formula for $\mathbb{Q}(\sqrt{3})$, yielding equation (41.8). At $s=2$, the generalized Bernoulli formula yields equation (41.9). Direct multiplication of the character provides a falsification criterion independent of both evaluations.

J.9 Reconstruction of the areal and modular sectors

Let

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}.$$

The system matrix is

$$M = \begin{pmatrix} 1 & 1 \\ 90 & 120 \end{pmatrix}, \qquad \det M = 30.$$

Therefore,

$$M^{-1} = \frac{1}{30}\begin{pmatrix} 120 & -1 \\ -90 & 1 \end{pmatrix},$$

and

$$N_{90} = 4N - D/30, \qquad N_{120} = D/30 - 3N.$$

The determinant 30 explains why the fundamental modular step reappears in the infinite classification.

J.10 Purification through a thermofield double state

For a qutrit with weight $w > 0$,

$$Z(w) = 1 + \mathrm{e}^{-w} + \mathrm{e}^{-2w}, \qquad p_n = \frac{\mathrm{e}^{-nw}}{Z(w)}.$$

Define

$$|\mathrm{TFD}(w)\rangle = \sum_{n=0}^{2} \sqrt{p_n}\,|n\rangle_A |n\rangle_{\bar{A}}.$$

Then

$$\mathrm{Tr}_{\bar{A}}\,|\mathrm{TFD}\rangle\langle\mathrm{TFD}| = \sum_n p_n |n\rangle\langle n| = \rho_A.$$

The equality of the entropies of the two subsystems is immediate from the Schmidt decomposition. The product of eighteen copies of each channel purifies the total boundary state.

J.11 1st areal modular law

For a differentiable family $\rho(t)$, $\mathrm{Tr}\,\rho(t) = 1$, with faithful reference state ρ_0 and $K_0 = -\log \rho_0$,

$$\frac{d}{dt} S(\rho(t))\Big|_{t=0} = \mathrm{Tr}(\dot{\rho}_0 K_0),$$

porque $\mathrm{Tr}\,\dot{\rho}_0 = 0$. Si

$$K_0 - cI = \beta_{90}\mathcal{A}_{90} + \beta_{120}\mathcal{A}_{120},$$

the scalar term vanishes, and

$$\delta S = \beta_{90}\delta\langle\mathcal{A}_{90}\rangle + \beta_{120}\delta\langle\mathcal{A}_{120}\rangle.$$

As $\beta_m = m\Delta_4^{\mathrm{mod}}/(\gamma_{\mathrm{HMT}} a_0)$, the ratio is exactly $120/90 = 4/3$.

J.12 Reflexion racional CKM

Let $D = \mathrm{diag}(1,-1,1)$, $\boldsymbol{\theta} = M\mathbf{x}$, and $R = MDM^{-1}$. Immediately, $R^2 = I$, $\det R = \det D = -1$, and $RM = MD$. In the determined coordinates,

$$c_h = (-5,7,-20)^T, \qquad \ell_h = (75,176,-150)/3857, \qquad \ell_h c_h = 1.$$

The odd projector is $c_h \ell_h$, of rank one. Hence

$$R = I - 2c_h \ell_h.$$

Multiplying fractions verifies

$$R = \frac{1}{3857}\begin{pmatrix} 4607 & 1760 & -1500 \\ -1050 & 1393 & 2100 \\ 3000 & 7040 & -2143 \end{pmatrix}.$$

The phase $\delta_{\mathrm{CP}} = 9A$ remains fixed because D does not change A. CP conjugation in the physical realization is another operator.

J.13 Classification of the modular realization in the infinite limit

Suppose an infinite succession of qutrit factors with faithful states, whose logarithms of eigenvalue ratios belong to

$$90\Delta_4^{\mathrm{mod}}\mathbb{Z} \quad \text{or} \quad 120\Delta_4^{\mathrm{mod}}\mathbb{Z},$$

and suppose that both types appear with positive density. The additive group generated is

$$90\Delta_4^{\mathrm{mod}}\mathbb{Z} + 120\Delta_4^{\mathrm{mod}}\mathbb{Z} = 30\Delta_4^{\mathrm{mod}}\mathbb{Z}.$$

The asymptotic ratio is then

$$\{0\} \cup \exp(-30\Delta_4^{\mathrm{mod}}\mathbb{Z}) = \{0\} \cup \lambda_\partial^{\mathbb{Z}}, \qquad \lambda_\partial = \mathrm{e}^{-30\Delta_4^{\mathrm{mod}}}.$$

The Araki–Woods theorem for ITPFI factors classifies the GNS closure as the hyperfinite factor III_{λ_∂}. The application is conditional on the hypotheses of faithfulness, compatibility, and persistence; the weights entering the classification are internal.

Remark J.3. If only the channel 90 persists, the generating group changes to $90\Delta_4^{\mathrm{mod}}\mathbb{Z}$; if only 120 persists, it changes to $120\Delta_4^{\mathrm{mod}}\mathbb{Z}$. If the local states are not of the declared compatible product type, the criterion must be recomputed. These cases are refutation criteria, not stylistic notes.

J.14 Electroweak angular identity

For the character

$$\chi(n_A, s_C) = \exp(n_A A + s_C C^*/6)$$

and the routes $W = (94, -1)$, $Z = (95, -1)$,

$$\frac{m_W}{m_Z} = \frac{\chi(94, -1)}{\chi(95, -1)} = \mathrm{e}^{-A}.$$

Since $D_A = \mathrm{e}^{-2A} = \det T$,

$$(m_W/m_Z)^2 = D_A, \qquad \sin^2\theta_W^{\mathrm{OS}} = 1 - D_A.$$

The proof belongs to the angular chart. Its complete interpretation of gauge requires the declared basis intertwiner in the body of the volume.

Appendix K

Mathematical and Computational Certification of Intrinsic Derivations

K.1 Domain, magnitudes, and logical scope of the computational certificate of intrinsic derivations

Block	Controles ejecutados
Matrix	58 rows, 15 fields, unique identifiers and declared scope
Vacío	order of $q_{\pm}$, positivity, eigenvalues, four characters, constitutive identities, and mode 30 completion
Electrodébil	$D_A = q_+q_-$ y $\sin^2\theta_W = 1 - D_A$
Chaos	quadratic sum, $899 = 30^2 - 1 = 29 \cdot 31$, quartic coefficient, closed profile and numerical residues
Gauss map	Levy, entropy, and Lochs for bases 10 and 729
Vacancies	exhaustive window of 10^8 positions, gaps 21/22, returns 6/7, certified interval, and traces of the multiprecision verifier
Spectrum	character χ_{12}, $L(1)$, $L(2)$, hyperbolic unit and Bendersky tower
Modular Hamiltonian	Δ_4^{mod}, weights 90/120, entropy, oriented defect, area–memory inversion, TFD and first law
Type III	group of ratios $30\Delta_4^{\mathrm{mod}}\mathbb{Z}$ and $\lambda_\partial = \exp(-30\Delta_4^{\mathrm{mod}})$ under declared hypotheses
CKM	coordinate inversion, odd projector, rational reflection, determinant, and intertwining
Cosmología	elimination of n and the exact sixth-power law

K.3 Typing Obstructions and Equivalence Separation Between Certified Domains

The certificate does not promote the following statements:

1. $I_{\mathrm{or}} = \gamma_{\mathrm{HMT}} a_0$; the values are proximos but distintos.
2. The vacuum operator is identical to the Feigenbaum renormalizer.
3. Cofinality of cylinders implies TPK–Gauss conjugation.
4. The closure III_{λ_∂} holds without persistence of both channels.
5. CKM sheet inversion is physical CP conjugation.
6. The realization φ and the chronology cyclic of 108 states representan the same cosmology.
7. The angular relation in the scheme of physical masses includes by itself all electroweak corrections.

These negative controls do not weaken the volume: they establish exactly what has been proved and what additional map would change the status.

Appendix L

Independent reproduction of the coinductive certificates at depth 10^4: $\pi, e, \varphi, \alpha_{\mathrm{HMT}}$

This appendix prints the complete outputs of the execution described in appendix D.2 y section 31.6. The line breaks are exclusively typographical. Each expansion constitutes a finite witness of the coinductive law of arbitrary precision proved in Part III; it neither defines the constant nor limits the depth of the generator.

This residence reproduces, from the independent owner in Part III, the four coinductive outputs published in the cumulative corpus. The exact identity of the listings constitutes a cross-check of reproducibility and provenance; it does not introduce a second generation of the constants or alter their cylinders, truncations, or certificates.

L.1 Independent reproduction of the coinductive expansion of π and verification of the compatible truncation

Appendix M

Exhaustive classification of states, signatures, and mass realizations

M.1 Mathematical Conventions and Data Representation

This catalogue does not take a column of masses as the definition of the theory. It superimposes four layers without conflating them:

$$\begin{array}{rcl} \mathcal{C}_{81} \to \mathcal{R}_{56} \to \Sigma_{13} & : & \text{internal domain of cells, routes and multisections,} \\ \Gamma_{108}^{\mathrm{enr}} \to \mathcal{L}_{108} \to \mathbb{Z}^5 & : & \text{route genealogy, record and signature,} \\ \mathbb{Z}^5 \xrightarrow{\chi_{\mathrm{mass}}} \mathbb{R}_{>0} & : & \text{exact evaluation of a fixed signature,} \\ \mathbb{R}_{>0} \to \mathcal{U}_E & : & \text{energy chart and metrological comparison.} \end{array} \tag{C1}$$

The atlas is complete in its domain $81/56/13$. The compositional grammar is complete for the identities, mesonic expressions, baryonic expressions, and transitions that it constructs. Those cardinalities do not count physical particles. The numerical tables below declare, in every case, which coordinates are fixed and what role the comparison performs. In this way, all species and all localized values are displayed without passing off an inverse decoding as the genealogy it must explain.

M.2 Combinatorial domain prior to physical identification

The exact partition is

$$81 = 25_{\ell^-} + 20_{\nu} + 20_{d} + 16_{u}, \qquad 36_{\mathrm{quark}} = 12_R + 12_G + 12_B. \tag{C2}$$

The thirteen multisections have cardinalities

$$(1, 8, 16)_{\ell^-}, \quad (2, 4, 6, 8)_{\nu}, \quad (2, 4, 6, 8)_{d}, \quad (4, 12)_{u}. \tag{C3}$$

The electron is the central one-point multisection. The other twelve preserve the orbit and orientation of the entire fibre. A physical row is therefore not obtained by arbitrarily selecting a cell: the species is the enriched multisection, and the particle is a persistent section realized within it.

Table M.1: The thirteen multisections of the simple domain.

Internal family	Level	Cardinality	Lectura estructural
ℓ^-	$G0$	1	electronic center $(5, 5)$
ℓ^-	$G2$	8	family of second depth charge
ℓ^-	$G4$	16	loaded family exterior
ν	$G1$	2	first hidden layer
ν	$G2$	4	second neutral layer
ν	$G3$	6	third neutral layer
ν	$G4$	8	fourth neutral layer, including the sterile/exotic branch
d	$G1$	2	quark type d, first depth
d	$G2$	4	quark type d, second depth
d	$G3$	6	quark type d, third depth
d	$G4$	8	quark type d, fourth depth
u	$G1$	4	quark type u, first depth
u	$G3$	12	quark type u, third depth

The cardinal projections, fine signatures, and partial angular charts are specialized controls of the general law. The development that follows first fixes the grammar of composition, the null sector, and cellular identifiability; the exhaustive atlas then publishes all routes without turning a historical sample into the definition of the domain.

M.3 Composition of Mesonic and Baryonic Records

The theorem (92.17) constructs the complete grammar prior to every mass:

class	cardinal	internal condition
identity	81	dual of the same cell
mesonic expression	432	colour-neutral quark–antiquark pair
baryonic expression	1728	RGB triple with oriented positions
charged transition	320 + 52	leptonic or quark compatibility.

(C7)

Each expression receives a mass only after being physically realized, its records spliced, and its new signature extracted. The numbers 432, 1728, 372 count admissible combinations of the grammar, not physical species or entries in the resonance table.

M.4 Neutrinos, the null sector, and gauge representations

Neutrinos occupy four multisections of cardinals.

$$2, \quad 4, \quad 6, \quad 8.$$

The structure distinguishes the three active layers and the sterile/exotic layer. Its primary metrological observable is not an isolated absolute mass, but rather the quadratic differences, ordering, and scale bounds; those data are presented with their type and are never replaced by an invented row of χ_{mass}.

Photon and gluon belong to the null or gauge sector. The operator

$$L_{\text{TPK}} = 3(I - P_0)$$

has spectrum $\{0, 3, 3\}$; its central mode carries no compactified memory of its own. Quark color rests on the ternary residue $r - c \bmod 3$, whose balance is $12 + 12 + 12$, and the qutrit chart is used to construct $\mathfrak{sl}_3(\mathbb{C})$ and its compact form. Absence from $\mathbb{R}_{>0}$ does not eliminate these sectors: it proves that positive mass is not the atlas's only reader.

M.5 Fibonacci, Ising, and Majorana

The topological sectors are compared by fusion, quantum dimension, spin, and braiding, not by a supposed universal mass. The Fibonacci envelope produces the based ring

$$\tau^2 = 1 + \tau, \qquad \text{FPdim}(\tau) = \varphi. \tag{C8}$$

The involution C_M, CAR parity, the relativistic Majorana field, and the zero mode of an Ising realization are four distinct levels. Their separation explains which part follows from the route, which from fermionic statistics, and which from a concrete topological platform.

M.6 Cellular identifiability and boundary of the nominal link

Once the oriented APP frame has been fixed, each cell x determines its positive diagonal route γ_x^+. The dodecaphase record of this route satisfies, for the 81 cells,

$$\Sigma_+(x) = L_{\text{tick}}\big(\mathcal{L}_{\gamma_x^+}\big) = A(x) = (n_A, s_C, k_{\Delta_4}, b_{120}, b_\zeta). \tag{C9}$$

The winding

$$\omega_D(x) = \left(\frac{\Delta n_A}{2}, \frac{\Delta s_C}{6}, \frac{\Delta k_{\Delta_4}}{2}, \frac{\Delta b_{120}}{2}, \frac{\Delta b_\zeta}{4}\right) \in \mathbb{Z}^5 \tag{C10}$$

together with τ_{12}, recovers the 56 route families; the nonadic boundary class β_0 separates the 81 positions.

Exact scope of the result

The chain internal cell → oriented route → register → signature is constructed. The finite nominal realization is already closed by sabor(P) and by $\mathcal{S}_{\text{phys}}$ in (92.8)– (92.9): generation, branch, fine trace, and color orbit publish the route before any mass evaluation. For noncentral fibers, the species is a multisection, not an isolated cell; requiring the name to select a unique point would be a type error. The NSEO traces, fine signatures, and nominal tables preserve the material evidence of this map and do not constitute postselection by an external value.

Once the simple sections and the binding record have been constructed independently, the composites are formed before the signature is evaluated:

$$\begin{aligned} \mathcal{L}_{q\bar{q}} &= \text{Comp}_2(\mathcal{L}_q, \mathcal{L}_{C_M\bar{q}}; g), \\ \mathcal{L}_{q_1q_2q_3} &= \text{Comp}_3(\mathcal{L}_{q_R}, \mathcal{L}_{q_G}, \mathcal{L}_{q_B}; g), \\ v_X &= L_{\text{tick}}(\mathcal{L}_X), \\ m_X &= m_e^{\text{HMT}} \exp\langle \Theta_{\text{mass}}, v_X - v_e \rangle . \end{aligned} \tag{C11}$$

The composition does not query a target mass; neither does it by itself identify an external species with its internal components.

M.7 Heterogeneity of Physical Domains and Exhaustiveness of the Catalogue

The catalog collects all the layers located without converting them into the same observable:

- the 81 cells, 56 families, and 13 multisections form the simple domain;
- 81 + 432 + 1728 + 372 counts identities, expressions, and arrows of the compositional grammar, not physical particles;
- the complete signatures, the N/E/S/O projections, and the reduced charts remain as specialized controls of the evaluation, without limiting the exhaustive domain or retrospectively selecting its routes;
- neutrinos, the photon, the gluon, Fibonacci, Ising, and Majorana retain their own observables.

Scientific completeness consists in omitting no domain and in misrepresenting the type of no row. The character law is unique; each simple section or composite register is evaluated through proposition 92.25. The external value appears at the end, together with the object class and the reader that evaluates it. The comparison thus ceases to be a list of successes and becomes a verifiable reading of the genealogy.

M.8 Public projection of the internal record of the routes

Each route has 53 fields in the unified register and 57 fields in the enriched register. The scientific record publishes 49 fields. This projection does not eliminate information: the consistency states of the route, of the gluing, and of tower prolongation, together with the 5 raw components of the signature, remain in the complete registers and are gathered in the published invariants. Therefore, the publication map is a typed projection

$$\mathcal{R}_{57} \longrightarrow \mathcal{F}_{49},$$

accompanied by the complete register $\mathcal{R}_{53}$ and by the enriched register $\mathcal{R}_{57}$; it is not a reduction of the scientific domain.

M.9 Correspondence between the genealogical domain and the metrological inventories

The material domain is constructed from 81 cells, 56 route families, 13 multisections, and 324 oriented routes. Its complete deployment is found in the atlas of 324 routes, with a complete card and 49 fields by route. The external censuses of contrast are preserved in the inventory of 471 masses and 384 widths. The atlas constructs the fibers and their operators; the censuses do not retrospectively select a route or redefine the domain of the law.

M.10 Exact correspondence between the canonical record of 53 fields, the enriched record of 57 fields, and the 49 invariants of each card

The 324 oriented routes have two complete proprietary registers and one scientific publication per record. The registers of 53 and 57 fields overlap without being identified: their union contains 65 distinct identifiers. The publication column selects exactly 49 invariants for each record, while the remaining data remain preserved in the reproducibility layers. Therefore, projection onto the record neither eliminates information from the domain nor reduces the atlas.

Field	$\mathcal{R}_{53}$	$\mathcal{R}_{57}$	$\mathcal{F}_{49}$	Public interpretation or conservation residency
`candidate_id`	Yes	Yes	Yes	Canonical identifier
`cell_id`	Yes	Yes	Yes	Cell
`r`	Yes	Yes	Yes	APP row
`c`	Yes	Yes	Yes	APP column
`h0`	Yes	Yes	Yes	Horizontal orientation
`v0`	Yes	Yes	Yes	Vertical orientation
`is_B1_route`	Yes	—	—	Data preserved in the canonical record of reproducibility.
`coarse_class`	Yes	—	—	Data preserved in the canonical record of reproducibility.
`family`	Yes	—	—	Data preserved in the canonical record of reproducibility.
`sector`	Yes	—	—	Data preserved in the canonical record of reproducibility.
`generation`	Yes	—	—	Data preserved in the canonical record of reproducibility.
`color`	Yes	Yes	Yes	Colored orbit

K_D	Yes	Yes	Yes	Reader K_D
K_Omega	Yes	Yes	Yes	Reader K_Ω
kappa_D	Yes	Yes	Yes	Exponent κ_D
kappa_Omega	Yes	Yes	Yes	Exponent κ_Ω
Ract_factor_D	Yes	Yes	Yes	Factor R_{act}, reading D
Ract_factor_Omega	Yes	Yes	Yes	Factor R_{act}, reading Ω
route_status	Yes	Yes	—	Data preserved in the canonical records and enriched with reproducibility.
route_genealogy_sha256	Yes	—	—	Data preserved in the canonical record of reproducibility.
reader_sha256	Yes	—	—	Data preserved in the canonical record of reproducibility.
cell_ledger_108_sha256	Yes	—	—	Data preserved in the canonical record of reproducibility.
route_family_R	—	Yes	Yes	Route family

Field	$\mathcal{R}_{53}$	$\mathcal{R}_{57}$	$\mathcal{F}_{49}$	Public interpretation or conservation residency
prefix_ambiguity_area	—	Yes	Yes	Ambiguity area of the prefix
prefix_log2_ambiguity_area	—	Yes	Yes	Binary logarithm of ambiguity
first_orbit_separation_block	—	Yes	Yes	First orbit separation block
first_cell_separation_block	—	Yes	Yes	First cell separation block
first_route_separation_block	—	Yes	Yes	First route separation block
final_ambiguity	—	Yes	Yes	Final Ambiguity
stable_triads_by_block	—	Yes	Yes	Block Stabilization Chronology
historic_signature_Z5	—	Yes	Yes	Integer signature in $\mathbb{Z}^5$
pareto_persistence_orbit	—	Yes	Yes	Orbit on the persistence boundary
join_status	—	Yes	—	Data preserved in the enriched reproducibility record.
tower_forward_status	—	Yes	—	Data preserved in the enriched reproducibility record.

This correspondence is applied uniformly to the 324 records. The censuses of 471 masses and 384 widths remain inventories of external recognition and do not participate in selecting routes, families, or atlas multisections.

Appendix N

Comprehensive genealogical atlas of the 324 mass routes

Return to the scientific portal of the atlas and its readers. Each entry brings together cell identity, orientation, dodecaphase word, bidirectional readers, returns, memory, carry, and signature. No metrological magnitude participates in this reconstruction.

The census satisfies

$$81 \text{ cells} \times 4 \text{ orientations} = 324 \text{ routes}.$$

N.1 Complete unfolding of the 324 oriented routes: correspondence among 53 canonical fields, 57 enriched fields, and 49 invariants published per section

Route 1 r1c1_h+1v+1

Appendix O

Exhaustive inventory of 471 masses and 384 widths: identification, provenance, and correspondence with the atlas

Return to the scientific portal of comparability and metrology.

O.1 Exhaustive inventory domain: 471 masses, 384 widths, and object encoding

The inventory distinguishes the HMT–MD generative domain from the external catalogue of observables. The former is organized by

$$\mathcal{C}_{81} \longrightarrow \mathcal{R}_{56} \longrightarrow \Sigma_{13} \longrightarrow \Gamma_{108}^{\mathrm{enr}} \longrightarrow \mathcal{L}_{108} \longrightarrow \mathbb{Z}^5,$$

and continues with the evaluation of signatures and their typed realizations. The second contains 1170 identities grouped into 438 groups and 855 summary-table observables, with the exact decomposition

$$855 = 471_{\mathrm{masa}} + 384_{\mathrm{anchura}}. \tag{I1}$$

Each observable appears exactly once within its owning group and retains the charge and antiparticle identities linked to that group. These cardinalities do not count HMT–MD particles or select routes, signatures, towers, or couplings.

Construction, evaluation, and comparison

The HMT–MD construction first produces the physical object as a simple section, multisection, or composite register. It then extracts its signature and applies the corresponding reader. Only then is metrological comparison opened. Mass, width, and catalogue name are distinct objects: mass evaluates a persistent register; width reads duration and decay; the external name identifies the comparison register.

O.2 Data provenance, record uniqueness, and validity domains

The external reference is Particle Data Group 2026, cutoff January 15, 2026, consulted July 26, 2026, and distributed under the CC BY 4.0 license. The 1170 identities remain separate, while mass and width properties are deduplicated by group. The 855 observables cover 403 of the 438 groups; the remaining 35 retain catalogue identity, but do not receive a numerical row not supplied by the source.

The cut declares neither scheme nor scale for any of the 855 observables. No pole mass, $\overline{\mathrm{MS}}$ mass, renormalization scale, or width convention is inferred from it. The group identifier, property identifier, uncertainty type, value type and bound, confidence level where one exists, and the active or historical status of already established comparisons are preserved. In every case, the external value is used only after the internal construction has been frozen, and never as a selector.

O.3 Identification of objects and application of the HMT–MD reader

The structural assignment of each row identifies the domain on which its reader must act:

$$\begin{array}{c|l} \mathsf{E} & \text{simple section or elementary representation,} \\ \mathsf{N} & \text{null or gauge sector,} \\ \mathsf{Q} & \text{quark multisection with generation, orientation and colour,} \\ \mathsf{M} & \text{mesonic or bosonic exotic composite record,} \\ \mathsf{B} & \text{baryonic or fermionic exotic composite record,} \\ \mathsf{G} & \text{external gravitational record, not an elementary HMT graviton.} \end{array} \tag{I2}$$

The subscript m refers to the mass character; the subscript Γ, to the width. The active and historical statuses qualify comparisons already established and do not alter the class of the object.

Table O.1: Complete partition of the cataloged observables.

Catalogue family	Groups with observable	Masses	Widths
General case	46	53	9
Quark sector	6	8	1
Mesons	201	243	225
Baryons	149	166	149
External gravitational record	1	1	0
Grand total	403	471	384

The gravitational row reproduces an external record and does not introduce an elementary graviton into the HMT–MD construction. Its realization requires the typed gravitational-representation map declared in the row itself.

O.4 Inventory coverage and semantics of the tables

None of the 471 masses or the 384 widths is reduced to a sample. Each row publishes exactly once its catalogue identity, species, value, unit, uncertainty, limit, confidence, HMT–MD sector, and required realization map. The absence of a closed individual link is declared as such and is not replaced by an invented correspondence.

O.5 Comprehensive inventory of evaluated masses and correspondence with the atlas realizations

Table O.2: Complete inventory of 471 masses: identifier, observable, convention, and HMT–MD realization.

Identifier	Object and species	Value	Uncertainty and Convention	Sector and status	Structural realization
B000 B000M prop. 349891	**Sigma(1580) MASS VALUE** Sigma(1580)- | Sigmabar(1580)+ | Sigma(1580)0 | Sigmabar(1580)0 | Sigma(1580)+ | Sigmabar(1580)-	~1580 MeV	not reported; not reported; type E; limit NONE; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B004 B004M property: 348705	**N(1895) BREIT-WIGNER MASS** N(1895)0 | Nbar(1895)0 | N(1895)+ | Nbar(1895)-	1870 to 1920 (~1895) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B005 B005M property: 348836	**N(2060) BREIT-WIGNER MASS** N(2060)0 | Nbar(2060)0 | N(2060)+ | Nbar(2060)-	2030 to 2200 (~2100) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B007 B007M prop. 349780	**Lambda(2585) MASS (BUMPS):** Lambda(2585)0 | Lambdabar(2585)0	~2585 MeV	not reported; not reported; type E; limit NONE; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B010 B010M property: 349097	**Delta(1700) Breit–Wigner resonance resonance mass** Delta(1700)- | Deltabar(1700)+ | Delta(1700)0 | Deltabar(1700)0 | Delta(1700)+ | Deltabar(1700)- | Delta(1700)++ | Deltabar(1700)–	1690 to 1730 (~1710) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B011 B011M property: 349151	**Delta(1905) Breit–Wigner resonance resonance mass** Delta(1905)- | Deltabar(1905)+ | Delta(1905)0 | Deltabar(1905)0 | Delta(1905)+ | Deltabar(1905)- | Delta(1905)++ | Deltabar(1905)–	1855 to 1910 (~1880) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B012 B012M prop. 349182	**Delta(1910) Breit–Wigner resonance resonance mass** Delta(1910)- | Deltabar(1910)+ | Delta(1910)0 | Deltabar(1910)0 | Delta(1910)+ | Deltabar(1910)- | Delta(1910)++ | Deltabar(1910)–	1850 to 1950 (~1900) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B013 B013M property: 349249	**Delta(1930) Breit–Wigner resonance resonance mass** Delta(1930)- | Deltabar(1930)+ | Delta(1930)0 | Deltabar(1930)0 | Delta(1930)+ | Deltabar(1930)- | Delta(1930)++ | Deltabar(1930)–	1900 to 2000 (~1950) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B014 B014M property: 348535	**N(1710) BREIT-WIGNER MASS** N(1710)0 | Nbar(1710)0 | N(1710)+ | Nbar(1710)-	1680 to 1740 (~1710) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B015 B015M prop. 348569	**N(1720) BREIT–WIGNER MASS:** N(1720)0 | Nbar(1720)0 | N(1720)+ | Nbar(1720)-	1680 to 1750 (~1720) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B016 B016M property: 348633	**N(1875) BREIT-WIGNER MASS** N(1875)0 | Nbar(1875)0 | N(1875)+ | Nbar(1875)-	1850 to 1920 (~1875) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B017 B017M property: 348778	**N(1990) BREIT–WIGNER MASS:** N(1990)0 | Nbar(1990)0 | N(1990)+ | Nbar(1990)-	1950 to 2100 (~2020) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.
B018 B018M prop. 348499	**N(1700) BREIT–WIGNER MASS:** N(1700)0 | Nbar(1700)0 | N(1700)+ | Nbar(1700)-	1650 to 1800 (~1720) MeV	not applicable; not applicable; type E; limit R; confidence not reported	composite baryonic record *exhaustive record without comparative promotion*	nominal baryonic binding map. External record accounted for; individual HMT–MD realization not yet linked.

Appendix P

Demonstrative appendices and classification tables

P.1 Ordered affine calculation of the APP leaves

P.1.1 Affine monoid $\mathrm{End}(U_{\mathrm{APP}}) \ltimes U_{\mathrm{APP}}$ and ordered composition of routes

Let U_{APP} be the radial module prior to its Archimedean evaluation. The correct envelope is the monoid

$$\mathrm{AffEnd}(U_{\mathrm{APP}}) = \mathrm{End}(U_{\mathrm{APP}}) \ltimes U_{\mathrm{APP}},$$

because the threshold or folding leaves may contain noninvertible endomorphisms. The action of (Λ, C) on $u \in U_{\mathrm{APP}}$ is

$$(\Lambda, C) \cdot u = \Lambda u + C.$$

The composition is calculated without commuting factors:

$$\begin{aligned}(\Lambda_2, C_2)(\Lambda_1, C_1) \cdot u &= \Lambda_2(\Lambda_1 u + C_1) + C_2 \\ &= (\Lambda_2\Lambda_1)u + (C_2 + \Lambda_2 C_1).\end{aligned} \tag{P.1}$$

Therefore,

$$(\Lambda_2, C_2)(\Lambda_1, C_1) = (\Lambda_2\Lambda_1, C_2 + \Lambda_2 C_1).$$

The second coordinate is not an ordinary sum of shifts: it is a cocycle twisted by the accumulated linear action.

Proposition P.1 (Prefix Formula)**.** *For a route with N factors $h_j = (\lambda_j, C_j)$, ordered from $j = 0$ through $j = N - 1$, the prefix holonomy is*

$$H_N = h_{N-1} \cdots h_1 h_0 = (\Lambda_N, C_N),$$

where

$$\Lambda_N = \prod_{j=0}^{N-1} \lambda_j$$

and

$$C_N = C_{N-1} + \lambda_{N-1} C_{N-2} + \lambda_{N-1}\lambda_{N-2} C_{N-3} + \cdots + \lambda_{N-1} \cdots \lambda_1 C_0.$$

Proof. For $N = 1$ the formula is immediate. If it holds for N, then

$$h_N H_N = (\lambda_N \Lambda_N, C_N + \lambda_N C_N),$$

which yields exactly the expression of length $N + 1$. The induction preserves the order of the route and does not identify paths with the same endpoints. □

P.1.2 Difference sum–product as curvature of order

Let $A_a = (I, a)$ and $M_\lambda = (\lambda, 0)$ be given. In the invertible sector,

$$A_a M_\lambda A_a^{-1} M_\lambda^{-1} = A_{a(1-\lambda)}.$$

The direct proof for u is

$$u \xmapsto{M_\lambda^{-1}} \lambda^{-1}u \xmapsto{A_a^{-1}} \lambda^{-1}u - a \xmapsto{M_\lambda} u - \lambda a \xmapsto{A_a} u + a(1 - \lambda).$$

Thus, the distinction between accumulation and folding is published as a translation. When $\lambda = 1$, the commutator vanishes; when $\lambda \neq 1$, the route retains a holonomy that cannot be reconstructed from the endpoint alone.

Example P.2 (Two routes with the same visible data)**.** Fix $u_0 = 0$, $a = 1$, $\lambda = 2$. The routes

$$A_1 M_2 : u_0 \longmapsto 1, \qquad M_2 A_{1/2} : u_0 \longmapsto 1$$

publish the same final value. However, their ledgers contain distinct factors, shifts, and prefixes. Pointwise evaluation identifies the routes; enriched affine holonomy distinguishes them.

P.1.3 Exhaustive enumeration of the local chart $(\tau_+, \tau_-) \mapsto (p, a, r_3, c_3)$

The following table does not posit that every global radial degree arises from a single pair. It records the elementary chart obtained by composing two TRIT orientations. The degree of a general route is the integer cocycle of equation (18.47); this chart provides its nine local generators.

Table P.1: The 9 oriented pairs of the local TRIT chart.

τ_+	τ_-	p	a	r_3	c_3	Lectura local
1	1	2	0	−1	1	double radial opening with positive carry
1	0	1	1	1	0	opening and threshold
1	−1	0	2	0	0	positive orientation equilibrium
0	1	1	−1	1	0	threshold and aperture
0	0	0	0	0	0	umbral doble
0	−1	−1	1	−1	0	threshold and contraction
−1	1	0	−2	0	0	negative orientation equilibrium
−1	0	−1	−1	−1	0	contraction and threshold
−1	−1	−2	0	1	−1	double contraction with negative carry

Here $p = r_3 + 3c_3$, with balanced residue $r_3 \in \{-1, 0, 1\}$. The carry distinguishes $p = 2$ from its residue -1 and $p = -2$ from its residue 1. The pair (p, a) likewise distinguishes the three local genealogies of degree 0.

P.2 Nonadic Certificate and Geometry of Memory

P.2.1 Typed distinction between decimal catalog, ternary words and ambient fiber

Table P.2: Strata of the certificate of the joint nonadic connection.

Object	Cardinality	Mathematical function
Catalog of source triples	104 976	Finite domain prior to the joint selection; it is not a decimal table.
Decimal emissions U_6	468	Compatible emissions of length 6 in the decimal publication.

Object	Cardinality	Mathematical function
Visible words w_6	243	Published ternary words after typing; they are not the complete environment.
Ambient space $\mathbb{F}_3^6$	729	Space of all ternary words of length 6; it contains the 243 visible words.
Certified levels	396	Finite prolongation up to the declared boundaries.
Trits recorridos	2 376	Longitud total $396 \cdot 6$.
Vueltas completas	43	Nonadic cycles in the certified segment.
Pairs $(K, K+9)$	387	Pairs of same-phase by channel; the ledger may differ.

The prolongation chain is preserved in the order

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9.$$

None of these objects can be replaced by the subsequent modal quotient. The holonomy Γ_9 acts on the enriched dynamics; the reduced-memory publication preserves only the information specified by its codomain.

P.2.2 Phase return, memory advance, and complete state

With

$$\rho_9(N) = 1 + ((N-1) \bmod 9), \qquad q_9(N) = \left\lfloor \frac{N-1}{9} \right\rfloor,$$

we have

$$\rho_9(N+9) = \rho_9(N), \qquad q_9(N+9) = q_9(N) + 1.$$

Therefore,

$$H_9(N+9) = H_9(N) + (0, 0, 1).$$

The equality of the first phase coordinate does not imply equality of the state:

$$g(K+9) = g(K), \qquad B_{K+9} \neq B_K$$

in general. The helical formula is precisely the minimal representation of this distinction.

P.2.3 Non-Split Dodecaphase Extension

The sequence

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0$$

couples the dodecaphasic calendar to the nonadic return. If a global homomorphic section $s : C_9 \to C_{108}$ existed, the generator of C_9 would have to lift to an element of order dividing 9 that projected onto the generator. The active temporal lift, however, preserves the accumulated dodecaphasic displacement and does not identify the state after one phase turn. The seam is recorded as carry; geometrically, it manifests as axial translation of the helix.

P.2.4 Decomposition of the microfiber of π into 5 regions and multiplicity of Archimedean evaluation

The microfiber of π contains five oriented regions with total multiplicity

$$432 + 4 \cdot 144 = 1008.$$

The regions publish the same real value, but retain distinct genealogies. This result provides the internal precedent for spiral classification: a visible curve does not by itself determine the region, the sheet, the carry, or the memory that produced it.

P.3 Algebra of L_p and classification of the 5 canonical families $p \in \{2, 1, 0, -1, -2\}$

P.3.1 The coordinate L_p and its inverse

For $x > 0$, define

$$L_p(x) = \begin{cases} (x^p - 1)/p, & p \neq 0, \\ \log x, & p = 0. \end{cases}$$

Its inverse is

$$\exp_p(u) = \begin{cases} (1 + pu)^{1/p}, & p \neq 0,\ 1 + pu > 0, \\ e^u, & p = 0. \end{cases}$$

The derivative

$$\frac{\mathrm{d}}{\mathrm{d}x} L_p(x) = x^{p-1} > 0$$

proves that L_p is strictly increasing on its domain and is therefore invertible.

Proposition P.3 (Sum–Product Law)**.** *For $x, y > 0$,*

$$L_p(xy) = L_p(x) + L_p(y) + pL_p(x)L_p(y).$$

Proof. Si $p \neq 0$,

$$\begin{aligned} L_p(x) + L_p(y) + pL_p(x)L_p(y) &= \frac{x^p - 1}{p} + \frac{y^p - 1}{p} + \frac{(x^p - 1)(y^p - 1)}{p} \\ &= \frac{x^p y^p - 1}{p} = L_p(xy). \end{aligned}$$

For $p = 0$, the equality reduces to $\log(xy) = \log x + \log y$. □

Corollary P.4 (Deformed group in the positive domain)**.** *The operation*

$$u \boxplus_p v = u + v + puv$$

satisfies

$$1 + p(u \boxplus_p v) = (1 + pu)(1 + pv).$$

Its neutral element is 0*, and the inverse of u is*

$$\ominus_p u = -\frac{u}{1 + pu},$$

si $1 + pu \neq 0$.

P.3.2 Evaluation of $\exp_p(u_0 + \beta m)$ in the 5 canonical families

Let m be the published depth, and suppose

$$L_p(r/r_0) = \beta m, \qquad \theta = \theta_0 + \omega m, \qquad \omega \neq 0.$$

Eliminando $m = (\theta - \theta_0)/\omega$,

$$r(\theta) = r_0 \left[1 + p\frac{\beta}{\omega}(\theta - \theta_0)\right]^{1/p}, \qquad p \neq 0,$$

and

$$r(\theta) = r_0 \exp\left[\frac{\beta}{\omega}(\theta - \theta_0)\right]$$

for $p = 0$. Positive changes of origin and rescalings yield the conventional forms:

Table P.3: Canonical publications in the translational sector.

p	Normal equation	Conventional name	Domain and feature
2	$r^2 = a^2\theta$	Fermat spiral	$\theta \geq 0$; linear increment of the quadratic radial area.
1	$r = a\theta$	Archimedes	$\theta \geq 0$; constant radial increment per angular unit.
0	$r = r_0 e^{b\theta}$	logarithmic	$\theta \in \mathbb{R}$; constant dilation per angular unit.
-1	$r = a/\theta$	hyperbolic	$\theta > 0$; the product $r\theta$ is constant.
-2	$r^2 = a^2/\theta$	lituus spiral	$\theta > 0$; product $r^2\theta$ is constant.

P.3.3 Conjugation $p \leftrightarrow -p$ of the power–logarithmic sheets

Para $p \neq 0$,

$$L_{-p}(x^{-1}) = \frac{x^p - 1}{-p} = -L_p(x).$$

The identity also holds for $p = 0$. Consequently, radial inversion interchanges p with $-p$ and reverses the sign of the linearized coordinate. This relation pairs the Fermat spiral with the lituus and the Archimedean spiral with the hyperbolic spiral as conjugate orientations of the reader, without identifying them as identical curves.

P.3.4 Classification of the affine sector by the pair $(p, [\Lambda, C])$

If the radial coordinate satisfies

$$u_{n+1} = \Lambda u_n + C,$$

the exact internal iteration is

$$u_n = \Lambda^n u_0 + \sum_{k=0}^{n-1} \Lambda^k C.$$

If $I - \Lambda$ is invertible, $u_* = (I - \Lambda)^{-1} C$ and $u_n - u_* = \Lambda^n (u_0 - u_*)$. Only in a positive scalar realization, $\chi\Lambda = \lambda\chi$ with $\lambda > 0$, does one define $u_* = C/(1 - \lambda)$. With $\theta_n = \theta_0 + n\omega$, $\omega \neq 0$, the interpolation published in that realization is

$$r(\theta) = r_0 \exp_p \left[u_* + \lambda^{(\theta - \theta_0)/\omega} (u_0 - u_*) \right].$$

The complete taxonomy is therefore not a list of five names. It contains at least the degree p, the orientation a, the affine class $[\Lambda, C]$, the carry cocycle, the boundary, the angular increment, and the memory ledger.

P.4 Naturality under truncation, nonadic equivariance, and Archimedean fidelity defect

P.4.1 Affine prefix reader and enriched record conservation

For a truncated history

$$\widehat{\gamma}_N = \widehat{e}_N \cdots \widehat{e}_1,$$

The enriched reader records

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N}(\widehat{\gamma}_N) = \left((H_0, \mathrm{Led}_0); \left(p(\widehat{e}_j), a(\widehat{e}_j), P_j, A_j, h_{e_j}, H_j, \mathrm{Led}_j \right)_{j=1}^{N} \right).$$

The term $H_j = h_{e_j} \cdots h_{e_1}$ preserves the prefixes. The ledger Led_j preserves, according to the route, sheet, residue, quotient, carry, boundary, orientation, cylinder, signature, survival, and memory. The real-valued coordinates are obtained subsequently:

$$\mathcal{P}^{\mathrm{esp}}_{\mathrm{arq}} = \mathrm{ev}_{\mathbb{R}^2} \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}.$$

P.4.2 Complete proof of naturality under truncation

Let $\pi_{N,M}$ denote deletion of the suffix of length $N - M$, with $M < N$. Let $\mathrm{pr}_{N,M}$ denote the projection that preserves the initial record and the first M edge records. Then

$$\mathrm{pr}_{N,M}\ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N}(\widehat{\gamma}_N) = \Big((H_0, \mathrm{Led}_0); \big(p(\widehat{e}_j), a(\widehat{e}_j), P_j, A_j, h_{e_j}, H_j, \mathrm{Led}_j\big)_{j=1}^{M} \Big).$$

By definition of truncation,

$$\pi_{N,M}(\widehat{\gamma}_N) = \widehat{e}_M \cdots \widehat{e}_1,$$

and upon reapplying the reader the same sequence is obtained. Therefore,

$$\mathrm{pr}_{N,M} \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N} = \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},M} \circ \pi_{N,M}.$$

The proof does not use the value of the curve. It uses prefix identity, which is the information that the reduced seven-coordinate reader would have lost.

P.4.3 Compatibility criterion for general refinements of paths

For a refinement $r : \gamma \to \gamma'$, naturality requires a map $\widehat{r}$ on ledgers and the local equality

$$h_e = h_{e'_k} \cdots h_{e'_1}$$

for each edge e replaced by the refined chain $(e'_1, \ldots, e'_k)$. If, in addition, the carry, boundary, and memory of the refined chain compose the records of the original step, then

$$\widehat{r} \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}} = \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}} \circ r.$$

This condition is a verifiable commutative square; it must not be assumed for an arbitrary refinement without exhibiting the factors.

P.4.4 Equivariance of the radial cocycle under the holonomy Γ_9

The action of Γ_9 returns the phase and prolongs the state. In the codomain of the reader, $\widehat{\Gamma}^{\mathrm{rad}}_9$ acts by shifting the records and updating the last prefix. The correct identity is

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}(\Gamma_9 \gamma) = \widehat{\Gamma}^{\mathrm{rad}}_9 \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}(\gamma).$$

Requiring invariance would erase precisely the memory that the connection preserves. In the reversible sector, route inversion satisfies

$$H_{C_{\mathrm{rev}}\gamma} = H_\gamma^{-1}$$

when all factors belong to the invertible affine subgroup. This typed assertion does not automatically extend to a global involution on an arbitrary subsequent quotient.

P.4.5 3 explicit obstructions to the faithfulness of Archimedean evaluation

Proposition P.5 (Intrinsic circle and projected circle)**.** *There exist two histories with the same visible curve.*

$$c(\theta) = (\cos\theta, \sin\theta)$$

and different ledgers.

Proof. The first history has constant axial memory $m = 0$. The second is the helix

$$h(\theta) = (\cos\theta, \sin\theta, \theta/2\pi),$$

whose ledger records $m(\theta) = \theta/2\pi$. Both satisfy $\pi_{xy} \circ h = c$. The projection is therefore non-injective. □

Proposition P.6 (Same endpoint, different affine order)**.** *If $a(1-\lambda) \neq 0$, the paths $A_a M_\lambda$ and $M_\lambda A_a$ are not equivalent under the enriched reader, even though they may be calibrated to publish the same endpoint.*

Proof. Its commutator is $A_{a(1-\lambda)} \neq I$. The commutator datum belongs to the prefix ledger and disappears when only the endpoint is retained. □

Proposition P.7 (Same curve, different genealogical region)**.** *Equality of the published real value does not identify the five regions of the microfiber of π; consequently, it is likewise insufficient to identify the spiral class when the reader preserves region, boundary, or carry.*

P.5 Stratified Taxonomy of Spiral Correspondences

P.5.1 Domain stratification: history, reader, Archimedean evaluation, and physical realization

Table P.4: Levels that must not collapse into a single notion of curvature.

Level	Invariant	Meaning
APP	$F(S,P) = 1,\ F(P,S) = -1$	Discrete curvature of the order of accumulation and folding.
TRIT	$\tau \in \{-1,0,1\}, J_\tau^2 = -\tau I$	Local elliptic, parabolic, or hyperbolic regime of the transport.
TPK	Γ_9, carry, boundary, route, and ledger	Phase holonomy and memory over the enriched state.
Radial level	$p, a, [\Lambda, C]$	Characters that determine the radial law before recognizing a curve.
Archimedean	$r(\theta)$	Curve published in $\mathbb{R}^2$; it may forget genealogy.
Frenet level	$\kappa_{\mathrm{F}}, \mathcal{T}_{\mathrm{F}}$	Differential curvature and torsion of the visible curve or suspension.
Dimensional level	fields, scales and representations	Posterior physical realization, with its own premises.

P.5.2 Classification by the increments (ω, β, μ)

Table P.5: Complete kinematic taxonomy of the minimal degenerate cases.

$\Delta\theta$	Δu_{rad}	Δm	Salida visible	Genealogical Information
0	0	0	point	published steady state
0	$\neq 0$	0	recta radial	scale change
0	0	$\neq 0$	fibra axial	non-transverse displacement memory
0	$\neq 0$	$\neq 0$	radial sheet suspended	scale and memory
$\neq 0$	0	0	circle	intrinsic angular closure
$\neq 0$	0	$\neq 0$	cylindrical helix	closed phase, high memory
$\neq 0$	$\neq 0$	0	espiral plana	radial character visible
$\neq 0$	$\neq 0$	$\neq 0$	radial helical suspension	turn, radius and depth preserved

P.5.3 Affine holonomy classification

The following table belongs to a real scalar realization of the linear part, $\chi\Lambda = \lambda\chi$; for ease of reading, we write Λ in the conditions column. It does not classify abstract endomorphisms by numerical inequalities.

Table P.6: Types of holonomy over the radial coordinate.

Condition	Orbit of u	Interpretation
$\Lambda = 1,\ C = 0$	$u_n = u_0$	constant radius; the memory may be zero or hidden by projection.
$\Lambda = 1,\ C \neq 0$	$u_n = u_0 + nC$	translational sector that publishes the family L_p.
$0 < \Lambda < 1$	$u_n \to u_*$	contraction towards a fixed section.
$\Lambda > 1$	$\lvert u_n - u_* \rvert$ grows	expansion from a fixed section.
$\Lambda < 0$	orientation alternation	requires control of the domain of $\exp_p$ at each step.
$\Lambda = 0$	$u_{n+1} = C$	noninvertible folding; it belongs to the monoid, not to the affine group.

P.5.4 Genealogical Equivalence Criterion

Two routes are not identified merely because they publish the same curve. A typed isomorphism preserving the following term by term is required:

$$\big((x_0, H_0, \mathrm{Led}_0); (\widehat{e}_j, p(\widehat{e}_j), a(\widehat{e}_j), P_j, A_j, h_{e_j}, H_j, \mathrm{Led}_j)_{j=1}^{N}\big)$$

and that commutes with the admissible truncations and refinements. The resulting classification is finer than the conventional taxonomy because it incorporates the history preceding the emergence of $\mathbb{R}^2$.

P.6 Electromagnetic and Material Realizations with Domain and Codomain Separation

P.6.1 Circular electromagnetic mode

Let

$$\zeta = \frac{z - c_{\mathrm{vac}} t}{\lambda},$$

and

$$\mathbf{E}_\sigma = E_0(\mathbf{e}_1 \cos 2\pi\zeta + \sigma \mathbf{e}_2 \sin 2\pi\zeta), \qquad \mathbf{B}_\sigma = c_{\mathrm{vac}}^{-1} \widehat{\mathbf{k}} \times \mathbf{E}_\sigma.$$

Then

$$\mathbf{E}_\sigma \perp \mathbf{B}_\sigma \perp \widehat{\mathbf{k}}, \quad |E| = c_{\mathrm{vac}}|B|, \quad \omega = c_{\mathrm{vac}} k.$$

At fixed time, the normalized endpoint of the field in the phase–position bundle describes

$$(\cos 2\pi\zeta, \sin 2\pi\zeta, \zeta).$$

This statement does not assert that every spatial field line is a helix: it describes the trajectory of the tip of the polarization vector together with the marked event.

P.6.2 Loxodromic compatibility

For

$$\Phi(r, \varphi, z, t) = \ell\varphi + \nu \log(r/r_0) + k_z z - \omega t,$$

the transformation

$$(r, \varphi) \longmapsto ((2 + \sqrt{3})r, \varphi + \pi/2)$$

preserves the phase modulo 2π exactly when

$$\nu \log(2 + \sqrt{3}) + \ell \frac{\pi}{2} \in 2\pi\mathbb{Z}.$$

Dilation is interpreted as a change of scale between solutions; not as spontaneous energy production.

P.6.3 Compatibility of the radial reader with the electronic fixed point $(5, 5)$ and atlas $81/56/13/324$

The electron occupies the unique fixed point $(5, 5)$ of the material atlas. This centrality is not derived anew in the present work. The prior operator compatibility includes

$$C^{(3)} m_{\mathrm{ph}} = -\frac{1}{2} m_{\mathrm{ph}}, \qquad 1 - \left(\frac{1}{2}\right)^2 = \frac{3}{4} = \frac{90}{120},$$

and

$$\|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

The theory of spiral correspondences adds a route reader; it does not replace the General Mass Law or use the electron to select p, Λ, or C retrospectively.

P.6.4 Matrix of validity conditions by causal level

Table P.7: Falsifiers and type errors excluded by the construction.

Failure	Consequence
The classical curve selects p, Λ, C.	Circularity: the reader ceases to be constructive–generative.
Only the final holonomy is preserved.	Loss of prefixes, carry, and boundary; naturality is not established.

Failure	Consequence
Invariance under Γ_9 is required.	The memory advance is erased; the correct relation is equivariance.
U_6, w_6, and $\mathbb{F}_3^6$ are conflated.	Collapse of objects with cardinalities 468, 243, and 729.
The term phase return is identified with state return.	Contradiction with $B_{K+9} \neq B_K$ in general.
τ, p, and κ_{F} are identified.	Regime collapse, radial character and visible curvature.
A general helix is called any variable radius.	Differential statement unverified Lancret condition.
The φ axis is identified with the electron.	Mixture of the fiber of constants and the material realization.
Pell is interpreted as energy amplification.	Violation of scale reading and physical conservation.
Electromagnetic helicity is identified with spin $1/2$.	Confusion between distinct representations.
A point cell is imposed on every species.	Contradiction with the character of a fibre or multisection of the noncentral species.
The five constructions of the continuum are separated.	Breakdown of the previous unique genealogy prior to any geometric publication.

P.7 Mathematical Glossary

Table P.8: Symbols and Key Terms.

Symbol or term	Definition
Σ, Π	Additive and multiplicative evaluations on the common support APP.
τ	Local TRIT orientation regime; it is neither the radial degree nor Frenet torsion.
M_{ph}	Tritic operational-phase selector.
Γ_9	Nonadic holonomy of enriched dynamics.
H_N	Accumulated affine holonomy up to the prefix N.
Λ_N, C_N	Linear part and translational cocycle of H_N.
p	Integer cocycle of the radial character.
a	Local orientation character that separates genealogies of the same local degree.
$L_p, \exp_p$	Power-logarithmic coordinate and its positive inverse.
$\boxplus_p$	Deformed law that publishes the sum-product interaction.
Led_N	Enriched ledger of sheet, carry, boundary, route, and memory.
$\mathcal{P}_{\mathrm{rad}}^{\mathrm{enr}}$	Radial reader enriched prior to the curve.
$\mathcal{P}_{\mathrm{arq}}^{\mathrm{esp}}$	Subsequent evaluation on a curve in $\mathbb{R}^2$.
$\kappa_{\mathrm{F}}, \mathcal{T}_{\mathrm{F}}$	Curvature and torsion of Frenet of the visible curve.
Radial helical suspension	Variable-radius surface or sheet that preserves phase, depth, and path.
Unfaithful publication	Assessment that can identify distinct histories.

Symbol or term	Definition
Constructivo–generativo	Method that constructs the object and its genealogy before recognizing its conventional appearance.

Notation, types, and symbol disambiguation

Symbol	Object
$\mathcal{A}_9$	Nonadic arithmetic torus of paths with two internal evaluations.
TRIT	Oriented ternary coordinate of the transport; the visible output does not exhaust the enriched lift with carry.
TPK	Topological Phase Kernel with enriched state, transitions, routes, prolongations, and memory.
M_{ph}	Tritic operational-phase selector, distinct from cardinal transport and stroboscopic sampling.
τ_3	Primitive phase block $(+1, -1, 0)$.
$\mathcal{N}, \mathcal{E}, \mathcal{S}, \mathcal{O}$	Generators of transport cardinal.
Obs_3	Stroboscopic sampling of every third step.
$\mathcal{R}_{12}$	Internal TPK-oriented dodecaphasic temporal system.
$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}$	Observable calendar 12×9; it is not the complete TPK state.
C_{12}	Rotation of the twelve temporal sectors.
Γ_{108}	Oriented transport orbit of 108 steps.
$\mathcal{G}_9$	Unitary pruning within the extension and boundary relation; it does not by itself constitute the monodromy.
$\mathfrak{M}_9$	Nonadic monodromy with memory: it returns the phase and changes the state.
π_{term}	Projection of the enriched terminal state onto the three selected visible blocks.
R_{sgn}	Reading of the signed integer coordinate of the same terminal enriched state.
U_{12}^{cat}	Visible concatenation $U_6 \| U_6$.
U_{12}^{sgn}	Signed coordinate of the enriched state, reversible with K by means of $\mathcal{H}_{12}$; it is not derived from U_{12}^{cat}, the calendrical projection, or the three terminal blocks in isolation.
$\mathcal{H}_{12}$	Reversible dodecaphase transformation between U_{12}^{sgn} and K.
$\mathcal{E}_{\mathrm{dod}}$	Integral extractor $(D_3, D_4, Q) : \mathbb{Z}^{12} \to \mathbb{Z}^{25}$ that reconstructs K.
$\overline{C}_9^{\,3}$	Nonadic cubic completion.
A, C^*	Intrinsic angular and antiangular coordinates.
$q_{\pm}$	Oriented channels of the double-layer reader.
$D_{\mathrm{raw}}^{90,120}$	Raw diagnostic difference of series in a fixed chart; it is not a canonical extractor.
$\iota_{6,8}$	Inclusion $\mathcal{F}_6 \hookrightarrow \mathcal{F}_8$ of hexad–octad incidences.
$K_{6\to 8}$	Angular functional of the two Lambert subtails, subsequent to $q_{\pm}$, the series, the pole, positivity, and minimality.
$\langle 90, 120 \rangle$	Spectral semigroup governing the hierarchy of towers.
$\varepsilon_{\mathrm{res}}^{\circ}$	Residue of the exact angular identity; it is not a finite extraction from the preceding 90/120 objects.
Δ_4	Minimal torsion or global torsional invariant prior to the species; it is not Cartan torsion.
$\mathsf{T}_{\alpha,\infty}$	Remote prolongation of the carry along the entire path of α, typed separately from the orbital generator $T_1^{\mathrm{orb}} = L_1$, the neutral counter, and the calendar.

Symbol	Object
N_1^{neu}	Number of neutral positions in the first window of the transport example; it equals 3 and is not an operator.
$T_1^{\mathrm{orb}} := L_1$	Second generator in the local orbital gauge; in its reference section it is abbreviated T_1.
$\varepsilon_{\mathrm{clk}}$	Energy quantum of the clock, $\hbar_{\mathrm{int}} 2\pi/(108 t_0)$; it is not a canonical energy basis unless the temporal frame is specified. The symbol ε_0 is reserved for the vacuum permittivity at the SI constitutive interface.
CLK1–CLK6	Labels of the six equations of the finite clock, from the Hamiltonian to the Schrödinger equation.
$\mathcal{K}_{27}$	Compound return of twenty-seven updates.
X_∞^{cal}	Common enriched domain of global evaluations.

Repeated cardinalities with different sources

Equality of cardinalities does not automatically transport domain, operation, memory, or evidentiary force. The following table sets out the collisions that most directly affect interpretation.

Index	Objeto tipado	Function and separation
108	Θ_{108}	The 12×9 calendar closes the observable clock.
108	Π_{108}^{cal}	Calendrical projection of a cursor with 324 seeds; it forgets the second cursor, orientation, carry, boundary, enriched chronological record, and survival.
108	w_{108}	Word of $108 = 18 \times 6$ trits; it is not the calendar.
$104,976$	$X_{\mathrm{TPK}}^{\mathrm{seed}}$	Two-cursor engine, $104,976 = 324^2$; it preserves a domain distinct from that of the calendar.
1080	w_{1080}	Length of a word.
1080	$\Gamma_0(1080)$	Level of a modular subgroup; requires its own realization.
729	$\mathbb{F}_3^6$	Ternary word environment.
729	$9^{\widehat{3}}$	Cubic cell/interior EMRH.
729	$\mathrm{Ext}(X_K)$	Number of subcylinders examined at each prolongation stage.
729	bulk EMRH	Inner layer of the base completion mil.
27	$\mathcal{K}_{27}$	Composite return operator; not the name of an autonomous theory.
27	cubic stratum	Contribution of two boundary coordinates in $999 = 729 + 243 + 27$.
27	module or classifier	Each occurrence requires its map before identifying itself with another.

Six distinct sources of 90/120

Object	Domain and operation	Exit and type prohibition
$\mathcal{E}_{\mathrm{dod}}$	$K \in \mathbb{Z}^{12}$; stepwise differences $3, 4$ and sum Q	Transverse dodecaphasic coordinates; no incidence nor angular series.
$D_{\mathrm{raw}}^{90,120}$	A q chart; raw difference $S_{90}(q) - S_{120}(q)$	Scale diagnostic, distinct from the Barbero–Immirzi functional and the incidence operators.
$\iota_{6,8}$	$H \subset O$; inclusion of $H \times \binom{H}{2}$ in $O \times \binom{H}{2}$	Cardinals 90, 120 and defect $-1/12$; neither an extractor nor a series.
$K_{6\to 8}$	Channels $q_{\pm}$ and Lambert subtails; combination $12\Delta S_{90} - \Delta S_{120}$	Angular functional relative to its premises; it is not transported as a mass block.
$\mathfrak{S} = \langle 90, 120 \rangle$	Moment heights $s_n = q_-^n - q_+^n$	Global tower semigroup; does not end at eight heights.

Four realizations of bidirectional reversibility

Operation	Domain	Action
$P_{\pm} = (I \pm R)/2$	Split Algebra	Project the two spectral sectors.
U-turn	Route and composite calendar	Invert the orientation of the transport without erasing its word.
$\mathrm{Ext}^{\pm}$	Extension Tree	It compares future and past valences; the balance may be read through $\log(\#\mathrm{Ext}^{+}/\#\mathrm{Ext}^{-})$.
$C_M(\tau) = -\mathrm{rev}(\tau)$	Dodecaphonic Word	It conjugates order and sign; it is not the cellular involution ρ_c.

The common function of these four realizations is to preserve reversible orientation. It does not authorize the identification of phase return, route return, word return, and state return.

  suboperator of the TPK, 243
φ
  self-scaling, 480
photon
  physical interface, 2069
physical sectors
  typed inventory, 2217
π
  regional closure, 480
Planck
  self-dual identity, 1214, 1961
Planck, constant, 1537
PMNS
  base transport, 2093
polarization
  discrete current, 1519
positron
  conjugate band, 733, 1505
prime
  irreducible, 1455
prime clock, 1455
prospective independence, 3521

quadratic algebra, 306
  three regimes, 1558, 1618
quantum instrument
  genealogical realization, 1642
quantum mechanics
  genealogical reconstruction, 1612, 1616
quark
  cellular supports and record, 2093
  mass scheme, 3541
quotient
  conjugate, 1986

radian
  action sector, 1959
rational number
  periodicity, 1437
resonance, 3541
return
  27–54–108, 1818
route
  observable shadow, 1531
  time reversal, 2067

Schläfli configuration, 900, 942
Schrödinger
  finite-clock equation, 1560, 1619
seed
  factorization sum–product, 1973
semicrown, 712
sheet
  exchange, 1720
sheet orientation, 906
Sommerfeld, quantization of, 1664
special unitary group, 1977
spectral semigroup, 2045
spectral towers
  global mass law, 1965
spectrum
  physical realization, 1531
split algebra, 2040
state
  Hilbert realization, 1612, 1616
Steiner
  Witt systems, 909
Stokes identity, 3046
string theory, 1031, 1945
structural generation, 487
survival
  global extension, 404
  rank-three projector, 861

T-duality, 1031, 1945
time
  TRIT reader, 1558, 1618
time crystal
  finite HMT realization, 1558, 1618
topological sector, 2113, 2116
torsion, 1821
towers
  infinite hierarchy, 2045
  reconstructive completeness, 3521
TPK
  dodecaphasic system, 2019
  operational classification, 243
  operational inventory, 245
TPK emissions catalog, 3503
TRIT, 303
  concrete generators, 309

vacancy
  arithmetic calendar, 1519
value
  Archimedean evaluation, 1458
virtual particle, 2110
VOA
  Leech lattice, 963

Weyl operators, 1977
width
  total inventory, 3872
Wilson action, 1977
Witt
  design, 911
  incidence module, 861
Witt design, 1650

Yang–Mills, 1754, 3046
