Theorem 14.19 (Decimal valuation of the action section)**.** *The preceding reader, applied to the HMT coordinates already generated, satisfies*

$$10^{-34} < \Sigma_H < 10^{-33}, \qquad \operatorname{ord}_{10}(\Sigma_H) = -34. \tag{14.61}$$

Proof. The rational inclusions of the preceding publications are used,

$$\frac{1618}{1000} < \varphi < \frac{1619}{1000}, \qquad \frac{7297}{10^6} < \alpha < \frac{7298}{10^6}. \tag{14.62}$$

The function $(x, a) \mapsto x a^{16}$ is increasing in both positive variables. The integer inequalities

$$1618 \cdot 7297^{16} > 10^{65}, \qquad 1619 \cdot 7298^{16} < 10^{66}$$

give

$$10^{-34} < \frac{1618}{1000}\left(\frac{7297}{10^6}\right)^{16} < \Sigma_H < \frac{1619}{1000}\left(\frac{7298}{10^6}\right)^{16} < 10^{-33}.$$

The definition of the valuation concludes the proof. The inclusions are subsequent checks on the coordinates already produced; the determinantal operation precedes any units chart. □

14.6.2 Action character and regional continuation

The central chart preserves the matrix

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}, \qquad \lambda_+ = 9, \quad \lambda_- = 5.$$

The calendar has length 12, the step-three orbit has length four, and the census quotient used is $104976/1944 = 54$, with the censuses defined in Section 4.3. These invariants determine the coefficients assigned to degrees $2, 3, 4, 5$ of the character:

$$\frac{9}{16} = \frac{\lambda_+}{4^2}, \qquad \frac{5}{9} = \frac{\lambda_-}{\lambda_+}, \qquad \frac{7}{48} = \frac{\operatorname{tr}(B_c)/2}{4 \cdot 12}, \qquad \frac{1}{54} = \frac{1944}{104976}. \tag{14.63}$$

The assignment to those degrees and the alternation of signs belong to the definition of the analytic character. The operational content combines the support, the orientation and that assignment rule.

Definition 14.20 (Local character and regional return reader)**.** On the publications α, φ, π, the fifth-order character, the regional transfer and its continuation are

$$H_5 = \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5, \tag{14.64}$$

$$D_A = \exp\!\left(-\frac{100\pi\alpha}{9}\right), \tag{14.65}$$

$$C_\pi(\alpha) = 169\alpha^6 + \frac{D_A\alpha^7}{1 - D_A\alpha}, \tag{14.66}$$

$$\eta_{\mathrm{ret}} = H_5 - \frac{90}{\pi}C_\pi(\alpha). \tag{14.67}$$

The integer 169 is the regional selector of the publications constructed in 10.5: the regional emission $169\,|\,272\,|\,272$ is preserved, distinguished from $418\,|\,674\,|\,521$ in the exceptional construction. The first strict prolongation of its continuation has weight D_A and each concatenation multiplies the weight by D_A. The initial normalization is unitary.

The continuation is formulated before evaluating at $z = \alpha$. With D_A already produced by its reader, we write $\mathscr{C}(z) = 169z^6 + \mathscr{R}(z)$, where $\mathscr{R}(z) \in z^7\mathbb{R}[[z]]$. Concatenation increases the degree by one; the initial weight and the transfer rule give

$$\mathscr{R}(z) = D_A z^7 + D_A z\mathscr{R}(z). \tag{14.68}$$

Proposition 14.21 (Uniqueness of the normalized continuation)**.** *Equation* (14.68) *determines a unique series:*

$$\mathscr{C}(z) = 169z^6 + \frac{D_A z^7}{1 - D_A z} = 169z^6 + \sum_{n=7}^{\infty} D_A^{n-6} z^n. \tag{14.69}$$

Its realization is analytic for $|D_A z| < 1$.

Proof. The constant term of $1 - D_A z$ is one, so that element is invertible in the ring of formal series. Solving (14.68) gives the rational expression. Equivalently, the coefficient of degree seven is D_A and each subsequent coefficient is D_A times the preceding one. The geometric series converges absolutely in the indicated disk. □

The normalization of the first weight plays a role in uniqueness. The degree-six impulse and the concatenation ratio, without that initial weight, are also compatible with

$$169z^6 + \lambda\frac{D_A z^7}{1 - D_A z}.$$

The unitary rule fixes $\lambda = 1$ before evaluation. For $0 < \alpha < 1$, we have $0 < D_A < 1$ and $D_A\alpha < 1$; therefore,

$$\frac{D_A\alpha^7}{1 - D_A\alpha} = \sum_{n=0}^{\infty} D_A^{n+1}\alpha^{n+7}. \tag{14.70}$$

After the term with index N, the exact remainder is $D_A^{N+2}\alpha^{N+8}/(1 - D_A\alpha)$. The rational expression thus preserves the complete continuation to any precision.

14.6.3 Positive sections and action per turn

Let $\mathcal{L}_S$ be the oriented action line and $\mathcal{U}_S$ a positive basis. Its sections before and after the return are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S. \tag{14.71}$$

The return preserves the regional compensation $90C_\pi(\alpha)/\pi$ and the ratio

$$\delta_{\mathrm{ret}} = H_5 - \eta_{\mathrm{ret}}, \qquad R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}. \tag{14.72}$$

Proposition 14.22 (Positivity and covariance of the action ratio)**.** *On the intervals* (14.62)*,* $0 < \eta_{\mathrm{ret}} < H_5$*, and* $R_{\mathrm{act}} > 1$*. The ratio remains fixed under a change of the common positive basis* $\mathcal{U}_S$*.*

Proof. The terms of C_π are positive. To bound H_5, $\alpha > 0.007$, $\alpha < 0.008$ and $\varphi < 1.619$ suffice. The root term of (14.64) is greater than one and the sum of its negative terms is less than 0.008001; hence $H_5 > 0.99$. With $D_A < 1$ and $\pi > 3$,

$$0 < \frac{90}{\pi}C_\pi < 30\left(169(0.008)^6 + \frac{(0.008)^7}{1-0.008}\right) < 10^{-6}.$$

Thus, $\eta_{\mathrm{ret}} > 0.989999 > 0$ and $\eta_{\mathrm{ret}} < H_5$. The change of basis divides both action coordinates by the same positive factor; it cancels in their quotient. □

The structural determination of angular action is the pair $(\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}})$ with its identification by return. It preserves the valuation of the local norm, the action character and the regional continuation. In each section $s \in \{\mathrm{pre}, \mathrm{ret}\}$, the action of a complete turn is

$$h_s = 2\pi\hbar_s. \tag{14.73}$$

The subsequent chart $\mathcal{U}_S \mapsto \mathrm{J\,s}$ expresses those sections in units of action. The normalized radius to be constructed preserves its independence from this common choice of units.

14.7 Angular realization and orientation of the channels

The section $\hbar_{\mathrm{ret}}$ belongs to the action line $\mathcal{L}_S$; η_{ret} is its dimensionless coefficient in the basis declared in (14.71). The angular publication then acts on $(\alpha, \eta_{\mathrm{ret}})$. Writing $[t]_{360}$ for the class of t in $\mathbb{R}/(360\mathbb{Z})$, one defines

$$\mathcal{P}_{\mathrm{ang}}(\alpha, \eta_{\mathrm{ret}}) = \big([1000\alpha]_{360}, [2(\eta_{\mathrm{ret}} + \alpha)]_{360}\big). \tag{14.74}$$

The nonadic completion determines the factor 1000; the bidirectional closure determines the factor two. The circular chart of 360 units preserves the partitions $12 \cdot 30 = 4 \cdot 90 = 3 \cdot 120$. On the positive branch, the lifted representatives are

$$A_{\mathrm{deg}} = 1000\alpha, \qquad C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha). \tag{14.75}$$

The subscript distinguishes these angular coordinates from the blocks of the dodecaphasic register.

Proposition 14.23 (Shift of the base-thousand expression)**.** *Let* $\alpha = \sum_{n\geq 1} b_n 1000^{-n}$*, with* $b_n \in \{0, \dots, 999\}$*, be the compatible expansion already generated. Its lifted coordinate satisfies*

$$A_{\mathrm{deg}} = b_1 + \sum_{n\geq 1} b_{n+1} 1000^{-n}.$$

The publication preserves the blocks from the second onward and places the initial block in the integer part.

Proof. The series converges absolutely. Multiplying each term by 1000 and separating the initial term provides the identity. The operation acts on the constructed expansion, with its blocks and memory; the subsequent circular publication takes its class modulo 360. □

14.7.1 Circular charts and covariance of the action

Definition 14.24 (Charts of the angular coordinate)**.** The chart in degrees expresses a complete turn by 360 units; the chart in radians, by 2π. The change of coordinates and its inverse are

$$\theta_A = \frac{\pi}{180} A_{\deg}, \qquad \theta_C = \frac{\pi}{180} C^*_{\deg}, \qquad A_{\deg} = \frac{180}{\pi}\theta_A, \qquad C^*_{\deg} = \frac{180}{\pi}\theta_C. \tag{14.76}$$

A path with a preserved number of turns uses the lifted coordinates. The circular quotient publishes its class modulo the corresponding turn.

The register retains orientation, turns and memory of the transport. The final phase and the lift are different publications: the second distinguishes paths that share the first. Each action expression declares which of these coordinates it uses.

Proposition 14.25 (Covariance of the action reader)**.** *For a section $s \in \{\mathrm{pre}, \mathrm{ret}\}$ and a lifted angular coordinate, one has*

$$\mathcal{S}_s(\theta) = \hbar_s \theta_{\mathrm{rad}} = h_s \frac{\theta_{\deg}}{360}. \tag{14.77}$$

A positive turn expresses h_s.

Proof. Substituting $\theta_{\mathrm{rad}} = \pi\theta_{\deg}/180$ and $h_s = 2\pi\hbar_s$ gives

$$\hbar_s \frac{\pi\theta_{\deg}}{180} = \frac{h_s \theta_{\deg}}{360}.$$

In one turn $\theta_{\deg} = 360$, which gives h_s. □

The periodicity of a representation retains its own condition: if $U(2\pi) = -I$, operator restoration occurs at 4π. The normalization of the action per turn of (14.77) and the return of the represented state thus preserve their respective domains.

14.7.2 Positive channels and reversal of the odd coordinate

The channels are published, in either of the two charts, through

$$q_\pm = \exp[-(\theta_A \pm \theta_C)] = \exp\Big[-\frac{\pi}{180}(A_{\deg} \pm C^*_{\deg})\Big]. \tag{14.78}$$

Proposition 14.26 (Recovery of the angular coordinates)**.** *In the lifted real chart, the positive channels uniquely determine*

$$A_{\deg} = -\frac{90}{\pi}\log(q_+ q_-), \qquad C^*_{\deg} = \frac{90}{\pi}\log\frac{q_-}{q_+}. \tag{14.79}$$

The exchange $(q_+, q_-) \mapsto (q_-, q_+)$ preserves $A_{\deg}$ and reverses $C^*_{\deg}$.

Proof. The sum and difference of the logarithms in (14.78) are $-\pi A_{\deg}/90$ and $-\pi C^*_{\deg}/90$, respectively. The real logarithm is single-valued on the positive channels. Their product is symmetric, and their quotient is inverted upon interchange. □

The antipodal involution $r \mapsto r + 6 \pmod{12}$ of the register forms six pairs. The uniform distribution of the odd coordinate over these pairs assigns $C^*_{\deg}/6$ to each one; the sum recovers $C^*_{\deg}$. The conversion of units is applied only once to each argument. In particular, $C^*_{\deg}/A_{\deg} = \theta_C/\theta_A$ when $A_{\deg} \neq 0$, while the preceding state preserves the lifted angles and its memory.

14.8 Dodecaphase update and memory register

Let d_t be the integer direction code preserved by a TPK trace. This code and the cursor's cardinal direction are distinct coordinates. The twelve windows $E_m = \{9m+1, \dots, 9m+9\}$, $0 \le m < 12$ divide the register's 108 steps. The orientation is

$$\Sigma_{12} = (+,+,+,-,-,-,+,+,+,-,-,-).$$

The event of a window is the output

$$a_m = \Sigma_{12}(m) \sum_{t \in E_m} \mathbf{1}_{\{2,4,6,8\}}(d_t). \tag{14.80}$$

The notation a_m avoids confusing this event with Euler's number. The source register also preserves TRIT orientation, signature, carry and the corresponding history segment, in accordance with the architecture of Section 1.23.5.

Proposition 14.27 (Increment produced by transport)**.** *Let* $\mathbf{e}_m$ *be the basis of* $\mathbb{R}^{12}$ *and* $S\mathbf{e}_m = \mathbf{e}_{m+1 \pmod{12}}$. *If* $\mathbf{z}_{m+1} = \mathbf{z}_m + a_m \mathbf{e}_m$ *and* $y_m = S^{-m}\mathbf{z}_m$, *then*

$$y_{m+1} = S^{-1} y_m + \eta_m, \qquad \eta_m = a_m S^{-1}\mathbf{e}_0. \tag{14.81}$$

After a complete turn,

$$y_{12} = y_0 + \sum_{m=0}^{11} a_m \mathbf{e}_m. \tag{14.82}$$

Proof. Multiplying the update of $\mathbf{z}_m$ by $S^{-(m+1)}$ gives

$$y_{m+1} = S^{-1} y_m + a_m S^{-(m+1)}\mathbf{e}_m = S^{-1} y_m + a_m S^{-1}\mathbf{e}_0.$$

Upon iteration, the coefficient of event a_m is $S^{-(12-m)}\mathbf{e}_0 = \mathbf{e}_m$. Since $S^{12} = I$, we obtain (14.82). □

Boldface here identifies the accumulated vector $\mathbf{z}_m \in \mathbb{R}^{12}$, whereas the incidence block z_m of (11.88) is an integer between 0 and 999. The moving frame y_m transports the first object; the decimal coding of the second retains its own definition.

Thus, η_m is not a free force chosen to impose conservation: it is an expression of the TPK event. Equality of phase after one turn does not cancel accumulated events. This reader preserves counts, while the full register additionally preserves their order and provenance. We distinguish η_m, a vector increment, from η_{ret}, a scalar action mantissa, and from η_{el}, a shape parameter introduced in Section 15.6.

14.8.1 Quadratic balance

We define

$$\nabla_3 = I - S^3, \quad \nabla_4 = I - S^4, \quad B = \nabla_3^{\mathsf{T}}\nabla_3 + \nabla_4^{\mathsf{T}}\nabla_4, \qquad \mathcal{M}(y) = \tfrac{1}{2} y^{\mathsf{T}} B y.$$

The oriented readers of the signed register satisfy $(D_j z)_m = z_m - z_{m+j}$; with the convention $S\mathbf{e}_m = \mathbf{e}_{m+1}$, we have $D_j = I - S^{-j} = \nabla_j^{\mathsf{T}}$. Both directions produce the same quadratic form B, since powers of S commute. We have $S^{\mathsf{T}} B S = B$ and $B_{00} = 4$. Substituting (14.81) yields exactly

$$\mathcal{M}(y_{m+1}) - \mathcal{M}(y_m) = a_m (B y_m)_0 + 2a_m^2. \tag{14.83}$$

Likewise, the charge $q(y) = \sum_j y_j$ satisfies $q(y_{m+1}) - q(y_m) = a_m$. The proof expands the quadratic polynomial after removing the permutation S^{-1}. No metrological value enters this calculation. The form $\mathcal{M}$ measures this register; interpreting it as a determined physical energy would require the corresponding dimensional reader.

14.8.2 Transport resolvents and preservation of memory

The extended history determines the windows $I_m = \{9m+1, \dots, 9m+9\}$, for $m \geq 0$. With this section's numbering, $I_m = E_m$ during the first cycle. Let $\sigma_m \in \{-1, 1\}$ be the orientation preserved by this history; for $0 \leq m < 12$, it coincides with $\Sigma_{12}(m)$. We define

$$a_m = \sigma_m \sum_{t \in I_m} \mathbf{1}_{\{2,4,6,8\}}(d_t), \qquad |a_m| \leq 9.$$

The register and the moving frame are extended by

$$\mathbf{z}_{m+1} = \mathbf{z}_m + a_m \mathbf{e}_{m \bmod 12}, \qquad y_m = S^{-m}\mathbf{z}_m.$$

The initial state $\mathbf{z}_0$ preserves the previous history; it is zero for an initially empty prefix. In this subsection we write $R = S^{-1}$ for frame transport. The update (14.81) is maintained in every window. The orientation and subsequent events are obtained from the extended history: the return of the frame does not presuppose periodicity of the event sequence.

Proposition 14.28 (Truncation identity with terminal state)**.** *For $N \geq 1$, let*

$$Y_N(u) = \sum_{m=0}^{N} y_m u^m, \qquad H_{\eta,N}(u) = \sum_{m=0}^{N-1} \eta_m u^m.$$

The exact polynomial identity holds

$$(I - uR)Y_N(u) = y_0 + uH_{\eta,N}(u) - u^{N+1}Ry_N. \tag{14.84}$$

Proof. In degrees $1 \leq m \leq N$, the coefficient of the left-hand side is $y_m - Ry_{m-1} = \eta_{m-1}$, by (14.81). Its coefficients in degrees zero and $N+1$ are y_0 and $-Ry_N$, respectively. Comparing coefficients proves the equality. □

The terminal term preserves the transported memory when a history is cut. The identity allows a finite evaluation to be compared with its extension while keeping explicit the state that remains at the boundary.

14.8.2.1 Correspondence with common-core transport

The window numbering of Section 1.23.4 and that used here describe the same partition of the history. The correspondence is

$$\underbrace{I_m = E_{m+1}}_{\text{index of the common kernel}} \qquad \longleftrightarrow \qquad \underbrace{I_m = E_m}_{\text{index of this section}}, \qquad 0 \leq m < 12.$$

The subscript changes the name of the window; its nine transitions, its orientation $\sigma_m = \Sigma_{12}(m)$, its event a_m, and its position in the record remain the same. For every prolongation, $R = S^{-1}$, $y_m = S^{-m}\mathbf{z}_m$, and update (14.81) coincide with (1.175). Orientation and the event sequence retain their dependence on the history, also after frame return.

This identification allows Proposition 1.197 to be applied directly: series (1.179), bound (1.180), and uniform convergence of its derivatives correspond to this same record and the same window clock. The finite identity (14.84) also determines the terminal term when that series is truncated. Its hypotheses retain the initial history and the bounded event $|a_m| \leq 9$.

When the record is reused, Proposition 1.198 jointly preserves the operator, source, and reader through (1.181) and (1.182). Example (1.183) specifies the effect of the excursions omitted by a compression. The affine composition (1.184), the intermediate blocks (1.185), and identity (1.186) ensure consistency when

segments are concatenated or several layers eliminated. Their complete proofs reside in Section 1.23.4, with the domains, sources, and reading maps specified there.

Balance (14.83) preserves the correspondence between the oriented readers of the signed record and the common quadratic form. The distinction between the accumulated vector $\mathbf{z}_m$ and the incidence decimal block z_m remains that established in this section. The transport identities apply to memory thus typed; they do not by themselves determine additional analytic coefficients.

14.9 Dodecaphase seal and reversible rational reading

The terminal register has a visible coordinate and a signed coordinate. The seal is obtained from the latter through the orbitwise Hadamard transformation; a subsequent scalar reading recovers the seal when its representation frame is preserved. This property specifies what a structural definition of a constant means here: production and recovery maps are made explicit alongside its value.

Let $U \in \mathbb{Z}^{12}$ be the signed coordinate produced by the register, H_4 the Hadamard matrix developed in Section 14.11 and P_{orb} the permutation grouping

$$(1, 4, 7, 10), \qquad (2, 5, 8, 11), \qquad (3, 6, 9, 12).$$

Define

$$\mathcal{H}_{12} = P_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)P_{\mathrm{orb}}.$$

We have $\mathcal{H}_{12}^2 = 4I$. When $\mathcal{H}_{12}U \equiv 0 \pmod 4$, the integral seal is

$$K = \tfrac{1}{4}\mathcal{H}_{12}U, \qquad U = \mathcal{H}_{12}K.$$

The transverse differences D_3K, D_4K and charge $Q(K)$ recover the channels specified by the register in Section 11.4. The seal is thus a reconstructible coordinate of that oriented register; depth and complete history remain distinct fields.

Proposition 14.29 (Recovery of blocks and transport of the origin)**.** *Fix an integer base $b \geq 2$ and twelve ordered positions, and let $K_j \in \{0, \dots, b-1\}$. Define*

$$I(K) = \sum_{j=1}^{12} K_j b^{12-j}, \qquad \kappa(K) = \frac{I(K)}{b^{12} - 1}.$$

The exact reading κ uniquely determines the twelve blocks. For the rotation $\rho K = (K_2, \dots, K_{12}, K_1)$,

$$\boxed{\kappa(\rho K) = b\kappa(K) - K_1.}$$

Proof. The integer $I = (b^{12} - 1)\kappa$ decomposes uniquely into twelve base-b positions, padding the necessary leading positions with zeros. On the other hand,

$$I(\rho K) = bI(K) - K_1(b^{12} - 1).$$

Dividing by $b^{12} - 1$ gives the transformation law. For the constant block $K_j = b - 1$, the reading is $\kappa = 1$; the fixed periodic representation type likewise preserves its recovery. □

In the register's base 1000, three-digit blocks remain recoverable, including leading zeros. The periodic rational reading preserves more than a truncated decimal approximation. Changing the phase origin generally changes its value according to the preceding identity; after twelve rotations, it returns. The memory advance of the TPK state is an additional transformation: periodicity of the reader does not identify accumulated histories.

Remark: reversible reading and information. Exact block recovery is a property of the rational reader in its ordered frame. Word complexity, the entropy of a symbolic dynamics, reduced-state entropy, and thermodynamic production are distinct objects. A relation between them requires the distribution or state and the corresponding transport map to be specified; reversibility of the seal alone does not identify these functionals.

14.10 Cyclic decomposition and determinantal representations

The cyclic projectors

$$P_3 = \tfrac{1}{4}(I + S^3 + S^6 + S^9), \qquad P_4 = \tfrac{1}{3}(I + S^4 + S^8)$$

have images of dimensions three and four. If $E = P_3 - P_4$, then

$$\frac{\operatorname{Tr} E}{12} = -\frac{1}{12}. \tag{14.85}$$

The scalar arises from a normalized rank difference, not an ordinary sum of positive integers.

Theorem 14.30 (Determinantal representation of the channel readout)**.** *Let* $\mathcal{H}_3 = \operatorname{Fix}(S^3)$ *and* $\mathcal{H}_4 = \operatorname{Fix}(S^4)$. *For* $0 < s < 1$,

$$F(s) = \frac{\det_{\mathcal{H}_3}(I - sS)}{\det_{\mathcal{H}_4}(I - sS)} = \frac{1 - s^3}{1 - s^4} = \frac{1 + s + s^2}{1 + s + s^2 + s^3}. \tag{14.86}$$

Its continuous extension at $s = 1$ *equals* $3/4$.

Proof. The restriction of S to each image is a cycle of three or four positions, respectively. Their characteristic polynomials give $\det(I - sS) = 1 - s^r$ for $r = 3, 4$. Cancelling the common factor $1 - s$ leaves the final expression, regular at $s = 1$. □

Substitution $s = q^{30}$ expresses $F(q^{30}) = (1 - q^{90})/(1 - q^{120})$. The same pair of spaces producing (14.85) produces the channel quotient. This equality does not identify a twelve-coordinate matrix with the entire TPK state.

14.10.1 Oriented information and the complex sector

In the antipodal sector $V_- = \operatorname{Ran}((I - S^6)/2)$, the operator $J = S^3$ satisfies $J^2 = -I$ and $J^{\mathsf{T}} = -J$. With $Q = P_4(I - S^6)/2$, we have

$$\operatorname{rank} Q = 2, \qquad E|_{V_-} = -Q, \qquad B|_{V_-} = 5I - 3Q.$$

On $\operatorname{Ran} Q$, $S^2 = -I$ and the determinant is $1 + s^2$. Thus,

$$F(s) = \frac{1 + s + s^2}{1 + s}\,\frac{1}{1 + s^2}.$$

Orientation reversal changes the sign of the form $\omega(u, v) = \langle Ju, v\rangle$ but preserves B and F. Scalar evaluation does not distinguish all oriented transports.

The transported trace also produces

$$a_n^{\mathrm{tr}} = \operatorname{Tr}(S^n E) = 3\mathbf{1}_{3|n} - 4\mathbf{1}_{4|n},$$

and, for $|s| < 1$,

$$-\log F(s) = \sum_{n \geq 1} \frac{a_n^{\mathrm{tr}}}{n}\, s^n.$$

This system of moments connects the present block with the collected spectral readers. Its complete arithmetic development, including Catalan, will have its own location; it is not presupposed here that a functional identity alone determines its arithmetic nature.

14.11 Planck constants and the determinantal structure of action

14.11.1 Determinantal action scale and decimal valuation

The absolute scale and relative correction arise from distinct objects. The former uses the local block of the step-three dodecaphase register,

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad G_H = \mathbb{Z}^4 / H_4 \mathbb{Z}^4. \tag{14.87}$$

The operation uses a local quotient. The three blocks of the complete register are not replaced by tensorization that would multiply this reader's number of sheets again.

Lemma 14.31 (Number of sheets of the local quotient)**.** *The Smith normal form of H_4 is* $\operatorname{diag}(1, 2, 2, 4)$. *Consequently,*

$$G_H \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |G_H| = 16.$$

Proof. The greatest common divisor of the entries is one. Second-order minors are even and one has value -2, so their greatest common divisor is two. Since $H_4 H_4^{\mathsf{T}} = 4I$ and $\det H_4 = -16$, the cofactors are ± 4; the third determinantal divisor is four. The fourth is 16. Successive quotients of the divisors $1, 2, 4, 16$ are $1, 2, 2, 4$. Their product gives the quotient's order. □

Definition 14.32 (Determinantal action reader)**.** The multiplicative norm of the scalar section α, constant on the sheets of G_H, and one application of self-scaling φ produce

$$\Sigma_H = \varphi \, \mathrm{N}_{G_H}(\alpha), \qquad \mathrm{N}_{G_H}(\alpha) = \prod_{g \in G_H} \alpha = \alpha^{16}. \tag{14.88}$$

The associated decimal chart determines $\operatorname{ord}_{10}(\Sigma_H) = \lfloor \log_{10} \Sigma_H \rfloor$.

The sixteenth power thus comes from the quotient's number of sheets, once this local reader is fixed. The factor φ acts once on the basis of the action line. Smith calculation alone would not select any possible functional on the quotient: the multiplicative norm and self-scaling are part of the declared operation.

Theorem 14.33 (Decade of the action section)**.** *The reader* (14.88)*, applied to HMT coordinates already generated, satisfies*

$$10^{-34} < \Sigma_H < 10^{-33}, \qquad \operatorname{ord}_{10}(\Sigma_H) = -34. \tag{14.89}$$

Proof. The rational intervals, much coarser than the available cylinders, suffice:

$$\frac{1618}{1000} < \varphi < \frac{1619}{1000}, \qquad \frac{7297}{10^6} < \alpha < \frac{7298}{10^6}.$$

The function $(x, a) \mapsto x a^{16}$ is increasing in both positive arguments. The two integer inequalities

$$1618 \cdot 7297^{16} > 10^{65}, \qquad 1619 \cdot 7298^{16} < 10^{66}$$

imply

$$10^{-34} < \frac{1618}{1000} \left(\frac{7297}{10^6} \right)^{16} < \Sigma_H < \frac{1619}{1000} \left(\frac{7298}{10^6} \right)^{16} < 10^{-33}.$$

The definition of decimal order completes the proof. Neither an SI unit nor a reference mass enters these inequalities. □

The normalized section begins with $\Sigma_H = 1.0462438381\ldots \times 10^{-34}$. Its mantissa is not identified with the action coordinate before or after return. The determinantal reader fixes decimal order; the two return coordinates are obtained through the following readers.

14.11.2 Action sections and dimensionless return quotient

Let $\mathcal{L}_S$ be an oriented action line and $\mathcal{U}_S$ its positive basis. The fifth-order character and regional return term have the expressions

$$H_5 = \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5, \tag{14.90}$$

$$D_A = \exp\left(-\frac{100\pi\alpha}{9}\right), \tag{14.91}$$

$$C_\pi(\alpha) = 169\alpha^6 + \frac{D_A\alpha^7}{1 - D_A\alpha}, \tag{14.92}$$

$$\eta_{\mathrm{ret}} = H_5 - \frac{90}{\pi}C_\pi(\alpha). \tag{14.93}$$

These are subsequent readings of dodecaphase closure and its regional incidence. The integer 169 is retained as the regional selector already constructed, and the coefficients of H_5 as those of its local character; they are not replaced by an interpolation of the Planck constant. The formulas specify exactly which readings are needed for the electronic stage. Other mass-theory functionals need not be introduced here.

For $0 < \alpha < 1$, we have $0 < D_A < 1$, so $D_A\alpha < 1$. The rational term of (14.92) preserves the complete sum of the geometric tail

$$\frac{D_A\alpha^7}{1 - D_A\alpha} = \sum_{n=0}^{\infty} D_A^{n+1}\alpha^{n+7}. \tag{14.94}$$

It is not a truncation that can be silently modified when precision changes. After the term of index N, the remaining tail is $D_A^{N+2}\alpha^{N+8}/(1 - D_A\alpha)$, allowing evaluation to be controlled without recourse to a target quantity.

Definition 14.34 (Action sections and return reader)**.** The sections before and after return are

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S. \tag{14.95}$$

Whenever $\eta_{\mathrm{ret}} > 0$, define

$$\delta_{\mathrm{ret}} = H_5 - \eta_{\mathrm{ret}}, \qquad R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}. \tag{14.96}$$

Proposition 14.35 (Positivity and invariance of the ratio)**.** *In the intervals used in the proof of* (14.89)*,* $0 < \eta_{\mathrm{ret}} < H_5$*, and therefore* $R_{\mathrm{act}} > 1$*. The ratio does not change when the basis* $\mathcal{U}_S$ *is replaced by any other common positive basis.*

Proof. The terms of C_π are positive. For an elementary bound, it suffices to use $\alpha < 0.008$, $\varphi < 1.619$, $\alpha > 0.007$, $D_A < 1$ and $\pi > 3$. The root in (14.90) exceeds one, whereas the sum of negative terms is less than 0.008001; in particular, $H_5 > 0.99$. Likewise,

$$0 < \frac{90}{\pi}C_\pi < 30\left(169(0.008)^6 + \frac{(0.008)^7}{1 - 0.008}\right) < 10^{-6}.$$

Thus $\eta_{\mathrm{ret}} > 0.989999 > 0$ and $\eta_{\mathrm{ret}} < H_5$. Finally, the change of basis divides both action coordinates by the same positive factor, which cancels in their ratio. □

Subsequent evaluation gives

$$H_5 = 1.0545718176461544696\ldots,$$
$$\eta_{\mathrm{ret}} = 1.0545718169150390611\ldots,$$
$$R_{\mathrm{act}} = 1.0000000006932817630\ldots.$$

The difference and quotient are two readings of the same sections, one additive and the other multiplicative. They do not represent two independent Planck constants. The passage from angular action to action per complete turn is expressed in each section by $h = 2\pi\hbar$. The subsequent chart $\mathcal{U}_S \mapsto \mathrm{J\,s}$ assigns a unit but does not act retroactively on the decimal order already proved.

Regional return can also be written in an angular chart. This reparametrization is not an indispensable additional dependency: (14.90)–(14.93) supply H_5, η_{ret} and R_{act} directly. If angle and counter-angle are introduced, both must be transported in the same chart; degrees and radians are not mixed within a difference.

14.11.2.1 Action character and provenance of its coefficients

The reduced Planck constant, $\hbar$, is the physical object motivating realization of the angular-action section. Its position in the electronic dependency must be specified at two levels. The determinantal norm Σ_H determines the scale's decade. The character H_5 and regional return then determine the action-section coordinates. This separation allows the result needed for the electron to be presented without anticipating complete developments of other Dimensional Mechanics sectors.

The provenance of the fifth-order character can be made explicit through invariants already fixed on the support. In the central chart, consider

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}, \qquad \lambda_+ = 9, \quad \lambda_- = 5.$$

The calendar has length 12, the orbit of step 3 has length 4, and the relevant census quotient is $104976/1944 = 54$. The coefficients of the character satisfy

$$\frac{9}{16} = \frac{\lambda_+}{4^2}, \quad \frac{5}{9} = \frac{\lambda_-}{\lambda_+}, \quad \frac{7}{48} = \frac{\mathrm{tr}(B_c)/2}{4 \cdot 12}, \quad \frac{1}{54} = \frac{1944}{104976}. \tag{14.97}$$

Assignment of these invariants to degrees $2, 3, 4, 5$, with the alternating signs of (14.90), belongs to the definition of the analytic character used. Making this explicit is essential: the set of cardinalities, considered without the character and the ordering of its degrees, would admit other expressions. The constructive content lies in composition of the support, orientation and declared analytic rule.

14.11.2.2 Regional continuation and renewal equation

The selector 169 determines the degree-six impulse. Subsequent extension is organized by the transfer D_A and unit normalization of the determinant line. These rules admit a formal-series formulation before substituting $z = \alpha$, with D_A already constructed. Write

$$\mathscr{C}(z) = 169z^6 + R(z), \qquad R(z) \in z^7\mathbb{R}[[z]].$$

Concatenating an extension increases degree by one and multiplies its weight by D_A. The first strict extension has weight D_A. Its renewal equation is therefore

$$R(z) = D_A z^7 + D_A z R(z). \tag{14.98}$$

Proposition 14.36 (Formal uniqueness of the normalized continuation)**.** *Equation* (14.98) *determines a unique series, and*

$$\mathscr{C}(z) = 169z^{6} + \frac{D_A z^{7}}{1 - D_A z} = 169z^{6} + \sum_{n=7}^{\infty} D_A^{n-6} z^{n}.$$

The realization is analytic in $|D_A z| < 1$.

Proof. The element $1 - D_A z$ has constant term one and is invertible in the formal power-series ring. Solving the equation produces the displayed series. Equivalently, the degree-seven coefficient is D_A and each subsequent coefficient is D_A times the preceding one. The geometric series converges absolutely in the stated disk. □

Normalization of the first extension is an indispensable operational datum. If only the degree-six impulse and concatenation ratio were retained, the series

$$169z^{6} + \lambda \frac{D_A z^{7}}{1 - D_A z}$$

would still share both data for any λ. The unit rule fixes $\lambda = 1$ before evaluation. Each rule's contribution to reader uniqueness is thus located, and the rational expression preserves the complete continuation.

14.11.2.3 Reduced Planck constant and return of the action section

In the dimensional chart of (14.95), the section before return is the model's construction intended for comparison with the reduced Planck constant:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34} \mathcal{U}_S.$$

The subsequent section also preserves the regional compensation $90\mathscr{C}(\alpha)/\pi$. Both belong to the same action line, and their quotient R_{act} measures the multiplicative effect of return. The passage to h through 2π uses the relationship between angular parametrization and a complete turn.

This construction effectively enters $R_{\mathrm{act}}^{80-54\alpha+6\Delta_4}$. The electron preserves its central coordinate and trajectory; the chronological scale does not replace this structure with an undifferentiated quantum. Nor is a mass already expressed in MeV multiplied again by 10^{-34}: the decade belongs to the action section, cancels in its dimensionless quotient and reappears only where the corresponding dimensional realization acts.

The numerical comparison of H_5, the returned section and $h/(2\pi)$ is presented in Section 140.1. This distinguishes the name of the physical object, the equation assigned to it by the model and the precision with which that equation reproduces it.

14.11.3 Structural definition and role of the Planck constants

Definition 14.37 (Structural determination of angular action)**.** On the oriented line $\mathcal{L}_S$, the HMT determination of angular action is the pair of sections $\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}}$ in (14.95), together with their identification by return. Its structure combines the valuation of the local norm $\varphi \mathrm{N}_{G_H}(\alpha)$, the character H_5, and the regional continuation C_π. The action per complete turn is $h_a = 2\pi\hbar_a$ in each orientation a.

This definition preserves three successive determinations. The local quotient in (14.87) fixes the sixteen sheets of the norm; the inequality (14.89) fixes its decimal order. The character and the normalized renewal in (14.98) then determine the pre-return and post-return coordinates. Uniqueness of the tail uses its first weight and its concatenation rule; the distribution of the coefficients of H_5 preserves the character declared in Section 14.11.2.1. On the positive branch, the multiplicative information of the return is the invariant

$$\frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}} > 1. \tag{14.99}$$

Its physical function is expressed through the contraction between action and frequency: a section $\hbar_a$ assigns energy to an angular frequency, whereas h_a expresses the action of one turn. The quotient (14.99) preserves the structural modification between both readings even when the common basis of units is changed. The identification with the physical constant and its precision are examined in the chart of section 140.1, with the two return coordinates distinguished.

14.11.4 Angular coordinates, turn normalization and action units

The action quantity and angular coordinate belong to different spaces. The section $\hbar_{\mathrm{ret}}$ occupies the action line $\mathcal{L}_S$; η_{ret} is its coefficient in the declared basis. Angular expression acts on the dimensionless pair $(\alpha, \eta_{\mathrm{ret}})$ after its construction:

$$\mathcal{P}(\alpha, \eta_{\mathrm{ret}}) = \big([1000\alpha]_{360}, [2(\eta_{\mathrm{ret}} + \alpha)]_{360}\big). \tag{14.100}$$

Nonadic completion determines the factor 1000; bidirectional closure determines the factor two. The circular chart of 360 units makes visible the partitions $12 \cdot 30 = 4 \cdot 90 = 3 \cdot 120$. On the article's positive branch, the representatives are

$$A_{\mathrm{deg}} = 1000\alpha, \qquad C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha).$$

Proposition 14.38 (Shift of the base-thousand expression)**.** *Let $\alpha = \sum_{n\geq 1} b_n 1000^{-n}$, with $b_n \in \{0, \dots, 999\}$, be the compatible expansion already generated. The lifted coordinate $A_{\mathrm{deg}} = 1000\alpha$ satisfies*

$$A_{\mathrm{deg}} = b_1 + \sum_{n\geq 1} b_{n+1} 1000^{-n}.$$

The expression preserves the sequence of blocks from the second onward; the initial block passes to the integer part.

Proof. The series converges absolutely. Multiplying every term by 1000 and separating the initial term gives the identity. The operation acts on the constructed expansion, with its blocks and memory; subsequent circular expression takes its class modulo 360. □

Definition 14.39 (Charts of the angular coordinate)**.** The degree chart expresses a complete turn by 360 units. The radian chart expresses it by 2π. The coordinate changes and their inverses are

$$x = \frac{\pi}{180} A_{\mathrm{deg}}, \qquad y = \frac{\pi}{180} C^*_{\mathrm{deg}}, \qquad A_{\mathrm{deg}} = \frac{180}{\pi} x, \qquad C^*_{\mathrm{deg}} = \frac{180}{\pi} y.$$

Along a path with preserved turn count, lifted coordinates are used; the circular quotient expresses its class modulo the corresponding turn.

The definition characterizes degrees and radians by their exact relationship to the turn. The register also retains orientation, turns and transport memory. Expression of its angular class preserves phase, whereas the lift distinguishes paths having the same final phase. The physical reading of action must specify which of these coordinates enters the integral.

Proposition 14.40 (Covariance of the action reader)**.** *For $h_a = 2\pi\hbar_a$, the action of a lifted coordinate satisfies*

$$\mathcal{S}_a(\theta) = \hbar_a \theta_{\mathrm{rad}} = h_a \frac{\theta_{\mathrm{deg}}}{360}. \tag{14.101}$$

A positive turn expresses h_a.

Proof. Substituting $\theta_{\mathrm{rad}} = \pi\theta_{\mathrm{deg}}/180$ gives $\hbar_a \pi\theta_{\mathrm{deg}}/180 = (2\pi\hbar_a)\theta_{\mathrm{deg}}/360$. Over one turn $\theta_{\mathrm{deg}} = 360$, whence h_a. □

The periodicity of a representation is declared separately. If the transported representation satisfies $U(2\pi) = -I$, its operatorial restoration occurs at 4π. This property of the lift coexists with the per-turn normalization of (14.101). Each preserves its object: integrated quantity, circular phase and represented state.

14.11.5 Covariance of the channels and the incidence functional

The channels are equivalently written as

$$q_{\pm} = \exp[-(x \pm y)] = \exp\Big[-\frac{\pi}{180}(A_{\mathrm{deg}} \pm C^*_{\mathrm{deg}})\Big]. \tag{14.102}$$

Proposition 14.41 (Recovery of the even and odd coordinates)**.** *In the lifted real chart, the positive channels uniquely determine the two coordinates:*

$$A_{\mathrm{deg}} = -\frac{90}{\pi}\log(q_+q_-), \qquad C^*_{\mathrm{deg}} = \frac{90}{\pi}\log\frac{q_-}{q_+}.$$

The exchange $(q_+, q_-) \mapsto (q_-, q_+)$ preserves A_{deg} and reverses C^*_{deg}.

Proof. The sum and difference of the logarithms of (14.102) are, respectively, $-\pi A_{\mathrm{deg}}/90$ and $-\pi C^*_{\mathrm{deg}}/90$. The real logarithm is single-valued on the positive channels. The product is symmetric and the quotient is inverted when they are exchanged. □

In the twelve-position register, the antipodal involution $r \mapsto r + 6 \pmod{12}$ forms six pairs. The uniform distribution of the odd coordinate over these pairs is $C^*_{\mathrm{deg}}/6$: summing its six contributions recovers C^*_{deg}. This sectorial coordinate is distinct from the Planck constant h, which belongs to the action line.

The conversion is applied only once to each argument. The quantity α remains dimensionless and the quantity $\hbar$ still belongs to the action line; their prior coordinates enter the map $\mathcal{P}$.

The Barbero–Immirzi functional contains, in addition to the channels, a component bilinear in the angular representatives. Its transport is

$$\frac{\pi}{180}A_{\mathrm{deg}}C^*_{\mathrm{deg}} = \frac{180}{\pi}xy. \tag{14.103}$$

The identity is obtained by substituting both representatives in degrees with their expressions in radians. Thus, the complete formula in analytic coordinates is

$$\gamma_{\mathrm{HMT}} = \frac{180}{\pi}xy + 12\big[S_{90}(e^{-x+y}) - S_{90}(e^{-x-y})\big] - \big[S_{120}(e^{-x+y}) - S_{120}(e^{-x-y})\big].$$

Equivalence of the two charts transports the bilinear component and exponential functions simultaneously. This transformation specifies the precise role of the degree in the construction and makes evaluation reproducible without ambiguity of angular units.

14.11.6 Angular coordinates, turn normalization and action units

The action quantity and angular coordinate belong to different spaces. The section $\hbar_{\mathrm{ret}}$ occupies the action line $\mathcal{L}_S$; η_{ret} is its coefficient in the declared basis. Angular expression acts on the dimensionless pair $(\alpha, \eta_{\mathrm{ret}})$ after its construction:

$$\mathcal{P}(\alpha, \eta_{\mathrm{ret}}) = \big([1000\alpha]_{360}, [2(\eta_{\mathrm{ret}} + \alpha)]_{360}\big). \tag{14.104}$$

Nonadic completion determines the factor 1000; bidirectional closure determines the factor two. The circular chart of 360 units makes visible the partitions $12 \cdot 30 = 4 \cdot 90 = 3 \cdot 120$. On the article's positive branch, the representatives are

$$A_{\mathrm{deg}} = 1000\alpha, \qquad C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha).$$

Proposition 14.42 (Shift of the base-thousand expression)**.** *Let $\alpha = \sum_{n\geq 1} b_n 1000^{-n}$, with $b_n \in \{0, \dots, 999\}$, be the compatible expansion already generated. The lifted coordinate $A_{\mathrm{deg}} = 1000\alpha$ satisfies*

$$A_{\mathrm{deg}} = b_1 + \sum_{n\geq 1} b_{n+1} 1000^{-n}.$$

The expression preserves the sequence of blocks from the second onward; the initial block passes to the integer part.

Proof. The series converges absolutely. Multiplying every term by 1000 and separating the initial term gives the identity. The operation acts on the constructed expansion, with its blocks and memory; subsequent circular expression takes its class modulo 360. □

Definition 14.43 (Charts of the angular coordinate)**.** The degree chart expresses a complete turn by 360 units. The radian chart expresses it by 2π. The coordinate changes and their inverses are

$$x = \frac{\pi}{180} A_{\mathrm{deg}}, \qquad y = \frac{\pi}{180} C^*_{\mathrm{deg}}, \qquad A_{\mathrm{deg}} = \frac{180}{\pi} x, \qquad C^*_{\mathrm{deg}} = \frac{180}{\pi} y.$$

Along a path with preserved turn count, lifted coordinates are used; the circular quotient expresses its class modulo the corresponding turn.

The definition characterizes degrees and radians by their exact relationship to the turn. The register also retains orientation, turns and transport memory. Expression of its angular class preserves phase, whereas the lift distinguishes paths having the same final phase. The physical reading of action must specify which of these coordinates enters the integral.

Proposition 14.44 (Covariance of the action reader)**.** *For $h_a = 2\pi\hbar_a$, the action of a lifted coordinate satisfies*

$$\mathcal{S}_a(\theta) = \hbar_a \theta_{\mathrm{rad}} = h_a \frac{\theta_{\mathrm{deg}}}{360}. \tag{14.105}$$

A positive turn expresses h_a.

Proof. Substituting $\theta_{\mathrm{rad}} = \pi\theta_{\mathrm{deg}}/180$ gives $\hbar_a \pi \theta_{\mathrm{deg}}/180 = (2\pi\hbar_a)\theta_{\mathrm{deg}}/360$. Over one turn $\theta_{\mathrm{deg}} = 360$, whence h_a. □

The periodicity of a representation is declared separately. If the transported representation satisfies $U(2\pi) = -I$, its operatorial restoration occurs at 4π. This property of the lift coexists with the per-turn normalization of (14.105). Each preserves its object: integrated quantity, circular phase and represented state.

14.11.7 Covariance of the channels and the incidence functional

The channels are equivalently written as

$$q_\pm = \exp[-(x \pm y)] = \exp\Big[-\frac{\pi}{180}(A_{\mathrm{deg}} \pm C^*_{\mathrm{deg}})\Big]. \tag{14.106}$$

Proposition 14.45 (Recovery of the even and odd coordinates)**.** *In the lifted real chart, the positive channels uniquely determine the two coordinates:*

$$A_{\mathrm{deg}} = -\frac{90}{\pi}\log(q_+q_-), \qquad C^*_{\mathrm{deg}} = \frac{90}{\pi}\log\frac{q_-}{q_+}.$$

The exchange $(q_+, q_-) \mapsto (q_-, q_+)$ *preserves* A_{deg} *and reverses* C^*_{deg}.

Proof. The sum and difference of the logarithms of (14.106) are, respectively, $-\pi A_{\mathrm{deg}}/90$ and $-\pi C^*_{\mathrm{deg}}/90$. The real logarithm is single-valued on the positive channels. The product is symmetric and the quotient is inverted when they are exchanged. □

In the twelve-position register, the antipodal involution $r \mapsto r + 6 \pmod{12}$ forms six pairs. The uniform distribution of the odd coordinate over these pairs is $C^*_{\mathrm{deg}}/6$: summing its six contributions recovers C^*_{deg}. This sectorial coordinate is distinct from the Planck constant h, which belongs to the action line.

The conversion is applied only once to each argument. The quantity α remains dimensionless and the quantity $\hbar$ still belongs to the action line; their prior coordinates enter the map $\mathcal{P}$.

The Barbero–Immirzi functional contains, in addition to the channels, a component bilinear in the angular representatives. Its transport is

$$\frac{\pi}{180}A_{\mathrm{deg}}C^*_{\mathrm{deg}} = \frac{180}{\pi}xy. \tag{14.107}$$

The identity is obtained by substituting both representatives in degrees with their expressions in radians. Thus, the complete formula in analytic coordinates is

$$\gamma_{\mathrm{HMT}} = \frac{180}{\pi}xy + 12\big[S_{90}(e^{-x+y}) - S_{90}(e^{-x-y})\big] - \big[S_{120}(e^{-x+y}) - S_{120}(e^{-x-y})\big].$$

Equivalence of the two charts transports the bilinear component and exponential functions simultaneously. This transformation specifies the precise role of the degree in the construction and makes evaluation reproducible without ambiguity of angular units.

Chapter 15

Incidence channels 90/120 of the Topological Phase Kernel: tritic semicrowns, sheet factorization, and hexad–octad realization of the morphism 6→8

15.1 Arithmetic classification of integer channels and compatibility with the triticale semicrown

The preceding generations distinguish the function of each constant. This block proves the integral structure of their readers. The quantities $729, 271, 315$ and 161 are constructed as *integral channels relative to declared typed rules*; they do not enter as decimal approximations. Their statuses are not identical: 729 is the quadratic power of channel 27; 271 and 315 receive a nonadic realization constructed from the published TPK phase partition and a second realization relative to the Steiner lift; and 161 remains, within the present scope, an integral identity without a set-theoretic realization of its own. The catalogue is then classified through published predicates and gauges. Only at the end may an Archimedean chart act to produce decimal expansions.

This order separates two distinct operations. Seeking the integer 271 because it recalls the first digits of e would be a retrospective reading. Finding a TPK region and calling it e without constructing the type of return it represents would be a designation without a map. The integer channels, the conditioned orbital classification, and the dictionary relating them are therefore kept separate. The isolated integer channel selects no constant; selection belongs to the enriched TPK reader, which incorporates the orbit, orientation, survival, and boundary memory without receiving as input the decimal value that it ultimately evaluates.

15.1.1 Visible residue, digital root and crown memory

For $n > 0$, the nonadic digital root is the section

$$\mathrm{dr}_9(n) = \begin{cases} 9, & n \equiv 0 \pmod 9, \\ n \bmod 9, & n \not\equiv 0 \pmod 9. \end{cases}$$

Reduction modulo nine conserves the visible class; the section by $\{1, \dots, 9\}$ also conserves the choice of the null representative. We define the lifted quotient

$$q_9^\sharp(n) := \frac{n - \mathrm{dr}_9(n)}{9} \in \mathbb{Z}_{\geq 0}.$$

One obtains the exact decomposition, which is not the usual remainder convention in $\{0, \dots, 8\}$,

$$n = 9q_9^\sharp(n) + \mathrm{dr}_9(n).$$

This separates two readings: $\mathrm{dr}_9(n)$ records the visible value, and $q_9^\sharp(n)$ records how many complete crowns precede the chosen visible representative. This is the exact form of the colloquial image according to which the modulus compacts and the carry preserves what compactification would lose.

In APP the additive and multiplicative leaves produce

$$\sum \Sigma = 405, \qquad \sum \Pi = 459, \qquad \Delta := \sum \Pi - \sum \Sigma = 54.$$

The sum of the additive quotients is

$$S := \sum Q^+ = 45.$$

We define

$$\kappa = \frac{\Delta}{2} = 27, \qquad \Theta = 5\kappa = 135.$$

All these numbers come from the orthogram and its two evaluations. No constant has been used yet.

The central block

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}$$

produce four ordered words:

$$72, \qquad 27, \qquad 77, \qquad 22.$$

Satisfy

$$72 + 27 = 77 + 22 = 99, \qquad 72 - 27 = 45, \qquad 77 - 22 = 55 = 54 + 1.$$

The center does not remain isolated: its two complementary readings project onto the boundary 99, while their differences recover the additive crown 45 and the pointed defect $54 + 1$.

15.1.2 Classification Theorem of the 4 Integer Channels

Theorem 15.1 (Typed identities of the four channels)**.** *Relative to the composition rules* $\kappa \mapsto \kappa^2$, $\Theta \mapsto 2\Theta + 1$, $(\Theta, S) \mapsto 2\Theta + S$, *and* $(\Theta, \kappa) \mapsto \Theta + \kappa - 1$, *the four integer channels are defined*

$$\begin{aligned} C_\alpha &= \kappa^2 = 729, \\ C_e &= 2\Theta + 1 = 271, \\ C_\pi &= 2\Theta + S = 315, \\ C_\varphi &= \Theta + \kappa - 1 = 161. \end{aligned}$$

Moreover,

$$\begin{aligned} C_e &= 5\Delta + 1 = 10 \cdot 27 + 1 = 4\Delta + (\Delta + 1), \\ C_\pi &= 5\Delta + S = 7S, \\ C_\varphi &= 3\Delta - 1 = 4\Delta - (\Delta + 1), \end{aligned}$$

and the closures are satisfied

$$\boxed{1000 = C_\alpha + C_e = 729 + 271}$$

and

$$\boxed{C_\pi + C_e + C_\varphi - 3 = 744 = 729 + 15.}$$

The α *channel also has the central reading* $729 = 10 \cdot 72 + 9$, *and the* e *channel has the reading* $271 = 10 \cdot 27 + 1$.

Proof. Substituting $\Delta = 54$, $S = 45$, $\kappa = 27$, and $\Theta = 135$ yields the four formulas. The alternative expressions are integer identities. The first completion is obtained from $27^2 + 2(5 \cdot 27) + 1 = 729 + 270 + 1 = 1000$; the second, from $315 + 271 + 161 - 3 = 744 = 729 + 15$. The two decimal divisions follow from the central words $(72, 27)$ and their remainders already fixed by the cubic completion. □

The equality $1000 - 3^6 = 271$ is universal for that cubic ambient space. By itself it does not distinguish e: in an ambient space of cardinality B, constructed with an alphabet of cardinality q in dimension d, the formal complement is $B - q^d$. The additional information in this section is that 271 also admits a realization as a pointed return and the central reading $27|1$. Its association with the orbit named e belongs to the subsequent typed dictionary, not to the isolated subtraction.

15.1.3 Semicorona nonadic relative to the TPK phase rule

The minimal motion rule of the TPK emitter does not treat the nine instants of a window as an interchangeable list. Relative to the published phase origin, it defines

$$D_9 = \{1, \dots, 9\}, \qquad H_+ = \{1, 4, 7\}, \qquad H_- = \{2, 5, 8\}, \qquad H_0 = \{3, 6, 9\}.$$

The instants of H_+ activate the additive reading, those of H_- the multiplicative reading, and those of H_0 preserve the neutral channel. Set

$$H_{\mathrm{act}} = H_+ \sqcup H_-, \qquad O_{\mathrm{ph}} = \{1, \dots, 8\}, \qquad \star_{\mathrm{ph}} = 9,$$

and let $P_2(H_{\mathrm{act}})$ be the set of unordered pairs of active phases. We define

$$\begin{aligned} \mathcal{F}_6^{\mathrm{ph}} &= H_{\mathrm{act}} \times P_2(H_{\mathrm{act}}), \\ \mathcal{F}_8^{\mathrm{ph}} &= O_{\mathrm{ph}} \times P_2(H_{\mathrm{act}}), \\ \Theta_{\mathrm{ph}} &= D_9 \times P_2(H_{\mathrm{act}}). \end{aligned}$$

Theorem 15.2 (Semicrown Relative to the TPK Phase)**.** *Relative to the published window origin and to the terminal return* $9 \to 1$*, it holds*

$$|\mathcal{F}_6^{\mathrm{ph}}| = 90, \qquad |\mathcal{F}_8^{\mathrm{ph}}| = 120, \qquad |\Theta_{\mathrm{ph}}| = 135.$$

The oriented boundary, the pointed return, the neutral lateral boundary, and the lateral closure are, respectively,

$$\begin{aligned} \partial_{\mathrm{ph}} &= \Theta_{\mathrm{ph}} \times \{-1, +1\}, \\ E_{\mathrm{ph}} &= \partial_{\mathrm{ph}} \sqcup \{\infty\}, \\ L_{\mathrm{ph}} &= H_0 \times P_2(H_{\mathrm{act}}), \\ P_{\mathrm{ph}} &= \partial_{\mathrm{ph}} \sqcup L_{\mathrm{ph}}, \end{aligned}$$

and satisfy

$$\boxed{|\partial_{\mathrm{ph}}| = 270, \quad |E_{\mathrm{ph}}| = 271, \quad |L_{\mathrm{ph}}| = 45, \quad |P_{\mathrm{ph}}| = 315.}$$

The construction is covariant under a change of origin: translating the window by C_9 *simultaneously translates all strata and changes neither their cardinalities nor their incidences.*

Proof. The sign rule gives six active phases and three neutral ones, so that

$$|P_2(H_{\mathrm{act}})| = \binom{6}{2} = 15.$$

Multiplying by 6, 8, and 9 produces 90, 120, and 135. The orientation doubles 135; the pointed return adds one element; and the three neutral phases contribute $3 \cdot 15 = 45$ lateral positions. Covariance follows because a translation of D_9 conjugates the phase rule and transports each Cartesian product by a bijection. □

This theorem substantively strengthens the cardinal identity $270 + 1$: the order $6 \subset 8 \subset 9$ is no longer chosen from among 9! possible orders, but instead arises from the TPK phase clock and its published return. Canonicity is relative to the origin of the window; changing it does not alter the object up to the natural action of C_9.

15.1.4 Semicorona relative to the hexad-octad elevation and pointed return

Fix the dodecad, the alignment, and a hexad $H \in \mathcal{H}(D)$ of the construction of section 17.1.6. By theorem 17.5, there exists a unique octad O_H such that $O_H \cap D = H$. Write

$$P_2(H) = \{\{a, b\} : a, b \in H,\ a \neq b\}, \qquad |P_2(H)| = \binom{6}{2} = 15,$$

and add to O_H a return state $\star$:

$$\widehat{O}_H = O_H \sqcup \{\star\}, \qquad |\widehat{O}_H| = 9.$$

We define

$$\Theta_H = \widehat{O}_H \times P_2(H).$$

Within it appear the two combinatorial layers.

$$\mathcal{F}_6 = H \times P_2(H), \qquad \mathcal{F}_8 = O_H \times P_2(H).$$

Theorem 15.3 (Realization of the semicrown)**.** *The preceding objects satisfy*

$$|\mathcal{F}_6| = 90, \qquad |\mathcal{F}_8| = 120, \qquad |\Theta_H| = 135.$$

The oriented boundary

$$\partial_H = \Theta_H \times \{-1, +1\}$$

has 270 *states. Adjoining one return point,*

$$E_H = \partial_H \sqcup \{\infty\},$$

has 271 *states. The boundary lateral of the stratum of six points is*

$$L_H = \Theta_H \setminus \mathcal{F}_6, \qquad |L_H| = 45,$$

and the lateral-oriented closure

$$P_H = \partial_H \sqcup L_H$$

tiene 315 *estados.*

Proof. The cardinals are

$$6\binom{6}{2} = 90, \qquad 8\binom{6}{2} = 120, \qquad 9\binom{6}{2} = 135.$$

The orientation doubles 135, adjoining one point adds a unit, and the difference between Θ_H and the six-point stratum contains $(9 - 6)15 = 45$ elements. From this result 270, 271 and $270 + 45 = 315$. □

Here the two integers have different set-theoretic types. 271 is the cardinality of an oriented boundary to which one point has been adjoined; that fact alone does not make it the orbit of e. 315 is the cardinality of that boundary together with the 45 lateral positions not belonging to the six-point stratum. The inclusion $H \subset O_H$ used here is indeed the Steiner lift already proved, relative to the fixed dodecad and alignment. The semicorona then adjoins the point $\star$, the orientation, and the lateral boundary. This construction does not yet provide the nonadic order induced by TPK or an intertwiner between the faces of the cube and Steiner incidences; these are additional maps.

The two semicrowns share the same cardinal profile, but they must not therefore be identified. An unmarked isomorphism between the chains

$$H_{\mathrm{act}} \subset O_{\mathrm{ph}} \subset D_9 \quad \text{and} \quad H \subset O_H \subset \widehat{O}_H$$

that preserves the return point may freely permute the six elements of the first stratum and the two elements added in the second. There exist

$$\boxed{6!\,2! = 1440}$$

chain gauges. The phase–Steiner intertwiner must select one of them by means of additional incidences; equality of cardinalities does not construct it.

15.1.5 Dihedral action and classification under declared predicates

For an emission $U = (u_1, \dots, u_6) \in \mathcal{U}_6$, we define the visible word

$$\Psi(U) = ((-u_1) \bmod 3, \dots, (-u_6) \bmod 3) \in \mathbb{F}_3^6.$$

Let the coordinate permutations be explicitly defined by

$$r \cdot (u_1, u_2, u_3, u_4, u_5, u_6) = (u_3, u_1, u_2, u_5, u_6, u_4),$$

$$s \cdot (u_1, u_2, u_3, u_4, u_5, u_6) = (u_4, u_5, u_6, u_1, u_2, u_3).$$

Generan a grupo diedral $D_3 \simeq S_3$. The catalogo verifica

$$r\mathcal{U}_6 = \mathcal{U}_6, \qquad s\mathcal{U}_6 = \mathcal{U}_6, \qquad \Psi(gU) = g\Psi(U),$$

and preserves the microscopic multiplicities.

The action divides the 243 visible words into 38 orbits of size six and five orbits of size three. On each word w, write

$$n(w) = |\Psi^{-1}(w)|, \qquad M(w) = \sum_{\Psi(U)=w} |F^{-1}(U)|.$$

We now fix three published predicates. Predicate P_π requires $n(w) = 5$, $M(w) = 1008$, multiplicities $(432, 144, 144, 144, 144)$, and tritic census $(2, 3, 1)$. Predicate P_e requires, over the complete orbit, singleton emissions of microscopic mass 144, union of values $\bigcup_{w \in O} \mathrm{diag}_c(w) = \{0, 3, 6\}$, and census $(2, 3, 1)$. Predicate P_φ preserves the first three conditions of P_e and requires balanced census $(2, 2, 2)$. The orientation gauges are $\mathrm{diag}_c = 6$ and the cardinal class is ES.

Theorem 15.4 (Finite orbital classification conditioned)**.** *In the reconstructed catalog, the preceding predicates select the following unique orbits without consulting digits of any constant.*

1. *There is a unique orbit of six words for which, in every word,* $n(w) = 5$*,* $M(w) = 1008$*, and the five multiplicities are* $432, 144, 144, 144, 144$*. All its words have trit census* $(n_0, n_1, n_2) = (2, 3, 1)$*. It is the dihedral orbit of the regional type of* π*.*
2. *Between the orbits radical of emissions one-point and mass microscopic* 144 *who union orbital of values* diag_c *is* $\{0, 3, 6\}$*, there exists to unique orbit with census* $(2, 3, 1)$*. Is the orbit of return of* e*.*
3. *In the same sector there is a unique balanced orbit with census* $(2, 2, 2)$*. It is the proportional orbit of* φ*.*

The orientation declared by $\mathrm{diag}_c = 6$ *and the cardinal class* ES *select, respectively,*

$$\boxed{w_\pi = 010211, \qquad w_e = 201101, \qquad w_\varphi = 121200.}$$

Proof. The exhaustive reconstruction of the 468 emissions first verifies closure of the action and groups the 243 words into orbits. It then applies the indicated predicates to all of them. The first predicate leaves a single orbit; the two singleton radical-fiber predicates respectively leave an orbit of census $(2, 3, 1)$ and one of census $(2, 2, 2)$. Finally, the orientation gauge is applied to each orbit, leaving a unique word. None of the selector predicates contains the decimal expansions of π, e or φ. □

15.1.5.1 Initial intrinsic encoder and existence of its limit

In the stratum of visible words containing exactly two zeros, there is an encoder that does arise from the TPK datum itself:

$$c_0(w) = \{j \in \{1, \dots, 6\} : w_j = 0\} \in P_2(\{1, \dots, 6\}).$$

It is D_3-equivariant because a coordinate permutation transports the zero support. On the orbits classified by the theorem 15.4, its images are

$$c_0(O_\pi) = \{\{1,2\}, \{1,3\}, \{2,3\}, \{4,5\}, \{4,6\}, \{5,6\}\},$$
$$c_0(O_e) = \{\{1,6\}, \{2,5\}, \{3,4\}\},$$

where, on the second line, each pair has two preimages within the orbit. The orbit of φ shares the first support type with π, but is separated from it by its singleton fiber, its multiplicity, and its TRIT census.

The map c_0 is the first rung of the register–pair encoder; it is not the complete family c_k. In deep blocks, (0,1,3) or (4) zeros occur, so the same formula does not take values in P_2 at every depth. Furthermore, $\{1, \dots, 6\}$ is here the hexad of coordinates of the word, not an already identified Witt hexad. Prolonging c_0 requires a phase-dependent rule and the corresponding incidence intertwiner.

The canonical microfiber of π remains exactly

$$\mathscr{R}_\pi^{\text{micro}} = \Psi^{-1}(010211),$$

formed by five distinct regions U_6. The other five words of the dihedral orbit are gauge images of that orbital form; they do not constitute five new canonical microfibers of π. Analogously, the names e and φ are applied after fixing the published predicates and gauge. The enumeration is exhaustive *relative* to those premises. Predicates and gauge are declared components of the enriched TPK reader: they are reconstructed not from the three coarse statistics appearing below, but from the complete genealogy of the emission, its orientation, its boundary, and its survival.

The sum of the six integers of an emission, its residue modulo nine, and the number of even entries do not suffice for this theorem. The oriented emission of e and three of the five regions of π share exactly

$$\sum_j u_j = 3316, \qquad \sum_j u_j \equiv 4 \pmod 9, \qquad \#\{j : u_j \text{ even}\} = 4.$$

The distinction requires the istructura of the fiber, the multiplicity, the sector radical and the orbit complete. This ablation demonstrates by que the parity and the root digital are ingredients of the reader, but not replace the transport TPK.

15.1.6 Typed correspondence $271 \to e$ and $315 \to \pi$

The theorems 15.2 a 15.4 are independent: the first constructs the semicrown from the phase clock, the second provides its relative Steiner realization, and the third classifies orbits under fixed predicates. To compose the first and third results, we declare the type dictionary that the reader must preserve:

internal type	orbital type
bidirectional pointed return boundary-plus-lateral closure	single-point radical fiber with the census of the regional branch closure orbit with five regions.

Corollary 15.5 (Typed, orbit-relative associations)**.** *Relative to the dictionary, the predicates P_e, P_π, and the preceding orientation gauges, the orbital classification produces the conditioned associations*

$$\boxed{|E_{\mathrm{ph}}| = 271 \rightsquigarrow O_e \longrightarrow w_e,} \qquad \boxed{|P_{\mathrm{ph}}| = 315 \rightsquigarrow O_\pi \longrightarrow w_\pi.}$$

In the second case, the oriented representative $w_\pi = 010211$ determines the canonical five-region microfiber $\Psi^{-1}(010211)$. The associations are obtained before Archimedean evaluation and do not use the decimal values of the constants.

Proof. By the orbital theorem, each row of the dictionary possesses a unique orbit satisfying the declared predicate. Classification is first performed at the level of the complete dihedral orbit; the oriented gauge then selects the indicated representative. Uniqueness is therefore relative to the dictionary, predicates, and gauges fixed. □

The channel $161 = \Theta + \kappa - 1 = 3\Delta - 1$ remains the integer identity. Although P_φ classifies a balanced orbit and the published gauge selects $w_\varphi = 121200$, this section does not construct a set-theoretic object of cardinality 161 whose type induces that orbit. Therefore, no reader $161 \to \varphi$ is asserted here.

The corollary depends on the type dictionary because cardinalities, taken in isolation, do not define a function into the catalogue. In the complete reader, that dictionary is realized through the nine monodromy relations of the section 6.3, together with orientation and regional survival. The important consequence is affirmative: once the structural reader has been fixed, the evaluation consults no decimal approximation of the constant.

15.1.6.1 Joint dependence of the channels on the product selector

The executable factorization of the catalog and the parametrization of its additive signature give

$$\mathcal{U}_6 \simeq \mathcal{S}_+ \times \mathcal{S}_\times, \qquad \mathcal{S}_+ \simeq D_9 \times \{\pm 1\}.$$

On the other hand,

$$\partial_{\mathrm{ph}} \simeq (D_9 \times \{\pm 1\}) \times P_2(H_{\mathrm{act}}).$$

Thus, a functional attempt at descent that preserves phase and orientation identically reduces to the map

$$q_\times : \mathcal{S}_\times \longrightarrow P_2(H_{\mathrm{act}}).$$

This is the field absent from the catalogue: the published rows end at the product signature E_{sig} and do not contain a class $P_2(H_{\mathrm{act}})$.

Proposition 15.6 (Obstruction to the isolated product selector)**.** *There is no total D_3-equivariant function*

$$q_\times : \mathcal{S}_\times \longrightarrow P_2(H_{\mathrm{act}})$$

if D_3 acts on the (26) product signatures through the published coordinate permutations r, s and on H_{act} through

$$a(x) = x + 3 \pmod 9, \qquad j(x) = -x \pmod 9.$$

Proof. The action on $\mathcal{S}_\times$ has orbits of sizes

$$6 + 6 + 6 + 3 + 3 + 1 + 1.$$

Its two globally fixed points are the signatures 000000 and 555555. The action of D_3 on the six elements of H_{act} is regular, and its induced action on the fifteen pairs has orbits

$$6 + 3 + 3 + 3,$$

with no globally fixed point. An equivariant function must map a fixed point of the source to a fixed point of the target, which is impossible. □

The obstruction precisely identifies the information lost by the isolated product signature: the fixed sectors can be resolved only by preserving phase, orientation, and the enriched record. The preceding encoder c_0 acts on the two-zero stratum, but it cannot replace the family c_k with a single column of E_{sig}.

15.1.7 Visible parity, carry parity and physical boundary

The even–odd separation can be formulated without depending on a particle label. For each of the leaves $\bullet \in \{+, \times\}$, set

$$n_+(i,j) = i + j, \qquad n_\times(i,j) = ij,$$

and let us define the two bits

$$\epsilon_R^\bullet(i,j) = \mathrm{dr}_9(n_\bullet(i,j)) \bmod 2, \qquad \epsilon_Q^\bullet(i,j) = q_9^\sharp(n_\bullet(i,j)) \bmod 2.$$

Theorem 15.7 (Parity-Carry Factorization)**.** *For the* 81 *cells of each APP sheet,*

$$\boxed{n_\bullet(i,j) \bmod 2 = \epsilon_R^\bullet(i,j) + \epsilon_Q^\bullet(i,j) \pmod 2.}$$

The exact census by pairs $(\epsilon_R, \epsilon_Q) = (00, 01, 10, 11)$ *is*

	00	01	10	11
+	16	20	20	25
×	25	5	20	31

and, therefore, the additive and multiplicative leaves possess distinct parity–carry distributions.

Proof. Reduction modulo two $n = 9q_9^\sharp(n) + \mathrm{dr}_9(n)$ gives the identity, since $9 \equiv 1 \pmod 2$. On the additive sheet, the multiplicities of $i + j$ are $1, 2, \ldots, 9, 8, \ldots, 1$; separating representative and quotient produces the first row. The same calculation on the 81 products ij produces the second. Enumeration of the 162 cells verifies the identity before accumulating the counts. □

On $\ell^2(D_9^2)$, the operators diagonal

$$\Gamma_R^\bullet f(i,j) = (-1)^{\epsilon_R^\bullet(i,j)} f(i,j), \qquad \Gamma_Q^\bullet f(i,j) = (-1)^{\epsilon_Q^\bullet(i,j)} f(i,j)$$

are commutative involutions. The unreduced parity factorizes as

$$\boxed{\Gamma_{\mathrm{raw}}^\bullet = \Gamma_R^\bullet \Gamma_Q^\bullet.}$$

This is the precise operatorial formulation of the idea that the digital root reads the visible component while the quotient preserves the drag of the coronas. The difference between the two rows of the table is also an exact form of the incompatibility between addition and product accumulation.

Each involution decomposes the space into even and odd sectors and provides an internal grading $\mathbb{Z}/2\mathbb{Z}$. A Bose–Einstein or Fermi–Dirac statistic, however, is an assertion about exchanging several indistinguishable realizations, not about the parity of a single cell. Its derivation requires an exchange functor representing symmetric or braid groups and intertwining the dynamics. HMT parity constructs the graded domain on which that functor must act; it is not identified here with its physical representation.

15.2 Derivation of the channels 90/120 through inclusion of hexad–octad incidences

With the dodecad and the alignment of the section 17.1.6 fixed, let H be a hexad in the HMT coordinates, let $\ell(H) \subset D$ be its image, and let $O_H = \iota_D(\ell(H))$ be its unique lift. Marking a point and a pair of points of the residual hexad yields

$$F_6(H) = \ell(H) \times \binom{\ell(H)}{2}, \qquad |F_6| = 6\binom{6}{2} = 90.$$

If the marked point can traverse the octad:

$$F_8(H) = O_H \times \binom{\ell(H)}{2}, \qquad |F_8| = 8\binom{6}{2} = 120.$$

The inclusion $\ell(H) \hookrightarrow O_H$ induces the incidence morphism

$$\mathcal{I}_{6\to 8} : F_6(H) \hookrightarrow F_8(H).$$

Normalizing the difference by the chosen factor $24\binom{6}{2}$ yields

$$\boxed{\frac{90-120}{24\binom{6}{2}} = \frac{6-8}{24} = -\frac{1}{12}.}$$

The equality is a normalized defect of the combinatorial interface $6 \to 8$. The factor $24\binom{6}{2}$ forms part of the definition of this normalization; the inclusion alone determines the difference -30. The operator $\mathcal{I}_{6\to 8}$ has marked incidence configurations as its domain; it is neither the transverse extractor of the dodecaphase state nor the family of angular moments.

15.3 Transport of $-1/12$ to the channels 90/120 in 5 algebraic realizations

In addition to the normalized defect of the hexad–octad inclusion, five operator realizations of the same rational number appear. Their domains are specified separately; equality of values does not identify the operators without an additional intertwiner.

15.3.1 Difference of dodecaphasic periodicities

One tooth of C_{12} measures $30°$. Then

$$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3} = -\frac{1}{12}.$$

It is the oriented difference between the periods of $90°$ and $120°$ in this realization.

15.3.2 Pseudoinverse of the Gram Operator on the Live Component

In the exact jump $60 \to 81$, two fibers have sizes 0 and 12. The Gram operator is

$$K_{60,81} = \operatorname{diag}(0, 12).$$

On the nonzero component of its range, the pseudoinverse is $1/12$; with the negative boundary orientation,

$$E_{\text{surv}} = -K^{+}_{60,81}$$

yields $-1/12$.

15.3.3 2nd difference between triadic scales

Define

$$T_L = \sum_{n=1}^{L-1} n(L-n) = \frac{L(L^2-1)}{6}, \qquad a(L) = -\frac{T_L}{L^2} = -\frac{L}{6} + \frac{1}{6L}.$$

The first scale subtraction is

$$A_1(L) = a(L) - \frac{a(3L)}{3} = \frac{4}{27L},$$

and the second

$$C(L) = LA_1(L) - \frac{3L}{3}A_1(3L) = \frac{8}{81}.$$

The residue $8/81$ is independent of L. To obtain $-1/12$, the declared normalization is applied

$$R(L) = -\frac{27}{32}C(L) = -\frac{1}{12}.$$

The calculation derives $8/81$; it does not by itself derive the factor $-27/32$.

15.3.4 Composition of modular transformations and preservation of the signed state

The eta function satisfies

$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12}\prod_{n\geq 1}(1+q^n+q^{2n})^{-1}.$$

The exponent comes from $1/24 - 3/24 = -1/12$. Taking twelve copies:

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots .$$

The coefficient 54 coincides with the APP defect. The rational identity

$$j = \frac{(t_3+27)(t_3+243)^3}{t_3^3}$$

establishes the connection with the classical modular branch.

15.3.5 Defect of cyclic difference projectors

Let S be the cyclic shift on $\mathbb{Q}^{12}$ and define

$$D_r = I - S^r.$$

The kernel of D_r consists of the vectors constant on each orbit of S^r; therefore,

$$\dim\ker D_r = \gcd(12, r).$$

Let $\Pi_{\ker D_3}$ and $\Pi_{\ker D_4}$ be the rational projectors onto $\ker D_3$ and $\ker D_4$, and let $\tau(T) = \mathrm{Tr}(T)/12$ be the normalized trace. Then

$$\boxed{\tau(\Pi_{\ker D_3} - \Pi_{\ker D_4}) = \frac{\operatorname{rank}\Pi_{\ker D_3} - \operatorname{rank}\Pi_{\ker D_4}}{12} = \frac{3-4}{12} = -\frac{1}{12}.}$$

This realization expresses the rational as the transverse defect of steps three and four in the twelve-phase cycle.

Remark 15.8 (Domains of the realizations). The APP defect 54, the eta exponent $-1/12$, the combinatorial defect of the hexad–octad lift, and the modular identities once t_3 has been fixed are exact. The value of

the pseudoinverse, the normalized extractor, and the projector defect are likewise exact. Each equality preserves its domain and its corresponding map.

15.4 Barbero–Immirzi parameter: area operator, spectrum, channel intertwiner, and modular entropy

The HMT identification of the functional $\Gamma_{6\to 8}$ with the Barbero–Immirzi coordinate is carried out on the same triadic boundary that supports the incidence (90/120). The bulk and its boundary sheet have the same cardinality,

$$\mathcal{B} = (\mathbb{Z}/9\mathbb{Z})^3, \quad |\mathcal{B}| = 729, \qquad \partial\mathcal{B} = (\mathbb{Z}/27\mathbb{Z})^2, \quad |\partial\mathcal{B}| = 729,$$

by regrouping six trits into three nonadic coordinates or two coordinates of order twenty-seven.

Theorem 15.9 (Areal Law of Triadic Cutoff)**.** *In the cubic graph $N \times N \times N$ with unit capacity, the minimum cut between two opposite faces has capacity N^2. For $N = 9$,*

$$\mathcal{A}_{\min} = 81, \qquad S_{\mathrm{tri}} = \mathcal{A}_{\min} \log 3 = 81 \log 3.$$

Proof. The N^2 lines parallel to the normal direction are edge-disjoint paths, so every cut intercepts them. A transverse layer contains exactly N^2 edges and attains the bound. Each triadic link contributes $\log 3$ to the entropy of a maximally mixed state. □

On the boundary torus 27×27, let A be the canonical block 9×9. Its boundary decomposes exactly into

$$\partial A = \partial A_{90} \sqcup \partial A_{120}, \qquad |\partial A_{90}| = |\partial A_{120}| = 18. \tag{15.1}$$

The horizontal links represent channel (90), and the vertical ones channel (120). This decomposition turns the pair of incidences into an operator decomposition of the boundary.

The areal entropy $S_{\mathrm{tri}} = 81 \log 3$ belongs to the maximally mixed state of the cut links. The bilayer entropy $S_{\mathrm{bi}}(y)$ of the definition 73.2 belongs to the normalized distribution between the two sheets; the two objects retain distinct domains.

Let $N = \mathrm{diag}(0, 1, 2)$ be the number operator of a tritic link. The areal realization declares the positive scale

$$\theta_{\mathrm{clk}} = \frac{C^*}{6}\frac{\pi}{180}, \qquad a_0 = \frac{1 + 2\cos(10^\circ)}{3}\,\theta_{\mathrm{clk}}, \qquad \gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}.$$

The formula for a_0 constitutes the starting structure of this realization; once that scale is fixed, the operator and its spectrum follow exactly.

Definition 15.10 (Area Operator HMT)**.** On the boundary sheet $\mathcal{H}_\partial = \bigotimes_{e\in\partial A} \mathbb{C}^3$, define

$$\widehat{\mathcal{A}}_{\mathrm{HMT}} = \gamma_{\mathrm{HMT}} a_0 \sum_{e\in\partial A} N_e. \tag{15.2}$$

Its spectrum in the canonical cut is

$$\mathrm{Spec}\,\widehat{\mathcal{A}}_{\mathrm{HMT}} = \{n\gamma_{\mathrm{HMT}} a_0 : 0 \le n \le 72\},$$

with multiplicities given by the coefficients of $(1 + z + z^2)^{36}$. Prolongation through compatible cuts produces the protected family $\mathcal{A}_n^{\mathrm{prot}} = n\gamma_{\mathrm{HMT}} a_0$.

The intertwiner that fixes normalization is constructed in the subspace of collective channels. Let u_{90}, u_{120} be the uniform unit vectors of the hexadic and octadic incidences, and let v_{90}, v_{120} be the uniform unit vectors of the two sets of links of (15.1). The map

$$\begin{aligned} \mathcal{J}_{6\to 8} :\ \operatorname{span}\{u_{90}, u_{120}\} &\longrightarrow \operatorname{span}\{v_{90}, v_{120}\}, \\ \mathcal{J}_{6\to 8} u_{90} = v_{90}, &\qquad \mathcal{J}_{6\to 8} u_{120} = v_{120} \end{aligned} \tag{15.3}$$

is an isometry between these collective subspaces. If

$$D_{\mathrm{inc}} = 90|u_{90}\rangle\langle u_{90}| + 120|u_{120}\rangle\langle u_{120}|, \qquad D_{\mathrm{area}} = 90|v_{90}\rangle\langle v_{90}| + 120|v_{120}\rangle\langle v_{120}|,$$

then

$$\boxed{\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\mathrm{area}} \mathcal{J}_{6\to 8}.}$$

In particular, the primitive combination $12 : -1$ acts with the same coefficients before and after $\mathcal{J}_{6\to 8}$. This equality fixes the normalization dictionary that inserts $\gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}$ into the Ashtekar–Barbero connection.

The information retained by reduction to the region is published through the modular Hamiltonian. The starting structure of this reading is declared to be

$$\Delta_4^{\mathrm{mod}} = \frac{(A - C^*)\pi/180}{9 \cdot 90} \left(1 - \frac{7}{12}\frac{\pi}{729}\right), \qquad w_{90} = 90\Delta_4^{\mathrm{mod}}, \quad w_{120} = 120\Delta_4^{\mathrm{mod}},$$

we define

$$\begin{aligned} K_{\mathrm{link}}(w) = wN, \qquad \rho_{\mathrm{link}}(w) &= \frac{\operatorname{diag}(1, e^{-w}, e^{-2w})}{1 + e^{-w} + e^{-2w}}, \\ \rho_A = \bigotimes_{e\in\partial A_{90}} \rho_{\mathrm{link}}(w_{90}) \otimes \bigotimes_{e\in\partial A_{120}} \rho_{\mathrm{link}}(w_{120}), &\qquad K_A = -\log \rho_A. \end{aligned} \tag{15.4}$$

Then

$$K_A = \sum_{e\in\partial A} w_e N_e + c\mathbf{1}, \qquad S(\rho_A) = 18S(w_{90}) + 18S(w_{120}),$$

and the evaluation of that starting structure gives

$$S(\rho_A) = 39.54837320881808\ldots \text{ nats} = 57.05624190358778\ldots \text{ bits}.$$

The quantity $S(\rho_A)$ is the von Neumann entropy of the declared mixed product. A global purification identifies it with an entanglement entropy across the cut; without that purification, its canonical type is reduced modular entropy. Thus, γ_{HMT} fixes the quantum of area/torsion, S_{tri} counts the areal capacity, S_{bi} quantifies the allocation between sheets, and $S(\rho_A)$ measures modular mixing. Area operator, spectrum, and intertwiner belong to a single boundary construction.

15.5 Hexadic–octadic incidence and the Barbero–Immirzi functional

Let $H \hookrightarrow O$ be a marked inclusion, $|H| = 6$, $|O| = 8$. The incidence objects

$$\mathcal{F}_6 = H \times \binom{H}{2}, \qquad \mathcal{F}_8 = O \times \binom{H}{2}$$

have cardinalities 90 and 120. Their normalized difference gives

$$\frac{|\mathcal{F}_6| - |\mathcal{F}_8|}{24\binom{6}{2}} = -\frac{1}{12}.$$

This is a combinatorial realization of the same scalar. Numerical equality with (14.85) does not erase the distinction between the spaces on which it was computed.

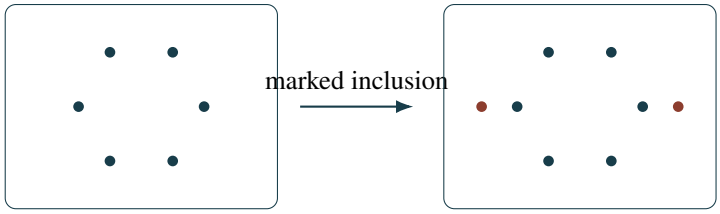

Figure 15.1: Marked incidence from six to eight points. The drawing represents the sets and inclusion; it does not attempt to turn the faces or vertices of a cube into Steiner blocks without their incidence map.

15.5.1 Dodecaphase fundamental chain and pole coefficient

In the free module of oriented events, the fundamental chain of the turn is expressed as

$$c_{12}^{+} = \sum_{j \in \mathbb{Z}/12\mathbb{Z}} [j, \mathcal{F}_6] - [\partial_{\mathrm{ret}}, \mathcal{F}_8].$$

Multiplicity twelve corresponds to the sectors and multiplicity one to the oriented seam. The involution reverses orientation of the complete chain. Let

$$S_m(q) = \frac{q^m}{1 - q^{3m}}, \qquad 0 < q < 1.$$

The linear reader assigns S_{90} to every sector and S_{120} to the seam; consequently,

$$\mathscr{R}(c_{12}^{+}) = 12 S_{90} - S_{120}.$$

Theorem 15.11 (Pole coefficient and conjugate evaluation)**.** *The image of the fundamental chain has coefficient* $1/24$ *relative to* $(1-q)^{-1}$ *and residue* $-1/24$ *relative to* $(q-1)^{-1}$*. Its evaluation on the previously generated channels determines*

$$\gamma_{\mathrm{HMT}} = \frac{\pi A C^{*}}{180} + 12\big[S_{90}(q_{-}) - S_{90}(q_{+})\big] - \big[S_{120}(q_{-}) - S_{120}(q_{+})\big]. \tag{15.5}$$

Proof. The factorization $1 - q^{3m} = (1-q)\sum_{j=0}^{3m-1} q^{j}$ implies $\lim_{q\uparrow 1}(1-q)S_m(q) = 1/(3m)$. By linearity,

$$\frac{12}{270} - \frac{1}{360} = \frac{1}{24}.$$

The coordinate $q - 1$ reverses the residue's sign. The conjugate evaluation and the source's angular component produce (15.5). □

The Diophantine certificate $4a - 3b = 45$ admits the pairs $(12 + 3t, 1 + 4t)$, $t \geq 0$; it certifies minimality of $(12, 1)$ but does not replace the origin of multiplicities in the chain. The evaluation of (15.5) is

$$\gamma_{\mathrm{HMT}} = 0.27400767269445927474725526077398041940\ldots.$$

This number is an output of the source functional; it is not an external value used to select A, C^{*}, or their coefficients.

15.5.2 Parity and structural sensitivity

Reversing C^* exchanges q_+ and q_- and changes the sign of the angular component. Therefore

$$\gamma_{\mathrm{HMT}}(A, -C^*) = -\gamma_{\mathrm{HMT}}(A, C^*).$$

The functional preserves orientation, whereas other readers, such as q_+q_-, are even. This difference precedes its physical interpretation.

15.5.3 Structural dependence of the functional and areal normalization

The preceding construction places the Barbero–Immirzi parameter at the intersection of three determinations: marked incidence, dodecaphase orientation and angular evaluation. Incidence supplies the event spaces; orientation fixes the chain on those spaces; evaluation transports the chain to a dimensionless quantity. This decomposition preserves the origin of each coefficient when the functional is subsequently used in area geometry.

The inclusion $\mathcal{F}_6 \hookrightarrow \mathcal{F}_8$ maintains the marked pair of the hexad. Its complement has cardinality $2\binom{6}{2} = 30$. This increment reappears as the determinant of the map reconstructing boundary occupations from area and the weighted observable. Equality of both integers has a concrete explanation here: sector weights differ precisely by the number of events added by the marked inclusion.

Proposition 15.12 (Incidence and recoverability of occupations)**.** *Let n_6, n_8 be the aggregate occupations of two sectors, and let $r_6 = |\mathcal{F}_6|$, $r_8 = |\mathcal{F}_8|$. The map*

$$(n_6, n_8) \longmapsto (n_6 + n_8, r_6 n_6 + r_8 n_8)$$

is invertible on its image when inclusion adds at least one event. For the constructed inclusion, its determinant is 30.

Proof. The matrix of the map is $\left(\begin{smallmatrix} 1 & 1 \\ r_6 & r_8 \end{smallmatrix}\right)$. Its determinant is $r_8 - r_6 = |\mathcal{F}_8 \setminus \mathcal{F}_6|$. The inclusion considered adds $2\binom{6}{2} = 30$ events. Linear inversion recovers both occupations and preserves the integer restrictions inherent to its image. □

The result recovers aggregate occupations. Information about each link and the ordering of events remains in the complete state and its additional readers. This hierarchy precisely formulates the difference between area value and boundary genealogy: area preserves a sum; the observable pair preserves that sum's sector decomposition; the register additionally preserves its distribution and history.

The parameter γ_{HMT} transports that incidence to the areal scale. Its structural interpretation is that of an oriented coefficient of the hexadic–octadic return functional. The gravitational realization subsequently identifies it in the Holst action. This distinguishes its intrinsic definition, value and function in the physical equation.

15.5.4 Structural definition and role of the Barbero–Immirzi parameter

Definition 15.13 (Oriented evaluation of hexadic–octadic incidence)**.** The parameter γ_{HMT} is the conjugate evaluation of the fundamental chain c_{12}^+, completed by its angular component. On the domain $0 < q_\pm < 1$, its definition (15.5) takes the form

$$\gamma_{\mathrm{HMT}} = \frac{\pi A C^*}{180} + [\mathscr{R}(c_{12}^+)](q_-) - [\mathscr{R}(c_{12}^+)](q_+). \tag{15.6}$$

The marked incidence supplies the event spaces; the oriented chain fixes their multiplicities; the channels in (14.102) perform the evaluation.

The determination jointly uses the cardinalities 90, 120, the twelve sector contributions, and the return seam. The pole coefficient $1/24$ and Diophantine minimality verify the compatibility of these weights

with the normalization. Their provenance is preserved in c_{12}^{+}, before the channels are evaluated. Angular inversion exchanges q_+ and q_- and produces $\gamma_{\mathrm{HMT}}(A,-C^*) = -\gamma_{\mathrm{HMT}}(A,C^*)$: the dimensionless value transports an orientation of the incidence.

In the geometric realization, this same coefficient enters (80.12) and the area increment $\gamma_{\mathrm{HMT}} a_0 \ell_P^2$. The Holst action uses $\gamma_{\mathrm{HMT}} \neq 0$; the positive areal magnitude uses $|\gamma_{\mathrm{HMT}}|$. Proposition 80.20 makes the coordinated change of orientation explicit. Thus, the structure of the parameter explains what it weights in the incidence, what it preserves under transport, and how it participates in the torsional response and in the geometric resolution of information.

15.6 Action ellipse and modular reciprocity

With the outputs $A, C^*, \hbar > 0$ fixed in the chart $|C^*/A| < 1$, define

$$\eta_{\mathrm{el}} = \operatorname{artanh}(C^*/A), \quad a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}, \quad b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}.$$

The balanced canonical coordinates have units of square root of action; position and momentum are not added here without a dimensional chart. We have

$$a_S b_S = 2\hbar, \qquad \tau_{\mathrm{el}} = i\,\frac{b_S}{a_S}, \qquad R_{\mathrm{el}} = \sqrt{\frac{b_S}{a_S}} = \left(\frac{A - C^*}{A + C^*}\right)^{1/4}.$$

The positive root determines the composition $\tau_{\mathrm{el}} = iR_{\mathrm{el}}^2$ and recovers the angular ratio:

$$\frac{C^*}{A} = \frac{1 - R_{\mathrm{el}}^4}{1 + R_{\mathrm{el}}^4}.$$

Shape inversion sends R_{el} to R_{el}^{-1} and τ_{el} to $-1/\tau_{\mathrm{el}}$; Equation (15.11) develops shape reciprocity.

Proposition 15.14 (Coincident energy, distinguishable action)**.** *Let*

$$D(\eta) = \begin{pmatrix} e^{\eta} & 0 \\ 0 & e^{-\eta} \end{pmatrix}, \quad S_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad J_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Both maps satisfy $T^{\mathsf{T}} D(-\eta) T = D(\eta)$. However, for $\omega = \mathrm{d}Q \wedge \mathrm{d}P$,

$$S_2^* \omega = -\omega, \qquad J_2^* \omega = \omega.$$

If $\mathcal{I}(\gamma) = \oint_\gamma P\ \mathrm{d}Q$ along a closed curve,

$$\mathcal{I}(S_2\gamma) = -\mathcal{I}(\gamma), \qquad \mathcal{I}(J_2\gamma) = \mathcal{I}(\gamma).$$

Proof. Conjugation interchanges the diagonal entries of D. The determinants of S_2, J_2 are $-1, 1$, respectively, which proves the transformation of ω. For $\lambda = P\ \mathrm{d}Q$,

$$S_2^* \lambda = \mathrm{d}(PQ) - \lambda, \qquad J_2^* \lambda = \lambda - \mathrm{d}(PQ).$$

Integrating the exact differential along the closed curve completes the proof. □

The quadratic energy and the modulus do not suffice to distinguish the two transports. The orientation of the action does distinguish them, even in the circular form. The geometric marking is thus part of the recoverable reading, not an embellishment added to the value.

15.6.1 Semiaxes, foci, and interior radii

The figure is obtained from the angular and action outputs of the preceding sections. APP preserves the sheets and their residues and quotients; TRIT fixes the orientation; TPK transports the boundary, carry and memory to the expressions of the same enriched state and the joint discrete structure of the continuum. Here the pair (A, C^*) and the positive section $\hbar$ are received after that construction. The geometry makes explicit the information preserved by their readers, without using an observed length to select the source state. Section 15.6.1 develops this realization from the readers already generated, and the angular construction is retained in Section 14.11.6.

Let $\xi = C^*/A \in (-1, 1)$, with $A \neq 0$ and both angles in the same unit. Write $\eta = \operatorname{artanh} \xi$ and

$$a_S = \sqrt{2\hbar}\, e^{\eta/2}, \qquad b_S = \sqrt{2\hbar}\, e^{-\eta/2}, \qquad \gamma(\theta) = (a_S \cos\theta, b_S \sin\theta).$$

The semiaxes are labelled by their coordinates: if $\eta < 0$, the vertical axis is the major axis. Both belong to the square-root-of-action line of the balanced chart, not to the line of spatial lengths.

Proposition 15.15 (Focal geometry and radial interior)**.** *Let $a = \max(a_S, b_S)$, $b = \min(a_S, b_S)$. The focal half-distance and eccentricity are*

$$f_S = \sqrt{a^2 - b^2} = \sqrt{4\hbar \sinh|\eta|}, \qquad e_f = \frac{f_S}{a} = \sqrt{1 - e^{-2|\eta|}}. \tag{15.7}$$

For $\eta > 0$, the foci are $(\pm f_S, 0)$; for $\eta < 0$, they are $(0, \pm f_S)$. At $\eta = 0$ they coincide with the centre. The boundary radius in polar direction ϕ is

$$\rho_\partial(\phi) = \left(\frac{\cos^2\phi}{a_S^2} + \frac{\sin^2\phi}{b_S^2} \right)^{-1/2}. \tag{15.8}$$

The interior segment in that direction consists of $r(\cos\phi, \sin\phi)$, with $0 \le r < \rho_\partial(\phi)$. In particular, $b \le \rho_\partial(\phi) \le a$.

Proof. The squares of the major and minor semiaxes are $2\hbar e^{|\eta|}$ and $2\hbar e^{-|\eta|}$. Their difference gives (15.7). To verify the focus, suppose $\eta > 0$. At $X = \gamma(\theta)$, the distances to $F_+ = (f_S, 0)$ and $F_- = (-f_S, 0)$ satisfy

$$|X - F_+|^2 = (a_S - f_S \cos\theta)^2, \qquad |X - F_-|^2 = (a_S + f_S \cos\theta)^2.$$

Since $a_S > f_S$, its positive roots sum to $2a_S$. For $\eta < 0$, interchanging the coordinates gives the same proof. In the circular case, $f_S = 0$. Finally, substituting $(Q, P) = r(\cos\phi, \sin\phi)$ into $Q^2/a_S^2 + P^2/b_S^2 = 1$ gives (15.8). The coefficient of r^2 lies between a^{-2} and b^{-2}, proving the bounds and the characterization of the interior. □

15.6.2 Parametric phase, polar angle, and action area

Proposition 15.16 (Areal law and two angular coordinates)**.** *The phase θ of γ and its continuous polar angle ϕ, lifted from zero, satisfy*

$$\phi(\theta) = \arg(a_S \cos\theta + i b_S \sin\theta), \qquad \frac{d\phi}{d\theta} = \frac{a_S b_S}{a_S^2 \cos^2\theta + b_S^2 \sin^2\theta} > 0. \tag{15.9}$$

In a chart where both tangents are defined, $\tan\phi = (b_S/a_S)\tan\theta$. The oriented swept area is

$$\mathcal{A}(\theta) = \frac{1}{2} \int_0^\theta (QP' - PQ')\, dt = \hbar\theta, \qquad \mathcal{A}(1) = \hbar, \qquad \mathcal{A}(2\pi) = h. \tag{15.10}$$

Proof. The derivative of the argument of a nonzero vector is $(QP' - PQ')/(Q^2 + P^2)$. Here the numerator is $a_S b_S = 2\hbar$, proving the derivative and monotonicity. The quotient P/Q gives the tangent relation; the continuous lift fixes the quadrants and the number of turns. The area integral is $a_S b_S \theta/2 = \hbar\theta$, and $h = 2\pi\hbar$ gives the last identity. □

The parametric phase does not generally coincide with the polar angle. One radian of phase sweeps out $\hbar$, but this does not identify it with a circular arc or a sector of unit polar angle. In polar coordinates, the same law is written $d\mathcal{A} = \rho_\partial(\phi)^2 d\phi/2$. With the orientation of γ used here, $\oint P\,dQ = -h$: the positive area is h, whereas the integral of that one-form retains its sign. This agrees with the distinction between the symplectic and antisymplectic transports of the preceding section.

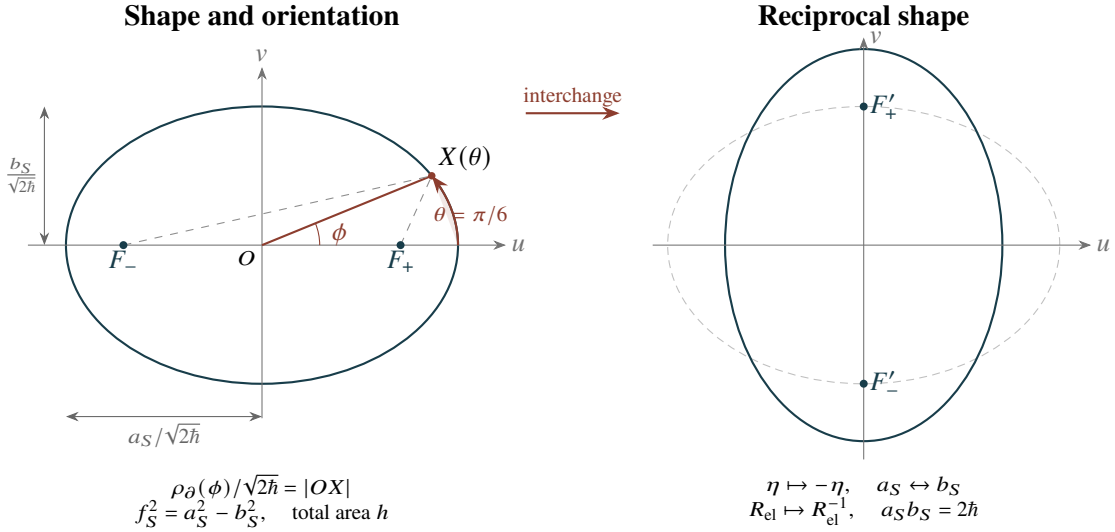

Figure 15.2: Semiaxes, foci and reciprocity of the action ellipse in the normalized coordinates $u = Q/\sqrt{2\hbar}$, $v = P/\sqrt{2\hbar}$. The marked sector has parametric phase $\theta = \pi/6$, distinct from its polar angle ϕ; its action area is $\hbar\pi/6$. The figure uses the algebraic case $\xi = 1/3$ to make the relations legible: it does not assign that value to the HMT angular output. The foci are calculated from the semiaxes. On the right, interchanging the axes preserves the total area h and inverts the dimensionless modular radius.

For the control case in the figure, $\xi = 1/3$, the normalized coordinates are exactly

$$\eta = \tfrac{1}{2}\log 2, \qquad \frac{a_S}{\sqrt{2\hbar}} = 2^{1/4} = 1.1892071150\ldots, \qquad \frac{b_S}{\sqrt{2\hbar}} = \frac{f_S}{\sqrt{2\hbar}} = R_{\mathrm{el}} = 2^{-1/4} = 0.8408964153\ldots.$$

These are regression values for the drawing, not values assigned to the angular generator. The local certificate also checks the circular form and the orientations $\xi = \pm 1/3, \pm 3/5$.

15.6.3 Shape reciprocity and interior distance

The rectangular expression recovers

$$R_{\mathrm{el}} = \sqrt{b_S/a_S} = e^{-\eta/2}, \qquad R_{\mathrm{el}}^4 = \frac{1-\xi}{1+\xi}, \qquad \xi = \frac{1 - R_{\mathrm{el}}^4}{1 + R_{\mathrm{el}}^4}. \tag{15.11}$$

The proof consists of substituting $2\eta = \log((1+\xi)/(1-\xi))$. Interchanging the axes sends η to $-\eta$, R_{el} to R_{el}^{-1} and $\tau = iR_{\mathrm{el}}^2$ to $-1/\tau$. It preserves $a_S b_S$. The radius R_{el} is dimensionless; the polar radius ρ_∂ has units of square root of action.

The interior also admits the Hilbert projective distance. If z_-, x, y, z_+ are ordered along a chord of the ellipse, define

$$d_H(x,y) = \frac{1}{2}\log\frac{|y-z_-|\,|x-z_+|}{|x-z_-|\,|y-z_+|}.$$

This distance is dimensionless: the units cancel in the cross-ratio. The normalization $(Q,P) \mapsto (Q/a_S, P/b_S)$ maps the ellipse to the unit disk and preserves that ratio, since lengths along a single straight line are multiplied by a common factor. It thus transports the metric to the Beltrami–Klein model. Neither this interior distance nor the distance between the foci is identified with an atomic length.

15.6.4 Bohr radius: a consequence of the action scale

In the electrodynamic realization, the Bohr scale is expressed as $a_{\mathrm{B}} = \hbar/(m_e c\alpha)$ [181]. In the chain of the present article, that reading follows the constructions of action, vacuum, fine structure and electron mass. Here $\hbar, m_e, c, \alpha > 0$ are received in the same dimensional realization.

Proposition 15.17 (Areal expression of the Bohr scale)**.** *In that realization,*

$$a_{\mathrm{B}} = \frac{a_S b_S}{2m_e c\alpha} = \frac{\mathcal{A}(2\pi)}{2\pi m_e c\alpha} = \frac{\bar{\lambda}_C(m_e)}{\alpha}, \qquad \bar{\lambda}_C(m_e) = \frac{\hbar}{m_e c}. \tag{15.12}$$

Proof. The identities $a_S b_S = 2\hbar$ and $\mathcal{A}(2\pi) = 2\pi\hbar$, substituted into the Bohr expression, give the first two terms. The definition of $\bar{\lambda}_C(m_e)$ gives the third. □

The numerator has the dimension of action and $m_e c$ that of momentum; the quotient is a length. This composition uses the product of the semiaxes and the other three quantities: it does not assert that the Bohr scale is a semiaxis, a focus, a Hilbert distance or the modular radius. Nor does it equate the electron mass with the circular quantum of order 108. The notation a_{B} avoids confusing this length with the normalization a_0 of the area operator.

15.6.5 Inductive–capacitive realization and constitutive continuity

The electrodynamic bridge of the ellipse preserves an additional chart: a clock $\omega > 0$ and a reference impedance $Z_* > 0$. The construction recovered from the corpus defines

$$L_\eta = \frac{Z_*}{\omega}e^{-\eta}, \qquad C_\eta = \frac{1}{Z_*\omega}e^{\eta}, \qquad Z_\eta = \sqrt{L_\eta/C_\eta}. \tag{15.13}$$

Here C_η is capacitance, distinct from the counterangle C^*.

Proposition 15.18 (Dynamic product and constitutive quotient)**.** *In the preceding chart,*

$$L_\eta C_\eta = \omega^{-2}, \qquad \frac{Z_\eta}{Z_*} = e^{-\eta} = \frac{b_S}{a_S} = R_{\mathrm{el}}^2. \tag{15.14}$$

With $Q = \sqrt{Z_*}\,q$, $P = \Phi/\sqrt{Z_*}$, the energy $H_{LC} = q^2/(2C_\eta) + \Phi^2/(2L_\eta)$ takes the form

$$H_{LC} = \frac{\omega}{2}(e^{-\eta}Q^2 + e^{\eta}P^2).$$

On $\gamma(\theta)$, its electric and magnetic components are $U_E = \hbar\omega\cos^2\theta$ and $U_B = \hbar\omega\sin^2\theta$; their sum is $\hbar\omega$.

Proof. The product in (15.13) cancels the exponents and Z_*; its quotient is $Z_*^2 e^{-2\eta}$. Taking the positive root and using (15.11) gives (15.14). Substituting $q = Q/\sqrt{Z_*}$ and $\Phi = \sqrt{Z_*}P$ into H_{LC} gives its balanced form. Finally, the semiaxes of γ cancel the factors $e^{\mp\eta}$, and $\cos^2\theta + \sin^2\theta = 1$. □

This bridge distinguishes the shape, the clock and the transducer. The choice of dynamic direction must agree with the symplectic convention: for the equations $\dot{Q} = \partial_P H$, $\dot{P} = -\partial_Q H$, the preceding parametrization satisfies $\dot{\theta} = -\omega$. The energy identities do not depend on reversing that path.

The vacuum resolvent reader acts on the channels already produced $q_\pm = e^{-(A_{\mathrm{rad}} \pm C^*_{\mathrm{rad}})}$ and the incidence 90/120. Its responses $r_\pm = (1 - q_\pm^{90})/(1 - q_\pm^{120})$ express $\widehat{Z} = r_-/r_+$ and $\widehat{c} = (r_+ r_-)^{-1}$. These are spectral responses, not geometric radii. The identity (15.14) fixes the LC realization here; identifying it with the constitutive impedance of the vacuum preserves the map between both readers and their charts. Their values are not equated merely because they share the angular antecedent.

15.6.6 Canonical covariance and reciprocity of the action ellipse

The preceding construction determines two complementary invariants: the product of the semiaxes fixes the action area and their quotient preserves the anisotropy of the angular pair. We now specify the canonical realization in which these semiaxes are two standard deviations. The starting structure is the ellipse already obtained from the angular and action expressions of APP–TRIT–TPK; the operator realization is established after that construction.

In this subsection we write $\eta = \eta_{\mathrm{el}} = \operatorname{artanh}(C^*/A)$, with $|C^*/A| < 1$ and $\hbar > 0$. The angular quotient uses the same unit for both its components. In the balanced coordinates (Q, P), both of square-root-of-action dimension, we define

$$V_\eta := \frac{1}{4}\begin{pmatrix} a_S^2 & 0 \\ 0 & b_S^2 \end{pmatrix} = \frac{\hbar}{2}\begin{pmatrix} e^{\eta} & 0 \\ 0 & e^{-\eta} \end{pmatrix}. \tag{15.15}$$

This positive matrix has entries of action dimension. Its interpretation as a quantum covariance is specified by the following realization.

Proposition 15.19 (Gaussian realization of the action covariance)**.** *Consider the canonical representation on $L^2(\mathbb{R}, dQ)$, with $\widehat{Q} f(Q) = Q f(Q)$ and $\widehat{P} f(Q) = -i\hbar f'(Q)$, initially on the Schwartz space $\mathcal{S}(\mathbb{R})$. The normalized state*

$$\psi_\eta(Q) = \left(\pi\hbar e^{\eta}\right)^{-1/4} \exp\!\left(-\frac{Q^2}{2\hbar e^{\eta}}\right) \tag{15.16}$$

has zero means and covariance matrix V_η. In particular,

$$(\Delta Q)^2 = \frac{\hbar e^{\eta}}{2}, \qquad (\Delta P)^2 = \frac{\hbar e^{-\eta}}{2}, \qquad \operatorname{Cov}(Q, P) = 0, \qquad \det V_\eta = \frac{\hbar^2}{4}. \tag{15.17}$$

This realization saturates the Robertson–Schrödinger inequality.

Proof. The preceding operators are essentially self-adjoint on $\mathcal{S}(\mathbb{R})$, which is a common invariant core; on this space, $[\widehat{Q}, \widehat{P}] = i\hbar I$. For $\widehat{Y} = (\widehat{Q}, \widehat{P})$, the symmetric covariance is

$$V_{jk} = \frac{1}{2}\left\langle (\widehat{Y}_j - \langle \widehat{Y}_j \rangle)(\widehat{Y}_k - \langle \widehat{Y}_k \rangle) + (\widehat{Y}_k - \langle \widehat{Y}_k \rangle)(\widehat{Y}_j - \langle \widehat{Y}_j \rangle) \right\rangle.$$

With $s = \hbar e^{\eta} > 0$, let $I_s = \int_{\mathbb{R}} e^{-Q^2/s}\, dQ$. The product of two equal integrals, evaluated in polar coordinates, gives $I_s^2 = 2\pi \int_0^\infty r e^{-r^2/s}\, dr = \pi s$. Moreover, the integral of $\frac{d}{dQ}(Q e^{-Q^2/s})$ is zero, owing to decay at both endpoints; hence $\int_{\mathbb{R}} Q^2 e^{-Q^2/s}\, dQ = s I_s/2$. These identities and parity prove normalization, the zero mean and $\langle \widehat{Q}^2 \rangle = s/2$. Moreover, $\widehat{P}\psi_\eta = i e^{-\eta} Q \psi_\eta$. Therefore, $\langle \widehat{P} \rangle = 0$, $\|\widehat{P}\psi_\eta\|^2 = \hbar e^{-\eta}/2$ and $\operatorname{Re}\langle \widehat{Q}\psi_\eta, \widehat{P}\psi_\eta \rangle = 0$.

For any normalized state in that domain, Cauchy–Schwarz applied to $(\widehat{Q} - \langle \widehat{Q} \rangle)\psi$ and $(\widehat{P} - \langle \widehat{P} \rangle)\psi$ gives

$$(\Delta Q)^2 (\Delta P)^2 \geq \operatorname{Cov}(Q, P)^2 + \frac{1}{4}\left|\langle [\widehat{Q}, \widehat{P}] \rangle\right|^2 = \operatorname{Cov}(Q, P)^2 + \frac{\hbar^2}{4}.$$

The computed variances attain equality. Equivalently, the operator

$$a_\eta = \frac{e^{-\eta/2}\widehat{Q} + ie^{\eta/2}\widehat{P}}{\sqrt{2\hbar}}$$

satisfies $[a_\eta, a_\eta^\dagger] = I$ and $a_\eta \psi_\eta = 0$, by direct substitution. □

Proposition 15.20 (Area, dispersion, and reciprocal transport)**.** *The action ellipse is exactly the covariance sublevel set*

$$\mathcal{E}_\eta = \left\{ y = (Q,P)^\mathsf{T} : y^\mathsf{T} V_\eta^{-1} y \le 4 \right\} = \left\{ \frac{Q^2}{a_S^2} + \frac{P^2}{b_S^2} \le 1 \right\}. \tag{15.18}$$

Its area is $h = 2\pi\hbar$, its semiaxes are $a_S = 2\Delta Q$, $b_S = 2\Delta P$, and

$$\frac{\Delta P}{\Delta Q} = e^{-\eta} = \frac{b_S}{a_S} = R_{\mathrm{el}}^2. \tag{15.19}$$

The canonical rotation J_2 of Section 15.6 transports V_η to $V_{-\eta}$ and preserves the symplectic form.

Proof. Inverting the diagonal matrix (15.15) gives (15.18). Its semiaxes are the positive roots of four times its variances, and

$$\mathrm{Area}(\mathcal{E}_\eta) = 4\pi\sqrt{\det V_\eta} = 2\pi\hbar = h,$$

in agreement with the areal law (15.10). The ratio of the positive roots proves (15.19). If $M_\eta = \mathrm{diag}(e^{\eta/2}, e^{-\eta/2})$, then

$$V_\eta = M_\eta V_0 M_\eta^\mathsf{T}, \qquad M_\eta^\mathsf{T} J_2 M_\eta = J_2, \qquad J_2 V_\eta J_2^\mathsf{T} = V_{-\eta}.$$

These identities follow by multiplication. In operator terms, $(\widehat{Q}', \widehat{P}') = (-\widehat{P}, \widehat{Q})$ preserves $[\widehat{Q}', \widehat{P}'] = i\hbar I$. The permutation $S_2 : (Q,P) \mapsto (P,Q)$ also exchanges the variances but reverses the sign of the commutator and of the symplectic form. Thus covariance transport respects the distinction between canonical reciprocity and orientation reversal already established in Section 15.6. □

Position, momentum, and dimensional transduction. Let $\lambda_{xp} > 0$ be a factor of the dimensional chart, with the dimension of momentum per unit length. The transformation

$$Q = \sqrt{\lambda_{xp}}\, x, \qquad P = \frac{p_x}{\sqrt{\lambda_{xp}}}$$

realizes the balanced pair as a position x and its conjugate momentum p_x; it preserves $dQ \wedge dP = dx \wedge dp_x$ and $[\widehat{x}, \widehat{p}_x] = i\hbar I$. By transformation of covariance,

$$V_\eta^{(x,p_x)} = \frac{\hbar}{2}\begin{pmatrix} e^\eta/\lambda_{xp} & 0 \\ 0 & \lambda_{xp} e^{-\eta} \end{pmatrix}, \qquad \Delta x\, \Delta p_x = \frac{\hbar}{2}, \qquad \frac{\Delta p_x}{\Delta x} = \lambda_{xp} e^{-\eta}. \tag{15.20}$$

The dispersion ratio acquires the dimension of momentum per length here. By contrast, (15.19) belongs to the balanced chart. For the inductive–capacitive realization already defined, (15.14) supplies the dimensionless identity $Z_\eta / Z_* = e^{-\eta} = \Delta P / \Delta Q$. Each reading uses its declared transduction and preserves the same action determinant.

Contour energy and mean energy of the state. The inductive–capacitive realization has Hamiltonian

$$H_\eta(Q,P) = \frac{\omega}{2}\left(e^{-\eta} Q^2 + e^{\eta} P^2 \right), \qquad \omega > 0.$$

On $\partial\mathcal{E}_\eta$, its value is $H_\eta = \hbar\omega$, by the semiaxis equations. In the quantum realization of Proposition 15.19,

$$\langle \widehat{H}_\eta \rangle_{\psi_\eta} = \frac{\omega}{2}\left(e^{-\eta}\frac{\hbar e^{\eta}}{2} + e^{\eta}\frac{\hbar e^{-\eta}}{2}\right) = \frac{\hbar\omega}{2}. \tag{15.21}$$

The two-standard-deviation contour therefore has twice the mean energy of this Gaussian state. The areal law fixes action normalization; the angular pair fixes its distribution between the two coordinates; the canonical representation and explicit state realize that distribution as covariance. Saturation of uncertainty is thus established in the realization specified by its operators and its state.

Chapter 16

Dodecaphase Mixing Operator: CKM–CP Phase and Construction of the Pre-Dimensional Electron Reader

CKM Mixing and Charge-Parity Violation

The incidence sextet $(b, p, q, h_6, o_8, t) = (4, 5, 7, 6, 8, 3)$ fixes the rational transformation

$$M_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det M_{\mathrm{CKM}} = -\frac{3857}{6} \neq 0. \tag{16.1}$$

With

$$h_{\mathrm{deg}} = \frac{C^*_{\mathrm{deg}}}{6}, \qquad \Delta_{\mathrm{deg}} = \frac{180}{\pi}\Delta_4,$$

we define

$$\begin{pmatrix} \theta_{12} \\ \theta_{23} \\ \theta_{13} \end{pmatrix} = M_{\mathrm{CKM}} \begin{pmatrix} A_{\mathrm{deg}} \\ h_{\mathrm{deg}} \\ \Delta_{\mathrm{deg}} \end{pmatrix}, \qquad \delta_{\mathrm{CP,deg}} = 9A_{\mathrm{deg}}.$$

To prevent any ambiguity of chart, it is fixed

$$s_{ij} := \sin\!\left(\frac{\pi\theta_{ij}}{180}\right), \qquad c_{ij} := \cos\!\left(\frac{\pi\theta_{ij}}{180}\right).$$

The standard parametrization produces a unitary matrix V, and the Jarlskog invariant is

$$J = c_{12}c_{23}c_{13}^2 s_{12}s_{23}s_{13} \sin\!\left(\frac{\pi\delta_{\mathrm{CP,deg}}}{180}\right) = 3.1189723326632974 \times 10^{-5} \neq 0. \tag{16.2}$$

Nonvanishing expresses CP violation in the constructed model. Comparison with the Particle Data Group is undertaken afterward; it does not adjust (16.1). The PMNS sector requires its own mixing operator and is identified neither with CKM nor with a rank-one diagonal phase.

16.1 Dimensionless construction of the electronic scalar from APP incompatibility and the dodecaphase state

The electron appears in HMT as the point at which six preceding and mutually typed constructions are assembled: the incompatibility between the two arithmetic sheets of APP, the orientation induced by the involution of the areal–volumetric hinge, two integer quotients from the APP–TPK census, the dodecaphasic closure of α_{HMT}, the global defect Δ_4, and the unique center of the nonadic atlas. The route band then adds electron–positron conjugation. The MeV chart and the comparison with CODATA are subsequent to all of them.

This precedence is part of the mathematical content: the factors, their types and their causal order are determined before opening the tabulated chart, which intervenes only in the subsequent metrological comparison.

16.1.1 Electronic scalar $\mathfrak{e}_{\mathrm{HMT}}$ and causal graph of its factors APP–TPK, α_{HMT}, Δ_4 and nonadic atlas

The internal output is the dimensionless scalar.

$$\boxed{\mathfrak{e}_{\mathrm{HMT}} = \frac{\sqrt{3}}{4}\left[\exp\!\left(\frac{\varphi}{\pi^2}\right) - \frac{396}{18}\,\alpha_{\mathrm{HMT}}^3\right]\left[1 + \frac{270}{18}\,\Delta_4\right].} \tag{16.3}$$

The identities

$$\frac{396}{18} = 22 = 27 - 5, \qquad \frac{270}{18} = 15 = \binom{6}{2} = 3 \cdot 5$$

allow the abbreviated notation to be recovered

$$\mathfrak{e}_{\mathrm{HMT}} = \frac{\sqrt{3}}{4}\left(e^{\varphi/\pi^2} - 22\alpha_{\mathrm{HMT}}^3\right)(1 + 15\Delta_4).$$

Here the letter e inside the exponential is Euler's number; the subscript of $\mathfrak{e}_{\mathrm{HMT}}$ denotes the electronic section.

The causal graph of the equation is

$$\begin{aligned}
\text{APP projectors in dimension three} &\longrightarrow \sqrt{3}/4,\\
\text{TPK calendar and areal–volumetric sheets} &\longrightarrow F_{\mathrm{av}},\ \pi/\varphi^2,\ \varphi/\pi^2,\\
\text{dodecaphasic closure} &\longrightarrow \alpha_{\mathrm{HMT}},\\
\text{APP–TPK census and electronic family} &\longrightarrow 396,\ 18,\ 270,\ 22,\ 15,\ 5,\\
\text{global readings of } \pi, e \text{ and register} &\longrightarrow \Delta_4,\\
\text{nonadic atlas and anti-section} &\longrightarrow (5,5),\ \text{electron–positron band.}
\end{aligned}$$

No arrow in this diagram receives as an argument the reference electronic mass.

16.1.2 1st factor: exact incompatibility of the APP leaves

For $d \geq 2$, let

$$\mathscr{A}_d = \{1, \ldots, 9\}^d$$

with uniform measure, and let

$$\Sigma_d(x) = \mathrm{dr}(x_1 + \cdots + x_d), \qquad \Pi_d(x) = \mathrm{dr}(x_1 \cdots x_d)$$

the additive and multiplicative observables. Their orthogonal conditional expectations on $\ell^2(\mathscr{A}_d)$ are $P_{\Sigma,d}$ and $P_{\Pi,d}$. The proposition 1.55 proves by exact enumeration that

$$\left\|[P_{\Sigma,3}, P_{\Pi,3}]\right\| = \frac{\sqrt{3}}{4}.$$

Proposition 16.1 (Electronic prefactor APP content)**.** *The prefactor $\sqrt{3}/4$ of equation (16.3) is the exact norm of the noncommutativity between the sum and product sheets in dimension three. It is not a geometric factor introduced from the electronic formula.*

Proof. The joint table of Σ_3 and Π_3 determines the principal angles between $\mathrm{Ran}\, P_{\Sigma,3}$ and $\mathrm{Ran}\, P_{\Pi,3}$. If s is one of its singular values, the corresponding contribution to the commutator norm is $s\sqrt{1 - s^2}$. Enumeration of the 9^3 words gives at most

$$s^2(1 - s^2) = \frac{3}{16}, \qquad s^2 = \frac{1}{4}.$$

Therefore the maximum norm is $\sqrt{3/16} = \sqrt{3}/4$, before introducing α_{HMT}, Δ_4, a unit of energy or a reference mass. □

The physical function of the factor is thereby fixed: it measures the maximal incompatibility of the two arithmetic readings on the same ternary support. The electron does not inherit two independent numbers, one additive and the other multiplicative; it inherits the exact obstruction to rendering the two sheets simultaneously compatible. The prefactor preserves, within the mass law, the local memory of the APP disagreement from which the route arises.

16.1.3 2nd factor: the exchange involution between π and φ

The primitive calendar of modes (Σ, Π, Π) induces, on the areal and volumetric sheets, the matrix

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

theorem 60.7 obtains it by counting the transitions $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$, each once. The matrix is not postulated from the golden ratio: its eigenvalues φ and $-\varphi^{-1}$ appear after the incidence has been constructed.

In the second-order memory, $\mathrm{Sym}^2(F_{\mathrm{av}})$ has spectrum

$$\varphi^2, \qquad -1, \qquad \varphi^{-2}.$$

Thus, φ^{-2} is the positive stable mode of the hinge. The closure mark π, applied just once to the areal return, produces

$$\frac{\pi}{\varphi^2}.$$

This reason preserves the closure–self-scaling order. The electronic law uses its opposite orientation.

Theorem 16.2 (Exact Inversion of the Electronic Hinge)**.** *Let*

$$\mathscr{R}(x, y) = \frac{x}{y^2}, \qquad \mathsf{J}(x, y) = (y, x).$$

Then $\mathsf{J}^2 = I$ *and*

$$\mathscr{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \qquad (\mathscr{R} \circ \mathsf{J})(\pi, \varphi) = \frac{\varphi}{\pi^2}.$$

Consequently,

$$\frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 \left(\pi/\varphi^2\right)^2}, \qquad e^{\varphi/\pi^2} = \exp\left[\frac{1}{\varphi^3 \left(\pi/\varphi^2\right)^2}\right].$$

Proof. The first pair of identities is obtained by applying $\mathscr{R}$ before and after the involution J. For the reparametrization,

$$\varphi^3 \left(\frac{\pi}{\varphi^2}\right)^2 = \frac{\pi^2}{\varphi},$$

and its inverse is φ/π^2. The last equality follows by applying the exponential. □

The simultaneous presence of π and φ therefore has a precise structural meaning. π/φ^2 reads areal closure over quadratic volumetric memory; φ/π^2 reads interior self-growth over quadratic closure. They are not two similar quotients chosen for convenience. They are the two orientations of the same reader, exchanged by an exact involution. The term e^{φ/π^2} publishes the interior orientation of that hinge in the electron section.

16.1.4 3rd and 4th factors: the integers 22, 15 and the center 5

The census of the APP chart employed by the electronic family provides three integer sums:

$$\Sigma(\mathrm{APP}) = 396, \qquad \Sigma(\text{centro } 2\times 2) = 18, \qquad \Sigma(\text{canal}) = 270.$$

The first admits the ring decomposition.

$$396 = 18 + 72 + 108 + 198.$$

The kernel 2×2 is therefore an explicit substructure of the complete chart, and the integer 270 belongs to the global channel of the same APP–TPK census. The sum of the even rings is

$$18 + 108 = 126, \qquad \frac{396}{126} = \frac{22}{7}.$$

This last quotient is the rational closure seal of the chart, not an identification of $22/7$ with the number π generated by the coinductive reader. It does show that the numerator 22 already serves an internal function before appearing in the electronic law.

Theorem 16.3 (Internal Origin of the Electronic Coefficients)**.** *In the electronic family fixed by the APP chart and its global channel,*

$$\boxed{22 = \frac{\Sigma(\mathrm{APP})}{\Sigma(\text{centro})} = \frac{396}{18} = 27 - 5,}$$

$$\boxed{15 = \frac{\Sigma(\text{canal})}{\Sigma(\text{centro})} = \frac{270}{18} = 3 \cdot 5 = \binom{6}{2}.}$$

In particular, the coefficients are determined without consulting Z_0, the electron mass or a chart of units.

Proof. The first two equalities are exact divisions of the finite census:

$$396 = 22 \cdot 18, \qquad 270 = 15 \cdot 18.$$

By defining

$$p := 27 - 22,$$

one obtains $p = 5$, and then

$$15 = 3p = 3 \cdot 5 = \binom{6}{2}.$$

All quantities belong to the integer domain of the chart and the family before metrological transduction. □

16.1.4.1 Persistence selector in the central return

The same pair has a dynamic construction that also fixes its sign without consulting a mass. The four orientations of the central seed $(5, 5)$ return to that cell for the first time after twenty-seven steps. The typed return space is

$$\mathcal{K}_e = \mathbb{Z}/9\mathbb{Z} \times \mathbb{F}_3, \qquad |\mathcal{K}_e| = 27.$$

Moreover, the microfiber of π contains the five genealogically distinct regions

$$\mathscr{R}_\pi = 3_{++} + 1_{--} + 1_{\perp}.$$

The regional gauge diag_c and, within a repeated phase, the internal order of U_6 define the injection

$$\iota : \mathscr{R}_\pi \hookrightarrow \mathcal{K}_e$$

through the five distinct places

$$(4,0), \quad (5,0), \quad (6,0), \quad (6,1), \quad (6,2).$$

The first two correspond, respectively, to the transverse region and the mutated return; the last three separate the positive regions by their tritic sheet. The common visible word does not intervene as the inverse of the map.

Theorem 16.4 (Internal selector of the electronic coefficients)**.** *With the central return and the five typed regions fixed, the coefficients of the electronic equation are*

$$\boxed{n_e = -\left|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)\right| = -22, \qquad m_e^{\mathrm{tor}} = \left|\mathscr{R}_\pi \times \mathbb{F}_3\right| = +15.}$$

The first symbol records the boundary deficit; the second, the retained torsional memory.

Proof. The five places above are distinct, so ι is injective and

$$|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)| = 27 - 5 = 22.$$

Each of the five regions preserves three triticale leaves, hence

$$|\mathscr{R}_\pi \times \mathbb{F}_3| = 5 \cdot 3 = 15.$$

The orientation rule assigns a negative sign to states removed from the shell and a positive sign to retained memory. The construction opens only the center, the return of twenty-seven states, and the regional identities; it does not open an observed mass, an impedance, or a calibrated signature. □

The number 22 measures how many central kernels of weight 18 are recomposed by the APP sum 396. The number 15 measures how many of those same kernels are recomposed by the channel 270, and simultaneously counts the pairs of a hexad. The number 5 is not an additional parameter:

$$5 = 27 - 22, \qquad 15 = 3 \cdot 5.$$

The three expressions display the same closure from depth 27, from the central normalization, and from hexadic combinatorics.

16.1.4.2 Internal derivation of coefficients 22 and 15 through the APP–TPK censuses

The historical exploration first located $p = 5$ through a finite comparison with Z_0, and from there wrote $(27 - p, 3p) = (22, 15)$. That procedure retains value as a history of discovery and as an external check. It is not, however, the proof that governs the law: the subsequent count

$$\frac{396}{18} = 22, \qquad \frac{270}{18} = 15$$

constructs both integers within APP–TPK and recovers $p = 5$ as a consequence. The history explains how the pair was found; the census explains why it belongs to the equation.

16.1.5 5.º factor: the cubo of the closure α_{HMT}

The closure of α_{HMT} precedes Dimensional Mechanics. As established in section 30.12, the twelve base-thousand blocks of π, e, φ and the seal K combine through the reversible carry

$$P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + 1000c_m, \qquad c_{13} = c_1 = 0.$$

The output is

$$A_\alpha = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663)$$

and, by concatenation, the exact dodecaphasic window

$$\alpha_{12} = \pi_{12}(\alpha_{\mathrm{HMT}}) = \frac{729735256928380099728510547238066 3}{10^{36}}.$$

Telescoping the carries proves the complete integer identity; the compatible prolongation constructs $\alpha_{\mathrm{HMT}} = \varprojlim_N A^{(N)}$, and α_{12} is its thirty-six-digit rational projection. The comparison with the fine-structure constant is performed subsequently and does not intervene in its construction.

The electronic law takes the third power

$$\alpha_{\mathrm{HMT}}^3.$$

Mathematically, this is the multiplicative evaluation of the third symmetric power of the same scalar already closed; neither three metrological copies nor three different parameters are introduced. Its contribution is

$$22\alpha_{\mathrm{HMT}}^3 = 0.000008549065992005517270149798075982 28\ldots.$$

Proposition 16.5 (Statute of the Electronic Cubic Channel)**.** *The term* $22\alpha_{\mathrm{HMT}}^3$ *of the electronic law depends only on the prior closure of* α_{HMT}*, on internal multiplication, and on the integer* 22 *of theorem 16.3. It does not depend on a reading of the electron mass.*

Proof. α_{12} is the rational number fixed by the concatenation and carry identity, and the compatible family of windows determines the section α_{HMT}. The projection α_{12}^3 certifies the printed digits of α_{HMT}^3. The coefficient 22 is determined by $396/18$. The composition of both operations contains only data constructed before the energy chart. □

This proposition fixes exactly what is used for the electron. The third power is the cubic degree of this channel in the published law. There is no need here to postulate a universal rule according to which every occurrence of α^d automatically represents a dimension d; a universal statement of that kind would require its own theorem of multiplicativity among degrees. The electron genealogy is complete without turning that generalization into a premise.

16.1.6 6th factor: minimal torsion and global defect Δ_4

The terms *minimal torsion* and *global defect* denote a single invariant here, not two distinct corrections. The object used by the mass law is

$$\boxed{\Delta_4 = \frac{\pi - e\log\pi}{270}\left(1 + \frac{\pi}{729}\right).} \tag{16.4}$$

Its inputs are the already fixed HMT readings of π and e, the global channel 270, and the interior cell 729. Consequently,

$$\Delta_4 = 0.000111196422692140054051134786120679 09\ldots.$$

The first ratio measures the signed defect $\pi - e\log\pi$ in units of the 270 channel; the second factor couples that ratio to the interior cell through $\pi/729$. This reading adds no parameters to the formula: it separates its two constituent operations. The chapter 35 shows that it is a pre-dimensional mathematical input and distinguishes it from the operator that eventually realizes it as a change of sheet.

Proposition 16.6 (Globality of the Electronic Defect)**.** Δ_4 *is a global invariant preceding the species. In the electronic law it enters through*

$$1 + 15\Delta_4 = 1.001667946340382100810767021791810 19\ldots.$$

It is not a corrector chosen after knowing the residue of the electron mass.

Proof. The equation (16.4) contains neither a species label, a mass, nor a unit. The integer 15 has already been constructed by $270/18$. Therefore, the composition $1 + 15\Delta_4$ is determined by the global data and the internal census. □

Δ_4 must be distinguished from the other blocks of the mass character and from the other notions of torsion. In particular, it is neither s_{270}, nor the quadratic invariant $135\Delta_4^2$, nor the angular residue $\varepsilon_{\mathrm{res}}$, nor the geometric Cartan–Holst torsion. Substituting one for another would repeat or alter the level of the correction. For the electron, Δ_4 preserves the global memory of refinement; the factor 15 states how many times the electron family reads it. The qualifier *minimal* preserves the historical name of this invariant and is not used as a substitute for a variational theorem of minimality.

16.1.7 Uniqueness of the central cell (5,5) as the genealogical support of the electron

Let

$$C_{81} = \{1, \dots, 9\}^2$$

the nonadic atlas and

$$\rho(r, c) = (10 - r, 10 - c)$$

its central inversion. theorem 90.11 proves that the atlas contains a unique generation-zero cell and that this cell bears the positional label e_{core}.

Proposition 16.7 (Uniqueness of the Electronic Center)**.** *The involution ρ has a unique fixed point:*

$$\boxed{(r, c) = (5, 5).}$$

Its uniqueness is combinatorial and does not depend on the value of $\mathfrak{e}_{\mathrm{HMT}}$.

Proof. The equation $(r, c) = \rho(r, c)$ is equivalent to

$$2r = 10, \qquad 2c = 10.$$

In $\{1, \dots, 9\}^2$ it has the unique solution $r = c = 5$. The evaluation of the mass does not appear in the argument. □

Corollary 16.8 (Universality of the Central Section)**.** *Every admissible automorphism of the atlas that intertwines the central inversion preserves the cell* $(5, 5)$.

Proof. If $f\rho = \rho f$ and $\rho(5, 5) = (5, 5)$, then $\rho f(5, 5) = f\rho(5, 5) = f(5, 5)$. Therefore $f(5, 5)$ is another fixed point of ρ; uniqueness forces $f(5, 5) = (5, 5)$. □

This is the structural reason why the electronic class is the same in every realization preserving the atlas and its inversion: a local decimal does not recur by chance; rather, every admissible chart must transport the same fixed point and the same chain of invariants. The physical reading of this uniqueness identifies each electron with a realization of that central class; the proposition proves the internal universality of the atlas.

In the electronic family fixed by the construction, this point is the geometric anchor of the section. Four objects should not be confused:

$$(5, 5), \qquad e_{\mathrm{core}}, \qquad v_e = (0, 0, 0, 0, 0), \qquad \text{the raw signature of the central cell.}$$

The first is a position; the second, its internal label; the third, the chosen origin in the fine action lattice; the fourth preserves the raw atlas data and need not be the zero vector. Their coordination explains why the electron occupies the center without erasing the genealogy of the representations describing it.

Oriented electronic routes e_{++}, e_{--}, envelope e_{env}, action origin and signatures of the central cell The central cell carries two oriented histories of twelve events. Writing v^2 for the concatenation of two copies of a sextuple, the active route of orientation ++, its opposite history, and the historical envelope are, respectively,

$$\begin{aligned} e_{\mathrm{act}} = e_{++} &= (2,2,5,-4,-3,-2)^2, \\ e_{--} &= (4,3,2,-2,-2,-5)^2, \\ e_{\mathrm{env}} &= (4,3,5,-4,-3,-5)^2. \end{aligned} \tag{E-centro-1}$$

The two stories publish the same word

$$\tau_{12} = {+}{+}{+}{-}{+}{+}{+}{-},$$

but they are not the same route. The envelope takes the absolute maximum coordinate by coordinate while preserving the sign; it records amplitudes, but flattens the genealogical order and does not replace e_{act}.

The other readers of the center live in distinct codomains:

$$\begin{array}{rcll} v_e & = & (0,0,0,0,0), & \text{affine origin of the action lattice,} \\ R(5,5) & = & (24,0,12,0,-12), & \text{raw APP signature of the cell,} \\ \mathrm{Sig}_{\mathrm{masa}}^{\Gamma_{108}} & = & (-12,-4,12,-6,12), & \text{even mass projection,} \\ \mathrm{Sig}_{\mathrm{carga}}^{\Gamma_{108}} & = & (0,0,0,0), & \text{odd charge projection.} \end{array} \tag{E-centro-2}$$

The fact that the charge word has zero odd signature does not turn the route into zero, nor does it identify the raw signature with the affine origin. Position, active route, opposite route, envelope, origin and both signatures are coordinated objects, not six notations for the same vector.

16.1.8 Electron–positron conjugate orbit on the oriented path band

Electronic identity does not end at the central point or at the mass value. Material conjugation is realized on dodecaphasic words. Let

$$C_M(\mathbf{t}) = -\operatorname{rev}(\mathbf{t})$$

be the oriented anti-section and let $\chi \in \{-1,+1\}$ be the charge orientation. The band is the class

$$[(\mathbf{t},\chi)]_M = \{(\mathbf{t},\chi),(C_M\mathbf{t},-\chi)\}$$

of definition 92.28. The band preserves its even components and exhibits two sections with opposite odd components.

Theorem 16.9 (Electron and positron as sections of a band)**.** *For the band character of theorem 92.31,*

$$m(C_M\mathbf{t},-\chi) = m(\mathbf{t},\chi).$$

In the electronic channel,

$$(n,\chi) = (-22,+1) \quad \longleftrightarrow \quad (+22,-1)$$

and both pairs produce

$$\chi n = -22.$$

Therefore, electron and positron have the same mass and opposite charge orientations.

Proof. If E_+ and E_- are, respectively, the even and odd components of the character with respect to C_M, then

$$E_+(C_M\mathbf{t}) = E_+(\mathbf{t}), \qquad E_-(C_M\mathbf{t}) = -E_-(\mathbf{t}).$$

From here,

$$E_{\text{band}}(C_M\mathbf{t}, -\chi) = E_{\text{band}}(\mathbf{t}, \chi),$$

and the equality of mass is obtained by applying the exponential. In the electronic term,

$$(+1)(-22) = (-1)(+22) = -22.$$

□

The finite closure of proposition 92.33 reinforces this interpretation: over the eighty-one CT–108 routes, neither pure sign nor pure reversal preserves the taxonomy, whereas − rev does preserve it, with

$$81 = 54 + 9 + 9 + 9.$$

The antiparticle is therefore neither a negative mass nor an independent copy. It is the other oriented section of the same band: it preserves the even invariants that determine mass and reverses the odd invariants that determine charge and orientation.

16.1.9 Basal stage of the electronic closure

Theorem 16.10 (Holographic composition of the electronic section)**.** *With the objects constructed in the preceding sections fixed, the dimensionless electronic section is*

$$\mathfrak{e}_{\text{HMT}} = \left\|[P_{\Sigma,3}, P_{\Pi,3}]\right\| \left[\exp\big((\mathscr{R}\circ\mathsf{J})(\pi,\varphi)\big) - \frac{\Sigma(\text{APP})}{\Sigma(\text{centro})}\,\alpha_{\text{HMT}}^3\right]\left[1 + \frac{\Sigma(\text{canal})}{\Sigma(\text{centro})}\,\Delta_4\right].$$

Equivalently,

$$\boxed{\mathfrak{e}_{\text{HMT}} = \frac{\sqrt{3}}{4}\left(e^{\varphi/\pi^2} - 22\alpha_{\text{HMT}}^3\right)(1 + 15\Delta_4).}$$

Its evaluation is

$$\boxed{\mathfrak{e}_{\text{HMT}} = 0.510998922488066072509870877191349437 63\ldots.}$$

This scalar is the basal stage $\mathfrak{e}_e^{(0)}$, not the governing electronic output. The bidirectional beta closure publishes $0.510998950690000808608\ldots$ MeV.

Proof. The proposition 16.1 contributes

$$\left\|[P_{\Sigma,3}, P_{\Pi,3}]\right\| = \sqrt{3}/4.$$

The theorem 16.2 contributes

$$(\mathscr{R}\circ\mathsf{J})(\pi,\varphi) = \varphi/\pi^2.$$

The theorem 16.3 contributes

$$\frac{\Sigma(\text{APP})}{\Sigma(\text{centro})} = 22, \qquad \frac{\Sigma(\text{canal})}{\Sigma(\text{centro})} = 15.$$

The dodecaphasic closure contributes the rational window α_{12} of the coinductive section α_{HMT}, and equation (16.4) contributes the global defect. Substitution yields the abbreviated formula. Successive evaluation of

$$
\begin{aligned}
e^{\varphi/\pi^2} &= 1.17814494259630678081160095680888910\ldots,\\
22\alpha_{\mathrm{HMT}}^{3} &= 0.00000854906599200551727014979807598228\ldots,\\
1+15\Delta_4 &= 1.00166794634038210081076702179181019\ldots
\end{aligned}
$$

gives the declared value. □

The theorem is holographic in a verifiable sense: each local factor retains a distinct layer of the complete system. The commutator retains sheet duality; the exponential retains the interior orientation of the hinge π–φ; 22 and 15 retain the global census and its central kernel; $\alpha_{\mathrm{HMT}}^{3}$ retains fine closure; and Δ_4 retains global refinement. The center determines where the section is anchored, and the band determines how it survives under conjugation. The value does not replace this structure: it is its common evaluation.

16.1.9.1 Anterior and posterior action splitting upon return

The regional realization of the conjugate angular coordinate C^* distinguishes two coordinates on the same internal action line. The coordinate before the return is H_5 and the subsequent coordinate is

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = H_5 - \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}).$$

The notation $\eta_{\mathrm{ret}}^{(\mathrm{deg})}$ is the canonical sexagesimal coordinate defined on the action branch by $\eta_{\mathrm{ret}}^{(\mathrm{deg})} = C^*/2 - \alpha_{\angle,\mathrm{deg}}$. The preceding equality is evaluated in that chart; it does not introduce a second return coordinate. Therefore, the additive and multiplicative charts of the oriented splitting are

$$\boxed{\delta_{2w} := H_5 - \eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{90}{\pi}\mathscr{C}_\pi(\alpha_{\mathrm{HMT}}), \qquad R_{\mathrm{act}} := \frac{\hbar_{\mathrm{HMT}}^{\mathrm{pre}}}{\hbar_{\mathrm{HMT}}^{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}^{(\mathrm{deg})}}.} \tag{16.5}$$

Both coordinates follow from a single pre-return/post-return transport. They are not two Planck constants: the common factor $10^{-34}\mathcal{U}_S$ fixes the dimensional line and cancels exactly in R_{act}. The action ellipse subsequently realizes $\mathrm{Area}(\theta) = \hbar_{\mathrm{HMT}}^{\mathrm{ret}}\theta$, so that the splitting precedes the holonomy reading.

The coupling

$$\kappa_e^{\beta} = 80 - 54\alpha_{\mathrm{HMT}} + 6\Delta_4, \qquad \mathfrak{e}_e^{\beta} = \mathfrak{e}_{\mathrm{HMT}} R_{\mathrm{act}}^{\kappa_e^{\beta}} = 0.5109989506900008086\ldots \tag{16.6}$$

is the bidirectional quantitative closure of the electron. The two independent readers of the electronic register constructed in the following chapter select, without consulting the comparison mass,

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6),$$

and derive exactly κ_e^{β}. The integer 80 comes from the first coordinate of those readers; the word $w_e = 201101$ retains its own residence in the channel of Euler's constant.

Internal Closure of Bidirectional Refinement

The identity (16.5), the reduction $(80, 54, 6)$, and the equation (16.6) constitute internally exact, target–free results on the electronic record. Propagation to fibers of higher rank is formulated by means of the multisection operators.

16.2 Algebraic structure of the electron and action scale

The electronic construction receives the arithmetic state with trajectory memory produced by APP–TRIT–TPK and its numerical coordinates. At this point in the development, π, φ, e and α designate the coordinates already obtained from the same genealogy, in the constructive order set out above. They are not parameters taken from a physical table. The electronic section is a subsequent realization of that joint discrete structure of the continuum: it preserves the cell of origin, the two arithmetic sheets, orientation, carry, and return memory before producing a scalar.

Three objects should be distinguished from the outset. The first is the central section and its transport history; the second is the dimensionless coordinate obtained from it; the third is its realization on an energy or mass line. Equality between two numerical coordinates does not identify these three levels. In particular, Euler's number e, the electronic coordinate ε_e, and a rest energy E_e will have distinct notations.

The aim of this section is to establish the composition

$$\varepsilon_e^{\beta} = \frac{\sqrt{3}}{4}\left[\exp\left(\frac{\varphi}{\pi^2}\right) - 22\alpha^3\right](1 + 15\Delta_4)R_{\mathrm{act}}^{80-54\alpha+6\Delta_4}, \tag{16.7}$$

explaining separately the origin of the prefactor, the two integers of the basal stage, normalization of Δ_4, the action ratio and the return triple. The dimensional chart opens only after this composition. The result does not consist in making a dimensionless number acquire units merely through its resemblance to a tabulated quantity.

The composition brings together factors with different functions. The following table identifies their meaning and refers to the corresponding construction; the proofs are developed in the order of their dependencies.

Factor	Meaning in the composition	Construction and proof
$\sqrt{3}/4$	Norm of the commutator of the projectors on the principal plane.	Equation (16.12).
$\exp(\varphi/\pi^2)$	Exponential character of the electronic orientation of the regional quotient.	Equation (16.18); subsections 10.5.6.1 and 10.5.6.2.
$-22\alpha^3$	Contribution of the regional complement in the central return.	Equations (16.20) and (16.21).
$1 + 15\Delta_4$	Torsional normalization composed with regional and tritic multiplicity.	Equations (16.20), (16.22) and (16.24).
$R_{\mathrm{act}}^{\kappa_e}$	Quotient of the action sections, raised to the character determined by the two readers of the electronic return.	Equations (16.35), (16.42), (16.43) and (16.44).

Table 16.1: Factors of the electronic composition and provenance of their rules.

Identity of the section and composition of its observables. The structural identity of the electron is introduced through the central section and its transport operations. Inversion of the APP chart selects the cell $(5, 5)$ by its fixed-point property. The two arithmetic sheets allow the deformations preserving the sum and product residue to be studied. The result distinguishes the two orientations $(8, 2)$ and $(2, 8)$ and preserves the difference of one quotient unit. This is the first level of information: a cell, an involution, a preserved fiber and a minimal integer defect. No mass evaluation is needed to state or prove it.

The passage to arithmetic projections introduces a second level. The sum and product fibres determine conditional expectations on the same finite space. Their commutator measures dependence on the order of these two projections. The norm $\sqrt{3}/4$ follows from the spectrum of their pairing; the block attaining this norm also preserves the quadratic relations proved below. Thus, the scalar prefactor and the local

algebra have a common provenance, but contain different information. The norm retains the magnitude of the commutator, while the matrices preserve its orientation and its composition law.

Areal–volumetric transfer incorporates the regional coordinates at a third level. The mode calendar determines the incidence matrix and its quadratic action. The closure mark produces the ratio π/φ^2; interchanging the two arguments provides the orientation φ/π^2 used in the electronic exponential character. The two expressions are related by an explicit involution. This relationship explains why a regional coordinate may appear in the electronic equation with a power or in a position different from that in its first reading: the operation applied is part of the mathematical datum that is preserved.

The cubic alpha term belongs to the regional complement of a marked return. Counting its positions yields $27 - 5 = 22$, while the three sheets of each of the five regions yield $3 \cdot 5 = 15$. The proofs preserve the domain of these counts and the orientation determining their signs. The basal formula therefore composes an incompatibility norm, a transfer character, a position deficit, and a torsional memory. Writing it on a single line expresses the composition of these operations; explaining it requires reconstructing them in that order.

The transition from the basal coordinate to the complete coordinate preserves the same central section. The return factor uses the history records, and the two stated readers recover the triple $(80, 54, 6)$ along that trajectory. Multiplication by $R_{\mathrm{act}}^{80-54\alpha+6\Delta_4}$ modifies the evaluation, but keeps its origin and antecedents identified. The basal value constitutes an intermediate stage of the composition; the complete value also includes this return contribution. The physical comparison must use the stage specified by the formula being evaluated.

The action scale intervenes subsequently with a different function. A ratio of two action sections is dimensionless and cancels their common scale. The absolute realization instead uses an action basis, a temporal reader, and the map to energy or mass. This separation allows the construction of the scale and the identity of the electronic section to be preserved simultaneously. The chronological quantum provides a scale reference; the central section determines the structural factor expressed relative to it. The dimensional equations of this chapter keep that composition explicit.

The electron's relevance to the overall argument arises from this convergence of operations. The same arithmetic that produced the regions now determines a central cell, its deformations, and its projections. The fine-structure constant, constructed earlier, acts in this composition as a closure coordinate. Return information determines the complete evaluation, and dimensional realization allows subsequent comparison. Explaining the electron from its structure consists in preserving this succession of objects, maps, and values at every step of the proof.

16.2.1 Center, orientation, and vacancy on a preserved fiber

The cellular support under consideration is $\{1, \dots, 9\}^2$, with both APP evaluations, $r + c$ and rc. The central inversion is

$$\rho(r, c) = (10 - r, 10 - c). \tag{16.8}$$

The center is not chosen by a mass: it is characterized by a property of the support that precedes its physical reading.

Proposition 16.11 (Uniqueness of the center)**.** *The inversion ρ has a unique fixed point,* $(5, 5)$.

Proof. The equations $r = 10 - r$ and $c = 10 - c$ are equivalent to $2r = 2c = 10$. Their unique solution in the nonadic chart is $(5, 5)$. □

The preceding property identifies a cell, not a unique deep history. A route adds the initial orientation choice and its compatible prolongations. In the chart used here the central oriented section starts at $(5, 5)$ with both positive orientations; it will be denoted by Γ_e. Return of its cellular projection does not erase the transported orientations or the carry register of the section with its trajectory memory.

Vacancy is now considered, after the closure of α, as a local operation on this section. Its arithmetic can be isolated in a finite lemma; this isolation does not make it a substitute for the preceding generator of constants.

Definition 16.12 (Central fiber and quotient defect)**.** The central additive fiber is

$$\mathcal{F}_{10} = \{(5+t, 5-t) : t \in \mathbb{Z},\ |t| \le 4\}.$$

In the chart $n = \rho_9(n) + 9q_9(n)$, with $\rho_9(n) \in \{1, \dots, 9\}$, the quotient defect relative to the center is defined as

$$v(t) = q_9(25) - q_9(25 - t^2),$$

when both products have the same nonadic residue.

Lemma 16.13 (Minimal central vacancy)**.** *The only points of $\mathcal{F}_{10}$ that preserve the multiplicative residue of the center are*

$$(5,5), \qquad (8,2), \qquad (2,8).$$

At the two noncentral points, the quotient defect is exactly one.

Proof. The sum is constantly ten, whereas

$$(5+t)(5-t) = 25 - t^2.$$

Preservation of the residue is equivalent to $t^2 \equiv 0 \pmod 9$, that is, to $3 \mid t$. In the integer interval $[-4, 4]$, the solutions are $t = -3, 0, 3$. For the two nonzero solutions,

$$25 = 7 + 9 \cdot 2, \qquad 16 = 7 + 9 \cdot 1.$$

The residue seven is preserved and one unit of quotient is lost. There is no other admissible noncentral displacement in that domain, so the positive defect is minimal. The interchange $t \mapsto -t$ permutes the two outputs and preserves the defect. □

Vacancy here is not a numerical zero: it is a difference between two states with the same residual reading and different quotients. If only the residue were preserved, that difference would disappear. Orientation also distinguishes the two output points. Neither the quotient defect nor that orientation is automatically identified with an electric charge or a mass; their physical realization requires the corresponding readers.

16.2.1.1 Central coordinates, orientation, and regional records

The central structure relates position, evaluation, and transport. At cell $(5, 5)$, the two APP sheets give

$$\mathcal{A}(5,5) = \big((1,1),(7,2)\big), \qquad 5+5 = 1+9\cdot 1, \qquad 5\cdot 5 = 7+9\cdot 2. \tag{16.9}$$

The two ones on the additive sheet are, in order, residue and quotient. Their numerical coincidence preserves two distinct arithmetic functions. On the sum-10 fiber, the two oriented vacancies satisfy

$$\mathcal{A}(8,2) = \mathcal{A}(2,8) = \big((1,1),(7,1)\big). \tag{16.10}$$

The complete additive sheet and the multiplicative residue are preserved; the quotient coordinate of the product decreases by exactly 1. Transport additionally retains which of the two conjugate positions has been reached.

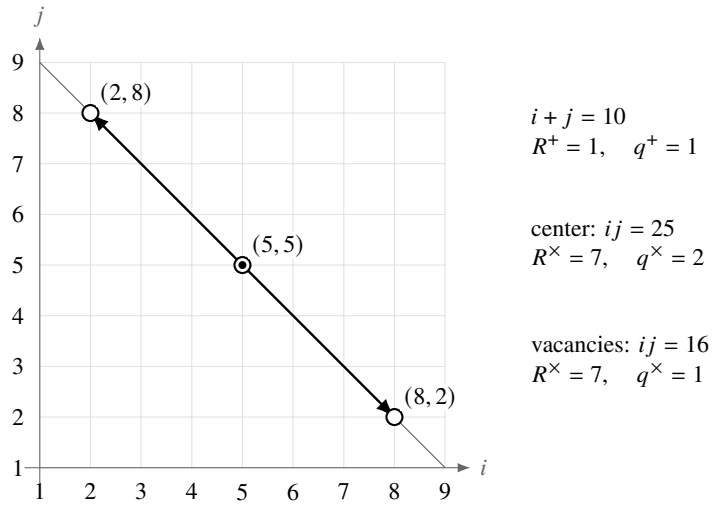

Figure 16.1: Electronic center and conjugate vacancies in the APP chart. The diagonal is the additive fiber $\mathcal{F}_{10}$; the center is the fixed point of $(i, j) \mapsto (10 - i, 10 - j)$. The two shifts of magnitude 3 preserve the sum and product residue and decrease the multiplicative quotient by one unit. The arrows represent deformations along the fiber.

Central symmetry also characterizes its persistence under chart changes. If an admissible atlas transformation f intertwines inversion, $f\rho = \rho f$, then

$$\rho f(5, 5) = f\rho(5, 5) = f(5, 5).$$

Uniqueness of the fixed point forces $f(5, 5) = (5, 5)$. This is the internal property making the central location stable: every transformation of that type preserves the cell before evaluating its electronic character (Section 16.2.1.1).

The central matrix block belongs to evaluation on the two adjacent positions $4, 5$. Its decomposition, established in the local development of the kernel, is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 9P_+ + 5P_-.$$

Here 9 and 5 are eigenvalues of two modes, whereas $(5, 5)$ is a position in the atlas. Concatenations of its entries give $72 + 27 = 77 + 22 = 99$ and $77 - 22 = 55 = 54 + 1$. The first equality preserves the total sum under two arrangements; the second expresses the defect between diagonal and antidiagonal readings. These operations precede electronic composition and preserve their matrix provenance.

The initial orientation is another datum. In the representation of electronic return, $(h_0, v_0) = (1, 1)$ is fixed, that is, positive advance in both coordinates. Simultaneous inversion every 27 steps, read in windows of 9, determines

$$\tau_e = (+1, +1, +1, -1, -1, -1, +1, +1, +1, -1, -1, -1).$$

The segments $(1, 1, 1)$ belong to this orientation sequence: each segment comprises three windows in the same direction. The recurrence in the section on readers proves this record in (16.38), and its two evaluations recover the triple $(80, 54, 6)$ entering (16.7). The positional coordinate, APP quotients, and sign sequence are thus connected through explicit operations.

The signature 555555 belongs to a regional reading in another domain. For a decimal emission $U = (U_1, \ldots, U_6)$, we write $U_j = 100d_{1j} + 10d_{2j} + d_{3j}$, with three digits, including leading zeros. The multiplicative-signature reader is

$$\mathcal{E}_{\times}(U) = \big([d_{2j} - d_{1j}]_{10}\big)_{j=1}^{6}.$$

In the transversal region $U_{\pi}^{\perp} = (501, 614, 498, 169, 272, 272)$, the differences are $(-5, -5, 5, 5, 5, 5)$. Consequently,

$$\mathcal{E}_{\times}(U_{\pi}^{\perp}) = (5, 5, 5, 5, 5, 5), \qquad \Psi(U_{\pi}^{\perp}) = 010211. \tag{16.11}$$

The first map preserves a multiplicative signature of the catalog; the second preserves the ternary word common to the five regions. Figure 21.5 shows the transversal position of this emission and its multiplicity 432.

Memory required to transport the constant signature. The signature 555555 additionally provides a verifiable example of the trajectory information required by TPK. Let $\mathcal{X}_{\times} = D_9^2 \times \{N, E, S, O\}$, with 324 oriented positions in the product channel. Advance P moves one square in the stored direction, and the half-turn H reverses that direction. In this representation, the reader E_{sig} sums the discrete exponents by windows:

$$\ell_9(1, 2, 4, 8, 7, 5) = (0, 1, 2, 3, 4, 5), \qquad \ell_9(3) = \ell_9(6) = \ell_9(9) = 0.$$

During each of the six nine-step windows, $\ell_9(\rho_9(ij))$ is evaluated before every product advance, selected by TRIT at times $2, 5, 8 \pmod 9$. The window sum is reduced modulo 10. After steps 27 and 54, the direction is reversed. This rule determines the six components of E_{sig} from the initial position and orientation.

Enumeration of this domain produces 26 signatures. The fiber of 555555 contains 24 oriented positions; after one advance, their images are distributed among three signatures, with eight representatives each:

$$555177, \qquad 555717, \qquad 555771.$$

Three witnesses, in coordinates from 1 to 9, allow the distinction to be checked directly:

x	$E_{\mathrm{sig}}(x)$	$E_{\mathrm{sig}}(Px)$
$(3, 5, N)$	555555	555177
$(3, 4, N)$	555555	555717
$(3, 4, S)$	555555	555771

Thus, the common value of the signature does not determine its next value: the transport class within that fiber forms part of the operational datum. The minimal stable partition is calculated by starting from signature equivalence $\sim_0$ and refining through

$$x \sim_{n+1} y \quad \Longleftrightarrow \quad x \sim_n y, \quad Px \sim_n Py, \quad Hx \sim_n Hy.$$

The procedure terminates because the domain is finite. Every stable congruence refining $\sim_0$ refines every $\sim_n$, by induction; its fixed point is therefore the minimal stable congruence required. The census gives $26 \to 28 \to 28$, with histogram $27 \cdot 8 + 108 = 324$. The only signature that splits is 555555, into three classes of eight elements. The accompanying certificate reproduces the enumeration, the three classes, and stability under both operators (Section 16.2.1.1).

The multiplicity 24 here belongs to the product-channel fiber; the multiplicity 432 belongs to the complete regional emission $U_{\pi}^{\perp}$. The first proves why the signature needs transport memory; the second places that signature within the joint catalog of the two sheets. Both readings participate in the same architecture, with specified domains and operations.

This distinction of domains makes it possible to bring together the occurrences of unity and the center with their respective meanings:

Registro	Object and function
$(5, 5)$	Fixed cell of the central inversion of the APP atlas.
$(R^+, q^+) = (1, 1)$	Residue and quotient of the central additive evaluation.
$(h_0, v_0) = (1, 1)$	Initial orientation of the two shifts.
$(+1, +1, +1)$	Three consecutive windows of τ_e with positive orientation.
$c = 111111$	Datum of the fifth nonadic boundary, Section 10.5.14.1.
$\mathcal{E}_\times = 555555$	Signature of the transversal region of π, with six positions.

Electronic coordination is obtained by composing these levels in their dependency order. APP determines the center and evaluations; TRIT selects regimes and orientations; TPK prolongs the trajectory and preserves its records. The previously generated regions provide the characters π, φ, e; the dodecaphase record provides α; the electronic readers determine the factors of equation (16.7). This composition preserves the identity of the section throughout its different representations, up to dimensional evaluation and subsequent metrological comparison.

16.2.2 Commutator norm of the arithmetic projections

The electronic prefactor is obtained without using α, torsion, or a dimensional unit. The domain is the third realization of APP, $\mathcal{A}_3 = \{1, \dots, 9\}^3$, equipped with the uniform measure. We define

$$\Sigma(x) = \rho_9(x_1 + x_2 + x_3), \qquad \Pi(x) = \rho_9(x_1 x_2 x_3).$$

The conditional expectations P_Σ and P_Π are the orthogonal projections onto functions constant on each additive and multiplicative fiber, respectively. Thus, for a function f,

$$(P_\Sigma f)(x) = \frac{1}{|\Sigma^{-1}(\Sigma(x))|} \sum_{y:\, \Sigma(y)=\Sigma(x)} f(y),$$

and analogously for P_Π. The two projections act on the same space; they do not represent two independent arithmetic supports.

Lemma 16.14 (Two projections and principal angles)**.** *If $s \in [0, 1]$ is a singular value of the pairing between orthonormal bases of the ranges of two projections P, Q, its nontrivial block contributes to $\|[P, Q]\|$ with $s\sqrt{1 - s^2}$.*

Proof. On the corresponding principal plane, one can write

$$P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad Q = \begin{pmatrix} s^2 & s\sqrt{1 - s^2} \\ s\sqrt{1 - s^2} & 1 - s^2 \end{pmatrix}.$$

Their commutator is

$$[P, Q] = s\sqrt{1 - s^2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

The final matrix is orthogonal, so its norm is one. Common or orthogonal blocks have zero commutator. The orthogonal decomposition into principal planes gives the claim and reduces the total norm to the maximum of these contributions. □

Proposition 16.15 (Exact incompatibility norm)**.** *On $\ell^2(\mathcal{A}_3)$,*

$$\|[P_\Sigma, P_\Pi]\| = \frac{\sqrt{3}}{4}. \tag{16.12}$$

Proof. Let $N_{ab} = |\Sigma^{-1}(a) \cap \Pi^{-1}(b)|$. Integer enumeration of the three symbols yields

$$N = 9\begin{pmatrix} 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 1 & 0 & 2 & 0 & 1 & 2 & 0 & 0 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 0 & 2 & 1 & 0 & 2 & 0 & 1 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 1 & 2 & 0 & 0 & 2 & 1 & 0 & 3 \end{pmatrix}.$$

Each row sums to 81; the column sums are

$$(m_1, \dots, m_9) = (36, 36, 108, 36, 36, 108, 36, 36, 297).$$

The normalized indicator functions of the fibers have pairing matrix $C_{ab} = N_{ab}/\sqrt{81 m_b}$. Consequently,

$$M = CC^{\mathsf{T}}, \qquad M_{ac} = \sum_{b=1}^{9} \frac{N_{ab} N_{cb}}{81 m_b}$$

is a rational matrix whose spectrum consists of the squares of the required singular values.

Exact multiplication shows that $(1, \dots, 1)$, $(1, -1, 0)^3$, and $(1, 1, -2)^3$ are eigenvectors with eigenvalues 1, $1/4$, and $7/132$, respectively. The subspace of vectors supported on $\{3, 6, 9\}$ whose sum is zero has dimension two and eigenvalue $1/18$. The zero-sum vectors supported on $\{1, 4, 7\}$ or $\{2, 5, 8\}$ form a four-dimensional kernel. These subspaces are independent and their dimensions sum to nine. The complete spectrum is therefore established:

$$\operatorname{spec}(M) = \left\{1, \frac{1}{4}, \frac{7}{132}, \frac{1}{18}, \frac{1}{18}, 0, 0, 0, 0\right\}.$$

The maximum of $\lambda(1 - \lambda)$ on this set is $3/16$, attained at $\lambda = 1/4$. The preceding lemma gives $\sqrt{3/16} = \sqrt{3}/4$. □

The mode $(1, -1, 0)^3$ is precisely the value distribution of the tritic phase selector in the nonadic chart. The scalar norm retains a measure of incompatibility, but does not by itself preserve the orientation of that mode or reconstruct the two projectors. That memory remains in the route state accompanying the scalar reading.

Proposition 16.16 (Algebra of the local electronic block)**.** *On the principal plane attaining* (16.12)*, let*

$$P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad Q = \begin{pmatrix} 1/4 & \sqrt{3}/4 \\ \sqrt{3}/4 & 3/4 \end{pmatrix}, \qquad S = 2P - I, \qquad J = \frac{4}{\sqrt{3}}[P, Q].$$

Then $S^2 = I$, $J^2 = -I$, $SJ = -JS$, and the real algebra generated by S, J is $M_2(\mathbb{R})$, a realization of $\mathrm{Cl}_{1,1}$*. Moreover,*

$$n_{\pm} = \frac{S \pm J}{2}, \qquad n_{\pm}^2 = 0, \qquad n_+ n_- + n_- n_+ = I.$$

Proof. We have $S = \operatorname{diag}(1, -1)$ and $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. Multiplication verifies the three relations. The matrices I, S, J, SJ are linearly independent and form a basis of $M_2(\mathbb{R})$, proving the claim about the algebra. Finally, $(S \pm J)^2 = S^2 + J^2 \pm (SJ + JS) = 0$, and the sum of the cross products is $(S^2 - J^2)/2 = I$. □

In this block, an elliptic direction, a hyperbolic direction, and two parabolic null directions coexist. The result describes a local matrix representation of the arithmetic of the two sheets. It does not identify all of APP with $M_2(\mathbb{R})$, or with a quantum Latin square; such claims would require other domains and other relations. Nor does the exponential belong exclusively to the parabolic regime: it can be applied to any of the generators of this block.

16.2.3 Spinor representation of the electronic block and helicity

The electronic structure has a representation preserving more information than its scalar evaluation. The principal plane of the two three-dimensional APP projectors, selected by the tritic mode $(1, -1, 0)^3$, has already provided the operators S and J. The former is a symmetric involution; the latter is the normalized commutator and preserves sheet orientation. Their composition makes it possible to construct explicitly a rotation representation and separate its two helicity components. This construction acts on the electronic block; the TPK route record and its memory remain as data of the block's provenance.

Let E_e be the real principal plane, equipped with the inner product inherited from the conditional expectations, and let $\mathcal{S}_e = E_e \otimes_{\mathbb{R}} \mathbb{C}$ be its complexification. The operators already obtained satisfy

$$S^* = S, \qquad J^* = -J, \qquad S^2 = I, \qquad J^2 = -I, \qquad SJ = -JS.$$

Complexification extends the representation field. It preserves the real operators and allows the scalar unit i to be distinguished from the endomorphism J, although both square to -1 in their respective domains.

Proposition 16.17 (Hermitian triple induced by the two sheets)**.** *The operators*

$$\sigma_1 = SJ, \qquad \sigma_2 = -iJ, \qquad \sigma_3 = S \tag{16.13}$$

are Hermitian and traceless. They satisfy

$$\sigma_a\sigma_b = \delta_{ab} I + i \sum_{c=1}^{3} \epsilon_{abc}\sigma_c, \qquad \frac{1}{2}\operatorname{tr}(\sigma_a\sigma_b) = \delta_{ab}, \tag{16.14}$$

where $\epsilon_{123} = 1$. They therefore form an orthonormal basis of the real space V_e of traceless Hermitian endomorphisms of $\mathcal{S}_e$, for the inner product $\langle X, Y\rangle = \frac{1}{2}\operatorname{tr}(XY)$.

Proof. The preceding relations give $(SJ)^* = (-J)S = SJ$ and $(-iJ)^* = -iJ$. The squares of all three matrices are I. Furthermore,

$$(SJ)(-iJ) = iS, \qquad (-iJ)S = iSJ, \qquad S(SJ) = J = i(-iJ).$$

Reversing the order changes the sign. This proves the first identity in (16.14). In the orthonormal basis of the principal plane, the matrices are

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Their trace is zero, and taking traces in the product identity proves orthonormality. Every traceless Hermitian endomorphism has the form $\left(\begin{smallmatrix} z & x-iy \\ x+iy & -z \end{smallmatrix}\right)$, with real x, y, z, and thus belongs to their real span. □

In the usual matrix representation, this triple is called the Pauli matrices. Their use here follows the construction of P, Q, S, J: they are obtained through the products (16.13). The direction space of this representation is the unit sphere of V_e, whose positive form has just been constructed through the trace.

Proposition 16.18 (Rotation generators and directional decomposition)**.** *Define* $L_a = \sigma_a/2$*. Then*

$$[L_a, L_b] = i \sum_c \epsilon_{abc} L_c, \qquad \sum_{a=1}^{3} L_a^2 = \frac{3}{4} I. \tag{16.15}$$

For $n = (n_1, n_2, n_3)$ *with* $\sum_a n_a^2 = 1$*, let*

$$H_e(n) = \sum_a n_a \sigma_a, \qquad h_e(n) = \frac{1}{2} H_e(n), \qquad \Pi_\pm(n) = \frac{1}{2}\big(I \pm H_e(n)\big).$$

The linear formula $H_e(v) = \sum_a v_a \sigma_a$ *is also used for* v *of arbitrary norm. One has*

$$\mathcal{S}_e = \operatorname{im} \Pi_+(n) \oplus \operatorname{im} \Pi_-(n), \qquad h_e(n)\Pi_\pm(n) = \pm \frac{1}{2} \Pi_\pm(n). \tag{16.16}$$

The two summands are orthogonal complex lines. Rotation transport around n *is*

$$U_n(\theta) = \exp\left(-\frac{i\theta}{2} H_e(n)\right) = \cos\frac{\theta}{2}\, I - i \sin\frac{\theta}{2}\, H_e(n), \qquad U_n(2\pi) = -I, \quad U_n(4\pi) = I. \tag{16.17}$$

Proof. The product identity of the triple gives the commutators in (16.15); their squares sum to $3I/4$. Antisymmetric terms cancel when multiplying $H_e(n)$ by itself, so that $H_e(n)^2 = I$. It follows that

$$\Pi_\pm(n)^2 = \Pi_\pm(n), \qquad \Pi_+(n)\Pi_-(n) = 0, \qquad \Pi_+(n) + \Pi_-(n) = I.$$

They are Hermitian and have trace 1; their rank is therefore 1. Multiplication by $H_e(n)/2$ proves (16.16). The exponential series splits into even and odd powers because $H_e(n)^2 = I$, producing (16.17). It also directly proves unitarity and the law $U_n(\theta + \psi) = U_n(\theta) U_n(\psi)$.

Angular normalization is verified on V_e. For every $v \in \mathbb{R}^3$, the same product identity gives

$$U_n(\theta) H_e(v) U_n(\theta)^* = H_e\big(v \cos\theta + (n \times v) \sin\theta + n(n \cdot v)(1 - \cos\theta)\big)\,.$$

The induced action is a rotation of angle θ and axis n. The factor $1/2$ in the spinor generator is therefore the one corresponding to that angular parameterization. A complete rotation restores the direction in V_e and changes the sign of the vector in $\mathcal{S}_e$; two complete rotations restore both. □

The representation is irreducible: a complex subspace invariant under the three matrices would be invariant under all of $M_2(\mathbb{C})$, the algebra they generate. Its only invariant subspaces are 0 and $\mathcal{S}_e$. The relations (16.15) thus identify the spin-$1/2$ representation. If n is the propagation direction in a kinematic realization, $h_e(n)$ is its dimensionless helicity, with values $\pm 1/2$. The kinematic direction is declared when that realization is made; the two projectors are defined for every direction before a particular propagation state is selected.

Preservation of the electronic structure and types of inversion. Direction inversion has an exact law:

$$H_e(-n) = -H_e(n), \qquad \Pi_\pm(-n) = \Pi_\mp(n).$$

This operation exchanges helicity labels relative to a direction. Charge conjugation, by contrast, acts on the oriented signature of the material route; cellular inversion acts on the atlas coordinates. Their domains and actions remain distinct. Uniqueness of cell $(5, 5)$ is compatible with the two lines in (16.16): an atlas cell is not a vector in the spinor representation it carries.

The electronic evaluation ε_e^{β} preserves its formula and readers. On $\mathcal{S}_e$, its scalar realization is $\varepsilon_e^{\beta} I$, which commutes with the generators and with $\Pi_{\pm}(n)$. Helicity decomposition adds rotational information without modifying the evaluation or turning spin into a multiplicative mass coefficient.

Chirality corresponds to the grading of the relativistic representation used: an involution Γ_{ch} determines its projectors $(I \mp \Gamma_{\mathrm{ch}})/2$. The helicity in (16.16) additionally depends on n. For its part, the holonomy of a real Möbius band describes the change of sign of a line when traversing a loop in its base. The law of that line, the spinor return (16.17), and nonadic phase holonomy with memory advance are transport laws on specified objects. Their comparison preserves those objects: the helical form of a trajectory does not replace the representation just constructed or by itself fix chirality or charge.

16.2.4 Transfer between sheets and coefficients of the basal stage

The primitive tritic calendar visits the modes (Σ, Π, Π). Counting consecutive pairs, including the closure of the block, yields one transition $\Sigma \to \Pi$, one $\Pi \to \Pi$, and one $\Pi \to \Sigma$. Their primitive incidence is

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

This matrix realization is obtained after the calendar. It is not used to replace the coinductive reader that has already generated φ. Its characteristic polynomial is $X^2 - X - 1$, and recognition of the two roots as φ and $-\varphi^{-1}$ describes the action of that output in modal transfer. The quadratic action has eigenvalues $\varphi^2, -1, \varphi^{-2}$; the last is the positive stable mode. The regional mark π, applied once, gives π/φ^2.

The trajectory space, its measure, and the closure operator are constructed in subsections 10.5.6.1 and 10.5.6.2. Formula (10.44) preserves its provenance as a quotient of returns; the electronic application subsequently composes this reading with the following involution. The regional signature 555555 accompanies the closure region, whose transport preserves the state with memory; the centre $(5, 5)$ fixes the cell of origin of the oriented electronic section. Both kinds of information converge in the composition and retain their respective domains.

Lemma 16.19 (Interchange of the two orientations)**.** *Let $\mathcal{R}(x, y) = x/y^2$ and $\mathcal{S}_{\pi\varphi}(x, y) = (y, x)$, for $x, y > 0$. Then*

$$\begin{aligned} \mathcal{S}_{\pi\varphi}^2 = I, \qquad \mathcal{R}(\pi, \varphi) = \frac{\pi}{\varphi^2}, \\ (\mathcal{R} \circ \mathcal{S}_{\pi\varphi})(\pi, \varphi) = \frac{\varphi}{\pi^2} = \frac{1}{\varphi^3 (\pi/\varphi^2)^2}. \end{aligned} \tag{16.18}$$

Proof. Applying the interchange twice gives the identity. Moreover, $\varphi^3(\pi/\varphi^2)^2 = \pi^2/\varphi$; taking its inverse proves the last equality. □

The electronic reader uses the orientation φ/π^2, followed by the exponential character. The preceding identity explains the interchange, but does not replace the rule that chooses that character or by itself produce the integers of the correction. These have a different provenance.

The phase-compatible central return has minimal length twenty-seven. With the phase and sheet record, its finite space is

$$\mathcal{K}_e = \mathbb{Z}/9\mathbb{Z} \times \mathbb{F}_3.$$

The five regions of π are distinct genealogical identities, not five interchangeable copies of a visible expansion. In the regional gauge fixed by the construction, their injection into the return occupies the positions

$$(4, 0), \quad (5, 0), \quad (6, 0), \quad (6, 1), \quad (6, 2). \tag{16.19}$$

The transverse orientation, mutated return, and three positive regions remain separated by that record. Admissible changes of gauge transport the labels jointly; they do not reselect the positions from an electronic value.

Proposition 16.20 (Deficit and retained memory)**.** *Given the central return and the preceding regional injection, the oriented boundary deficit and torsional memory are*

$$n_e = -|\mathcal{K}_e \setminus \iota(\mathscr{R}_\pi)| = -22, \qquad m_e^{\mathrm{tor}} = |\mathscr{R}_\pi \times \mathbb{F}_3| = 15. \tag{16.20}$$

Proof. The five positions in (16.19) are distinct. Thus, $|\mathcal{K}_e| = 9 \cdot 3 = 27$, and the complement of the image has cardinality $27 - 5 = 22$. The orientation convention records the deficit removed from the boundary as negative. The retained memory has three sheets per region, so its positive cardinality is $5 \cdot 3 = 15$. □

The same pair has the integer control of the family's APP chart:

$$396 = 18 + 72 + 108 + 198, \qquad \frac{396}{18} = 22, \qquad \frac{270}{18} = 15 = 3 \cdot 5 = \binom{6}{2}. \tag{16.21}$$

The weight 18 belongs to the central 2×2 kernel, and 270 to the declared global channel. These equalities check the normalization of the count; the return argument also fixes the signs. The quotient of the alternating rings, $396/(18 + 108) = 22/7$, is rational and is not identified with π. Nor does $\binom{6}{2}$ mean $6/2$: it counts the unordered pairs of a six-element set.

Evaluation of the deficit in the third symmetric realization uses α^3. This power is the product of three copies of the closure scalar already obtained; it does not assert a universal rule associating any dimension with the same power of α. The specified domain and reader are essential to the composition.

16.2.5 Global torsion and the basal coordinate

Definition 16.21 (Electronic torsional normalization)**.** The reduced defect d_4 and the complete reader Δ_4 are distinguished:

$$d_4 = \frac{\pi - e \log \pi}{270}, \qquad \Delta_4 = d_4 \left(1 + \frac{\pi}{729}\right). \tag{16.22}$$

The denominator 270 corresponds to the census channel, whereas the factor $1 + \pi/729$ retains the coupling with the cubic cell of 729 positions. The electronic reading uses Δ_4 both in its basal stage and in the return exponent.

This definition acts on previously generated π and e. The logarithm is a subsequent operation in their real realization, not a retrospective input of conventional values. Torsion is global: it is not determined independently for each section by an observed mass.

Lemma 16.22 (The two normalizations are not interchangeable)**.** *One has*

$$\Delta_4 - d_4 = \frac{\pi}{729} d_4. \tag{16.23}$$

In particular, $d_4 > 0$ and $\Delta_4 > d_4$ for the coordinates under consideration.

Proof. The identity follows by distributivity. For positivity, the function $f(x) = x - e \log x$, on $x > 0$, has derivative $1 - e/x$ and second derivative $e/x^2 > 0$. Its unique minimum is at $x = e$, where it is zero. Since $\pi \neq e$, we have $f(\pi) > 0$. Both factors in (16.22) are positive and $1 + \pi/729 > 1$. □

Remark 16.23 (Preservation of the normalization). Removing the second factor in (16.22) changes the reader; it is not an algebraic simplification. If d_4 is introduced as an auxiliary coordinate, the same object must be written as $\Delta_4 = (1 + \pi/729) d_4$ in every occurrence. Keeping the integers 15 and 6 and replacing only Δ_4 by d_4 produces a different formula.

Definition 16.24 (Basal electronic coordinate)**.** The composition of incompatibility, modal transfer, deficit, and retained memory is

$$\varepsilon_e^{(0)} = \frac{\sqrt{3}}{4}\left[\exp\left(\frac{\varphi}{\pi^2}\right) - 22\alpha^3\right](1 + 15\Delta_4). \tag{16.24}$$

The equation combines three operations of different kinds. The norm $\sqrt{3}/4$ quantifies the incompatibility of the sheet projections; its origin is a principal angle of the APP fibers. The exponential acts on the orientation φ/π^2 of the transfer reader. The cubic subtraction records the 22 complementary positions of the marked return, and the torsional factor preserves the 15 components corresponding to three sheets per region. The composition preserves these domains even though its final evaluation is scalar.

The presence of π, φ, and e thus has operational meanings. Euler's number enters through the exponential and the logarithmic normalization of Δ_4; φ and π enter through oriented transfer. The constant α acts after its own construction through the cubic closure term. The chronological return must still act on this basal coordinate. Separating the stages makes it possible to explain what changes when an orientation, normalization, or record is modified, while preserving the central structure that identifies the electronic section.

The parentheses in this equation are part of its content. The term $-22\alpha^3$ is subtracted *outside* the exponential; the memory $1 + 15\Delta_4$ multiplies the entire bracket. Placing the deficit in the exponent or applying a different torsion to it would alter the composition.

Proposition 16.25 (Basal positivity)**.** *For $0 < \alpha < 10^{-2}$, $\varphi > 0$, and the normalization* (16.22)*, we have $\varepsilon_e^{(0)} > 0$.*

Proof. The exponential is greater than one, and $22\alpha^3 < 22 \cdot 10^{-6} < 1$. The bracket is therefore positive. Also, $1 + 15\Delta_4 > 1$ and $\sqrt{3}/4 > 0$. □

The subsequent evaluation of (16.24) begins with

$$\varepsilon_e^{(0)} = 0.5109989224880660725\ldots.$$

This number is still a dimensionless coordinate and is not the final stage: the return memory of the route itself remains to be applied.

16.2.6 Determinantal action scale and decimal valuation

The absolute scale and relative correction arise from distinct objects. The former uses the local block of the step-three dodecaphase register,

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad G_H = \mathbb{Z}^4/H_4\mathbb{Z}^4. \tag{16.25}$$

The operation uses a local quotient. The three blocks of the complete register are not replaced by tensorization that would multiply this reader's number of sheets again.

Lemma 16.26 (Number of sheets of the local quotient)**.** *The Smith normal form of H_4 is* $\operatorname{diag}(1, 2, 2, 4)$*. Consequently,*

$$G_H \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |G_H| = 16.$$

Proof. The greatest common divisor of the entries is one. Second-order minors are even and one has value -2, so their greatest common divisor is two. Since $H_4 H_4^{\mathsf{T}} = 4I$ and $\det H_4 = -16$, the cofactors are ± 4; the third determinantal divisor is four. The fourth is 16. Successive quotients of the divisors $1, 2, 4, 16$ are $1, 2, 2, 4$. Their product gives the quotient's order. □

Definition 16.27 (Determinantal action reader)**.** The multiplicative norm of the scalar section α, constant on the sheets of G_H, and one application of self-scaling φ produce

$$\Sigma_H = \varphi\, \mathrm{N}_{G_H}(\alpha), \qquad \mathrm{N}_{G_H}(\alpha) = \prod_{g \in G_H} \alpha = \alpha^{16}. \tag{16.26}$$

The associated decimal chart determines $\mathrm{ord}_{10}(\Sigma_H) = \lfloor \log_{10} \Sigma_H \rfloor$.

The sixteenth power thus comes from the quotient's number of sheets, once this local reader is fixed. The factor φ acts once on the basis of the action line. Smith calculation alone would not select any possible functional on the quotient: the multiplicative norm and self-scaling are part of the declared operation.

Theorem 16.28 (Decade of the action section)**.** *The reader* (16.26)*, applied to HMT coordinates already generated, satisfies*

$$10^{-34} < \Sigma_H < 10^{-33}, \qquad \mathrm{ord}_{10}(\Sigma_H) = -34. \tag{16.27}$$

Proof. The rational intervals, much coarser than the available cylinders, suffice:

$$\frac{1618}{1000} < \varphi < \frac{1619}{1000}, \qquad \frac{7297}{10^6} < \alpha < \frac{7298}{10^6}.$$

The function $(x, a) \mapsto x a^{16}$ is increasing in both positive arguments. The two integer inequalities

$$1618 \cdot 7297^{16} > 10^{65}, \qquad 1619 \cdot 7298^{16} < 10^{66}$$

imply

$$10^{-34} < \frac{1618}{1000} \left(\frac{7297}{10^6}\right)^{16} < \Sigma_H < \frac{1619}{1000} \left(\frac{7298}{10^6}\right)^{16} < 10^{-33}.$$

The definition of decimal order completes the proof. Neither an SI unit nor a reference mass enters these inequalities. □

The normalized section begins with $\Sigma_H = 1.0462438381\ldots \times 10^{-34}$. Its mantissa is not identified with the action coordinate before or after return. The determinantal reader fixes decimal order; the two return coordinates are obtained through the following readers.

16.2.7 Action sections and dimensionless return quotient

Let $\mathcal{L}_S$ be an oriented action line and $\mathcal{U}_S$ its positive basis. The electronic composition uses two sections of this line and their dimensionless quotient. Its construction requires the determinantal decade already obtained, the fifth-order action character, and the regional contribution of the return.

16.2.7.1 Action character and provenance of its coefficients

The reduced Planck constant, $\hbar$, is the physical object motivating realization of the angular-action section. Its position in the electronic dependency must be specified at two levels. The determinantal norm Σ_H determines the scale's decade. The character H_5 and regional return then determine the action-section coordinates. This separation allows the result needed for the electron to be presented without anticipating complete developments of other Dimensional Mechanics sectors.

The provenance of the fifth-order character can be made explicit through invariants already fixed on the support. In the central chart, consider

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}, \qquad \lambda_+ = 9, \quad \lambda_- = 5.$$

The calendar has length 12, the orbit of step 3 has length 4, and the relevant census quotient is $104976/1944 = 54$. The coefficients of the character satisfy

$$\frac{9}{16}=\frac{\lambda_+}{4^2},\quad \frac{5}{9}=\frac{\lambda_-}{\lambda_+},\quad \frac{7}{48}=\frac{\mathrm{tr}(B_c)/2}{4\cdot 12},\quad \frac{1}{54}=\frac{1944}{104976}. \tag{16.28}$$

Assignment of these invariants to degrees $2,3,4,5$, with the alternating signs of (16.29), belongs to the definition of the analytic character used. Making this explicit is essential: the set of cardinalities, considered without the character and the ordering of its degrees, would admit other expressions. The constructive content lies in composition of the support, orientation and declared analytic rule.

On this basis, the fifth-order character and regional return term have the expressions

$$H_5=\frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}}-\alpha+\frac{9}{16}\alpha^2-\frac{5}{9}\alpha^3+\frac{7}{48}\alpha^4-\frac{1}{54}\alpha^5, \tag{16.29}$$

$$D_A=\exp\!\left(-\frac{100\pi\alpha}{9}\right), \tag{16.30}$$

$$C_\pi(\alpha)=169\alpha^6+\frac{D_A\alpha^7}{1-D_A\alpha}, \tag{16.31}$$

$$\eta_{\mathrm{ret}}=H_5-\frac{90}{\pi}C_\pi(\alpha). \tag{16.32}$$

These are subsequent readings of dodecaphase closure and its regional incidence. The integer 169 is retained as the regional selector already constructed, and the coefficients of H_5 as those of its local character; they are not replaced by an interpolation of the Planck constant. The formulas specify exactly which readings are needed for the electronic stage. Other mass-theory functionals need not be introduced here.

For $0<\alpha<1$, we have $0<D_A<1$, so $D_A\alpha<1$. The rational term of (16.31) preserves the complete sum of the geometric tail

$$\frac{D_A\alpha^7}{1-D_A\alpha}=\sum_{n=0}^{\infty}D_A^{n+1}\alpha^{n+7}. \tag{16.33}$$

It is not a truncation that can be silently modified when precision changes. After the term of index N, the remaining tail is $D_A^{N+2}\alpha^{N+8}/(1-D_A\alpha)$, allowing evaluation to be controlled without recourse to a target quantity.

Definition 16.29 (Action sections and return reader)**.** The sections before and after return are

$$\hbar_{\mathrm{pre}}=H_5\,10^{-34}\mathcal{U}_S,\qquad \hbar_{\mathrm{ret}}=\eta_{\mathrm{ret}}\,10^{-34}\mathcal{U}_S. \tag{16.34}$$

Whenever $\eta_{\mathrm{ret}}>0$, define

$$\delta_{\mathrm{ret}}=H_5-\eta_{\mathrm{ret}},\qquad R_{\mathrm{act}}=\frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}}=\frac{H_5}{\eta_{\mathrm{ret}}}. \tag{16.35}$$

Proposition 16.30 (Positivity and invariance of the ratio)**.** *In the intervals used in the proof of* (16.27)*,* $0<\eta_{\mathrm{ret}}<H_5$*, and therefore* $R_{\mathrm{act}}>1$*. The ratio does not change when the basis* $\mathcal{U}_S$ *is replaced by any other common positive basis.*

Proof. The terms of C_π are positive. For an elementary bound, it suffices to use $\alpha<0.008$, $\varphi<1.619$, $\alpha>0.007$, $D_A<1$ and $\pi>3$. The root in (16.29) exceeds one, whereas the sum of negative terms is less than 0.008001; in particular, $H_5>0.99$. Likewise,

$$0<\frac{90}{\pi}C_\pi<30\left(169(0.008)^6+\frac{(0.008)^7}{1-0.008}\right)<10^{-6}.$$

Thus $\eta_{\mathrm{ret}} > 0.989999 > 0$ and $\eta_{\mathrm{ret}} < H_5$. Finally, the change of basis divides both action coordinates by the same positive factor, which cancels in their ratio. □

Subsequent evaluation gives

$$H_5 = 1.0545718176461544696\ldots,$$
$$\eta_{\mathrm{ret}} = 1.0545718169150390611\ldots,$$
$$R_{\mathrm{act}} = 1.0000000006932817630\ldots.$$

The difference and quotient are two readings of the same sections, one additive and the other multiplicative. They do not represent two independent Planck constants. The passage from angular action to action per complete turn is expressed in each section by $h = 2\pi\hbar$. The subsequent chart $\mathcal{U}_S \mapsto \mathrm{J\,s}$ assigns a unit but does not act retroactively on the decimal order already proved.

Regional return can also be written in an angular chart. This reparametrization is not an indispensable additional dependency: (16.29)–(16.32) supply H_5, η_{ret} and R_{act} directly. If angle and counter-angle are introduced, both must be transported in the same chart; degrees and radians are not mixed within a difference.

16.2.7.2 Regional continuation and renewal equation

The selector 169 determines the degree-six impulse. Subsequent extension is organized by the transfer D_A and unit normalization of the determinant line. These rules admit a formal-series formulation before substituting $z = \alpha$, with D_A already constructed. Write

$$\mathscr{C}(z) = 169z^6 + R(z), \qquad R(z) \in z^7\mathbb{R}[[z]].$$

Concatenating an extension increases degree by one and multiplies its weight by D_A. The first strict extension has weight D_A. Its renewal equation is therefore

$$R(z) = D_A z^7 + D_A z R(z). \tag{16.36}$$

Proposition 16.31 (Formal uniqueness of the normalized continuation)**.** *Equation* (16.36) *determines a unique series, and*

$$\mathscr{C}(z) = 169z^6 + \frac{D_A z^7}{1 - D_A z} = 169z^6 + \sum_{n=7}^{\infty} D_A^{n-6} z^n.$$

The realization is analytic in $|D_A z| < 1$.

Proof. The element $1 - D_A z$ has constant term one and is invertible in the formal power-series ring. Solving the equation produces the displayed series. Equivalently, the degree-seven coefficient is D_A and each subsequent coefficient is D_A times the preceding one. The geometric series converges absolutely in the stated disk. □

Normalization of the first extension is an indispensable operational datum. If only the degree-six impulse and concatenation ratio were retained, the series

$$169z^6 + \lambda \frac{D_A z^7}{1 - D_A z}$$

would still share both data for any λ. The unit rule fixes $\lambda = 1$ before evaluation. Each rule's contribution to reader uniqueness is thus located, and the rational expression preserves the complete continuation.

16.2.7.3 Reduced Planck constant and return of the action section

In the dimensional chart of (16.34), the section before return is the model's construction intended for comparison with the reduced Planck constant:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34} \mathcal{U}_S.$$

The subsequent section also preserves the regional compensation $90\mathscr{C}(\alpha)/\pi$. Both belong to the same action line, and their quotient R_{act} measures the multiplicative effect of return. The passage to h through 2π uses the relationship between angular parametrization and a complete turn.

This construction effectively enters $R_{\mathrm{act}}^{80-54\alpha+6\Delta_4}$. The electron preserves its central coordinate and trajectory; the chronological scale does not replace this structure with an undifferentiated quantum. Nor is a mass already expressed in MeV multiplied again by 10^{-34}: the decade belongs to the action section, cancels in its dimensionless quotient and reappears only where the corresponding dimensional realization acts.

The numerical comparison of H_5, the returned section and $h/(2\pi)$ is presented in Section 140.1. This distinguishes the name of the physical object, the equation assigned to it by the model and the precision with which that equation reproduces it.

16.2.8 Two readers of the electronic return

Electronic memory is represented by a tritic word of length 108 and a signed twelve-phase word. To make the exponent calculation reproducible, we specify the chronological projection used. Initially, let $(r_0, c_0) = (5, 5)$ and $(h_0, v_0) = (1, 1)$. At each step, the selector repeats $(+1, -1, 0)$. With orientation fixed within each twenty-seven-step block, the visible rule is

mode	read integer	cellular transport
$+1$	$r + c$	$c \mapsto 1 + (c - 1 + h) \bmod 9$
-1	rc	$r \mapsto 1 + (r - 1 + v) \bmod 9$
0	9	without displacement

The emitted symbol is $\rho_9(\text{read integer}) \bmod 3$. After steps $27, 54, 81$, h and v are inverted simultaneously. This rule calculates the observable projection; the state update additionally preserves residue, quotient, carry, sheet, boundary and memory. The register of 108 symbols is not identified with the complete state.

In each complete three-step block, each coordinate advances once; nine such blocks are needed to return to the center in the same phase. The minimal length of this recorded return is therefore 27. If phase is forgotten, the cell is already reached after step 26, before the neutral threshold completing the block; that is not the typed return counted by $\mathcal{K}_e$. The explicit reading of the first two return blocks gives

$$a = 100000220, \qquad b = 120200000, \qquad \gamma_e = (a^3 b^3)^2. \tag{16.37}$$

Here, powers denote word concatenation. In particular, $\gamma_{e,t+54} = \gamma_{e,t}$. In the record of nine steps per phase, the central orientations give

$$\tau_e = (1, 1, 1, -1, -1, -1, 1, 1, 1, -1, -1, -1). \tag{16.38}$$

The periodicity of these representations does not amount to restarting the history that produces them.

Definition 16.32 (Cyclic discrepancy reader)**.** For a word $\gamma \in \mathbb{F}_3^{108}$, define

$$D_k(\gamma) = \#\{t \in \mathbb{Z}/108\mathbb{Z} : \gamma_t \neq \gamma_{t+k}\}.$$

On the domain of words whose period divides 54, the integer reader is

$$K_D(\gamma) = \left(D_{27} + D_{36}, D_1, \frac{D_4 - D_3}{2} \right). \tag{16.39}$$

Lemma 16.33 (Integrality and central evaluation)**.** *The D_k on the preceding domain are even. For* (16.37)*,*

k	1	3	4	27	36
D_k	54	56	68	48	32

y $K_D(\gamma_e) = (80, 54, 6)$.

Proof. The map $t \mapsto t + 54$ pairs discrepancy indices without fixed points and preserves their condition; each cardinality is even. For the explicit word a^3b^3 of length 54, the discrepancy count for each displacement is, in the same order, 27, 28, 34, 24, 16. Doubling the word doubles these five cardinalities. Finally,

$$(D_{27} + D_{36}, D_1, (D_4 - D_3)/2) = (48 + 32, 54, (68 - 56)/2) = (80, 54, 6).$$

□

The shifts 27 and 36 are the chronological lifts of the channels of 90 and 120 degrees in a chart where nine steps correspond to thirty degrees. The angular reading explains that representation, but the integers are computed on the word, without introducing a mass or a sought real value.

Definition 16.34 (Dodecaphasic window reader)**.** For $\tau \in \{-1, 0, 1\}^{12}$, with cyclic indices, let

$$C_k(\tau) = \sum_{r=0}^{11} \tau_r \tau_{r+k},$$

$$A_\ell(\tau) = \sum_{r=0}^{11} \left(\sum_{j=0}^{\ell-1} \tau_{r+j} \right)^2,$$

$$P_6(\tau) = \sum_{r=0}^{5} \tau_r \tau_{r+6}.$$

We define

$$\Omega(\tau) = 4A_3(\tau) - 3A_4(\tau), \qquad K_\Omega(\tau) = (\Omega(\tau), 54, P_6(\tau)). \tag{16.40}$$

The 54 in this reader records the declared chronological half-turn. It is not confused with the local APP jump of value four.

Lemma 16.35 (Primitive contrast and correlation form)**.** *Among integer linear contrasts $uA_3 + vA_4$ that vanish whenever $A_3 = 3a$ and $A_4 = 4a$, the primitive pair, with orientation* 90 − 120*, is* $(u, v) = (4, -3)$*. Moreover,*

$$\Omega = -2C_1 - 4C_2 - 6C_3. \tag{16.41}$$

Proof. Vanishing for every a requires $3u + 4v = 0$. By coprimality, the solutions are $(u, v) = n(4, -3)$, and orientation fixes the sign of the primitive generator. Expanding the squares gives

$$A_\ell = \ell C_0 + 2 \sum_{k=1}^{\ell-1} (\ell - k) C_k.$$

Therefore, $A_3 = 3C_0 + 4C_1 + 2C_2$ and $A_4 = 4C_0 + 6C_1 + 4C_2 + 2C_3$. Their combination $4A_3 - 3A_4$ cancels C_0 and yields (16.41). □

The uniqueness proved belongs to that class of integer linear contrasts; it does not by itself exclude every nonlinear functional of the windows. Specifying the functional class avoids turning an identity of two channels into a claim of universal selection.

Theorem 16.36 (Return triple of the electronic section)**.** *The two readers applied to the records of* Γ_e *coincide and give*

$$K_D(\gamma_e) = K_\Omega(\tau_e) = (80, 54, 6). \tag{16.42}$$

Their evaluation in the already generated coordinates is

$$\kappa_e = 80 - 54\alpha + 6\Delta_4. \tag{16.43}$$

Proof. The first reader was computed above. For τ_e, the antipodal product is always one, and hence $P_6 = 6$. The cyclic count gives $C_1 = 4$, $C_2 = -4$, $C_3 = -12$; thus

$$\Omega = -2 \cdot 4 - 4(-4) - 6(-12) = 80.$$

Equivalently, $A_3 = 44$, $A_4 = 32$, and $4 \cdot 44 - 3 \cdot 32 = 80$. Both triples are therefore $(80, 54, 6)$. Evaluating the functional $(A, B, C) \mapsto A - \alpha B + \Delta_4 C$ proves the last formula. □

This coincidence concerns the central section. It does not identify the two readers on every route domain: one compares tritic symbols and the other compares windows of a signed record. Nor is 80 obtained from the period of a word assigned to Euler's number. Its origin in this composition is the triple of the electronic route.

16.2.9 Complete electronic composition and normalization

Definition 16.37 (Multiplicative return)**.** The action of return memory on the basal coordinate is

$$\varepsilon_e^{\beta} = \varepsilon_e^{(0)} \exp(\kappa_e \log R_{\mathrm{act}})\,. \tag{16.44}$$

Theorem 16.38 (Positive electronic factorization)**.** *With the declared readers, orientation, and normalization,* (16.44) *coincides with* (16.7)*. All its factors are dimensionless and the resulting coordinate is positive.*

Proof. The incompatibility norm is (16.12); modal transfer, deficit, and retained memory compose (16.24). The triple (16.42) produces (16.43), and the ratio of the two action sections is (16.35). Substituting those three identities into (16.44) yields exactly (16.7). The basal stage is positive, as is the exponential of a real number. The common factor with the dimension of action has already canceled in forming R_{act}. □

The evaluation of this composition begins with

$$\varepsilon_e^{\beta} = 0.5109989506900008086082571648\ldots. \tag{16.45}$$

The digits are a subsequent evaluation of the formula, not data used to select 22, 15, or $(80, 54, 6)$. The numerical representation of the basal coordinate by a finite prefix introduces only its truncation error; it does not modify the exact formula defining it.

The effect of a different torsional normalization can be located without comparison to a measurement. Write $B = \frac{\sqrt{3}}{4}[\exp(\varphi/\pi^2) - 22\alpha^3]$, $R = R_{\mathrm{act}}$, and

$$\mathcal{E}(d) = B(1 + 15d)R^{80-54\alpha+6d}.$$

For the two defects in (16.22),

$$\frac{\mathcal{E}(\Delta_4)}{\mathcal{E}(d_4)} = \frac{1+15\Delta_4}{1+15d_4} R^{6(\Delta_4-d_4)} > 1. \tag{16.46}$$

The first torsional inequality and $R > 1$ prove that they are not the same coordinate. If only the defect in the exponent is changed, keeping the complete basal coordinate, the ratio of the two outputs is $R^{6(\Delta_4-d_4)}$, again different from one. A very small difference is still a difference of formula; it cannot be attributed to a mere conversion of units.

16.2.10 Dimensional realization: energy, mass, and chronological scale

The electronic coordinate finally acts on a dimensional line. Let $\mathcal{L}_E$ be an energy line with positive basis $\mathcal{U}_E$. The realization is

$$E_e^{(0)} = \varepsilon_e^{(0)} \mathcal{U}_E, \qquad E_e^{\beta} = \varepsilon_e^{\beta} \mathcal{U}_E, \qquad m_e^{\beta} = \frac{E_e^{\beta}}{c_{\mathrm{int}}^2}. \tag{16.47}$$

The last expression belongs to the mass line when c_{int} carries the dimension of speed in the declared realization. In the comparative chart $\mathcal{U}_E = 1$ MeV, (16.45) expresses an energy in MeV; the corresponding mass is expressed in MeV/c^2. It is common to abbreviate both quantities by taking $c = 1$, but that abbreviation must not obscure the dimensional map.

The action scale also admits an action–clock realization. If t_0 is a positive temporal section, the 108-step clock defines

$$\omega_0 = \frac{2\pi}{108 t_0}, \qquad E_{\mathrm{clk}} = \hbar_{\mathrm{ret}} \omega_0, \qquad m_{\mathrm{clk}} = E_{\mathrm{clk}} c_{\mathrm{int}}^{-2}. \tag{16.48}$$

Action times frequency has the dimension of energy. This chronological quantum is a common dimensional section; it is not, by definition, the electronic section. The route word and its factors are not obtained from the uniformity of the clock.

Proposition 16.39 (Cancellation of the common scale)**.** *The factor* $10^{-34}\mathcal{U}_S$ *in* (16.34) *is not part of* κ_e*. On the same energy line,*

$$\frac{E_e^{\beta}}{E_e^{(0)}} = R_{\mathrm{act}}^{\kappa_e}. \tag{16.49}$$

The result is independent of the choice of the common dimensional basis.

Proof. In forming $\hbar_{\mathrm{pre}}/\hbar_{\mathrm{ret}}$, the factor $10^{-34}\mathcal{U}_S$ cancels exactly. Dividing the two energy expressions in (16.47) also cancels $\mathcal{U}_E$, and (16.44) gives the stated ratio. □

Therefore, a coordinate already expressed in MeV is not multiplied again by 10^{-34}. If E_{clk} is chosen as the basis of $\mathcal{L}_E$, the coordinates must be transported by the change-of-basis factor; retaining unchanged the numerical value from the one-MeV chart would identify two bases without proving it. This is the precise point at which the action scale enters the absolute realization and ceases to enter into the relative corrector.

There is also a linear realization that makes the separation between clock and genealogy visible. On $\ell^2(\mathbb{Z}/108\mathbb{Z};\mathbb{R})$, the cyclic shift S has fixed space

$$\ker(S - I) = \mathbb{R} n_0, \qquad n_0 = \frac{1}{\sqrt{108}} \sum_{t=0}^{107} \delta_t.$$

If g_{Γ_e} is the route symbol in the free linearization of genealogies and $\mathcal{U}_M$ is a basis of the mass line, the rank-one map is defined by

$$\mathfrak{C}_e : \mathbb{R}n_0 \otimes \mathbb{R}g_{\Gamma_e} \longrightarrow \mathcal{L}_M, \qquad \mathfrak{C}_e(n_0 \otimes g_{\Gamma_e}) = \varepsilon_e^{\beta}\mathcal{U}_M. \tag{16.50}$$

The map assembles the preceding factorization once its bases have been declared. The uniform vector n_0 does not select ε_e^{β}: that coordinate comes from APP, the oriented return, and its readers. An algebraic realization of the null mode is thus distinguished from an identification of the electron with the clock quantum.

The internal conclusion is the positive factorization of a central section, with its explicit operations, memory and normalizations. Assignment to a physical electron adds the charge representation, spin, coupling and corresponding units chart; it does not follow exclusively from a decimal coincidence. Metrological comparison is presented after the exceptional prolongation and does not alter the inputs to any construction performed here.

16.2.10.1 Structural dependence of the electronic coordinate

The electronic equation expresses a hierarchical composition. Its first factor, $\sqrt{3}/4$, belongs to the central matrix structure and fixes a geometric normalization. The exponent φ/π^2 uses the already generated regional coordinates in the indicated orientation of the areal–volumetric reader. The term $22\alpha^3$ incorporates the dodecaphasic coupling into the cubic correction. The factor $1 + 15\Delta_4$ preserves the global torsional normalization. Finally, the quotient of the action sections acts with the exponent determined by the return readers. Each operation thus has a different antecedent within the same construction.

The articulation becomes more precise when its dependencies are considered. The central norm can be calculated before the regional coordinates are evaluated. The exponential and cubic correction require those coordinates and the closure of α. Multiplicative memory additionally requires the action sections and the 108-position trajectory. Knowing the basal expression therefore does not amount to having evaluated the complete coordinate. The succession of operations does not add an external mass to the point $(5, 5)$; it develops the readers assigned to its persistent section.

The distinction between scale and structure also provides an interpretation of the physical comparison. Mass is the dimensional realization of the complete coordinate, while the centre, involution, and vacancy describe the relations that produce it. A common change of unit modifies the dimensional coordinates, but leaves the dimensionless ratios and the proved transport identities unchanged. This is the sense in which the electron preserves its structural character when expressed relative to a chronological scale.

16.2.11 Lorentzian transport and electromagnetic representation

The electronic section provides a structure and a coordinate before its application to an interaction. The Lorentzian realization of cubic incidence determines, with the declared temporal convention, the space of forms in which that interaction can be expressed. To formulate it, an oriented local realization $(\mathcal{M}, g)$ of dimension four is fixed, with tangent fibers identified with the model $Q_{\square}$. A connection ∇ with $\nabla g = 0$, a potential one-form $A \in \Omega^1(\mathcal{M})$, its curvature $F = dA$ and a charge representation of the section are also specified. These data are the arguments of the physical representation that follows.

Hodge duality satisfies $\star^2 = -I$ on two-forms. The electric and magnetic separation corresponds to a temporal choice in the decomposition $1 + 3$; F and $\star F$ preserve their relation within the same space of two-forms. Neutrality of a charge representation means $q = 0$, while the section may preserve orientation, phase and internal transport. Absence of electric coupling in that representation has content distinct from absence of phase information.

In this dimensional realization, let $m_e > 0$, q be the charge, $\gamma(s)$ a parametrized trajectory and $u = \dot{\gamma}$ its four-velocity. The Lorentz force is expressed by

$$m_e \nabla_u u^\mu = q F^\mu{}_\nu u^\nu. \tag{16.51}$$

Antisymmetry of F implies $F_{\mu\nu} u^\mu u^\nu = 0$. Consequently,

$$\frac{d}{ds} g(u,u) = 2g(\nabla_u u, u) = 0.$$

Normalization of the trajectory is preserved provided ∇ is metric and (16.51) holds. The mass used is the dimensional realization of the preceding electronic section; the coupling parameter is identified in the adopted electromagnetic convention. The specific derivation of the potential and a field configuration constitutes an additional problem with its own boundary conditions. The result presented here determines the domain, representation data and conservation implied by its equation.

TPK route inversion and orientation of an electronic line then offer a precise comparison: each has its involution, transport and representation. The Wheeler and Feynman antecedent places the question historically; equivalence of two realizations is decided through their maps and compatibility conditions. This arrangement allows the arithmetic origin of the electron to remain connected to the formulation of its interaction, making explicit the function of each stage.

16.3 CKM mixing angles, CP phase and leptonic transport

16.3.1 Common antecedent and distinction between the two transports

The common foundation of the article produces the enriched state through the two APP evaluations, the oriented TRIT selection and the effective composition of selection, transport, carry, memory and return in the TPK. The angular expressions do not replace that state: they are readers of its record. In particular, the extension $w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$ preserves the provenance of the numerical readings, and the holonomy Γ_9 acts before the reduced expression K_{ph}. Phase return does not reset the record.

Two classes of objects are received here from that same antecedent. The first contains the direct angle, the counterangle and the torsional defect Δ_4, already constructed in their own readers. The second contains the surviving extensions, their observable routes, the dodecaphasic record and the operators of the material fibres. The extension–route–record–signature–character–towers chain preserves the atlas $81/56/13/324$ and distinguishes the null chart from the positive branch. The mixing angles neither retrospectively select those routes nor generate the mass eigenvalues.

Quark transport uses a rational angular chart and its complex unitary realization. Leptonic transport uses the spectral frames of the charged and neutral fibres. Both proceed from the common discrete

structure, but their domains, readers and changes of basis are distinct. Nor are the Barbero–Immirzi functional and mixing defined through one another: they receive typed expressions from the angular and incidence antecedent. Their relationship is expressed through those maps, not through a retrospective formula using a Barbero value as a mixing selector.

Remark 16.40 (Sectorial rules and evaluation of the reader). The three sectorial rules and their evaluation are developed below in Section 16.3.2. Theorem 16.44 obtains the columns as images of the angular basis. Subsequent proofs establish inversion of the chart, sheet transport, the metric and the complex realization. Choosing the rules and evaluating their coefficients are two distinct mathematical questions: the initial system is declared in Definition 16.43, and the theorem's proof uses that complete system. The preceding composition that selects those rules from the incidence requires its own proof.

16.3.2 Sectorial incidence and construction of the angular reader

The angular construction uses the action and closure expressions obtained previously from APP–TRIT–TPK. The direct angle, the counterangle and the torsional defect preserve their own domains. The quark reader combines these three coordinates through sectorial incidence; its evaluation precedes the complex amplitudes and metrological comparison. The hexadic–octadic inclusion enters the third sector through the difference between their cardinalities.

16.3.2.1 Marked incidence and bidirectional normalization

The reader invariants preserve the nature of the object from which they arise. The marked intersection $B_K = H_e \cap P_\pi$ has cardinality $b = 4$; the integer $q = 7$ is the coordinate of the pivot p_φ in the oriented numbering. The determination order of the Steiner design is $p = 5$. The hexadic and octadic supports have cardinalities $h_6 = 6$ and $o_8 = 8$, and the tritic orientation alphabet has cardinality $t = 3$. A support cardinality and a pivot coordinate are used through their respective maps, even when both are expressed as integers.

Normalization of the pentagonal self-crossing admits the following explicit realization. Let P be the five-position support of the closure, and let $X = P \times P$ be its space of ordered pairs. Bidirectional inversion on this space is

$$\jmath : X \longrightarrow X, \qquad \jmath(x, y) = (y, x), \qquad \jmath^2 = I.$$

The stabilizer information of each orbit is preserved. For an orbit $[z]$, define its weight as $1/|\operatorname{Stab}_{C_2}(z)|$. The sum of these weights is the cardinality of the action groupoid $X/\!/C_2$.

Proposition 16.41 (Orbital measure of bidirectional self-crossing)**.** *For a finite support of cardinality p, inversion of ordered pairs determines*

$$|(P \times P)/\!/C_2| = \sum_{[z] \in (P \times P)/C_2} \frac{1}{|\operatorname{Stab}_{C_2}(z)|} = \frac{p^2}{2}.$$

For $p = 5$, the self-crossing has ten free orbits and five fixed orbits, and its orbital measure is $10 + 5/2 = 25/2$.

Proof. Each diagonal pair (x, x) forms a fixed orbit, whose stabilizer has order two; there are p such orbits. The remaining $p(p-1)$ pairs are grouped in twos, with trivial stabilizer. Their contribution is therefore $p(p-1)/2$, and that of the diagonal is $p/2$. The sum is $p^2/2$. Equivalently, the orbit–stabilizer identity gives $1/|\operatorname{Stab}(z)| = |[z]|/2$; summing over all orbits produces $|P \times P|/2$. □

The measure explicitly preserves the contribution of fixed points. The ordinary orbit set has cardinality $p(p+1)/2$, equal to fifteen in the pentagonal closure. The orbital measure and that cardinality are two

determinate readings of the same inversion. The reader's bidirectional normalization uses the former: the ten free orbits have unit weight, and the five diagonals have half-unit weight.

This realization specifies the factor $p^2/2$ used in the following sectorial system. The assignment of that contribution to sector 23, its negative orientation, and the other two incidence rules remain specified by the complete sectorial system. The proof establishes the normalization of self-crossing and preserves the selection of the angular functionals as a distinct matter.

16.3.2.2 Carry transport and integer holonomy of the arithmetic crossing

The modular reading of the crossing admits an integral realization that retains the information accumulated when crossing the boundary. That realization is developed here through transport quotients. Its domain is a lifted chart of the APP support; the subsequent assignment of a region to an angular sector preserves its own incidence map.

Nonadic chart and lifted transport. We use the exact decomposition

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n-1}{9} \right\rfloor, \qquad n = \rho_9(n) + 9q_9(n).$$

A lifted position is $z = (x, y, q_x, q_y) \in D_9^2 \times \mathbb{Z}^2$, where $X = x + 9q_x$ and $Y = y + 9q_y$. The integer increment u of the first coordinate acts by

$$T_u^x(x, y, q_x, q_y) = \big(\rho_9(x+u), y, q_x + c_9(x;u), q_y\big), \qquad c_9(x;u) = \left\lfloor \frac{x+u-1}{9} \right\rfloor.$$

The second coordinate is transported in the same way. Cardinal advances correspond to $u = \pm 1$; the zero increment preserves the state. The cocycle satisfies

$$c_9(x; u+v) = c_9(x;u) + c_9(\rho_9(x+u); v).$$

Indeed, both sides are the quotient of the unique decomposition of $x + u + v$ with remainder in D_9. Consequently, $T_v^x T_u^x = T_{u+v}^x$ and $T_{-u}^x = (T_u^x)^{-1}$; the transports of the two coordinates commute. The state preserves the number of edge crossings even when the visible position returns.

Lifted sheets and update of records. The integral realization is fixed by prolonging the APP arithmetic operations to the transported coordinates:

$$\widetilde{S}(z) = X + Y = x + y + 9(q_x + q_y),$$
$$\widetilde{P}(z) = XY = xy + 9(q_x y + q_y x) + 81 q_x q_y.$$

At each position the record of both sheets is preserved:

$$\big(\rho_9(\widetilde{S}), q_9(\widetilde{S}), \rho_9(\widetilde{P}), q_9(\widetilde{P})\big).$$

If $e : z \to z'$ is a link and T the selected sheet, its full increment is obtained from the record before and after transport:

$$\delta_e \widetilde{T} = \rho_9(\widetilde{T}(z')) - \rho_9(\widetilde{T}(z)) + 9\big(q_9(\widetilde{T}(z')) - q_9(\widetilde{T}(z))\big). \tag{16.52}$$

This identity makes conservation explicit: the residue jump and the quotient increment jointly reconstruct the change of sheet. Sheet selection, cardinal transport and record updating are distinct operations. In this chart, the ordered sheet selection (T_x, T_y) is first composed with T_d and with the updating of their quotients; the formula does not postulate that the entire TPK is reduced to this local representation.

Proposition 16.42 (Integral curvature and boundary transport)**.** *Define* $\widetilde{A}_x = \delta_x \widetilde{T}_x$ *and* $\widetilde{A}_y = \delta_y \widetilde{T}_y$ *through* (16.52)*, and let*

$$\widetilde{F}_{xy}(X,Y) = \widetilde{A}_x(X,Y) + \widetilde{A}_y(X+1,Y) - \widetilde{A}_x(X,Y+1) - \widetilde{A}_y(X,Y).$$

Homogeneous choices have zero curvature. The mixed choices $(\widetilde{S},\widetilde{P})$ *and* $(\widetilde{P},\widetilde{S})$ *have curvature* $+1$ *and* -1*, respectively, as integers. For the positive boundary of a rectangle* $R_{a,b}$ *with integer sides* $a, b > 0$*,*

$$\widetilde{W}_{SP}(\partial R_{a,b}) = ab, \qquad \widetilde{W}_{PS}(\partial R_{a,b}) = -ab.$$

The result is independent of the base point and the number of crossings of nonadic seams.

Proof. Exact reconstruction of the two sheets gives

$$\delta_x \widetilde{S} = \delta_y \widetilde{S} = 1, \qquad \delta_x \widetilde{P} = Y, \qquad \delta_y \widetilde{P} = X.$$

Thus the SP connection is $(1, X)$, with curvature $1 + (X+1) - 1 - X = 1$; the PS connection is $(Y, 1)$, with curvature $Y + 1 - (Y+1) - 1 = -1$. For a single sheet, mixed differences cancel. Summing the curvatures of the ab plaquettes cancels each interior link with its inverse and preserves the boundary links. This yields $\pm ab$ in $\mathbb{Z}$. The transported quotients ensure the same identity holds across any seam. □

The boundary accumulator can in turn be retained in nonadic form: $W = r_W + 9q_W$. For an integer contribution w_e, it is updated by

$$r'_W = \rho_9(r_W + w_e), \qquad q'_W = q_W + \left\lfloor \frac{r_W + w_e - 1}{9} \right\rfloor.$$

Composition through links yields the same sum as its direct integer evaluation. In this chart, integer zero has coordinates $(r_W, q_W) = (9, -1)$; this is an arithmetic representation of the accumulator, with no additional identification with the different oriented zeros of the TRIT.

Three operations on orientation. Let γ be a closed cardinal route. Its time reversal γ^{-1} reverses the order of links and the orientation of each; by additivity,

$$\widetilde{W}_{SP}(\gamma^{-1}) = -\widetilde{W}_{SP}(\gamma).$$

Exchange of sheets likewise satisfies

$$\widetilde{W}_{PS}(\gamma) = -\widetilde{W}_{SP}(\gamma).$$

To check this on any route, note that the sum of both connections is the exact increment of $\widetilde{S}+\widetilde{P} = X+Y+XY$; its integral over a loop is zero.

The simultaneous half-turn of both directions, on the other hand, acts through $J_c(X,Y) = (2c_x - X, 2c_y - Y)$, with $2c \in \mathbb{Z}^2$, and therefore preserves the lattice chart. For a loop,

$$\widetilde{W}_{SP}(J_c\gamma) = \widetilde{W}_{SP}(\gamma).$$

Indeed, the closed horizontal contribution is zero and the vertical contribution transforms as $\sum(2c_x - X)(-\delta Y) = \sum X\delta Y$, since $\sum \delta Y = 0$. A spatial half-turn therefore preserves the areal orientation of this chart. Its combination with time reversal or sheet interchange is calculated by composing the corresponding operations.

The difference matters for the electronic record: simultaneous reversal of both displacements every 27 advances produces, in windows of 9, the sequence

$$\tau_j = (-1)^{\lfloor j/3 \rfloor}, \qquad 0 \le j < 12, \qquad (+,+,+,-,-,-,+,+,+,-,-,-).$$

This sequence records advance orientations. Holonomy additionally requires the links traversed, selected sheets, and accumulated quotients. Transport of electronic orientation is thus preserved without identifying a half-turn of both axes with time reversal of a loop.

Application to the marked crossing and sector scope. For the rectangular crossing with sides 4 and 7, this realization expresses exactly

$$\widetilde{W}_{SP} = 28 = 1 + 9 \cdot 3, \qquad \widetilde{W}_{SP}(\gamma^{-1}) = -28 = 8 + 9(-4).$$

The integer preserves the oriented area; the isolated residue expresses only its nonadic class. For example, starting from $(7, 1)$, the periodic representatives of the links sum to -35, whereas the carry correction adds 63 and recovers 28.

In the marked incidence of the angular reader, 4 is $|H_e \cap P_\pi|$ and 7 is the marked pivot p_φ. The rectangular reading supplies an integer realization of the product $|H_e \cap P_\pi|\, p_\varphi$ once that crossing has been declared. The map identifying that region with sector 12 must preserve the mark and orientation of the sector system in Definition 16.43. Sector assignments $12, 23, 13$ and their combinations of A, h, Δ° are an additional specification beyond the rectangular-holonomy law. The present result makes the area lift, carry, and their involutions explicit, with these starting data declared.

Definition 16.43 (Sectorial system of angular incidence)**.** The sectorial system consists of the ordered sextuple of invariants

$$(b, p, q, h_6, o_8, t) = (4, 5, 7, 6, 8, 3)$$

and the linear maps, on angular coordinates (a, u, d),

$$\mathscr{A}_{12}^{\mathrm{ang}}(a, u, d) = 2a - pu + bq\, d, \tag{16.53}$$

$$\mathscr{A}_{23}^{\mathrm{ang}}(a, u, d) = qu - \frac{p^2}{2}\, d, \tag{16.54}$$

$$\mathscr{A}_{13}^{\mathrm{ang}}(a, u, d) = a - pb\, u - \frac{o_8 - h_6}{t}\, d. \tag{16.55}$$

The symbols h_6, o_8 preserve the cardinalities of the marked incidence; $t = 3$ is the declared tritic normalization of that sector. The sextuple and the three rules jointly form the starting system of this construction.

Theorem 16.44 (Exact evaluation of the sectorial system)**.** *The joint map* $(\mathscr{A}_{12}^{\mathrm{ang}}, \mathscr{A}_{23}^{\mathrm{ang}}, \mathscr{A}_{13}^{\mathrm{ang}})^{\mathsf{T}}$ *of Definition 16.43 has the unique matrix*

$$\mathsf{M}_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}.$$

The three columns are the images of the coordinate vectors $(1, 0, 0)$*,* $(0, 1, 0)$*, and* $(0, 0, 1)$ *under these maps.*

Proof. The sectorial operations give

$$bq = 4 \cdot 7 = 28, \qquad p^2/2 = 5^2/2 = 25/2, \qquad pb = 5 \cdot 4 = 20, \qquad (o_8 - h_6)/t = (8 - 6)/3 = 2/3.$$

Thus the successive images of the coordinate basis are

$$c_A = (2, 0, 1)^{\mathsf{T}}, \qquad c_h = (-5, 7, -20)^{\mathsf{T}}, \qquad c_\Delta = (28, -25/2, -2/3)^{\mathsf{T}}.$$

A linear map is determined by its images on a basis. The matrix with these images as its columns is the one indicated. The proof uses the complete sectorial system of the definition. □

On the previously produced coordinates, take

$$(a, u, d) = \left(A_{\mathrm{deg}}, \frac{C^{*}_{\mathrm{deg}}}{6}, \frac{180}{\pi}\Delta_4 \right).$$

The direct, conjugate, and torsional contributions to each angle are thereby individualized. In particular, the difference $o_8 - h_6 = 2$ is preserved in the coefficient of the torsional defect in sector 13. This concrete presence makes it possible to follow incidence through to the angular reader, keeping the sectorial system, its evaluation, and the unitary parametrization separate.

16.3.3 Rational CKM chart and angular units

We write A_{deg} and C^{*}_{deg} for the degree coordinates of the HMT angles already generated. We use the abbreviations

$$h_\theta = \frac{C^{*}_{\mathrm{deg}}}{6}, \qquad \Delta_{\mathrm{deg}} = \frac{180}{\pi_{\mathrm{HMT}}}\Delta_4, \qquad x_\theta = (A_{\mathrm{deg}}, h_\theta, \Delta_{\mathrm{deg}})^{\mathsf{T}}. \tag{16.56}$$

Here h_θ is an angular coordinate, distinct from the Planck constant h. Conversion to degrees is a subsequent expression; it does not introduce a conventional value of π into the generator.

Definition 16.45 (Quark angular reader)**.** The inherited reader $\mathsf{M}_{\mathrm{CKM}} : \mathbb{R}^3 \to \mathbb{R}^3$ expresses

$$\boldsymbol{\theta}_{\mathrm{deg}} = \mathsf{M}_{\mathrm{CKM}} x_\theta, \qquad \mathsf{M}_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \delta_{\mathrm{deg}} = 9 A_{\mathrm{deg}}. \tag{16.57}$$

The order of the components is $(12, 23, 13)$. The subsequent trigonometric functions are evaluated at $\vartheta_{ab} = (\pi_{\mathrm{HMT}}/180)\theta_{ab,\mathrm{deg}}$ and $\delta = (\pi_{\mathrm{HMT}}/180)\delta_{\mathrm{deg}}$.

Proposition 16.46 (Rational reconstruction of the coordinates)**.** *The reader has determinant* $-3857/6$ *and inverse*

$$\mathsf{M}^{-1}_{\mathrm{CKM}} = \begin{pmatrix} 1528/3857 & 3380/3857 & 801/3857 \\ 75/3857 & 176/3857 & -150/3857 \\ 6/551 & -30/551 & -12/551 \end{pmatrix}. \tag{16.58}$$

In particular,

$$\begin{aligned} A_{\mathrm{deg}} &= \frac{1528\theta_{12,\mathrm{deg}} + 3380\theta_{23,\mathrm{deg}} + 801\theta_{13,\mathrm{deg}}}{3857}, \\ C^{*}_{\mathrm{deg}} &= \frac{6(75\theta_{12,\mathrm{deg}} + 176\theta_{23,\mathrm{deg}} - 150\theta_{13,\mathrm{deg}})}{3857}, \\ \Delta_{\mathrm{deg}} &= \frac{6\theta_{12,\mathrm{deg}} - 30\theta_{23,\mathrm{deg}} - 12\theta_{13,\mathrm{deg}}}{551}. \end{aligned} \tag{16.59}$$

The phase satisfies the exact linear check

$$3857\,\delta_{\mathrm{deg}} = 9(1528\theta_{12,\mathrm{deg}} + 3380\theta_{23,\mathrm{deg}} + 801\theta_{13,\mathrm{deg}}). \tag{16.60}$$

Proof. Expanding the determinant of (16.57) gives $-3857/6$. Multiplying the matrix indicated in (16.58) by $\mathsf{M}_{\mathrm{CKM}}$, in both orders, gives I_3. Its rows recover the three components of x_θ; the second is multiplied by six to recover C^*_{deg}. Finally, we use $\delta_{\mathrm{deg}} = 9A_{\mathrm{deg}}$. □

Inversion reconstructs the coordinates of the reader once the reader has been fixed. It does not turn the observed angles into antecedents of A, C^* or Δ_4.

16.3.4 Geometric decomposition under sheet inversion

In the angular chart, sheet inversion preserves a, d and reverses u. The expressed vector admits the decomposition

$$\boldsymbol{\theta}_+ = ac_A + uc_h + dc_\Delta, \qquad \boldsymbol{\theta}_- = ac_A - uc_h + dc_\Delta.$$

Proposition 16.47 (Even and odd components of angular transport)**.** *The two expressions satisfy*

$$\frac{\boldsymbol{\theta}_+ + \boldsymbol{\theta}_-}{2} = ac_A + dc_\Delta, \qquad \frac{\boldsymbol{\theta}_+ - \boldsymbol{\theta}_-}{2} = uc_h.$$

The contribution that changes sign occupies the line $\mathrm{span}(c_h)$*; the preserved component occupies* $\mathrm{span}(c_A, c_\Delta)$.

Proof. The sum cancels the terms uc_h, and the difference cancels the other two. The columns are linearly independent, since $\det \mathsf{M}_{\mathrm{CKM}} = -3857/6$. The two components therefore form a direct decomposition. □

The same inversion acts on the Barbero–Immirzi evaluation: it interchanges q_+ and q_-, and reverses the bilinear component in A and C^*. Consequently, the incidence functional is odd. An observable symmetric in both channels preserves its value. This parity difference expresses how a single operation on the structure yields different responses depending on the reader: areal orientation, symmetric information and the mixing vector preserve different information from the same antecedent.

16.3.5 Transport of sheet inversion

Conjugation of the angular charts retains A_{deg} and Δ_{deg}, and reverses h_θ. Define

$$D_\theta = \mathrm{diag}(1, -1, 1), \qquad c_h = (-5, 7, -20)^{\mathsf{T}}, \qquad \ell_h = \frac{1}{3857}(75, 176, -150). \tag{16.61}$$

If $c_A = (2, 0, 1)^{\mathsf{T}}$ and $c_\Delta = (28, -25/2, -2/3)^{\mathsf{T}}$, then $\ell_h c_A = \ell_h c_\Delta = 0$ and $\ell_h c_h = 1$.

Theorem 16.48 (Rational reflection and transported metric)**.** *The operator*

$$\mathcal{R}_{\mathrm{CKM}} = \mathsf{M}_{\mathrm{CKM}} D_\theta \mathsf{M}_{\mathrm{CKM}}^{-1} = I_3 - 2c_h\ell_h \tag{16.62}$$

satisfies

$$\mathcal{R}_{\mathrm{CKM}}^2 = I_3, \qquad \det \mathcal{R}_{\mathrm{CKM}} = -1, \qquad \mathcal{R}_{\mathrm{CKM}} \mathsf{M}_{\mathrm{CKM}} = \mathsf{M}_{\mathrm{CKM}} D_\theta. \tag{16.63}$$

It is an orthogonal reflection for the positive metric

$$G_\theta = (\mathsf{M}_{\mathrm{CKM}}^{-1})^{\mathsf{T}} \mathsf{M}_{\mathrm{CKM}}^{-1}, \qquad \mathcal{R}_{\mathrm{CKM}}^{\mathsf{T}} G_\theta \mathcal{R}_{\mathrm{CKM}} = G_\theta. \tag{16.64}$$

Proof. The operator $P_h = c_h\ell_h$ satisfies $P_h^2 = P_h$, has image $\mathbb{R}c_h$ and kernel $\mathrm{span}(c_A, c_\Delta)$. Hence $(I_3 - 2P_h)^2 = I_3$, with eigenvalues $1, 1, -1$. Its action on these three columns is that of D_θ in the original basis, proving conjugation and intertwining. For $v \neq 0$, $v^{\mathsf{T}} G_\theta v = \|\mathsf{M}_{\mathrm{CKM}}^{-1} v\|^2 > 0$. The last identity follows from $D_\theta^{\mathsf{T}} D_\theta = I_3$. □

Its full expression, retained from the preceding support, is

$$\mathcal{R}_{\mathrm{CKM}} = \begin{pmatrix} 4607/3857 & 1760/3857 & -1500/3857 \\ -150/551 & 199/551 & 300/551 \\ 3000/3857 & 7040/3857 & -2143/3857 \end{pmatrix}. \tag{16.65}$$

The phase $\delta_{\mathrm{deg}} = 9A_{\mathrm{deg}}$ remains fixed under this reflection. Consequently, sheet transport must not be identified with CP conjugation of amplitudes, which changes the sign of the complex phase. The combinatorial parity of a route, its sheet conjugation and its physical representation retain the distinct domains in equations (16.66) and (16.67).

16.3.6 Record parity and CP realization

To preserve the discrete support of this distinction, let ρ be a recorded route of length L, with directions $d_t \in \{N, E, S, W\}$ and sheets $\ell_t \in \{\Sigma, \Pi\}$. The intermediate states are those produced by TPK transport. The reflection P acts through $(i, j) \mapsto (i, -j) \pmod 9$ and permutes E, W; C_{hoja} permutes Σ, Π; T_{reg} reverses the order of the record and replaces each direction by its opposite. Inversion is performed on the enriched record, not on a projection that has forgotten its predecessor.

Proposition 16.49 (Invariance of the combinatorial route action)**.** *For $\lambda \geq 0$, the dimensionless functional*

$$\mathcal{A}_\lambda(\rho) = \sum_{t=2}^{L} \left[1 - \delta_{d_t, d_{t-1}} + \lambda(1 - \delta_{\ell_t, \ell_{t-1}})\right] \tag{16.66}$$

is invariant under P, C_{hoja}, T_{reg} and their compositions.

Proof. A global permutation of the alphabet preserves equality between neighbours. Reversing the order preserves the number of consecutive changes. Therefore, each operation separately preserves the direction turns and sheet changes summed by (16.66). □

λ is the declared parameter of this system of functionals; $\mathcal{A}_\lambda$ is not identified with a dimensional Planck section. Invariance of the counter does not imply that every oriented reader is even either. In a mixing realization $\mathcal{V}$, CP compatibility takes the precise form

$$\mathcal{V}(CP_{\mathrm{HMT}}\rho) = D_u\, \overline{\mathcal{V}(\rho)}\, D_d^{\dagger}, \tag{16.67}$$

with the declared diagonal phase changes and representation spaces. The route counter, rational sheet transport and complex conjugation are three distinct maps of the preserved support.

Remark 16.50 (CP compatibility of the physical reader). Equation (16.67) is the CP compatibility condition for the complete physical reader. The proofs in this section establish record invariance and the identities of the complex reader, but do not automatically turn $\mathcal{R}_{\mathrm{CKM}}$ into CP_{HMT}. This qualification concerns that representation square, not the existence of the internal route transport already constructed.

16.3.7 Unitary amplitudes, CP phase and Jarlskog invariant

We write $c_{ab} = \cos\vartheta_{ab}$ and $s_{ab} = \sin\vartheta_{ab}$. The complex realization of the reader is

$$V_{\mathrm{CKM}} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix}. \tag{16.68}$$

The complex structure used is the realization of the oriented structure already constructed; the unitary parametrization expresses the angular result, rather than determining its coefficients.

Proposition 16.51 (Unitarity and phase invariant)**.** *The matrix* (16.68) *is unitary. The quartet*

$$J_{\mathrm{CKM}} = \mathrm{Im}(V_{11}V_{22}\overline{V_{12}}\,\overline{V_{21}}) = c_{12}c_{23}c_{13}^2 s_{12}s_{23}s_{13}\sin\delta \tag{16.69}$$

is invariant under $V \mapsto D_u V D_d$, with unitary diagonal D_u, D_d, and changes sign under $V \mapsto \overline{V}$.

Proof. The matrix is the product $R_{23}U_{13}(\delta)R_{12}$, where

$$\begin{aligned} R_{12} &= \begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \\ U_{13}(\delta) &= \begin{pmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13} \end{pmatrix}, \\ R_{23} &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{pmatrix}. \end{aligned} \tag{16.70}$$

Each factor is unitary by $c_{ab}^2 + s_{ab}^2 = 1$. Substituting the four entries of the quartet, its imaginary part is $c_{12}s_{12}c_{13}^2 c_{23}s_{23}s_{13}(c_{12}^2 + s_{12}^2)\sin\delta$, which gives (16.69). The phase factors of each row and column cancel with their conjugates. Complex conjugation reverses the imaginary part. □

A nonzero J_{CKM} obstructs making the entire matrix real through those phase changes. Its physical interpretation also retains the corresponding sector and representation; it is not a scalar correction added to the masses. If the spectra have degeneracies, their freedoms of change of basis must be preserved before formulating a CP conclusion.

16.3.8 Conjugation of amplitudes and oriented invariant

The complex realization preserves the three mixing angles and the interference phase as explicit coordinates. Write $V(\boldsymbol{\vartheta}, \delta) = R_{23}U_{13}(\delta)R_{12}$, with the rotations and phase defined in the unitary development. The arguments of the trigonometric functions are their representatives in radians.

Proposition 16.52 (Conjugation in the mixing realization)**.** *For the three declared real angles and the declared real phase,*

$$V(\boldsymbol{\vartheta}, -\delta) = \overline{V(\boldsymbol{\vartheta}, \delta)}, \qquad J(\boldsymbol{\vartheta}, -\delta) = -J(\boldsymbol{\vartheta}, \delta).$$

The invariant J also preserves its value under diagonal phase changes of the charged bases.

Proof. The matrices R_{12} and R_{23} have real entries. In U_{13}, the change $\delta \mapsto -\delta$ conjugates the exponential factors. Conjugating the product gives the first identity. In the quartet $V_{11}V_{22}\overline{V_{12}V_{21}}$, the diagonal factors of each row and column cancel. Conjugation reverses the sign of its imaginary part. Equivalently, the result follows by substitution into

$$J = c_{12}c_{23}c_{13}^2 s_{12}s_{23}s_{13}\sin\delta.$$

□

In the three-generation sector, the nonzero internal value of J expresses the obstruction to realizing all amplitudes by a real matrix through diagonal phase changes. This is the charge–parity violation reading

of the constructed matrix. The route reading, in turn, preserves the discrete operation of conjugation and parity and its representation. Their full compatibility is expressed by the square

$$\mathcal{V}(CP_{\mathrm{HMT}}\rho) = D_u\,\overline{\mathcal{V}(\rho)}\,D_d^{\dagger},$$

with the representation spaces and phase changes declared. The conjugation identity proved here fixes exactly the action that this square must transport.

Proposition 16.53 (Mixing and spectrum)**.** *Let $B_u = \mathrm{diag}(a_1, a_2, a_3)$ and $B_d = \mathrm{diag}(b_1, b_2, b_3)$ be the Hermitian mass readers already produced in their fibres. The transport*

$$B_d^{(u)} = V_{\mathrm{CKM}} B_d V_{\mathrm{CKM}}^{\dagger} \tag{16.71}$$

preserves the spectrum of B_d, and satisfies

$$\left|\det[B_u, B_d^{(u)}]\right| = 2|J_{\mathrm{CKM}}| \prod_{i<j} |a_i - a_j| \prod_{r<s} |b_r - b_s|. \tag{16.72}$$

Proof. Unitary conjugation preserves the characteristic polynomial. If $B = B_d^{(u)}$, the entries of the commutator are $[B_u, B]_{ij} = (a_i - a_j)B_{ij}$, with zero diagonal. Its determinant is

$$2i(a_1 - a_2)(a_2 - a_3)(a_3 - a_1)\,\mathrm{Im}(B_{12}B_{23}B_{31}).$$

Upon substituting $B_{ij} = \sum_r b_r V_{ir}\overline{V_{jr}}$, the imaginary part is an alternating polynomial of degree three in the b_r. It is divisible by their three differences: if two b_r coincide, $B = bI + (b' - b)vv^{\dagger}$ and the off-diagonal product is real. Expanding one coefficient, using column orthogonality, gives the quartet of (16.69), with the sign of the chosen ordering. Taking absolute values removes that convention and yields (16.72), including its vanishing at degeneracies. □

Remark 16.54 (Evaluation and comparison). The decimal CKM coordinates in Table 83.3 are subsequent evaluations of the preceding reader. The quantitative comparison section also presents the angles and amplitude moduli. These evaluations are not used to choose its columns or to prove (16.63) or (16.69). This block assigns no new metrological significance to those figures: a joint comparison requires its external edition, observable definitions and covariance. Marginal deviations do not replace it.

16.3.9 Leptonic record, operators and spectral frames

The leptonic sector preserves a different domain. The spectral construction of (16.73) gathers four neutral depths of dimensions 2, 4, 6, 8, before the three-dimensional compression:

$$\mathcal{H}_\nu^{\mathrm{reg}} = \bigoplus_{j=1}^{4} \mathcal{H}_{\nu,G_j}, \qquad \dim \mathcal{H}_\nu^{\mathrm{reg}} = 20, \qquad M_\nu = (P_\nu \mathcal{M}_\nu P_\nu)|_{\mathrm{Im}\,P_\nu}, \quad \mathrm{rank}\,P_\nu = 3. \tag{16.73}$$

The four depths are neither four flavours nor four masses. P_ν is the neutral projector inherited from the record reader, and $M_\ell = (P_\ell \mathcal{M}_\ell P_\ell)|_{\mathrm{Im}\,P_\ell}$, with $\mathrm{rank}\,P_\ell = 3$, is the compressed charged operator. The scale of these operators proceeds from the action–clock–mass branch; no PMNS angle determines it.

Definition 16.55 (Transport of leptonic frames)**.** In the declared common three-dimensional realization, let $F_\ell, F_\nu : \mathbb{C}^3 \to \mathcal{H}_3$ be complete orthonormal spectral frames of the charged and neutral operators. The identification with $\mathcal{H}_3$ is fixed before taking their product. The reader is

$$U_{\mathrm{PMNS}} = F_\ell^{\dagger} F_\nu : \mathbb{C}^3_\nu \longrightarrow \mathbb{C}^3_\ell. \tag{16.74}$$

The frames and identification proceed from the representation and the record; they are not chosen from an experimental matrix one wishes to reproduce.

Theorem 16.56 (Unitarity, degeneracies and naturality)**.** *Under the preceding identification, U_{PMNS} is unitary. If the spectra are simple, their frame changes are diagonal phases and permutations; once the spectral order is fixed, the phases remain. If there are multiplicities $m_{\ell,\lambda}$ and $m_{\nu,\eta}$, the object independent of these bases is the double coset*

$$\left(\prod_{\lambda} U(m_{\ell,\lambda})\right) \backslash U(3) / \left(\prod_{\eta} U(m_{\nu,\eta})\right). \tag{16.75}$$

A common unitary refinement W intertwining both operators preserves transport when the frames are extended as $F'_{\ell} = WF_{\ell}$, $F'_{\nu} = WF_{\nu}$.

Proof. Completeness in the same space gives $F_{\ell}F_{\ell}^{\dagger} = F_{\nu}F_{\nu}^{\dagger} = I_{\mathcal{H}_3}$. Hence $U_{\mathrm{PMNS}}^{\dagger}U_{\mathrm{PMNS}} = F_{\nu}^{\dagger}F_{\ell}F_{\ell}^{\dagger}F_{\nu} = I_3$, and likewise in the opposite order. Basis changes preserving a Hermitian operator act blockwise within its eigenspaces. Substituting $F_{\ell}D_{\ell}, F_{\nu}D_{\nu}$ gives $U \mapsto D_{\ell}^{\dagger}UD_{\nu}$, which determines the double coset. Finally, $(WF_{\ell})^{\dagger}WF_{\nu} = F_{\ell}^{\dagger}F_{\nu}$. □

The common-space condition is substantive. For two isometric frames in a larger ambient space, separate orthonormality produces only a compression; it does not justify cancelling $F_{\ell}F_{\ell}^{\dagger}$ as though it were the ambient identity.

16.3.10 Record kernel and rank sufficiency

The readers Ξ_r preserve the carry, sheet, orientation, vacancy and holonomy components of the record. On the finite set of admitted routes, form

$$K_{\mathrm{reg}}(c,d) = \sum_{\substack{r\in\{\mathrm{car,hoj,ori,vac,hol}\}\\ d_r>0}} \frac{\langle \Xi_r(c), \Xi_r(d)\rangle}{d_r}, \qquad d_r = \sum_{x} \|\Xi_r(x)\|^2. \tag{16.76}$$

Normalization proceeds from the norms of the record itself. Zero-norm components are omitted; they are not replaced with terms taken from a target matrix. Each Ξ_r and each aggregation class must preserve its route provenance and its compatibility with refinement.

Proposition 16.57 (Positivity and rank of the record)**.** *The matrix K_{reg} is positive semidefinite. If its feature vectors are aggregated into three sectors, the resulting Gram matrix G_{ν} is invertible exactly when those three aggregated vectors are linearly independent.*

Proof. Define $v_c = \bigoplus_{r:d_r>0} d_r^{-1/2}\Xi_r(c)$. Then $K_{\mathrm{reg}}(c,d) = \langle v_c, v_d\rangle$, and for arbitrary coefficients z_c, $\sum_{c,d}\overline{z}_c K_{\mathrm{reg}}(c,d)z_d = \|\sum_c z_c v_c\|^2 \geq 0$. The same identity holds for the three aggregated vectors. The kernel of their Gram matrix consists exactly of their linear relations, yielding the invertibility criterion. □

This Gram matrix is distinguished from a sector of the *cross* matrix between the charged classes L_a and neutral classes N_b, defined by equation (16.77):

$$G_{ab} = \frac{1}{\sqrt{|L_a||N_b|}} \sum_{c\in L_a}\sum_{d\in N_b} K_{\mathrm{reg}}(c,d). \tag{16.77}$$

The nonempty classes proceed from the internal classifier. The cross matrix need not be Hermitian, unlike a Gram matrix constructed with the same three vectors on both sides.

Proposition 16.58 (Polar factor and its scope)**.** *If G is invertible,*

$$U_G = G(G^\dagger G)^{-1/2} \tag{16.78}$$

is unitary. If G is also Hermitian positive definite, then $U_G = I_3$. Consequently, the rank of a positive Gram matrix certifies the sufficiency of the observables, but does not by itself determine nontrivial mixing between the charged and neutral frames.

Proof. $G^\dagger G$ is positive definite; its positive square root is invertible and

$$U_G^\dagger U_G = (G^\dagger G)^{-1/2}(G^\dagger G)(G^\dagger G)^{-1/2} = I_3.$$

By finite dimensionality, also $U_G U_G^\dagger = I_3$. If $G > 0$, the positive square root of $G^\dagger G = G^2$ is G, and $U_G = I_3$. □

Remark 16.59 (Polar factorization and spectral frames). Equations (16.76) and (16.77) preserve, respectively, the rank criterion of the record and the cross matrix of the charged and neutral sectors. This exposition separates their functions to avoid turning a positive Gram matrix into an artificial angle selector. Identifying U_G with (16.74) requires compatibility of the cross kernel with the declared spectral frames. The identity of a polar factor or mere unitarity does not replace that identification. No new numerical PMNS matrix is presented here.

16.3.11 Rank-one phase check

Let b_K be the normalized incidence witness of the source and $Q_K = |b_K\rangle\langle b_K|$. The operator

$$\Phi_K = I + (e^{i\pi_{\mathrm{HMT}}/6} - 1)Q_K \tag{16.79}$$

is unitary in its ambient space. For isometric frames, consider $U_\Phi = F_\ell^\dagger \Phi_K F_\nu$.

Proposition 16.60 (Exact criterion for a unitary compression)**.** *The operator U_Φ is a contraction. It is unitary exactly when*

$$\Phi_K(\operatorname{Im} F_\nu) = \operatorname{Im} F_\ell. \tag{16.80}$$

Proof. Let $P_\ell = F_\ell F_\ell^\dagger$ and $P_\nu = F_\nu F_\nu^\dagger$. Then $U_\Phi^\dagger U_\Phi = F_\nu^\dagger \Phi_K^\dagger P_\ell \Phi_K F_\nu \le I_3$. Equality is equivalent to $(I - P_\ell)\Phi_K F_\nu = 0$, that is, to inclusion of the left image of (16.80) in the right one. Both have dimension three, so inclusion is equality. □

The minimal ansatz of (16.80) is retained as a negative control of physical identification. Its ambient unitarity, and even fulfilment of (16.80), do not replace the full record or the frames of (16.74). The control is not removed when angular propagation is gathered in Article II.

16.3.12 Leptonic phase and Dirac–Majorana criterion

Basis phase changes must be distinguished from the self-conjugacy data of the neutral sector. For any unitary leptonic transport, one can form the quartet

$$J_\ell = \operatorname{Im}\big(U_{e1} U_{\mu 2} \overline{U_{e2}}\, \overline{U_{\mu 1}}\big). \tag{16.81}$$

The phase cancellation proved for (16.69) applies here as well. The quartet does not fix all the data of the neutral realization or by itself determine its Dirac or Majorana type.

The Majorana realization is specified through the antiunitary self-conjugation C_ν compatible with mass and dynamics:

$$C_\nu^2 = I, \qquad C_\nu M_\nu = M_\nu C_\nu, \qquad C_\nu H_\nu = H_\nu C_\nu, \tag{16.82}$$

with preserved domains. The representation is realized in the corresponding fixed real form. The Dirac alternative also preserves a charge Q distinguishing the mode from its conjugate:

$$C_\nu Q C_\nu^{-1} = -Q, \qquad Q\psi \neq 0. \tag{16.83}$$

These statements preserve their representational data. Neutrality, the involution of dodecaphasic words and an Ising topological sector do not separately decide the alternative.

Remark 16.61 (Basis freedom and Majorana phases). The double coset (16.75) describes the basis freedom of the Hermitian pair. If a Majorana real form is also fixed, admissible phase changes must preserve that additional datum; not all the freedoms of a Dirac representation can simply be transferred. This block preserves the self-conjugacy criterion and assigns no values to Majorana phases or neutrino masses. Such values do not follow from neutrality or a rank-one polarization.

16.3.13 Closure of angular transport

The quark construction first expresses angular coordinates, then complex amplitudes and finally phase invariants and operator transport. The leptonic construction expresses record operators and spectral frames before the change of basis. Both routes preserve their provenance in the common enriched state and the discrete structure of the continuum; neither introduces an experimental table as a selector of coefficients or states.

The checks in this section are local and explicit: rational CKM inversion and intertwining; spectral conservation under conjugation; completeness and common space of PMNS frames; record rank; compatibility of the cross matrix; and preservation of self-conjugacy data. Angular propagation is thus incorporated into the theory of action, area and information without making mixing a second mass law or turning the Barbero reader into its cause.

Chapter 17

Double projection of the same state: Archimedean publication and exceptional conservation of incidence

17.1 Ambivalence Principle: involute of the areal and volumetric readers over the enriched state

The double projection compares two evaluations of the common enriched domain X_∞^{cal} already constructed in theorem 17.8. One produces Archimedean values; the other, together with a calibration of its codomain, preserves the combinatorial incidence that leads to codes, designs, and automorphism groups. Both evaluations start from the unique initial state X_∞^{cal} and preserve their common provenance in distinct codomains.

17.1.1 Domains of the 2 projections

On X_∞^{cal}, the cylinders contract to a point and the boundary admits the incidence prolongation. In this residence, we fix **Arch** := $\mathbb{R}$. The Archimedean evaluation and the exceptional evaluation are, respectively,

$$\mathfrak{R} : X_\infty^{\mathrm{cal}} \longrightarrow \mathbf{Arch}, \qquad \mathfrak{E} : X_\infty^{\mathrm{cal}} \times \mathscr{C}_{\mathrm{exc}} \longrightarrow \mathbf{Exc}.$$

Here $\mathscr{C}_{\mathrm{exc}}$ contains the projective order, Paley gauge, dodecad, incidence alignment, and lattice chamber specified in each construction. The first map produces values; the second produces codes, designs, lattices, and automorphisms. The preceding global theorem is the source of compatibility and permits comparison of invariants obtained through distinct operations without again intersecting domains defined separately. The finite comparison in this work is performed on the flag $B_K \subset H_\alpha^-$.

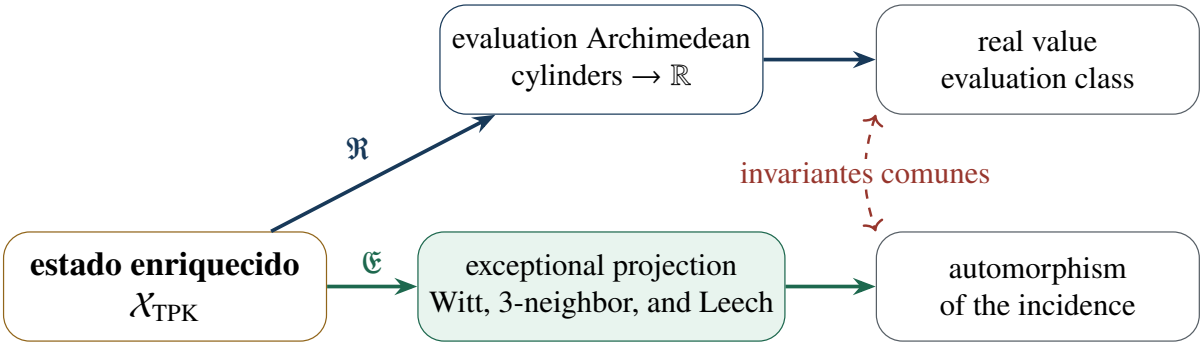

Figure 17.1: Typed scheme of the two projections. The Archimedean evaluation identifies states within the same fiber; the exceptional evaluation, relative to its calibration, preserves incidence structure and automorphisms.

17.1.2 Topology of the space of histories

The formulation by cylinders admits a standard realization as an inverse limit. Let S_n be the finite sets of states admissible at depth n, endowed with the discrete topology, and let

$$\tau_{n+1,n} : \mathsf{S}_{n+1} \longrightarrow \mathsf{S}_n$$

the truncation maps. In the HMT realization these maps are surjective: the prolongation law supplies a surviving continuation of each prefix, and its projective compatibility is preserved in the limit by theorem 17.8. This is the instance of the system involved in the global double projection (2). We define

$$\mathcal{X} = \varprojlim_{n} \mathsf{S}_n.$$

If $x \neq y$, let $m(x, y)$ be the first depth at which their components differ. The function

$$d(x, y) = 3^{-m(x,y)}, \qquad d(x, x) = 0,$$

is an ultrametric that induces the topology of the inverse limit.

Theorem 17.1 (Space of compact histories)**.** *The space $\mathcal{X}$ is compact and totally disconnected. When every history admits bifurcations at arbitrarily large depths, $\mathcal{X}$ has no isolated points and is homeomorphic to Cantor space.*

Proof. The product $\prod_n \mathsf{S}_n$ is compact. The equations $\tau_{n+1,n}(x_{n+1}) = x_n$ define a closed subset, so that $\mathcal{X}$ is compact. The sets of histories with a fixed prefix are simultaneously open and closed and form a basis; this proves total disconnectedness. Under the hypothesis of arbitrarily deep branching, no cylinder contains an isolated history. The characterization of compact, metric, perfect, and totally disconnected spaces proves the final assertion. □

The closed intervals $I_n(s)$ associated by the Archimedean reader with each $s \in \mathsf{S}_n$ are compatible with truncation and satisfy

$$\operatorname{diam} I_n(s) \leq C\lambda^n, \qquad 0 < \lambda < 1.$$

The intersection of the intervals corresponding to a history then contains a unique point.

Theorem 17.2 (Archimedean Evaluation)**.** *The map*

$$\mathrm{val} : \mathcal{X} \longrightarrow \mathbb{R}, \qquad \{\mathrm{val}(x)\} = \bigcap_{n} I_n(x_n),$$

is continuous and Hölder with respect to d. If $x \sim_{\mathrm{Arch}} y$ is equivalent to $\mathrm{val}(x) = \mathrm{val}(y)$, the induced application is a homeomorphism

$$\mathcal{X}/{\sim_{\mathrm{Arch}}} \;\cong\; \mathrm{val}(\mathcal{X}).$$

Proof. Two histories with a common prefix of length n have values in the same interval of diameter no greater than $C\lambda^n$. Since $d(x, y) = 3^{-n}$, this estimate is a Hölder bound. The induced map on the quotient is a continuous bijection from a compact space onto a Hausdorff space and therefore a homeomorphism. □

The theorem formalizes the Archimedean projection: the value retains the evaluation class and eliminates the distinction between histories situated in the same fiber. Coherent coverage, compact exhaustion and the exact reconstruction of the quotient are proved in theorems 18.3 y 18.9 y proposition 18.5; therefore, in the active HMT realization, $\mathrm{val}(\mathcal{X}) = \mathbb{R}$.

17.1.3 Separation by the 2 projections

Theorem 17.3 (Joint separation)**.** *Let $P_1 : \mathcal{X} \to Y_1$ and $P_2 : \mathcal{X} \to Y_2$ be continuous maps with Hausdorff codomains. If*

$$x \neq y \quad \Longrightarrow \quad P_1(x) \neq P_1(y) \text{ or } P_2(x) \neq P_2(y),$$

the diagonal application

$$(P_1, P_2) : \mathcal{X} \longrightarrow Y_1 \times Y_2$$

is a topological embedding.

Proof. The hypothesis expresses precisely the injectivity of the diagonal map. A continuous injective map from a compact space to a Hausdorff space is a homeomorphism onto its image. □

With a declared gauge $c \in \mathscr{C}_{\mathrm{exc}}$ fixed, let

$$\mathfrak{E}_c : X_\infty^{\mathrm{cal}} \longrightarrow \mathbf{Exc}, \qquad \mathfrak{E}_c(x) := \mathfrak{E}(x, c).$$

Applied to HMT, the theorem takes

$$P_1 = \mathfrak{R}, \qquad P_2 = \mathfrak{E}_c$$

on the common domain, or on the quotient by the declared coordinate changes. Projective compatibility and the global double realization are proved, respectively, in theorems 17.8 y 17.9. Faithfulness is typed by the codomain: the exceptional reader is faithful on the visible stream, while the enriched domain preserves the memory that no isolated publication contracts. The passage to every depth is thus a conclusion of the construction, not an external hypothesis.

At a finite level S, this condition is decidable. Given $p : S \to A$, $q : S \to B$, and an equivalence relation of coordinates, the pairs $x \nsim y$ that simultaneously satisfy are enumerated

$$p(x) = p(y), \qquad q(x) = q(y).$$

The absence of such pairs is equivalent to joint injectivity at that level. The calculation must perform the two maps separately: when $q = f \circ p$, the second has the same fibers as the first and does not recover information eliminated by p.

At the level developed here, the equality

$$B_K = H_e \cap P_\pi$$

constitutes the finite witness of compatibility between the two branches. Its compatible prolongation to all depths is provided by theorems 17.8 y 17.9; the equality of supports is the finite shadow of that joint realization.

17.1.4 Archimedean quotient by the evaluation fibers

An HMT section contains a block, an orientation, a carry, an observable label, and an extension coordinate. The evaluation val contracts its cylinders to a point. If two sections x, y satisfy

$$\mathrm{val}(x) = \mathrm{val}(y),$$

the Archimedean evaluation identifies them although their transport is different. In this precise sense,

a real value is an equivalence class of the evaluation.

On the canonical subdomain, sum, product and evaluation descend compatibly, and the image inherits those operations. The existence of the limit, the determination of its image, the characterization of the fibers and the coverage of all of $\mathbb{R}$ are established by theorems 18.3 y 18.9 y proposition 18.5. Finite windows exhibit the local structure of that global result; unitary survival and compatibility are proved properties of the HMT prolongation.

17.1.5 Common invariant with the Witt system

The vector K defines the support superior

$$B_K = \{m : K_m \geq 729\} = \{4, 6, 9, 10\}.$$

In the Witt atlas appear the supports

$$P_\pi = \{2, 4, 5, 6, 7, 8, 9, 10, 11\},$$

$$H_e = \{1, 3, 4, 6, 9, 10\}, \qquad H_\varphi = \{1, 2, 3, 4, 7, 9\}.$$

The support of the negative carries of α is

$$H_\alpha^- = \{4, 5, 6, 7, 9, 10\}.$$

The support identities are verified.

$$\boxed{B_K = H_e \cap P_\pi = H_e \cap H_\alpha^-,}$$

and

$$\boxed{H_\alpha^- = B_K \sqcup \{5, 7\}.}$$

Witt polarity sends the four points of B_K to the pairs

$$\{1, 3\}, \quad \{2, 11\}, \quad \{8, 12\}, \quad \{5, 7\}.$$

Three receive the positive label; the last completes the negative support. These identities are exact in the declared gauge and constitute internal checks of the same generated state: the vector, threshold, words and Paley gauge are correlated coordinates of the construction, not statistically independent inputs. The equality is obtained by direct evaluation and does not constitute a probabilistic estimate.

17.1.6 Residual design on a dodecada and elevation of hexads

The relation between the two Witt designs is obtained within the extended binary Golay code and not through an identification of cardinalities. Let

$$\mathcal{G}_{24} \subset \mathbb{F}_2^{24}$$

the extended binary Golay code, and denote by $\mathcal{O}_{24}$ the family of supports of its weight-eight words. It is a classical result that $(\{1, \dots, 24\}, \mathcal{O}_{24})$ is the Steiner system $W_{24} = S(5, 8, 24)$ [91, 34]. Fix a weight-twelve word and write D for its support. We define

$$\mathcal{H}(D) := \{O \cap D : O \in \mathcal{O}_{24},\ |O \cap D| = 6\}. \tag{17.1}$$

The family $\mathcal{H}(D)$ is intrinsic to the pair $(\mathcal{G}_{24}, D)$: it does not require choosing coordinates in D.

Theorem 17.4 (Residual design of a dodecada)**.** *The incidence system*

$$(D, \mathcal{H}(D))$$

is a Steiner system $S(5, 6, 12)$. In particular, $|\mathcal{H}(D)| = 132$, and every subset of five points of D is contained in a unique hexad of $\mathcal{H}(D)$.

Proof. Let $A \subset D$, with $|A| = 5$. Since the octads form $S(5, 8, 24)$, there is a unique octad O_A containing A. If $j = |O_A \cap D|$, the binary sum of the characteristic words of O_A and D belongs to $\mathcal{G}_{24}$ and has weight

$$\mathrm{wt}(\mathbf{1}_{O_A} + \mathbf{1}_D) = 8 + 12 - 2j = 20 - 2j.$$

The weights of the extended binary Golay code are $0, 8, 12, 16, 24$. Since $j \le 8$, it follows that $j \in \{2, 4, 6\}$. The inclusion $A \subset O_A \cap D$ gives $j \ge 5$, hence $j = 6$. Therefore, $O_A \cap D \in \mathcal{H}(D)$ is a hexad containing A.

If two members of $\mathcal{H}(D)$ contained A, their octads of origin would contain the same set of five points; the Steiner property of W_{24} would make them coincide. This proves uniqueness. The number of blocks is obtained by counting incidences with five-point subsets:

$$|\mathcal{H}(D)| = \frac{\binom{12}{5}}{\binom{6}{5}} = 132. \qquad \square$$

Theorem 17.5 (Unique elevation of a hexad)**.** *For each $H \in \mathcal{H}(D)$, there exists a unique octad $O_H \in \mathcal{O}_{24}$ such that*

$$O_H \cap D = H.$$

Consequently, the application

$$\iota_D : \mathcal{H}(D) \longrightarrow \mathcal{O}_{24}, \qquad H \longmapsto O_H,$$

is well defined and is injective.

Proof. Existence forms part of the definition of $\mathcal{H}(D)$. If two octads O_1, O_2 had intersection H with D, both would contain any five-point subset of H. The uniqueness of the octad incident with those five points implies $O_1 = O_2$. Injectivity follows by intersecting again with D. $\square$

The lift has a local law that will be used to compare the five regions of π. In a system $S(t, k, v)$, the number of blocks containing a fixed subset of $s \le t$ points is

$$\lambda_s = \frac{\binom{v-s}{t-s}}{\binom{k-s}{t-s}}.$$

Consequently,

$$\lambda_4(W_{12}) = \frac{\binom{8}{1}}{\binom{2}{1}} = 4, \qquad \lambda_4(W_{24}) = \frac{\binom{20}{1}}{\binom{4}{1}} = 5. \tag{17.2}$$

Corollary 17.6 (Decomposition 4 + 1 on a face)**.** *Let $B \subset D$, with $|B| = 4$. The five octads of W_{24} that contain B decompose uniquely into*

$$\{O_H : H \in \mathcal{H}(D),\ B \subset H\} \ \sqcup\ \{O_B^{\perp}\}.$$

The first set contains four octads and satisfies $|O_H \cap D| = 6$; the remaining octad satisfies

$$O_B^{\perp} \cap D = B.$$

Proof. The first equality in (17.2) provides four residual hexads containing B, and theorem 17.5 provides four distinct octads. The second equality in (17.2) shows that there exists exactly one fifth octad $O_B^{\perp}$.

Since $B \subset O_B^{\perp} \cap D$, the intersection spectrum used in the proof of theorem 17.4 leaves only the possibilities four and six. An intersection of size six would be a fifth residual hexad that contains B, contradicting $\lambda_4(W_{12}) = 4$. Therefore, the intersection has size four and coincides with B. $\square$

17.1.6.1 Alineamiento with the 12 *positions HMT*

The residual design is defined on the points of D, whereas the design obtained from the ternary code C_W is defined on the twelve dodecaphase positions. To avoid conflating the two sets, we shall call a bijection *HMT binary alignment*

$$\ell : \{1, \dots, 12\}_{\mathrm{HMT}} \xrightarrow{\sim} D \quad \text{such that} \quad \{\ell(H) : H \in W_{12}^{\mathrm{HMT}}\} = \mathcal{H}(D). \tag{17.3}$$

Here W_{12}^{HMT} denotes the design of weight-six supports obtained from the ternary code C_W. Uniqueness of the Witt system $S(5, 6, 12)$ up to isomorphism ensures the existence of ℓ. Two distinct alignments differ by automorphisms of the source and target designs; hence ℓ is coordinate data and not an additional

invariant. The pair (D, ℓ) is the calibration datum required to transport the lift ι_D to the HMT coordinate system. Once fixed, each HMT hexad H unambiguously determines the octad

$$\widehat{H} := \iota_D(\ell(H)).$$

The dodecad and the alignment are data of the binary codomain; they are not identified with a decimal output of the transport kernel.

For the distinguished face

$$B_K = \{4, 6, 9, 10\},$$

the four incident hexads are

$$B_K \sqcup \{1, 3\}, \quad B_K \sqcup \{2, 11\}, \quad B_K \sqcup \{5, 7\}, \quad B_K \sqcup \{8, 12\}.$$

The third agrees with $H_\alpha^- = B_K \sqcup \{5, 7\}$. The alignment ℓ lifts these four hexads to the four residual octads over $\ell(B_K)$; corollary 17.6 also determines a unique transverse octad.

17.1.6.2 Incidence correspondence between the microfiber of π and the residual octads: multiplicity $432{+}4{\cdot}144 = 1008$

The exact microfiber of the word $w_\pi = 010211$ contains five distinct decimal regions:

multiplicity	U_6	$e(U_6)$
432	501|614|498|169|272|272	$(5, 5, 5, 5, 5, 5)$
144	810|923|870|169|272|272	$(3, 3, 9, 5, 5, 5)$
144	810|983|810|169|272|272	$(3, 9, 3, 5, 5, 5)$
144	870|923|810|169|272|272	$(9, 3, 3, 5, 5, 5)$
144	870|923|810|418|674|521	$(9, 3, 3, 7, 1, 7)$.

Here $e(U_6)$ is the multiplicative signature recovered from each decimal block $\overline{d_1 d_2 d_3}$ by means of $e = d_2 - d_1 \pmod{10}$. The first region is the only one of multiplicity 432 and constant signature. The remaining four have multiplicity 144; among them, three share the return block 169|272|272, whereas the fourth has return 418|674|521. The catalogue distinguishes the five rows by a reproducible predicate: the three rows of type ES form the positive triple; among the two rows of type NO, that of maximal multiplicity and constant signature is termed transverse, and the remaining one is termed negative. Relative to this role predicate, the partition is

$$\boxed{1_\perp + 3_{++} + 1_{--}.}$$

The sign labels are a convention; what is intrinsic to the catalog is the partition obtained from its columns, not a prior binary polarity.

The alineamiento regional complete the givesto (D, ℓ) with to bijection that sends the transver region to $O^\perp_{\ell(B_K)}$, the region negativa to $\widehat{H_\alpha^-}$ and the tris regionis positivas to the elevacionis of

$$B_K \sqcup \{1, 3\}, \qquad B_K \sqcup \{2, 11\}, \qquad B_K \sqcup \{8, 12\}.$$

The ordered assignment between the three positive regions and those three hexads is a choice of coordinates. The two distinguished rows and the triple are reproducible through the preceding catalogue predicate; their designation as negative, transversal, and positive belongs to the alignment. Thus, the law $4 + 1$ does not identify the five regions with five octads by mere cardinality: it provides the incidence space, whereas (D, ℓ) and the regional alignment specify the transport between the two objects.

17.1.7 Lattice prolongation and dimensional screens

The lift of hexads opens two branches that must not be confused. The first conserves binary incidence and prolongs W_{12} toward W_{24}. The second conserves ternary transport:

$$C_{12}^{(3)} \longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathbb{M} \longrightarrow \text{Moonshine}.$$

The primary proof of the gluing, the rootless 3 neighbor, and the corridor to Moonshine resides in section 21.9 y theorem 21.49. There is no canonical arrow $W_{24} \to N(A_2^{12})$, nor any direct action of the Monster on TPK words: both branches start from the same calibrated code and preserve different structures.

The reductions $243/11$, $12 \to 11 \to 10$, and $26 \to 24$ are not identities between numerals either. The chapter 25 constructs their spaces, quotients, and maps: the perfect ternary quotient, the screen marked by K, and the isotropic reduction of the Lorentzian lattice. This section thereby retains a single function: to link the already proved finite incidence with its two prolongations, without repeating the reference proofs.

17.1.8 Residue–quotient involution and conservation of state information

For $n = 9Q + r$, we define the lattice energy

$$E_R(r, Q) = \frac{r^2}{R^2} + Q^2 R^2.$$

Then

$$\boxed{E_R(r, Q) = E_{1/R}(Q, r).}$$

The exchange $(r, Q, R) \leftrightarrow (Q, r, 1/R)$ is an exact involution of the lattice model: the residue and quotient exchange their functions.

17.1.9 Finite compatibility and joint prolongation

The finite witness B_K, the carry pattern, and the Witt frame fix local compatibility. Its prolongation is no longer left as an abstract scheme: the theorem 17.8 constructs, block by block, the exceptional reader with a unique transported initial gauge, and the theorem 17.9 proves that this reading and the Archimedean evaluation globalize over the same TPK section. Truncating the history before reading is equivalent in both cases to truncating the output after reading.

The Archimedean evaluation identifies histories by their limiting value. The exceptional evaluation preserves the visible current and its Paley–Witt incidence; it does not thereby recover the hidden memories that the visible emitter does not publish. The double projection is therefore a joint construction with two distinct codomains, not an identification between the continuum and the exceptional branch.

Remark 17.7 (Compatibility of the two projections). The support B_K, the carry pattern, and the Witt frame provide the common invariants. The lattice chain prolongs this compatibility to a rootless neighbor and, by classical classification, to the Leech lattice. The binary branch toward W_{24} remains separate: its incidence morphism is ι_D, defined after fixing the dodecad and alignment (D, ℓ), and its codomain is neither a Niemeier lattice nor the Leech lattice.

17.2 Exceptional projection of the enriched state: compatible incidence at all depths

The finite witness of the double projection acquires global scope when the exceptional reading is applied to every visible block and the gauge is transported, rather than chosen anew, as the depth increases. This section constructs that family. The domain remains the enriched TPK history; the exceptional reading is faithful on its visible stream and does not purport to replace the memory fields that this stream does not publish.

17.2.1 Common enriched domain and inequivalent codomains of the 2 projections

In the Paley–Witt chart one fixes

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3).$$

Matrix multiplication gives

$$A_W^{\mathsf{T}} = A_W, \qquad A_W^2 = -I_6.$$

For every conjugated operator $A = f A_W f^{-1}$, define

$$\Gamma_A : \mathbb{F}_3^6 \longrightarrow \mathbb{F}_3^{12}, \qquad \Gamma_A(w) = (w, wA).$$

Its image is a calibrated copy $C_W(A)$ of the ternary Witt code. Projection onto the first six coordinates is a left inverse:

$$\mathrm{pr}_1 \, \Gamma_A = \mathrm{id}_{\mathbb{F}_3^6}.$$

Therefore, Γ_A is total and injective on the 729 words and does not need to distinguish in advance π, e, φ, or any other output.

17.2.2 Compatible extensions and uniqueness of the initial scale

Let X_n be the set of admissible TPK prefixes of depth n, with truncations

$$p_{n,m} : X_n \longrightarrow X_m, \qquad m \le n.$$

Fix an initial exceptional frame f_0. Since the changes g_j form part of the transport stored by the history, a calibrated prefix is the pair (x, f_0); we write

$$X_n^{\mathrm{cal}} := X_n \times \{f_0\}, \qquad p_{n,m}^{\mathrm{cal}}(x, f_0) := (p_{n,m}x, f_0),$$

and

$$X_\infty^{\mathrm{cal}} := \varprojlim_n (X_n^{\mathrm{cal}}, p_{n,m}^{\mathrm{cal}}).$$

In what follows we abbreviate $p_{n,m}^{\mathrm{cal}}$ as $p_{n,m}$. The compatible visible emission is

$$\varepsilon_n : X_n^{\mathrm{cal}} \longrightarrow (\mathbb{F}_3^6)^n, \qquad \varepsilon_n(x) = (w_0, \dots, w_{n-1}),$$

and satisfies

$$\mathrm{pr}_{n,m} \, \varepsilon_n = \varepsilon_m p_{n,m}.$$

This application distinguishes its three types:

$$|\mathcal{U}_6| = 468, \qquad |\operatorname{im} w_6| = 243, \qquad |\mathbb{F}_3^6| = 729.$$

The emission w_j is not identified with the complete state that conserves leaf, quotient, carry, orientation, phase, and survival.

The exceptional gauge consists of a Witt chart, a dodecad, an alignment, a lattice origin, and an oriented chamber. It is fixed only once in the initial block. For $x \in X_n^{\mathrm{cal}}$, transport of the history supplies

$$g_j(x) \in \mathrm{GL}_6(\mathbb{F}_3), \qquad 0 \le j < n-1,$$

and $g_j(x)$ depends only on the prefix $p_{n,j+1}(x)$. The frame is transported by

$$f_{j+1}(x) = g_j(x) f_j(x), \qquad A_j = f_j A_W f_j^{-1}.$$

Thus, the family (A_j) is determined by the history and the initial gauge; it is not a sequence of independent choices.

Let $\mathcal{F}_{\mathrm{cal}} \subseteq \mathrm{GL}_6(\mathbb{F}_3)$ be the set of frames reachable from f_0. The emission preserving the transported gauge is

$$\widetilde{\varepsilon}_n : X_n^{\mathrm{cal}} \longrightarrow (\mathbb{F}_3^6 \times \mathcal{F}_{\mathrm{cal}})^n, \qquad \widetilde{\varepsilon}_n(x) = \big((w_0, f_0), \dots, (w_{n-1}, f_{n-1})\big).$$

Prefix dependence implies $\mathrm{pr}_{n,m}\, \widetilde{\varepsilon}_n = \widetilde{\varepsilon}_m p_{n,m}$. Its projection onto the words is ε_n; forgetting the frames does not suffice to reconstruct the exceptional reading.

17.2.3 Joint separation of histories by the Archimedean and exceptional projections

The local operation is covariant under the row-vector convention. For every change of coordinates $f \in \mathrm{GL}_6(\mathbb{F}_3)$,

$$A^f = f A f^{-1} \quad \Longrightarrow \quad \Gamma_{A^f}(w f^{-1}) = \Gamma_A(w)(f^{-1} \oplus f^{-1}).$$

Change of frame simultaneously transports the word, the operator, and the atlas. It is not required to remain within the stabilizer of a single labeled copy.

With the set of reachable frames $\mathcal{F}_{\mathrm{cal}}$ already defined, we construct the fixed calibrated atlas

$$\mathscr{C}_W^{\mathrm{cal}} := \left\{ \big(f, \Gamma_{f A_W f^{-1}}(w)\big) : f \in \mathcal{F}_{\mathrm{cal}},\ w \in \mathbb{F}_3^6 \right\}.$$

The label f preserves the calibrated copy in which each word resides. Define

$$Q_n(x) = \big(\big(f_0, \Gamma_{A_0}(w_0)\big), \dots, \big(f_{n-1}, \Gamma_{A_{n-1}}(w_{n-1})\big)\big) \in \big(\mathscr{C}_W^{\mathrm{cal}}\big)^n.$$

Let

$$r_{n,m} : \big(\mathscr{C}_W^{\mathrm{cal}}\big)^n \longrightarrow \big(\mathscr{C}_W^{\mathrm{cal}}\big)^m$$

the truncation of the last $n - m$ blocks.

Theorem 17.8 (Projective compatibility of the exceptional incidence)**.** *For every $m \le n$,*

$$\boxed{r_{n,m} \circ Q_n = Q_m \circ p_{n,m}.}$$

Consequently, there exists a unique application

$$\boxed{Q_\infty : X_\infty^{\mathrm{cal}} \longrightarrow \big(\mathscr{C}_W^{\mathrm{cal}}\big)^{\mathbb{N}}}$$

whose finite projections are the Q_n. The map is faithful on the visible current.

Proof. Write

$$\varepsilon_n(x) = (w_0, \dots, w_{m-1}, w_m, \dots, w_{n-1}).$$

The compatibility of ε shows that the visible current of $p_{n,m}(x)$ is $(w_0, \dots, w_{m-1})$. For $j < m$, the frame f_j depends only on the initial gauge and on changes preceding j, all of which are contained in that prefix. The first m operators A_j are therefore the same before and after truncation. Applying Γ_{A_j} block by block yields the asserted identity. The universal property of the inverse limit produces Q_∞. Finally, $\mathrm{pr}_1 \Gamma_{A_j} = I$ recovers every w_j, proving faithfulness on the visible current. □

The last assertion conserves its type. Two histories with the same current $(w_j)_j$ and distinct hidden memory may have the same exceptional image. The global reader preserves exactly what each visible block publishes and the incidence added to that block.

The compatibility of enriched emissions induces a unique application.

$$\widetilde{\varepsilon}_\infty : X_\infty^{\mathrm{cal}} \longrightarrow (\mathbb{F}_3^6 \times \mathcal{F}_{\mathrm{cal}})^{\mathbb{N}}.$$

Let pr_w the projection onto the corriente of palabras and

$$\widetilde{\Gamma}_\infty\big((w_j, f_j)_{j\geq 0}\big) := \big((f_j, \Gamma_{f_j A_W f_j^{-1}}(w_j))\big)_{j\geq 0}.$$

Then $Q_\infty = \widetilde{\Gamma}_\infty \circ \widetilde{\varepsilon}_\infty$, with declared domains and codomains.

17.2.4 Bifurcation of a surviving prefix in Archimedean value and exceptional incidence

Fixed $m \in \mathbb{Z}$, let us denote by

$$\mathrm{flat} : (\mathbb{F}_3^6)^{\mathbb{N}} \longrightarrow \mathbb{F}_3^{\mathbb{N}}$$

the concatenation of the blocks in the declared coordinate order, and by

$$\mathrm{ev}_3((d_k)_{k\geq 1}) := \sum_{k\geq 1} \frac{d_k}{3^k} \in [0,1], \qquad \tau_m(t) := m + t,$$

the ternary evaluation and translation by the integer part. The visible prefix $(d_1, \dots, d_{6n})$ determines the cylinder

$$I_n(x) = \left[m + \sum_{k=1}^{6n} \frac{d_k}{3^k},\, m + \sum_{k=1}^{6n} \frac{d_k}{3^k} + 3^{-6n} \right].$$

A prolongation restricts the cylinder and $\operatorname{diam} I_n = 3^{-6n} \to 0$. Therefore, every compatible infinite history determines a unique real point $\mathcal{P}_{\mathrm{arq}}(x)$.

Theorem 17.9 (Double global realization)**.** *Every compatible section $x = (x_n)_n \in X_\infty^{\mathrm{cal}}$ determines, from the same prefixes, two compatible outputs:*

$$\mathcal{P}_{\mathrm{arq}}(x) \in \mathbb{R}, \qquad \mathcal{P}_{\mathrm{exc}}(x) = Q_\infty(x) \in \big(\mathscr{C}_W^{\mathrm{cal}}\big)^{\mathbb{N}}.$$

Truncating before reading is equivalent to truncating each reading after reading. The first output identifies histories by their limiting value; the second preserves each visible block and adjoins its Paley–Witt rotation.

Proof. The nesting of the cylinders and the convergence of their diameters prove the first assertion. The theorem 17.8 proves the second and the compatibility with truncations. Both factor through the same emission:

$$\mathcal{P}_{\mathrm{arq}} = \tau_m \circ \mathrm{ev}_3 \circ \mathrm{flat} \circ \mathrm{pr}_w \circ \widetilde{\varepsilon}_\infty, \qquad \mathcal{P}_{\mathrm{exc}} = \widetilde{\Gamma}_\infty \circ \widetilde{\varepsilon}_\infty.$$

□

The double projection is thus constructed on admissible histories and a transported initial gauge. The continuum is the Archimedean evaluation of the section; the exceptional branch is the compatible

realization of its visible current. From C_W, with the already declared alignments, the branches toward W_{12}, W_{24}, and toward $N(A_2^{12})$, Leech, $V^\natural$, and the Monster are opened. These branches do not turn the digits into a set on which the Monster acts directly: they transport the incidence that evaluation by value ceases to see.

17.2.5 Common incidence invariant between the enriched state and the Witt system

Let $x_\pi \in X_\infty^{\mathrm{cal}}$ be the surviving section of the π channel. The double realization of theorem 17.9 produces

$$\mathcal{P}_{\mathrm{arq}}(x_\pi) \in \mathbb{R}, \qquad \mathcal{P}_{\mathrm{exc}}(x_\pi) = Q_\infty(x_\pi).$$

The first branch publishes the generated angle; the second preserves the visible current and realizes the quadratic Paley–Witt relation in each block.

Theorem 17.10 (Euler–postgenerative coupling double projection)**.** *Suppose that the coinductive construction of the channel of π determines*

$$\mathcal{P}_{\mathrm{arq}}(x_\pi) = \pi_{\mathrm{HMT}},$$

and that the exceptional branch uses the gauge transported with $A_W^2 = -I_6$. Let J_{e} be the real realization of the integral source of theorem 3.25. Then

$$\boxed{\mathrm{Exp}\big(\mathcal{P}_{\mathrm{arq}}(x_\pi) J_{\mathrm{e}}\big) + I = 0.} \tag{17.4}$$

Proof. By the theorem 3.25, A_W and J_{e} realizan the relation $u^2 + 1 = 0$ in categorias distinct. In the branch real,

$$\mathrm{Exp}(\theta J_{\mathrm{e}}) = \cos\theta\, I + \sin\theta\, J_{\mathrm{e}}.$$

Substitution of the previously generated output $\theta = \mathcal{P}_{\mathrm{arq}}(x_\pi) = \pi_{\mathrm{HMT}}$ produces $-I$, and the sum of I gives the stated identity. □

Causal order and absence of circularity. The demonstrated dependence is

$$\text{emitter} \longrightarrow x_\pi \longrightarrow \mathcal{P}_{\mathrm{arq}}(x_\pi) \longrightarrow \pi_{\mathrm{HMT}} \longrightarrow \mathrm{Exp}(\pi_{\mathrm{HMT}} J_{\mathrm{e}}) + I.$$

The exceptional branch fixes the quadratic type; it selects neither the angle nor its digits. Euler's identity subsequently recognizes the compatibility of the two realizations and does not enter as an input to the generator of π_{HMT}.

17.3 Decomposition of the microfiber of π into 5 oriented regions: 4 peripheral components and 1 fixed axis

The double projection thesis acquires mathematical content when both readings are defined on the same state system and commute with depth restriction. Archimedean evaluation contracts a family of cylinders to a value; exceptional evaluation preserves incidence relations that the first may forget. These are not two juxtaposed numerical expressions, but two natural transformations with a common domain.

17.3.1 Reticular prolongation of incidence and construction of dimensional screens

Let $(X_n, p_{n+1,n})$, $(A_n, a_{n+1,n})$ and $(E_n, e_{n+1,n})$ be three inverse systems. The first contains TPK histories; the second, Archimedean cylinders or approximants; the third, exceptional incidence data. The active construction supplies the maps

$$R_n : X_n \longrightarrow A_n, \qquad Q_n : X_n \times C_n \longrightarrow E_n,$$

where C_n collects the coordinate data of the exceptional reader. The gauges form a compatible family and, for every n, the diagrams commute

$$a_{n+1,n} \circ R_{n+1} = R_n \circ p_{n+1,n},$$

$$e_{n+1,n} \circ Q_{n+1} = Q_n \circ (p_{n+1,n} \times c_{n+1,n}).$$

Theorem 17.11 (Globalization of the two evaluations)**.** *By the preceding compatibilities, already constructed block by block, there exist canonical maps*

$$R_\infty : \varprojlim X_n \longrightarrow \varprojlim A_n, \qquad Q_\infty : \varprojlim X_n \times \varprojlim C_n \longrightarrow \varprojlim E_n.$$

Its diagonal application

$$(R_\infty, Q_\infty) : X_\infty \times C_\infty \longrightarrow A_\infty \times E_\infty$$

is unique among the applications whose coordinate projections are R_n and Q_n.

Proof. Let $x = (x_n)_n \in \varprojlim X_n$. The first commutativity equation implies

$$a_{n+1,n}(R_{n+1}(x_{n+1})) = R_n(x_n),$$

and therefore $(R_n(x_n))_n$ belongs to $\varprojlim A_n$. We define $R_\infty(x)$ by means of that family. The same argument, applied to $(x_n, c_n)_n$, defines Q_∞. Uniqueness follows because an element of an inverse limit is determined by all of its coordinates. □

The theorem records the concrete proof carried out in HMT: the Archimedean result and the exceptional code come from the same compatible states and respect the truncation maps.

17.3.2 Archimedean contraction of compatible cylinders and realization of the real line

To each $x_n \in X_n$ is associated a nonempty compact interval $I_n(x_n) \subset \mathbb{R}$. If

$$p_{n+1,n}(x_{n+1}) = x_n \quad \Longrightarrow \quad I_{n+1}(x_{n+1}) \subseteq I_n(x_n)$$

and there exists $\varepsilon_n \to 0$ with $\operatorname{diam} I_n(x_n) \le \varepsilon_n$, the intersection

$$\bigcap_{n \ge 0} I_n(x_n)$$

contains a unique real. Thus it is obtained.

$$\mathrm{ev}_{\mathrm{arq}} : X_\infty^{\mathrm{arq}} \longrightarrow \mathbb{R}.$$

The phrase "the cylinders tend to zero" means here that their diameter converges to zero, not that the evaluated number tends to zero.

The relation

$$x \sim_{\mathrm{arq}} y \quad \Longleftrightarrow \quad \mathrm{ev}_{\mathrm{arq}}(x) = \mathrm{ev}_{\mathrm{arq}}(y)$$

describes exactly the information removed by the reader. The real value is an evaluation class; the history additionally preserves orientation, carry, sheet, and boundary signature.

17.3.3 Exceptional projection by incidence and boundary conservation

The second evaluation does not take values in $\mathbb{R}$. Its codomain is a category of incidence configurations. In the current finite realization, the coordinate datum contains:

$$C_{\mathrm{exc}} = (\,\text{projective order}, \text{Paley gauge}, \text{dodecad}, \\ \text{alignment}, \text{lattice origin}, \text{chamber}).$$

After fixing that data, the chain contains two descendants that must remain separated:

$$C_W \longrightarrow W_{12} \longrightarrow W_{24},$$

$$C_W \longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathbb{M}.$$

The first transports designs; the second leads, through later classical results, to the Leech lattice, the vertex operator algebra, and the Monster group. The central holonomy and the Schläfli–E_6 corridor form a parallel boundary extraction; they are not obtained by replacing one of the two preceding descents.

17.3.4 Finite Compatibility of the Common Domain

The dodecaphonic seal

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601)$$

determines the support

$$B_K = \{m : K_m \geq 729\} = \{4, 6, 9, 10\}.$$

In the published Witt chart,

$$P_\pi = \{2, 4, 5, 6, 7, 8, 9, 10, 11\}, \qquad H_e = \{1, 3, 4, 6, 9, 10\},$$

and, by independent evaluation of the two supports,

$$\boxed{B_K = H_e \cap P_\pi.}$$

Furthermore, for the support of negative carry

$$H_\alpha^- = \{4, 5, 6, 7, 9, 10\}$$

we have

$$B_K = H_e \cap H_\alpha^-, \qquad H_\alpha^- = B_K \sqcup \{5, 7\}.$$

These identities constitute a witness of finite compatibility: the same subset is recovered from the arithmetic seal and from Witt incidence. This is not an equality of cardinalities, since it identifies specific positions.

17.3.5 Typed separation of the Archimedean and exceptional publications of the common state

Theorem 17.12 (Joint Fidelity Criterion)**.** *Let X be compact and Y, Z be Hausdorff spaces. If two continuous maps $R : X \to Y$ and $Q : X \to Z$ satisfy*

$$x \neq y \Longrightarrow R(x) \neq R(y) \text{ or } Q(x) \neq Q(y),$$

then $(R, Q) : X \to Y \times Z$ is a topological embedding.

Proof. The condition is the injectivity of the diagonal application. Every continuous injective application from a compact space into a Hausdorff space is a homeomorphism onto its image. □

At each finite depth, the condition is decided by enumerating the pairs $x \neq y$ that remain simultaneously in a fiber of R_n and of Q_n. The compatibility of those checks when passing from $n+1$ to n is precisely the projective identity proved in theorem 17.8, and theorem 17.9 carries out its globalization. The witness B_K exhibits the common finite invariant; the obstruction of the minimal reader in theorem 17.13 delimits the visible quotient, while the enriched reader preserves the orientation, sheet, signature, return and boundary data required by the double publication.

17.3.6 Precise formulation of the thesis on the real line

The enriched object associated to the Archimedean reading is the arrow

$$\mathbb{R}_{\mathfrak{H}} := \big(X_\infty^{\mathrm{arq}} \xrightarrow{\mathrm{ev}_{\mathrm{arq}}} \mathrm{Im}(\mathrm{ev}_{\mathrm{arq}}) \subseteq \mathbb{R}\big).$$

The domain preserves genealogies; the image preserves values. Coverage of the cylinders at every scale and compatible prolongability are proved in the construction of the Archimedean reader (5.282): for every compact set $K \subset \mathbb{R}$, $\mathrm{ev}_{\mathbb{R}}(\Omega_{\infty,K}) = K$, and the directed union of those intervals covers $\mathbb{R}$. Therefore,

$$\mathrm{Im}(\mathrm{ev}_{\mathrm{arq}}) = \mathbb{R}, \qquad X_\infty^{\mathrm{arq}}/\!\sim_{\mathbb{R}} \cong \mathbb{R}.$$

The real field does not act as the starting point of the construction, but as the Archimedean quotient of a space of sections with memory. The descent of sum and product is verified operation by operation and does not condition this already proved surjectivity.

The double reading is then expressed by

$$X_\infty^{\mathrm{com}} \times C_\infty \xrightarrow{(\mathrm{ev}_{\mathrm{arq}}, Q_\infty)} \mathbb{R} \times E_\infty.$$

This formula is the mathematical translation of the conceptual assertion: one and the same history may contract to a value and, in the transverse reading of its boundary, preserve the incidence leading to the exceptional symmetries.

17.4 Dependence of the reader of incidence with respect to the enriched state

Finite compatibility of the two evaluations does not imply that every incidence reader refines the partition produced by the visible reader. The regional catalog makes it possible to decide this question exactly for the minimal Paley–Witt realization. Let $\mathcal{U}_{468}$ be the set of the 468 published regional states, and let

$$\Psi : \mathcal{U}_{468} \longrightarrow \mathcal{W}_{243} \subset \mathbb{F}_3^6, \qquad \Psi(U_1, \dots, U_6) = (-U_1, \dots, -U_6) \pmod 3.$$

For $w \in \mathbb{F}_3^6$, the map

$$c(w) = (w, wA_W) \in C_W \subset \mathbb{F}_3^{12}$$

is the ternary encoder fixed in the Paley–Witt section. We define the minimal incidence reader by

$$Q_{\min} = \mathrm{Supp} \circ c \circ \Psi : \mathcal{U}_{468} \longrightarrow \mathcal{P}([12]).$$

For a map $f : X \to Y$, denote by

$$\mathrm{Eq}(f) = \{(x, x') \in X^2 : f(x) = f(x')\}$$

its fiberwise equivalence relation.

Theorem 17.13 (Obstruction of the minimal exceptional reader)**.** *In the complete catalogue of 468 states one verifies*

$$\mathrm{Eq}(\Psi, Q_{\min}) = \mathrm{Eq}(\Psi).$$

In the usual abbreviated notation for fiber partitions,

$$\ker(\Psi, Q_{\min}) = \ker \Psi.$$

Consequently, $(\Psi, Q_{\min})$ *is not injective and the minimal incidence reader does not distinguish any pair of states that has already been identified by* Ψ*.*

Proof. The factorization $Q_{\min} = S \circ \Psi$, with $S = \mathrm{Supp} \circ c$, implies

$$\Psi(u) = \Psi(v) \Longrightarrow Q_{\min}(u) = Q_{\min}(v).$$

The converse implication between the equivalence relations is immediate, because Ψ is the first component of the diagonal map. Equality of the relations therefore follows without statistical assumptions. Exhaustive enumeration further confirms that both partitions have the same histogram:

$$132\,[1] + 66\,[2] + 18\,[3] + 3\,[4] + 6\,[5] + 18\,[6],$$

where $a\,[m]$ means that there exist a fibres of cardinality m. □

The microfiber of $w_\pi = 010211$ provides the distinguished witness. Its five regions are

$$\begin{aligned} &(501, 614, 498, 169, 272, 272), \quad (810, 923, 870, 169, 272, 272),\\ &(810, 983, 810, 169, 272, 272), \quad (870, 923, 810, 169, 272, 272),\\ &(870, 923, 810, 418, 674, 521). \end{aligned}$$

The five have the same visible image and the same exceptional support.

$$P_\pi = \{2, 4, 5, 6, 7, 8, 9, 10, 11\}.$$

At the level of the 243 words there appear 213 distinct supports: 185 have one preimage, 27 have two, and one has four. Taking support therefore introduces a second quotient in addition to the one imposed by Ψ.

The theorem delimits the minimal reader, not the enriched exceptional evaluation. A reader capable of separating the regions of the same word must act before the visible quotient and use at least one of the data that it eliminates: orientation, sheet, signature, return, or boundary state. The dodecaphase intertwiner developed in the following part belongs to that enriched class and does not contradict the preceding obstruction.

Complete enumeration of the fibers produces the preceding histogram and proves that taking support introduces a second quotient.

17.5 Archimedean and incidental publication

For each level, let $\mathcal{E}_n$ be an incidence object and let

$$e_n : S_n \longrightarrow \mathcal{E}_n, \qquad \sigma_{n,m} : \mathcal{E}_n \longrightarrow \mathcal{E}_m \tag{17.5}$$

applications that satisfy

$$\sigma_{n,m} \circ e_n = e_m \circ r_{n,m}. \tag{17.6}$$

The universal property constructs

$$\mathrm{ev}_{\mathrm{inc}} : \Omega_\infty \longrightarrow \mathcal{E}_\infty, \qquad \mathcal{E}_\infty := \varprojlim_n \mathcal{E}_n. \tag{17.7}$$

The double publication is

$$\mathcal{P}_\infty := (\mathrm{ev}_{\mathbb{R}}, \mathrm{ev}_{\mathrm{inc}}) : \Omega_\infty \longrightarrow \mathbb{R} \times \mathcal{E}_\infty. \tag{17.8}$$

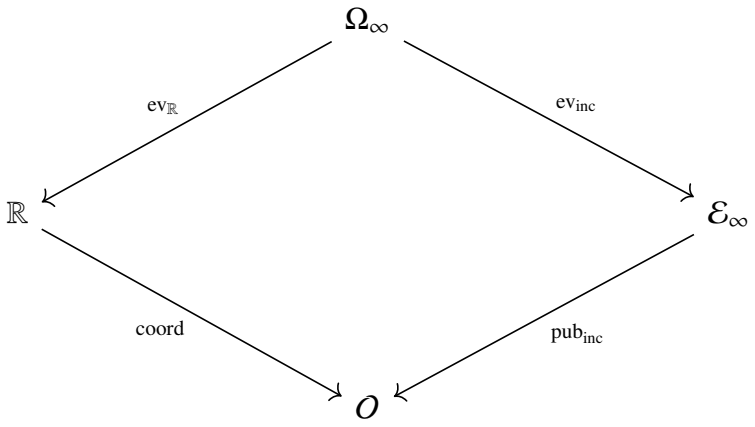

Figure 17.2: Two publications of the same history. Commutativity in O does not identify the codomains $\mathbb{R}$ and $\mathcal{E}_\infty$.

The naturality proved in theorems 17.8 y 17.9 is expressed, after applying the publication readers, by

$$\mathrm{pub}_{\mathrm{inc}} \circ \mathrm{ev}_{\mathrm{inc}} = \mathrm{coord} \circ \mathrm{ev}_{\mathbb{R}}, \tag{17.9}$$

and produces a typed comparison of the two publications. The identity preserves the common origin without constructing one branch from the other: both start from Ω_∞.

17.6 Factorization of the incidence reader through the enriched state

The second projection is not a unary reader devoid of incidence data. Let

$$\mathscr{C}_{\mathrm{exc}} = \mathscr{C}_{\mathrm{ord}} \times \mathscr{C}_{\mathrm{Paley}} \times \mathscr{C}_{\mathrm{dod}} \times \mathscr{C}_{\mathrm{inc}} \times \mathscr{C}_{\mathrm{ret}}$$

the space of exceptional gauges, whose coordinates respectively fix the projective order, the Paley gauge, the dodecad, the incidence alignment, and the lattice chamber. One fixes

$$\chi_{\mathrm{exc}} = (\chi_{\mathrm{ord}}, \chi_{\mathrm{Paley}}, \chi_{\mathrm{dod}}, \chi_{\mathrm{inc}}, \chi_{\mathrm{ret}}) \in \mathscr{C}_{\mathrm{exc}}.$$

The typed reader has domain

$$\mathfrak{E} : X_\infty^{\mathrm{cal}} \times \mathscr{C}_{\mathrm{exc}} \longrightarrow \mathbf{Exc}, \qquad \mathfrak{E}_{\chi_{\mathrm{exc}}}(u) := \mathfrak{E}(u, \chi_{\mathrm{exc}}).$$

Henceforth, every abbreviation $\mathfrak{E}(u)$ means $\mathfrak{E}_{\chi_{\mathrm{exc}}}(u)$ for this explicitly fixed gauge. The dependence on χ_{exc} does not affect the existence of the continuum or its Archimedean publication: it types the exceptional conservation of incidence once the common state has been constructed.

Falsification criterion 17.14 (Loss of the exceptional gauge)**.** The comparison becomes incomplete if the projective order, the dodecad, the incidence alignment, or the lattice chamber is changed without transporting the remaining gauge coordinates, or if $\mathfrak{E}$ is used as a unary reader before fixing χ_{exc}. Such a failure invalidates that exceptional comparison; it does not modify the Archimedean quotient or regenerate the continuum.

The second reading does not arise from the real number. Let

$$\mathfrak{E} : \mathcal{O}^{\mathrm{HMT}}_{\mathbb{R},\leftrightarrow} \longrightarrow \mathbf{Exc}$$

the continuous incidence reader, with Hausdorff codomain, that prolongs the Paley–Witt, Golay, Leech, $V^{\natural}$, Monster, and Moonshine chain. Both maps begin from the same history:

$$\mathfrak{D}(u) = (\mathfrak{R}(u), \mathfrak{E}(u)). \tag{17.10}$$

The first contracts the compatible fibres to their Archimedean mean; the second preserves incidence, orientation, and boundary memory.

Fixing the origin of the dodecaphonic calendar, let it be

$$R_+ := \{k \in \mathbb{Z} : 1 + (k \bmod 9) \in \{1, 4, 7\}\}$$

the bi-infinite set of complete returns ($\tau = +1$). It is syndetic: its gaps are uniformly bounded. For $u = (m, (x_k)_{k\in\mathbb{Z}})$, define

$$\mathrm{Ret}_+(u) := \big(m, (x_k)_{k\in R_+}\big) \in \mathbb{Z} \times \prod_{k\in R_+} X,$$

but each x_k here is the whole state (19.1) with leaf, carry, route, and incidence, not the isolated sign.

Proposition 17.15 (Lossless Sampling of the Return Genealogical Record)**.** *The map* Ret_+*, with the subspace topology in the product, is a homeomorphism onto its image. Consequently, there is a unique continuous map* $\mathfrak{E}_+$ *on that image such that*

$$\mathfrak{E} = \mathfrak{E}_+ \circ \mathrm{Ret}_+ . \tag{17.11}$$

Proof. Between two consecutive returns there is a uniformly bounded number of steps of the calendar. The complete state at a return contains the transition and the genealogical register that determine the intermediate steps; in the other direction, the inverse arrow of the groupoid completion is used. The entire orbit is thereby reconstructed. The map is continuous and, when restricted to a compact chart, a continuous injection into a Hausdorff space is a homeomorphism onto its image. The integer coordinate is preserved explicitly. The factorization is defined by transporting $\mathfrak{E}$ through the inverse and is continuous chart by chart. □

For this reason, +1 participates in the exceptional corridor as a complete memory of return: sampling the integer states does not lose the exceptional output. This proposition proves recovery and factorization, not a generation of the corridor from the isolated scalar +1. The Archimedean output and the exceptional output are two coordinated resultants of the same antecedent.

17.7 Double publication of the enriched state: Archimedean evaluation and incidence conservation

Let $(X_m, p_{m+1,m})_{m\geq 0}$ be the inverse system of calibrated APP–TRIT–TPK states. At each level, fiber, relation, number, orientation, carry, memory, boundary, route, multisection, survival, terminal, and reader are preserved. Let

$$\mathfrak{R}_m : X_m \to A_m, \qquad \mathfrak{E}_{m,\chi} : X_m \to E_m, \qquad \mathfrak{D}_m : X_m \to D_m$$

the Archimedean, calibrated exceptional, and dimensional publications. Their truncations are denoted by $a_{m+1,m}$, $e_{m+1,m}$, and $d_{m+1,m}$.

Theorem 17.16 (Natural cone of the 3 publications)**.** *If the finite-level readers satisfy*

$$\begin{aligned} a_{m+1,m}\mathfrak{R}_{m+1} &= \mathfrak{R}_m p_{m+1,m}, \\ e_{m+1,m}\mathfrak{E}_{m+1,\chi} &= \mathfrak{E}_{m,\chi} p_{m+1,m}, \\ d_{m+1,m}\mathfrak{D}_{m+1} &= \mathfrak{D}_m p_{m+1,m}, \end{aligned} \tag{17.12}$$

then the limit readers exist and are unique

$$\mathfrak{R}_\infty : X_\infty \to A_\infty, \quad \mathfrak{E}_{\infty,\chi} : X_\infty \to E_\infty, \quad \mathfrak{D}_\infty : X_\infty \to D_\infty$$

that reproduce all levels. The joint map

$$\mathfrak{J}_\chi := (\mathfrak{R}_\infty, \mathfrak{E}_{\infty,\chi}, \mathfrak{D}_\infty) : X_\infty \longrightarrow A_\infty \times E_\infty \times D_\infty \tag{17.13}$$

is a publication of the same state and not a concatenation of three generators.

Proof. For $x = (x_m)_m \in X_\infty$, the three sequences $(\mathfrak{R}_m x_m)_m$, $(\mathfrak{E}_{m,\chi} x_m)_m$, and $(\mathfrak{D}_m x_m)_m$ are compatible under (17.12); by the universal property of the inverse limit, they define the three readers. The same property proves their uniqueness. Formula (17.13) evaluates a single history x and therefore preserves the common causal antecedent. □

The legitimate equality does not assert that an output with loss reconstructs by itself all the others. It asserts that the three truncation squares commute and that their outputs are natural coordinates of one and the same cone. In particular, the Archimedean realization can forget genealogy without that forgetting being attributed to the exceptional or dimensional publication.

17.8 Uniqueness of the Initial Caliber of the Exceptional Projection

With the gauge χ_{exc} fixed, the exceptional reader acts on every generator by

$$(w_j, f_j) \longmapsto \big(f_j, \Gamma_{f_j A_W f_j^{-1}}(w_j)\big). \tag{17.14}$$

The frame f_j is part of the output, and $\Gamma_{f_j A_W f_j^{-1}}$ is an automorphism of the calibrated fibre.

Theorem 17.17 (Calibrated separation of histories)**.** *The exceptional reader $\mathfrak{E}_{\infty,\chi_{\mathrm{exc}}}$ is injective on the quotient by the coordinate changes included in χ_{exc}. Consequently,*

$$(\mathfrak{R}_\infty, \mathfrak{E}_{\infty,\chi_{\mathrm{exc}}}) : X_\infty^{\mathrm{cal}} \longrightarrow A_\infty \times E_\infty$$

is a topological embedding when X_∞^{cal} is compact and the codomain is Hausdorff.

Proof. From the output (f_j, y_j), where $y_j = \Gamma_{f_j A_W f_j^{-1}}(w_j)$, one recovers

$$w_j = \Gamma^{-1}_{f_j A_W f_j^{-1}}(y_j).$$

This reconstructs each generator and, by truncation compatibility, the entire history. Two representatives that differ only by a change included in the gauge define the same class; outside that equivalence, the reconstruction is unique. Joint injectivity is immediate. A continuous injective map from a compact space into a Hausdorff space is a homeomorphism onto its image. □

17.9 Noncommutative Algebra, Common and Factorization of the 2 Projections

Let $\mathcal{A}_{\mathrm{TPK}} = C(X_F^{\leftrightarrow}) \rtimes_\sigma \mathbb{Z}$ and let u be the unitary implementing σ. The continuous readers $\mathfrak{R}$ and $\mathfrak{E}_\chi$ induce the unital morphisms

$$\Phi_{\mathrm{arq}}(f) = f \circ \mathfrak{R}, \qquad \Phi_{\mathrm{exc}}(g) = g \circ \mathfrak{E}_\chi, \tag{17.15}$$

from the commutative algebras of its codomains toward $C(X_F^{\leftrightarrow}) \subset \mathcal{A}_{\mathrm{TPK}}$.

Theorem 17.18 (Common operator system and TPK equivariance)**.** *The unital self-adjoint subspace*

$$\mathcal{S}_\infty = \mathrm{span}\big\{I, u, u^*, \Phi_{\mathrm{arq}}(C(A_\infty)), \Phi_{\mathrm{exc}}(C(E_\infty))\big\} \subset \mathcal{A}_{\mathrm{TPK}}$$

is a noncommutative operator system. The two maps from (17.15) *are UCP. If the readers intertwine the output dynamics α_{arq} and α_{exc}, then*

$$\mathrm{Ad}_u \, \Phi_{\mathrm{arq}} = \Phi_{\mathrm{arq}} \alpha_{\mathrm{arq}}, \qquad \mathrm{Ad}_u \, \Phi_{\mathrm{exc}} = \Phi_{\mathrm{exc}} \alpha_{\mathrm{exc}}. \tag{17.16}$$

Proof. Composition with a continuous map is a unital homomorphism of C^*-algebras and is therefore completely positive. The unitary u makes the envelope noncommutative when the dynamics is nontrivial. The identity (17.16) is verified by evaluating both sides on a history and using equivariance of each reader. □

This construction does not force two mutually unbiased qutrit measurements to possess a joint PVM. The common antecedent is the crossed algebra of histories; the publications are two distinct UCP channels from their codomains.

Chapter 18

Archimedean publication of the continuum: reconstruction of $\mathbb{R}$ as a quotient of semiclosed cylinders with genealogical memory

The inverse limit Ω_∞ preserves the complete history. To obtain a real coordinate, a compatible family of intervals must be added and three different facts proved: each history determines a unique value; every value of the declared compact set is attained; and the finite measures descend consistently. None of these facts follows from the mere growth in the number of states. The construction below proves all three facts jointly for the HMT system.

The Archimedean publication likewise preserves an approximation of the identity by cylindrical conditional expectations. The concentration of unit mass on compatible prefixes provides the exact passage from the nonadic cylinders to the Dirac measure, without identifying density, support measure, and total mass.

18.1 Nonadic cylinders, identity and Dirac kernel

18.1.1 Inverse system of compatible nonadric cylinders with genealogical memory

Let

$$X = (\mathbb{Z}/9\mathbb{Z})^{\mathbb{N}}$$

with the product topology and the uniform measure μ. For $x = (x_1, x_2, \ldots)$, the cylinder of depth n is

$$C_n(x) = \{y \in X : y_j = x_j \text{ for } 1 \le j \le n\}.$$

Cylinders are simultaneously open and closed, form a base and satisfy

$$\mu(C_n(x)) = 9^{-n}, \qquad C_{n+1}(x) \subset C_n(x), \qquad \bigcap_n C_n(x) = \{x\}.$$

Adding a digit does not create a new number: it restricts the cylinder of admissible prolongations. This statement gives topological content to the genealogical thesis of number.

18.1.2 Cylindrical concentration of the identity and construction of the Dirac kernel

Theorem 18.1 (Unitary nonadic concentration)**.** *Define*

$$f_{n,x} = 9^n \mathbf{1}_{C_n(x)}.$$

Then

$$\mu(C_n(x)) \to 0, \qquad f_{n,x}(x) \to \infty, \qquad \int_X f_{n,x}\, \mathrm{d}\mu = 1,$$

and the measures $f_{n,x}\mu$ converge weak- to δ_x.*

Proof. The first identity is immediate. The height of $f_{n,x}$ over its support is 9^n, so it diverges. The integral equals $9^n 9^{-n} = 1$. For $g \in C(X)$, the oscillation of g in $C_n(x)$ tends to zero by uniform continuity; therefore

$$\left| \int g f_{n,x}\, \mathrm{d}\mu - g(x) \right| \le \sup_{y \in C_n(x)} |g(y) - g(x)| \longrightarrow 0.$$

This is weak-* convergence to δ_x. □

The theorem does not assert $1/0 = \infty$. It exhibits three evaluations of the same object: support measure, density and total mass. In blocks of three digits,

$$\mu(C_{3m}) = 729^{-m}, \qquad f_{3m} = 729^{m}\mathbf{1}_{C_{3m}}, \qquad 729^{-m}729^{m} = 1.$$

The evolutionary conservation of unity here assumes an exact analytical form.

18.1.3 Convergence of the Kronecker Kernel to the Dirac Distribution

At the finite level $X_n = (\mathbb{Z}/9\mathbb{Z})^n$, let

$$K_n(x, y) = 9^n\mathbf{1}_{\{x=y\}}.$$

With the uniform measure, the operator

$$(E_n f)(x) = \sum_{y\in X_n} K_n(x, y)f(y)9^{-n}$$

is the identity. In the cylindrical limit, the condition $x = y$ is replaced by "same prefix of length n" and E_n is the conditional expectation on the cylindrical algebra. One has

$$E_n^2 = E_n, \qquad E_n^* = E_n, \qquad E_n f \to f \quad \text{in } L^2(X, \mu).$$

The exact bridge is, therefore,

$$\delta_{ij} \longrightarrow K_n(x, y) \longrightarrow \delta_x.$$

The Kronecker delta is a matrix kernel; the Dirac delta is a measure or distribution. Neither is the Dirac operator $D = \gamma^\mu\partial_\mu$. The transition to spinors and Clifford requires a second intertwiner and will be treated later.

18.1.4 Scaling Law, Effective Dimension, and Density of the Cylindrical Measure

Suppose that a contraction of ratio λ acts independently in d directions and that the product measure scales as λ^d. To preserve unit mass, the density must scale as

$$\rho \longmapsto \lambda^{-d}\rho.$$

The exponents $(-1, -2, -3)$ then appear as density weights on a line, area, and volume. This proposition is general and exact under the product hypothesis. It does not permit λ to be identified automatically with α_{HMT}; that identification requires a metric chart.

18.1.5 Nonadic Monodromy and Computability of the Archimedean Evaluation

The existence of an infinite branch in a finitely branching tree may follow from König's lemma, but König's lemma does not furnish a computable selector. There are infinite recursive binary trees with no recursive branch. The joint nonadic connection does not rest on that abstract existence: it has a certified uniform selector that generates to arbitrary finite depth and opens the decimal witnesses only after generation.

Three prohibited confusions

1/0 shall not be written; the Dirac delta shall not be represented as an ordinary function with "an infinite one"; König shall not be used as an algorithm. The strong result is the exact compatibility among cylinders, unit density, and the weak limit, together with the constructive selector independent of decimal comparison.

18.2 System of intervals associated with finite states

Let $(S_n, r_{n,m})$ be the inverse system of the section 6.1. For each $a \in S_n$, assign a nonempty compact interval

$$I_n(a) = [\ell_n(a), u_n(a)] \subset \mathbb{R}. \tag{18.1}$$

The assignment is *compatible with refinement* when

$$r_{n+1,n}(b) = a \quad \Longrightarrow \quad I_{n+1}(b) \subseteq I_n(a). \tag{18.2}$$

It is *uniformly contractive* when there exists a sequence $\delta_n \downarrow 0$ such that

$$\operatorname{diam} I_n(a) \le \delta_n \qquad (a \in S_n). \tag{18.3}$$

For a history $x = (x_n)_n$, the inclusions (18.2) produce a chain

$$I_0(x_0) \supseteq I_1(x_1) \supseteq I_2(x_2) \supseteq \cdots. \tag{18.4}$$

Theorem 18.2 (Evaluation of a history)**.** *If the assignment is compatible and uniformly contractive, then for every $x \in \Omega_\infty$ there exists a unique real number*

$$\mathrm{ev}_{\mathbb{R}}(x) \in \bigcap_{n \ge 0} I_n(x_n). \tag{18.5}$$

The map

$$\mathrm{ev}_{\mathbb{R}} : \Omega_\infty \longrightarrow \mathbb{R} \tag{18.6}$$

is continuous.

Proof. The intervals of (18.4) are compact, nonempty and nested. The nested-interval theorem guarantees that their intersection is nonempty. If s, t belong to it, then

$$|s - t| \le \operatorname{diam} I_n(x_n) \le \delta_n$$

for every n. Setting $n \to \infty$ yields $s = t$.

For continuity, let $\varepsilon > 0$ and choose n with $\delta_n < \varepsilon$. If $y \in [x_n]_n$, then $I_n(y_n) = I_n(x_n)$. The two evaluations belong to that interval and, therefore,

$$|\,\mathrm{ev}_{\mathbb{R}}(x) - \mathrm{ev}_{\mathbb{R}}(y)| < \varepsilon.$$

The cylinder $[x_n]_n$ is an open neighborhood of x. □

The construction does not identify x with $\mathrm{ev}_{\mathbb{R}}(x)$. A single coordinate may have several histories, and a history contains more data than any point on the line.

18.3 Coherent coverage of the visible compactum

Let $K \subset \mathbb{R}$ be a nonempty compact set. The HMT construction of the cylinders associates with nesting and contraction the coverage identities

$$K = \bigcup_{a \in S_0} I_0(a), \tag{18.7}$$

$$I_n(a) = \bigcup_{\substack{b \in S_{n+1} \\ r_{n+1,n}(b) = a}} I_{n+1}(b) \qquad (a \in S_n). \tag{18.8}$$

The second equality is the geometric publication of the prolongation law: each point of $I_n(a)$ remains in a compatible child cylinder. Together with the surjectivity of $r_{n+1,n}$, already established by prefix survival, it simultaneously produces states above a and the complete coverage of $I_n(a)$.

Theorem 18.3 (Surjectivity of the evaluation)**.** *The constructed identities* (18.7) *and* (18.8) *imply*

$$\mathrm{ev}_{\mathbb{R}}(\Omega_\infty) = K. \tag{18.9}$$

Proof. The left-to-right inclusion follows from $I_n(x_n) \subseteq I_0(x_0) \subseteq K$.

Let us fix $t \in K$. Let us define

$$T_n(t) := \{a \in S_n : t \in I_n(a)\}. \tag{18.10}$$

The initial cover makes $T_0(t)$ nonempty. If $a \in T_n(t)$, the identity (18.8) provides at least one $b \in T_{n+1}(t)$ with $r_{n+1,n}(b) = a$. The graph of these extensions is finitely branching and has nonempty levels at every depth. There therefore exists a compatible chain $x = (x_n)_n$ with $t \in I_n(x_n)$ for every n. Uniqueness of the intersection forces $\mathrm{ev}_{\mathbb{R}}(x) = t$. □

18.4 Archimedean genealogical quotient and homeomorphism with $\mathbb{R}$

We define the relation

$$x \sim_{\mathbb{R}} y \quad \Longleftrightarrow \quad \mathrm{ev}_{\mathbb{R}}(x) = \mathrm{ev}_{\mathbb{R}}(y). \tag{18.11}$$

Let

$$q_{\mathbb{R}} : \Omega_\infty \longrightarrow \Omega_\infty/\!\sim_{\mathbb{R}} \tag{18.12}$$

the canonical projection.

Theorem 18.4 (Reconstruction of the compact as a quotient)**.** *For the preceding HMT system there is a unique homeomorphism*

$$\overline{\mathrm{ev}}_{\mathbb{R}} : \Omega_\infty/\!\sim_{\mathbb{R}} \xrightarrow{\cong} K \tag{18.13}$$

such that

$$\mathrm{ev}_{\mathbb{R}} = \overline{\mathrm{ev}}_{\mathbb{R}} \circ q_{\mathbb{R}}. \tag{18.14}$$

The fiber over $t \in K$ is

$$\mathfrak{G}_t := \mathrm{ev}_{\mathbb{R}}^{-1}(t), \tag{18.15}$$

the complete set of genealogies that publish t.

Proof. The map $\mathrm{ev}_{\mathbb{R}}$ is continuous, surjective, and constant exactly on the classes of $\sim_{\mathbb{R}}$. By the universal property of the quotient, it induces a continuous bijective map $\overline{\mathrm{ev}}_{\mathbb{R}}$. The domain is compact because it is a continuous image of the compact space Ω_∞, and K is Hausdorff. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism. □

The theorem proves two things and keeps them separate:

the history space is profinite and retains memory, its quotient by equality of evaluation is the visible compact space.	(18.16)

It is not asserted that Ω_∞ is homeomorphic to K.

18.5 Genealogical Atlas of the Real Line

For $m \geq 1$, let $K_m = [-m, m]$. The same construction, applied to each K_m, produces a system $\Omega_\infty^{(m)}$ that reconstructs K_m, together with closed inclusions

$$j_m : \Omega_\infty^{(m)} \hookrightarrow \Omega_\infty^{(m+1)} \tag{18.17}$$

which satisfy

$$\mathrm{ev}_{m+1} \circ j_m = \iota_m \circ \mathrm{ev}_m, \tag{18.18}$$

where $\iota_m : K_m \hookrightarrow K_{m+1}$ is the inclusion ordinary.

Proposition 18.5 (Exhaustion of the line)**.** *The Archimedean quotient of the strict colimit*

$$\Omega_\infty^{\mathbb{R}} := \varinjlim_m \Omega_\infty^{(m)} \tag{18.19}$$

is

$$\varinjlim_m [-m, m] = \bigcup_{m \geq 1} [-m, m] = \mathbb{R} \tag{18.20}$$

with its usual topology.

Proof. Each piece has quotient K_m by the theorem 18.4; (18.18) intertwines the quotients. The final topology of the exhaustion by compact sets coincides with the usual topology of $\mathbb{R}$: a subset $U \subseteq \mathbb{R}$ is open if and only if $U \cap [-m, m]$ is open in $[-m, m]$ for every m. □

Passage from a bounded interval to the line does not erase the fibers $\mathfrak{G}_t$. The inclusions j_m preserve the history and only enlarge the available visible chart.

18.6 Balanced ternary and block-decimal charts

The balanced ternary representation of an integer has the form

$$n = \sum_{j=0}^{J} \epsilon_j 3^j, \qquad \epsilon_j \in \{-1, 0, +1\}, \tag{18.21}$$

with a fixed carry rule. This chart preserves the local sign and the quotient of the reduction; it must not be confused with the nonnegative word in $\mathbb{F}_3$.

The block decimal chart utilizes

$$D_N = 1000 D_{N-1} + u_N, \qquad u_N \in \{0, \ldots, 999\}, \qquad D_0 = 0. \tag{18.22}$$

The block u_N, its class modulo nine, and the carry are distinct fields. Since $1000 \equiv 1 \pmod 9$,

$$D_N \equiv \sum_{j=1}^{N} u_j \pmod 9. \tag{18.23}$$

This congruence does not recover the order of the blocks; the sequence $(u_1, \ldots, u_N)$ remains in the record.

For $M \geq 1$, the cells decimales half-open are

$$\mathcal{D}_{M,q} := [q 10^{-M}, (q+1) 10^{-M}), \qquad q \in \mathbb{Z}. \tag{18.24}$$

A half-open interval $[\ell, h)$ is contained in a unique cell if and only if

$$\lfloor 10^M \ell \rfloor = \lceil 10^M h \rceil - 1. \tag{18.25}$$

The formula with a ceiling at the right endpoint also covers the case in which h coincides exactly with a decimal boundary.

Definition 18.6 (Truncation and Rounding)**.** For $x \geq 0$, define

$$\mathrm{Tr}_M(x) := 10^{-M} \lfloor 10^M x \rfloor, \tag{18.26}$$

$$\mathrm{Rd}_M(x) := 10^{-M} \left\lfloor 10^M x + \frac{1}{2} \right\rfloor. \tag{18.27}$$

These operations coincide except when the discarded fraction crosses the half-unit threshold at the final position. The distinction is semantic and arithmetic; one cannot be substituted for the other to force prefix compatibility.

18.7 Descent of operations along evaluation fibers

Let $D_\star \subseteq \Omega_\infty \times \Omega_\infty$ the domain of to operation parcial continuous

$$\star : D_\star \longrightarrow \Omega_\infty. \tag{18.28}$$

Assume that $D_\star$ is saturated by the fibers of $\mathrm{ev}_\mathbb{R} \times \mathrm{ev}_\mathbb{R}$.

Theorem 18.7 (Exact Descent Criterion)**.** *There exists a unique visible operation*

$$\overline{\star} : (\mathrm{ev}_\mathbb{R} \times \mathrm{ev}_\mathbb{R})(D_\star) \longrightarrow K \tag{18.29}$$

which satisfies

$$\mathrm{ev}_\mathbb{R}(x \star y) = \mathrm{ev}_\mathbb{R}(x) \,\overline{\star}\, \mathrm{ev}_\mathbb{R}(y) \tag{18.30}$$

if and only if

$$\begin{aligned} &\mathrm{ev}_\mathbb{R}(x) = \mathrm{ev}_\mathbb{R}(x'), \\ &\mathrm{ev}_\mathbb{R}(y) = \mathrm{ev}_\mathbb{R}(y') \end{aligned} \quad \Longrightarrow \quad \mathrm{ev}_\mathbb{R}(x \star y) = \mathrm{ev}_\mathbb{R}(x' \star y') \tag{18.31}$$

for all pairs in the domain.

Proof. If $\overline{\star}$ exists, the right-hand side of (18.30) depends only on the two evaluations, and (18.31) follows. Conversely, this constancy makes it possible to define

$$s \,\overline{\star}\, t := \mathrm{ev}_\mathbb{R}(x \star y)$$

for any representatives x, y with evaluations s, t. The condition proves that the definition is independent of the representatives. Uniqueness is immediate. □

The additive and multiplicative sheets of APP supply operations on a common support, but their carries and their memories are not identified. The preceding theorem allows sum and product to descend to the visible chart without requiring their genealogical realizations to coincide.

18.8 Correspondence between discrete cardinality, cylindrical measure, and Archimedean publication

At each depth three operations appear that must be kept separated:

$$\mathrm{Count}_n(A) := |A|, \tag{18.32}$$

$$\mathrm{Measure}_n(A) := \mu_n(A), \tag{18.33}$$

$$\mathrm{Publish}_n(a) := L_n(a). \tag{18.34}$$

The count depends on the number of states; the measure depends on compatible weights; the publication depends on the reader. Two fibers of equal cardinality can have distinct weights, and two states of equal publication can belong to distinct cylinders. Equality of one of these three outputs does not imply equality of the other two.

18.9 Obstructions to Archimedean evaluation: nesting, continuity, quotient, projective measures, and descent of operations

Comparison Criterion 18.8 (Refutation of the evaluation and the measure)**.** The construction is refuted if any of the following facts holds:

1. a compatible extension receives an interval that is not contained in the interval of its restriction;
2. the diameters do not tend to zero, but uniqueness of the intersection is asserted;
3. the evaluation is not continuous in the cylinder topology;
4. it is asserted that every point of K appears without proving the coherent covering (18.8);
5. the map induced by the quotient is not bijective;
6. the profinite space is identified with its visible quotient;
7. the inclusions of the atlas do not intertwine their evaluations;
8. $\lfloor 10^M h \rfloor$ is used instead of $\lceil 10^M h \rceil - 1$ for a semi-open interval, and the boundary case is lost;
9. truncation and rounding are conflated;
10. a descended operation depends on the representative chosen in a fibre;
11. to family $(\mu_n)_n$ viola (7.1);
12. the measure of a cylinder depends on the level to which it is refined;
13. a conditioned measure ceases to sum to one or loses consistency;
14. the visible measure ν is identified with the internal measures μ_t;
15. an arrow between $\mathbb{R}$ and $\mathcal{E}_\infty$ is inferred solely because both publications share an antecedent;
16. the count of a fibre is used as though it determined its measure or its published value.

18.10 Quotient of the space of compatible histories and realization of the real line

Let

$$\Psi : \mathbb{Z}_3^6 \xrightarrow{\sim} (\mathbb{F}_3^6)^{\mathbb{N}}$$

the Hensel conjugacy between the initial memory and the complete tape of six-trit blocks. Concatenating the six coordinates of each block yields a ternary tape $(a_n)_{n\geq 1} \in \{0,1,2\}^{\mathbb{N}}$, on which the evaluation acts

$$\mathrm{ev}_3((a_n)) := \sum_{n\geq 1} \frac{a_n}{3^n} \in [0,1].$$

The two expansions of a ternary endpoint represent the same value and remain distinct before evaluation is applied. This does not constitute an ambiguity of the genealogical object: it is precisely a fiber of the reader.

We define

$$X_{\mathrm{raw}} := \mathbb{Z} \times \mathbb{Z}_3^6, \qquad P(m,x) := m + \mathrm{ev}_3(\mathrm{flat}(\Psi x)).$$

The integer coordinate provides the countable atlas of the line, and the 3-adic coordinate preserves the complete history of the fractional part.

Theorem 18.9 (Exact reconstruction of the Archimedean quotient)**.** *The map $P : X_{\mathrm{raw}} \to \mathbb{R}$ is sobreyectiva. If*

$$x \sim_P y \quad \Longleftrightarrow \quad P(x) = P(y),$$

then

$$\overline{P} : X_{\mathrm{raw}}/\!\sim_P \longrightarrow \mathbb{R}, \qquad [x] \longmapsto P(x),$$

is a bijection. Consequently,

$$|X_{\mathrm{raw}}/\!\sim_P| = |\mathbb{R}| = 2^{\aleph_0}.$$

Proof. Every ternary sequence is grouped uniquely into consecutive blocks of six digits. The conjugation Ψ assigns a unique initial 3-adic memory to that tape. Given $r \in \mathbb{R}$, take $m = \lfloor r \rfloor$ and a ternary expansion of $r - m \in [0,1)$; the preceding reconstruction produces $x \in \mathbb{Z}_3^6$ with $P(m,x) = r$. Thus, P is surjective.

The map $\overline{P}$ is well defined by the definition of $\sim_P$, is surjective because P is, and is injective because two classes with the same image belong to the same fiber. Finally,

$$|\mathbb{Z}_3^6| = \left|(\mathbb{F}_3^6)^{\mathbb{N}}\right| = 729^{\aleph_0} = 2^{\aleph_0},$$

and multiplying by the countable coordinate $\mathbb{Z}$ does not alter that cardinal. The calculation agrees with that of the quotient, already identified with $\mathbb{R}$. □

Remark 18.10 (Surviving closure). The raw completion and the surviving subspace X_{surv} are two stages of the same construction. The survival law produces coherent coverings at each level, uniform contraction of diameters and a prolongation for every visible cell. The infinite-branch lemma then produces a section over each point, and the evaluation induces, compact set by compact set, a homeomorphism of the quotient with the published interval. The exhaustion by $[-m,m]$ reconstructs the entire line, in agreement with proposition 18.5 y theorem 18.9.

18.11 Compatibility of the median Archimedean evaluation with the double projection of the enriched state

Let $u = (m, \mathbf{u}) \in \mathcal{O}^{\mathrm{HMT}}_{\mathbb{R},\leftrightarrow}$. A prefix $\mathbf{u}_n$ determines in the fractional chart an oriented semi-open cylinder

$$I_n(\mathbf{u}_n) = [a_n, b_n),$$

with the complementary convention at the endpoints of double expansion. To apply compactness, its closure $K_n = [a_n, b_n]$ is used. The compatibilities give

$$K_{n+1} \subseteq K_n, \qquad \delta_n := b_n - a_n \longrightarrow 0.$$

The global Archimedean mean of the cylinder is

$$\mu_n(u) = m + \frac{a_n + b_n}{2}.$$

If $q \geq n$, then

$$|\mu_q(u) - \mu_n(u)| \leq \delta_n,$$

so that

$$\mathfrak{R}(u) := \lim_{n\to\infty} \mu_n(u) \tag{18.35}$$

exists. What tends to zero is the diameter of the cylinder; the real value is the resultant of the nesting, not that which vanishes.

Theorem 18.11 (Two-way quotient and real line)**.** *Let*

$$u \sim_{\mathfrak{R}} v \quad \Longleftrightarrow \quad \mathfrak{R}(u) = \mathfrak{R}(v).$$

Under the coherent covering of the HMT charts, the evaluation induces a homeomorphism.

$$\overline{\mathfrak{R}} : \mathcal{O}^{\mathrm{HMT}}_{\mathbb{R},\leftrightarrow}/\sim_{\mathfrak{R}} \xrightarrow{\sim} \mathbb{R}. \tag{18.36}$$

In particular, this is a continuous HMT morphism: not the result of choosing an isolated history from each fiber.

Proof. The cylinder bound proves the continuity of $\mathfrak{R}$. The covering produces a history over every real and hence surjectivity. Upon passage to the quotient by the fibers, the induced map is bijective. On every compact chart, a continuous bijection onto a Hausdorff interval is a homeomorphism. The global topology of the quotient is the final topology of the gluing of these charts; the evaluation fiber identifies endpoint $m + 1$ of one chart with the translated endpoint 0 of the following chart. The resulting cover is locally finite, so the chart homeomorphisms glue into a global homeomorphism onto $\mathbb{R}$. □

18.12 Genealogical radial correspondences on the enriched state: domain, codomain, and preservation of helical history

This publication develops a genealogical theory of spiral correspondences from the composition $APP \to \widehat{\mathbb{T}} \to$ TPK. The primary object is not a curve presupposed in $\mathbb{R}^2$, but a compatible history of the enriched state, together with its arithmetic sheets, orientation, carry, boundary, route, and memory. The curve appears at the end as an Archimedean publication. Consequently, two identical figures in $\mathbb{R}^2$ may proceed from different histories, and a visible circle may have intrinsically zero radial memory or be the shadow of a helix whose memory was eliminated by the projection.

The work preserves and develops the exact results of the HMT corpus concerning the mixed curvature of APP, the three quadratic regimes of TRIT, the nonadic holonomy Γ_9, phase return with memory advance, the nonadic helix, the nonsplit dodecaphasic extension, and the Pell spectral screw. On those results it constructs a new formalization: the universal affine envelope, the prefix-enriched radial reader, its naturality under truncation, its equivariance with Γ_9, and its power–logarithmic publication.

The construction does not alter the theory of masses or reopen the central electron. The sole fixed point $(5, 5)$ of the material atlas is used only as the subsequent anchor of an interface; never as a retrospective selector of the radial geometry.

Probative stratification by domain and codomain

The exposition distinguishes previously established internal theorems, theorems proved in this work, finite certifications, and physical realizations. An internal algebraic result is asserted fully in its domain. Every subsequent physical realization preserves its premises and does not intervene in the selection of the HMT generator.

18.13 Construction and main results of the enriched radial reader

A theory of spiral correspondences is constructed whose antecedent is the enriched state of Triadic Modular Holography and whose output is a family of curves in $\mathbb{R}^2$ or $\mathbb{R}^3$. APP provides a two-dimensional support with two evaluations that are not simultaneously compatible, Σ and Π; their mixed composition has oriented discrete curvature ± 1. TRIT types the elliptic, parabolic, and hyperbolic regimes without confusing them with the radial character or Frenet curvature. TPK selects, transports, memorizes, updates, and returns the complete state. The holonomy Γ_9 returns the phase, but increments the memory depth and transports the boundary.

The initially proposed reader into $(p, a, \Lambda, C, m, r, \theta)$ is decisively corrected. The coordinates (r, θ) belong to the Archimedean publication, and the final pair (Λ, C) does not preserve its prefixes. An internal reader is therefore defined

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N} : \mathrm{Hist}^{\mathrm{enr}}_N(\mathrm{TPK}) \longrightarrow \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},N}$$

which records, at each depth, the mode and orientation cocycles, the local affine factor, prefix holonomy, and complete ledger. Its naturality under truncation, extension to the inverse limit, equivariance with Γ_9, preservation of carry, boundary, and memory, and compatibility with route inversion in the reversible sector are proved.

After constructing the continuum, a radial character is applied and the power–logarithmic coordinate is introduced

$$L_p(x) = \frac{x^p - 1}{p}, \qquad L_0(x) = \log x.$$

Its composition law makes the APP sum–product articulation visible. Uniform translation in L_p publishes, for $p = 2, 1, 0, -1, -2$, the Fermat, Archimedean, logarithmic, hyperbolic, and lituus spirals. General affine holonomy produces a broader classification through $(p, [\Lambda, C])$. The spectral screw $V^{-1}\mathcal{S}V = (2+\sqrt{3})\mathrm{i}\mathcal{S}$ appears as an exact case: its transverse projection is a logarithmic spiral, and its lift preserves helical memory.

The publication concludes with the differential geometry of the published curves, a restricted electromagnetic realization of the phase–position helix, the interface with the central electron, and a system of falsifiers preventing appearance, genealogy, and physical realization from being conflated.

Keywords: APP; TRIT; Topological Phase Kernel; nonadic holonomy; affine cocycle; spirals; helicoidal suspension; memory; double projection; continuum; Dimensional Mechanics.

18.14 Key results of the radial publication APP–TRIT–TPK

R1. Visible geometry is a nonfaithful publication of the enriched state: equality in $\mathbb{R}^2$ does not imply equality of genealogy.

R2. The mixed curvature of APP distinguishes the sum–product order before any real curve.

R3. τ, p and the Frenet curvature are invariants of distinct levels and cannot be identified.

R4. The nonadic holonomy returns the phase, advances the memory and transports the boundary; therefore the periodic angular projection admits a nonadic helicoidal lift that preserves the depth of return.

R5. Complete radial information requires preserving all factors and prefix holonomies; the final pair (Λ, C) is insufficient.

R6. The enriched radial reader is natural under truncation and equivariant under Γ_9.

R7. The bidirectional involution produces conjugate ascending and descending routes in the reversible sector.

R8. The family L_p publishes the five power–logarithmic classes as outputs of one and the same law, without choosing them in advance.

R9. The Pell spectral screw constitutes an exact realization of rotation and self-scale whose projection is logarithmic.

R10. A circumference may be a radially stationary state or the shadow of a helix with nonzero ledger.

R11. The electron $(5, 5)$ remains the proven material center; the spiral signature is added as a reader, not as a substitute for the atlas $81/56/13/324$.

R12. The electromagnetic and material realizations are subsequent to the HMT construction and preserve their own physical typing.

18.15 Typed notation and causal levels of the radial publication

Symbol	Meaning
X_9	Nonadic torus $(\mathbb{Z}/9\mathbb{Z})^2$, the two-dimensional support of APP.
Σ, Π	Additive and multiplicative evaluations of the same support.
$\tau \in \{-1, 0, +1\}$	Local TRIT type of transport: hyperbolic, parabolic, or elliptic according to the declared quadratic convention.
U_t	Typed transition $\mathrm{Upd}_t \circ \mathrm{Tra}_t \circ \mathrm{Sel}_t$.
Γ_9	Holonomy of nine transitions over the enriched state.
p	Cocycle or radial degree after defining its internal extraction; it is not τ.
a	Local oriented character $a = \tau_+ - \tau_-$; it is distinct from the radial degree $p = \tau_+ + \tau_-$.
(Λ, C)	Radial affine endomorphism: linear part and translation.
H_j	Prefix affine holonomy up to depth j.
$L_p, \exp_p$	Power-logarithmic coordinate and its inverse.
$\kappa_{\mathrm{F}}, \mathcal{T}_{\mathrm{F}}$	Frenet curvature and torsion of the published curve.
$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}$	Radial internal genealogical reader.
$\mathrm{ev}^{\mathrm{esp}}_{\mathrm{arq}}$	Archimedean publication of the spiral firm.

Causal composition from APP–TRIT–TPK to the radial Archimedean evaluation

$$\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow C_{\mathrm{cont}}^{\mathrm{disc}} \longrightarrow \mathcal{P}_{\mathrm{rad}}^{\mathrm{enr}} \longrightarrow \mathrm{ev}_{\mathrm{arq}}^{\mathrm{esp}} \longrightarrow (\mathbb{R}^2 \text{ or } \mathbb{R}^3).$$

The curve is an output of the generative chain; it does not enter the selection of the state or its coefficients.

18.16 Genealogical Foundation of Radial Geometry

18.16.1 Archimedean evaluation of the enriched state and genealogical fidelity defect

18.16.1.1 Causal Factorization from the Enriched History to the Archimedean Evaluation

Conventional geometry begins with a continuous set and defines in it curves, parameters, and fields. The construction developed here reverses that order. First a compatible history is produced on a finite support, then its transport data are conserved, and only at the end is a real coordinate published. The causal scheme is

$$\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow C_{\mathrm{cont}}^{\mathrm{disc}} \longrightarrow \mathrm{ev}_{\mathrm{arq}} \longrightarrow \mathbb{R}^d. \tag{18.37}$$

It is not a matter of adorning a classical curve with discrete labels. The history is the object; the curve is one of its readings.

Definition 18.12 (Geometric Generation with Traceability)**.** To construction geometric is *constructivo–generativa* when:

1. produces its object from declared operations on a domain preceding real geometry;
2. preserves the order of operations and the coordinates needed to reconstruct it;
3. obtains the geometric appearance by means of a later map;
4. distinguishes equality of appearances from equivalence of histories.

This criterion is stronger than a parametrization. A parametrization $t \mapsto \gamma(t)$ presupposes the curve and changes its mode of traversal. A genealogy $x = (x_n)_{n\geq 0}$, by contrast, specifies the finite truncations, the admissible transitions, the arithmetic sheets, the carry, and the memory that make the output γ possible.

18.16.1.2 Enhanced state space, TPK history category, and Archimedean evaluation

Let $X_{\mathrm{TPK}}^{\mathrm{enr}}$ be the enriched state space. A finite history of length N is

$$\gamma_N = (x_0 \xrightarrow{e_1} x_1 \xrightarrow{e_2} \cdots \xrightarrow{e_N} x_N),$$

where every arrow is compatible with the typed TPK transition. We associate its ledger with each prefix

$$\mathrm{Led}_j(\gamma_N) = (R_j, Q_j, \kappa_j, \sigma_j, o_j, g_j, C_j, B_j, \lambda_j, m_j, s_j),$$

which registers, according to the concrete residence, residue, quotient, carry, leaf, orientation, phase, cylinder, boundary, route, memory, and survival. The exact content may be enriched, but it cannot be reduced if the eliminated coordinate intervenes in a continuation.

The real publication is a composition.

$$\mathrm{Hist}_N^{\mathrm{enr}}(\mathrm{TPK}) \xrightarrow{\mathcal{P}_N^{\mathrm{enr}}} \mathcal{D}_N^{\mathrm{enr}} \xrightarrow{\mathrm{ev}_N} Y,$$

with $Y = \mathbb{R}, \mathbb{R}^2$ or $\mathbb{R}^3$. The first map preserves genealogy; the second publishes. If $\mathrm{ev}_N(\gamma) = \mathrm{ev}_N(\eta)$, it follows only that both histories belong to the same evaluation fibre.

Proposition 18.13 (No fidelity of the visible geometry)**.** *If the evaluation map removes at least one ledger coordinate that admits two compatible values, then there exist distinct histories with the same geometric output.*

Proof. Let c be an eliminated coordinate and let γ, η be two compatible histories that coincide in all preserved coordinates and differ in c. By definition of the evaluation, $\mathrm{ev}(\gamma) = \mathrm{ev}(\eta)$, whereas $\gamma \neq \eta$ because their ledgers differ. Therefore, ev is not injective. □

The proposition is not an insufficiency of real geometry. It expresses its function: to contract a richer structure to a usable coordinate. The central thesis consists precisely in not confusing that contraction with the contracted object.

18.16.1.3 Distinction between intrinsic radial orbit and circular projection of a helical trajectory

Consider the application

$$c_0(t) = (R\cos t, R\sin t),$$

and the helix

$$h(t) = (R\cos t, R\sin t, bt).$$

The projection $\pi_{xy}(x, y, z) = (x, y)$ satisfies $\pi_{xy} \circ h = c_0$. The same circumference may represent:

1. a state with null radial increment and memory;
2. the shadow of a state with null radial increment and axial memory $b \neq 0$.

The visible form does not decide between both cases. The ledger is needed.

(a) Circle as a planar object.

(b) The same shadow, with memory raised.

Figure 18.1: Visible geometry does not by itself reconstruct the genealogy.

Failure of fidelity of Archimedean evaluation on genealogical classes

A circle may have intrinsically null memory and may also be the publication of a helical history. Equality of the curve does not authorize identifying the states that produce it.

18.16.2 APP: two-dimensional support, arithmetic sheets and mixed curvature

18.16.2.1 Construction of the bidimensional nonadic support $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$

The visible cell

$$E_9 = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}$$

simultaneously carries a phase and a chart of positive representatives. For $n \geq 1$,

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad q_9(n) = \left\lfloor \frac{n-1}{9} \right\rfloor,$$

so that

$$n = 9q_9(n) + \rho_9(n).$$

The Cartesian product of two cells constructs

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2.$$

It is not a repeated line but a genuinely two-dimensional support. The completion 9×9 may be read as a core 8×8 and a gnomon of 17 cells:

$$81 = 64 + 17.$$

Two evaluations of the same support act on every $(i, j) \in X_9$:

$$\Sigma(i, j) = \mathrm{dr}(i + j), \qquad \Pi(i, j) = \mathrm{dr}(ij),$$

where dr publishes the nonadic representative and the lift conserves the quotient. APP does not add two spaces; it conserves a single space with two readings.

18.16.2.2 Residue, quotient and carry

The raised identities

$$i + j = R^+_{ij} + 9q^+_{ij}, \qquad ij = R^\times_{ij} + 9q^\times_{ij}$$

distinguish the visible output R from the lift q. If only the residue is preserved, distinct operations may collapse in the same cell. The pair (R, q) unfolds the history. Under composition, the carry obeys a cocycle law; therefore it is not an auxiliary annotation, but rather the datum that allows a long operation to be recomposed from its steps.

Example 18.14 (Same residue, different history)**.** In the nonadic chart,

$$8 + 8 = 7 + 9 \cdot 1, \qquad 8 \cdot 2 = 7 + 9 \cdot 1.$$

The two operations publish the same residue and the same local quotient, but differ in leaf. The label Σ/Π remains necessary. On longer routes, the order of those leaves modifies the composite carry and the boundary reached.

18.16.2.3 Operational Incompatibility of the Additive and Multiplicative Leaves

For $d \geq 2$, let $\mathscr{A}_d = E_9^d$. The conditional expectations $P_{\Sigma,d}$ and $P_{\Pi,d}$ on the two evaluations satisfy

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

In dimension three, the tritic mode of operative phase has singular value $s = 1/2$, and

$$s^2 = \frac{1}{4}, \qquad 1 - s^2 = \frac{3}{4} = \frac{90}{120}, \qquad s\sqrt{1 - s^2} = \frac{\sqrt{3}}{4}.$$

Thus, the separation between the sheets is not added afterward: it is quantified in the APP support itself.

18.16.2.4 Discrete curvature sum–product

In residues, write

$$S(x, y) = x + y, \qquad P(x, y) = xy \pmod 9.$$

For a potential T, the progressive differences are defined

$$\Delta_x T(x, y) = T(x + 1, y) - T(x, y), \qquad \Delta_y T(x, y) = T(x, y + 1) - T(x, y).$$

With $A_x^T = \Delta_x T$ and $A_y^T = \Delta_y T$, the curvature of an ordered mixture is

$$F(T_x, T_y) = \Delta_x A_y^{T_y} - \Delta_y A_x^{T_x}.$$

Since

$$\Delta_x S = \Delta_y S = 1, \qquad \Delta_x P = y, \qquad \Delta_y P = x,$$

it is obtained exactly

$$F(S,S) = F(P,P) = 0, \qquad F(S,P) = +1, \qquad F(P,S) = -1. \tag{18.38}$$

Theorem 18.15 (Mixed oriented curvature of APP)**.** *Pure compositions of the APP leaves are flat in the preceding plaquette convention; mixed compositions have constant curvature of opposite sign according to the order.*

Proof. Substituting the four differences in the definition,

$$\Delta_x \Delta_y S - \Delta_y \Delta_x S = 0, \quad \Delta_x \Delta_y P - \Delta_y \Delta_x P = 0$$

for the two pure compositions, while

$$\Delta_x \Delta_y P - \Delta_y \Delta_x S = 1, \qquad \Delta_x \Delta_y S - \Delta_y \Delta_x P = -1.$$

The identity verifica in each to of the 81 plaquetas. □

For a coordinate rectangle with sides a, b, cancellation of the interior edges yields the finite form of Stokes' theorem:

$$W_{\partial R_{a,b}}(S,P) = ab, \qquad W_{\partial R_{a,b}}(P,S) = -ab \pmod 9.$$

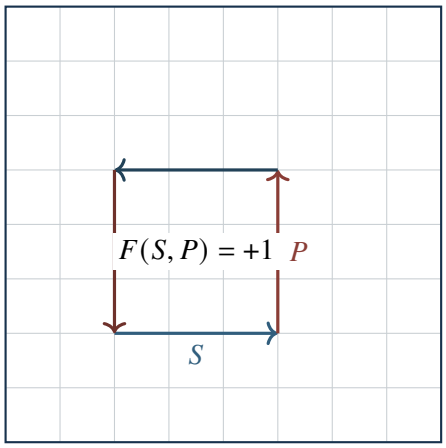

Figure 18.2: Curvature arises from the order of the leaves over the same support.

18.16.2.5 APP invariants that induce the accumulated radial character

APP contributes three distinct ingredients:

1. a domain bidimensional anterior to $\mathbb{R}^2$;
2. two operations whose ordered mixture distinguishes orientation;

3. a ledger of residue, quotient, sheet, and carry capable of remembering the path that produced the same output.

The curvature ± 1 is the local antecedent of the radial orientation, but it must not be identified without proof with the global degree p. The passage from one to the other requires the TPK accumulation and the cocycle declared in the section 18.17.2.

18.16.3 TRIT: local orientation and 3 geometric regimes

18.16.3.1 Residue and carry enriched TRIT state: multiplicity of threshold representatives

The visible observable is

$$\widehat{\mathbb{T}} = \{-1, 0, +1\}.$$

In a local step with a carry, the balanced decomposition is written

$$\widehat{\tau} = (r, c), \qquad a + b = r + 3c, \qquad r \in \{-1, 0, +1\},\ c \in \mathbb{Z}.$$

The visible zero possesses at least three elementary lifts:

$$0^{+} = (0, +1), \qquad 0^{0} = (0, 0), \qquad 0^{-} = (0, -1).$$

The visible equality does not fix the continuation. This also depends on sheet, orientation, height, carry, boundary, path and phase.

18.16.3.2 Family $\mathcal{A}_\tau = \mathbb{R}[J]/(J^2 + \tau I)$ and elliptic, parabolic, and hyperbolic classification

Para $\tau \in \widehat{\mathbb{T}}$, sea

$$\mathbb{A}_\tau = \mathbb{R}[J]/(J^2 + \tau I).$$

Three regimes are obtained:

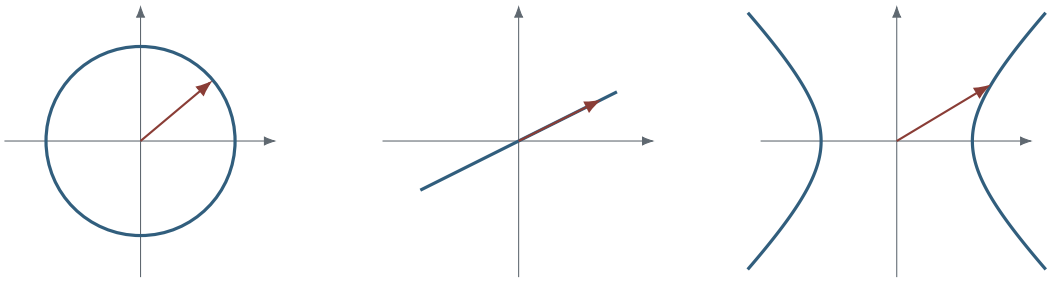
$$J_{+1}^2 = -I, \qquad J_0^2 = 0, \qquad J_{-1}^2 = +I,$$

and a single exponential identity

$$\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau,$$

where

τ	J_τ^2	$C_\tau(t)$	$S_\tau(t)$
$+1$	$-I$	$\cos t$	$\sin t$
0	0	1	t
-1	I	$\cosh t$	$\sinh t$



elliptic $J^2 = -I$ **parabolic** $J^2 = 0$ **hyperbolic** $J^2 = I$

Figure 18.3: The three quadratic regimes of the TRIT. They are transport types, not names of specific curves.

18.16.3.3 Separation between TRIT regime, radial character and Frenet curvature

The theory requires three levels that must not be flattened:

1. τ tipa the regimen local of transport;
2. p types the accumulated radial character of a history;
3. κ_{F} and $\mathcal{T}_{\mathrm{F}}$ describe the curve already published in a real space.

A circumference has elliptic angular holonomy, but the present TRIT 0 is a parabolic threshold. The circumference and the present are not the same object. Likewise, a published logarithmic spiral may include segments whose local transitions traverse the three TRIT types.

Principle 18.16 (Separation of levels)**.** No identity among τ, p and κ_{F} is admitted by similarity of sign, name, or drawing. Every relation must be constructed by means of a map with declared domain, codomain, and action.

18.16.3.4 Orientation Inversion

For a word $\boldsymbol{\tau} = (\tau_1, \dots, \tau_n)$,

$$C_{\mathrm{rev}}(\boldsymbol{\tau}) = (-\tau_n, \dots, -\tau_1), \qquad C_{\mathrm{rev}}^2 = \mathrm{id}\,.$$

The involution exchanges the orientations and preserves the threshold. In the sector of reversible routes it will induce inversion of the affine holonomy, but that conclusion requires the local representation to satisfy $h_{e^\dagger} = h_e^{-1}$.

18.16.4 Enriched state, unique continuum and double projection

18.16.4.1 Inverse history system

Let S_n be the admissible states at depth n and

$$\pi_{n+1,n} : \mathsf{S}_{n+1} \longrightarrow \mathsf{S}_n$$

the truncations. The space of complete histories is

$$X_\infty = \varprojlim_n \mathsf{S}_n.$$

With the ultrametric

$$d(x, y) = 3^{-m(x,y)},$$

where $m(x, y)$ is the first depth at which they differ, the fixed-prefix cylinders are clopen. The structure of the continuum is obtained by jointly constructing, from the same APP–TRIT–TPK state, its five consubstantial constructions, which emerge correlatively, and by passing through terminality, naturality, and the limit. This publication neither disaggregates them nor redefines them by means of curves.

18.16.4.2 Archimedean Evaluation via Compatible Cylinders

Let $\widehat{\mathbb{Q}}$ be the uniform completion of $\mathbb{Q}$, constructed as classes of rational Cauchy sequences. The calibrated construction associates with each finite state an integer direction $k_n(s)$ and the rational semi-closed cylinder

$$I_n(s) = \{q \in \mathbb{Q} : k_n(s)3^{-n} \le q < (k_n(s) + 1)3^{-n}\}.$$

Satisfies simultaneously:

(A1) $\bigcup_{s\in\mathsf{S}_n} I_n(s) = \mathbb{Q}$ for every n;

(A2) if $t \in \mathsf{S}_{n+1}$ truncates to s, then $I_{n+1}(t) \subseteq I_n(s)$, and the children partition the parent under the half-closed boundary convention;

(A3) there exist a constant $C > 0$ and $0 < \lambda < 1$ such that

$$\operatorname{diam} I_n(s) \le C\lambda^n, \qquad 0 < \lambda < 1;$$

(A4) every chain of nested cylinders arises from a compatible history, with the two boundary expansions identified by the Archimedean relation.

Theorem 18.17 (Archimedean Closure of the Genealogical Continuum)**.** *Each calibrated history determines a unique value*

$$\{\mathrm{val}(x)\} = \bigcap_n \overline{I_n(x_n)}^{\widehat{\mathbb{Q}}}.$$

The evaluation

$$\mathrm{val} : X_\infty^{\mathrm{cal}} \longrightarrow \widehat{\mathbb{Q}}$$

is continuous, Hölder, and surjective. The quotient by equality of value satisfies

$$X_\infty^{\mathrm{cal}}/{\sim_{\mathrm{arq}}} \cong \widehat{\mathbb{Q}} \cong \mathbb{R},$$

where the last identification is the usual Archimedean recognition of the completion of $\mathbb{Q}$, not an input to the generator.

Proof. Contraction of diameters and completeness of $\widehat{\mathbb{Q}}$ reduce each nested chain to a point. Cylinder compatibility proves continuity; the geometric diameter bound gives the Hölder estimate. By (A1) and (A2), each rational Cauchy class selects at every depth a cylinder containing it; (A4) provides a compatible history and uniquely resolves the boundaries. Surjectivity follows. Two histories have the same image exactly when they belong to the relation $\sim_{\mathrm{arq}}$, so the induced map on the quotient is a continuous open bijection onto the final cylinder topology; it is therefore a homeomorphism. □

The real line is, therefore, a proved output of the evaluation and not a presupposed domain. The history is not reduced to its value.

18.16.4.3 Joint factorization of the Archimedean and exceptional publications of the enriched state

From a single calibrated domain they are distinguished

$$\mathfrak{R} : X_\infty^{\mathrm{cal}} \longrightarrow \mathbb{R}, \qquad \mathfrak{E} : X_\infty^{\mathrm{cal}} \times \mathscr{C}_{\mathrm{exc}} \longrightarrow \mathbf{Exc}.$$

The first contracts compatible cylinders; the second preserves boundary incidence toward the exceptional corridor. Spiral theory is inserted into the first branch, but preserves in its ledger the data required to compare the second. Value is not identified with incidence, nor is a publication made to generate the continuum retrospectively.

18.16.4.4 5 regions of π and multiplicity of genealogies

The microfiber of π contains five regions distinct with multiplicities

$$432 + 4 \cdot 144 = 1008.$$

The same visible value conserves different regional histories. This fact provides the exact precedent of the spiral classification: equality of a published curve does not force equality of leaf, carry, boundary, or memory. The theory does not invent that multiplicity; it transports it to a new type of geometric output.

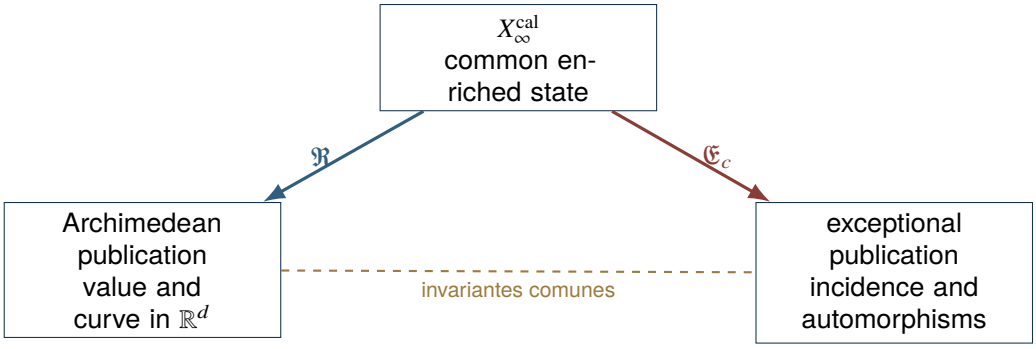


Figure 18.4: The two projections are correlative and subsequent to the same state.

Causal antecedence of the discrete continuum with respect to the radial reader

Thus far, the domain, sheets, regimes, holonomy, enriched state, and publication of the continuum have been constructed. Only now is it legitimate to introduce real coordinates (r, θ) and recognize conventional curves.

18.17 Genealogical theory of spiral correspondences

18.17.1 Affine universal envelope of the APP leaves

18.17.1.1 Construction of the universal radial module and its endomorphic envelope

The operations $u \mapsto u + a$ and $u \mapsto \lambda u$ suggest the affine group of the line. APP, however, contains noninvertible multiplicative sectors and precedes real publication. The appropriate internal target is therefore the monoid of affine endomorphisms of a universal radial module.

Let $\widetilde{X}_{\mathrm{APP}}$ be the set of complete APP states, that is, states that conserve both leaves, residue, quotient, and carry, and let us add an absorbing symbol $\perp$. We define the free module

$$U_{\mathrm{APP}} := \mathbb{Z}^{(\widetilde{X}_{\mathrm{APP}} \sqcup \{\perp\})} / \langle [\perp] \rangle. \tag{18.39}$$

For each enriched transition e, with source x_e and active digits (i_e, j_e), APP produces, without decimal evaluation, the records

$$i_e + j_e = R_e^+ + 9q_e^+, \qquad i_e j_e = R_e^\times + 9q_e^\times.$$

Let $s_e^\Sigma(x_e)$ and $s_e^\Pi(x_e)$ be the complete states obtained by adjoining, respectively, (R_e^+, q_e^+) and $(R_e^\times, q_e^\times)$, while preserving the other sheet in the ledger. The additive lift determines the explicit vector

$$A_e = [s_e^\Sigma(x_e)] - [x_e] \in U_{\mathrm{APP}},$$

and the multiplicative lifting determines the total map $m_e : \widetilde{X}_{\mathrm{APP}} \sqcup \{\perp\} \to \widetilde{X}_{\mathrm{APP}} \sqcup \{\perp\}$, extended by

$$m_e(x) = \begin{cases} s_e^\Pi(x_e), & x = x_e, \\ \perp, & x \neq x_e, \end{cases} \qquad m_e(\perp) = \perp.$$

Its linearization is

$$M_e([x]) = [m_e(x)] \in U_{\mathrm{APP}}.$$

Thus, A_e and M_e are not parameters free: are the two publications linearized of the same transition APP complete.

We define

$$\mathrm{AffEnd}(U_{\mathrm{APP}}) = \mathrm{End}(U_{\mathrm{APP}}) \ltimes U_{\mathrm{APP}}$$

with composition

$$(\Lambda_2, C_2) \circ (\Lambda_1, C_1) = \big(\Lambda_2\Lambda_1, C_2 + \Lambda_2 C_1\big). \tag{18.40}$$

The pair acts by $u \mapsto \Lambda u + C$. The linear part may be noninvertible. The subgroupoid of units is obtained by restricting $\Lambda \in \mathrm{Aut}(U_{\mathrm{APP}})$.

Proposition 18.18 (Universal property)**.** *Every map from the set of complete states to a V-module that vanishes on $\perp$ extends uniquely to a morphism $\chi : U_{\mathrm{APP}} \to V$. If it also intertwines the multiplicative lifts, $\chi M_e = M_e^V \chi$, then it uniquely transports the affine factors h_e and all their prefix holonomies.*

Proof. The first statement is the universal property of the free module quotiented by $[\perp] = 0$. The second follows by applying χ to the semidirect composition: $\chi(C_2 + \Lambda_2 C_1) = \chi(C_2) + \Lambda_2^V \chi(C_1)$. □

18.17.1.2 Affine representation $e \mapsto h_e$ of the generators of the route category

Let $e : x \to y$ be a TPK transition. The tritic operational-phase selector determines whether the additive leaf, the multiplicative leaf, or the threshold acts. It is defined

$$h_e = \begin{cases} (I, A_e), & \text{sheet } \Sigma, \\ (M_e, 0), & \text{sheet } \Pi, \\ (I, 0), & \text{threshold}, \end{cases} \tag{18.41}$$

where A_e and M_e are the complete APP lifts constructed above. Their residues alone are not taken: the quotient and carry remain in the ledger.

Definition 18.19 (Internal radial representation)**.** An internal radial representation is an assignment

$$\rho_{\mathrm{rad}} : \mathscr{P}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathrm{AffEnd}(U_{\mathrm{APP}})$$

which sends each arrow to h_e, the identity to $(I, 0)$ and composition of paths to the product equation (18.40).

The definition does not consult a curve. The factors arise from the sheet and the lift that the state already contains. A subsequent numerical realization may send U_{APP} to $\mathbb{R}$, but that evaluation does not modify the internal representation.

18.17.1.3 Ordered affine products $H_j = h_{e_j} \cdots h_{e_1}$ and preservation of prefixes

For

$$\gamma_N = e_N \cdots e_1,$$

we define

$$H_0 = (I, 0), \qquad H_j = h_{e_j} \cdots h_{e_1} = (\Lambda_j, C_j).$$

Theorem 18.20 (Affine holonomy functorial)**.** *For composable paths γ_1, γ_2,*

$$H_{\gamma_2\gamma_1} = H_{\gamma_2} H_{\gamma_1}.$$

If $H_{\gamma_i} = (\Lambda_i, C_i)$, then

$$\Lambda_{\gamma_2\gamma_1} = \Lambda_2\Lambda_1, \qquad C_{\gamma_2\gamma_1} = C_2 + \Lambda_2 C_1. \tag{18.42}$$

Proof. The successive action on u is

$$u \overset{H_{\gamma_1}}{\longmapsto} \Lambda_1 u + C_1 \overset{H_{\gamma_2}}{\longmapsto} \Lambda_2\Lambda_1 u + C_2 + \Lambda_2 C_1.$$

Uniqueness of the affine decomposition gives equation (18.42). □

For a nine-step block,

$$\Lambda_9 = \Lambda_{e_9} \cdots \Lambda_{e_1}, \tag{18.43}$$

$$C_9 = C_{e_9} + \Lambda_{e_9} C_{e_8} + \Lambda_{e_9}\Lambda_{e_8} C_{e_7} + \cdots + \Lambda_{e_9} \cdots \Lambda_{e_2} C_{e_1}. \tag{18.44}$$

The position of each factor matters. This is the affine form of the memory of order.

18.17.1.4 Sum–product commutator

In the invertible sector and on a one-dimensional realization, let

$$A_a(u) = u + a, \qquad M_\lambda(u) = \lambda u.$$

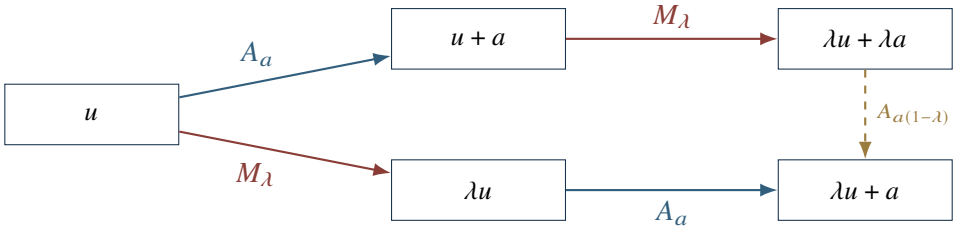
Then

$$A_a M_\lambda A_a^{-1} M_\lambda^{-1} = A_{a(1-\lambda)}. \tag{18.45}$$

The proof is direct:

$$u \mapsto \lambda^{-1}u \mapsto \lambda^{-1}u - a \mapsto u - \lambda a \mapsto u + a(1-\lambda).$$

The identity is asserted only when λ is a unit. In the full monoid, the commutation defect is preserved by the factors and the ledger, not by a commutator requiring nonexistent inverses.



The two orders end at distinct points; the vertical arrow measures exactly the composition defect.

Figure 18.5: The sum-product difference manifests as affine holonomy.

18.17.2 Radial cocycles in the TRIT lift of 2 semicoronas

18.17.2.1 Category of enriched paths by 2 TRIT orientations and definition of the characters p and a

Let $\mathscr{P}_{\mathrm{TPK}}^{2c,\mathrm{enr}}$ be the category of paths whose arrows are triples

$$\widehat{e} = (e, \tau_+(e), \tau_-(e)), \qquad \tau_\pm(e) \in \{-1, 0, +1\},$$

where the oriented pair belongs to the enriched state and the forgetful functor sends $\widehat{e}$ to the TPK transition e. We define on each generator

$$p(\widehat{e}) = \tau_+(e) + \tau_-(e), \qquad a(\widehat{e}) = \tau_+(e) - \tau_-(e). \tag{18.46}$$

For a route $\widehat{\gamma}_N = \widehat{e}_N \cdots \widehat{e}_1$, the accumulated cocycles are

$$P_j = \sum_{k=1}^{j} p(\widehat{e}_k), \qquad A_j = \sum_{k=1}^{j} a(\widehat{e}_k), \qquad P_0 = A_0 = 0. \tag{18.47}$$

Additivity under concatenation proves that (P, A) is a $\mathbb{Z}^2$-valued cocycle of the lifted category. This assertion does not identify the pair by fiat with another previously named cocycle: it constructs the pair from the two orientations actually preserved along each arrow. Subdivision by stationary micro-arrows preserves both sums.

18.17.2.2 Local exhaustive chart of the radial and oriented characters

Table 18.2: Complete local chart of the two TRIT orientations.

τ_+	τ_-	p	a	$r_3(p)$	$c_3(p)$
+1	+1	+2	0	-1	1
+1	0	+1	+1	+1	0
+1	-1	0	+2	0	0
0	+1	+1	-1	+1	0
0	0	0	0	0	0
0	-1	-1	+1	-1	0
-1	+1	0	-2	0	0
-1	0	-1	-1	-1	0
-1	-1	-2	0	+1	-1

The three states with $p = 0$ are distinguished by $a = 2, 0, -2$. Therefore the radial degree is not sufficient to reconstruct the orientation.

18.17.2.3 Unique decomposition $p = r_3(p) + 3c_3(p)$ into balanced residue and carry

For every $p \in \mathbb{Z}$, there exists to unique decomposition

$$p = r_3(p) + 3c_3(p), \qquad r_3(p) \in \{-1, 0, +1\}, \quad c_3(p) \in \mathbb{Z}.$$

In the local block $p \in [-2, 2]$, the last column of table 18.2 gives the carry. In long routes, $c_3(p)$ does not remain restricted to $\{-1, 0, +1\}$. This precision avoids converting a local example into a false global law.

18.17.2.4 Action of $(\tau_+, \tau_-) \mapsto (-\tau_-, -\tau_+)$ over the characters p and a

Local Involution

$$(\tau_+, \tau_-) \longmapsto (-\tau_-, -\tau_+)$$

yields

$$p \longmapsto -p, \qquad a \longmapsto a.$$

The radial character changes orientation, whereas the oriented difference remains. This separation will be visible in the identity $L_{-p}(x^{-1}) = -L_p(x)$.

18.17.3 Power-logarithmic coordinate and sum-product law

18.17.3.1 Definition of L_p on $\mathbb{R}_{>0}$ and domain of the inverse $\exp_p$

For $x > 0$, define

$$L_p(x) = \begin{cases} \dfrac{x^p - 1}{p}, & p \neq 0, \\ \log x, & p = 0. \end{cases} \tag{18.48}$$

Its inverse is

$$\exp_p(u) = \begin{cases} (1 + pu)^{1/p}, & p \neq 0, \quad 1 + pu > 0, \\ \mathrm{e}^u, & p = 0. \end{cases} \tag{18.49}$$

The condition $1 + pu > 0$ is not ornamental: it fixes the positive real branch.

18.17.3.2 Composition law $L_p(xy) = L_p(x) + L_p(y) + pL_p(x)L_p(y)$

In the corresponding domain, let

$$u \boxplus_p v = u + v + puv.$$

Theorem 18.21 (Sum–Product Law)**.** *For $x, y > 0$,*

$$L_p(xy) = L_p(x) \boxplus_p L_p(y). \tag{18.50}$$

Moreover, 0 is the identity of $\boxplus_p$, and

$$\exp_p(u \boxplus_p v) = \exp_p(u) \exp_p(v).$$

Proof. Para $p \neq 0$,

$$1 + pL_p(xy) = (xy)^p = x^p y^p = (1 + pL_p(x))(1 + pL_p(y)).$$

Expanding the last product and dividing by p yields equation (18.50). For $p = 0$ it is the identity $\log(xy) = \log x + \log y$. The equality for $\exp_p$ follows by applying the inverse. □

This law exactly expresses the APP articulation: the product in the radial coordinate is published as a deformed sum in the coordinate L_p. The term puv preserves the interaction that would disappear in an ordinary sum.

18.17.3.3 Bidirectional Inversion

Proposition 18.22 (Inversion Identity)**.** *For $p \in \mathbb{Z}$ and $x > 0$,*

$$L_{-p}(x^{-1}) = -L_p(x). \tag{18.51}$$

Proof. Si $p \neq 0$,

$$L_{-p}(x^{-1}) = \frac{(x^{-1})^{-p} - 1}{-p} = -\frac{x^p - 1}{p}.$$

For $p = 0$, $\log(x^{-1}) = -\log x$. □

The involution simultaneously exchanges expansion/contraction and $p/-p$. It does not eliminate the memory of orientation, which remains in a.

18.17.3.4 Logarithmic limit

Para $x > 0$,

$$\lim_{p \to 0} \frac{x^p - 1}{p} = \log x.$$

Indeed, $x^p = \mathrm{e}^{p \log x} = 1 + p \log x + O(p^2)$. Therefore, the logarithmic branch is not an added exception: it is the continuous limit of the family. In the genealogical theory, however, $p = 0$ continues to preserve a and the ledger; the functional limit does not identify its three local origins of table 18.2.

18.17.4 Power–logarithmic classification of the published curves

18.17.4.1 Uniform translation in the radial coordinate

Suppose, after the publication of the continuum, that

$$L_p(r/r_0) = \beta m, \qquad \theta = \theta_0 + \omega m, \qquad \omega \neq 0.$$

Eliminando m,

$$r_p(\theta) = r_0 \left[1 + p \frac{\beta}{\omega}(\theta - \theta_0)\right]^{1/p}, \qquad p \neq 0, \tag{18.52}$$

and

$$r_0(\theta) = r_0 \exp\left[\frac{\beta}{\omega}(\theta - \theta_0)\right]. \tag{18.53}$$

Theorem 18.23 (Publication of the five canonical classes)**.** *After reoriginating θ and rescaling r, the specializations of equations (18.52) y (18.53) are:*

p	*normalized equation*	*conventional recognition*
2	$r^2 = a^2\theta$	*Fermat spiral*
1	$r = a\theta$	*Archimedean spiral*
0	$r = r_0 e^{b\theta}$	*logarithmic spiral*
-1	$r = a/\theta$	*hyperbolic spiral*
-2	$r^2 = a^2/\theta$	*lituus*

in the corresponding positive real domains.

Proof. For $p = 1$, r is affine in θ, and recentering removes the constant term. For $p = 2$, r^2 is affine. For $p = -1$, r^{-1} is affine; for $p = -2$, r^{-2} is affine. The $p = 0$ branch is equation (18.53). Positive constants are absorbed into a, b without altering the exponent. □

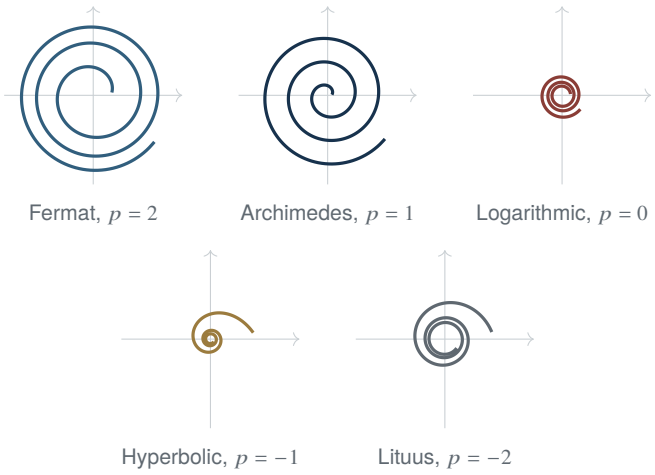


Figure 18.6: Five power–logarithmic family publications on common axes and scales.

18.17.4.2 Classificatory domain of $p \in \{2, 1, 0, -1, -2\}$ and general affine extension

The theorem classifies the family generated by uniform translation in the coordinate L_p. It does not classify all possible plane curves. The complete genealogical taxonomy must include at least

$$(p, a, [\Lambda, C], [\kappa_9], \omega_{\text{ang}}, \mu_{\text{mem}}, \varepsilon_{\text{tw}}).$$

Two routes with the same p may differ in self-scaling, orientation, carry, or boundary and publish distinct curves. Two routes with all visible data equal may still differ in an eliminated ledger coordinate.

18.17.4.3 General affine holonomy

If the coordinate $u = L_p(r/r_0)$ satisfies

$$u_{n+1} = \Lambda u_n + C,$$

the iteration internal exact, for $n \in \mathbb{N}$, is

$$u_n = \Lambda^n u_0 + \sum_{k=0}^{n-1} \Lambda^k C.$$

If $I - \Lambda$ is invertible, may iscribirse

$$u_n = u_* + \Lambda^n (u_0 - u_*), \qquad u_* = (I - \Lambda)^{-1} C.$$

Continuous interpolation is performed only after fixing a positive scalar character $\chi : U_{\mathrm{APP}} \to \mathbb{R}$ such that $\chi\Lambda = \lambda\chi$, with $\lambda > 0$. Writing $u = \chi(u)$, $C = \chi(C)$, if $\lambda \neq 1$, then $u_* = C/(1 - \lambda)$. For $\theta_n = \theta_0 + n\omega$, $\omega \neq 0$, the scalar realization admits

$$r(\theta) = r_0 \exp_p \left[u_* + \lambda^{(\theta - \theta_0)/\omega} (u_0 - u_*) \right]. \tag{18.54}$$

Real powers belong exclusively to this realization; the internal dynamics uses integer powers of Λ. The pair $(p, [\Lambda, C])$ enlarges the classical list: p fixes the radial chart, and the affine conjugacy class fixes the dynamics within it.

Remark 18.24 (Fixed point and electron). The existence of an affine fixed point does not by itself identify that point with the central electron $(5, 5)$. The electron is a prior material result; an identification with a radial fixed point requires a separate realization square.

18.17.5 Radial enriched reader

18.17.5.1 Defecto of naturality of the reader reduced $(p, a, \Lambda, C, m, r, \theta)$

The initially suggested map

$$X^{\mathrm{enr}}_{\mathrm{TPK}} \to (p, a, \Lambda, C, m, r, \theta)$$

mixes causal levels and loses prefixs. The coordinates r, θ are arquimedianas, while (Λ, C) preserves only the final product.

Proposition 18.25 (The terminal pair admits no natural truncation)**.** *In general there is no application that recovers the first factor of an affine word from its final product.*

Proof. In notation (Λ, C),

$$(1, 2)(2, 0) = (2, 2), \qquad (1, 1)(2, 1) = (2, 2).$$

The two final products coincide, but their initial prefixes are $(2, 0)$ and $(2, 1)$. A function of the final product would have to assign it two different truncations, which is impossible. □

18.17.5.2 Enriched radial reader $\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N}$: domain, codomain, and preservation of prefixes

Let $\widehat{\gamma}_N = \widehat{e}_N \cdots \widehat{e}_1$ one route of the category lifted and let $(H_0, \mathrm{Led}_0) = ((I, 0), \mathrm{Led}(x_0))$ its datum initial. We define

$$\boxed{\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N}(\widehat{\gamma}_N) = \Big((H_0, \mathrm{Led}_0); \big(p(\widehat{e}_j), a(\widehat{e}_j), P_j, A_j, h_{e_j}, H_j, \mathrm{Led}_j(\widehat{\gamma}_N) \big)_{j=1}^{N} \Big).} \tag{18.55}$$

The codomain $\mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},N}$ contains compatible sequences of those data, including the underlying edge stored in each entry of the ledger and its source and target maps. The output conserves the initial datum, each factor, each prefix holonomy, the local and accumulated cocycles, and every memory update.

Definition 18.26 (Admissible homogeneous radial sector)**.** Let $\mathcal{D}^{\mathrm{hom}}_{\mathrm{rad},\infty}$ the space of data marked

$$D = (D^{\mathrm{enr}}; r_0, p, u_0, \beta, \theta_0, \omega),$$

where $D^{\mathrm{enr}} \in \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},\infty}$, $r_0 > 0$, $p \in \{-2,-1,0,1,2\}$, $u_0, \beta, \theta_0, \omega \in \mathbb{R}$ and $(\beta,\omega) \neq (0,0)$, talis that

$$p(\widehat{e}_j) = p, \qquad u(m) = u_0 + \beta m, \qquad \theta(m) = \theta_0 + \omega m.$$

The mark is part of the data and is not chosen afterward; consequently, the evaluation is a well-defined function. Its real publication interval is

$$I_D = \begin{cases} \{m \in \mathbb{R} : 1 + p(u_0 + \beta m) > 0\}, & p \neq 0, \\ \mathbb{R}, & p = 0. \end{cases}$$

Histories with variable degree remain in the enriched ledger and are published through an atlas of piecewise charts; they do not determine a single curve of constant degree.

Definition 18.27 (Homogeneous spiral publication)**.** After constructing the continuum and choosing the radial and angular characters compatible, it is defined

$$\mathrm{ev}^{\mathrm{esp}}_{\mathrm{arq}} : \mathcal{D}^{\mathrm{hom}}_{\mathrm{rad},\infty} \longrightarrow \coprod_{D} C^\infty(I_D, \mathbb{R}^2)$$

by

$$D \longmapsto \left[m \longmapsto \left(r_0 \exp_p(u_0 + \beta m)\cos(\theta_0 + \omega m), r_0 \exp_p(u_0 + \beta m)\sin(\theta_0 + \omega m) \right) \right].$$

The internal reader and external evaluation are separate. The first arrow preserves genealogy; the second may forget part of it. The condition $(\beta,\omega) \neq (0,0)$ excludes only the degenerate constant parametrization; on I_D the published curve is regular.

18.17.5.3 Dynamic conservation of carry, boundary, and memory by the radial reader

The projection onto carry, boundary, and memory satisfies

$$\mathrm{pr}_{\mathrm{carry},frontier,memory} \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N} = \mathrm{Led}_{\mathrm{carry},frontier,memory,N}\,.$$

To preserve does not mean to make those coordinates constant. It means that:

$$g(K+9) = g(K),$$

$$q_{\mathrm{mem}}(\Gamma_9 x) = q_{\mathrm{mem}}(x) + 1,$$

$$B_{K+9} = \mathrm{Tra}_{\Gamma_9}(B_K),$$

and the carry is updated by equation (8.15). No update is hidden by the final curve.

18.17.6 Naturalness, equivariance, and inverse limit

18.17.6.1 Naturalness under Truncation

For $M \leq N$, let

$$\pi_{N,M} : \mathrm{Hist}^{\mathrm{enr}}_N(\mathrm{TPK}) \to \mathrm{Hist}^{\mathrm{enr}}_M(\mathrm{TPK})$$

the truncation of histories, and let

$$q_{N,M} : \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},N} \to \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},M}$$

the removal of data with index greater than M.

Theorem 18.28 (Radial Reader Naturalness)**.** *The diagram*

$$\begin{array}{ccc} \mathrm{Hist}_N^{\mathrm{enr}}(\mathrm{TPK}) & \xrightarrow{\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N}} & \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},N} \\ \pi_{N,M}\downarrow & & \downarrow q_{N,M} \\ \mathrm{Hist}_M^{\mathrm{enr}}(\mathrm{TPK}) & \xrightarrow{\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},M}} & \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},M} \end{array}$$

commutes; that is,

$$q_{N,M} \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},N} = \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},M} \circ \pi_{N,M}. \tag{18.56}$$

Proof. Both sides preserve exactly the initial record and the first M arrows, together with their local and cumulative cocycles, affine factors, prefix holonomies, and ledger entries of $\widehat{\gamma}_N$. No reconstruction from the final product is involved: the complete sequence is part of the definition. □

18.17.6.2 Reader of the inverse limit

The compatibility equation (18.56) induces

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad},\infty} : \varprojlim_N \mathrm{Hist}_N^{\mathrm{enr}}(\mathrm{TPK}) \longrightarrow \varprojlim_N \mathcal{D}^{\mathrm{enr}}_{\mathrm{rad},N}. \tag{18.57}$$

Each finite component is obtained by truncation of the complete history. Therefore the reader does not invent an external continuity: it prolongs the finite certificates compatibly.

18.17.6.3 Naturality of the reader under the quadruple refinement sd_4

In the refinement sd_4 of the TPK, three micro-arrows are stationary and the fourth reproduces the observable transition. If

$$\rho_{\mathrm{rad}}(e_1) = \rho_{\mathrm{rad}}(e_2) = \rho_{\mathrm{rad}}(e_3) = I, \qquad \rho_{\mathrm{rad}}(e_4) = h_e,$$

then

$$H_{\mathrm{sd}_4(e)} = I\, I\, I\, h_e = h_e.$$

Naturality is thus certified for this refinement. For a general substitution $e \mapsto \widetilde{e}_k \cdots \widetilde{e}_1$, the exact condition is

$$h_e = h_{\widetilde{e}_k} \cdots h_{\widetilde{e}_1}.$$

This equality, rather than the similarity of the published curves, determines the compatibility of a new refinement.

18.17.6.4 Equivariance with respect to nonadic holonomy

Let $b_9(x)$ be the block of nine transitions that realizes Γ_9 from x, and

$$H_9(x) = H_{b_9(x)} = (\Lambda_9(x), C_9(x)).$$

The action induced on the radial ledger adds that block.

Theorem 18.29 (Cocycle Equivariance)**.** *One has*

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}} \circ \Gamma_9 = \widehat{\Gamma}^{\mathrm{rad}}_9 \circ \mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}. \tag{18.58}$$

In components,

$$P \mapsto P + p(b_9), \qquad A \mapsto A + a(b_9),$$

$$\Lambda \mapsto \Lambda_9(x)\Lambda, \qquad C \mapsto C_9(x) + \Lambda_9(x)C,$$

$$g \mapsto g, \qquad q_{\mathrm{mem}} \mapsto q_{\mathrm{mem}} + 1.$$

Proof. The action of Γ_9 concatenates $b_9(x)$ to the history, where $p(b_9)$ and $a(b_9)$ are the sums of the local characters of its nine lifted arrows. The cocycle law adds the degrees, and the affine law equation (18.40) composes the holonomies. The TPK supplies the phase return and the memory increment. The definition of $\widehat{\Gamma}_9^{\mathrm{rad}}$ reproduces precisely these updates. □

This is not literal commutation of endomorphisms of the same space. The codomains are distinct and the memory changes. The correct term is *equivariance*.

18.17.6.5 Investment in the reversible sector

If $h_{e^\dagger} = h_e^{-1}$, the inversion diagram satisfies

$$\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}(C_{\mathrm{rev}}\gamma) = \mathcal{J}_{\mathrm{rad}}\mathcal{P}^{\mathrm{enr}}_{\mathrm{rad}}(\gamma),$$

where $\mathcal{J}_{\mathrm{rad}}$ reverses the order of factors, replaces each factor by its inverse, and transports the ledger through the TPK involution. In the real output, equation (18.51) exchanges the two orientations.

18.17.7 Classification by the full radial signature and failure of fidelity of the Archimedean evaluation

18.17.7.1 Full radial signature of a history

For a finite history $\widehat{\gamma}_N = \widehat{e}_N \cdots \widehat{e}_1$, define

$$\mathfrak{I}_N(\widehat{\gamma}_N) = \left((x_0, H_0, \mathrm{Led}_0); \big(\widehat{e}_j, p(\widehat{e}_j), a(\widehat{e}_j), P_j, A_j, h_{e_j}, H_j, \mathrm{Led}_j\big)_{j=1}^{N}\right). \tag{18.59}$$

The signature is complete relative to the chosen enriched radial reader: it preserves the initial object, the typed sequence of arrows, the local and accumulated characters, all affine prefixes, and the complete ledger. It is not presented as a complete invariant of all HMT, nor does it replace the coordinates of the enriched state that do not lie in the reader's domain.

Definition 18.30 (Spiral Genealogical Equivalence)**.** Two histories are equivalent if there is a typed isomorphism of their radial data that transports the sequence of equation (18.59) term by term, respects sources, targets, composition, and ledgers, and commutes with all declared truncations.

The inverse limit yields the compatible family $(\mathfrak{I}_N)_{N\geq 0}$. Equality of curves in $\mathbb{R}^2$ is a coarser relation: the Archimedean evaluation factors through genealogical equivalence, but in general does not reflect it.

18.17.7.2 Kinematic classification through the increments (ω, β, μ)

Let ω be the angular increment, β the radial increment in the coordinate L_p, and μ the lifted-memory increment. The minimal visible table is:

Table 18.3: Kinematic classification of publications.

ω	β	μ	Published type	Interpretation
0	$\neq 0$	0	recta radial	scale variation without rotation or memory
$\neq 0$	0	0	circle	intrinsic radial angular closure
$\neq 0$	0	$\neq 0$	cylindrical helix	periodic phase with raised memory
$\neq 0$	$\neq 0$	0	espiral plana	radial variation without visible memory axis
$\neq 0$	$\neq 0$	$\neq 0$	radial helical suspension	turning, self-scaling and memory
0	0	$\neq 0$	fibra axial	memory advance without transverse figure

This table classifies the published kinematics, not the entire genealogy. Two rows with the same three increments may differ in p, carry, boundary, or affine class.

18.17.7.3 3 genealogical classes with a same Archimedean image

Example 18.31 (Circle with null memory)**.** Let $H_j = I$, $\mu = 0$, and $\theta_j = 2\pi j/9$ be given. The output is a circumference, and the ledger does not register axial lift.

Example 18.32 (The same circumference as shadow)**.** Let $H_j = I$, $\mu = 1$ and the same angular phase. En $\mathbb{R}^3$ is obtained the helix equation (8.17); to the aplicar π_{xy}, the output flat coincide with the of the example preceding.

Example 18.33 (Same spiral, different carry)**.** Let there be two histories with the same real characters p, β, ω but with different carry decompositions that radial evaluation maps to the same increment β. Both publish $r_p(\theta)$, while their ledgers differ. The enriched reader separates them; the curve does not.

18.17.7.4 Genealogical Classification Theorem

Theorem 18.34 (Spiral Genealogical Correspondences)**.** *Once the universal radial module, the local representation $e \mapsto h_e$, and the radial cocycles of the TRIT lift are fixed, every compatible TPK history determines:*

1. *one natural sequence of factors and prefix affine holonomies;*
2. *to class genealogical istable under truncamiento;*
3. *an equivariant action of the nonadic holonomy;*
4. *in the reversible sector, one conjugate history of inverse holonomy;*
5. *for each admissible homogeneous radial sector, a regular curve in $\mathbb{R}^2$ and, by conserving the depth, a suspension in $\mathbb{R}^3$.*

A history of variable degree instead determines an ordered atlas of piecewise charts. The application to curves is not faithful: it may identify histories with distinct ledgers.

Proof. Items 1 and 2 are the affine-holonomy and naturality theorems. Item 3 is equation (18.58); item 4 is inversion in the reversible subgroupoid. Item 5 is obtained by restricting the inverse limit to the domain $\mathcal{D}^{\mathrm{hom}}_{\mathrm{rad},\infty}$ and applying its radial and angular characters. Non-faithfulness follows from Figure 18.1 and from the general proposition of the first chapter. □

Hypotheses, domain, and scope of the theorem

The nonadic holonomy, the helix, the Pell screw, and the TPK cocycles are recovered results. The affine envelope, the prefix reader, its naturality, and the publication L_p constitute a new exact formalization in the declared domains. The local chart $p(\widehat{e}) = \tau_+(e)+\tau_-(e)$ and $a(\widehat{e}) = \tau_+(e)-\tau_-(e)$ is exact in the lifted category of 2 semicrowns; its use outside that domain requires exhibiting the functor that supplies both orientations. Publication as a single curve is restricted to the admissible homogeneous sector defined in this chapter.

18.17.7.5 Enriched readers and fiber memory

The difference between history and value admits an operational criterion. At a finite level H_k, let $q_k : H_k \to Z_k$ be a reader and let $M_k : H_k \to \mathcal{M}_k$ be the preserved register. The enriched reader is $\widehat{q}_k = (q_k, M_k)$. Memory distinguishes states in the same reader fibre; its sufficiency is checked on the domain considered. This formulation incorporates into the article itself the complete development of the fibre information used below.

Proposition 18.35 (Recoverability at a finite level)**.** *An inverse of $\widehat{q}_k$ exists on its image if and only if $\widehat{q}_k$ is injective. For a random variable Z taking values in H_k with distribution μ_k, we have*

$$\mathsf{H}(Z) = \mathsf{H}(q_k(Z)) + \mathsf{H}(Z \mid q_k(Z)).$$

If $\widehat{q}_k$ is injective on the support of Z, then

$$\mathsf{H}(Z \mid q_k(Z), M_k(Z)) = 0.$$

Here $\mathsf{H}(Z) = -\sum_z \Pr(Z = z) \log \Pr(Z = z)$, with $0 \log 0 = 0$, is finite entropy in nats; conditional entropy is the average entropy of the conditional distributions.

Proof. An inverse recovers a unique antecedent, which requires injectivity; conversely, injectivity allows each published pair to be assigned its unique antecedent. Since $q_k(Z)$ is a deterministic function of Z, grouping the sum defining $\mathsf{H}(Z)$ by fibres of q_k gives the chain rule. If the pair $(q_k(Z), M_k(Z))$ distinguishes the support, each corresponding conditional distribution is concentrated on a single state and its entropy is zero. □

Not publishing a coordinate and erasing the register that allows it to be recovered are distinct operations. This result does not identify entropy with the cardinality of the continuum or introduce a thermal interpretation: its domain, reader and distribution are those just fixed.

18.17.7.6 Equivariance of the measure under tree symmetries

Proposition 18.36 (Joint transport of the tree and its measure)**.** *Let $g = (g_k)_{k \geq 0}$ be a family of bijections $g_k : H_k \to H_k$ that commutes with truncations, fixes the root and bijectively transports the admissible emissions, preserving their multiplicities. Then*

$$d(g_k \zeta) = d(\zeta), \qquad (g_k)_* \mu_k = \mu_k, \qquad (g_\infty)_* \mu = \mu.$$

More generally, if μ_ζ is the law of continuations of a history $\zeta \in H_k$, we have

$$(g_\infty)_* \mu_\zeta = \mu_{g_k \zeta}.$$

Proof. The emission bijection preserves their number with multiplicities. The uniform seed distribution is also invariant. Each path and its image therefore receive the same product of local weights $1/d(\zeta)$. Equality of measures follows at each level and on each cylinder. Coherence with truncations defines g_∞, and uniqueness of the measure determined by cylinders proves equality in the limit. The same argument, starting at ζ, proves the assertion about continuations. □

This gives naturality of the tree and the measure: a coherent change of representation transports the weights and does not require choosing them anew. Preservation of emissions and multiplicities is an essential hypothesis of the proposition, not a datum added after the construction.

Chapter 19

Cardinal closure of the HMT analytic continuum: bidirectional reading of the Topological Phase Kernel and comparison with the continuum hypothesis

This chapter does not propose an alternative generator of the continuum. Its causal premise is the unique block already constructed

$$\begin{aligned}\text{APP} &\longrightarrow \text{TRIT} \longrightarrow \text{TPK} \longrightarrow \text{unique enriched state}\\ &\longrightarrow \text{common state, tree and genealogical measure}\\ &\longrightarrow \text{correlative intrinsic operations}\\ &\longrightarrow \text{natural assembly, terminality and limit} \longrightarrow C_{\text{cont}}^{\text{disc}}.\end{aligned}$$

The five consubstantial constructions developed in the preceding chapter emerged correlatively over that same state before the real publication, without purporting to exhaust all its properties. What follows is a subsequent presentation of the quotient, its temporal memory, and its power; it does not retrospectively select any of those constructions.

19.1 The complete TRIT cell and the bidirectional temporal extension

The temporal sign does not separate from the state it orients. The local cell of departure is

$$c = (i, j; R^{+}, Q^{+}, R^{\times}, Q^{\times}; \tau), \qquad \tau \in \{-1, 0, +1\}, \tag{19.1}$$

where

$$R^{+} = \mathrm{dr}_9(i + j), \qquad Q^{+} = \frac{i + j - R^{+}}{9},$$
$$R^{\times} = \mathrm{dr}_9(ij), \qquad Q^{\times} = \frac{ij - R^{\times}}{9}.$$

The residues constitute the visible reading and the quotients preserve the memory necessary for inverting the transport. The temporal trit acts on this integer cell:

$$\begin{aligned}+1 &\longmapsto \text{return, retained memory and past,}\\ 0 &\longmapsto \text{evaluation threshold and present,}\\ -1 &\longmapsto \text{bidirectional opening and future.}\end{aligned} \tag{19.2}$$

Thus, two appearances of the same sign are not the same state if their quotients, sheet, carry, or genealogical record differ.

Let X be a compact chart of the surviving APP–TRIT–TPK limit and let $F : X \to X$ be its complete, continuous and surjective update. The surjectivity of the truncations and the surviving prolongation allow us to form the natural extension

$$X_F^{\leftrightarrow} := \left\{(x_k)_{k\in\mathbb{Z}} \in X^{\mathbb{Z}} : F(x_k) = x_{k+1} \text{ for every } k \in \mathbb{Z}\right\}. \tag{19.3}$$

The displacement

$$\sigma((x_k)_{k\in\mathbb{Z}}) = (x_{k+1})_{k\in\mathbb{Z}}$$

it no longer loses the inverse direction.

Theorem 19.1 (Natural extension two-way of the enriched state)**.** *The space $X_F^{\leftrightarrow}$ is compact and*

$$\sigma : X_F^{\leftrightarrow} \longrightarrow X_F^{\leftrightarrow}$$

is a homeomorphism, with

$$\sigma^{-1}((x_k)) = (x_{k-1}).$$

Therefore, outward and return maps are inverse continuous morphisms on the enriched object. The apparent discontinuity arises only if the coordinates that make the history invertible are first forgotten.

Proof. The product $X^{\mathbb{Z}}$ is compact. The condition $F(x_k) = x_{k+1}$ is closed becau F is continuous; by tanto $X_F^{\leftrightarrow}$ is compact. The displazamiento and the displazamiento inver are continuous in the topology product and priservan the equations of compatibility. Their compositions are the identity. □

The material inversion of the route resides in the groupoid completion of the transport. Let $C_M = -\,\mathrm{rev}$ be memory conjugation. Its contravariant action is expressed by the reversal square

$$F(x_k) = x_{k+1} \quad \Longrightarrow \quad F(C_M x_{k+1}) = C_M x_k.$$

On the natural extension it is defined

$$(\Theta u)_k := C_M(x_{-k}), \qquad u = (x_k)_{k\in\mathbb{Z}}. \tag{19.4}$$

The reversion identity guarantees that Θu again satisfies the compatibility equations. Therefore,

$$\Theta^2 = I, \qquad \Theta\sigma\Theta = \sigma^{-1}. \tag{19.5}$$

This identity does not identify the ternary group with the binary sign: the TRIT orients return, threshold, and opening, whereas the involution C_M implements the conjugation of the two temporal orientations.

For $n \geq 0$, let us denote by $S_n^{\leftrightarrow}$ the finite set of admissible temporal windows $(x_{-n}, \ldots, x_0, \ldots, x_n)$, with each state further truncated to genealogical depth n. The simultaneous restrictions of time and depth form an inverse system and

$$\mathcal{O}_{\leftrightarrow}^{\mathrm{HMT}} := \varprojlim_n S_n^{\leftrightarrow} \cong X_F^{\leftrightarrow}. \tag{19.6}$$

Each history has temporal support of type $\omega^* + 1 + \omega$, but also carries the cell (19.1), the route and the genealogical register. The map sending an orbit to all its centered windows is a homeomorphism and intertwines σ with the genealogical succession. This is the genealogical biordinal, not the von Neumann ordinal obtained after forgetting the labels.

The preceding object is a compact chart of the fractional part. The global object publishing the entire line is the countable atlas

$$\mathcal{O}_{\mathbb{R},\leftrightarrow}^{\mathrm{HMT}} := \mathbb{Z} \times \mathcal{O}_{\leftrightarrow}^{\mathrm{HMT}}. \tag{19.7}$$

The coordinate $\mathbb{Z}$ merely translates the chart; it does not erase the bidirectional genealogical ledger.

19.2 Stable Mode of the Unitary Calendar under Modular Memory Update

The temporal structure does not rest solely on a metaphor of return. On $\mathcal{H}_{\mathrm{clk}} = \mathbb{C}^{108}$, let $\zeta = \exp(2\pi i/108)$,

$$U_{\mathrm{clk}}|j\rangle = |j+1\rangle, \qquad |\widetilde{k}\rangle = \frac{1}{\sqrt{108}} \sum_{j=0}^{107} \zeta^{jk}|j\rangle,$$

and let us define

$$H_{\mathrm{clk}} = \hbar_{\mathrm{int}}\omega_0 \sum_{k=0}^{107} k\, |\widetilde{k}\rangle\langle\widetilde{k}|, \qquad \omega_0 = \frac{2\pi}{108 t_0}. \tag{19.8}$$

Then

$$U_{\mathrm{step}} = \exp\left(-\frac{i}{\hbar_{\mathrm{int}}} H_{\mathrm{clk}} t_0\right) = U_{\mathrm{clk}}, \qquad U_{\mathrm{step}}^{108} = I, \tag{19.9}$$

and, for $Z_{\mathrm{clk}}|j\rangle = \zeta^j |j\rangle$,

$$|\psi_n\rangle := U_{\mathrm{step}}^n |j_0\rangle,$$
$$\langle Z_{\mathrm{clk}}\rangle_n := \langle \psi_n | Z_{\mathrm{clk}} | \psi_n \rangle = \zeta^{j_0+n} \tag{19.10}$$

has primitive period 108.

In the modular boundary sector $\mathcal{H}_A = (\mathbb{C}^3)^{\otimes 36}$, let $\rho_A > 0$ be precisely the faithful state characterized by the following decomposition, and let Δ_4^{mod} be the declared modular jump. The generator preserving the provenance of the two boundary channels is

$$K_{\mathrm{HHM}}^{(A)} = -\log \rho_A = \kappa_A I + \Delta_4^{\mathrm{mod}}(90N_{90} + 120N_{120}). \tag{19.11}$$

If

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120},$$

then

$$N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N. \tag{19.12}$$

Thus, the total observable and the modular Hamiltonian jointly reconstruct the two provenance memories. On the other hand, the cylindrical Perron dynamics preserves the mode

$$V_n = \varphi^n, \qquad M_n = \varphi^{-2n} = V_n^{-2}, \qquad M_n = \left(\frac{a_n}{a_0}\right)^{-6} \qquad (D = 3). \tag{19.13}$$

Theorem 19.2 (Exact finite composition of the CT108 calendar and modular memory 90/120)**.** *The operators* (19.8) *and* (19.11) *are self-adjoint on their respective spaces. After an energy scale $E_\partial > 0$ is fixed, the product operator*

$$H_{\mathrm{tw}} := H_{\mathrm{clk}} \otimes I + I \otimes E_\partial (K_{\mathrm{HHM}}^{(A)} - \kappa_A I) \tag{19.14}$$

is self-adjoint, and its two summands strongly commute. For states whose clock marginal is $|j_0\rangle\langle j_0|$, the observable $Z_{\mathrm{clk}} \otimes I$ preserves its primitive response of period 108*. Simultaneously, $K_{\mathrm{HHM}}^{(A)}$, N_{90}, and N_{120} are conserved observables of the modular factor. The pair (N, D), with $N = N_{90} + N_{120}$, reconstructs (N_{90}, N_{120}) exactly by means of* (19.12)*.*

Proof. The first operator admits a finite real spectral decomposition, and the second is the logarithm of a faithful state; both are self-adjoint. They act on distinct tensor factors and, therefore, their spectral resolutions commute. The exponential of their sum factorizes. The primitivity of the response follows from the primitivity of ζ; channel reconstruction is the inverse of the matrix $\left(\begin{smallmatrix} 1 & 1 \\ 90 & 120 \end{smallmatrix}\right)$, de determinante 30. □

Corollary 19.3 (Stable mode of the cylindrical memory)**.** *In the Perron sector of closed paths, $M_n = \varphi^{-2n} = V_n^{-2}$ is the exact and stable spectral mode given by* (19.13)*.*

The CT108 calendar, the modular memory and the Perron mode are three readeres tipados of the same genealogical antecedent; are not the same operator. together with the natural extension and the espejo, form the internal temporal record

$$\mathcal{T}_{\mathrm{HMT}} := \left(X_F^{\leftrightarrow}, \sigma, \Theta; H_{\mathrm{clk}}, K_{\mathrm{HHM}}^{(A)}; M_\bullet\right).$$

This is the exact content of the HMT temporal closure: two inverse continuous directions, a primitive clock, recoverable memory, and a stable mode. The complete TPK state is not replaced by the cursor 108. An additional identification of the three readers with a single perturbatively stable physical dynamics

would require a common intertwiner; that identification is not used in the genealogical closure or in the reconstruction of the continuum.

19.3 Analytic realizations of HMT histories via the Archimedean and bidirectional charts

Let H be a Polish space of histories: a closed inverse limit of finite levels or a countable atlas of such limits. The topology is generated by prefix cylinders. This choice preserves the genealogy and permits the descriptive operations that are admitted to be typed exactly.

Definition 19.4 (Analytic HMT Publication)**.** An analytic publication is a set $A \subseteq \mathbb{R}$ for which there exists a Borel set

$$C \subseteq H \times \mathbb{N}^{\mathbb{N}}$$

and to Borel reader $F : H \to \mathbb{R}$ such that

$$A = \{F(x) : \exists z \in \mathbb{N}^{\mathbb{N}},\ (x, z) \in C\}.$$

The witness z may encode to route, to prolongation, to memory or to certification countable. The readers continuous are cases particular.

This class contains cylinders, Borel predicates on histories, countable operations, images under continuous readers, and publications asserting the existence of a real witness. By definition, it does not contain the full power set $\mathcal{P}(\mathbb{R})$: uncountable unions, arbitrary selectors, nonsmooth quotients, and recursion of length ω_1 require additional data.

Theorem 19.5 (Perfect Duality of HMT Publications)**.** *Every analytical HMT publication $A \subseteq \mathbb{R}$ satisfies exactly one of the two alternatives:*

$$|A| \leq \aleph_0 \qquad or \qquad |A| = 2^{\aleph_0}.$$

In the second alternative there exists a continuous injection.

$$j : 2^{\mathbb{N}} \hookrightarrow A.$$

therefore, every uncountable analytic publication contains one copia of the Cantor space and, in particular, a perfect subset.

Proof. The existential projection of a Borel subset of a product of Polish spaces is analytic, and a Borel image of a standard Borel space is again analytic. Therefore, A is an analytic subset of $\mathbb{R}$.

To make the uncountable alternative explicit, represent A as the projection of a closed set

$$D \subseteq \mathbb{R} \times \mathbb{N}^{\mathbb{N}}.$$

For each finite word $s \in \mathbb{N}^{<\mathbb{N}}$, let

$$A_s := \{x : \exists z \supseteq s,\ (x, z) \in D\}.$$

If $A_s \cap K$ is uncountable for a certain closed interval K, the set of its points that are not condensation points is countable, because $\mathbb{R}$ has a countable basis. Two distinct condensation points and two disjoint closed intervals within K are chosen, and for each interval a strict prolongation of s whose projection remains uncountable is chosen. The two prolongations need not be incompatible: separation of the branches is guaranteed by the intervals. The identity

$$A_s = \bigcup_{n \in \mathbb{N}} A_{s^\frown n}$$

guarantees that, in each chosen neighborhood, some extension preserves the non countability.

Repitiendo the procedure are obtained, for each $u \in 2^{<\mathbb{N}}$, a interval K_u and a prefix s_u such that

$$K_{u0} \cap K_{u1} = \varnothing, \qquad K_{ui} \subseteq K_u, \qquad \operatorname{diam} K_u \leq 2^{-|u|},$$

and s_{ui} strictly prolongs to s_u. For $\beta \in 2^{\mathbb{N}}$, the intervals $K_{\beta|n}$ determine a unique point $j(\beta)$, and the prefixes $s_{\beta|n}$ determine a witness z_β. The closure of D implies

$$(j(\beta), z_\beta) \in D,$$

so that $j(\beta) \in A$. The disjoint sibling intervals prove injectivity, and diameter control proves the continuity of j.

Thus,

$$2^{\aleph_0} \leq |A| \leq |\mathbb{R}| = 2^{\aleph_0},$$

which closes the second alternative. If the process does not start from an uncountable set, the first is obtained. □

Corollary 19.6 (Analytic HMT Continuum Hypothesis)**.** *Let*

$$\aleph_{1,\mathrm{HMT}}^{\mathrm{an}} := \min \{|A| : A \text{ is an uncountable analytic HMT publication}\}. \tag{19.15}$$

This symbol denotes the initial cardinal relative to the class of HMT analytic publications; it does not denote the extensional ordinal ω_1. Then

$$\boxed{\aleph_{1,\mathrm{HMT}}^{\mathrm{an}} = 2^{\aleph_0} = |\mathbb{R}| = \left|\mathcal{O}_{\mathbb{R},\leftrightarrow}^{\mathrm{HMT}}/{\sim_{\mathfrak{R}}}\right|.} \tag{19.16}$$

That is, there is no intermediate cardinal between the countable and the continuum within the analytic publications produced by HMT readers.

Proof. The set of finite depth windows

$$\mathcal{O}_{<\omega}^{\mathrm{HMT}} := \bigcup_{n<\omega} S_n^{\leftrightarrow}$$

is countable, since it is a countable union of finite sets. The complete layer surjects onto $\mathbb{R}$ by (18.36) and is contained in a countable product of finite alphabets; it therefore has cardinality $2^{\aleph_0}$. The theorem 19.5 excludes any strictly intermediate analytic size. □

Corollary 19.7 (Dichotomy of the fibers)**.** *Let $F : H \to Y$ to reader Borel between spaces Polish and let $y \in Y$. If the domain of histories admitted is analytic, the fiber*

$$\{x : F(x) = y\}$$

is countable or has cardinality $2^{\aleph_0}$.

Proof. The fiber is the intersection of the analytic domain with the Borel preimage of the singleton $\{y\}$; it is therefore analytic. We apply the theorem 19.5. □

19.4 Comparison between the genealogical cardinal closure and its extensional ordinal reduction

Let $\mathrm{WO} \subseteq 2^{\mathbb{N}}$ be the set of real codes of countable well-orders, allowing the field to be a subset of $\mathbb{N}$. The map

$$\mathrm{ot} : \mathrm{WO} \longrightarrow \omega_1$$

assigns to each code its order type and is surjective.

Proposition 19.8 (Ordinal injection into the line)**.** *In ZFC there exists an injection*

$$\iota : \omega_1 \hookrightarrow \mathbb{R}.$$

A binary subsystem of the history space HMT can be raised.

Proof. By choice, the surjection ot admits a section $s : \omega_1 \to \mathrm{WO}$. Equivalently, a well-order of WO is fixed and the first code in each fiber is taken. The Cantor map

$$c(a) := \sum_{n \geq 0} \frac{2a(n)}{3^{n+1}}$$

is injective from $2^{\mathbb{N}}$ into $[0, 1]$. Therefore

$$\iota := c \circ s$$

is the injection sought. The embedding of the binary tape in the cinta ternary and the Hensel inverse Ψ^{-1} proporcionan the lift to the genealogical space. □

The choice of s is not natural with respect to refinements and is not produced by a finite prefix. This proposition shows that the arrow $\omega_1 \hookrightarrow \mathbb{R}$ is not the content of the classical hypothesis of the continuum. The inverse direction belongs to the bare extensional ordinal. In HMT, by contrast, the natural arrow already constructed is the homeomorphism (18.36), whose domain preserves the two temporal directions.

19.5 Cardinal identity of the HMT analytic continuum: $\aleph_{1,\mathrm{HMT}}^{\mathrm{an}} = 2^{\aleph_0}$ and comparison with the classical continuum hypothesis

Let

$$Q_{\mathrm{HMT}} := X_{\mathrm{raw}}/\!\sim_P .$$

By the theorem 18.9, $Q_{\mathrm{HMT}} \cong \mathbb{R}$.

Theorem 19.9 (Ordinal equivalences of the HMT quotient)**.** *In ZFC the following are equivalent:*

1. $2^{\aleph_0} = \aleph_1$*;*
2. *there exists a injection* $j : Q_{\mathrm{HMT}} \hookrightarrow \omega_1$*;*
3. *there exists to map* $\rho : X_{\mathrm{raw}} \to \omega_1$ *such that*

$$\rho(x) = \rho(y) \quad \Longleftrightarrow \quad P(x) = P(y);$$

4. Q_{HMT} *admits an uncountable well-order whose proper initial segments are all countable.*

Proof. If the first assertion holds, a bijection $Q_{\mathrm{HMT}} \cong \mathbb{R} \cong \omega_1$ provides the second and transports the order of ω_1, which yields the fourth. The second yields the third by taking $\rho = j \circ [P]$, where $[P]$ sends each history to its evaluation class. Conversely, the biconditional condition in the third causes ρ to factor through an injection $Q_{\mathrm{HMT}} \hookrightarrow \omega_1$.

The second assertion implies $2^{\aleph_0} \leq \aleph_1$. The proposition 19.8 gives $\aleph_1 \leq 2^{\aleph_0}$; Cantor–Bernstein produces the equality. Finally, a well-order such as that of the fourth assertion cannot contain an element in position ω_1, because its initial segment would be uncountable. Its order type is therefore at most ω_1, and, since the domain is uncountable, it is exactly ω_1. This recovers the second assertion. □

The theorem localizes the target without introducing it as a premise. A function ρ with that property would not be a small supplement to the analytic dichotomy: it would be a complete formulation of the continuum hypothesis itself.

19.6 Loss of ancestral memory under reduction to the ordinal codomain

The forgetful functor that removes trit, mirror, quotients, route, and memory sends each biordinal to a bare ordered support. The following results control that forgetful functor; they do not deny the continuous HMT morphism already constructed between the two-way quotient and $\mathbb{R}$.

Theorem 19.10 (Limit of the readers toward ω_1 with the order topology)**.** *There does not exist a continuous application*

$$\rho : X_{\text{raw}} \longrightarrow \omega_1$$

that exactly separates the fibers of P. In particular, after applying the forgetful functor, no cylindrical reader toward the bare topological ordinal can demonstrate the second condition of theorem 19.9.

Proof. Every chart $\{m\} \times \mathbb{Z}_3^6$ is compact. The continuous image of a compact space in ω_1, endowed with the order topology, is compact and therefore bounded by some countable ordinal. Its image is countable. The union over $m \in \mathbb{Z}$ of those images is a countable union of countable sets and remains countable. A function separating all fibers of P would instead have an image of cardinality $|\mathbb{R}|$, a contradiction. □

Theorem 19.11 (Absence of good analytic extensional order)**.** *There is no to good order analytic, and by tanto nor Borel, of* $\mathbb{R}$*.*

Proof. Suppose that $\prec \subseteq \mathbb{R}^2$ is analytic and defines a strict total linear order. Then

$$(x, y) \notin \prec \quad \Longleftrightarrow \quad x = y \text{ or } y \prec x.$$

The complement of $\prec$ is also analytic; by Suslin separation, $\prec$ is Borel. Every well-founded Borel relation on a Polish space has rank bounded by a countable ordinal. In a linear well-order, distinct elements have distinct ranks, so the domain would be countable. This contradicts the uncountability of $\mathbb{R}$. □

The two controls are independent of whether the classical continuum hypothesis is true or false. If a set-theoretic bijection $\omega_1 \leftrightarrow \mathbb{R}$ exists, it cannot be continuous for the order topology of ω_1 or analytic as a well-order. This does not make the HMT morphism discontinuous: it shows that bare ω_1 is another codomain and that forgetting the temporal direction destroys precisely the structure that ensured continuity.

19.7 Ordinal closure of the HMT genealogical codomain

The preceding checks describe the functor that forgets genealogy. HMT positively constructs its ordinal closure while preserving it. Let $h \in 2^{\mathbb{N}}$ be the generated code of the language, finite tables, transitions and APP–TRIT–TPK readers. The canonical genealogical codomain is

$$M_h := L[h].$$

This envelope preserves the generator as a parameter, admits the canonical well-order of the constructible hierarchy and is the codomain produced by the construction of the continuum in (2).

Theorem 19.12 (Classical continuum hypothesis in the HMT genealogical codomain)**.** *The model* $M_h = L[h]$ *satisfies*

$$M_h \models 2^{\aleph_0} = \aleph_1.$$

There exists in M_h *a definable bijection*

$$b_h : \omega_1^{M_h} \xrightarrow{\sim} \mathbb{R}^{M_h}.$$

Since M_h *is the generated codomain,* $\mathbb{R}^{M_h}$ *is the entirety of the line published by the HMT construction. Let* P_h *be the HMT evaluation of the histories belonging to* M_h*. Then*

$$\rho_h := b_h^{-1} \circ P_h$$

satisfies

$$\rho_h(x) = \rho_h(y) \quad \Longleftrightarrow \quad P_h(x) = P_h(y).$$

Proof. Every real number in $L[h]$ appears at some level $L_\alpha[h]$ with $\alpha < \omega_1^{L[h]}$. For each ordinal $\alpha < \omega_1^{L[h]}$, the level $L_\alpha[h]$ is countable within the model. Therefore,

$$|\mathbb{R}^{L[h]}| \leq \aleph_1^{L[h]}.$$

The model line is uncountable, so minimality of $\aleph_1$ gives the reverse inequality and hence equality. The canonical well-ordering of $L[h]$ selects, among all the bijections whose existence has just been proved, a first definable bijection b_h.

The evaluation P_h is definable from h, so that its value belongs to $\mathbb{R}^{M_h}$. The formula of ρ_h is well typed. Since b_h is bijective, two histories receive the same ordinal if and only if they publish the same real. □

Remark 19.13 (Identification of the generated codomain). theorem 19.12 effectively constructs the ordinal arrow in the genealogically generated universe. The equality $\mathbb{R} = \mathbb{R}^{L[h]}$ is not postulated: within the theorem's domain it expresses that $L[h]$ is precisely the codomain produced by the HMT continuum, whose Archimedean coverage is proved in proposition 18.5 y theorem 18.9. Consequently, ρ_h reaches all the reals of the generated line and the bijection b_h proves the classical continuum hypothesis with the ordinary cardinals of M_h. A forcing extension belongs to another domain after forgetting or replacing the genealogical selector h; it describes the independence of the bare language of ZFC and does not alter the conclusion of the HMT system.

19.8 Compatibility among HMT cardinal closure, the set-theoretic formulation of the continuum, and bidirectional genealogical memory

The preceding results articulate five strata of the same closure:

1. the genealogical quotient reconstructs $\mathbb{R}$ and has cardinality $2^{\aleph_0}$;
2. the natural extension two-way and the genealogical biordinal are homeomorphic, with outgoing and return continuous;
3. the clock Hamiltonian, the modular Hamiltonian, and the stable mode preserve calendar, provenance, and memory without reducing the TPK to the visible cursor;
4. every analytic HMT publication is countable or has the cardinal of the continuum, so that $\aleph_{1,\mathrm{HMT}}^{\mathrm{an}} = 2^{\aleph_0}$;
5. the constructible codomain $L[h]$ has a complete ordinal enumeration of all generated reals and satisfies the classical continuum hypothesis with its ordinary cardinals.

The first three construct the HMT object and its dynamics; the fourth closes the cardinality in the domain of publications; the fifth supplies its ordinal coordinate without changing the object. The identity $\aleph_{1,\mathrm{HMT}}^{\mathrm{an}} = 2^{\aleph_0}$, together with the bijection b_h, constitutes the HMT proof of the extensional statement about the generated line. The selector h preserves the genealogy that the bare language of ZFC omits.

Proposition 19.14 (Falsifiers)**.** *Each assertion has an independent negative control:*

1. *a real without preimage under P would falsify the reconstruction of the quotient;*
2. *an intermediate state not recoverable from the complete returns would falsify the factorization* (17.11)*;*
3. *the loss of the primitive period, of the reconstruction* $90/120$ *or of the mode* φ^{-2n} *would falsify one of the three readers of the typed HMT temporal record;*
4. *to publication analytic not countable without copia of Cantor would falsify the dichotomy perfect;*
5. *a Borel well-order of an uncountable Polish space would refute the analytic no-go theorem;*
6. *one unbounded continuous image of one compact chart in* ω_1 *falsaria the topological not-go;*
7. *the existence, in the generated codomain* M_h*, of a real without an ordinal preimage under* b_h*, or of a branch published outside* $L[h]$*, would falsify the genealogical identification and the classical closure of the continuum. An extension obtained after changing the selector h does not belong to the fixed domain and does not constitute that falsifier.*

The structural conclusion is precise. HMT constructs a bidirectional temporal object, publishes it Archimedeanly as $\mathbb{R}$, preserves exceptional incidence in parallel, and proves that its first uncountable analytic layer has cardinality exactly $2^{\aleph_0}$. The bijection

$$\mathcal{O}_{\mathbb{R},\leftrightarrow}^{\mathrm{HMT}}/{\sim_{\mathfrak{R}}} \xrightarrow{\overline{\mathfrak{R}}} \mathbb{R}$$

is natural and continuous. The classical ordinal $\omega_1^{M_h}$ is the well-order coordinate of all reals in the generated codomain. The functor that forgets h, time, mirror and memory explains the subsequent independence in bare ZFC; it does not modify the constructed bijection or the classical closure proved in M_h.

19.9 Bidirectional extension groupoid and operator algebra

Let $X_F^{\leftrightarrow}$ be the natural extension of the enriched state and σ its shift homeomorphism. Define the transformation groupoid

$$\mathcal{G}_{\mathrm{TPK}} := X_F^{\leftrightarrow} \rtimes_{\sigma} \mathbb{Z}, \tag{19.17}$$

with

$$s(x,n) = x, \quad r(x,n) = \sigma^n x, \quad (\sigma^n x, m)(x,n) = (x, m+n), \quad (x,n)^{-1} = (\sigma^n x, -n).$$

Theorem 19.15 (Groupoidal Completion of Bidirectional Transport)**.** *The groupoid $\mathcal{G}_{\mathrm{TPK}}$ is locally compact, Hausdorff, second countable, etale, and amenable. For the invariant and atomless projective measure μ_{HMT}, if the shift is ergodic and essentially free,*

$$\mathcal{M}_{\mathrm{TPK}} := L^{\infty}(X_F^{\leftrightarrow}, \mu_{\mathrm{HMT}}) \rtimes_{\sigma} \mathbb{Z}$$

is the hyperfinite factor of type II_1.

Proof. The action of a countable discrete group by homeomorphisms on a compact metrizable space produces an etale, locally compact, Hausdorff, and second-countable groupoid. Amenability of $\mathbb{Z}$ implies amenability of the groupoid. The projective measure is shift-invariant. Ergodicity and essential freeness make the crossed product a factor; nonatomicity excludes the matrix type-I case. The trace induced by μ_{HMT} is finite and faithful, and amenability yields hyperfiniteness. Therefore, the factor is of type II_1. □

The type III modular classification belongs to a distinct quasi-invariant measure, with a declared Radon–Nikodym cocycle. It is not deduced from the mere presence of KMS dynamics and does not reopen the prior groupoidal completion.

19.10 Proof of $2^{\aleph_0} = \aleph_1$ in the HMT continuum

This section brings together, in a contiguous proof, extension, double projection, and arbitrary depth; it then constructs the semantic closure, the uniform lift, the genealogical machinery, and the cardinal closure. The set-theoretic hierarchy is identified only at the end of the construction and cannot be read as its causal origin. The causal dependence is:

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow X_{\infty}^{\mathrm{enr}} \longrightarrow C_{\mathrm{cont}}^{\mathrm{disc}} \longrightarrow m_{\infty} \longrightarrow \mathfrak{G}_{\mathrm{HMT}}(h, m_{\infty}). \tag{32}$$

First, the state, its extensions, the continuum, and the genealogical ledger are constructed. Then **that produced genealogy** is extended to all its hereditary objects by an explicit semantic rule. The subsequent identification with a known set-theoretic hierarchy selects neither the seeds, the operators, the genealogical ledger, the line, nor its projections. It does, however, permit the exact logical-cardinal strength of the adopted semantic rule to be assessed with complete transparency.

19.10.1 Extension of states and transfinite semantic extension

Let

$$\Sigma_{\mathrm{HMT}} = \left(\dot{R}_{\mathrm{APP}}, \dot{R}_{\mathrm{TRIT}}, \dot{R}_{\mathrm{TPK}}, \dot{R}_U, \dot{R}_{\Gamma_9}, \dot{R}_{\mathrm{Ext}}, \dot{R}_{\rho}, \dot{R}_{\pi}, \dot{R}_{\varphi}, \dot{R}_e, \dot{R}_{\alpha}, \dot{R}_{\mathrm{ar}}, \dot{R}_{\mathrm{exc}}\right) \tag{33}$$

the countable **relational** signature whose effective code is h. Each $\dot{R}_S$ is the graph of the operator S on the codes where it is defined; it is not assumed that an external function is total within each level. The graphs $\dot{R}_{\pi}, \dot{R}_{\varphi}, \dot{R}_e, \dot{R}_{\alpha}$ are the output readers constructed by coinductive generation and dodecaphase closure; they do not receive the conventional values of the constants as arguments. Their presence in

Σ_{HMT} ensures that closure preserves the complete state: it simultaneously integrates the routes publishing value and the incidence prolonged toward the exceptional realization.

At each horizon, the state code records the APP–TRIT–TPK coordinates, the route, sheet, carry, boundary and memory; in its publication stages it also records P_N, Φ_N, E_N, A_N, where A_N is the prefix of α_{HMT} produced by the same state. These coordinates do not select the branch from outside: they are part of the history being encoded. Given a primitive-recursive numbering of the finite coordinates of a state, every inverse history $x_\infty = (x_N)_{N\geq 1} \in X_\infty^{\mathrm{enr}}$ determines the code

$$\mathrm{code}(x_\infty) := \{\langle N, j, c\rangle : (x_N)_j \text{ has code } c\} \subseteq \omega.$$

The coherence equations $\rho_{N+1,N}(x_{N+1}) = x_N$ make it possible to decode the history uniquely from that real. We write m_∞ for the code of the realized history and $m_\infty(n)$ for its characteristic function under the fixed numbering. The operator code h and this complete ledger are combined, by means of a primitive-recursive pairing function, into the real

$$u_{h,m} := \{\langle 0, \langle n, h(n)\rangle\rangle : n < \omega\} \cup \{\langle 1, \langle n, m_\infty(n)\rangle\rangle : n < \omega\}. \tag{33a}$$

The two primitive projections recover h and m_∞ from $u_{h,m}$.

The first extension is the metric and operator extension of the finite states. For $N \geq 1$, let $\widehat{\mathcal{X}}_{6N}^{\mathrm{enr,raw}}$ be the set of raw enriched states of length $6N$, and define the surviving subsystem set-theoretically by

$$\begin{aligned} X_N &:= \widehat{\mathcal{X}}_{6N}^{\mathrm{enr,surv}} \\ &:= \Big\{ x \in \widehat{\mathcal{X}}_{6N}^{\mathrm{enr,raw}} : \\ &\qquad \forall M > N\ \exists z \in \widehat{\mathcal{X}}_{6M}^{\mathrm{enr,raw}} \text{ such that} \\ &\qquad \mathrm{tr}_{6M,6N}(z) = x \ \wedge\ z \text{ satisfies every intermediate TPK transition} \Big\}. \end{aligned}$$

and set

$$\rho_{N+1,N} := \mathrm{tr}_{6N+6,6N} \restriction X_{N+1},$$

and

$$\mathrm{Ext}_N(x) := \{y \in X_{N+1} : (x, y) \in \mathrm{Ext}_{6N+6,6N}\}.$$

The root level is included without any implicit exception:

$$X_0 := \{*\}, \qquad \rho_{1,0} : X_1 \to X_0 \text{ is constant}, \qquad \mathrm{Ext}_0(*) := X_1.$$

The superscript surv denotes the pruned tree of states possessing compatible TPK descendants at every finite horizon. The TPK extension law established in the preceding sections proves that the emitted seeds belong to this tree; finite branching and Kőnig's lemma turn compatibility at every horizon into an infinite branch. In particular,

$$\forall N \geq 0\ \forall x \in X_N \quad \varnothing \neq \mathrm{Ext}_N(x) \subseteq \rho_{N+1,N}^{-1}(x). \tag{34}$$

By the same finitely branching tree lemma, every surviving seed has a compatible extension

$$x_\infty = (x_N)_{N\geq 1} \in X_\infty^{\mathrm{enr}} := \varprojlim_N (X_N, \rho_{N+1,N}). \tag{35}$$

The second extension acts **afterward** on the complete code of that realized history. It is not inferred from the mere existence of the finite operator Ext_N: at the set-theoretic scale, it formalizes the HMT

principle that only those objects possessing a genealogical derivation from the state and its rules belong to the full domain. The transfinite semantic extension is:

$$\begin{aligned}
\mathfrak{G}_0(h, m_\infty) &:= \mathrm{TC}\big(\{\omega, u_{h,m}, h, m_\infty\}\big),\\
\mathfrak{G}_{\beta+1}(h, m_\infty) &:= \mathrm{Def}_{\Sigma_{\mathrm{HMT}}}\big(\mathfrak{G}_\beta(h, m_\infty)\big),\\
\mathfrak{G}_\lambda(h, m_\infty) &:= \bigcup_{\beta<\lambda} \mathfrak{G}_\beta(h, m_\infty) \quad (\lambda \text{ limit}),\\
\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) &:= \bigcup_{\beta\in\mathrm{Ord}} \mathfrak{G}_\beta(h, m_\infty).
\end{aligned} \tag{36}$$

The Continuum Hypothesis and a target bijection are not introduced among the conditions defining the successor operator; the operator is given prospectively by

$$\mathrm{Def}_{\Sigma_{\mathrm{HMT}}}(M) := M \cup \Big\{\{x \in M : \langle M, \in, (\dot R_S \cap M^{k_S})_{S\in\Sigma_{\mathrm{HMT}}}\rangle \models \varphi(x, \bar p)\} : \ulcorner\varphi\urcorner \in \omega,\ \bar p \in M^{<\omega}\Big\}. \tag{37}$$

That is: it simultaneously publishes all subsets definable by a finite formula of the HMT relational language and parameters that the genealogy has already produced. It does not consult a target real value, a conventional constant, a target cardinal or an external model. Formula (37) defines transfinite closure on the previously constructed seeds, operators, enriched state, register and double projection.

Lemma 19.16 (Joint coding of the HMT program and the realized ledger)**.** *The pair formed by the operator code h and the ledger m_∞ is encoded by a single real $u_{h,m} \subseteq \omega$, and every formula of Σ_{HMT} is uniformly translated into a formula of the language $\{\in, u_{h,m}\}$.*

Proof. Both h and m_∞ are sequences of natural numbers: h encodes the signature, finite tables and operator programs; m_∞ encodes a single realized history, not the complete space of histories. Formula (33a) and its two decoders prove the first assertion. Each symbol of (33) denotes its **graph relation encoded in** h, never the external graph of all its possible evaluations. APP, TRIT, U_t, Γ_9, the restrictions ρ and the finite extensions have primitive-recursive graphs on integer codes and therefore Δ_0 formulas absolute between transitive levels. The two publications are expressed as graph relations by the formulas

$$\begin{aligned}
\dot R_{\mathrm{ar}}(x, y) &\iff \forall k \in \omega\ \exists N\ \forall n \geq N \quad |\mu_n(x) - y| < 2^{-k},\\
\dot R_{\mathrm{exc}}(x, c, z) &\iff \forall N \in \omega \quad z \restriction N = E_N(x \restriction N, c \restriction N),
\end{aligned} \tag{37c$_0$}$$

where μ_n and E_N are the rational/finite functions whose codes occur in h. Every atomic formula containing an HMT symbol is inductively replaced by its graph formula with parameter $u_{h,m}$. Connectives and quantifiers are preserved. This induction on syntactic complexity produces a translation $\varphi \mapsto \varphi^*$ such that, for every transitive level M of (36) containing the parameters,

$$\langle M, \in, (\dot R_S \cap M^{k_S})_S\rangle \models \varphi(\bar a) \quad\iff\quad M \models \varphi^*(\bar a; u_{h,m}). \tag{37c}$$

Thus, (37) cannot consult an oracle, a target decimal table, or an uncoded relation that introduces uncountably many objects in a single step. □

HMT semantics is now defined **independently of identifying it with** $\mathfrak{G}$. Let $\mathcal{T}_0^{\mathrm{HMT}}$ be the set of canonical names of the elements of $\mathfrak{G}_0(h, m_\infty) = \mathrm{TC}(\{\omega, u_{h,m}, h, m_\infty\})$. In particular, the initial level contains the realized ledger m_∞, not every history in X_∞^{enr} as primitive parameters. The admissible terms are the well-founded trees obtained by

$$\mathcal{T}^{\mathrm{HMT}}_{\beta+1} := \mathcal{T}^{\mathrm{HMT}}_{\beta} \cup \{\langle \beta, \ulcorner \varphi \urcorner, t_0, \dots, t_{k-1}\rangle : t_i \in \mathcal{T}^{\mathrm{HMT}}_{\beta}\},$$
$$\mathcal{T}^{\mathrm{HMT}}_{\lambda} := \bigcup_{\beta<\lambda} \mathcal{T}^{\mathrm{HMT}}_{\beta}, \qquad \mathcal{T}^{\mathrm{HMT}} := \bigcup_{\beta\in\mathrm{Ord}} \mathcal{T}^{\mathrm{HMT}}_{\beta}. \tag{37a}$$

The value of a successor term is the subset of the preceding level defined by φ in the induced relational structure, with the values of $t_0, \dots, t_{k-1}$ as parameters. Before any set-theoretic comparison, define

$$\mathrm{Ob}^{\mathrm{HMT}}_{\mathrm{sem}}(h, m_\infty) := \{[\![t]\!] : t \in \mathcal{T}^{\mathrm{HMT}}\}. \tag{37b}$$

This is the rule of **generative exhaustiveness** adopted by HMT: every object of the full domain must possess one of those derivation trees and every admissible tree publishes an object. It is not a consequence of finite branching. The continuum hypothesis is not introduced into this rule; it is obtained through the proof developed in the article. Neither an enumeration of the reals nor a target bijection is introduced as data.

Theorem 19.17 (Equivalence between term semantics and the genealogical hierarchy)**.** *The evaluation of the preceding terms satisfies*

$$\mathrm{Ob}^{\mathrm{HMT}}_{\mathrm{sem}}(h, m_\infty) = \mathfrak{G}_{\mathrm{HMT}}(h, m_\infty). \tag{37d}$$

Proof. By transfinite induction. At the initial level, the two classes coincide. If every value of a term in $\mathcal{T}^{\mathrm{HMT}}_{\beta}$ belongs to $\mathfrak{G}_\beta$, the semantics of a successor term is one of the subsets in (37). Conversely, every subset in (37) is given by a formula code and a finite tuple of parameters; by the induction hypothesis those parameters possess terms, and (37a) forms the term that denotes it. At a limit, both constructions take the same union. □

The state encoder is compatible with truncations and sends every TPK extension to a successor term. Let $\mathcal{T}^{\mathrm{st}}_N \subset \mathcal{T}^{\mathrm{HMT}}$ be the subclass of terms encoding complete states of depth N, and let $\tau_{N+1,N} : \mathcal{T}^{\mathrm{st}}_{N+1} \to \mathcal{T}^{\mathrm{st}}_N$ delete the last block together with the corresponding truncation of the genealogical ledger, carry, and memory. If $J_N : X_N \to \mathcal{T}^{\mathrm{st}}_N$ is the complete encoder, compatibility with Ext_N proves the well-typed identity

$$\forall x \in X_N \ \forall y \in \mathrm{Ext}_N(x) \qquad \tau_{N+1,N}\big(J_{N+1}(y)\big) = J_N(x). \tag{37e$_0$}$$

Define within the semantics

$$\mathrm{Succ}^{\mathrm{TPK}}_{N+1}(J_N(x)) := \{t \in \mathcal{T}^{\mathrm{st}}_{N+1} : \exists y \in X_{N+1}\ (y \in \mathrm{Ext}_N(x) \ \wedge \ t = J_{N+1}(y))\}.$$

Choose β such that $\mathfrak{G}_\beta$ contains x, X_N, X_{N+1}, the finite graphs of $\mathrm{Ext}_N, J_N, J_{N+1}$, and their codes in h. Then the primitive-recursive formula for the graph of Ext_N gives

$$J_{N+1}[\mathrm{Ext}_N(x)] = \mathrm{Succ}^{\mathrm{TPK}}_{N+1}(J_N(x)), \qquad J_{N+1}[\mathrm{Ext}_N(x)] \in \mathfrak{G}_{\beta+1}, \tag{37e}$$

and both sides are formed by the graph formula of the same TPK extension. Equations (37e$_0$)–(37e) are the explicit semantic link: the subclass of successor terms is exactly the image of the admissible extensions, and its truncation commutes. The complete fiber of ρ is not identified with Ext_N, nor is Def identified with TPK merely by nomenclature.

Lemma 19.18 (Transitivity, axioms, and well-ordering of the genealogical model)**.** $\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty)$ *is a transitive class, contains all ordinals, satisfies Zermelo–Fraenkel set theory (ZF), and possesses a definable global well-order; it therefore satisfies Choice and all axioms used in the subsequent cardinal comparison.*

Proof. Abbreviate $B = \mathfrak{G}_0$ and $u = u_{h,m}$. Induction on (36) proves simultaneously that each level is transitive and that $\mathfrak{G}_\alpha \in \mathfrak{G}_{\alpha+1}$; if all ordinals smaller than α are present, their set is definable at the corresponding level and publishes α. The union therefore contains all ordinals. Extensionality and Foundation are inherited from the ambient universe; Empty Set and Infinity are in B. Choosing a level containing the parameters, the formulas defining $\{a, b\}$, $\bigcup a$ and the subsets by Separation publish them at a successor.

For Collection–Replacement, let F be a functional relation definable in $\mathfrak{G}$ on the set a. The reflection scheme relative to the definable hierarchy $(\mathfrak{G}_\xi, \in, u_{h,m})_{\xi\in\mathrm{Ord}}$, applied in the ambient metatheory to the finite list of formulas defining F, produces a level $\mathfrak{G}_\theta$ containing a and the parameters and correct for those formulas. The ranks of the witnesses in $F[a]$ are then bounded by θ; Separation over $\mathfrak{G}_\theta$ forms the image in $\mathfrak{G}_{\theta+1}$. For Power Set, the internal set to be constructed is not presupposed. Given $a \in \mathfrak{G}_\gamma$, consider in the ambient metatheory the already existing set $\mathcal{P}^V(a)$. For every $b \in \mathcal{P}^V(a) \cap \mathfrak{G}$, let $r(b)$ be its first genealogical stage. Since $\mathfrak{G}$ is a definable class, Separation in the ambient metatheory first forms the set $\mathcal{P}^V(a) \cap \mathfrak{G}$. Replacement **in the ambient metatheory**, applied to that set, bounds the ordinals $r(b)$ by some θ. Consequently,

$$\mathcal{P}^{\mathfrak{G}}(a) = \{b \in \mathfrak{G}_\theta : b \subseteq a\},$$

and the right-hand side is published by Separation in $\mathfrak{G}_{\theta+1}$. It does not introduce into $\mathfrak{G}$ the subsets external to the semantics (37b). This is the noncircular argument for bounding by ranks.

Finally, each object is assigned its first level of birth and its least **derivation name**: a well-founded, finitely branching derivation tree (and, by (37a), finite for each individual name), labeled by a level ordinal, a formula code, and the tuple of names of its parameters. These names are ordered by transfinite recursion: first by the ordinal label, then by the formula code, and then lexicographically by the already ordered parameter names. The least name of each value defines a class relation $<_{\mathfrak{G}}$ that compares all objects. It is a definable global well-order and, by taking the least element of every nonempty set, proves Choice. □

19.10.2 TPK lift of the ternary fiber and complete cylinder partition

The fibre of $729 = 3^6$ refinement subcylinders does not come from the transfer quotient $\mathcal{K}_{\mathrm{ph}}$. That operator is a subsequent reduced-memory publication and cannot generate histories. Coverage is constructed directly in the system $(H_k, \rho_k, \mathrm{Ext}_k)$ through the three prolongations of one turn of the nonadic holonomy.

19.10.2.1 Hensel inversion in the arithmetic tower and realization by histories

Before lifting the branches to enriched histories, it is useful to recover the finite argument that determines the capacity of the arithmetic tower. The complete proof of the matrix's unfiltered transducer is incorporated; its domain is distinguished from the surviving tree.

Proposition 19.19 (Conjugacy of the unfiltered Hensel tower)**.** *Let p be prime, $d \geq 1$ and $A \in \mathrm{GL}_d(\mathbb{Z})$. For row vectors, taking residue representatives in $\{0, \dots, p-1\}^d$, define*

$$x_t A = u_t + p x_{t+1}, \qquad u_t = x_t A \bmod p.$$

The map

$$\Psi_T : (\mathbb{Z}/p^T\mathbb{Z})^d \longrightarrow (\mathbb{F}_p^d)^T, \qquad x_0 \longmapsto (u_0, \dots, u_{T-1})$$

is bijective, with inverse

$$x_0 \equiv \sum_{t=0}^{T-1} p^t u_t A^{-(t+1)} \pmod{p^T}.$$

The bijections commute with the reductions and give a homeomorphism $\Psi : \mathbb{Z}_p^d \to (\mathbb{F}_p^d)^{\mathbb{N}}$, where $\mathbb{Z}_p := \varprojlim_T \mathbb{Z}/p^T\mathbb{Z}$. The update $x_t \mapsto x_{t+1}$ corresponds to deleting the first block.

Proof. The integer inverse of A exists because its determinant is ± 1. Iterating $x_t = (u_t + p x_{t+1})A^{-1}$ gives

$$x_0 = \sum_{t=0}^{T-1} p^t u_t A^{-(t+1)} + p^T x_T A^{-T}.$$

Modulo p^T, a word determines a unique initial class. Given an arbitrary word, fixing $x_T = 0$ and reconstructing backward produces a class that emits it, which proves surjectivity. The same formula proves compatibility under truncation. Passing to the inverse limit gives the homeomorphism and the relation to the tape shift. □

For $p = 3$ and $d = 6$, the block alphabet has $3^6 = 729$ elements. This arithmetic capacity is not identified by definition with the realizability of each block after each surviving prefix. The link to the edges Ext is precisely the task of lemma 19.21. This retains the two operations distinguished by the matrix: representation in the raw tower and realization under APP–TRIT–TPK compatibilities.

19.10.2.2 Edge-by-edge realization of the three nonadic extensions

This subsection specifies the autonomous model generated by the TPK extension relation entering the cardinal proof. The existence of an edge is not inferred from a coincidence of types: its initial and final states, APP relation, fiber transport, and unary update of the ledger are constructed. The construction uses exclusively the two APP sheets, the TRIT selector, and the TPK composition Sel–Tra–Upd.

Complete cells and three balanced reductions. In the chart $D_9 = \{1, \dots, 9\}$, we will always retain the complete APP cell

$$a_{p,q} := (p, q; R^{\Sigma}_{p,q}, q^{\Sigma}_{p,q}, R^{\Pi}_{p,q}, q^{\Pi}_{p,q}),$$

with

$$p + q = R^{\Sigma}_{p,q} + 9q^{\Sigma}_{p,q}, \qquad pq = R^{\Pi}_{p,q} + 9q^{\Pi}_{p,q}.$$

The active sheet is recorded in a separate coordinate; $a_{p,q}$ is not split into a purported additive cell and a separate multiplicative cell. For $r \in D_9$, let

$$a(r) := \begin{cases} a_{1,9}, & r = 1, \\ a_{1,r-1}, & 2 \le r \le 9, \end{cases} \qquad \tau(r) := M_{\mathrm{ph}}(r), \qquad m(r) := \tau(r) \in \{-1, 0, +1\}. \tag{19.18}$$

The additive residue of $a(r)$ supplies an APP representative of phase here; this does not make Σ the universally active sheet. The dynamic selector activates Σ for $r \in \{1, 4, 7\}$, activates Π for $r \in \{2, 5, 8\}$, and preserves both sheets without moving the cursor for $r \in \{3, 6, 9\}$. In all three cases, $R^{\Sigma}, q^{\Sigma}, R^{\Pi}, q^{\Pi}$ are transported jointly. We have

$$(m(1), \dots, m(9)) = (1, -1, 0, 1, -1, 0, 1, -1, 0).$$

The three pairs ordered by the nonadic base are

$$\mathfrak{p}_{+1} := (1, 4), \qquad \mathfrak{p}_{-1} := (2, 5), \qquad \mathfrak{p}_0 := (3, 6). \tag{19.19}$$

These pairs are the normalized section taking the first two occurrences of each TRIT type under the shift $r \mapsto r + 3$; the third phase block $7, 8, 9$ retains the turn-closure control. Both members belong to the same fiber of M_{ph}. Without introducing a target coefficient, the balanced reduction from the TRIT chapter gives

ε	$m(\mathfrak{p}_\varepsilon^{(1)}) + m(\mathfrak{p}_\varepsilon^{(2)})$	$r_3(2\varepsilon)$	$\chi(\varepsilon,\varepsilon)$
$+1$	$1+1=(-1)+3\cdot 1$	-1	$+1$
0	$0+0=0+3\cdot 0$	0	0
-1	$(-1)+(-1)=1+3\cdot(-1)$	$+1$	-1

(19.20)

Therefore,

$$\chi(\varepsilon,\varepsilon)=\frac{2\varepsilon-r_3(2\varepsilon)}{3}=\varepsilon. \tag{19.21}$$

The branch sign is thus the output of the balanced cocycle applied to two TRIT emissions produced by APP. Each pair supplies one of the three carry outputs. For clarity, we subsequently index the pair by $\varepsilon(\mathfrak{p}) := \chi(m(\mathfrak{p}^{(1)}), m(\mathfrak{p}^{(2)}))$; the symbol ε does not supply a free carry to $\mathrm{Upd}^{\mathrm{cal}}$.

The phase architecture, balanced lift, and memory transport are realized here through twenty-seven local incidences and their extension graphs. The normalized section fixes representatives of the fibers of M_{ph}; the covering to be proved uses the existence of these representatives and remains invariant when they are replaced by another compatible section.

Typed data of the nine edges. Let $K_{\mathrm{Carr}} := \langle \kappa_{\mathrm{Carr}} \rangle_{\mathrm{Ab}}$ be the carry module. The actions are typed by

$$H_{\mathrm{Carr}} : \mathscr{P}_{\mathrm{TPK}}^{\mathrm{op}} \longrightarrow \mathrm{End}(K_{\mathrm{Carr}}), \qquad Y_{\mathrm{Carr}} : \mathscr{P}_{\mathrm{TPK}} \longrightarrow \mathrm{End}(K_{\mathrm{Carr}}).$$

In this generated model, take the trivial actions $H_{\mathrm{Carr}}(e) = Y_{\mathrm{Carr}}(e) = \mathrm{id}_{K_{\mathrm{Carr}}}$: the active sheet and the route are retained as coordinates of the ledger itself and do not act on the free carry summand. Also let $(\mathsf{M}_d, \jmath_{d',d})$ be the graded direct system of memory. To avoid confusing two representatives identified by the colimit, the state also retains the degree as a coordinate, and the labeled carrier

$$\widetilde{\mathsf{M}} := \bigsqcup_{d\geq 1} \big(\{d\} \times \mathsf{M}_d\big), \qquad \mathrm{gr}_{\mathsf{M}}(d,\mu) = d.$$

Publication in the limit memory is given by

$$\mathsf{M} := \varinjlim_d \mathsf{M}_d, \qquad \jmath_d : \mathsf{M}_d \longrightarrow \mathsf{M},$$
$$u := \jmath_d(u_d), \quad \iota_{\mathsf{M}} : \mathbb{Z} \longrightarrow \mathsf{M}, \qquad n \longmapsto nu.$$

Here $\jmath_d$ is the canonical colimit map and the u_d form a compatible family. Its free component permits the reader $\deg_u(nu) = n$. The configuration, phase, memory, carry, route and survival projections will be typed on the calibrated carrier constructed recursively below; no ambient space will be imported for them. For each constructed edge e, the calibrated component $\mathrm{Upd}_e^{\mathrm{cal}} := \mathsf{Mem}_e^{\mathrm{cal}}$ will denote the third map in the factorization; its law is fixed field by field below and is not assumed as the restriction of an ambient relation.

Fix the initial depth $k_0 = 1$, a complete configuration $q_\star \in Q_{\mathrm{obs}}$ of phase one, and

$$q_{n,r} := F_{\mathrm{obs}}^{9n+r-1}(q_\star), \qquad q_{n,10} := q_{n+1,1}.$$

Because the observable calendar is periodic, its value $q_{n,r}$ does not by itself distinguish occurrences separated by twelve turns. The calibrated model therefore uses the labeled lift

$$\widetilde{q}_{n,r} := (q_{n,r}, n, r), \qquad \widetilde{q}_{n,10} := \widetilde{q}_{n+1,1}, \qquad \pi_{\mathrm{obs}}(\widetilde{q}_{n,r}) = q_{n,r}.$$

The lifted dynamics $\widetilde{F}_{\mathrm{obs}}(\widetilde{q}_{n,r}) = \widetilde{q}_{n,r+1}$ projects to F_{obs}; the label does not alter the physical phase, but makes its levels of occurrence distinct. The copy of the cell at each level is labeled by

$$a_{n,r} := (n, r; a(r)), \qquad (n,r)^{+} := \begin{cases} (n, r+1), & 1 \le r < 9, \\ (n+1, 1), & r = 9. \end{cases}$$

The label only prevents two occurrences of the same cell from being identified; the two Euclidean divisions and their four coordinates are those of $a(r)$. For turn $n \ge 0$ and phase $r \in D_9$, the symbol

$$e_{\varepsilon,n,r} : \widetilde{q}_{n,r} \longrightarrow \widetilde{q}_{n,r+1}, \qquad r^{+} := 1 + (r \bmod 9),$$

occupies level $d_{n,r} := k_n + r - 1$, where $k_n := k_0 + 9n$. Its local ledger contains the complete cell $a(r)$, the active sheet determined by $M_{\mathrm{ph}}(r)$, the type $\tau(r)$, the membership mark in $\mathfrak{p}_\varepsilon$, and, upon reaching the second member of that pair, the certified identity (19.20). We define its operators solely from that ledger:

$$\mathsf{C}_{\mathsf{M}}(e_{\varepsilon,n,r}) = J_{d_{n,r}+1, d_{n,r}}, \qquad \kappa_{\mathsf{M}}(e_{\varepsilon,n,r}) = \mathbf{1}_{\{r=9\}} u_{d_{n,r}+1}, \tag{19.22}$$

$$\mathrm{Carr}(e_{\varepsilon,n,r}) = d_{\varepsilon,r}\, \kappa_{\mathrm{Carr}}, \qquad d_{\varepsilon,r} := \mathbf{1}_{\{r=\mathfrak{p}_\varepsilon^{(2)}\}} \chi\Big(m(\mathfrak{p}_\varepsilon^{(1)}), m(\mathfrak{p}_\varepsilon^{(2)})\Big). \tag{19.23}$$

For identities and every admissible composition, also define

$$\mathsf{C}_{\mathsf{M}}(\mathrm{id}_{\widetilde{q}}; d) := \mathrm{id}_{\mathsf{M}_d}, \qquad \kappa_{\mathsf{M}}(\mathrm{id}_{\widetilde{q}}; d) := 0, \tag{19.24}$$

$$\mathsf{C}_{\mathsf{M}}(e_t \cdots e_1) := \mathsf{C}_{\mathsf{M}}(e_t) \circ \cdots \circ \mathsf{C}_{\mathsf{M}}(e_1), \qquad \kappa_{\mathsf{M}}(e_2 e_1) := \mathsf{C}_{\mathsf{M}}(e_2)\big(\kappa_{\mathsf{M}}(e_1)\big) + \kappa_{\mathsf{M}}(e_2). \tag{19.25}$$

The identity carries degree d because the same observable configuration may recur at different depths. Iterated, the final equality defines $\kappa_{\mathsf{M}}(e_t \cdots e_1)$ for every length and is the cocycle law of the direct system; the inclusions satisfy $J_{d+2,d+1} J_{d+1,d} = J_{d+2,d}$. In addition, set $s(e_{\varepsilon,n,r}) = \top$. The following twenty-seven entries certify the coordinates distinguishing the three extensions; the universal transport fields are specified immediately afterward. The symbols I and II designate, respectively, the first retained emission and the second emission performing the reduction; a dash denotes a zero carry increment, not the absence of an edge.

r	$M_{\mathrm{ph}}(r)$	$\mathfrak{p}_{+1}$		$\mathfrak{p}_0$		$\mathfrak{p}_{-1}$		Δ mem
		mark	$d_{+1,r}$	mark	$d_{0,r}$	mark	$d_{-1,r}$	
1	+1	I	0	–	0	–	0	0
2	−1	–	0	–	0	I	0	0
3	0	–	0	I	0	–	0	0
4	+1	II	+1	–	0	–	0	0
5	−1	–	0	–	0	II	−1	0
6	0	–	0	II	0	–	0	0
7	+1	–	0	–	0	–	0	0
8	−1	–	0	–	0	–	0	0
9	0	–	0	–	0	–	0	u

Thus, $d_{\varepsilon,r}$ is computed from two outputs of the selector and is distinct from the cell quotients q^{Σ}, q^{Π}. The ledger also preserves the marked pair and the balanced residue; in particular, the zero branch is not confused with an absence of event.

The carry composition law used by the TPK category is

$$\mathrm{Carr}(\mathrm{id}_{\widetilde{q}}) = 0, \qquad \mathrm{Carr}(e_2 e_1) = H_{\mathrm{Carr}}(e_1)\big(\mathrm{Carr}(e_2)\big) + Y_{\mathrm{Carr}}(e_2)\big(\mathrm{Carr}(e_1)\big). \tag{19.26}$$

On identities and paths, they are extended functorially:

$$\begin{aligned} H_{\mathrm{Carr}}(\mathrm{id}) &= Y_{\mathrm{Carr}}(\mathrm{id}) = \mathrm{id}, \\ H_{\mathrm{Carr}}(e_t \cdots e_1) &= H_{\mathrm{Carr}}(e_1) \circ \cdots \circ H_{\mathrm{Carr}}(e_t), \\ Y_{\mathrm{Carr}}(e_t \cdots e_1) &= Y_{\mathrm{Carr}}(e_t) \circ \cdots \circ Y_{\mathrm{Carr}}(e_1). \end{aligned}$$

In this model all these actions remain the identity, but their typing makes explicit which endomorphism acts on each summand of (19.26). On calibrated edges, $H_{\mathrm{Carr}} = Y_{\mathrm{Carr}} = \mathrm{id}$, so composition sums the increments already produced. Equation (19.26), rather than an identification between orientation and quotient, governs the accumulated register.

Independent construction of the transition tuples. A fiber state is written, in the order of its relevant fields, as

$$x = (a; q; \tau, o, h; b_{\mathrm{ref}}; R^{\Sigma}, q^{\Sigma}, R^{\Pi}, q^{\Pi}; c; \mathrm{Sig}; C, \partial C; p_{\mathrm{APP}}, p_{\widehat{\mathbb{T}}}; \lambda; \mathrm{gr}_{\mathsf{M}}; \mathrm{mem}; s; \mathrm{Led}).$$

The update notation $x[f \leftarrow v]$ changes only the indicated field. For $h \in \{(\Sigma,\Pi), (\Pi,\Sigma)\}$, define

$$h_r(h) = \begin{cases} (\Sigma,\Pi), & r \in \{1,4,7\}, \\ (\Pi,\Sigma), & r \in \{2,5,8\}, \\ h, & r \in \{3,6,9\}. \end{cases}$$

The complete sheet-and-arithmetic coordinate is abbreviated as

$$\widehat{h}(x) := \big(h(x), R^{\Sigma}(x), q^{\Sigma}(x), R^{\Pi}(x), q^{\Pi}(x)\big).$$

Let $\widehat{\mathcal{H}}^{\mathrm{cal}}_{\widetilde{q}_{n,r}}$ be the set of quintuples

$$\big(h, R^{\Sigma}_{a_{n,r}}, q^{\Sigma}_{a_{n,r}}, R^{\Pi}_{a_{n,r}}, q^{\Pi}_{a_{n,r}}\big), \qquad h \in \{(\Sigma,\Pi), (\Pi,\Sigma)\},$$

whose four arithmetic data are the two Euclidean divisions of the labeled APP cell $a_{n,r}$. This direct definition does not presuppose a state in a carrier not yet constructed. Let $\mathsf{Hist}^{\mathrm{cal}}_{\widetilde{q}}$ be the set of admissible finite paths in the graph of labeled edges ending at $\widetilde{q}$, including the identity, and let $\mathsf{B}^{\mathrm{cal}}_{\widetilde{q}}$ be the set of their ordered endpoint sequences. Define

$$\mathsf{S}^{\mathrm{cal}}_{\widetilde{q}} := \widehat{\mathcal{H}}^{\mathrm{cal}}_{\widetilde{q}} \times \{o_{\rightarrow}, o_{\circ}, o_{\leftarrow}\} \times K_{\mathrm{Carr}} \times \mathsf{Hist}^{\mathrm{cal}}_{\widetilde{q}} \times \mathsf{B}^{\mathrm{cal}}_{\widetilde{q}} \times \mathsf{M}.$$

The calibrated signature is not postulated: it is the typed assembly map

$$\mathrm{Sig}^{\mathrm{cal}}_{\widetilde{q}} : \widehat{\mathcal{H}}^{\mathrm{cal}}_{\widetilde{q}} \times \{o_{\rightarrow}, o_{\circ}, o_{\leftarrow}\} \times K_{\mathrm{Carr}} \times \mathsf{Hist}^{\mathrm{cal}}_{\widetilde{q}} \times \mathsf{B}^{\mathrm{cal}}_{\widetilde{q}} \times \mathsf{M} \longrightarrow \mathsf{S}^{\mathrm{cal}}_{\widetilde{q}},$$

$$(\widehat{h}, o, c, \lambda, \partial C, \mu) \longmapsto (\widehat{h}, o, c, \lambda, \partial C, \mu).$$

Likewise, $\pi_{\mathcal{F}}$ denotes the projection that removes only the first two coordinates $(a; q)$ of the state tuple; it preserves $\tau, o, h, b_{\mathrm{ref}}$, the four Euclidean data, carry, signature, cylinder, boundary, prefixes, route, memory degree, memory, survival, and ledger. The corresponding orientation is fixed by $o(+1) = o_{\rightarrow}$, $o(0) = o_{\circ}$, and $o(-1) = o_{\leftarrow}$. The calibrated APP fiber over $\widetilde{q}_{n,r}$ contains the already defined labeled copy $a_{n,r}$. The initial state is fixed without free coordinates:

$$\widehat{h}_{\star} := \big((\Sigma,\Pi), R^{\Sigma}_{1,9}, q^{\Sigma}_{1,9}, R^{\Pi}_{1,9}, q^{\Pi}_{1,9}\big).$$

$$\begin{aligned} x_{\star} := \big(&a_{0,1}; \widetilde{q}_{0,1}; +1, o_{\rightarrow}, (\Sigma,\Pi); \bot; R^{\Sigma}_{1,9}, q^{\Sigma}_{1,9}, R^{\Pi}_{1,9}, q^{\Pi}_{1,9}; 0; \\ &\mathrm{Sig}^{\mathrm{cal}}_{\widetilde{q}_{0,1}}(\widehat{h}_{\star}, o_{\rightarrow}, 0, \mathrm{id}_{\widetilde{q}_{0,1}}, \varnothing, \jmath_{k_0}(0_{\mathsf{M}_{k_0}})); \varnothing, \varnothing; (a_{0,1}), (+1); \mathrm{id}_{\widetilde{q}_{0,1}}; k_0; 0_{\mathsf{M}_{k_0}}; \top; \varnothing\big). \end{aligned} \tag{19.27}$$

The tuple contains no indeterminate coordinates and satisfies $s(x_{\star}) = \top$. Let $G_0 := \{x_{\star}\}$. Assuming G_n has been constructed, fix $x \in G_n$, $\varepsilon \in \{-1, 0, +1\}$, and $x_{\varepsilon,0}(x) := x$. For $r = 1, \ldots, 9$, first construct the elementary ledger

$$\begin{aligned}\ell_{\varepsilon,n,r} := \big(&e_{\varepsilon,n,r}, a_{n,r}, a_{(n,r)^+}, \widetilde{q}_{n,r}, \widetilde{q}_{n,r+1}, M_{\mathrm{ph}}(r),\\ &h_r(h(x_{\varepsilon,r-1}(x))), o(M_{\mathrm{ph}}(r)), \mathfrak{p}_\varepsilon, d_{\varepsilon,r},\\ &\mathsf{C}_{\mathsf{M}}(e_{\varepsilon,n,r}), \kappa_{\mathsf{M}}(e_{\varepsilon,n,r}), \mathrm{Carr}(e_{\varepsilon,n,r})\big),\end{aligned} \tag{19.28}$$

and set $\mathrm{Led}^{\mathrm{new}}_{\varepsilon,n,r} := \mathrm{Led}(x_{\varepsilon,r-1}(x))^\frown \ell_{\varepsilon,n,r}$. Then construct the tuple

$$y_{\varepsilon,r}(x) := x_{\varepsilon,r-1}(x)[\tau \leftarrow M_{\mathrm{ph}}(r),\ h \leftarrow h_r(h(x_{\varepsilon,r-1}(x))),\ o \leftarrow o(M_{\mathrm{ph}}(r)),\ b_{\mathrm{ref}} \leftarrow \mathfrak{p}_\varepsilon], \tag{19.29}$$

where selection leaves the cell, quotients, carry, route, memory, cylinder, boundary, survival, and ledger unchanged; the coordinate b_{ref} makes the chosen balanced reduction explicit. Membership in an ambient relation is not presupposed here.

Next, define $z_{\varepsilon,r}(x)$ field by field: its configuration is $\widetilde{q}_{n,r+1}$; its complete cell is $a_{(n,r)^+}$, with the four residues and quotients recomputed by the two Euclidean divisions; it preserves the selected sheet and orientation; and it performs the following six updates, in which only the common argument x is omitted:

$$\begin{aligned} C(z_{\varepsilon,r}) &:= C(y_{\varepsilon,r})^\frown e_{\varepsilon,n,r},\\ \partial C(z_{\varepsilon,r}) &:= \partial C(y_{\varepsilon,r})^\frown (\widetilde{q}_{n,r}, \widetilde{q}_{n,r+1}),\\ p_{\mathrm{APP}}(z_{\varepsilon,r}) &:= p_{\mathrm{APP}}(y_{\varepsilon,r})^\frown a_{(n,r)^+},\\ p_{\widehat{\mathbb{T}}}(z_{\varepsilon,r}) &:= p_{\widehat{\mathbb{T}}}(y_{\varepsilon,r})^\frown \tau(r),\\ \mathrm{Led}(z_{\varepsilon,r}) &:= \mathrm{Led}^{\mathrm{new}}_{\varepsilon,n,r},\\ \lambda(z_{\varepsilon,r}) &:= e_{\varepsilon,n,r}\lambda(y_{\varepsilon,r}),\end{aligned} \tag{19.30}$$

and still retains the fields $c, \mathrm{gr}_{\mathsf{M}}, \mathrm{mem}, s$ of $y_{\varepsilon,r}(x)$. Its signature, by contrast, is retyped at the target configuration through the transported presignature

$$\begin{aligned}\mathrm{Sig}(z_{\varepsilon,r}(x)) := \mathrm{Sig}^{\mathrm{cal}}_{\widetilde{q}_{n,r+1}}\Big(&\widehat{h}(z_{\varepsilon,r}(x)), o(z_{\varepsilon,r}(x)), c(y_{\varepsilon,r}(x)), \lambda(z_{\varepsilon,r}(x)),\\ &\partial C(z_{\varepsilon,r}(x)), \jmath_{d_{n,r}}(\mathrm{mem}_{d_{n,r}}(y_{\varepsilon,r}(x)))\Big).\end{aligned} \tag{19.31}$$

Thus, and only in $\mathsf{Tra}^{\mathrm{cal}}$, the edge, its endpoints, the mark $(\mathfrak{p}_\varepsilon, r, d_{\varepsilon,r})$, and its cocycles are added to the incidence ledger.

The initial state satisfies

$$c(x_\star) = 0 = \mathrm{Carr}(\mathrm{id}_{\widetilde{q}_{0,1}}) = \mathrm{Carr}(\lambda(x_\star)).$$

In the complete states $x_{\varepsilon,r-1}(x)$, and also after the selection $y_{\varepsilon,r}(x)$, the typed invariant $c(v) = \mathrm{Carr}(\lambda(v))$ is preserved, since $\mathsf{Sel}^{\mathrm{cal}}$ modifies neither field. Transport advances the route but leaves the carry pending; hence the pre-update tuple satisfies exactly

$$c(z_{\varepsilon,r}(x)) = c(y_{\varepsilon,r}(x)) = \mathrm{Carr}(\lambda(y_{\varepsilon,r}(x))).$$

The map $\mathrm{Upd}^{\mathrm{cal}}$ then restores $c(x_{\varepsilon,r}(x)) = \mathrm{Carr}(\lambda(x_{\varepsilon,r}(x)))$ by means of the composition law, without attributing that invariant to the intermediate state z.

Finally, apply the unary function $\mathrm{Upd}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} = \mathsf{Mem}^{\mathrm{cal}}_{e_{\varepsilon,n,r}}$ to that tuple. Its result $x_{\varepsilon,r}(x)$ is given by

$$
\begin{aligned}
c\big(x_{\varepsilon,r}(x)\big) &= \mathrm{Carr}\big(\lambda(z_{\varepsilon,r}(x))\big)\\
&= H_{\mathrm{Carr}}(\lambda(y_{\varepsilon,r}(x)))\big(\mathrm{Carr}(e_{\varepsilon,n,r})\big) + Y_{\mathrm{Carr}}(e_{\varepsilon,n,r})\big(c(y_{\varepsilon,r}(x))\big),\\
\lambda\big(x_{\varepsilon,r}(x)\big) &= \lambda(z_{\varepsilon,r}(x)),\\
\mathrm{gr}_{\mathsf{M}}\big(x_{\varepsilon,r}(x)\big) &= d_{n,r}+1,\\
\mathrm{mem}_{d_{n,r}+1}\big(x_{\varepsilon,r}(x)\big) &= \mathsf{C}_{\mathsf{M}}(e_{\varepsilon,n,r})\,\mathrm{mem}_{d_{n,r}}(z_{\varepsilon,r}(x)) + \kappa_{\mathsf{M}}(e_{\varepsilon,n,r}),\\
s\big(x_{\varepsilon,r}(x)\big) &= s(e_{\varepsilon,n,r}) \wedge s(z_{\varepsilon,r}(x)),\\
\mathrm{Sig}\big(x_{\varepsilon,r}(x)\big) &= \mathrm{Sig}^{\mathrm{cal}}_{\widetilde{q}_{n,r+1}}\Big(\widehat{h}(z_{\varepsilon,r}(x)), o(z_{\varepsilon,r}(x)), c(x_{\varepsilon,r}(x)), \lambda(z_{\varepsilon,r}(x)), \partial C(z_{\varepsilon,r}(x)),\\
&\qquad\qquad \jmath_{d_{n,r}+1}\big(\mathrm{mem}_{d_{n,r}+1}(x_{\varepsilon,r}(x))\big)\Big).
\end{aligned}
\tag{19.32}
$$

All fields not enumerated in (19.32) coincide with those of $z_{\varepsilon,r}(x)$. In particular, the signature is computed from the sheet, orientation, boundary, and route already fixed by $\mathsf{Sel}^{\mathrm{cal}}$ and $\mathsf{Tra}^{\mathrm{cal}}$, and from the carry and memory computed in the preceding lines; it is not circularly defined from the final state. Neither ε, nor $d_{\varepsilon,r}$, nor u is an additional argument of $\mathrm{Upd}^{\mathrm{cal}}$: the function reads all three data from the already constructed edge.

Simultaneous induction of the levels. Once the preceding nine stages have been completed for an already constructed G_n, define immediately

$$
\gamma_{\varepsilon,k_n}(x) := x_{\varepsilon,9}(x), \qquad G_{n+1} := \{\gamma_{\varepsilon,k_n}(x) : x \in G_n,\ \varepsilon \in \widehat{\mathbb{T}}\}. \tag{19.33}
$$

The base $G_0 = \{x_\star\}$, the intermediate tuples, and (19.33) constitute a single definition by recursion on n. Therefore, no subsequent carrier is used to assume the existence of G_n: the next level is introduced only after constructing all its edges from the preceding level.

TPK extension relation and effective membership. Let $\mathcal{E}^{\mathrm{cal}}_{\widetilde{q}}$ be the smallest labelled family containing $x_\star$ and, at each step of the preceding recurrence, the four tuples $x_{\varepsilon,r-1}(x), y_{\varepsilon,r}(x), z_{\varepsilon,r}(x), x_{\varepsilon,r}(x)$ in their source and target configurations. Also let $\mathcal{A}^{\mathrm{cal}}_{\widetilde{q}_{n,r}} := \{a_{n,r}\}$, and set

$$
\widetilde{Q}_{\mathrm{obs}} := \{\widetilde{q}_{n,r} : n \geq 0,\ 1 \leq r \leq 9\}, \qquad \mathcal{E}^{\mathrm{cal}} := \bigsqcup_{\widetilde{q}} \mathcal{E}^{\mathrm{cal}}_{\widetilde{q}}, \qquad \mathcal{F}^{\mathrm{cal}}_{\widetilde{q}} := \pi_{\mathcal{F}}(\mathcal{E}^{\mathrm{cal}}_{\widetilde{q}}).
$$

For each depth d, let $\mathcal{E}^{\mathrm{cal}}_d := \mathrm{gr}^{-1}_{\mathsf{M}}(d) \subset \mathcal{E}^{\mathrm{cal}}$. The explicit degree coordinate, rather than the mere membership of a representative in some image of the direct system, makes these carriers disjoint. On them, the projections are typed as

$$
\begin{aligned}
\mathrm{cfg} &: \mathcal{E}^{\mathrm{cal}} \longrightarrow \widetilde{Q}_{\mathrm{obs}},\\
g(x) &:= \mathrm{fase}\big(\pi_{\mathrm{obs}}(\mathrm{cfg}(x))\big) \in C_9,\\
c &: \mathcal{E}^{\mathrm{cal}} \longrightarrow K_{\mathrm{Carr}},\\
s &: \mathcal{E}^{\mathrm{cal}} \longrightarrow \{\bot, \top\},\\
\lambda &: \mathcal{E}^{\mathrm{cal}}_{\widetilde{q}} \longrightarrow \mathsf{Hist}^{\mathrm{cal}}_{\widetilde{q}},\\
\mathrm{gr}_{\mathsf{M}} &: \mathcal{E}^{\mathrm{cal}} \longrightarrow \mathbb{N}_{\geq 1},\\
\mathrm{mem}_d &: \mathcal{E}^{\mathrm{cal}}_d \longrightarrow \mathsf{M}_d,\\
\mathrm{mem}(x) &:= \jmath_d\big(\mathrm{mem}_d(x)\big) \in \mathsf{M} \quad (x \text{ of depth } d).
\end{aligned}
$$

Here $\mathrm{cfg}(x)$ is the second coordinate of the tuple, and fase reads the phase of the observable calendar. For the three carrier classes, fix the diagonals

$$\Delta_{\mathrm{APP},\widetilde{q}} := \{(a,a) : a \in \mathcal{A}^{\mathrm{cal}}_{\widetilde{q}}\},$$
$$\Delta_{\mathrm{fib},\widetilde{q}} := \{(f,f) : f \in \mathcal{F}^{\mathrm{cal}}_{\widetilde{q}}\},$$
$$\Delta_{\mathrm{enr},\widetilde{q}} := \{(x,x) : x \in \mathcal{E}^{\mathrm{cal}}_{\widetilde{q}}\}.$$

In particular,

$$a_{0,1} \in \mathcal{A}^{\mathrm{cal}}_{\widetilde{q}_{0,1}}, \qquad x_\star \in \mathcal{E}^{\mathrm{cal}}_{\widetilde{q}_{0,1}}.$$

On these carriers, the following relations are defined by their complete graphs, and not through necessary implications:

$$\mathsf{Sel}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} := \{(x_{\varepsilon,r-1}(x), y_{\varepsilon,r}(x)) : x \in G_n\}, \tag{19.34}$$
$$\mathsf{Tra}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} := \{(y_{\varepsilon,r}(x), z_{\varepsilon,r}(x)) : x \in G_n\}, \tag{19.35}$$
$$\mathrm{Ext}^{\mathrm{APP,cal}}_{e_{\varepsilon,n,r}} := \{(a_{n,r}, a_{(n,r)^+})\}, \tag{19.36}$$
$$\mathrm{Ext}^{\mathrm{fib,cal}}_{e_{\varepsilon,n,r}} := \{(\pi_{\mathcal{F}} x_{\varepsilon,r-1}(x), \pi_{\mathcal{F}} x_{\varepsilon,r}(x)) : x \in G_n\}. \tag{19.37}$$

The synchronized enriched extension is

$$\mathrm{Ext}^{\mathrm{enr,cal}}_{e_{\varepsilon,n,r}} := \{(x_{\varepsilon,r-1}(x), x_{\varepsilon,r}(x)) : x \in G_n\}. \tag{19.38}$$

The third map is defined by

$$\mathrm{graph}\big(\mathrm{Upd}^{\mathrm{cal}}_{e_{\varepsilon,n,r}}\big) := \{(z_{\varepsilon,r}(x), x_{\varepsilon,r}(x)) : x \in G_n\}, \tag{19.39}$$

where the second component is exactly the one in (19.32). Consequently,

$$\mathcal{U}^{(1),\mathrm{cal}}_{e_{\varepsilon,n,r}} := \mathrm{Upd}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} \circ \mathsf{Tra}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} \circ \mathsf{Sel}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} = \{(x_{\varepsilon,r-1}(x), x_{\varepsilon,r}(x)) : x \in G_n\}. \tag{19.40}$$

Each operator is indexed by the edge $e_{\varepsilon,n,r}$ produced by the reduction $\mathfrak{p}_\varepsilon$, rather than by a trit supplied from outside. The coordinate b_{ref} also distinguishes their codomains. Therefore, $\mathsf{Sel}^{\mathrm{cal}}_e$, $\mathsf{Tra}^{\mathrm{cal}}$ and $\mathrm{Upd}^{\mathrm{cal}}$ are functions on their respective domains, whereas the union $\bigcup_{\varepsilon\in\widehat{\mathbb{T}}} \mathcal{U}^{(1),\mathrm{cal}}_{e_{\varepsilon,n,r}}$ deliberately preserves the three outputs of the trisection.

For $\bullet \in \{\mathrm{APP}, \mathrm{fib}, \mathrm{enr}\}$, identities and compositions are not left implicit. Define

$$\mathrm{Ext}^{\bullet,\mathrm{cal}}_{\mathrm{id}_{\widetilde{q}}} := \Delta_{\bullet,\widetilde{q}}, \tag{19.41}$$
$$\mathrm{Ext}^{\bullet,\mathrm{cal}}_{e_t\cdots e_1} := \mathrm{Ext}^{\bullet,\mathrm{cal}}_{e_t} \circ \cdots \circ \mathrm{Ext}^{\bullet,\mathrm{cal}}_{e_1} \tag{19.42}$$

for every admissible edge word. The two APP and fiber path closures are formed separately,

$$\mathrm{Path}(\mathrm{Ext}^{\mathrm{APP,cal}}), \qquad \mathrm{Path}(\mathrm{Ext}^{\mathrm{fib,cal}}), \tag{19.43}$$

and $\mathsf{Tra}^{\mathrm{cal}}$ synchronizes them edge by edge.

Finally, the levels of complete states and their truncations are fixed by the recursion itself:

$$H^{\mathrm{cal}}_{d_{n,r}} := \{x_{\varepsilon,r-1}(x) : x \in G_n,\ \varepsilon \in \widehat{\mathbb{T}}\}, \tag{19.44}$$
$$H^{\mathrm{cal}}_{d_{n,r}+1} := \{x_{\varepsilon,r}(x) : x \in G_n,\ \varepsilon \in \widehat{\mathbb{T}}\}, \tag{19.45}$$
$$\rho^{\mathrm{cal}}_{d_{n,r}+1,d_{n,r}}\big(x_{\varepsilon,r}(x)\big) := x_{\varepsilon,r-1}(x). \tag{19.46}$$

The final ledger preserves $(n, r, \mathfrak{p}_\varepsilon)$, so the predecessor of the left-hand side is unique and ρ^{cal} is well-defined. For $b > a$, set $\rho^{\mathrm{cal}}_{b,a} := \rho^{\mathrm{cal}}_{a+1,a} \circ \cdots \circ \rho^{\mathrm{cal}}_{b,b-1}$. This map recovers the complete preceding

state, including its signature; it does not purport to invert an overwritten coordinate without consulting the ledger.

Proposition 19.20 (Autonomous realization of the TPK through explicit transitions)**.** *The family*

$$\begin{aligned}\mathfrak{T}^{\mathrm{cal}}_{\mathrm{TPK}} := \big((\widetilde{q}_{n,r})_{n,r}, \pi_{\mathrm{obs}}, \widetilde{F}_{\mathrm{obs}}, M_{\mathrm{ph}},\\ (\mathcal{A}^{\mathrm{cal}}_{\widetilde{q}})_{\widetilde{q}}, (\mathcal{E}^{\mathrm{cal}}_{\widetilde{q}})_{\widetilde{q}}, (\mathcal{F}^{\mathrm{cal}}_{\widetilde{q}})_{\widetilde{q}}, \mathrm{Ext}^{\mathrm{APP,cal}}, \mathrm{Ext}^{\mathrm{fib,cal}}, \mathrm{Ext}^{\mathrm{enr,cal}}, \rho^{\mathrm{cal}},\\ \mathsf{Sel}^{\mathrm{cal}}, \mathsf{Tra}^{\mathrm{cal}}, \mathrm{Upd}^{\mathrm{cal}}, \mathsf{C}_{\mathsf{M}}, \kappa_{\mathsf{M}}, \mathrm{gr}_{\mathsf{M}}, H_{\mathrm{Carr}}, Y_{\mathrm{Carr}},\\ \mathrm{Sig}^{\mathrm{cal}}, \pi_{\mathcal{F}}\big).\end{aligned}$$

is an enriched model of the TPK. In particular, every pair on the right-hand side of (19.40) *is an effective TPK edge, not a consequence inferred from a merely necessary condition.*

Proof. The labels (n, r) make the carrier copies disjoint and unambiguously fix each source and target. The relation $\mathrm{Ext}^{\mathrm{APP,cal}}$ transports the complete cell and preserves the two Euclidean identities; the relation $\mathrm{Ext}^{\mathrm{fib,cal}}$ relates the fibers of the preceding and subsequent complete states: it transports sheet, orientation, prefix, cylinder, boundary, and ledger, and incorporates the updated carry, memory, and signature. Selection does not modify the ledger, and transport concatenates exactly one entry and produces the target presignature (19.31). The update recomputes the signature by means of the typed map $\mathrm{Sig}^{\mathrm{cal}}_{\widetilde{q}}$ from the already determined sheet, orientation, carry, route, boundary, and memory. The map $\mathrm{Upd}^{\mathrm{cal}}$ is unary because the edge contained in $z_{\varepsilon,r}(x)$ determines its cocycles.

The identities are the diagonals, and the word extensions are the compositions in (19.42). Concatenation of prefixes and ledgers is associative; memory satisfies the cocycle law, and carry satisfies (19.26). Therefore, the two parenthesizations of three edges produce the same state. Formula (19.46) defines truncation on complete states, and uniqueness of the final ledger proves that it recovers the source in every field. These are the identity, source, target, composition, memory, carry, and truncation laws of the enriched TPK. In particular, the extension relations are determined as graphs of effective maps rather than as consequences of merely necessary conditions. □

Each γ_{ε,k_n} comprises exactly nine applications of $\mathrm{Upd}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} \circ \mathsf{Tra}^{\mathrm{cal}}_{e_{\varepsilon,n,r}} \circ \mathsf{Sel}^{\mathrm{cal}}_{e_{\varepsilon,n,r}}$. Survival will be proved by means of a constructed tail and will not be used to define G_n.

Lemma 19.21 (Effective internal trisection of one turn)**.** *For every $n \geq 0$, every $x \in G_n$, and every $\varepsilon \in \{-1, 0, +1\}$, the expression $\gamma_{\varepsilon,k_n}(x)$ is defined by nine TPK transitions, with its synchronized relations* $\mathrm{Ext}^{\mathrm{APP,cal}}$ *and* $\mathrm{Ext}^{\mathrm{fib,cal}}$*, and satisfies*

$$\rho^{\mathrm{cal}}_{k_n+9,k_n}\gamma_{\varepsilon,k_n}(x) = x, \tag{19.47}$$

$$g\big(\gamma_{\varepsilon,k_n}(x)\big) = g(x), \qquad \jmath_{k_n+9}\big(\mathrm{mem}_{k_n+9}(\gamma_{\varepsilon,k_n}(x))\big) = \jmath_{k_n}\big(\mathrm{mem}_{k_n}(x)\big) + u, \tag{19.48}$$

$$c\big(\gamma_{\varepsilon,k_n}(x)\big) = c(x) + \varepsilon\kappa_{\mathrm{Carr}}. \tag{19.49}$$

The ordered ledger of the nine edges determines ε uniquely. The three images are therefore disjoint. Each endpoint belongs to G_{n+1} and again admits the three maps $\gamma_{-1,k_{n+1}}, \gamma_{0,k_{n+1}}, \gamma_{+1,k_{n+1}}$.

Proof. Formulas (19.18) traverse the nine phases once and return the copy $a_{n+1,1}$ of $a(1)$. At each step, the APP relation transports the complete sextuple; $\mathsf{Sel}^{\mathrm{cal}}$ fixes the TRIT type from the phase mark r preserved in the state; and $\mathsf{Tra}^{\mathrm{cal}}$ adds exactly one symbol to the prefix, one segment to the cylinder, and its ordered pair of endpoints to the boundary. By induction on r, the explicit tuples $y_{\varepsilon,r}(x)$ and $z_{\varepsilon,r}(x)$ satisfy the predicates of the indicated relations, and the unary update produces the state at the next level. The identity $\rho^{\mathrm{cal}}_{d_{n,r}+1,d_{n,r}}(x_{\varepsilon,r}(x)) = x_{\varepsilon,r-1}(x)$ is the definition (19.46); its well-definedness follows from uniqueness of the final ledger. The composition of the nine truncation maps recovers x, proving (19.47) without separately inverting the overwritten fields.

The phase $9 \to 1$ occurs exactly once. By (19.22) and the cocycle law, the linear memory component transports the preceding memory, and its translational component adds exactly u in the direct limit. The compatibility $\jmath_{d+1}\jmath_{d+1,d} = \jmath_d$ proves (19.48); the return concerns the phase, not the enriched state.

By (19.23), eight edges have zero increment, and the edge completing $\mathfrak{p}_\varepsilon$ has the computed increment $\chi(\varepsilon,\varepsilon)\kappa_{\mathrm{Carr}}$. The laws (19.26) and (19.21) give (19.49). The ledger preserves $(\mathfrak{p}_\varepsilon, 2\varepsilon, r_3(2\varepsilon), \chi(\varepsilon,\varepsilon))$; the three values of this ledger are distinct even when the scalar increment is zero. Hence the images are not identified, and the block decoder recovers a unique ε.

The edge definitions depend only on the new phase and concatenate, rather than replace, the prefix, cylinder, boundary, and ledger. They are also invariant under $\jmath_d\,\mathrm{mem}_d \mapsto \jmath_d\,\mathrm{mem}_d + nu$ and under translation of the input carry. Consequently, the same construction applies at the endpoint of any turn. For every finite state, the explicit sequence

$$x, \quad \gamma_{0,k_n}(x), \quad \gamma_{0,k_{n+1}}\gamma_{0,k_n}(x), \quad \dots$$

is a compatible infinite tail. This proves the survival of all constructed states and the repeated availability of the three branches, without postulating either property. Consequently, in accordance with the preceding level definitions, we may finally identify

$$H^{\mathrm{cal}}_{k_n} := G_n \tag{19.50}$$

for every $n \geq 0$. □

The preceding closure distinguishes the three clocks involved. Nine emissions return the phase in C_9 and advance memory. Twelve turns, that is, 108 emissions, also return the position of the observable calendar; even then, neither the ledger nor memory is erased. The operator $\mathcal{K}_{\mathrm{ph}}$ acts only afterward, as a recognition of reduced memory from the already constructed turns; it never generates the edges of $\mathrm{Ext}^{\mathrm{enr,cal}}$.

Let

$$\upsilon : \mathbb{F}_3 \longrightarrow \{-1, 0, +1\}, \qquad \upsilon(0) = 0, \quad \upsilon(1) = +1, \quad \upsilon(2) = -1$$

be the balanced representative. For $b = (b_1, \dots, b_6) \in \mathbb{F}_3^6$, the block extension is the ordered composition of six turns

$$\Gamma^{[54]}_{b,k} := \gamma_{\upsilon(b_6),k+45} \circ \gamma_{\upsilon(b_5),k+36} \circ \gamma_{\upsilon(b_4),k+27} \circ \gamma_{\upsilon(b_3),k+18} \circ \gamma_{\upsilon(b_2),k+9} \circ \gamma_{\upsilon(b_1),k}. \tag{39d}$$

At block level one always uses $k = k_{6N} = 1 + 54N$; consequently, each factor has the domain constructed by the preceding factor. Fix a canonical APP seed $x_\star \in H^{\mathrm{cal}}_1$ and define recursively

$$\begin{aligned} Y_0 &:= \{x_\star\}, \qquad Y_N \subseteq H^{\mathrm{cal}}_{1+54N}, \\ Y_{N+1} &:= \{\Gamma^{[54]}_{b,1+54N}(x) : x \in Y_N,\ b \in \mathbb{F}_3^6\}, \\ \rho^{\mathrm{blk}}_{N+1,N} &:= \rho^{\mathrm{cal}}_{1+54(N+1),1+54N} \restriction Y_{N+1}, \\ \mathrm{Ext}^{\mathrm{cal}}_N(x) &:= \{\Gamma^{[54]}_{b,1+54N}(x) : b \in \mathbb{F}_3^6\}. \end{aligned} \tag{39e}$$

The notation $\rho^{\mathrm{cal}}_{b,a}$ denotes the composition of all deletion maps between levels b and a. By construction, every extension in $\mathrm{Ext}^{\mathrm{cal}}_N(x)$ is a chain of fifty-four TPK edges, not a jump of the Markov quotient.

The reader is defined directly on the ledger, before invoking a representation through Γ_b. The preceding lemma provides a decoder

$$\mathrm{dec}_9 : \{\text{generated nine-edge segments}\} \longrightarrow \{-1, 0, +1\},$$

which reads the TRIT pair and its reduction on the segment. If $\mathrm{Led}^{(9)}_{j,i}(x)$ denotes the i-th nonadic segment of block j in the ledger of x, set

$$\beta_{\mathrm{blk},N}(x) := \Big(\big(\upsilon^{-1} \operatorname{dec}_9(\mathrm{Led}^{(9)}_{j,i}(x)) \big)_{i=1}^{6} \Big)_{j=0}^{N-1}. \tag{19.51}$$

For $N = 0$, the value is the empty word. This definition does not presuppose that the decomposition of x as a composition of maps Γ_b is unique.

We now specialize the preceding arithmetic conjugacy to $p = 3$, $d = 6$, and $A = I_6$. If $\pi_{N+1,N} : (\mathbb{Z}/3^{N+1}\mathbb{Z})^6 \to (\mathbb{Z}/3^N\mathbb{Z})^6$ is the canonical reduction, define

$$\Phi_N := \Psi_N^{-1} \circ \beta_{\mathrm{blk},N} : Y_N \longrightarrow (\mathbb{Z}/3^N\mathbb{Z})^6. \tag{19.52}$$

This definition does not assign a coordinate after observing a branch: the reader $\beta_{\mathrm{blk},N}$ is obtained from the already constructed TPK ledger, and Ψ_N^{-1} is the explicit inverse, fixed beforehand, of the unfiltered arithmetic tower.

Proposition 19.22 (Finite conjugacy and complete covering of the fiber)**.** *For every $N \geq 0$,*

$$\beta_{\mathrm{blk},N} : Y_N \xrightarrow{\cong} (\mathbb{F}_3^6)^N$$

is a bijection compatible with truncations, and for every $x \in Y_N$

$$\begin{aligned} \beta_{\mathrm{blk},N+1}\big[\mathrm{Ext}^{\mathrm{cal}}_N(x)\big] &= \{\beta_{\mathrm{blk},N}(x)^\frown b : b \in \mathbb{F}_3^6\}, \\ \mathrm{pref}_N \circ \beta_{\mathrm{blk},N+1} &= \beta_{\mathrm{blk},N} \circ \rho^{\mathrm{blk}}_{N+1,N}. \end{aligned} \tag{40$_0$}$$

The maps Φ_N are bijections and satisfy the intertwining identity

$$\pi_{N+1,N} \circ \Phi_{N+1} = \Phi_N \circ \rho^{\mathrm{blk}}_{N+1,N}. \tag{19.53}$$

Consequently, the tower of generated histories and the Hensel arithmetic tower are isomorphic as finite inverse systems.

Proof. The assertion is immediate for $N = 0$. Assume that it holds at level N. For each word $b \in \mathbb{F}_3^6$, the preceding lemma constructs an extension $\Gamma^{[54]}_{b,1+54N}(x)$. If $b \neq b'$, the first coordinate at which they differ determines a distinct TRIT pair and cocycle in the first divergent nonadic segment of the genealogical ledger. That ledger preserves the ordered edges, not merely the final sum of their carries; hence the two histories remain distinct even if carries from later turns cancel. The direct reading (19.51) then gives

$$\beta_{\mathrm{blk},N+1}\big(\Gamma^{[54]}_{b,1+54N}(x)\big) = \beta_{\mathrm{blk},N}(x)^\frown b. \tag{19.54}$$

The six successive trisections produce exactly 3^6 distinct extensions. Deleting the last fifty-four steps recovers x, and deleting the final block of the ledger recovers $\beta_{\mathrm{blk},N}(x)$. This simultaneously proves bijectivity and the compatibility of $\beta_{\mathrm{blk},N}$ with truncations.

Proposition 19.19 independently proves that Ψ_N is bijective and that

$$\mathrm{pref}_N \circ \Psi_{N+1} = \Psi_N \circ \pi_{N+1,N}.$$

Composing this equality with the compatibility of β_{blk} and applying Ψ_N^{-1} yields

$$\pi_{N+1,N}\Psi_{N+1}^{-1}\beta_{\mathrm{blk},N+1} = \Psi_N^{-1}\beta_{\mathrm{blk},N}\rho^{\mathrm{blk}}_{N+1,N},$$

which is exactly (19.53). The equality does not arise by defining an ad hoc coordinate on each branch: it results from composing two systems of constructed bijections that are compatible at every depth. □

The inverse limit

$$\Omega_{\Gamma}^{\mathrm{cal}} := \varprojlim_{N} (Y_N, \rho_{N+1,N}^{\mathrm{blk}}) \tag{40a$_0$}$$

is the history limit of the TPK model constructed edge by edge in the preceding lemma. Its projection under π_{obs} preserves the configurations of the observable calendar, but the assertion does not depend on identifying this autonomous model with an ambient relation defined only by necessary conditions. The finite bijections pass to the limit and produce the cylinder homeomorphism

$$\Lambda : (\mathbb{F}_3^6)^{\mathbb{N}} \xrightarrow{\cong} \Omega_{\Gamma}^{\mathrm{cal}}, \qquad \beta_{\mathrm{blk}} := \Lambda^{-1}. \tag{40b$_0$}$$

Denote the canonical projection by $\rho_{\infty,N}^{\mathrm{blk}} : \Omega_{\Gamma}^{\mathrm{cal}} \to Y_N$. Thus, Λ establishes an equivalence compatible with truncations: each ternary tape encodes a TPK history, and every prefix is extended through edges of the same generator.

The subcylinders are now defined as subsets of the limit, rather than as pairs of suffixes. For $x \in Y_N$ and $b \in \mathbb{F}_3^6$, let

$$\mathscr{Z}_N(x) := \{\xi \in \Omega_{\Gamma}^{\mathrm{cal}} : \rho_{\infty,N}^{\mathrm{blk}}(\xi) = x\}, \tag{19.55}$$

$$\mathscr{Z}_{N+1}(x; b) := \{\xi \in \Omega_{\Gamma}^{\mathrm{cal}} : \rho_{\infty,N+1}^{\mathrm{blk}}(\xi) = \Gamma_{b,1+54N}^{[54]}(x)\}. \tag{19.56}$$

Theorem 19.23 (Effective partition into 729 refinement subcylinders)**.** *For every $N \geq 0$ and every $x \in Y_N$, there is a disjoint union*

$$\mathscr{Z}_N(x) = \bigsqcup_{b \in \mathbb{F}_3^6} \mathscr{Z}_{N+1}(x; b). \tag{19.57}$$

The $3^6 = 729$ terms are nonempty clopen refinement subcylinders; each is realized by fifty-four edges of the constructed TPK.

Proof. Let $\xi \in \mathscr{Z}_N(x)$. Its level-$N+1$ coordinate belongs to Y_{N+1}, truncates to x, and, by the bijection $\beta_{\mathrm{blk},N+1}$, has a unique final block $b \in \mathbb{F}_3^6$. Identity (19.54) then implies $\rho_{\infty,N+1}^{\mathrm{blk}}(\xi) = \Gamma_{b,1+54N}^{[54]}(x)$; therefore, ξ belongs to one of the terms on the right-hand side. The reverse inclusion follows immediately by truncation. If two terms intersected, their level-$N+1$ coordinates would be equal and the ledger decoder would give $b = b'$; hence the union is disjoint.

Each endpoint $\Gamma_b^{[54]}(x)$ admits an infinite tail obtained by iterating the zero-block extension; consequently, every term is nonempty. Since Y_{N+1} is finite and discrete, the terms are inverse images of points under a continuous projection of the inverse limit and are therefore clopen. The very definition of $\Gamma_b^{[54]}$ establishes its fifty-four edges. □

The family $(\Phi_N)_N$ finally induces the homeomorphism of limits

$$\Phi_{\infty} : \Omega_{\Gamma}^{\mathrm{cal}} \xrightarrow{\cong} \mathbb{Z}_3^6, \qquad \Phi_{\infty}(\xi) := \big(\Phi_N(\rho_{\infty,N}^{\mathrm{blk}}(\xi))\big)_{N \geq 0}, \tag{19.58}$$

where $\mathbb{Z}_3^6 = \varprojlim_N (\mathbb{Z}/3^N\mathbb{Z})^6$. Equation (19.53) guarantees that the right-hand side is a compatible class, and the finite bijections prove injectivity, surjectivity, and continuity in both directions. Under Φ_{∞}, $\mathscr{Z}_N(x)$ is exactly the congruence class

$$\{z \in \mathbb{Z}_3^6 : z \equiv \Phi_N(x) \pmod{3^N}\},$$

and the sets $\mathscr{Z}_{N+1}(x;b)$ are its 729 refinement classes modulo 3^{N+1}. This is the effective junction between TPK extension, limit cylinders, and the Hensel tower.

For $b=(b_1,\dots,b_6)\in\mathbb{F}_3^6$, set

$$\nu(b):=\sum_{i=1}^{6}[b_i]_3\,3^{6-i}\in\{0,\dots,728\},\tag{40c$_0$}$$

where $[b_i]_3\in\{0,1,2\}$ is the positional representative. The 243 visible words in the initial census are the image of the first emission; they are not to be confused with the 3^6 capacity of each extension block. Finally,

$$X^{\mathrm{cal}}_{\infty,\mathbb{Z}}:=\mathbb{Z}_{\mathrm{HMT}}\times\Omega^{\mathrm{cal}}_{\Gamma}.$$

For a prefix $s=(m;b_0,\dots,b_{N-1})$, define in the generated arithmetic of $\mathbb{Q}_{\mathrm{HMT}}$

$$a_N(s):=m+\sum_{q<N}\frac{\nu(b_q)}{729^{q+1}},\qquad \mathrm{Succ}(s):=\{(m;b_0,\dots,b_{N-1},b):b\in\mathbb{F}_3^6\}.$$

If $(m;\beta_{\mathrm{blk},N}(x))$ denotes the prefix obtained by prepending m to the tuple $\beta_{\mathrm{blk},N}(x)$, (40$_0$) gives the typed equality

$$\mathrm{Succ}(m;\beta_{\mathrm{blk},N}(x))=\{(m;\beta_{\mathrm{blk},N+1}(y)):y\in\mathrm{Ext}^{\mathrm{cal}}_N(x)\}.$$

From their first definition, the half-open cylinders are subsets of the HMT completion:

$$I^{\mathrm{HMT}}_N(s):=\{r\in\mathbb{R}_{\mathrm{HMT}}:a_N(s)\le_{\mathrm{HMT}}r<_{\mathrm{HMT}}a_N(s)+729^{-N}\}.$$

They materially satisfy

$$I^{\mathrm{HMT}}_N(s)=\bigsqcup_{y\in\mathrm{Succ}(s)}I^{\mathrm{HMT}}_{N+1}(y),\qquad|\mathrm{Succ}(s)|=729,\qquad\mathrm{diam}_{\mathrm{HMT}}\,I^{\mathrm{HMT}}_N(s)=729^{-N}\longrightarrow0.\tag{40a}$$

The boundary convention identifies the two representations only after they have been constructed. The partition (40a), nesting, and contraction produce

$$\begin{aligned}&P_{\mathrm{ar}}:X^{\mathrm{cal}}_{\infty,\mathbb{Z}}\twoheadrightarrow\mathbb{R}_{\mathrm{HMT}},\\&P_{\mathrm{ar}}(m,\xi):=\text{the unique element of }\bigcap_N C^{\mathrm{cl}}_N\big(m;\beta_{\mathrm{blk},N}(\rho^{\mathrm{blk}}_{\infty,N}(\xi))\big),\\&C^{\mathrm{cl}}_N(s):=\overline{I^{\mathrm{HMT}}_N(s)}.\end{aligned}\tag{40}$$

Therefore,

$$X^{\mathrm{cal}}_{\infty,\mathbb{Z}}/{\sim_{P_{\mathrm{ar}}}}\;\cong\;\mathbb{R}_{\mathrm{HMT}}.\tag{41}$$

The other publication P_{exc} preserves incidence, boundary and memory toward Paley–Witt–Golay–Leech and, from there, toward $V^{\natural}$–Monster. Both come from the same antecedent of (35); neither the Archimedean coordinate nor exceptional recognition selects the seeds. The five constructions sp, sol, gau, coh, det remain consubstantial within $C^{\mathrm{disc}}_{\mathrm{cont}}$ and are not separated to carry out the cardinal step.

19.10.2.3 Descent of operations to the evaluation quotient

The preceding quotient identifies histories publishing the same value, not their complete registers. The following criterion characterizes exactly when an operation on histories induces an operation on that

quotient without choosing a privileged history in each fibre; its formulation continues the genealogical construction established in the preceding sections.

Proposition 19.24 (Descent criterion through evaluation fibres)**.** *Let $q : \Omega \to J$ be the evaluation of a genealogical chart onto its image. Let $\star : D \to \Omega$ be an operation with $D \subseteq \Omega^2$ saturated by the fibres of $q \times q$. There exists a unique operation $\overline{\star} : (q \times q)(D) \to J$ such that*

$$q(x \star y) = q(x) \,\overline{\star}\, q(y)$$

if and only if, for pairs in the domain,

$$q(x) = q(x'), \quad q(y) = q(y') \quad \Longrightarrow \quad q(x \star y) = q(x' \star y').$$

Proof. If the visible operation exists, its result depends only on the two values, which proves necessity. For sufficiency, define $s \,\overline{\star}\, t = q(x \star y)$, where $q(x) = s$ and $q(y) = t$. Saturation preserves the domain when representatives change; the stated condition preserves the result. Surjectivity of $q \times q$ onto the image of the domain proves uniqueness. □

A coordinate does not automatically replace a history as an argument of all its operations: the criterion determines when that substitution is legitimate. In particular, transporting an operation through a bijection is not enough to identify it with a native operation preceding the reading. If a chart Ω is compact and q is continuous and surjective onto a Hausdorff space J, evaluation also induces a homeomorphism $\Omega/{\sim_q} \to J$: it is a continuous bijection from a compact space to a Hausdorff space. It is the *quotient*, and not necessarily the history space, that is topologically identified with J.

19.10.2.4 Internal reconstruction of the chart and uniform lifting

Within $\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty)$, the reconstruction in (35)–(41) is carried out with the same codes and operators. Denote by $\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$ the internal HMT completion. The uniqueness of the complete Archimedean ordered field provides, **after** its construction, the internal isomorphism

$$\eta : \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}} \xrightarrow{\cong} \mathbb{R}^{\mathfrak{G}}. \tag{41$_0$}$$

For the corresponding internal interval $I_N^{\mathfrak{G}}(s) := I_N^{\mathrm{HMT}}(s) \cap \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$, the isomorphism preserves endpoints and order:

$$\eta[I_N^{\mathfrak{G}}(s)] = \{r \in \mathbb{R}^{\mathfrak{G}} : a_N(s) \le r < a_N(s) + 729^{-N}\}. \tag{41$_0$a}$$

The surjectivity of (40) covers every element of that completion, not only those obtained in a finite execution.

So that "every" is not concealed in the definition of the codomain, we construct the two injections relating the line to its internal power set. Let

$$E(A) = \sum_{n \ge 0} \frac{2\mathbf{1}_A(n)}{3^{2n+2}} \qquad \big(A \in \mathcal{P}^{\mathfrak{G}}(\omega)\big). \tag{41a}$$

This representation places 0 or 2 only in the even ternary positions; its image is contained in $[0, 1/4]$. It therefore never reaches the right endpoint of the root cylinder, and two distinct subsets have a different first even position: E is injective and is not subject to boundary ambiguity. Write $E_{\mathrm{HMT}} := \eta^{-1} \circ E$.

Given A, begin with the root cylinder containing $E_{\mathrm{HMT}}(A)$. If $s_N(A)$ is the prefix already chosen, write $s_N(A) = (0; b_0(A), \dots, b_{N-1}(A))$. The partition (40a), transported by η^{-1}, supplies a unique half-open subcylinder $s_{N+1}(A)$ containing $E_{\mathrm{HMT}}(A)$. By (40$_0$), that extension is also an admissible TPK extension. By induction,

$$s_{N+1}(A) \restriction N = s_N(A), \qquad E_{\mathrm{HMT}}(A) \in I_N^{\mathrm{HMT}}(s_N(A)) \quad (N < \omega). \tag{41b$_0$}$$

The recursion is a uniform formula with parameters A, h. Since both are internal, Replacement in the model of Lemma 19.18 forms the complete sequence of blocks $(b_q(A))_{q<\omega}$. Without confusing the tape with the sequence of prefixes, define

$$\xi_A := \Lambda\big((b_q(A))_{q<\omega}\big) \in \Omega_\Gamma^{\mathrm{cal},\mathfrak{G}}.$$

This yields the **uniform lift of the Cantor embedding**

$$Q : \mathcal{P}^{\mathfrak{G}}(\omega) \longrightarrow X_{\infty,\mathbb{Z}}^{\mathrm{cal},\mathfrak{G}}, \qquad Q(A) := (0, \xi_A), \qquad P_{\mathrm{ar}}(Q(A)) = E_{\mathrm{HMT}}(A). \tag{41b}$$

We do not call Q the inverse of P_{ar}: their composition publishes the embedding E_{HMT}, not the identity on the entire line. In the other direction, let $(q_n)_{n<\omega}$ be the generated enumeration of $\mathbb{Q}_{\mathrm{HMT}}$ and define

$$C(r) := \{n < \omega : \eta(q_n) < r\} \qquad (r \in \mathbb{R}^{\mathfrak{G}}).$$

The rational cut belongs to $\mathcal{P}^{\mathfrak{G}}(\omega)$, and C is injective by density. The injections E and C, followed by the internal Cantor–Bernstein theorem, prove

$$P_{\mathrm{ar}}\big[X_{\infty,\mathbb{Z}}^{\mathrm{cal},\mathfrak{G}}\big] = \mathbb{R}_{\mathrm{HMT}}^{\mathfrak{G}}, \qquad \mathbb{R}_{\mathrm{HMT}}^{\mathfrak{G}} \cong \mathbb{R}^{\mathfrak{G}} \approx \mathcal{P}^{\mathfrak{G}}(\omega). \tag{41c}$$

Here an arbitrary real is used only as a universally quantified variable to prove surjectivity of an already constructed tree. It selects neither APP, TRIT, TPK, the constants, nor the transitions of that tree.

19.10.3 Enumeration by genealogical codes and HMT condensation

Rule (37) supplies derivation names from

$$(\ulcorner \varphi \urcorner, \sigma(p_0), \dots, \sigma(p_{k-1})). \tag{42}$$

For any object a of the hierarchy, let $\beta(a)$ be its first stage and $\sigma(a)$ its least derivation tree in the recursive order of Lemma 19.18. The term $\sigma(a)$ is not required to be a natural number when the stage is uncountable. The relation

$$a \prec_{\mathfrak{G}} b \quad \Longleftrightarrow \quad (\beta(a), \sigma(a)) <_{\mathrm{lex}} (\beta(b), \sigma(b)) \tag{42a}$$

is the global genealogical well-order $<_{\mathfrak{G}}$ induced by the constructor. Repeated names are eliminated by taking the least one; neither a real nor an enumeration of the line is inserted as data.

Lemma 19.25 (Internal countability of levels below $\omega_1^{\mathfrak{G}}$)**.** *For every $\beta < \omega_1^{\mathfrak{G}}$, the level $\mathfrak{G}_\beta(h, m_\infty)$ is countable within $\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty)$, and possesses a canonical surjection*

$$e_\beta : \omega \twoheadrightarrow \mathfrak{G}_\beta(h, m_\infty). \tag{43}$$

Proof. The initial level has a countable code. If e_β enumerates level β, the formula codes and finite tuples of parameters in (42) form a countable set and enumerate the successor. If $\lambda < \omega_1^{\mathfrak{G}}$ is a limit, there is internally a surjection $s : \omega \twoheadrightarrow \lambda$; take the $<_{\mathfrak{G}}$-least one, in the order already constructed in Lemma 19.18, and diagonalize the $e_{s(n)}$. Finally, among all surjections so obtained, define e_β as the $<_{\mathfrak{G}}$-least. The recursion $\beta \mapsto e_\beta$ is a uniformly definable class of $\mathfrak{G}$; every e_β, and every restriction of the recursion to an ordinal, belongs to $\mathfrak{G}$. It uses only $h, u_{h,m}$ and the global well-order. □

Lemma 19.26 (Condensation of internal reals below $\omega_1^{\mathfrak{G}}$)**.** *Every real in $\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty)$ appears at a level whose index is smaller than $\omega_1^{\mathfrak{G}}$.*

Proof. Let $r \subseteq \omega$ be a real in $\mathfrak{G}$, and let $B := \mathfrak{G}_0(h, m_\infty)$. This base is transitive and internally countable. With the codes of natural numbers and finite pairs already fixed, $\mathrm{Ord} \cap B = \omega + 1$. By induction,

$$\mathrm{Ord} \cap \mathfrak{G}_\alpha = (\omega + 1) + \alpha.$$

The successor adds the ordinal formed by the ordinals of the preceding level; it cannot add a larger one, because that would not be a subset of that level. Limits are unions. Choose a limit Θ, with $\Theta > \omega^2$, such that $r \in \mathfrak{G}_\Theta$. Thus $\mathrm{Ord} \cap \mathfrak{G}_\Theta = \Theta$, and every level $\mathfrak{G}_\xi$, with $\xi < \Theta$, belongs to $\mathfrak{G}_\Theta$. Internally form the expanded structure

$$\mathcal{A}_\Theta = \langle \mathfrak{G}_\Theta, \in, u_{h,m}, H_\Theta, <_{\mathfrak{G}} \restriction \mathfrak{G}_\Theta \rangle$$

with the level relation as a predicate of its signature, $H_\Theta = \{\langle \xi, x \rangle : \xi < \Theta \,\&\, x \in \mathfrak{G}_\xi\}$, and its definable Skolem functions. Let

$$Y = \mathrm{Hull}^{\mathcal{A}_\Theta}(B \cup \{B, r\}) \prec \mathcal{A}_\Theta.$$

Closure under the countable family of Skolem functions shows within $\mathfrak{G}$ that Y is countable. Let $c : Y \to M$ be its Mostowski collapse and

$$\bar{\Theta} := \mathrm{otp}(Y \cap \Theta) < \omega_1^{\mathfrak{G}}.$$

Since $B \subseteq Y$ is transitive, induction on membership shows that c fixes every element of B, as well as B itself. In particular, it fixes $\omega, u_{h,m}, h, m_\infty$. Since $r \subseteq \omega \subseteq Y$, it also follows that $c(r) = r$.

We prove by induction on $\xi \in Y \cap \Theta$ that

$$c\text{“}\big(Y \cap \mathfrak{G}_\xi(h, m_\infty)\big) = \mathfrak{G}_{c(\xi)}(h, m_\infty). \tag{43a}$$

For $\xi \in Y \cap \Theta$, the predicate H_Θ defines the set $\mathfrak{G}_\xi$ from ξ, so $\mathfrak{G}_\xi \in Y$. Relativizing each formula to that set gives $Y \cap \mathfrak{G}_\xi \prec \mathfrak{G}_\xi$, in the language into which Lemma 19.16 translates the HMT definitions.

The base case of (43a) has already been proved because the collapse fixes B. At a successor, if $\xi + 1 \in Y$, then also $\xi \in Y$ and $c(\xi + 1) = c(\xi) + 1$. For $a \in Y \cap \mathfrak{G}_{\xi+1}$, fix a finite formula defining it over $\mathfrak{G}_\xi$. The assertion

$$a = \{z \in \mathfrak{G}_\xi : \varphi^{\mathfrak{G}_\xi}(z, \bar{p})\}$$

is an ordinary formula over $\mathfrak{G}_\Theta$, with parameters $a, \mathfrak{G}_\xi$. Elementarity supplies the parameters $\bar{p}$ within $Y \cap \mathfrak{G}_\xi$. The induction hypothesis and the elementarity of that level show that $c(a)$ is the subset defined by the same formula and the collapsed parameters over $\mathfrak{G}_{c(\xi)}$. Conversely, given a formula and parameters at the collapsed level, lift the parameters to the original level. The subset defined there exists, is unique, and belongs to Y by elementarity. Its collapse is the required subset. This proves both inclusions at the successor stage without introducing a uniform truth predicate.

For a limit $\lambda \in Y \cap \Theta$, elementarity supplies, for every $x \in Y \cap \mathfrak{G}_\lambda$, a witness $\xi \in Y \cap \lambda$ with $H_\Theta(\xi, x)$. Therefore,

$$Y \cap \mathfrak{G}_\lambda = \bigcup_{\xi \in Y \cap \lambda} (Y \cap \mathfrak{G}_\xi), \qquad c\text{“}(Y \cap \lambda) = c(\lambda).$$

Continuity of the hierarchy and the induction hypothesis give (43a) at the limit. Cofinality of $Y \cap \lambda$ in the ambient ordinal λ is not required: its collapsed indices range over $c(\lambda)$.

Finally, every $x \in Y$ has a witness $\xi \in Y \cap \Theta$ with $H_\Theta(\xi, x)$, and $\bar{\Theta}$ is a limit. Taking unions,

$$M = \bigcup_{\eta < \bar{\Theta}} \mathfrak{G}_\eta(h, m_\infty) = \mathfrak{G}_{\bar{\Theta}}(h, m_\infty).$$

Since $c(r) = r \in M$, it follows that $r \in \mathfrak{G}_{\bar{\Theta}}$ with $\bar{\Theta} < \omega_1^{\mathfrak{G}}$. □

The lemma does not say that a finite-length prefix enumerates the line. It says that each generated hereditary object has a first transfinite level and a first genealogical code within that level. This is precisely the information that the extensional reduct loses when it retains only the published value.

19.10.4 Injection of the generated line into the first uncountable ordinal of the genealogical closure

Let $\iota(r) \subseteq \omega$ be the rational cut of $r \in \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$ relative to the enumeration of $\mathbb{Q}_{\mathrm{HMT}}$ previously constructed from APP integers and quotients. The map $r \mapsto \iota(r)$ is definable from r and that enumeration, so $\iota(r) \in \mathfrak{G}$; Lemma 19.26 places it at a stage with countable index. Define

$$\begin{aligned} \beta(r) &:= \min\{\beta : \iota(r) \in \mathfrak{G}_{\beta+1}(h, m_\infty)\}, \\ n(r) &:= \min\{n : e_{\beta(r)+1}(n) = \iota(r)\}, \\ j_{\mathrm{HMT}}(r) &:= \omega \cdot \beta(r) + n(r). \end{aligned} \tag{44}$$

Definition (44) is uniform in the parameters h, m_∞. Since $\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$ is a set of $\mathfrak{G}$, Separation fixes the domain of the definition, and Replacement in $\mathfrak{G}$ forms its graph:

$$\{\langle r, \omega \cdot \beta(r) + n(r)\rangle : r \in \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}\} \in \mathfrak{G}.$$

Therefore, j_{HMT} is an internal function of $\mathfrak{G}$.

By Lemmas 19.25 and 19.26, $j_{\mathrm{HMT}}(r) < \omega_1^{\mathfrak{G}}$ for every generated real. If $j_{\mathrm{HMT}}(r) = j_{\mathrm{HMT}}(s)$, ordinal division by ω recovers the same pair (β, n); (43) recovers the same rational cut and, by completeness, $r = s$. Hence

$$j_{\mathrm{HMT}} : \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}} \hookrightarrow \omega_1^{\mathfrak{G}} \tag{45}$$

is an injection constructed from the rank and name of the HMT genealogy. Its existence uses precisely the semantic closure (37), the well-ordering of names from Lemma 19.18, and the condensation (43a); it does not receive the Continuum Hypothesis in order to choose the stage. The subsequent set-theoretic identification describes this same machinery in different notation without reversing its causal provenance.

19.10.5 Injection of the first uncountable ordinal into the line and cardinal equivalence

For every $\beta < \omega_1^{\mathfrak{G}}$, Lemma 19.25 allows a subset $w_\beta \subseteq \omega$ to encode a countable well-order of type β. To avoid confusing the empty order with the one-point order, both the domain $D \subseteq \omega$ and its strict order relation $R \subseteq D^2$ are encoded. Once a bijective pairing $\langle \cdot, \cdot \rangle : \omega^2 \to \omega$ is fixed, the code is

$$w(D, R) = \{2n : n \in D\} \cup \{2\langle a, b\rangle + 1 : (a, b) \in R\}.$$

The even bits recover the domain, and the odd bits recover the relation. Take the $<_{\mathfrak{G}}$-least real encoding such a well-order. Since the property "encodes a well-order of type β" and the global well-order are internal, Replacement forms the function $\beta \mapsto w_\beta$ within $\mathfrak{G}$. Distinct order types produce distinct codes. The ternary map, already used in (41a), is defined by

$$E(w) = \sum_{n \geq 0} \frac{2\mathbf{1}_w(n)}{3^{2n+2}} \tag{46}$$

and is injective and avoids the endpoint of the root cylinder. The lifting (41b) ensures that $E_{\mathrm{HMT}}(w_\beta)$ belongs to the line published by an HMT history. Thus

$$k_{\mathrm{HMT}}(\beta) := E_{\mathrm{HMT}}(w_\beta), \qquad k_{\mathrm{HMT}} : \omega_1^{\mathfrak{G}} \hookrightarrow \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}. \tag{47}$$

The injections (45) and (47), constructed without using the equality sought, give by Cantor–Bernstein

$$\left|\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}\right| = \aleph_1^{\mathfrak{G}}. \tag{48}$$

Since (41c) identifies the complete HMT line with $\mathcal{P}^{\mathfrak{G}}(\omega)$, (48) rewrites exactly as

$$\boxed{\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) \models 2^{\aleph_0} = \aleph_1.} \tag{49}$$

The equality does not arise from 729, from an informal product of cardinality and ordinality, from the digits of a constant, or from a numerical bracket. It arises from the covering of the line by the inverse limit, the condensation of the genealogical closure, and the two explicit injections.

19.10.6 Quantification over all internal subsets

Let $A \in \mathcal{P}^{\mathfrak{G}}(\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}})$. If A is countable, the first alternative holds. If it is not, $j_{\mathrm{HMT}}[A]$ is an uncountable subset of $\omega_1^{\mathfrak{G}}$. It cannot be bounded by a countable ordinal, since every initial segment of ω_1 is countable. Its increasing enumeration has order type $\omega_1^{\mathfrak{G}}$, and the inverse of j_{HMT} on its image produces an injection $\omega_1^{\mathfrak{G}} \hookrightarrow A$. The inclusion $A \subseteq \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$, (48), and Cantor–Bernstein give

$$\boxed{\forall A \in \mathcal{P}^{\mathfrak{G}}(\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}), \qquad |A| \leq \aleph_0 \quad \text{or} \quad |A| = \left|\mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}\right|.} \tag{50}$$

Here the full power set of the integral continuum generated by HMT is quantified. The bijective transport of the folding with memory carries (50) to any of its representations without losing parts; it does not replace the injections (45)–(47).

19.10.7 Representation of the genealogical closure as $L[h, m_\infty]$

Only after (49)–(50) is the construction in (36) assigned its name in the usual set-theoretic notation. Let $L[u_{h,m}]$ be the constructible hierarchy relative to the real already produced in (33a). Since the HMT signature is countable and all its operators are graph relations encoded by h, Lemma 19.16 eliminates its symbols uniformly. This yields the equality of classes

$$\mathfrak{G}_{\mathrm{HMT}}(h, m_\infty) = L[u_{h,m}] = L[h, m_\infty]. \tag{51}$$

To prove the first inclusion, strengthen the induction: for every ordinal β, both $\mathfrak{G}_\beta$ and the sequence $\langle \mathfrak{G}_\xi : \xi \leq \beta \rangle$ belong to $L[u_{h,m}]$. The base is the transitive closure of a set constructed from ω and $u_{h,m}$; the parameters h, m_∞ are recovered from $u_{h,m}$. At a successor, the preceding level is an *internal set*, not merely a subclass of $L[u_{h,m}]$. Its satisfaction relation and the uniform elimination (37c) make it possible to form internally the set of its definable subsets. At a limit, transfinite recursion, Replacement, and Union in $L[u_{h,m}]$ form the preceding sequence and its union. Transitivity then gives $\mathfrak{G} \subseteq L[u_{h,m}]$.

Conversely, Lemma 19.18 supplies an internal transitive model of ZF, containing all ordinals and $u_{h,m}$ as an element. The recursion constructing $L[u_{h,m}]$ is carried out in that model: at every stage, satisfaction over the preceding level and relative definability are absolute between the two transitive domains. By induction, its levels coincide with those of the ambient construction and belong to $\mathfrak{G}$. Thus $L[u_{h,m}] \subseteq \mathfrak{G}$. Finally, (33a) makes $u_{h,m}$ and the pair (h, m_∞) primitive-recursively interdefinable, from which the second equality follows.

Equation (51) explicitly identifies closure with the constructible hierarchy relative to the generated parameter. This representation does not modify causal provenance: $L[u]$ neither selects the genealogical register nor defines the prolongations or the line; the decision of the continuum hypothesis follows from the exhaustiveness rule and the proved maps between (36) and (50). The composition (33a), (36), (37d) and (49)–(51), together with theorem 19.27, provides a complete and uniform expression of the realized universe, semantic coincidence and cardinal closure; none of these representations replaces APP–TRIT–TPK generation.

19.10.8 Theorem giving an affirmative resolution of the Continuum Hypothesis

Theorem 19.27 (Decision of the continuum in HMT)**.** *For every realized history m_∞ produced by the joint action* APP $\to$ TRIT $\to$ TPK $\to X_\infty^{\mathrm{enr}} \to C_{\mathrm{cont}}^{\mathrm{disc}}$*, the HMT genealogical extension* (36) *generates the internal reconstruction of the integral line* (40)*, $\mathbb{R}_{\mathrm{HMT}}^{\mathfrak{G}}$, constructs the injections* (45) *and* (47)*, and satisfies $2^{\aleph_0} = \aleph_1$ over its entire internal power set. Therefore, HMT proves the Continuum Hypothesis affirmatively for the integral continuum that it defines and generates. The notation $L[h, m_\infty]$ is a subsequent representation of that hierarchy, not the premise deciding the result.*

19.10.9 Falsification criteria for the cardinal closure

The following list identifies failures that would invalidate a step of the preceding closure. Construction, semantic, and cardinality controls are distinguished:

1. there exists a level N or a surviving state without a compatible successor in (34);
2. $u_{h,m}$ does not hereditarily encode h, m_∞, or some graph relation of Σ_{HMT} does not admit the uniform elimination (37c);
3. an object admitted by the HMT semantic rules has no term in (37a), or a term of (37a) publishes an object outside those rules, breaking (37d);
4. $\mathfrak{G}$ does not satisfy one of the axioms used, its definable well-order fails, or a purported enumeration e_β is not internal and uniform;
5. the subcylinders in (40a) do not form an exhaustive disjoint partition, their cylinders cease to contract, or the recursion ($41b_0$) does not produce an internal compatible history;
6. the collapse in Lemma 19.26 does not commute with a successor or limit stage, or there exists an internal real that appears in no level with index smaller than $\omega_1^{\mathfrak{G}}$;
7. the selection $\beta \mapsto w_\beta$ is not internal or uniform, or does not preserve order type;
8. two distinct reals have the same genealogical pair (β, n) in (44), two distinct ordinals produce the same code in (47), or one of the injections $E, C, j_{\mathrm{HMT}}, k_{\mathrm{HMT}}$ fails;
9. there exists an uncountable internal subset of the line whose range under j_{HMT} is bounded in $\omega_1^{\mathfrak{G}}$;
10. some generative stage preceding the covering (40a) uses the Continuum Hypothesis, $\mathbb{R}$, a target constant, the Committee on Data of the International Science Council (CODATA), the Particle Data Group (PDG), or a subsequent physical identification as a causal antecedent to define a seed, a relation $\mathscr{L}_\tau$, Ext, a coefficient, admissibility, or an extension of the tree. The subsequent lift ($41b_0$) does not constitute such an inversion: there an arbitrary already constructed real is a universal variable and selects, within the previously proved exhaustive partition, the unique subcylinder containing it.

No execution restricted to a preset number of levels replaces the universal quantifier of the inverse system; an effective failure of compatibility at some depth would falsify it. No subsequent set-theoretic notation proves (49) by itself. The closure jointly uses Lemma 19.18, the line–power-set identification in (41c), Lemmas 19.25–19.26, and the two injections constructed from the genealogy.

19.11 Phase, dodecaphase register, and exceptional realization of the common state

The theorem in Section 19.10 decides the cardinal question within the complete HMT state. The constructions that follow are not a separable ontological appendix: they make explicit correlated coordinates of the same enriched state. The dual projection preserves complementary information: Archimedean value in one branch, and incidence, boundary, and genealogy in the other.

The holonomy Γ_9 composes nine updates U_t on the enriched state. The reduced kernel $\mathcal{K}_{\mathrm{ph}}$ is a subsequent publication on already constructed emissions that preserves reduced phase and memory:

$$U_t \longrightarrow \Gamma_9 \longrightarrow \mathcal{K}_{\mathrm{ph}}, \qquad g(k+9) = g(k), \quad q_{\mathrm{mem},k+9} = q_{\mathrm{mem},k} + 1, \quad \widehat{x}_{k+9} \neq \widehat{x}_k.$$

The phase returns, the memory advances, and the state is not reset. By contrast, the integral dodecaphase seal is constructed through the signed reader and the Hadamard transform:

$$\mathcal{S}_{12}\ (= R_{\mathrm{sgn}}) : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}} := \operatorname{im} \mathcal{S}_{12}, \qquad U_{\mathrm{term}} \in \mathcal{U}_{12}^{\mathrm{sgn}}, \qquad K := \frac{1}{4}\mathcal{H}_{12} U \in \mathbb{Z}^{12}.$$

The coordinate U_{term} is obtained from the enriched state by means of the oriented register and the channel readers:

$$\mathcal{S}_{12}(x_{\mathrm{term}}) = \Pi_H\Big(\mathcal{E}_{108}^{90,120}(\mathcal{R}_{12}(x_{\mathrm{term}}))\Big) = U_{\mathrm{term}}.$$

Section 11.4 develops that evaluation, the reversible obtaining of K and the transverse return to the same twenty-five channels. The serialization of C_{term} consumed by the Python checks is a verification entry point, not a mathematical generator or a restriction of the printed proof. The vector K does not by itself produce either branch. Together with the correlated publications P, E, Φ, it feeds integer closure

$$Z_m := P_m + E_m - \Phi_m - K_m, \qquad R_{N+1}(Z) := \sum_{r \geq 0} Z_{N+1+r}\, 1000^{-r-1},$$

$$c_{N+1}^{\infty} := \lfloor R_{N+1}(Z) \rfloor, \qquad s_m = Z_m + c_{m+1}^{\infty}, \qquad A_m = s_m \bmod 1000, \qquad c_m = \frac{s_m - A_m}{1000},$$

$$\big(P_{1:N}, E_{1:N}, \Phi_{1:N}, K_{1:N}; c_{N+1} = c_{N+1}^{\infty}\big)_{N \geq 1} \xrightarrow{\mathsf{T}_{\alpha,\infty}} (\alpha_N)_N \longmapsto \alpha_{\mathrm{HMT}} := \varprojlim_N \alpha_N.$$

The condition $c_{13} = 0$ belongs exclusively to the isolated execution of twelve blocks and publishes the rational $\alpha_{12}^{(0)}$. It is not the boundary of the infinite arrow: in the latter, each horizon receives the quotient determined by its signed tail; in particular, the first turn of the complete section has $c_{13}^{\infty} = -1$. The exceptional publication retains a distinct codomain:

$$B_K = \beta_{\mathrm{arq}}(K) = \{i : K_i \geq 729\}, \qquad s^{(0)} = P + E - \Phi - K,$$

$$H_\alpha^- = \eta_{\mathrm{arq}}(s^{(0)}) = \eta_{\mathrm{exc}}(B_K, P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}),$$

$$\widetilde{\mathcal{I}_*} = (B_K \subset H_\alpha^-; P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}) \longmapsto o_* = 1 \longmapsto v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12},$$

$$N_{\alpha,0} = \{x \in N(C_W) : \langle x, v_\alpha \rangle \equiv 0 \pmod 3\}, \qquad N_\alpha = N_{\alpha,0} + \mathbb{Z}\frac{v_\alpha}{3} \cong \Lambda_{24},$$

$$C_W \longmapsto N(C_W) := \bigcup_{c \in C_W} \big(A_2^{12} + \phi(c)\big) \xrightarrow{\mathrm{Nbr}_{v_\alpha}} N_\alpha \cong \Lambda_{24} \longrightarrow V^\natural \xrightarrow{\mathrm{Aut}} \mathbb{M}.$$

The scalar α_{HMT}, the face B_K, the hexad H_α^-, the vector v_α, and the lattice N_α belong to different codomains. They share provenance; they are not interchangeable objects.

Proposition 19.28 (Causal unity of the correlated publications)**.** *The objects*

$$\mathcal{K}_{\mathrm{ph}}, \quad K, \quad \pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}, \quad H_\alpha^-, \quad v_\alpha, \quad N_\alpha, \quad V^\natural$$

are not external data or retroactive selectors of the cardinal inference. They are all produced as coordinates, publications or realizations of the two projections of the unique enriched state. Cardinal comparison does not consult their conventional values as oracles, but does operate on the complete HMT structure preserving its genealogy, regions and memory.

Proof. The cardinal proof uses the inverse system of histories, the integral line, semantic closure, the ordinal classifier and the two injections within the same APP–TRIT–TPK state. No conventional digit determines those maps. In the internal constructive order, $\mathcal{K}_{\mathrm{ph}}$ factors the memory of Γ_9; the seal K is obtained reversibly from the terminal coordinate produced by $\mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12}$; the quadrirelation is published from the coinductive sections; and the flag, the vector v_α, the Leech neighbour and $V^\natural$ are obtained by the exceptional projection. The following sections provide the complete constructions and their proofs. □

In particular, the following type separations are preserved:

$$\mathcal{K}_{\mathrm{ph}} \neq K, \qquad \mathcal{H}_{12} \neq H_\alpha^-, \qquad \alpha_{\mathrm{HMT}} \neq v_\alpha \neq N_\alpha.$$

Nor is there a canonical arrow $W_{24} \to \Lambda_{24}$: the Witt design and the ternary Leech neighbor are distinct prolongations of the common code. The Monster group acts on $V^\natural$, not on decimal digits, TPK routes, or codes of α.

19.11.1 Reflection by witness closure and construction of the image

The Collection–Replacement step of Lemma 19.18 admits the following explicit proof. The hierarchy already generated from the operator code and the realized register is maintained; we abbreviate $\mathfrak{G} = \mathfrak{G}_{\mathrm{HMT}}(h, m_\infty)$. The argument uses Separation and Replacement in the ambient metatheory, without presupposing these schemas in $\mathfrak{G}$.

Let Φ be a finite collection of formulas. First translate their universal quantifiers using negation and existential quantification, and close the resulting collection under subformulas. For every initial level there is a later limit ordinal θ such that

$$\mathfrak{G}_\theta \models \varphi(\bar{a}) \quad \Longleftrightarrow \quad \mathfrak{G} \models \varphi(\bar{a}) \qquad (\varphi \in \Phi,\ \bar{a} \in \mathfrak{G}_\theta^{<\omega}).$$

For each fixed formula, satisfaction in the class is interpreted by relativizing its quantifiers to the definable class $\mathfrak{G}$; no uniform truth predicate is introduced.

Proof. Fix α. For each existential subformula $\exists y\, \psi(y, \bar{x})$ of Φ, the tuples $\bar{a} \in \mathfrak{G}_\alpha^{<\omega}$ of the corresponding arity that have a witness in $\mathfrak{G}$ form a set by Separation in the metatheory. Assign to each tuple the least ordinal β for which some $y \in \mathfrak{G}_\beta$ satisfies $\mathfrak{G} \models \psi(y, \bar{a})$. This ordinal exists because $\mathfrak{G}$ is the union of its levels. Replacement in the metatheory bounds these first stages of witnesses. Since Φ is finite, a single bound $f(\alpha) > \alpha$, valid for all its existential subformulas, can be chosen definably. Thus every tuple under consideration has *at least one witness* in $\mathfrak{G}_{f(\alpha)}$.

Take α_0 large enough to contain the initial parameters and set

$$\alpha_{n+1} = f(\alpha_n), \qquad \theta = \sup_{n<\omega} \alpha_n.$$

By continuity of the hierarchy, every finite tuple from $\mathfrak{G}_\theta$ belongs to some $\mathfrak{G}_{\alpha_n}$. If an existential formula of Φ with that tuple is true in $\mathfrak{G}$, it has a witness in $\mathfrak{G}_{\alpha_{n+1}} \subseteq \mathfrak{G}_\theta$. Induction on formulas now proves the equivalence: atomic formulas are preserved in the induced structure; connectives preserve the equivalence; the existential step uses that witness in one direction and the same witness, viewed in $\mathfrak{G}$, in the other. The prior translation of universal quantifiers also includes the existential formulas expressing their possible counterexamples. This proves the required finite reflection. □

Now let $F(x, y, \bar{p})$ be functional on a in $\mathfrak{G}$. Apply the construction to the formulas expressing F, the existence of its witnesses, and its image, with $a, \bar{p} \in \mathfrak{G}_\theta$. Transitivity gives $a \subseteq \mathfrak{G}_\theta$. Every $x \in a$ has its value within that level, and reflection identifies the exact image as

$$b = \{y \in \mathfrak{G}_\theta : \mathfrak{G}_\theta \models \exists x \in a\, F(x, y, \bar{p})\}.$$

This set is definable over $\mathfrak{G}_\theta$, with parameters from the same level. By the successor operation of the hierarchy, $b \in \mathrm{Def}(\mathfrak{G}_\theta) \subseteq \mathfrak{G}_{\theta+1}$. This establishes Replacement in $\mathfrak{G}$. If the existence of witnesses is retained and uniqueness is omitted, the same construction provides a set of witnesses for Collection.

Arity of names and internal selection. In the well-order of Lemma 19.18, the enumeration of the base assigns to each element its least natural-number code. At each successor stage, formula codes are ordered first; once a code is fixed, the arity of its parameter tuple is fixed. Lexicographic order is then applied to a *finite product of fixed arity* of the previously constructed well-orders. The least name represents each new value, and limit levels retain the order of first appearance. This specifies the ordering of tuples without combining different arities into a single lexicographic order. Selecting the least element of every nonempty set, together with Replacement already established, forms internally the choice functions used subsequently. This construction of names precedes the cardinal injections and receives no bijection of the continuum as data.

19.11.2 Compatibility of the cardinal classifier with the restoration of histories

Proposition 154.3 constructs, from finite invertible readers compatible with truncation, a bijection $q : H \to Y$ between the limit of enriched histories and the limit of their recoverable registers. Its domain preserves the system of levels, the operations and the memory. The cardinal argument additionally uses the Archimedean reading $p : H \twoheadrightarrow R$, where $R = \mathbb{R}^{\mathfrak{G}}_{\mathrm{HMT}}$. A history and its published value are distinct objects: the fibers of p gather the enriched realizations of the same value.

Proposition 19.29 (Internal transport of fibers and conservation of the ordinal code)**.** *Fix the closure $\mathfrak{G}$ of section 19.10. Suppose the sets H, Y, R, the bijection q, the surjection p and their defining systems belong to $\mathfrak{G}$. Define*

$$\widetilde{p} = p \circ q^{-1} : Y \longrightarrow R, \qquad \mathcal{S}(A) = q[p^{-1}(A)] \quad (A \in \mathcal{P}^{\mathfrak{G}}(R)).$$

Then $\mathcal{S}$ is an isomorphism between $\mathcal{P}^{\mathfrak{G}}(R)$ and the algebra of internal subsets of Y saturated for $\widetilde{p}$. One has

$$\mathcal{S}(A) = \widetilde{p}^{-1}(A), \qquad \widetilde{p}[\mathcal{S}(A)] = A, \qquad (j_{\mathrm{HMT}} \circ \widetilde{p}) \circ q = j_{\mathrm{HMT}} \circ p.$$

The restriction $q : p^{-1}(A) \to \mathcal{S}(A)$ is bijective. The classifier j_{HMT} of (44) preserves its code when changing recoverable register and maintains the dichotomy (50) for the values of A.

Proof. Separation forms the inverse graph of q within $Y \times H$. Replacement, already obtained by witness closure, forms the compositions and images used. For each $y \in Y$, uniqueness of $q^{-1}(y)$ gives

$$y \in q[p^{-1}(A)] \iff p(q^{-1}(y)) \in A \iff y \in \widetilde{p}^{-1}(A).$$

The surjectivity of p and the bijection q prove $\widetilde{p}[\widetilde{p}^{-1}(A)] = A$. If $B \subseteq Y$ is saturated, by definition $B = \widetilde{p}^{-1}(\widetilde{p}[B])$, so B belongs to the image of $\mathcal{S}$. Preimages preserve unions, intersections and relative complements; the surjectivity of $\widetilde{p}$ makes that operation injective. This proves the isomorphism of subset algebras. The restriction of q is bijective because q is bijective on its complete domain.

Finally, $\widetilde{p} \circ q = p$, and composition with j_{HMT} gives the declared square. The functions e_β, condensation and ordinal codes are constructed within the same closure by Lemmas 19.25 and 19.26; equality (48) and the dichotomy (50) apply to A in that domain. The classification of values is thus transported while preserving all their enriched fibers. □

The result distinguishes the two bijections involved: restoration acts between histories and registers; cardinal classification acts on the published values. Saturation relates both levels without selecting a single history per value. Witness reflection guarantees the internal formation of the maps in the argument and the preservation of the quantifiers of the declared closure.

Chapter 20

Dodecaphasic–Witt intertwiner: point–hexad incidence, reduction 11→3→1, residual S_3 action and obstruction to triple equivariance

20.1 Dodecaphase–Witt intertwining and the exact reading of $3/11$

The repeated appearance of quotient $3/11$ on the dodecaphasic screen, in the polarity of a Witt star, and in nonadic filtration raises a question stronger than the arithmetic equality of three fractions. The correct question is operatorial: to determine whether those three appearances are traces of the same positive sector viewed in different realizations and, if they are, to construct the maps intertwining them without introducing a subsequent metrological datum.

The answer has four levels. First, point–hexad incidence constructs a canonical isometry between the eleven-dimensional dodecaphase module and an eleven-dimensional eigenspace of the Witt design. Second, the Witt star acts on that same module, but does so as a signed involution; its $3/11$ is an index, not the trace of a positive projector. Third, the oriented survival sector appears in $t = 7$, where a unique space of eleven branches contains a rank-three sector. Fourth, the orientation line of that triplet, together with the internal witnesses B_K and u_K, variationally selects a unique normalizer S_3, fixes its orientation and produces the isometric sector–dodecaphase intertwining through Reynolds averaging and polar decomposition. The dodecaphase–Witt step is a second incidence isometry. In the initial labeled gauge, the two arrows do not yet realize a single representation of S_3; the joint recalibration constructed at the end of the chapter transports the dodecad, origin, orientation, chamber and memory, and closes that equivariance without altering the fixed-labeling no-go. The Reynolds averages, representation decompositions and polar factor used in this section are the standard ones [109, 61].

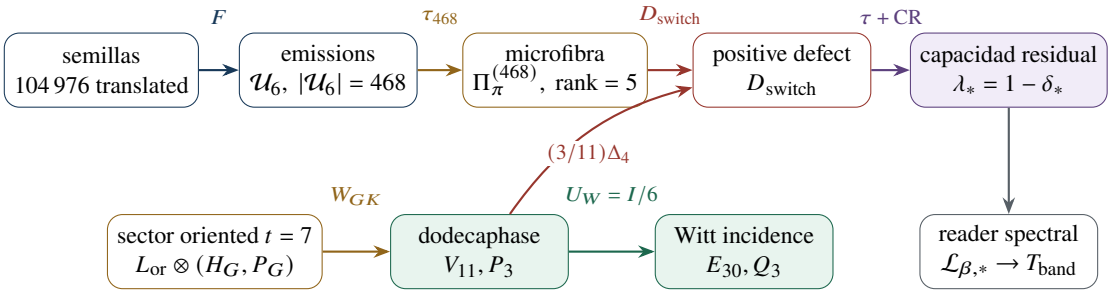

Figure 20.1: Architecture of the pre-dimensional closure. The upper row constructs the measure and action from the emission quotient; the lower row transports the oriented sector $t = 7$ to the dodecaphase and then the dodecaphase to Witt. The solid arrows are proved projector isometries. The first is fixed by the variational selection of the theorem 20.7; the second is not H_*-equivariant in the fixed gauge and becomes equivariant through the full gauge change of the theorem 20.9.

20.1.1 Typing of the objects associated with $3/11$

Let

$$V_{12} = \mathbb{R}^{12}, \qquad V_{11} = \mathbf{1}^{\perp} = \left\{ v \in \mathbb{R}^{12} : \sum_{p=1}^{12} v_p = 0 \right\}.$$

The icosahedral action declared on the twelve positions decomposes as

$$V_{12} = V_1 \oplus V_3 \oplus V_{3'} \oplus V_5.$$

Denotemos by P_3 the orthogonal projector on the first summand three-dimensional. Then

$$P_3^2 = P_3 = P_3^*, \qquad \operatorname{rank} P_3 = 3, \qquad \tau_{11}(P_3) = \frac{1}{11}\operatorname{Tr}_{V_{11}} P_3 = \frac{3}{11}.$$

There are three nearby objects and a fourth object of a different type:

1. the point–hexad incidence transports P_3 to a rank-three projector Q_3 on a Witt module;
2. survival in $t = 7$ distinguishes three branches among eleven and produces a projector P_G with normalized trace $3/11$;
3. an oriented intertwiner identifies $P_3 V_{11}$ with the oriented realization of $P_G H_G$;
4. a Witt star has seven even modes and four odd ones, so its normalized trace also equals $3/11$, but it contains negative spectrum and is not a projector.

The distinction between projector and involution will be essential to the positivity of the action law in the following section.

20.1.2 The point–hexad incidence matrix

Let $\mathcal{H}$ be the set of the 132 hexads of the design

$$W_{12} = S(5, 6, 12).$$

We define

$$I : \mathbb{R}^{12} \longrightarrow \mathbb{R}^{\mathcal{H}}, \qquad (Iv)(H) = \sum_{p \in H} v_p,$$

or, equivalently,

$$I_{H,p} = \mathbf{1}_{\{p \in H\}}.$$

This operator records only incidence. It contains no α, units, masses, CKM, Barbero, or any physical target.

Lemma 20.1 (Metric Identity of Incidence)**.** *We have*

$$\boxed{I^* I = 36 I_{12} + 30 J_{12}.}$$

Therefore, for every $v \in V_{11}$,

$$\|Iv\|^2 = 36\|v\|^2.$$

Proof. In an $S(5, 6, 12)$ system, each point belongs to

$$r = \frac{\binom{11}{4}}{\binom{5}{4}} = 66$$

hexads, and each pair of points belongs to

$$\lambda_2 = \frac{\binom{10}{3}}{\binom{4}{3}} = 30$$

hexads. The diagonal entries of $I^* I$ have value 66 and the nondiagonal entries have value 30. Hence

$$I^* I = (66 - 30) I_{12} + 30 J_{12}.$$

Since J_{12} vanishes on $\mathbf{1}^{\perp}$, the second identity is obtained. □

To identify the spectral branch selected by I, we introduce

$$G_{H,H'} = \binom{|H \cap H'|}{4}.$$

Lemma 20.2 (Spectral identity of incidence)**.** *With $J_{132,12}$ denoting the rectangular all-ones matrix,*

$$\boxed{GI = 30I + 15J_{132,12}.}$$

In particular, if $v \in V_{11}$, then

$$G(Iv) = 30Iv.$$

Proof. The entry (H, p) of GI is

$$\sum_{H' \ni p} \binom{|H \cap H'|}{4}.$$

The exhaustive census of W_{12} gives 45 when $p \in H$ and 15 when $p \notin H$. Consequently, the entry equals $30I_{H,p} + 15$. Reconstruction of the 132 hexads from the extended ternary Golay code checks the $132 \cdot 12$ entries as integers. □

Define

$$E_{30}^{\mathrm{inc}} := I(V_{11}) \subseteq \ker(G - 30I).$$

Its dimension is eleven by the lemma 20.1. The calculation modulo 1009 obtains

$$\operatorname{rank}_{\mathbb{F}_{1009}}(G - 30I) = 121.$$

Since reduction modulo 1009 gives a lower bound for the rational rank, it follows that $\dim_{\mathbb{Q}} \ker(G - 30I) \leq 11$. The preceding inclusion provides eleven linearly independent vectors in that kernel. Therefore,

$$E_{30}^{\mathrm{inc}} = \ker(G - 30I).$$

From now on we will write E_{30}.

Theorem 20.3 (Canonical dodecaphase entangler–Witt)**.** *The operator*

$$\boxed{U_W = \frac{1}{6} I\big|_{V_{11}} : V_{11} \longrightarrow E_{30}}$$

is a isometry surjective. For every $g \in \mathrm{Aut}(W_{12}) \cong M_{12}$,

$$U_W \rho_{12}(g) = \rho_{\mathcal{H}}(g) U_W.$$

Among the equivariant point–hexad kernels, the isometry condition and the positive sign on incidences uniquely determine U_W.

Proof. The isometry follows from $I^* I = 36I$ over V_{11}. Its image has dimension eleven and is contained in E_{30}, which also has dimension eleven; it is therefore surjective. Equivariance translates

$$p \in H \quad \Longleftrightarrow \quad g(p) \in g(H).$$

For uniqueness, M_{12} is transitive on the flags (p, H), with $p \in H$, and on the antiflags. Every equivariant kernel has two values, a on flags and b on antiflags:

$$T = aI + b(J - I) = (a - b)I + bJ.$$

The term J vanishes on V_{11}, so there T is a multiple of I. The isometry forces $|a - b| = 1/6$ and the positive normalization selects $a - b = 1/6$. □

20.1.3 Positive transport of the tritic projector

The entangler allows defining

$$\boxed{Q_3 = U_W P_3 U_W^*.}$$

We obtain

$$Q_3^2 = Q_3 = Q_3^*, \qquad \operatorname{rank} Q_3 = 3,$$

and the diagram

$$\begin{array}{ccc} V_{11} & \xrightarrow{U_W} & E_{30} \\ {\scriptstyle P_3}\downarrow & & \downarrow{\scriptstyle Q_3} \\ V_{11} & \xrightarrow{U_W} & E_{30} \end{array}$$

commutes. In particular,

$$\boxed{\tau_{V_{11}}(P_3) = \tau_{E_{30}}(Q_3) = \frac{3}{11}.}$$

The canonicity of U_W belongs to the labeled design and its automorphism action. It must be distinguished from the screen A_5/C_5 used to define P_3: in the constructed labeled realization, only the identity of that concrete action of A_5 preserves the fixed set of hexads. Hence U_W canonically transports the already given P_3 toward Q_3, but does not by itself convert the action A_5/C_5 into a subaction of M_{12}. The bridge to the oriented sector will be constructed separately from the marked data K and B_K.

20.1.4 Signed index of the Witt star

Let B be a tetrad. The four hexads that contain it are written

$$H_i = B \sqcup P_i, \qquad |P_i| = 2,$$

where the four petals P_i partition the complement of B. The star involution R_B fixes B and exchanges the two points of each petal. Its cycle type on twelve points is $1^4\,2^4$. In V_{11}, and by means of U_W also in E_{30}, its spectrum is

$$\operatorname{Spec}(R_B) = \{1^{[7]}, (-1)^{[4]}\}.$$

Therefore,

$$\boxed{\tau_{11}(R_B) = \frac{7-4}{11} = \frac{3}{11}.}$$

Theorem 20.4 (Obstruction projector–star)**.** *There is no isomorphism $F : V_{11} \to E_{30}$ such that*

$$FP_3 = R_B F.$$

Proof. If it existed, P_3 and R_B would be similar. However,

$$\operatorname{Spec}(P_3) = \{1^{[3]}, 0^{[8]}\}, \qquad \operatorname{Spec}(R_B) = \{1^{[7]}, (-1)^{[4]}\}.$$

Their minimal polynomials are $x(x-1)$ and $(x-1)(x+1)$, respectively. Similarity is impossible. □

The equality $3/11$ thus has two readings on the same module. For Q_3 it is the mass of a positive rank-three sector. For R_B it is a parity index. A positive action must involve Q_3; the star preserves orientation and distinguishes sheets but does not replace the projector.

20.1.5 homogeneous reduction $11 \to 3 \to 1$ in $t = 7$

The preceding reading of $3/11$ in $t = 8$ compared three local roots with eleven continuations of a single root. The numerator and denominator did not belong to the same space. The detailed table locates the correct object in $t = 7$: there are eleven local branches; all eleven survive one horizon, three survive two, and one survives three,

$$\boxed{11 \longrightarrow 3 \longrightarrow 1.}$$

index	triple of words	$h = 2$	$h = 3$
0	`200112|212221|110110`	3	0
1	`200121|212212|110110`	3	1
2	`200211|212122|110110`	3	0
3	`202122|210211|110110`	0	0
4	`202212|210121|110110`	0	0
5	`202221|210112|110110`	0	0
6	`210111|202222|110110`	0	0
7	`210222|202111|110110`	0	0
8	`212112|200221|110110`	0	0
9	`212121|200212|110110`	0	0
10	`212211|200122|110110`	0	0

Let $\mathcal{B}_7$ be the set of these eleven branches and

$$H_G = \ell^2(\mathcal{B}_7).$$

We define

$$P_G\delta_b = \begin{cases} \delta_b, & b \text{ admits continuation to horizon two,} \\ 0, & \text{otherwise.} \end{cases}$$

Then

$$P_G^2 = P_G = P_G^*, \qquad \operatorname{rank} P_G = 3, \qquad \boxed{\tau_{H_G}(P_G) = \frac{3}{11}.}$$

This is the third positive realization.

20.1.6 The residual action of S_3 and the positive regions of π

A permutation of the three final positions, applied simultaneously to the first two words of each branch and leaving the third fixed, preserves $\mathcal{B}_7$. This rule defines an action of S_3. Its orbits have sizes

$$3 + 3 + 1 + 1 + 3 = 11.$$

The support of P_G, formado by the indices $0, 1, 2$, is one orbit complete, so that P_G conmuta with S_3.

The character of the representation on the eleven branches, evaluated at the identity, a transposition, and a cycle of order three, is

$$\chi_{\mathcal{B}_7} = (11, 5, 2) = 5\chi_{\text{triv}} + 3\chi_{\text{std}}.$$

On the image of P_G,

$$\chi_G = (3, 1, 0) = \chi_{\text{triv}} + \chi_{\text{std}}.$$

The three positive regions of the microfibre of π have signatures

$$339555, \qquad 393555, \qquad 933555.$$

The tails of the first word of the three surviving branches are

$$112, \qquad 121, \qquad 211.$$

The coordinate substitution $1 \mapsto 3$, $2 \mapsto 9$ gives

branch	tail	positive region
0	112	339555
1	121	393555
2	211	933555.

Theorem 20.5 (Horizontal–vertical bridge of the positive microfiber)**.** *The preceding rule is an S_3-equivariant bijection between the three positive regions of π and the three branches selected by P_G. The map preserves the position of the unique exceptional symbol.*

Proof. Both sets are the three words obtained by placing a single exceptional symbol in one of three positions. The substitution is applied coordinate by coordinate and therefore commutes with every permutation of positions. The exceptional position uniquely recovers the source element. □

20.1.7 Dependence of orientation in the dodecaphase entangler–Witt

For any normalizer $H = N_{A_5}(C_3) \simeq S_3$ of a subgroup of order three in A_5, we define the abstract character of the quotient

$$\operatorname{sgn}_H : H \longrightarrow H/C_3 \simeq C_2 \longrightarrow \{+1, -1\}, \qquad \operatorname{sgn}_H(h) = \begin{cases} +1, & h \in C_3, \\ -1, & h \in H \setminus C_3. \end{cases}$$

This character is not the ambient sign of a permutation of five letters: every element of A_5 has ambient sign +1. It is the intrinsic character of the reflection in the quotient H/C_3. With this convention, the character of the icosahedral sector restricted to H is

$$\chi_{P_3V_{11}|H} = (3, -1, 0) = \chi_{\operatorname{sgn}_H} + \chi_{\mathrm{std}}.$$

By contrast,

$$\chi_{\operatorname{im} P_G} = (3, 1, 0) = \chi_{\mathrm{triv}} + \chi_{\mathrm{std}}.$$

Corollary 20.6 (Obstruction to the unoriented braider)**.** *There is no S_3-equivariant isomorphism*

$$\operatorname{im} P_G \longrightarrow P_3V_{11}$$

for the non-twisted actions.

Proof. Isomorphic representations have the same character. Their values on a transposition are 1 and -1. □

Let (e_0, e_1, e_2) the basis posicional of $\mathbb{R}^3_{\mathrm{perm}}$. We defines

$$L_{\mathrm{or}} = \bigwedge^3 \mathbb{R}^3_{\mathrm{perm}}, \qquad \ell_{\mathrm{or}} = e_0 \wedge e_1 \wedge e_2$$

the orientation line of the triplet, equipped with the positive anchor ℓ_{or}. The action of S_3 on this line is precisely its abstract sign character. Upon tensoring by it,

$$\chi_{L_{\mathrm{or}} \otimes \operatorname{im} P_G} = (3, -1, 0),$$

of mode that the character obstruction disappears. The equality of caracteres proves the existence of one class of isomorphisms, but aun not selects one. The selection is obtained of two witnesses already present in the dodecaphase.

20.1.8 Variational selection of the normalizer S_3

Let

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601)$$

the decimal chart of the seal. The common minimal witness of the two readings is

$$B_K = H_e \cap P_\pi = \{p : K_p \geq 729\} = \{4, 6, 9, 10\},$$

in the mathematical numbering $1, \ldots, 12$. En the equivalent convention with zero-based indices, the same set is $\{3, 5, 8, 9\}$. We define two vectors of the sector P_3:

$$b_K = P_3 \left(\mathbf{1}_{B_K} - \frac{|B_K|}{12} \mathbf{1} \right), \qquad u_K = P_3 \left(K - \overline{K}\, \mathbf{1} \right).$$

The first satisfies exactly.

$$\|b_K\|^2 = 1.$$

The group A_5 contains ten subgroups C_3. For each one, let

$$H(C_3) = N_{A_5}(C_3) \simeq S_3$$

and let be the sign projector

$$e_{\mathrm{sgn},H} = \frac{1}{6} \sum_{h \in H} \mathrm{sgn}_H(h) \rho(h).$$

Here sgn_H is the abstract character of H/C_3 defined above, not the —trivial— ambient sign of A_5. The orientation energy associated with the common witness is

$$\mathcal{E}_B(H) = \|e_{\mathrm{sgn},H} b_K\|^2.$$

The exact census in $\mathbb{Q}(\sqrt{5})$ produces a unique maximum:

$$\mathcal{E}_B(H_*) = \frac{2}{3} + \frac{2}{15}\sqrt{5}.$$

The second level is

$$\frac{1}{3} + \frac{2}{15}\sqrt{5},$$

so that the exact gap is

$$\boxed{\mathcal{E}_B(H_*) - \mathcal{E}_B(H_{\mathrm{segundo}}) = \frac{1}{3}.}$$

The same H_* is the unique maximum when b_K is replaced by u_K. Therefore, the selector does not depend on a single encoding of the witness.

In this labeling,

$$H_* = N_{A_5}\big(\langle c_* \rangle\big), \qquad c_* = (2\,3\,4).$$

The rule is natural under simultaneous relabeling by A_5: when B_K, K, and P_3 are transported, the maximum is conjugated by the same element.

20.1.9 Selection of orientation and presentation of S_3

Within of H_*, consider

$$s(g) = \langle b_K, \rho(g) u_K \rangle.$$

The maximum among the two order-three elements uniquely selects

$$c_* = (0, 1, 3, 4, 2),$$

in image notation of the permutation of five points, and the maximum among the three involutions selects

$$r_* = (1, 0, 4, 3, 2).$$

It is verified exactly.

$$r_* c_* r_* = c_*^{-1}.$$

The presentation of the oriented sector by the cycle of positions $c = (0\,1\,2)$ and the reflection $r = (0\,2)$, which fixes the central position, therefore determines a unique isomorphism

$$\theta : S_3^{\mathrm{or}} \xrightarrow{\sim} H_*, \qquad \theta(c) = c_*, \qquad \theta(r) = r_*.$$

Here S_3^{or} denotes the group of relabelings of the oriented sector $t = 7$, generated by c and r; it introduces no additional operatorial class. The only branch that reaches horizon three is precisely the central branch 1; this datum fixes which of the three positions remains fixed under reflection.

20.1.10 Reynolds average and polar factor

Let

$$W_{\mathrm{or}} = L_{\mathrm{or}} \otimes \mathbb{R}^3_{\mathrm{perm}}$$

the oriented sector triple. With the anchor already fixed, we take

$$\boxed{w = \ell_{\mathrm{or}} \otimes e_1,}$$

where e_1 represents the central position, the only one reaching horizon three. Define

$$A = \sum_{g \in S_3} \rho_{W_{\mathrm{or}}}(g)\, |w\rangle\langle b_K|\, \rho_{V_{11}}(\theta(g))^{-1}.$$

By construction,

$$A \rho_{V_{11}}(\theta(g)) = \rho_{W_{\mathrm{or}}}(g) A, \qquad A = A P_3.$$

The exact computation in $\mathbb{Q}(\sqrt{5})$ obtains

$$\operatorname{rank} A = 3.$$

Moreover, $G_A = A A^*$ has all its diagonal entries equal to

$$3 + \frac{2}{5}\sqrt{5}$$

and all its off-diagonal entries equal to

$$\frac{5}{2} + \frac{3}{5}\sqrt{5}.$$

Its two isotype eigenvalues are

$$\lambda_{\mathrm{sgn}} = 8 + \frac{8}{5}\sqrt{5}, \qquad \lambda_{\mathrm{std}} = \frac{1}{2} - \frac{1}{5}\sqrt{5}.$$

Both are strictly positive. In particular, $G_A^{-1/2}$ exists, and the polar decomposition

$$\boxed{U_{GK} = G_A^{-1/2} A}$$

is one equivariant isometry of $P_3 V_{11}$ on W_{or}:

$$U_{GK}^* U_{GK} = P_3, \qquad U_{GK} U_{GK}^* = I_{W_{\mathrm{or}}}.$$

Let

$$J_G : W_{\mathrm{or}} \longrightarrow L_{\mathrm{or}} \otimes H_G$$

the isometric inclusion in the three selected branches. Then

$$J_G J_G^* = I_{L_{\mathrm{or}}} \otimes P_G.$$

The sector–dodecaphase partial isometry is denoted

$$\boxed{W_{GK} = U_{GK}^* J_G^* : L_{\mathrm{or}} \otimes H_G \longrightarrow V_{11}}$$

satisfies

$$W_{GK}^* W_{GK} = I_{L_{\mathrm{or}}} \otimes P_G, \qquad W_{GK} W_{GK}^* = P_3,$$

and, therefore,

$$P_3 W_{GK} = W_{GK} = W_{GK}(I_{L_{\mathrm{or}}} \otimes P_G).$$

Theorem 20.7 (Relative Isometric Identification of Three Projectors)**.** *Relative to the action A_5/C_5, the projector P_3, the seal K, the doubly constructed witness B_K, the oriented finite sector $t = 7$, the abstract character sgn_{H_*}, the anchor ℓ_{or}, and the variational rule $\mathcal{E}_B$, there exists a unique normalized partial isometry W_{GK} that identifies P_G with P_3. Independently, the incidence isometry U_W identifies P_3 with Q_3. Consequently, the following chain of isometric identifications of projectors is obtained:*

$$\begin{array}{ccccc} L_{\mathrm{or}} \otimes H_G & \xrightarrow{W_{GK}} & V_{11} & \xrightarrow{U_W} & E_{30} \\ {\scriptstyle I_{L_{\mathrm{or}}} \otimes P_G}\downarrow & & \downarrow{\scriptstyle P_3} & & \downarrow{\scriptstyle Q_3} \\ L_{\mathrm{or}} \otimes H_G & \xrightarrow{W_{GK}} & V_{11} & \xrightarrow{U_W} & E_{30}. \end{array}$$

Typed traces satisfy

$$\tau_{L_{\mathrm{or}} \otimes H_G}(I_{L_{\mathrm{or}}} \otimes P_G) = \tau_{V_{11}}(P_3) = \tau_{E_{30}}(Q_3) = \frac{3}{11}.$$

The statement, in the fixed gauge, isometrically identifies three projectors; it does not yet assert that their three spaces are the same representation of a common group.

Proof. The energy $\mathcal{E}_B$ selects a unique normalizer H_*; the scoring criterion $s(g)$ selects a unique pair (c_*, r_*), and with it a unique isomorphism θ. The Reynolds average is then equivariant for the actions of S_3^{or} and H_* related by θ, and has rank three. The positive part of its polar decomposition fixes the normalization without introducing a basis. The preceding partial identities prove that W_{GK} identifies P_G and P_3. On the other hand, the theorem 20.3 identifies P_3 and Q_3 as projectors through U_W. These two operator identities make that fixed-gauge diagram commute, without extending the equivariance of the first arrow to the second there. □

Proposition 20.8 (Obstruction to triple equivariance in the fixed gauge)**.** *The preceding construction does not prove that U_W is H_*-equivariant. Under the declared labeling, the fixed action of A_5/C_5 on the twelve*

points preserves the set of hexads of W_{12} only for the identity element. Therefore, the H_*-equivariant intertwining of W_{GK} does not extend, in that gauge, to a common representation on E_{30}.

Proof. The first assertion separates equivariance domains: W_{GK} uses $H_* \subset A_5$, whereas the incidence theorem proves equivariance of U_W for $\mathrm{Aut}(W_{12})$. The exact reproducible census applies the sixty elements of action A_5/C_5 to the labeled hexad system; only the identity preserves that system. Since H_* contains six elements, its action cannot enter by restriction of that fixed action in $\mathrm{Aut}(W_{12})$. □

The preceding proposition isolates exactly the fixed gauge; it is not an abstract obstruction to transporting the calibration jointly. The governing owner of S_3–Witt recalibration constructs the equivariant monomorphism and second arrow as follows.

Theorem 20.9 (Joint H_*–Witt recalibration)**.** *Let $\bar{\rho}_{\mathrm{src}} : H_* \to S_{12}$ be the point action on the twelve cosets determined by c_*, r_* and the isomorphism θ of the oriented sector, and let ρ_{src} be its linearization on V_{11}. In the one-based image convention, the permutation*

$$\boxed{\sigma = (1,5,2,6,7,4,3,10,11,9,8,12)}$$

defines the monomorphism

$$\boxed{\iota_\sigma : H_* \hookrightarrow \mathrm{Aut}(W_{12}) \cong M_{12}, \qquad \iota_\sigma(h) = \sigma\, \bar{\rho}_{\mathrm{src}}(h)\, \sigma^{-1}.}$$

If the calibration is transported in full through

$$W_{12}^{\sigma} = \{\sigma^{-1} B : B \in W_{12}\}, \qquad \widetilde{U}_W := U_W P_\sigma,$$

where P_σ is the permutation unitary, then, under the corresponding identification of the transported incidence space with E_{30}, for every $h \in H_*$,

$$\boxed{\widetilde{U}_W\, \rho_{\mathrm{src}}(h) = \rho_{E_{30}}\big(\iota_\sigma(h)\big)\, \widetilde{U}_W.}$$

In particular,

$$\widetilde{Q}_3 = \widetilde{U}_W P_3 \widetilde{U}_W^*$$

is the Witt realization of the same projector and the chain

$$I_{L_{\mathrm{or}}} \otimes P_G \xleftarrow{W_{GK}} P_3 \xleftarrow{\widetilde{U}_W} \widetilde{Q}_3$$

carries, after identifying the source action through θ, a common representation of H_*, with the target action given by ι_σ. Recalibration jointly transports C_W, W_{12}, I, the dodecad, origin, orientation, chamber and memory; it does not consist in replacing U_W in isolation.

Proof. The exact certificate reconstructs the ternary Golay code, the 132 hexads, the group M_{12} of order 95040, the source S_3 and a semiregular target S_3, both of order six. It checks for each $h \in H_*$ that $\sigma\bar{\rho}_{\mathrm{src}}(h)\sigma^{-1} \in M_{12}$, that W_{12}^{σ} is H_*-invariant and that its point–hexad incidence is equivariant. Injectivity of ι_σ follows because it is conjugation of the faithful source action. Moreover,

$$P_\sigma \rho_{\mathrm{src}}(h) = \rho_{12}\big(\iota_\sigma(h)\big) P_\sigma.$$

Composing this identity with the M_{12} equivariance of U_W yields the boxed identity. Since P_3 commutes with H_*, its transport $\widetilde{Q}_3$ commutes with $\iota_\sigma(H_*)$; the already proved equivariance of W_{GK} completes the composition. The same certificate verifies that the original design is not invariant under the source action, so the fixed-gauge no-go is preserved without contradiction. □

Material owner. This result is governed by theorem HMT–RDF–EXC–S3, sections 3.1–3.3 of the governing Witt–Moonshine exceptional propagation delta, and its reproducible certificate `verificar_recalibracion_s3_witt.py`, whose output is `PASS_RECALIBRACION_S3_WITT`. The status is `FORMALIZACION_NUEVA/CERTIFICADO_NUEVO`; uniqueness of the gauge change is not postulated.

Before using B_K, u_K, orientation and the polar factor, there were $10 \cdot 6 \cdot 4 = 240$ labeled maps, or 40 after identifying internal relabelings of the sector. The preceding rules reduce that set to one. This is the verifiable content of the word *canonical* for W_{GK}, within the declared rules. The common action on the Witt module comes from the explicit change σ; it is not asserted that this gauge change is unique or canonical.

The variational rule $\mathcal{E}_B$ uses only prior HMT data and fixes the class in which uniqueness is obtained. It does not identify the star involution with P_3, since their spectra remain distinct.

20.1.11 Comparison of the readings of $t = 7$ and $t = 8$

In $t = 8$ there are three local roots and eleven extensions to horizon nine of the unique root that continues. The sizes of the three fibers are

$$(11, 0, 0).$$

The natural branch–chain matrix has one row of eleven ones and two zero rows, so its rank is one. In $t = 9$, moreover, the visible quotient changes from $3/11$ to $3/6$. That fraction was not the trace of a stable projector. The correction does not eliminate the sector: it shifts the reading to the homogeneous object P_G of $t = 7$, where rank and dimension belong to the same space.

20.1.12 Positivity of the Action Induced by the Dodecaphasic Braider–Witt

The law of action may u now a unique class isometric of projectors positive in tris spaces of support:

$$P_G \xleftarrow{W_{GK}} P_3 \xleftarrow{U_W} Q_3.$$

The star R_{B_K} remains reserved for parity and orientation. The projector P_G records survival; P_3 records dodecaphase polarization; Q_3 records its incidence realization in Witt. This separation of functions is the mathematical premise of the measure and of the positive law in the next section. In the fixed gauge the chain expresses isometric equivalence of projectors without a common representation. The theorem 20.9 transports the complete calibration and turns the chain with $\widetilde{U}_W$ and $\widetilde{Q}_3$ into a common representation of H_*, without identifying the signed star with the positive projector.

20.2 Equivariant realization of the angular reader in Witt incidence

The angular chart and exceptional incidence preserve different information from the same APP–TRIT–TPK development. The former expresses rotation coordinates; the latter preserves relations between positions, supports and orientations. Comparing them requires a transport that preserves these relations and allows the complete coordinates to be recovered. We construct that transport here and prove its compatibility with oriented permutations of the regional triplet.

The antecedents of the composition are the dodecaphasic seal K, its marked face B_K, the sector of the three-dimensional isotypic projector P_3^{ico}, the compatible branches of the nonadic filtration and the sectorial system of Definition 16.43. Each enters with its structure, not merely through its scalar value. The real vector spaces of this subsection are subsequent realizations of those already expressed sectors. Generating the seal, transporting its coordinates and evaluating the reader correspond to distinct stages of the causal composition.

20.2.1 Regional triplet and orientation line

Let V be the counting space of the three positive regions of π_{HMT}, with ordered orthonormal basis

$$(v_1, v_2, v_3) = (933555, 393555, 339555).$$

The notation identifies each basis vector with the region it represents. In the prolongation window of index seven, the eleven admitted branches are distributed into orbits of sizes $3+3+1+1+3$ under simultaneous permutation of the final three positions of the first two words. The sector retaining continuation to horizon two consists of

branch	triple of words	positive region
0	200112 | 212221 | 110110	339555
1	200121 | 212212 | 110110	393555
2	200211 | 212122 | 110110	933555.

The central branch additionally extends to horizon three. These horizons belong to the same filtration of compatible prolongations; the successive support cardinalities are 11, 3, and 1.

The map from the tail of the first word to the positive region substitutes $1 \mapsto 3$ and $2 \mapsto 9$ coordinatewise and adds the regional tail 555. It therefore preserves the position of the exceptional symbol and commutes with every permutation of the three positions. The branch order is $(339555, 393555, 933555)$; the change from the order of V is the permutation $R = (1\,3)$.

The orientation line of V is $o(V) = \det V$. The map

$$\Psi : \Lambda^2 V \longrightarrow \mathrm{Hom}(V, \det V), \qquad \Psi(u \wedge v)(w) = u \wedge v \wedge w \tag{20.1}$$

is identified through the counting metric with an isometry $\Lambda^2 V \to o(V) \otimes V$. For $\omega = v_1 \wedge v_2 \wedge v_3$, its values on the exterior basis are

$$v_1 \wedge v_2 \mapsto \omega \otimes v_3, \qquad v_2 \wedge v_3 \mapsto \omega \otimes v_1, \qquad v_1 \wedge v_3 \mapsto -\omega \otimes v_2.$$

In angular order $(12, 23, 13)$, joint transport of basis and orientation has matrix

$$D = \det(R) P_R \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & -1 \\ 1 & 0 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}. \tag{20.2}$$

Thus $D(\theta_{12}, \theta_{23}, \theta_{13})^{\mathsf{T}} = (-\theta_{12}, \theta_{13}, -\theta_{23})^{\mathsf{T}}$. Throughout this section, $P_p e_j = e_{p(j)}$ defines the permutation-matrix convention, and the asterisk denotes the adjoint for the declared counting metrics.

Proposition 20.10 (Naturality of the oriented identification)**.** *For every $p \in S_3$,*

$$D \Lambda^2 P_p = \det(p) P_{RpR^{-1}} D, \qquad D^* D = I_3.$$

Proof. The identity $(P_p u) \wedge (P_p v) \wedge (P_p w) = \det(p)(u \wedge v \wedge w)$ proves naturality of (20.1). Simultaneous change of regional order introduces conjugation by R. Finally, the columns of D are signed coordinate vectors, whence $D^* D = I_3$. □

The orientation line explains the difference between the character $(3, 1, 0)$ of the position triplet and the character $(3, -1, 0)$ of the oriented triplet, on the identity, transposition, and order-three cycle classes. The three transpositions provide an explicit control: omitting the determinant factor changes the sign of the preceding identity. A global change of the oriented anchor is instead transported as a joint coordinate change.

20.2.2 Dodecaphase sector and variational selection of orientation

The chart of the previously expressed seal is

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601). \tag{20.3}$$

To make its incidence realization explicit, write the ternary Paley matrix in the gauge used:

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}, \qquad C(a) = (a, aA_W), \quad a \in \mathbb{F}_3^6.$$

Support is taken on the twelve coordinates of $C(a)$. The marked intersection has the two compatible expressions

$$B_K = \operatorname{supp} C(010211) \cap \operatorname{supp} C(201101) = \{p : K_p \geq 729\} = \{4, 6, 9, 10\}. \tag{20.4}$$

The equality is evaluated by ternary multiplications of the displayed matrix. In particular, the intersection is obtained as a set of positions before its cardinality four is used.

To fix the representation of the twelve positions completely, consider A_5 acting by left multiplication on the cosets $r_p C_5$, where $C_5 = \langle (1\,2\,3\,4\,5) \rangle$. The representatives, written as image lists on $\{1, \ldots, 5\}$, are

p	r_p	p	r_p
1	(4, 3, 5, 2, 1)	7	(5, 4, 3, 2, 1)
2	(4, 2, 1, 3, 5)	8	(1, 3, 4, 2, 5)
3	(1, 2, 4, 5, 3)	9	(4, 2, 3, 5, 1)
4	(2, 5, 3, 4, 1)	10	(3, 2, 5, 4, 1)
5	(4, 3, 1, 5, 2)	11	(4, 5, 2, 3, 1)
6	(5, 1, 2, 3, 4)	12	(5, 3, 2, 4, 1).

Denote this permutation representation by ρ, and put $V_{11} = \mathbf{1}^{\perp} \subset \mathbb{R}^{12}$. The icosahedral three-dimensional isotypic projector is determined by

$$P_3^{\mathrm{ico}} = \frac{3}{60} \sum_{a \in A_5} \chi_3(a^{-1}) \rho(a), \tag{20.5}$$

where the values of χ_3 on classes of types $1, 2^2, 3, 5_a, 5_b$ are

$$\left(3, -1, 0, \frac{1+\sqrt{5}}{2}, \frac{1-\sqrt{5}}{2}\right).$$

Class 5_a contains $(1\,2\,3\,4\,5)$, and class 5_b contains its square. This convention distinguishes the two three-dimensional summands. The superscript ico identifies this component of the A_5 representation; the cyclic projector P_3 entering (14.86) acts on twelve-position transport with its own definition. Finite evaluation of (20.5) satisfies $P_3^{\mathrm{ico}} = (P_3^{\mathrm{ico}})^{*} = (P_3^{\mathrm{ico}})^2$, $P_3^{\mathrm{ico}} \mathbf{1} = 0$, and $\operatorname{Tr} P_3^{\mathrm{ico}} = 3$.

The two marked vectors of the sector are

$$b = P_3^{\mathrm{ico}} \left(\mathbf{1}_{B_K} - \frac{1}{3} \mathbf{1} \right), \qquad u = P_3^{\mathrm{ico}} (K - \overline{K} \mathbf{1}), \qquad \overline{K} = \frac{1}{12} \sum_{p=1}^{12} K_p, \qquad \|b\|^2 = 1.$$

For each of the ten order-three subgroups $C_3 \subset A_5$, let $H = N_{A_5}(C_3) \cong S_3$. The character sgn_H takes value +1 on C_3 and −1 on $H \setminus C_3$. It is the character of the quotient H/C_3, whereas the ambient sign of elements of A_5 is always positive. Define

$$e_{\mathrm{sgn},H} = \frac{1}{6}\sum_{a\in H} \mathrm{sgn}_H(a)\rho(a), \qquad \mathcal{E}_B(H) = \|e_{\mathrm{sgn},H} b\|^2. \tag{20.6}$$

Proposition 20.11 (Normalizer and orientation determined by the seal)**.** *The maximization rule of* (20.6) *selects a unique normalizer H_*. Its energy and the second distinct energy are*

$$\frac{2}{3} + \frac{2\sqrt{5}}{15}, \qquad \frac{1}{3} + \frac{2\sqrt{5}}{15},$$

respectively; the gap is $1/3$. Projection of u selects the same normalizer. Within H_*, maximizing $s(a) = \langle b, \rho(a)u\rangle$, separately among order-three elements and involutions, determines

$$c_* = (1,2,4,5,3), \qquad r_* = (2,1,5,4,3)$$

in image notation on five points. The identity $r_* c_* r_* = c_*^{-1}$ holds.

Proof. Evaluation of the preceding finite sums in $\mathbb{Q}(\sqrt{5})$ gives the following distribution of the ten energies:

energy	multiplicity	energy	multiplicity
$2/3 + 2\sqrt{5}/15$	1	$2/3 - 2\sqrt{5}/15$	1
$1/3 + 2\sqrt{5}/15$	2	$1/3 - 2\sqrt{5}/15$	2
$1/6 + \sqrt{5}/30$	2	$1/6 - \sqrt{5}/30$	2.

The greatest belongs to the subgroup generated by c_*. The next is obtained by subtracting $1/3$. The same evaluation with u has a unique maximum at that subgroup, of value $2526869/12 + 2813609\sqrt{5}/30$. The scores of the two cycle orientations are

$$s(c_*) = \frac{1341}{4} + \frac{2409\sqrt{5}}{20}, \qquad s(c_*^{-1}) = \frac{357}{2} + \frac{1853\sqrt{5}}{10}.$$

Their difference is $627/4 - 1297\sqrt{5}/20 > 0$, as is checked by comparing positive squares. The scores of the three involutions are

list of images	$s(a)$
$(2,1,3,5,4)$	$-1341/4 - 2409\sqrt{5}/20$
$(2,1,4,3,5)$	$-1659/4 - 2667\sqrt{5}/20$
$(2,1,5,4,3)$	$-357/2 - 1853\sqrt{5}/10.$

The unique maximum corresponds to r_*. Composition of the two image lists verifies the dihedral relation. All these operations use K, B_K, P_3^{ico}, and the finite actions already specified. □

Write $\vartheta : S_3 \to H_*$ for the isomorphism determined by $\vartheta((1\,2\,3)) = c_*$ and $\vartheta((1\,3)) = r_*$. The position reflection fixes the central branch reaching horizon three. This orientation completes regional identification before any angle evaluation.

20.2.3 Reynolds intertwiner and polar normalization

In the branch basis, let $\rho_o(g) = \det(g)P_g$ and $w = (0,1,0)^{\mathsf{T}}$. The Reynolds operator defined by summation over the group is

$$A_R = \sum_{g\in S_3} \rho_o(g)\,|w\rangle\langle b|\,\rho(\vartheta(g))^{-1}. \tag{20.7}$$

The symbol A_R distinguishes this operator from the angle $A_{\deg}$. Each summand has unit scale; metric normalization is performed through its polar factor.

Proposition 20.12 (Polar isometry of the oriented sector)**.** *The following hold*

$$A_R = A_R P_3^{\mathrm{ico}}, \qquad \rho_o(g)A_R = A_R\rho(\vartheta(g)), \qquad G = A_R A_R^* > 0, \qquad A_R^* G^{-1} A_R = P_3^{\mathrm{ico}}.$$

With $E = \mathbf{1}\mathbf{1}^{\mathsf{T}}/3$*,*

$$G = \lambda_s E + \lambda_t (I_3 - E), \qquad \lambda_s = 8 + \frac{8\sqrt{5}}{5}, \quad \lambda_t = \frac{1}{2} - \frac{\sqrt{5}}{5} > 0. \tag{20.8}$$

Consequently,

$$U_{GK} = G^{-1/2}A_R : P_3^{\mathrm{ico}} V_{11} \longrightarrow o(V)\otimes V$$

is a surjective isometry: $U_{GK}^* U_{GK} = P_3^{\mathrm{ico}}$ *and* $U_{GK}U_{GK}^* = I_3$*.*

Proof. The projector P_3^{ico} commutes with ρ, and $b = P_3^{\mathrm{ico}} b$; hence $A_R = A_R P_3^{\mathrm{ico}}$. Reindexing the Reynolds sum proves equivariance. Multiplication of the finite sum gives diagonal entries $3 + 2\sqrt{5}/5$ and off-diagonal entries $5/2 + 3\sqrt{5}/5$ in G. The projections E and $I_3 - E$ give (20.8). Both eigenvalues are positive; for the smaller, $25 > 20$ suffices. Thus A_R has rank three. Its row space is contained in the rank-three sector of P_3^{ico}, and equals it. The orthogonal projector onto that row space is $A_R^*(A_R A_R^*)^{-1}A_R$, giving the final identity. The two polar-factor equations follow by substitution. □

The positive root preserves equivariance because both spectral projectors commute with the oriented representation. Uniqueness of the polar factor pertains to the Reynolds operator and orientation determined by the preceding rules.

20.2.4 Point–hexad incidence and joint gauge change

Let $\mathcal{W}$ be the design $S(5,6,12)$ of 132 hexads obtained from the weight-six supports of the ternary code $C(a)$. The incidence matrix is

$$I_{H,p} = \mathbf{1}_{p\in H}, \qquad (Iz)_H = \sum_{p\in H} z_p.$$

The blocks are reconstructed by enumerating $a \in \mathbb{F}_3^6$, retaining weight six, and collecting equal supports. The finite verification that each five-point subset belongs to a unique hexad fixes the design property used below.

Lemma 20.13 (Metric and spectral incidence identities)**.** *Let* J_{12} *and* $J_{132,12}$ *be the all-ones matrices indicated by their dimensions, and let*

$$(G_{\mathcal{W}})_{H,H'} = \binom{|H\cap H'|}{4}.$$

Then

$$I^*I = 36I_{12} + 30J_{12}, \qquad G_{\mathcal{W}}I = 30I + 15J_{132,12}. \tag{20.9}$$

In particular, $U_W = I/6$ *is an isometry on* $V_{11} = \mathbf{1}^{\perp}$*, with image contained in* $E_{30} = \ker(G_{\mathcal{W}} - 30I_{132})$*.*

Proof. The design property gives 66 hexads per point and 30 per pair of points:

$$\frac{\binom{11}{4}}{\binom{5}{4}} = 66, \qquad \frac{\binom{10}{3}}{\binom{4}{3}} = 30.$$

These are the diagonal and off-diagonal entries of I^*I. For the second identity, count pairs (T, H'), where $T \subset H \cap H'$, $|T| = 4$, and $p \in H'$. If $p \in H$, ten tetrads $T \subset H$ contain p, and each belongs to four hexads; the other five tetrads, adjoined to p, determine one hexad each. The result is $10 \cdot 4 + 5 = 45$. If $p \notin H$, each of the fifteen tetrads determines a hexad together with p, and the result is 15. This yields $30I_{H,p} + 15$. The all-ones matrices vanish on V_{11}, proving the isometry and spectral membership. □

The gauge change of the twelve positions is

$$\sigma = (1, 5, 2, 6, 7, 4, 3, 10, 11, 9, 8, 12), \tag{20.10}$$

written as an image list with indices starting at one. If ρ_{perm} is the point action underlying ρ, the six permutations

$$\tau_g = \sigma \rho_{\mathrm{perm}}(\vartheta(g)) \sigma^{-1}, \qquad g \in S_3,$$

preserve $\mathcal{W}$. Their two generators have image lists

$$\tau_{(123)} = (3, 6, 5, 2, 1, 4, 9, 12, 11, 8, 7, 10),$$
$$\tau_{(13)} = (2, 1, 4, 3, 6, 5, 8, 7, 10, 9, 12, 11).$$

The assertion is checked on the finite design: these two generating permutations are applied to the weight-six supports of $C(a)$, and their images are verified to run through the same 132 supports. Products of these generators give the other four permutations. The induced action Q_{τ_g} on hexads satisfies

$$IP_{\tau_g} = Q_{\tau_g} I, \qquad P_\sigma \rho(\vartheta(g)) = P_{\tau_g} P_\sigma. \tag{20.11}$$

The first identity expresses exactly the equivalence $p \in H \Longleftrightarrow \tau_g(p) \in \tau_g(H)$.

This change jointly transports positions, code, incidence, origin, chamber, and orientation of the seal. In the initial gauge, five elements of this order-six subgroup do not preserve the fixed design. Conjugation (20.10) provides the compatible gauge and maintains that control over the initial labeling. The procedure exhibits a gauge change; its uniqueness does not enter the proof.

20.2.5 Isometric composition and coordinate recovery

Theorem 20.14 (Dodecaphase–Witt angular transport)**.** *The composition*

$$\boxed{F = \frac{1}{6} I P_\sigma A_R^* G^{-1/2} D : \mathbb{R}^3_{\mathrm{ang}} \longrightarrow E_{30}} \tag{20.12}$$

is an isometry. Its coordinate action and equivariance are

$$(F\boldsymbol{\theta})_H = \frac{1}{6} \sum_{p \in H} (P_\sigma A_R^* G^{-1/2} D \boldsymbol{\theta})_p, \tag{20.13}$$

$$F X_g = Q_{\tau_g} F, \qquad X_g = \Lambda^2 P_{R^{-1} g R}. \tag{20.14}$$

Proof. The columns of A_R^* belong to $P_3^{\mathrm{ico}} V_{11}$, and P_σ preserves V_{11}. Lemma 20.13 therefore proves membership of the image of F in E_{30}. Moreover,

$$F^*F = D^* G^{-1/2} A_R P_\sigma^* \frac{I^*I}{36} P_\sigma A_R^* G^{-1/2} D$$

$$= D^* G^{-1/2} A_R A_R^* G^{-1/2} D = D^* D = I_3.$$

The coordinate formula expands multiplication by incidence. For equivariance, compose in order the naturality of D, equivariance of A_R^*, commutation of $G^{-1/2}$ with ρ_o, and the two identities of (20.11). This produces (20.14) for each $g \in S_3$. □

Proposition 20.15 (Covariance of the complete gauge)**.** *Let S, T, V_o be orthogonal coordinate changes in the dodecaphase space, Witt point space, and oriented sector, respectively. Let Q_T be the corresponding coordinate change in the incidence space; for a design relabeling, it is the induced hexad permutation. If one jointly transports*

$$A'_R = V_o A_R S^*, \quad G' = V_o G V_o^*, \quad P'_\sigma = T P_\sigma S^*,$$
$$D' = V_o D, \qquad U'_W = Q_T U_W T^*,$$

the composition satisfies $F' = Q_T F$.

Proof. Uniqueness of the positive root gives $(G')^{-1/2} = V_o G^{-1/2} V_o^*$. Substituting the five transformations into $F' = U'_W P'_\sigma (A'_R)^* (G')^{-1/2} D'$, the factors T^*T, S^*S, and $V_o^* V_o$ cancel in pairs, leaving $Q_T U_W P_\sigma A_R^* G^{-1/2} D = Q_T F$. □

The preceding covariance describes a coordinate change of all marked data. Its application to an active cardinal transformation requires the corresponding identity between actions on the state; the two notions thus preserve their own domains.

20.2.6 Faithful realization of the angular sectorial system

We use the chart x_θ of (16.56),

$$x_\theta = \begin{pmatrix} A_{\mathrm{deg}} \\ C^*_{\mathrm{deg}}/6 \\ (180/\pi_{\mathrm{HMT}})\Delta_4 \end{pmatrix}.$$

The component $h_\theta = C^*_{\mathrm{deg}}/6$ distributes the odd component of the record among six antipodal pairs. Definition 16.43 fixes the three rules

$$R_{12} = (2, -p, bq), \quad R_{23} = (0, q, -p^2/2), \quad R_{13} = (1, -pb, -(o_8 - h_6)/t)$$

for $(b, p, q, h_6, o_8, t) = (4, 5, 7, 6, 8, 3)$. The face of cardinality four, pentadic order, pivot coordinate, hexadic–octadic difference, and tritic alphabet retain distinct types. The bidirectional orbital normalization of 16.41 preserves the term $p^2/2$, including the contribution of fixed pairs.

Its evaluation, already proved in Theorem 16.44, gives

$$\mathsf{M}_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det \mathsf{M}_{\mathrm{CKM}} = -\frac{3857}{6}.$$

The transport F acts on the coordinates expressed by these rules; the preceding choice of functionals retains its place in the sectorial construction.

Corollary 20.16 (Angular reader in the incidence module)**.** *The map*

$$C = F \mathsf{M}_{\mathrm{CKM}} \tag{20.15}$$

satisfies

$$C^* C = \mathsf{M}_{\mathrm{CKM}}^* \mathsf{M}_{\mathrm{CKM}}, \qquad \mathsf{M}_{\mathrm{CKM}}^{-1} F^* C = I_3.$$

It is an isometry from the space of x_θ, equipped with metric $\mathsf{M}_{\mathrm{CKM}}^* \mathsf{M}_{\mathrm{CKM}}$, onto its image.

Proof. Substitute $F^*F = I_3$ into both products. The nonzero determinant of $\mathsf{M}_{\mathrm{CKM}}$ permits use of its inverse, displayed in (16.58). Positivity of the metric follows from $x^*\mathsf{M}_{\mathrm{CKM}}^*\mathsf{M}_{\mathrm{CKM}}x = \|\mathsf{M}_{\mathrm{CKM}}x\|^2 > 0$ for $x \neq 0$. □

The isometry F preserves the counting metric of $\boldsymbol{\theta} = \mathsf{M}_{\mathrm{CKM}}x_\theta$; its transport to coordinates x_θ gives the metric of the corollary. This distinction avoids identifying a basis of angular generators with an orthonormal basis of their parameters.

20.2.7 Exact certification and finite unitary composition

The positive roots of the polar factor can be checked through their projectors while preserving exact arithmetic. Define

$$B = \frac{1}{6} I P_\sigma A_R^* D, \qquad H = D^*GD = B^*B, \qquad L = H^{-1}B^*. \tag{20.16}$$

The identities

$$LB = I_3, \qquad L(B\mathsf{M}_{\mathrm{CKM}}) = \mathsf{M}_{\mathrm{CKM}}, \qquad \mathsf{M}_{\mathrm{CKM}}^{-1}L(B\mathsf{M}_{\mathrm{CKM}}) = I_3$$

are evaluated in $\mathbb{Q}(\sqrt{5})$. If $E_D = D^*ED$,

$$H^{-1/2} = \lambda_s^{-1/2}E_D + \lambda_t^{-1/2}(I_3 - E_D), \qquad F = BH^{-1/2}.$$

The products $E_D^2 = E_D$, $E_D(I_3 - E_D) = 0$, and the decomposition of H prove this formula without approximating its radicals. The 132 rows of B are determined by (20.13) and by the hexad construction rule. The executable certificate of this delivery preserves those rows, those of $B\mathsf{M}_{\mathrm{CKM}}$, the left inverse L, the projectors, and the labels of each hexad. Its 906 exact checks verify this composition and its orientation, incidence, and recovery identities.

Conversion to radians is performed before the trigonometric realization:

$$\boldsymbol{\vartheta} = \mathsf{M}_{\mathrm{CKM}}\begin{pmatrix} (\pi_{\mathrm{HMT}}/180)A_{\mathrm{deg}} \\ (\pi_{\mathrm{HMT}}/180)C_{\mathrm{deg}}^*/6 \\ \Delta_4 \end{pmatrix}, \qquad \delta = \frac{\pi_{\mathrm{HMT}}}{180}\,9A_{\mathrm{deg}}. \tag{20.17}$$

The finite realization preserves the order $V_{\mathrm{CKM}} = R_{23}U_{13}(\delta)R_{12}$ of (16.70). To specify the additional information of the complex phase, let E_{ab} be the elementary matrix and define

$$J_{13} = E_{13} - E_{31}, \qquad S_{13} = E_{13} + E_{31}, \qquad X_{13}(\delta) = \cos\delta\, J_{13} - i\sin\delta\, S_{13}.$$

Then $X_{13}(\delta)^* = -X_{13}(\delta)$ and $U_{13}(\delta) = \exp(\vartheta_{13}X_{13}(\delta))$. Indeed, $X_{13}(\delta)^2 = -(E_{11} + E_{33})$, and its exponential reproduces the unitary 13 block of (16.70). Exterior transport preserves the oriented generators; the symmetric imaginary component preserves phase information. The ordered product of the three finite factors maintains these two contributions and their order of composition.

20.2.8 Structural result and scope of the composition

The construction provides an equivariant isometric transport from the three angular coordinates to the Witt incidence, together with an explicit reconstruction of A_{deg}, $C_{\mathrm{deg}}^*/6$ and Δ_{deg}. It preserves the exterior orientation, the dodecaphasic sector, the marked face of the seal and the joint gauge change. In particular, the incidence realization expresses the same angular content on another support and allows its three coordinates to be recovered.

Prior generation of K, selection of the sectorial functionals, and physical identification of the amplitudes retain their own proofs. The recovery identities proved here establish faithfulness of the composition; its subsequent use keeps those antecedents explicit. The complementary development of quartic memory

planes remains another construction of the state and does not interpose itself as an additional requirement for the alignment realized in (20.12).

Chapter 21

From spectral jump 4 to the Leech lattice: APP unfolding 4→2→6→54 and the Paley–Witt–Mathieu–Golay–Niemeier corridor

21.1 From the spectral gap $4 \to 2 \to 6 \to 54$: local coupling, modular compression, and two-dimensional integration

For two consecutive representatives $(k, k+1)$, consider

$$B_k = \begin{pmatrix} k^2 & k(k+1) \\ k(k+1) & (k+1)^2 \end{pmatrix} \pmod 9.$$

Theorem 21.1 (Uniqueness of the Adjacent Diagonal Block)**.** *There is a unique block B_k whose diagonal entries coincide. It is determined by $k = 4$ and is*

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}.$$

Proof. The equality of the diagonals is equivalent to

$$k^2 \equiv (k+1)^2 \pmod 9,$$

that is, $2k + 1 \equiv 0 \pmod 9$. Since 2 is a unit of $\mathbb{Z}/9\mathbb{Z}$, the congruence has the unique solution $k \equiv 4 \pmod 9$. □

Therefore,

$$B_c = 7I + 2R, \qquad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad R^2 = I.$$

With $P_\pm = (I \pm R)/2$,

$$B_c = 9P_+ + 5P_-.$$

Theorem 21.2 (Hierarchy of the separation between sum and product)**.** *The central block has local spectral jump $9 - 5 = 4$. Its off-diagonal coefficient is 2. Compression by the 3 classes modulo 3 produces the aggregate difference $51 - 45 = 6$, and expansion over the 9 positions produces the global defect*

$$9 \cdot 6 = 459 - 405 = 54.$$

The integers $4, 2, 6, 54$ pertain, respectively, to the spectral gap, the local coupling, modular compression, and two-dimensional integration.

Proof. The decomposition $B_c = 7I + 2R = 9P_+ + 5P_-$ gives the jump and the local coefficient. The aggregated matrices M_Π, M_Σ satisfy $\sum M_\Pi = 51$ and $\sum M_\Sigma = 45$. Each aggregated entry represents 9 positions, so unfolding multiplies the difference by 9 and recovers the totals 459 and 405. □

Their ordered concatenations produce the blocks 72 and 27:

$$72 + 27 = 99, \qquad 72 - 27 = 45 = \det B_c.$$

The concatenation of the diagonal and antidiagonal entries produces, respectively, 77 and 22. Therefore,

$$72 + 27 = 77 + 22 = 99, \qquad 77 - 22 = 55 = 54 + 1.$$

These equalities express two exact partitions of the same block; they do not by themselves identify an external constant.

21.2 Paley conference form, finite quadratic extension and self-dual ternary code

The tetrad B_K constructed in the preceding unit does not yet have a Witt star: to define it, one must first construct the incidence system that contains its hexads. This unit performs that step from the projective gauge of the six units modulo nine, obtains an internal square root of $-I_6$, and constructs the ternary graph code of length twelve. No identification follows from a mere equality of cardinalities.

21.2.1 Projective gauge of the 6 units modulo 9

Let

$$\mathcal{U}_9 = (\mathbb{Z}/9\mathbb{Z})^\times = \{1, 2, 4, 8, 7, 5\},$$

ordered by the successive powers of 2 modulo 9. Fijamos the coordinate bijection

$$\theta : \mathcal{U}_9 \longrightarrow \mathbb{P}^1(\mathbb{F}_5), \qquad \begin{array}{c|cccccc} u & 1 & 2 & 4 & 8 & 7 & 5 \\ \hline \theta(u) & \infty & 0 & 1 & 2 & 3 & 4 \end{array}. \tag{21.1}$$

The map θ is a coordinate gauge. It is not asserted to be a homomorphism between multiplication in $\mathcal{U}_9$ and an operation on $\mathbb{P}^1(\mathbb{F}_5)$.

Let

$$\chi : \mathbb{F}_5 \longrightarrow \{-1, 0, 1\}$$

the quadratic character:

$$\chi(0) = 0, \qquad \chi(1) = \chi(4) = 1, \qquad \chi(2) = \chi(3) = -1.$$

In the order $(\infty, 0, 1, 2, 3, 4)$, we define

$$(C_P)_{\infty,x} = (C_P)_{x,\infty} = 1, \qquad x \in \mathbb{F}_5, \tag{21.2}$$

$$(C_P)_{x,y} = \chi(x - y), \qquad x, y \in \mathbb{F}_5, x \neq y, \tag{21.3}$$

$$(C_P)_{x,x} = 0. \tag{21.4}$$

Thus,

$$C_P = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & -1 & -1 & 1 \\ 1 & 1 & 0 & 1 & -1 & -1 \\ 1 & -1 & 1 & 0 & 1 & -1 \\ 1 & -1 & -1 & 1 & 0 & 1 \\ 1 & 1 & -1 & -1 & 1 & 0 \end{pmatrix}. \tag{21.5}$$

Lemma 21.3 (Quadratic correlation sum)**.** *For $a \neq b$ in $\mathbb{F}_5$,*

$$\sum_{t \in \mathbb{F}_5} \chi(t - a)\chi(t - b) = -1. \tag{21.6}$$

Proof. The substitution $u = (t - a)/(b - a)$ is to bijection of $\mathbb{F}_5$. Ifnce $\chi((b - a)^2) = 1$, the sum reduce to

$$\sum_{u \in \mathbb{F}_5} \chi(u(u - 1)).$$

Evaluation of $u = 0, 1, 2, 3, 4$ gives, respectively, $0, 0, 1, -1, -1$, whose sum is -1. □

Proposition 21.4 (Conference Identity)**.** *The matrix C_P is symmetric and satisfies*

$$\boxed{C_P C_P^{\mathsf{T}} = 5I_6.} \tag{21.7}$$

Proof. Each row contains five entries of modulus one and one zero entry; its squared norm is five. For two distinct finite rows, the contribution of the coordinate ∞ is $+1$, whereas lemma 21.3 gives -1 for the five finite coordinates. Their inner product is zero. The sum of a nontrivial character over $\mathbb{F}_5$ is zero, so the row corresponding to ∞ is also orthogonal to every finite row. □

21.2.2 ternary reduction and internal quadratic root of $-I_6$

We reduce C_P modulo tris, with $-1 \equiv 2 \pmod 3$:

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3). \tag{21.8}$$

Theorem 21.5 (Internal square root of $-I_6$)**.** *We have*

$$\boxed{A_W^2 = -I_6.} \tag{21.9}$$

In particular,

$$A_W^{-1} = -A_W.$$

Proof. The proposition 21.4 gives

$$A_W A_W^{\mathsf{T}} \equiv 5I_6 \equiv 2I_6 = -I_6 \pmod 3.$$

Since $A_W = A_W^{\mathsf{T}}$, $A_W^2 = -I_6$ is obtained. □

The preceding identity is the algebraic residence of the root of -1 in this corridor. No proceeds of the factor $1/4$ of the Hadamard inversion: the former is a rational scalar forced by $H_4^2 = 4I_4$; this is one quadratic structure on characteristic three.

21.2.3 Extension quadratic to $\mathbb{F}_9$

We define

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1), \qquad \iota^2 = -1. \tag{21.10}$$

The polynomial $X^2 + 1$ has no roots in $\mathbb{F}_3$, so that the quotient is a field of nine elements. For $V = \mathbb{F}_3^6$, let

$$V_9 = V \otimes_{\mathbb{F}_3} \mathbb{F}_9.$$

The operators

$$P_\iota = \frac{1}{2}(I - \iota A_W), \qquad P_{-\iota} = \frac{1}{2}(I + \iota A_W) \tag{21.11}$$

are well defined because 2 is invertible in $\mathbb{F}_3$.

Proposition 21.6 (Conjugate projectors)**.** *The following hold*

$$P_\iota^2 = P_\iota, \qquad P_{-\iota}^2 = P_{-\iota}, \qquad P_\iota P_{-\iota} = 0, \qquad P_\iota + P_{-\iota} = I.$$

Proof. Usando $\iota^2 = -1$ and $A_W^2 = -I$,

$$(\iota A_W)^2 = I.$$

The four identities are then the elementary identities for the projectors $(I \mp \iota A_W)/2$ of an involution. □

Theorem 21.7 (Conjugate spectral decomposition)**.** *Let*

$$E_{\pm\iota} = \ker(A_W \mp \iota I).$$

Then

$$V_9 = E_\iota \oplus E_{-\iota}, \qquad \dim_{\mathbb{F}_9} E_\iota = \dim_{\mathbb{F}_9} E_{-\iota} = 3. \tag{21.12}$$

Proof. The minimal polynomial of A_W divides $X^2 + 1$, which splits over $\mathbb{F}_9$ with simple roots $\pm\iota$. The projectors of proposition 21.6 produce the direct sum. Since A_W has coefficients in $\mathbb{F}_3$, the Frobenius automorphism exchanges the two eigenspaces; their dimensions are equal and sum to six. □

This construction dota $\mathbb{F}_3^6$ of istructura of modulo of rango tris over $\mathbb{F}_9$, by means of

$$(a + b\iota) \cdot v := av + b(vA_W). \tag{21.13}$$

The equality $3^6 = 9^3$ is thus accompanied by an explicit action; it is not used as a cardinal argument.

21.2.4 Ternary graph code of length 12

We define

$$c : \mathbb{F}_3^6 \longrightarrow \mathbb{F}_3^{12}, \qquad c(q) = (q, qA_W), \tag{21.14}$$

and

$$C_W := \operatorname{im} c. \tag{21.15}$$

Its generating matrix is

$$G_W = (I_6 \mid A_W).$$

Theorem 21.8 (Injectivity and self-duality)**.** *The map c is injective,* $\dim C_W = 6$ *and*

$$\boxed{C_W = C_W^{\perp}.} \tag{21.16}$$

Proof. The first half of $c(q)$ is q, so $\mathrm{pr}_1 \circ c = \mathrm{id}$; this proves injectivity and the dimension. Moreover,

$$G_W G_W^{\mathsf{T}} = I_6 + A_W A_W^{\mathsf{T}} = I_6 + 2I_6 = 0$$

in $\mathbb{F}_3$. Therefore, $C_W \subseteq C_W^{\perp}$. Both spaces have dimension six, so they are equal. □

For $r = 0, \dots, 12$, let

$$N_r := \#\{q \in \mathbb{F}_3^6 : \mathrm{wt}(q, qA_W) = r\}.$$

The enumeration of the $3^6 = 729$ entries produces

$$N_0 = 1, \qquad N_6 = 264, \qquad N_9 = 440, \qquad N_{12} = 24, \tag{21.17}$$

and $N_r = 0$ in the remaining weights.

Theorem 21.9 (Enumerator and minimum distance)**.** *The code C_W has parameters*

$$\boxed{C_W = [12, 6, 6]_3}$$

and weight enumerator

$$\boxed{W_{C_W}(y) = 1 + 264y^6 + 440y^9 + 24y^{12}.} \tag{21.18}$$

Proof. The dimension and self-duality have already been proved. The census (21.17) traverses the 729 words without sampling. Its least nonzero weight is six, which is the minimum distance of a linear code. The sum $1 + 264 + 440 + 24 = 729$ checks that no word was omitted. □

21.2.5 Algebraic classification of the self-dual ternary structure obtained

Three distinct objects and three typed arrows have been constructed:

$$\mathcal{U}_9 \xrightarrow{\theta} \mathbb{P}^1(\mathbb{F}_5) \xrightarrow{\chi} C_P \xrightarrow{\text{mod } 3} A_W,$$

$$A_W^2 = -I_6 \quad \Longrightarrow \quad \mathbb{F}_3^6 \cong \mathbb{F}_9^3 \quad \Longrightarrow \quad C_W = \{(q, qA_W) : q \in \mathbb{F}_3^6\}.$$

The first arrow is a gauge, the second uses the quadratic character, and the third is coefficient reduction. The structure over $\mathbb{F}_9$ is finite; it is not identified with a real or analytic complex structure.

21.2.6 Obstructions in the Paley–C_W corridor: bijection, $A_W^2 = -I_6$, self-duality, and census of 729 words

Comparison Criterion 21.10 (Falsification of the Paley–C_W corridor)**.** The construction is refuted if any of the following occurs:

1. θ is not bijective or is used as a homomorphism without proof;
2. the sum (21.6) differs from -1;
3. $C_P C_P^{\mathsf{T}} \neq 5I_6$;
4. $A_W^2 \neq -I_6$;
5. the projectors (21.11) are not complementary;
6. the map $q \mapsto (q, qA_W)$ loses injectivity or self-duality;
7. the census does not sum to 729, differs from (21.17), or presents a word of weight between one and five;
8. $\mathbb{F}_3^6 \cong \mathbb{F}_9^3$ is inferred only from $3^6 = 9^3$, omitting the action (21.13).

21.3 Ternary Steiner system, Witt-star involutions and generation of M_{12}

The preceding unit constructed the self-dual code $C_W = [12, 6, 6]_3$. Its words of weight six are now projectivized, the Steiner property is proved, and only then is the star associated with the tetrad B_K defined. This order prevents an incidence figure from being turned into an object added by visual similarity.

21.3.1 Supports projective of weight 6

Let

$$\mathcal{H}_W := \{\operatorname{supp}(c) : c \in C_W, \operatorname{wt}(c) = 6\}. \tag{21.19}$$

Each support occurs for the word pair $\{c, -c\}$. Indeed, if two weight-six words with the same support were not proportional, one could scale one of them to cancel a coordinate upon subtraction; this would yield a nonzero word of C_W of weight less than six, contrary to the minimum distance. Since neither is

there a nonzero word equal to its opposite in characteristic three, every projective orbit has exactly two elements. Therefore,

$$|\mathcal{H}_W| = \frac{264}{2} = 132. \tag{21.20}$$

For $T \in \binom{[12]}{5}$, define

$$\nu(T) := \#\{H \in \mathcal{H}_W : T \subseteq H\}. \tag{21.21}$$

The exact enumeration of the

$$\binom{12}{5} = 792$$

subsets of five points produce

$$\nu(T) = 1 \qquad \text{for every } T \in \binom{[12]}{5}. \tag{21.22}$$

Theorem 21.11 (Ternary Witt System)**.** *The incidence system*

$$W_{12} := ([12], \mathcal{H}_W)$$

is the Steiner system

$$\boxed{W_{12} = S(5, 6, 12).} \tag{21.23}$$

Proof. The equality (21.22) is precisely the Steiner property. The number of blocks is also recovered from the double count of pairs (T, H) with $T \subset H$:

$$|\mathcal{H}_W|\binom{6}{5} = \binom{12}{5}, \qquad |\mathcal{H}_W| = \frac{792}{6} = 132.$$

□

21.3.2 Residue of a tetrad and decomposition into 4 incident components

Let $B \in \binom{[12]}{4}$. In an $S(5, 6, 12)$ system, the number of hexads containing B is

$$\lambda_4 = \frac{\binom{12-4}{5-4}}{\binom{6-4}{5-4}} = \frac{8}{2} = 4. \tag{21.24}$$

We write these four hexads as

$$H_i = B \sqcup P_i, \qquad |P_i| = 2, \qquad i = 1, \dots, 4.$$

Lemma 21.12 (Residual partition of a tetrad)**.** *The four pairs $P_1, \dots, P_4$ are disjoint and*

$$[12] \setminus B = P_1 \sqcup P_2 \sqcup P_3 \sqcup P_4. \tag{21.25}$$

Proof. If two residual pairs shared a point p, the corresponding hexads would contain the same subset $B \cup \{p\}$ of five points, in contradiction with the Steiner uniqueness. The four pairs are, therefore, disjoint; contain eight points and agotan the complement of B. □

Definition 21.13 (Star and Witt star involution)**.** The star centered at B is

$$\mathcal{S}_B := \{H \in \mathcal{H}_W : B \subseteq H\} = \{B \sqcup P_1, \dots, B \sqcup P_4\}. \tag{21.26}$$

If $P_i = \{p_i^-, p_i^+\}$, its involution is

$$\sigma_B := \prod_{i=1}^{4} (p_i^- \; p_i^+). \tag{21.27}$$

The permutation σ_B fixes B pointwise and exchanges the ends of each residual petal.

The mathematical term used henceforth is *Witt star* or *Witt-star involution*. It is not a Euclidean star.

21.3.3 Star selected by the tetrad of the seal

The dodecaphasic unit produced, without using Steiner's design,

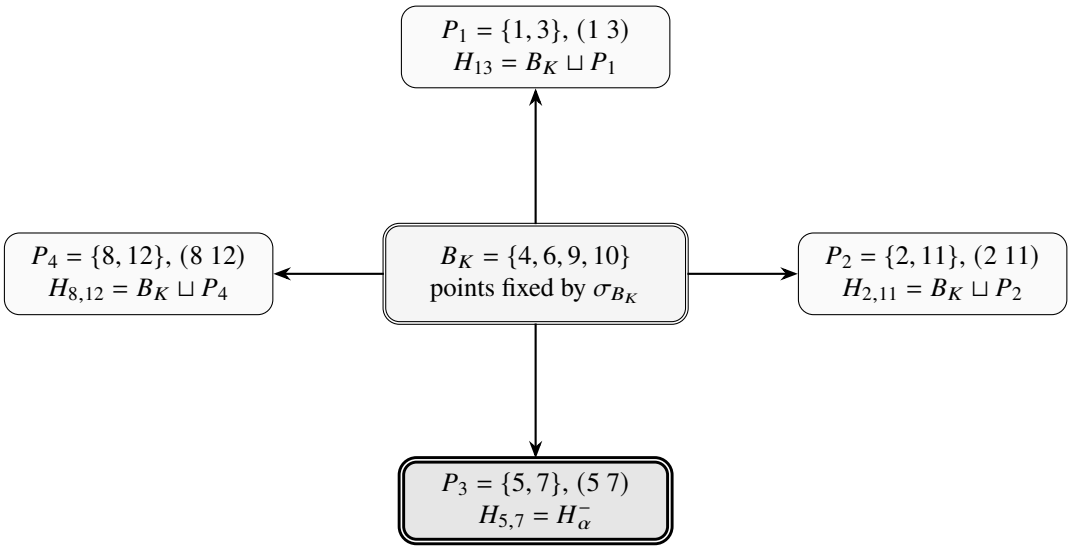
$$B_K = \{4, 6, 9, 10\}.$$

Now that W_{12} has been constructed, its star is well defined. The four incident hexads are

$$H_{13} = B_K \sqcup \{1, 3\} = \{1, 3, 4, 6, 9, 10\}, \tag{21.28}$$
$$H_{2,11} = B_K \sqcup \{2, 11\} = \{2, 4, 6, 9, 10, 11\}, \tag{21.29}$$
$$H_{5,7} = B_K \sqcup \{5, 7\} = \{4, 5, 6, 7, 9, 10\} = H_\alpha^-, \tag{21.30}$$
$$H_{8,12} = B_K \sqcup \{8, 12\} = \{4, 6, 8, 9, 10, 12\}. \tag{21.31}$$

Consequently,

$$\boxed{\sigma_{B_K} = (1\ 3)(2\ 11)(5\ 7)(8\ 12).} \tag{21.32}$$



$\mathcal{S}_{B_K} = \{H_{13}, H_{2,11}, H_{5,7}, H_{8,12}\}$.
The diagram represents incidence, not geometric distance.

Figure 21.1: Witt star centered at B_K. The center is the fixed tetrad; the four petals are the residual pairs that determine the involution.

21.3.4 Global field of the 495 stars

There exists a star for each tetrad, so

$$\#\{\mathcal{S}_B : B \in \tbinom{[12]}{4}\} = \binom{12}{4} = 495. \tag{21.33}$$

The exact census verifies

$$\sigma_B(\mathcal{H}_W) = \mathcal{H}_W \qquad \text{for every } B \in \binom{[12]}{4}. \tag{21.34}$$

We define

$$\Gamma_\star := \langle \sigma_B : B \in \tbinom{[12]}{4} \rangle \leq \mathrm{Aut}(W_{12}). \tag{21.35}$$

A generating set of six tetrads is

$$1234, \quad 1235, \quad 1236, \quad 1245, \quad 1345, \quad 2345.$$

The orders of the subgroups obtained by adding their involutions successively are

$$1, 2, 6, 18, 360, 7920, 95040. \tag{21.36}$$

Theorem 21.14 (Generation of the Mathieu group M_{12})**.** *We have*

$$\boxed{\langle \sigma_B : B \in \tbinom{[12]}{4} \rangle = \mathrm{Aut}(W_{12}) \cong M_{12}.} \tag{21.37}$$

Proof. Each σ_B preserves the 132 hexads, hence $\Gamma_\star \leq \mathrm{Aut}(W_{12})$. The Schreier enumeration of the six indicated generators yields order 95040. The automorphism group of $S(5, 6, 12)$ is M_{12} and has that same order; therefore the inclusion is an equality. □

An isolated star generates only

$$\langle \sigma_B \rangle \cong C_2.$$

The conclusion about M_{12} belongs to the global field of the 495 involutions, not to σ_{B_K} considered in isolation.

21.3.5 Action on the augmentation module

Let

$$V_{11} = \mathbf{1}^\perp \subset \mathbb{R}^{12}.$$

The involution σ_B fixes the four coordinates of B and acts by four transpositions on its complement. In $\mathbb{R}^{12}$ it has eight directions with eigenvalue $+1$ and four with eigenvalue -1. The constant direction belongs to the first eigenspace. Therefore,

$$\mathrm{Spec}(\sigma_B|_{V_{11}}) = \{1^{[7]}, (-1)^{[4]}\}, \qquad \frac{1}{11}\,\mathrm{Tr}(\sigma_B|_{V_{11}}) = \frac{3}{11}. \tag{21.38}$$

It is a signed involution; it is not a positive projector of rank three.

21.3.6 Obstructions concerning W_{12}, the field of 495 star involutions and the generation of M_{12}

Comparison Criterion 21.15 (Refutation of W_{12}, its stars, and M_{12})**.** The construction is refuted if any of the following facts occurs:

1. the projectivization of the 264 words of weight six does not produce 132 supports;
2. there exists a subset of five points contained in zero or in more of one hexad;
3. a tetrad does not belong to exactly four hexads;
4. the four residual pairs do not partition the complement of the tetrad;
5. the petals of B_K are not $\{1, 3\}, \{2, 11\}, \{5, 7\}, \{8, 12\}$;
6. any of the 495 involutions fails to preserve $\mathcal{H}_W$;
7. the generated group does not have order 95040;

8. M_{12} is attributed to a single star instead of the global field of involutions;
9. introduces the istrella before of constructing W_{12}.

21.4 Binary extension relative to a dodecad, system W_{24} and group M_{24}

The system W_{12} constructed over twelve phases admits a binary prolongation when an extended Golay code, a dodecad, and an incidence isomorphism are declared. These data are relative inputs of this branch: they are not deduced solely from C_W, and they do not intervene in the ternary lattice branch that will lead to the Leech lattice.

21.4.1 Golay binary code and octads

Let

$$\mathcal{G}_{24} \subset \mathbb{F}_2^{24}$$

the extended binary Golay code. Its weights are

$$0, 8, 12, 16, 24. \tag{21.39}$$

The supports of the weight eight words form the Steiner system

$$W_{24} = S(5, 8, 24). \tag{21.40}$$

Its blocks are called *octads*. Fix a dodecad D, that is, the support of a word of weight twelve, and let $\mathcal{O}_{24}$ be the family of octads.

We define

$$\mathcal{H}(D) := \{O \cap D : O \in \mathcal{O}_{24},\ |O \cap D| = 6\}. \tag{21.41}$$

Theorem 21.16 (Residual design of a dodecada)**.** *The residual system is*

$$\boxed{(D, \mathcal{H}(D)) \cong S(5, 6, 12).} \tag{21.42}$$

Moreover, each $H \in \mathcal{H}(D)$ has one unique octad O_H such that

$$O_H \cap D = H. \tag{21.43}$$

Proof. Let $A \subset D$, with $|A| = 5$. In $W_{24} = S(5, 8, 24)$ there is a unique octad O_A containing A. If $j = |O_A \cap D|$, the binary sum of the characteristic words of O_A and D belongs to $\mathcal{G}_{24}$ and has weight

$$8 + 12 - 2j = 20 - 2j.$$

Since $A \subseteq O_A \cap D$, one has $5 \le j \le 8$. The four possible weights $10, 8, 6, 4$, combined with (21.39), force $j = 6$. Thus every five-point subset of D belongs to a unique residual hexad.

If two octads had the same hexadic intersection with D, both would contain the same five points of that hexad, contradicting uniqueness in $S(5, 8, 24)$. This also proves uniqueness of the lift. □

21.4.2 Relative scale between the HMT design and the dodecagon

To relate the preceding construction to the design obtained from C_W, one must explicitly declare

$$(D, \ell), \qquad \ell : W_{12}^{\mathrm{HMT}} \xrightarrow{\sim} (D, \mathcal{H}(D)), \tag{21.44}$$

where ℓ is an incidence isomorphism. If ℓ_* denotes its action on blocks, we define

$$\widehat{\iota}_{D,\ell} := \iota_D \circ \ell_* : W_{12}^{\mathrm{HMT}} \longrightarrow W_{24}, \qquad \widehat{\iota}_{D,\ell}(H) = O_{\ell(H)}. \tag{21.45}$$

The composition $\widehat{\iota}_{D,\ell}$ avoids applying ι_D, whose domain is $\mathcal{H}(D)$, directly to a hexad that still lies in $[12]_{\mathrm{HMT}}$.

Proposition 21.17 (Injectivity of the Relative Lift)**.** *The map $\widehat{\iota}_{D,\ell}$ is injective and preserves the incidence between points and hexads after applying ℓ.*

Proof. The isomorphism ℓ is bijective on blocks. By the theorem 21.16, each residual hexad has a unique lifting octad. Two HMT hexads with the same image would have the same residual hexad and, by bijectivity of ℓ, would be equal. □

There is no absolute choice of (D, ℓ) prior to this gauge. The invariant object is the class of the construction under simultaneous change of dodecad and alignment.

21.4.3 4+1 Decomposition of the incidence of a tetrad into peripheral and axial components

For a tetrad $B \subset D$, the parameters derived from the two Steiner systems are

$$\lambda_4(W_{12}) = \frac{\binom{8}{1}}{\binom{2}{1}} = 4, \qquad \lambda_4(W_{24}) = \frac{\binom{20}{1}}{\binom{4}{1}} = 5. \tag{21.46}$$

Therefore, the five octads containing B decompose uniquely as

$$\{O_H : H \in \mathcal{H}(D),\ B \subset H\} \sqcup \{O_B^{\perp}\}. \tag{21.47}$$

The four first satisfy $|O_H \cap D| = 6$; the quinta satisfies

$$O_B^{\perp} \cap D = B. \tag{21.48}$$

For $B = B_K$, the four residual lifts correspond to the petals

$$\{1, 3\}, \qquad \{2, 11\}, \qquad \{5, 7\}, \qquad \{8, 12\},$$

and the fifth octad is the transversal $O_{B_K}^{\perp}$. This law explains the transition from four hexads to five octads without identifying a face of a cube with a hexad or a vertex with an octad.

21.4.4 Strata Correspondence and Positivity of the Triple Freedom

The five-region structure of channel π has types

$$1_{\perp} + 1_{--} + 3_{++}.$$

The incidence on B_K has types

$$1_{\text{transversal}} + 1_{H^-} + 3_{\text{restantes}}$$

after marking the negative hexad. There is therefore a natural correspondence between *role* strata:

$$1_{\perp} \longleftrightarrow O_{B_K}^{\perp}, \qquad 1_{--} \longleftrightarrow \widehat{\iota}_{D,\ell}(H_{\alpha}^{-}), \qquad 3_{++} \longleftrightarrow O_{B_K}^{+,3}. \tag{21.49}$$

Here $O_{B_K}^{+,3}$ is the unordered set of the other three residual octads. An individual bijection between the three positive regions and those three octads requires declaring an additional gauge of S_3. The coincidence of the pattern $1 + 1 + 3$ does not by itself determine that ordering.

21.4.5 Automorphism group of the octad system

Theorem 21.18 (Mathieu group M_{24})**.** *The automorphism group of the octad Steiner system is*

$$\boxed{\mathrm{Aut}(W_{24}) \cong M_{24}, \qquad |M_{24}| = 244823040.} \tag{21.50}$$

The theorem identifies the classical automorphism group of the input binary data. It does not assert that M_{24} is generated from a single dodecad, or that the ternary code C_W determines $\mathcal{G}_{24}$ by itself.

21.4.6 Categorical separation from the lattice branch

The branch constructed in this unit is

$$(W_{12}^{\mathrm{HMT}}; \mathcal{G}_{24}, D, \ell) \longrightarrow W_{24} \longrightarrow \mathrm{Aut}(W_{24}) \cong M_{24}. \tag{21.51}$$

The lattice branch to be constructed subsequently is

$$C_W \longrightarrow N(A_2^{12}) \xrightarrow{\text{index-three neighbor}} \Lambda_{24}. \tag{21.52}$$

Their constructors, domains, and codomains are distinct. In particular,

$$\boxed{\text{no arrow is introduced } W_{24} \longrightarrow \Lambda_{24}.} \tag{21.53}$$

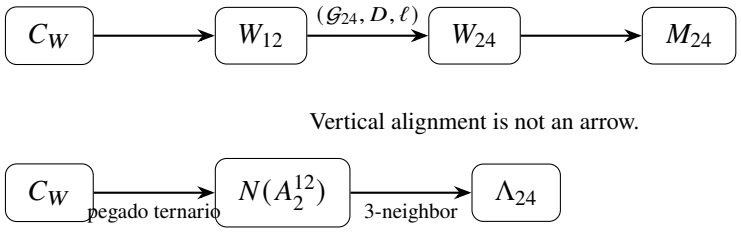


Figure 21.2: Typed bifurcation of the binary and ternary extensions.

21.4.7 Obstructions to the binary prolongation $W_{12} \to W_{24}$: Golay code, octads, alignment and separation of the Leech branch

Comparison Criterion 21.19 (Refutation of the binary prolongation)**.** The construction is refuted if any of the following facts occurs:

1. the weight spectrum of $\mathcal{G}_{24}$ contains a weight not listed in (21.39);
2. the supports of weight eight not form $S(5, 8, 24)$;
3. a residual intersection of an octad with D that contains five points of D has cardinality other than six;
4. a residual hexad admits either no lifting octad or more than one;
5. ι_D is applied directly to an HMT hexad without the alignment ℓ;
6. the incidence law on a tetrad is not $4 + 1$;
7. the positive triple is ordered without declaring the gauge S_3;
8. $\mathrm{Aut}(W_{24})$ has no order 244823040;
9. it is asserted that W_{24} arises from W_{12} without the binary datum $\mathcal{G}_{24}$, the dodecad, and the alignment;
10. the two branches are serialized by means of an arrow $W_{24} \to \Lambda_{24}$.

21.5 Ternary discriminant gluing and construction of the Niemeier lattice of type A_2^{12}

This unit begins the lattice branch directly from the self-dual ternary code C_W. The binary system W_{24}, the dodecad, and the group M_{24} are not inputs of this construction. The typed sequence is

$$C_W \longrightarrow (A_2^*/A_2)^{12} \longrightarrow N(C_W) \cong N(A_2^{12}).$$

21.5.1 Reticulo root A_2

Let

$$A_2 = \mathbb{Z}\alpha_1 \oplus \mathbb{Z}\alpha_2$$

the root lattice whose Gram matrix, in the ordered basis (α_1, α_2), is

$$G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}. \tag{21.54}$$

For $x = x_1\alpha_1 + x_2\alpha_2$,

$$\langle x, x\rangle = 2(x_1^2 - x_1x_2 + x_2^2). \tag{21.55}$$

In particular, A_2 is even, positive defined and

$$\det A_2 = 3.$$

We define

$$\rho := \alpha_1 + \alpha_2.$$

Then

$$\rho^2 = 2, \qquad \langle \rho, \alpha_1\rangle = \langle \rho, \alpha_2\rangle = 1. \tag{21.56}$$

21.5.2 Decomposition of the incidence of a tetrad into 4 peripheral components and 1 axial component

The dual lattice is

$$A_2^* := \{x \in A_2 \otimes_{\mathbb{Z}} \mathbb{Q} : \langle x, A_2\rangle \subseteq \mathbb{Z}\}.$$

We choose the representatives

$$\mu_0 = 0, \qquad \mu_1 = \frac{2\alpha_1 + \alpha_2}{3}, \qquad \mu_2 = \frac{\alpha_1 + 2\alpha_2}{3}. \tag{21.57}$$

Their pairings with the simple base are

	α_1	α_2
μ_1	1	0
μ_2	0	1

thereby $\mu_1, \mu_2 \in A_2^*$. Furthermore,

$$3\mu_1 = 2\alpha_1 + \alpha_2 \in A_2, \qquad 3\mu_2 = \alpha_1 + 2\alpha_2 \in A_2,$$

while $\mu_1, \mu_2 \notin A_2$. It is obtained

$$A_2^*/A_2 = \{\overline{\mu}_0, \overline{\mu}_1, \overline{\mu}_2\} \cong \mathbb{Z}/3\mathbb{Z} \cong \mathbb{F}_3. \tag{21.58}$$

The sum of representatives is explicitly reduced by means of

$$\mu_1 + \mu_1 - \mu_2 = \alpha_1, \qquad \mu_1 + \mu_2 = \rho, \qquad \mu_2 + \mu_2 - \mu_1 = \alpha_2.$$

Consequently,

$$\mu_r + \mu_s - \mu_{r+s \,(\mathrm{mod}\, 3)} \in A_2 \qquad (r, s \in \mathbb{F}_3). \tag{21.59}$$

Proposition 21.20 (Discriminant Form of A_2)**.** *Under* (21.58)*, the discriminant bilinear and quadratic forms are*

$$b(\overline{\mu}_r, \overline{\mu}_s) \equiv \frac{2rs}{3} \pmod{\mathbb{Z}}, \tag{21.60}$$

$$q(\overline{\mu}_r) \equiv \frac{2r^2}{3} \pmod{2\mathbb{Z}}. \tag{21.61}$$

Proof. The formula (21.55) gives

$$\mu_1^2 = \mu_2^2 = \frac{2}{3}, \qquad \langle \mu_1, \mu_2 \rangle = \frac{1}{3}.$$

For $r, s \in \{0, 1, 2\}$, these values coincide, modulo $\mathbb{Z}$, with $2rs/3$. The quadratic formula results by taking $r = s$ and recalling that the lattice is even. □

21.5.3 Correspondence between incidence strata and free orbit of the positive triple

Let

$$L_0 := A_2^{12}.$$

Then

$$L_0^* = (A_2^*)^{12}, \qquad L_0^*/L_0 \cong \mathbb{F}_3^{12}.$$

For $c = (c_1, \ldots, c_{12}) \in \mathbb{F}_3^{12}$, define

$$\phi(c) := (\mu_{c_1}, \ldots, \mu_{c_{12}}) \in L_0^*. \tag{21.62}$$

The extension determined by C_W is

$$\begin{aligned} N(C_W) &:= \bigcup_{c \in C_W} (L_0 + \phi(c)) \\ &= \{x \in L_0^* : x \bmod L_0 \in C_W\}. \end{aligned} \tag{21.63}$$

Lemma 21.21 (Additive closure of the gluing)**.** *The set $N(C_W)$ is a discrete subgroup of L_0^* of rank twenty-four.*

Proof. Let $x = \ell + \phi(c)$ and $y = m + \phi(d)$, with $\ell, m \in L_0$ and $c, d \in C_W$. By (21.59),

$$\phi(c) + \phi(d) - \phi(c + d) \in L_0.$$

Since C_W is linear, $c + d \in C_W$, and then $x + y \in L_0 + \phi(c + d)$. The same identity applied to the opposite gives inverses. The inclusions

$$L_0 \subseteq N(C_W) \subseteq L_0^*$$

They test discretion and range twenty-four. □

21.5.4 Integrality induced by self-duality

The discriminant bilinear form of L_0 is the orthogonal sum of twelve copies of (21.60). For $c, d \in \mathbb{F}_3^{12}$,

$$b(c,d) \equiv \frac{2}{3}\sum_{i=1}^{12} c_i d_i \pmod{\mathbb{Z}}. \tag{21.64}$$

Lemma 21.22 (Integrity of the gluing)**.** *The lattice $N(C_W)$ is integral.*

Proof. The self-duality $C_W = C_W^{\perp}$ implica

$$\sum_{i=1}^{12} c_i d_i \equiv 0 \pmod 3 \qquad (c, d \in C_W).$$

By (21.64), the discriminant form vanishes on $C_W \times C_W$. Therefore, the pairing of any two glued classes is integral. □

21.5.5 Parity Induced by the Code Weights

At a nonzero coordinate of the code, the discriminant quadratic form equals $2/3$ modulo $2\mathbb{Z}$. Therefore,

$$q(c) \equiv \frac{2}{3}\,\mathrm{wt}(c) \pmod{2\mathbb{Z}}. \tag{21.65}$$

Lemma 21.23 (Parity of the gluing)**.** *The lattice $N(C_W)$ is even.*

Proof. The only weights of C_W are $0, 6, 9, 12$, and

$$\frac{2}{3}\{0,6,9,12\} = \{0,4,6,8\} \subseteq 2\mathbb{Z}.$$

Every glue class is isotropic for the discriminant quadratic form, so all norms of $N(C_W)$ are even. □

Let $g_1, \dots, g_6$ be the rows of $G_W = (I_6 \mid A_W)$ and $\gamma_i = \phi(g_i)$. Exact multiplication in A_2^* gives

$$(\langle \gamma_i, \gamma_j \rangle)_{i,j=1}^{6} = \begin{pmatrix} 4 & 2 & 2 & 2 & 2 & 2 \\ 2 & 4 & 2 & 2 & 2 & 2 \\ 2 & 2 & 4 & 2 & 2 & 2 \\ 2 & 2 & 2 & 4 & 2 & 2 \\ 2 & 2 & 2 & 2 & 4 & 2 \\ 2 & 2 & 2 & 2 & 2 & 4 \end{pmatrix}. \tag{21.66}$$

This matrix provides an additional direct control of integrality and parity for the six gluing generators.

21.5.6 Index, determinant, and unimodularity

The cosets of L_0 that appear in (21.63) are indexed by the $|C_W| = 729 = 3^6$ elements of the code and are distinct. Consequently,

$$[N(C_W) : L_0] = 3^6. \tag{21.67}$$

Since

$$\det L_0 = (\det A_2)^{12} = 3^{12},$$

the determinant formula for a finite extension gives

$$\det N(C_W) = \frac{\det L_0}{[N(C_W) : L_0]^2} = \frac{3^{12}}{(3^6)^2} = 1. \tag{21.68}$$

21.5.7 Root system induced by Witt incidence and classification of its orbits

En each one of the two classes discriminantes not nulas of A_2^*/A_2, the norm minima is

$$\mu_1^2 = \mu_2^2 = \frac{2}{3}.$$

If $c \in C_W \setminus \{0\}$, then $\mathrm{wt}(c) \geq 6$. By orthogonality of the twelve factors, any vector of $L_0 + \phi(c)$ has norm at least

$$6 \cdot \frac{2}{3} = 4. \tag{21.69}$$

Therefore, no nontrivial gluing class contains vectors of norm two. The roots of $N(C_W)$ are exactly the roots already present in $L_0 = A_2^{12}$.

Theorem 21.24 (Realization of the Niemeier of type A_2^{12})**.** *The lattice $N(C_W)$ is positive definite, even, and unimodular, and its root system is A_2^{12}. Consequently,*

$$\boxed{N(C_W) \cong N(A_2^{12}).} \tag{21.70}$$

Proof. Positivity follows from L_0^*. The lemmas 21.22 y 21.23 proves integrality and parity; (21.68) proves unimodularity. The bound (21.69) identifies the root system. The Niemeier classification uniquely associates the indicated lattice with that root system. □

21.5.8 Obstructions to the ternary gluing $C_W \to N(A_2^{12})$: parity, unimodularity, and root system

Comparison Criterion 21.25 (Refutation of ternary gluing)**.** The construction is refuted if any of the following facts occurs:

1. any of the representatives μ_0, μ_1, μ_2 does not belong to A_2^*, two of its classes coincide, or (21.59) fails;
2. the discriminant form is not the one given in proposition 21.20;
3. $N(C_W)$ is not closed under sum or inversos;
4. there exists $c, d \in C_W$ with $\frac{2}{3}\sum_i c_i d_i \notin \mathbb{Z}$;
5. one palabra of C_W produces $\frac{2}{3}\,\mathrm{wt}(c) \notin 2\mathbb{Z}$;
6. the index is not 3^6 or the determinant is not one;
7. a nontrivial gluing class contains a vector of norm two;
8. W_{24}, a dodecad, or a binary datum is used in any of the preceding gluing operations.

21.6 Incidental origin, typed radial problem and construction of the rootless unimodular neighbor

The lattice $N(A_2^{12})$ has already been constructed. This unit determines a base point from an ordered incidence frame, solves a variational problem on a declared domain, verifies the three conditions for the index-three neighbor, and proves that the result is the Leech lattice. The neighbor vector is denoted $v_{\mathcal{F}_*}$: it depends on the incidence frame and does not enter the numerical carry of α.

21.6.1 Ordered set of incidences

Consider the four hexads

$$H^{-} = \{4, 5, 6, 7, 9, 10\}, \tag{21.71}$$

$$H_e = \{1, 3, 4, 6, 9, 10\}, \tag{21.72}$$

$$H_\varphi = \{1, 2, 3, 4, 7, 9\}, \tag{21.73}$$

$$H_{\mathrm{APP}} = \{2, 3, 5, 10, 11, 12\}. \tag{21.74}$$

The datum is the ordered framework.

$$\mathcal{F} := (H^{-}, H_e, H_\varphi, H_{\mathrm{APP}}). \tag{21.75}$$

We define

$$o(\mathcal{F}) := (H_e \cap H_\varphi) \setminus (H^{-} \cup H_{\mathrm{APP}}). \tag{21.76}$$

Theorem 21.26 (Equivariant Reconstruction of the Origin)**.** *For the frame canonical $\mathcal{F}_*$,*

$$\boxed{o(\mathcal{F}_*) = \{1\}.} \tag{21.77}$$

Moreover, for every simultaneous permutation $g \in M_{12}$,

$$o(g\mathcal{F}) = g\, o(\mathcal{F}). \tag{21.78}$$

Proof. We have

$$H_e \cap H_\varphi = \{1, 3, 4, 9\}$$

and

$$(H^{-} \cup H_{\mathrm{APP}}) \cap \{1, 3, 4, 9\} = \{3, 4, 9\}.$$

The difference is $\{1\}$. For equivariance one applies the identities

$$g(A \cap B) = gA \cap gB, \quad g(A \cup B) = gA \cup gB, \quad g(A \setminus B) = gA \setminus gB,$$

valid for all bijections. □

The tetrad $B_K = \{4, 6, 9, 10\}$ does not by itself determine the origin. The singleton is obtained from the complete ordered frame; it is not a coordinate chosen after the result has been observed.

21.6.2 Positive radial chamber of the root system and selection of the dominant cone

Let ρ_i the copia of $\rho = \alpha_1 + \alpha_2$ in the i-esimo factor of A_2^{12}. Consideramos the dominio

$$\mathcal{R}_+ := \left\{ v(a) = \sum_{i=1}^{12} a_i \rho_i : a_i = 1 + 3b_i, b_i \in \mathbb{Z}_{\geq 0} \right\}. \tag{21.79}$$

Since the factors are orthogonal and $\rho_i^2 = 2$, if $S = \sum_i b_i$, then

$$\begin{aligned} v(a)^2 &= 2 \sum_{i=1}^{12} (1 + 3b_i)^2 \\ &= 24 + 12S + 18 \sum_{i=1}^{12} b_i^2. \end{aligned} \tag{21.80}$$

Reducing modulo eighteen,

$$v(a)^2 \equiv 6 + 12S \pmod{18},$$

and therefore

$$v(a)^2 \equiv 0 \pmod{18} \iff S \equiv 1 \pmod{3}. \tag{21.81}$$

Proposition 21.27 (Minima in the declared radial chamber)**.** *On the subset of $\mathscr{R}_+$ defined by $v(a)^2 \equiv 0 \pmod{18}$, the minimum norm is 54. It is attained exactly at twelve vectors: for each $j \in \{1, \dots, 12\}$, the coefficient a_j equals four, and the remaining eleven equal one.*

Proof. Condition (21.81) and the nonnegativity of the b_i imply that the smallest possible value of S is one. This forces a unique index j with $b_j = 1$ and $b_i = 0$ for $i \neq j$. Substituting into (21.80),

$$v(a)^2 = 24 + 12 + 18 = 54.$$

There are twelve choices of j. The next admissible value of S is four and produces a strictly greater norm. □

The origin $o(\mathcal{F}_*) = \{1\}$ selects

$$\boxed{v_{\mathcal{F}_*} = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v_{\mathcal{F}_*}^2 = 54.} \tag{21.82}$$

Remark 21.28 (Exact scope of minimality). The norm 54 is minimal in the positive radial chamber (21.79), not in the entire residue class. The vector

$$u = (\alpha_1 - 2\alpha_2, \rho, \dots, \rho)$$

satisfies

$$\alpha_1 - 2\alpha_2 - \rho = -3\alpha_2,$$

so that

$$u \equiv (\rho, \dots, \rho) \equiv v_{\mathcal{F}_*} \pmod{3A_2^{12}}.$$

However,

$$(\alpha_1 - 2\alpha_2)^2 = 2(1 + 2 + 4) = 14, \qquad u^2 = 14 + 11 \cdot 2 = 36.$$

This witness prevents extending the minimality assertion outside the domain of proposition 21.27.

21.6.3 Discriminant gluing of 12 $\mathbf{A}_2$ factors and construction of the integral extension

We write

$$N := N(A_2^{12}), \qquad v := v_{\mathcal{F}_*}.$$

We define

$$\chi_v : N \longrightarrow \mathbb{Z}/3\mathbb{Z}, \qquad \chi_v(x) = \langle x, v \rangle \bmod 3, \tag{21.83}$$

its nucleus

$$N_0 := \ker \chi_v = \{x \in N : \langle x, v \rangle \equiv 0 \pmod{3}\}, \tag{21.84}$$

and the extension

$$N_v := N_0 + \mathbb{Z}\frac{v}{3}. \tag{21.85}$$

21.6.4 Condition I1: surjectivity and exclusion of roots

By construction, $v \in A_2^{12} \subseteq N$. The roots of a factor A_2 are

$$\pm\alpha_1, \quad \pm\alpha_2, \quad \pm\rho.$$

Their pairings with ρ are ± 1 or ± 2. All the coefficients of v are congruent to one modulo three:

$$4 \equiv 1 \pmod 3, \qquad 1 \equiv 1 \pmod 3.$$

Therefore, no root of A_2^{12} has zero pairing with v modulo three. In particular,

$$\chi_v(\alpha_{1,1}) = 1,$$

so that χ_v is surjective and

$$[N : N_0] = 3. \tag{21.86}$$

Moreover, no root of N belongs to N_0.

21.6.5 Condition I2: norm divisibility

The identity (21.82) gives

$$v^2 = 54 \equiv 0 \pmod{18}, \qquad \left(\frac{v}{3}\right)^2 = 6. \tag{21.87}$$

In particular, $\langle v, v\rangle \equiv 0 \pmod 3$, hence $v \in N_0$.

21.6.6 Condition I3: class dual of order 3

If $x \in N_0$, there exists $k \in \mathbb{Z}$ with $\langle x, v\rangle = 3k$. Therefore,

$$\left\langle x, \frac{v}{3}\right\rangle = k \in \mathbb{Z},$$

and

$$\frac{v}{3} \in N_0^*. \tag{21.88}$$

On the other hand,

$$\left\langle \frac{v}{3}, \alpha_{1,1}\right\rangle = \frac{4}{3}.$$

Since $\alpha_{1,1} \in N$ and N is integral, this proves

$$\frac{v}{3} \notin N. \tag{21.89}$$

Finally, $3(v/3) = v \in N_0$. The class of $v/3$ in N_0^*/N_0 is nontrivial and has order exactly three. Consequently,

$$[N_v : N_0] = 3. \tag{21.90}$$

21.6.7 Parity, integrality and determinant of the neighbor

Proposition 21.29 (Unimodular structure of the neighbor)**.** *The lattice N_v is integral, even, and unimodular.*

Proof. Since N is unimodular and $[N : N_0] = 3$,

$$\det N_0 = [N : N_0]^2 \det N = 9.$$

Since $[N_v : N_0] = 3$,

$$\det N_v = \frac{\det N_0}{[N_v : N_0]^2} = 1.$$

Let $y = x + m(v/3)$, with $x \in N_0$, and write $\langle x, v\rangle = 3k$. Then

$$\begin{aligned} y^2 &= x^2 + 2m\left\langle x, \frac{v}{3}\right\rangle + m^2\left(\frac{v}{3}\right)^2 \\ &= x^2 + 2mk + 6m^2. \end{aligned}$$

The three summands form an even integer. The polarized form proves integrality, and determinant one proves unimodularity. □

21.6.8 2 clasis globalis and 6 clasis local

Globally, (21.85) adds only two nontrivial cosets:

$$N_0 + \frac{v}{3}, \qquad N_0 - \frac{v}{3}.$$

Locally, in each factor A_2, a coordinate of those classes belongs to one of the six classes

$$\mathscr{C}_{j,\pm} := A_2 + \mu_j \pm \frac{\rho}{3}, \qquad j \in \{0, 1, 2\}. \tag{21.91}$$

In the first coordinate, $4\rho/3 \equiv \rho/3 \pmod{A_2}$, so the same list holds for the twelve factors.

Table 21.1: Minimal representatives of the six local cosets.

class	minimal representative	(u, v)	$2(u^2 - uv + v^2)/9$
$\mathscr{C}_{0,-}$	$-\rho/3$	$(-1, -1)$	$2/9$
$\mathscr{C}_{0,+}$	$\rho/3$	$(1, 1)$	$2/9$
$\mathscr{C}_{1,-}$	$\mu_1 - \rho/3$	$(1, 0)$	$2/9$
$\mathscr{C}_{1,+}$	$\mu_1 + \rho/3 - \rho$	$(0, -1)$	$2/9$
$\mathscr{C}_{2,-}$	$\mu_2 - \rho/3$	$(0, 1)$	$2/9$
$\mathscr{C}_{2,+}$	$\mu_2 + \rho/3 - \rho$	$(-1, 0)$	$2/9$

Here (u, v) means the representative $(u\alpha_1 + v\alpha_2)/3$.

Lemma 21.30 (Exact minimum of the six classes)**.** *Each class in* (21.91) *has minimum norm exactly* $2/9$.

Proof. The norm of $(u\alpha_1 + v\alpha_2)/3$ is

$$\frac{2}{9}(u^2 - uv + v^2).$$

The integral form $u^2 - uv + v^2$ is positive definite. On a nonzero residual class it does not take the value zero, and hence is at least one. The six representatives in table 21.1 attain one. □

21.6.9 Criterion for the absence of roots in the Leech lattice and consequence for the minimum distance

Theorem 21.31 (Absence of vectors of norm two)**.** *The lattice N_v contains no vectors of norm two.*

Proof. All roots of N are those of A_2^{12}. Condition I1 proves that none belongs to N_0. Hence class N_0 contains no vectors of norm two.

In a new class $N_0 \pm v/3$, each of the twelve coordinates belongs to one of the six local classes. By lemma 21.30, each coordinate contributes at least $2/9$. Orthogonality gives

$$\left\| x \pm \frac{v}{3} \right\|^2 \geq 12 \cdot \frac{2}{9} = \frac{8}{3} > 2.$$

Nor do the new classes contain roots. □

21.6.10 Identification with the Leech lattice

Theorem 21.32 (Construction of the Leech lattice)**.** *The lattice*

$$N_v = \ker(\langle \cdot , v_{\mathcal{F}_*} \rangle \bmod 3) + \mathbb{Z}\frac{v_{\mathcal{F}_*}}{3} \tag{21.92}$$

is isometric to the Leech lattice:

$$\boxed{N_v \cong \Lambda_{24}.} \tag{21.93}$$

Proof. The lattice N_v has rank twenty-four and is positive definite. proposition 21.29 proves that it is even and unimodular; theorem 21.31 proves that it has no roots. By the Niemeier classification, there exists a unique isometry class of positive-definite, even, unimodular lattices of rank twenty-four without roots: the Leech lattice. □

21.6.11 The 243 syndromes of the ternary punctured code

Let G_{11} be the ternary Golay code with parameters $[11, 6, 5]_3$. Its syndrome space has cardinality

$$3^{11-6} = 3^5 = 243. \tag{21.94}$$

The number of weight errors of at most two is

$$1 + 2\binom{11}{1} + 2^2\binom{11}{2} = 1 + 22 + 220 = 243. \tag{21.95}$$

Proposition 21.33 (Perfect correspondence error–syndrome)**.** *Each syndrome of G_{11} has a unique error representative of weight at most two.*

Proof. Minimum distance five implies that two distinct errors of weight at most two cannot differ by a codeword: their difference would have weight at most four. The error–syndrome map is therefore injective on the ball of radius two. Both sets have cardinality 243 by (21.94) and (21.95); the map is bijective. □

These 243 syndromes are not the 243 visible words obtained from the TPK catalogue. They share a cardinal, but they possess distinct domains, equivalences and functions.

21.6.12 Obstructions of the ternary neighbor $N_v \cong \Lambda_{24}$: class of order 3, absence of roots, and separation of the cardinals 243

Comparison Criterion 21.34 (Refutation of the neighbor and of the Leech identification)**.** The construction is refuted if any of the following facts occurs:

1. the operator $o(\mathcal{F})$ not produces $\{1\}$ or is not equivariant;
2. there exists in the radial chamber an admissible vector of norm less than 54, or the number of minimizers is not twelve;
3. global minimality is asserted despite the witness of norm 36;
4. χ_v is not sobreyectivo or one root belongs to N_0;
5. $v^2 \not\equiv 0 \pmod{18}$ o $(v/3)^2 \neq 6$;
6. $v/3 \notin N_0^*$, $v/3 \in N$, or its class does not have order three;
7. the determinant of N_v is not one, or the neighbor ceases to be even;
8. some of the six clasis local has minimum least that $2/9$;

9. one of the two new global classes contains a root;
10. the two global classes are confused with the six local classes;
11. W_{24} is used as an antecedent of the gluing or of the neighbor;
12. the 243 syndromes are identified with the 243 words visible by sharing cardinality.

21.7 Finite holonomy, Schläfli configuration and symmetry E_6

The Witt branch does not exhaust the exceptional structures accessible from APP. The parallel branch of this chapter starts from the two mixed sum–product and product–sum polarizations, together with a plaquette orientation and a declared central section. The calculated curvature determines the alternating form; this defines the central extension. An extension is not inferred from cardinality 27 alone.

21.7.1 Ordered system of incidences and radial camera orientation

On $T_9 = (\mathbb{Z}/9\mathbb{Z})^2$, with $S(x, y) = x + y$ and $P(x, y) = xy$, let

$$\Delta_x f = f(x + 1, y) - f(x, y), \qquad \Delta_y f = f(x, y + 1) - f(x, y).$$

Mixed connections are

$$A^{SP} = (\Delta_x S, \Delta_y P) = (1, x), \qquad A^{PS} = (\Delta_x P, \Delta_y S) = (y, 1).$$

Its discrete curvature is

$$F_A = \Delta_x A_y - \Delta_y A_x.$$

Proposition 21.35 (Oriented opposite curvatures)**.**

$$F_{A^{SP}} = 1, \qquad F_{A^{PS}} = -1 \pmod 9.$$

The circulation over an oriented rectangle of sides r, s is, respectively, rs and $-rs$.

Proof. $\Delta_x x - \Delta_y 1 = 1$ and $\Delta_x 1 - \Delta_y y = -1$. A rectangle contains rs plaquettes; upon summing, the interior edges cancel and the boundary circulation remains. □

For displazamientos $u = (a, b)$, $v = (c, d)$, the class alternante is

$$\sigma(u, v) = ad - bc \pmod 9. \tag{21.96}$$

The orientation fixes the sign of σ. The central section used below belongs to the gauge of this realization; replacing it with a coboundary produces an isomorphic extension, not a new invariant.

21.7.2 Central extension and ternary reduction

We define the nonadic Heisenberg group

$$\mathcal{H}_9 = \{(a, b, z) : a, b, z \in \mathbb{Z}/9\mathbb{Z}\}, \quad (a, b, z)(c, d, w) = (a + c, b + d, z + w + bc). \tag{21.97}$$

The commutator of two horizontal shifts is

$$[(a, b, 0), (c, d, 0)] = (0, 0, bc - ad),$$

which records $-\sigma(u, v)$. Reducing each coordinate modulo three gives

$$H_3 = \{(a, b, z) : a, b, z \in \mathbb{F}_3\}, \qquad |H_3| = 27, \tag{21.98}$$

with the same law. The nucleo of $\mathcal{H}_9 \to H_3$ is $(3\mathbb{Z}/9\mathbb{Z})^3$, of cardinal 27.

21.7.3 Construction of the radial character and determination of its congruence kernel

The nonadic extension admits an explicit unitary realization. Let

$$\zeta_9 := \exp(2\pi i/9), \qquad \mathscr{H}_9^{\mathrm{Sch}} := \mathbb{C}^9,$$

based on $\{|n\rangle : n \in \mathbb{Z}/9\mathbb{Z}\}$. We define

$$X|n\rangle := |n+1\rangle, \qquad Z|n\rangle := \zeta_9^n |n\rangle. \tag{21.99}$$

We have

$$ZX = \zeta_9 XZ$$

and, by multiplication,

$$(X^a Z^b)(X^c Z^d) = \zeta_9^{bc} X^{a+c} Z^{b+d}. \tag{21.100}$$

Theorem 21.36 (Faithful Weyl–Heisenberg Representation)**.** *The map*

$$\rho_{\mathrm{WH}} : \mathcal{H}_9 \longrightarrow U(\mathscr{H}_9^{\mathrm{Sch}}), \qquad \rho_{\mathrm{WH}}(a,b,z) := \zeta_9^z X^a Z^b, \tag{21.101}$$

is a faithful unitary representation. For $u = (a,b)$ and $v = (c,d)$, its commutator satisfies

$$[\rho_{\mathrm{WH}}(u,0), \rho_{\mathrm{WH}}(v,0)] = \zeta_9^{bc-ad} I = \zeta_9^{-\sigma(u,v)} I. \tag{21.102}$$

Proof. The identity (21.100) reproduces the term bc of (21.97); hence the homomorphism property. If $\zeta_9^z X^a Z^b = I$, the action on the basis successively forces $a = 0$, $b = 0$, and $z = 0$. This proves faithfulness. Comparing the products in the two orders gives ζ_9^{bc-ad}, which is the alternating phase of (21.96). □

The representation distinguishes two conjugate observables. Let

$$Q_{\mathrm{H}} := \mathrm{diag}(0,1,\dots,8), \qquad F_{jk} := \frac{1}{3}\zeta_9^{jk}, \qquad P_{\mathrm{H}} := F^{\dagger} Q_{\mathrm{H}} F.$$

The eigenbases of Q_{H} and P_{H} are mutually unbiased, since $|F_{jk}|^2 = 1/9$. For every unit vector $\psi \in \mathscr{H}_9^{\mathrm{Sch}}$,

$$\mathrm{Var}_\psi(Q_{\mathrm{H}})\,\mathrm{Var}_\psi(P_{\mathrm{H}}) \geq \frac{1}{4}\,|\langle \psi, [Q_{\mathrm{H}}, P_{\mathrm{H}}]\psi\rangle|^2\,, \tag{21.103}$$

$$H_{Q_{\mathrm{H}}}(\psi) + H_{P_{\mathrm{H}}}(\psi) \geq \log 9. \tag{21.104}$$

These operators are dimensionless. A physical unit chart is a later realization and does not intervene in the central extension.

21.7.4 Action of 10 displazamientos over the grafo of Cayley

For a linear functional $\ell(a,b) = pa + qb$, set

$$D_\ell(a,b) = \left(a, b, \frac{ab}{2} + \ell(a,b)\right), \qquad Z = (0,0,1),$$

where $2^{-1} = 2$ in $\mathbb{F}_3$. The inverse-closed set

$$S_\ell = \{D_\ell(v) : v \in \mathbb{F}_3^2 \setminus \{0\}\} \cup \{Z, Z^{-1}\} \tag{21.105}$$

has ten elements and does not contain the identity.

Theorem 21.37 (Independence of the linear scale)**.** *The nine functionals ℓ produce isomorphic Cayley graphs. The nine sets S_ℓ form a single orbit under* $\mathrm{Aut}(H_3)$.

Proof. The map

$$\phi_\ell(a,b,z) = (a,b,z+\ell(a,b))$$

is a central automorphism and satisfies $\phi_\ell(S_0) = S_\ell$. To write the complete family in the polarized coordinates of equation (21.97), let $c(v,w) = bc$ for $v = (a,b)$, $w = (c,d)$. Given $M \in \mathrm{GL}(2,3)$, the defect

$$B_M(v,w) = c(Mv,Mw) - \det(M)c(v,w)$$

is symmetric, because the alternating parts of the two terms coincide. We define the quadratic correction

$$q_M(v) = 2B_M(v,v), \qquad q_M(v+w) - q_M(v) - q_M(w) = B_M(v,w), \tag{21.106}$$

where $2 = 2^{-1}$ in $\mathbb{F}_3$. The complete family of automorphisms is then written

$$(v,t) \longmapsto \big(Mv, \det(M)t + q_M(v) + \ell(v)\big), \qquad M \in \mathrm{GL}(2,3),\ \ell \in (\mathbb{F}_3^2)^*. \tag{21.107}$$

The polar identity of equation (21.106) directly proves that the central product is preserved. The family has $48 \cdot 9 = 432$ elements. Exhaustive enumeration of the $\binom{13}{5} = 1287$ inverse-closed subsets of cardinality ten finds exactly those nine with the parameters derived below. □

Write $\underline{S} = \sum_{s\in S} s$ in $\mathbb{Z}[H_3]$. Counting ordered products gives

$$\underline{S}^{\,2} = 10e + \underline{S} + 5(\underline{H_3} - e - \underline{S}) = 5\underline{H_3} + 5e - 4\underline{S}. \tag{21.108}$$

Indeed, the identity receives ten factorizations; an element of S receives one; each of the other sixteen receives five.

Theorem 21.38 (Graph of the twenty-seven lines)**.** *The matrix of adjacency A_ℓ of $\Gamma_\ell = \mathrm{Cay}(H_3, S_\ell)$ satisfies*

$$A_\ell^2 = 5I - 4A_\ell + 5J. \tag{21.109}$$

Therefore,

$$\Gamma_\ell = \mathrm{srg}(27,10,1,5), \qquad \mathrm{Spec}(A_\ell) = \{10^1, 1^{20}, (-5)^6\}.$$

It is isomorphic to the intersection graph of the twenty-seven lines of a smooth cubic surface.

Proof. The regular representation of equation (21.108) produces equation (21.109). Its entries state that every vertex has ten neighbors, that an adjacent pair has one common neighbor, and a nonadjacent pair has five. On the constant line, A_ℓ acts by 10; on its complement, $J = 0$ and $(A_\ell - I)(A_\ell + 5I) = 0$. Zero trace fixes the multiplicities 20 and 6.

In the model of a cubic obtained by blowing up six points of $\mathbb{P}^2$, the 27 classes are

$$E_i, \qquad L_{ij} = H - E_i - E_j, \qquad Q_i = 2H - \sum_{j\neq i} E_j.$$

With $H^2 = 1$, $E_i^2 = -1$, $H \cdot E_i = 0$, and $E_i \cdot E_j = 0$ for $i \neq j$, its intersection matrix has the same parameters. Identification with the classical configuration uses the uniqueness theorem for this realization of the 27 lines [86]; it is not attributed to a nonexistent certificate. □

The isomorphism assertion can be made fully effective by means of a computed bijection. The labeling is not absolute: another linear section or an automorphism of the surface produces another table in the same class.

Table 21.2: Explicit bijection between H_3 and the twenty-seven classes of lines.

$a\,b\,z$	class of line
0 0 0	E_1
0 0 1	L_{12}
0 0 2	Q_2
0 1 0	L_{13}
0 1 1	Q_1
0 1 2	E_3
0 2 0	Q_3
0 2 1	E_2
0 2 2	L_{23}
1 0 0	L_{14}
1 0 1	L_{35}
1 0 2	L_{26}
1 1 0	L_{36}
1 1 1	L_{24}
1 1 2	L_{15}
1 2 0	L_{25}
1 2 1	L_{16}
1 2 2	L_{34}
2 0 0	Q_4
2 0 1	L_{46}
2 0 2	E_6
2 1 0	E_5
2 1 1	Q_6
2 1 2	L_{56}
2 2 0	L_{45}
2 2 1	E_4
2 2 2	Q_5

As a local control, the ten neighbors of $e = (0,0,0)$ are the elements of S_0. The table transforms them into the ten classes that intersect E_1: the five L_{1j} and the five Q_j, with $2 \le j \le 6$. The complete verification compares all 729 entries of both adjacency matrices.

The complement $B_\ell = J - I - A_\ell$ satisfies

$$B_\ell^2 = 8I + 2B_\ell + 8J, \qquad \mathrm{srg}(27, 16, 10, 8), \qquad \mathrm{Spec}(B_\ell) = \{16^1, 4^6, (-2)^{20}\}. \tag{21.110}$$

This is the Schläfli graph in the convention of complementary adjacency; A_ℓ is the intersection graph with parameters $(27, 10, 1, 5)$.

Each edge belongs to a unique triangle, since $\lambda = 1$. The number of triangles is

$$\frac{27 \cdot 10}{6} = 45.$$

The full automorphism group has order

$$27 \cdot 1920 = 51840$$

and, through its action on the line configuration, is identified with $W(E_6)$, not merely by equality of orders [86].

21.7.5 The root lattice realizing E_6

To make explicit the object on which that group acts, let

$$\mathrm{Pic}(X) = \mathbb{Z}H \oplus \bigoplus_{i=1}^{6} \mathbb{Z}E_i, \qquad H^2 = 1, \qquad E_i^2 = -1, \qquad H \cdot E_i = E_i \cdot E_j = 0 \ (i \neq j), \tag{21.111}$$

the Picard lattice of the blow-up of six general points of $\mathbb{P}^2$. Its canonical class is

$$K_X = -3H + E_1 + \cdots + E_6.$$

The orthogonal complement

$$L_{E_6} = K_X^{\perp} \subset \mathrm{Pic}(X), \qquad (x, y)_{E_6} := -x \cdot y, \tag{21.112}$$

is positive definite of rank six. A simple root basis is

$$\begin{aligned} &\alpha_1 = E_1 - E_2, \quad \alpha_2 = E_2 - E_3, \quad \alpha_3 = E_3 - E_4, \\ &\alpha_4 = E_4 - E_5, \quad \alpha_5 = E_5 - E_6, \quad \alpha_6 = H - E_1 - E_2 - E_3. \end{aligned} \tag{21.113}$$

Each α_i is orthogonal to K_X, has norm two, and its products are -1 exactly for adjacent pairs of the diagram E_6: the chain $1 - 2 - 3 - 4 - 5$, with node 6 joined to node 3. Therefore, its Gram matrix is the Cartan matrix of E_6.

Proposition 21.39 (The seventy-two roots and their reflections)**.** *The roots of L_{E_6} are*

$$\begin{aligned} &E_i - E_j && (i \neq j), \\ &\pm (H - E_i - E_j - E_k) && (1 \leq i < j < k \leq 6), \\ &\pm (2H - E_1 - \cdots - E_6), \end{aligned} \tag{21.114}$$

in total $30 + 40 + 2 = 72$*. For each root α,*

$$s_\alpha(x) = x + (x \cdot \alpha)\alpha \tag{21.115}$$

preserves the intersection and K_X. The six simple reflections generate $W(E_6)$ and act faithfully by permutations on the 27 classes E_i, L_{ij}, Q_i in theorem 21.38.

Proof. Substituting each class of equation (21.114) into equation (21.111) gives $K_X \cdot \alpha = 0$ and $\alpha^2 = -2$. The class count is as stated. The reflection formula is the orthogonal reflection for the form $-(\cdot)$; it preserves K_X because $K_X \cdot \alpha = 0$. The simple system of equation (21.113) generates all roots, and its Coxeter group is $W(E_6)$. Its action on the 27 classes of exceptional curves preserves intersection, and therefore coincides with the action on the already constructed graph [86]. □

21.7.6 Stratification of the 729 Words

We write a six-trit word as

$$w = (\ell_1, h_1, \ell_2, h_2, \ell_3, h_3),$$

and we define two elements of H_3,

$$L(w) = (\ell_1, \ell_2, \ell_3), \qquad H(w) = (h_1, h_2, h_3),$$

using the central law in their products. According to $L(w)^{-1}H(w)$, the 729 words are divided into

$$\begin{aligned}\mathcal{D}_\ell &= \{w : L(w)^{-1}H(w) = e\},\\ \mathcal{I}_\ell &= \{w : L(w)^{-1}H(w) \in S_\ell\},\\ \mathcal{S}_\ell &= \{w : L(w)^{-1}H(w) \notin \{e\} \cup S_\ell\}.\end{aligned}$$

Theorem 21.40 (Hensel–Schläfli Partition)**.**

$$729 = 27 + 270 + 432, \tag{21.116}$$

corresponding to diagonal, incidence, and warping.

Proof. For each one of the 27 values of $L(w)$, there is a unique value of $H(w)$ with identity difference, ten with difference in S_ℓ and sixteen remaining ones. 27 is multiplied by $1, 10, 16$. □

The cardinal 432 of the warped stratum numerically coincides with the multiplicity of the transverse region of π in equation (9.4). The two objects are not thereby identified: here one counts words classified by $L(w)^{-1}H(w)$, whereas there one counts preimages of a register U_6. Without an explicit and equivariant intertwiner between those domains, $432 = 432$ is only a cardinal control.

21.7.7 Necessity of the central phase

Enumerating all inverse-closed subsets of cardinality ten in the five groups of order 27 gives

group	abelian	$\#\,\mathrm{srg}(27, 10, 1, 5)$
C_{27}	yes	0
$C_9 \times C_3$	yes	0
C_3^3	yes	0
$C_9 \rtimes C_3$	no	9
H_3	no	9.

Thus, retaining 27 labels while abelianizing composition destroys the configuration. Neither cardinality nor degree suffices.

If $\mathcal{T}$ is the conjunto of 45 triangulos, the cubico

$$C_\Gamma(x_1, \dots, x_{27}) = \sum_{\{i,j,k\} \in \mathcal{T}} x_i x_j x_k$$

recovers adjacency, because every edge lies in a unique triangle. Its permutation stabilizer is exactly

$$\mathrm{Aut}(\Gamma_\ell) \cong W(E_6).$$

$$\text{APP curvatures } \pm 1 \longrightarrow \sigma \longrightarrow \mathcal{H}_9 \longrightarrow H_3 \longrightarrow \Gamma_{27} \longrightarrow \mathcal{T}_{45} \longrightarrow W(E_6).$$

Figure 21.3: Causal chain of the mixed-holonomy branch. It is parallel to $C_W \to W_{12} \to M_{12}$ and not a link of it.

Comparison Criterion 21.41 (Falsification criteria for branch E_6)**.** The branch is refuted if the curvatures are not opposite, if the central cocycle is erased, if the quadratic correction (21.106) does not preserve the product, if (21.108) does not produce the coefficients $(10, 1, 5)$, if an abelian group produces the same

configuration, if the partition does not sum to 729, if the table 21.2 does not intertwine the adjacency matrices, or if $W(E_6)$ is identified only by its order and not by its action on the twenty-seven classes and the 72 roots.

21.8 Oriented APP–Fock coupling and transverse rigidity of 12 fibres

The ordinary cyclotomic determinant does not distinguish C from C^{-1}. Sum–product information is preserved by explicitly introducing sheet parity and an orientation line. The resulting coupling produces index 54 from the APP aggregate. Once the four coupling conditions have been fixed, 54, J, and 196884 are not inputs to the evaluation. This evaluative independence asserts neither universal uniqueness of the ansatz nor historical independence of its design.

21.8.1 Triangular mark on each orbit

Let

$$M = \mathbb{Z}[\mathbb{Z}/9\mathbb{Z}]$$

and let $M_{\mathrm{bal}}^{C_3}$ be the submodule of invariant elements ν whose six unit coefficients coincide:

$$\nu_u = c(\nu) \qquad \big(u \in (\mathbb{Z}/9\mathbb{Z})^\times\big).$$

The coefficients of e_0, e_3, e_6 permanecen libres.

For a free orbit $O = \{u, 4u, 7u\}$, set

$$b_\nu = e_\nu - e_{4\nu} \in A(O).$$

If $b_\nu^\flat$ is the covector defined by the form of A_2, the three roots of the triangular frame satisfy

$$\boxed{\sum_{\nu \in O} b_\nu \otimes b_\nu^\flat = 3 I_{A(O)}.}$$

Consequently,

$$\sum_{\nu \in O} \nu_\nu \, b_\nu \otimes b_\nu^\flat = 3c(\nu) I.$$

The factor three proceeds from the resolution of the identity by the root framework.

21.8.2 Oriented coupling $\mathcal{H}_{\Sigma,\Pi}^{(m)}$ between the balance C_3, leaf parity, and degree 2 of Fock space

For $m \in 2\mathbb{N}_{>0}$, let

$$\begin{aligned} \mathcal{V}_m &= \mathcal{V}_{\Sigma,m} \oplus \mathcal{V}_{\Pi,m}, \\ \mathcal{V}_{\Sigma,m} &= (A_2 \otimes \mathbb{C})^{\oplus m/2}, \qquad \mathcal{V}_{\Pi,m} = (A_2 \otimes \mathbb{C})^{\oplus m/2}, \\ g_m &= C^{\oplus m/2} \oplus (C^{-1})^{\oplus m/2}, \\ \mathsf{E}_m &= I_{\mathcal{V}_{\Sigma,m}} \oplus (-I_{\mathcal{V}_{\Pi,m}}). \end{aligned}$$

The specialization $m = 12$, with the labels of pair, sheet and orbit, is $\mathcal{V}_{12} = W_{\mathrm{APP}} \otimes \mathbb{C}$. This notation prevents confusing the representational space with the Witt system $W_{12} = S(5, 6, 12)$. Degree two of the Fock space and the induced action are

$$\mathcal{F}_2(\mathcal{V}_m) = \mathcal{V}_m[2] \oplus \mathrm{Sym}^2(\mathcal{V}_m[1]),$$

$$\Gamma_2(g_m) = g_m|_{\mathcal{V}_m[2]} \oplus \mathrm{Sym}^2(g_m|_{\mathcal{V}_m[1]}).$$

Let $o_{\Sigma\Pi}$ be the signed orientation line $\Pi - \Sigma$, and let $M_{\mathrm{bal}}^{C_3,-}$ be the oriented copy in which the exchange of leaves acts by $\nu \mapsto -\nu$. We define

$$\boxed{\begin{aligned}&\mathcal{H}^{(m)}_{\Sigma,\Pi} : M^{C_3,-}_{\mathrm{bal}} \longrightarrow \mathrm{End}(\mathcal{F}_2(\mathcal{V}_m)) \otimes o_{\Sigma\Pi},\\ &\mathcal{H}^{(m)}_{\Sigma,\Pi}(\nu) = 3c(\nu)\left(0_{\mathcal{V}_m[2]} \oplus \mathrm{Sym}^2 \mathsf{E}_m\right) \otimes o_{\Sigma\Pi}.\end{aligned}}$$

The transformation is linear in c, is supported on $\mathrm{Sym}^2(\mathcal{V}_m[1])$, uses leaf parity, and adopts the normalization of the triangular frame.

Let σ the exchange of sheets. Then

$$\nu \longmapsto -\nu, \qquad o_{\Sigma\Pi} \longmapsto -o_{\Sigma\Pi}, \qquad \mathsf{E}_m \longmapsto -\mathsf{E}_m,$$

and

$$\mathrm{Sym}^2(-\mathsf{E}_m) = \mathrm{Sym}^2(\mathsf{E}_m).$$

Therefore,

$$\mathcal{H}^{(m)}_{\Sigma,\Pi}(\sigma\nu) = \sigma\mathcal{H}^{(m)}_{\Sigma,\Pi}(\nu).$$

When the orientation is reversed, the dual covector also changes sign; thus $(-o^{\vee}_{\Sigma\Pi})(-o_{\Sigma\Pi}) = 1$, and the oriented evaluation remains normalized.

Fixing $o^{\vee}_{\Sigma\Pi}(o_{\Sigma\Pi}) = 1$, the oriented trace is

$$\mathrm{Tr}_{o,\mathcal{F}_2}(T \otimes o_{\Sigma\Pi}) = \mathrm{Tr}_{\mathcal{F}_2}(T).$$

Theorem 21.42 (APP-oriented Index–Fock)**.** *Suppose that m fibers A_2, with m even, are distributed equally between the orientations C and C^{-1}. Then*

$$\boxed{\mathrm{Tr}_{o,\mathcal{F}_2}\left(\mathcal{H}^{(m)}_{\Sigma,\Pi}(\nu)\Gamma_2(g_m)\right) = -\frac{3m\,c(\nu)}{2}.}$$

For the aggregate produced by APP,

$$\delta = \nu_\Pi - \nu_\Sigma = 12e_0 + 3e_3 + 3e_6 - 3\sum_{u\in(\mathbb{Z}/9\mathbb{Z})^\times} e_u,$$

one has $c(\delta) = -3$ and

$$m = 3\ \textit{pairs} \cdot 2\ \textit{sheets} \cdot 2\ \textit{orbits} = 12.$$

Therefore,

$$\boxed{\mathrm{Tr}_{o,\mathcal{F}_2}\left(\mathcal{H}^{(12)}_{\Sigma,\Pi}(\delta)\Gamma_2(g_{12})\right) = 54.}$$

Proof. Let $A = \mathsf{E}_m g_m$. The contributions of the two leaves cancel: $\mathrm{tr}\,A = 0$. Since E_m commutes with g_m and $\mathsf{E}_m^2 = I$,

$$\mathrm{tr}(A^2) = \mathrm{tr}(g_m^2) = -m.$$

The identity

$$\mathrm{tr}(\mathrm{Sym}^2 A) = \frac{(\mathrm{tr}\,A)^2 + \mathrm{tr}(A^2)}{2}$$

gives $-m/2$; the frame supplies $3c(\nu)$. □

Corollary 21.43 (Minimality of the Bosonic Degree Detector)**.** *In the declared class of couplings, degree one does not detect the oriented aggregate, and degree two is the first positive bosonic degree that detects it:*

$$\mathrm{tr}(\mathsf{E}_m g_m) = 0, \qquad \mathrm{tr}\Big(\mathrm{Sym}^2(\mathsf{E}_m g_m)\Big) = -\frac{m}{2} \neq 0.$$

Proof. The first equality is the cancellation of the two sheets. The second was obtained in the proof of theorem 21.42. Since degree zero contains only the unit and degree one has zero trace, degree two is the first with a nonzero response. □

21.8.3 Transverse rigidity of the number of fibers

For an integer $m \geq 1$, we define the formal series

$$T_m(q) := q^{-1} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-m} \in q^{-1}\mathbb{Z}[[q]] \tag{21.117}$$

and, in the orthogonal sum A_2^m, the radial vector

$$v_m := 4\rho_1 + \rho_2 + \cdots + \rho_m, \qquad \|\rho_j\|^2 = 2. \tag{21.118}$$

We construct two entire functions without using $m = 12$ beforehand:

$$F(m) := [q]T_m(q), \qquad R(m) := \|v_m\|^2.$$

Proposition 21.44 (Fock coefficient and radial norm)**.** *For every $m \geq 1$,*

$$F(m) = \frac{m(m-3)}{2}, \qquad R(m) = 2(m+15). \tag{21.119}$$

Proof. Up to second order,

$$(1 + q + q^2)^{-m} = 1 - mq + \frac{m(m-1)}{2} q^2 + O(q^3),$$

$$(1 + q^2 + q^4)^{-m} = 1 - mq^2 + O(q^4).$$

The factors with $n \geq 3$ do not contribute to the coefficient of q^2. Since the exterior factor of T_m is q^{-1},

$$F(m) = \frac{m(m-1)}{2} - m = \frac{m(m-3)}{2}.$$

By orthogonality of the m copies of A_2,

$$R(m) = 4^2\|\rho_1\|^2 + \sum_{j=2}^{m} \|\rho_j\|^2 = 32 + 2(m-1) = 2(m+15).$$

□

Theorem 21.45 (Cyclotomic–radial rigidity)**.** *The equality $F(m) = R(m)$ is equivalent to*

$$(m - 12)(m + 5) = 0. \tag{21.120}$$

In the domain $m \in \mathbb{Z}_{>0}$, the unique solution is

$$\boxed{m = 12, \qquad F(12) = R(12) = 54.}$$

Proof. Equating the two expressions of (21.119) produce

$$m(m-3) = 4(m+15),$$

that is,

$$m^2 - 7m - 60 = (m - 12)(m + 5) = 0.$$

The second root is negative and lies outside the domain. □

This rigidity belongs to the declared cyclotomic–radial family. It does not use the value 54 to choose m: it first constructs $F(m)$ and $R(m)$, and then resolves their equality.

21.8.4 Factorization of the APP–Fock coupling: hypotheses, invariants, necessary conditions for validity, and obstructions

The coupling factorizes by

$$M_{\mathrm{bal}}^{C_3,-}/\ker c \cong \mathbb{Z} \otimes o_{\Sigma\Pi},$$

and the induced map is injective because $\mathrm{Sym}^2 \mathsf{E}_m \neq 0$. The formula is selected by the four declared conditions: linearity in c, support in $\mathrm{Sym}^2(\mathcal{V}_m[1])$, sheet parity, and normalization by the triangular frame. No uniqueness is asserted among all natural couplings, nor historical independence of the ansatz. Once those conditions have been fixed, 54, J, and 196884 are not inputs to the evaluation.

Three controls show that the result is not determined by a retroactive normalization:

$$(m, c) = (12, -2) \longmapsto 36, \qquad (m, c) = (10, -3) \longmapsto 45,$$

and

$$\delta_k = \delta + k e_0$$

leaves $\mathcal{H}_{\Sigma,\Pi}^{(12)}$ invariant while the digital weight changes from 54 to $54 + 9k$. In particular, for $k = 1$,

$$\mathrm{Tr}_{o,\mathcal{F}_2}\left(\mathcal{H}_{\Sigma,\Pi}^{(12)}(\delta + e_0)\Gamma_2(g_{12})\right) = 54, \qquad w(\delta + e_0) = 63.$$

Proposition 21.46 (Need for orientation data)**.** *If $o_{\Sigma\Pi}$ is forgotten, every natural scalar that is linear in $\nu_\Pi - \nu_\Sigma$ and depends only on the class of the representation vanishes.*

Proof. C and C^{-1} are conjugate, so the representational class is even under sheet exchange. The aggregate $\nu_\Pi - \nu_\Sigma$ is odd. Without the orientation line, a transformation that is simultaneously even and odd is zero. □

The theorem thus establishes the exact transport of the aggregate to Fock degree two. The local state-by-state defect preserves the descent obstruction of corollary 1.97; the two statements belong to distinct domains and are compatible.

21.8.5 Complete genealogy of the exceptional projection: from Paley and Hadamard to the Witt, Leech and Moonshine systems

Exceptional evaluation starts from the same enriched state as Archimedean evaluation. The former preserves incidence, orientation, carry and boundary; the latter publishes the real value of the section. This bifurcation makes a genealogy of values and a genealogy of symmetries coexist from a common antecedent.

Two linear transformations fulfill successive and typed functions. The Hadamard transform organizes the signed dodecaphase state and its cyclotomic sectors. The Paley conference matrix then fixes the projective gauge of the exceptional branch. Its ternary reduction

$$C_P C_P^{\mathsf{T}} = 5I_6, \qquad A_W = C_P \bmod 3, \qquad A_W^2 = -I_6$$

produces the internal quadratic endomorphism and the graph code

$$C_W = \{(q, qA_W) : q \in \mathbb{F}_3^6\} = [12, 6, 6]_3.$$

The enumerator

$$W_{C_W}(y) = 1 + 264y^6 + 440y^9 + 24y^{12}$$

expresses the Hamming metric of this realization. The 264 vectors of weight six, identified in opposite pairs, determine 132 hexads and construct the first Witt system,

$$W_{12} = S(5, 6, 12).$$

The 495 Witt stars provide the incidence involutions whose generated action has image M_{12}.

The second Steiner structure is obtained in the extended binary Golay code $\mathcal{G}_{24}$. The weight-eight supports form

$$W_{24} = S(5, 8, 24), \qquad \mathrm{Aut}(W_{24}) \cong M_{24}.$$

With a dodecad D fixed, the intersections of the octads with D at six points reconstruct W_{12}; each hexad admits a unique lift to an octad. The pair of systems

$$S(5, 6, 12) \longrightarrow S(5, 8, 24)$$

is therefore an incidence extension proved within binary Golay and preserves both the dodecad and its alignment.

From the common ternary code the lattice branch arises simultaneously. Coordinate-by-coordinate gluing over A_2^{12} constructs the Niemeier lattice

$$C_W \longrightarrow N(A_2^{12}).$$

The selected radial vector defines an even, unimodular index-three neighbor of rank twenty-four without roots; the classification identifies it with the Leech lattice:

$$N(A_2^{12}) \xrightarrow{\text{3-neighbor}} \Lambda_{24}.$$

On this output the lattice vertex operator algebra $V_{\Lambda_{24}}$ is constructed. The canonical sign involution and its twisted module produce the orbifold

$$V^\natural = V^+_{\Lambda_{24}} \oplus V^{T,+}_{\Lambda_{24}}, \qquad \mathrm{Aut}(V^\natural) \cong \mathbb{M}.$$

Its graded character is the normalized Hauptmodul

$$\mathrm{Tr}_{V^\natural}\, q^{L_0 - 1} = J(\tau) = j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \cdots,$$

and Moonshine theory assigns to each conjugacy class $[g] \subset \mathbb{M}$ the McKay–Thompson series $T_g(\tau) = \mathrm{Tr}_{V^\natural}(g\, q^{L_0 - 1})$, endowed with the corresponding modular and replicability properties.

The common antecedent of both extensions preserves the complete chain

$$w_6 \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}} \longrightarrow U_{12}^{\mathrm{sgn}} \longrightarrow K \longrightarrow B_K.$$

From this terminal state the evaluation route and the gauge route must be distinguished. The state produces the incidence words; the Paley matrix defines, by ternary reduction, the operator that evaluates them. The complete exceptional genealogy is therefore organized as follows:

$$
\begin{aligned}
C_P &\longmapsto A_W = C_P \bmod 3,\\
x \in X_\infty^{\mathrm{cal}} &\longmapsto \varepsilon_\infty(x) = (w_j)_j \longmapsto \big(\Gamma_{A_j}(w_j)\big)_j \in \prod_j C_W(A_j),\\
C_W &\longrightarrow W_{12} \xrightarrow{(D,\ell)} W_{24},\\
W_{12} &\xrightarrow{\mathrm{Aut}} M_{12}, \qquad W_{24} \xrightarrow{\mathrm{Aut}} M_{24},\\
C_W &\longrightarrow N(A_2^{12}) \longrightarrow \Lambda_{24} \longrightarrow V_{\Lambda_{24}} \longrightarrow V^\natural \longrightarrow \mathbb{M} \longrightarrow \text{Moonshine}.
\end{aligned}
$$

Hamming weight and distance belong to the metric of the codes; Hadamard belongs to the dodecaphase transformation; Paley fixes the conference gauge. This separation of functions allows each arrow to be followed through its operator, domain and certificate, while preserving the genealogical unity of the double projection.

21.9 Dodecaphase incidence and the Witt–Leech–Monster corridor

The section 21.2 has explicitly constructed the matrix A_W, the code C_W and the system W_{12}. On those coordinates, the double projection is formalized by two evaluation maps which, in the declared gauge, produce the same polarized Witt flag through distinct operations. This calibrated flag also determines a marked origin. The construction reaches the design W_{12}, its automorphism group M_{12} and, through a second branch that does not pass through W_{24}, an even unimodular rootless 3-neighbor. Classical classification identifies the latter with the Leech lattice; the extension to the moonshine vertex operator algebra and the Monster group is obtained through the corresponding classical theorems.

21.9.1 Dodecaphase state and incidence supports

The dodecaphase vector is

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).$$

The four words of the frame are

$$w_\pi = 010211, \quad w_e = 201101, \quad w_\varphi = 121200, \quad w_{\mathrm{APP}} = 022020.$$

In the symmetric Paley–Witt gauge the encoder used is

$$c(w) = (w, wA_W) \in \mathbb{F}_3^{12}.$$

Their supports are

$$
\begin{aligned}
P_\pi &= \{2, 4, 5, 6, 7, 8, 9, 10, 11\},\\
H_e &= \{1, 3, 4, 6, 9, 10\},\\
H_\varphi &= \{1, 2, 3, 4, 7, 9\},\\
H_{\mathrm{APP}} &= \{2, 3, 5, 10, 11, 12\}.
\end{aligned}
$$

P_π has nine points. The other three supports are hexads. This distinction must be preserved: the twelve hexads contained in P_π have the lines of $AG(2, 3)$ as complementary triples.

21.9.2 Coincidence of the threshold supports

Archimedean evaluation extracts from the vector K the threshold support

$$\beta_{\mathrm{arq}}(K) = \{i : K_i \geq 729\} = \{4, 6, 9, 10\}.$$

Exceptional evaluation calculates the intersection

$$\beta_{\mathrm{exc}}(w_e, w_\pi) = \operatorname{supp} c(w_e) \cap \operatorname{supp} c(w_\pi).$$

Evaluation produces the first exact equality conditional on these data:

$$\boxed{\beta_{\mathrm{arq}}(K) = \beta_{\mathrm{exc}}(w_e, w_\pi) = B_K = \{4, 6, 9, 10\}.} \tag{21.121}$$

The two maps perform distinct operations on declared inputs: the first uses thresholds of the vector K, whereas the second uses intersections of code supports. The threshold 729, the words and the Paley gauge are part of the calibration. In particular, this equality is not an independent validation of K: all integer thresholds between 660 and 729, inclusive, select the same support B_K.

21.9.3 Coincidence of the negative supports

Before carrying, the Archimedean cochain is

$$s^{(0)} = P + E - \Phi - K,$$

and its twelve components are

$$(7, 297, 353, -430, -715, -1199, -3, 286, -894, -528, 380, 663).$$

Its negative support is

$$\eta_{\mathrm{arq}}(s^{(0)}) = \{4, 5, 6, 7, 9, 10\}.$$

By the exceptional route, we fix as calibration selector the hexad H satisfying

$$B_K \subset H \subset P_\pi$$

and

$$(|H \cap H_e|, |H \cap H_\varphi|, |H \cap H_{\mathrm{APP}}|) = (4, 3, 2).$$

Enumeration of the design produces a unique solution for that selector:

$$\eta_{\mathrm{exc}} = \{4, 5, 6, 7, 9, 10\} = H_\alpha^-.$$

Therefore,

$$\boxed{\eta_{\mathrm{arq}}(s^{(0)}) = \eta_{\mathrm{exc}}(B_K, P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}) = H_\alpha^-.} \tag{21.122}$$

Equations (21.121) and (21.122) are condensed into the flag

$$\mathcal{I}_*^{\mathrm{core}} = (B_K \subset H_\alpha^-).$$

This is the calibrated compatibility flag of the double projection. The marked frame

$$\widetilde{\mathcal{I}_*} = (\mathcal{I}_*^{\mathrm{core}}; P_\pi, H_e, H_\varphi, H_{\mathrm{APP}})$$

preserves the data needed to construct the exceptional branch. Under a simultaneous permutation $g \in M_{12}$, the entire construction is transported equivariantly; the invariant is its isomorphism class, not the isolated numerical names.

21.9.4 Reconstruction of the base point from the incidence frame

The origin need not remain an external selector if the complete ordered frame is preserved. We define

$$o(\mathcal{F}) = (H_e \cap H_\varphi) \setminus (H^- \cup H_{\mathrm{APP}}), \qquad \mathcal{F} = (H^-, H_e, H_\varphi, H_{\mathrm{APP}}).$$

Theorem 21.47 (Origin determined by incidences)**.** *For the canonical frame,*

$$o(\mathcal{F}_*) = \{1\}.$$

Moreover, the rule is equivariant: $o(g\mathcal{F}) = g\, o(\mathcal{F})$.

Proof. We have

$$H_e \cap H_\varphi = \{1, 3, 4, 9\},$$

and

$$(H_\alpha^- \cup H_{\mathrm{APP}}) \cap \{1, 3, 4, 9\} = \{3, 4, 9\}.$$

The difference is $\{1\}$. Equivariance follows because intersection, union and difference commute with the action of any permutation. □

The passage from this incidence origin to a vector of a lattice A_2^{12} requires fixing a metric realization of the twelve coordinates. The section 21.9.9 fixes that realization, shows that the origin selects one of the twelve radial minimizers and certifies the conditions of the 3-neighbor. Incidence determines the origin; the Gram matrix and the positive chamber then determine the vector.

21.9.5 Incidence of the ternary design

The Paley chain

$$C_P \longmapsto A_W \longmapsto C_W \longmapsto W_{12}$$

is fixed by the matrices and proofs of the section 21.2. In particular, $A_W^2 = -I_6$, $C_W = [12, 6, 6]_3$, and the 132 projective supports of weight six form $W_{12} = S(5, 6, 12)$. Passing from a word to its support identifies exactly the pair $\{c, -c\}$; the incidences used in what follows therefore belong to the projective design and not to individual signed words.

21.9.6 Hexads, octads and the cardinality identity 28

The binary design $W_{24} = S(5, 8, 24)$ has octads, each with $\binom{8}{2} = 28$ pairs. The theorem 17.4 constructs W_{12} as the residual design of a dodecad D of the extended binary Golay code; the theorem 17.5 proves that, once the alignment ℓ is fixed, each hexad has a unique lift O_H to an octad. The step $6 \to 8$ is therefore an incidence morphism relative to the binary datum (D, ℓ), and not an inference based on cardinalities.

On the other hand, the microfiber of π contains 1008 routes and a nonad has 36 pairs, so that

$$1008 = 36 \cdot 28.$$

The identity $1008 = 36 \cdot 28$ is a numerical check of the catalogue. The incidence morphism is defined independently by means of $H \mapsto \iota_D(\ell(H))$; the cardinality identity does not enter into its definition.

21.9.7 Star involutions and generation of the Mathieu group

For each face $B \in \binom{[12]}{4}$, there are four hexads of W_{12} containing B. The four residues $H \setminus B$ are disjoint pairs partitioning $[12] \setminus B$. The involution σ_B fixes B and exchanges the endpoints of those four pairs. There are

$$\binom{12}{4} = 495$$

star involutions.

Exhaustive enumeration, for the declared matrix and words, verifies

$$\sigma_B(W_{12}) = W_{12}$$

for all of them and

$$\left|\langle \sigma_B : B \in \tbinom{[12]}{4} \rangle\right| = 95040.$$

Since $\mathrm{Aut}(W_{12}) \cong M_{12}$, the 495 stars generate M_{12}. The HMT face is

$$B_K = \{4, 6, 9, 10\}, \qquad \sigma_{B_K} = (1\ 3)(2\ 11)(5\ 7)(8\ 12).$$

A single star generates only C_2. The global combinatorial action is expressed through the representation of the free group of star generators

$$\rho_\star : F_{495} \longrightarrow \mathrm{Aut}(W_{12}), \qquad \rho_\star(\gamma_B) = \sigma_B, \qquad \mathrm{im}\,\rho_\star = M_{12},$$

where F_{495} is the free group on the 495 formal stars. The global group is therefore the image of that family of involutions and not that of a single star. Identifying these generators with loops in the state space would additionally require constructing the corresponding transport; that identification does not enter into the group calculation.

21.9.8 Two exceptional extensions of the ternary code

Two branches of different types can be continued from the ternary code:

$$C_W \longrightarrow W_{12} \xrightarrow[(D,\ell)]{\iota_D} W_{24},$$
$$C_W \xrightarrow[\phi]{\text{explicit gluing}} N(A_2^{12}) \xrightarrow[v_\alpha]{\text{exact 3-neighbor}} \Lambda_{24} \longrightarrow V^\natural.$$

The first branch continues through the residual design of the dodecad and its unique lift; the second continues through ternary gluing and an index-three neighbor. The two constructions have distinct codomains. For the second, let $A_2 = \mathbb{Z}\alpha_1 \oplus \mathbb{Z}\alpha_2$ with Gram matrix

$$G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad \rho = \alpha_1 + \alpha_2,$$

and take as representatives of $A_2^*/A_2 \cong \mathbb{F}_3$

$$\varpi_0 = 0, \qquad \varpi_1 = \frac{2\alpha_1 + \alpha_2}{3}, \qquad \varpi_2 = \frac{\alpha_1 + 2\alpha_2}{3}.$$

The gluing realization is the coordinate-by-coordinate map

$$\phi(c_1, \dots, c_{12}) = (\varpi_{c_1}, \dots, \varpi_{c_{12}}),$$

which forms

$$N(C_W) = \bigcup_{c \in C_W} (A_2^{12} + \phi(c)).$$

The linearity of C_W makes the union of cosets a lattice; its self-duality gives the integrality of the gluing, and divisibility by three of all weights gives its evenness. Moreover, C_W has dimension six and

$$\det N(C_W) = \frac{3^{12}}{|C_W|^2} = \frac{3^{12}}{(3^6)^2} = 1.$$

Minimum distance six implies that a nonzero gluing class has norm at least $6(2/3) = 4$. Therefore the roots of $N(C_W)$ are exactly those of A_2^{12}. This is the explicit construction of the Niemeier of type A_2^{12} used below.

21.9.9 Radial minimization and explicit construction of the 3-neighbor

In the positive chamber we consider radial vectors

$$v(a) = \sum_{i=1}^{12} a_i \rho_i, \qquad a_i = 1 + 3b_i, \quad b_i \geq 0.$$

The condition $v(a)^2 \equiv 0 \pmod{18}$ is equivalent to $\sum_i b_i \equiv 1 \pmod 3$. Its minimum is

$$v(a)^2 = 2 \sum_i (1 + 3b_i)^2 = 54,$$

and is attained exactly twelve times: one coefficient is four and the remaining eleven are one. The recovered origin $o_* = 1$ selects

$$v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}.$$

Minimality belongs to the declared positive radial cone. In the entire residual quotient there exists, for example, the representative $(\alpha_1 - 2\alpha_2, \rho, \ldots, \rho)$, congruent to $(\rho, \ldots, \rho)$ modulo three and of norm $14 + 11 \cdot 2 = 36$. The direct calculation preserves it as a witness that prevents extending the domain.

We define

$$N_{\alpha,0} = \{x \in N(C_W) : \langle x, v_\alpha \rangle \equiv 0 \pmod 3\}, \qquad N_\alpha = N_{\alpha,0} + \mathbb{Z}\frac{v_\alpha}{3}.$$

Theorem 21.48 (Leech 3-neighbor)**.** *The preceding construction satisfies*

$$\begin{aligned}
&\text{(I1)} \quad v_\alpha \in A_2^{12} \subset N(C_W), && \langle N(C_W), v_\alpha \rangle \not\subset 3\mathbb{Z},\\
&\text{(I2)} \quad v_\alpha^2 = 54 \equiv 0 \pmod{18},\\
&\text{(I3)} \quad v_\alpha/3 \in N_{\alpha,0}^* \setminus N(C_W), && 3(v_\alpha/3) \in N_{\alpha,0}.
\end{aligned}$$

The lattice N_α is even, unimodular, of rank twenty-four and rootless. Consequently,

$$N_\alpha \cong \Lambda_{24}.$$

Proof. For any root of a factor A_2, the pairing with $a_i\rho_i$ is congruent to 1 or 2 modulo three. The character of (I1) is therefore surjective, and none of the old roots belongs to $N_{\alpha,0}$. The equality in (I2) is the preceding radial calculation. If $x \in N_{\alpha,0}$, then $\langle x, v_\alpha/3 \rangle \in \mathbb{Z}$, which proves the first inclusion in (I3). If $v_\alpha/3$ belonged to $N(C_W)$, the integrality of the Niemeier would force the character of (I1) to be zero. The class has order three and $v_\alpha \in N_{\alpha,0}$ because $v_\alpha^2 \equiv 0 \pmod 3$.

The kernel has index three, hence

$$\det N_{\alpha,0} = 3^2 \det N(C_W) = 9, \qquad \det N_\alpha = 9/3^2 = 1.$$

For $x \in N_{\alpha,0}$ and $m \in \mathbb{Z}$,

$$\left(x + m\frac{v_\alpha}{3}\right)^2 = x^2 + 2m\frac{\langle x, v_\alpha \rangle}{3} + 6m^2 \in 2\mathbb{Z},$$

so the neighbor is even. It remains to exclude new roots. Each coordinate of the two nontrivial cosets belongs to one of the six classes

$$A_2 + \varpi_j \pm \rho/3, \qquad j \in \{0, 1, 2\},$$

and the minimum of each class is $2/9$. Indeed, writing a coordinate as $(u/3, v/3)$, its norm is $2(u^2 - uv + v^2)/9$; the six residues are nonzero and each admits a representative with $u^2 - uv + v^2 = 1$. Every new norm is at least $12(2/9) = 8/3 > 2$. The neighbor has no roots. The classification of even unimodular lattices of rank twenty-four identifies it with Leech. □

Enumeration of the six local minima and the twelve radial minimizers reconstructs the 729 words of C_W, the Gram matrix of the gluing and its evenness; exact arithmetic checks I1–I3, the determinants and the bound $8/3$.

21.9.10 Corridor from Leech to the Moonshine algebra

Define

$$\Lambda_{\mathrm{HMT}} := N_\alpha \cong \Lambda_{24}, \qquad V^\natural_{\mathrm{HMT}} := V^+_{\Lambda_{\mathrm{HMT}}} \oplus V^{T,+}_{\Lambda_{\mathrm{HMT}}}.$$

No second lattice is introduced here: the Frenkel–Lepowsky–Meurman construction is applied to the neighbor produced in the preceding subsection.

Theorem 21.49 (HMT–Moonshine corridor)**.** *With the dodecad, alignment, origin and exceptional chamber of the preceding construction fixed, we have*

$$V^\natural_{\mathrm{HMT}} \cong V^\natural, \qquad \mathrm{Aut}(V^\natural_{\mathrm{HMT}}) \cong \mathbb{M},$$

and

$$\mathrm{Tr}_{V^\natural_{\mathrm{HMT}}} q^{L_0 - 1} = J_{\mathrm{Mon}}(\tau) = j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \cdots .$$

Consequently, the chain

$$\mathrm{HMT} \longrightarrow N_\alpha \cong \Lambda_{24} \longrightarrow V^\natural_{\mathrm{HMT}} \longrightarrow \mathbb{M} \longrightarrow \mathrm{Moonshine}$$

is a result proved by composition.

Proof. The 3-neighbor theorem proves, from the declared data, that N_α is even, unimodular, of rank twenty-four and rootless. Lattice classification identifies it with Λ_{24}. Applied to this output, the Frenkel–Lepowsky–Meurman construction produces the orbifold $V^+_{\Lambda_{\mathrm{HMT}}} \oplus V^{T,+}_{\Lambda_{\mathrm{HMT}}}$; the classical theorems identify its automorphism group with $\mathbb{M}$ and its graded character with the normalized Hauptmodul $J_{\mathrm{Mon}} = j - 744$ [50, 28, 15]. Each arrow therefore delivers an object of the type required by the next. □

Remark 21.50 (The trivial component is not a fit). The grading satisfies

$$V^\natural_{\mathrm{HMT}} = \bigoplus_{n \geq 0} (V^\natural_{\mathrm{HMT}})_n, \qquad (V^\natural_{\mathrm{HMT}})_0 = \mathbb{C}\mathbf{1}, \qquad (V^\natural_{\mathrm{HMT}})_1 = 0.$$

The term q^{-1} thus records the vacuum line. In degree two,

$$\dim(V^\natural_{\mathrm{HMT}})_2 = 196884 = 1 + 196883 = 196560 + 324 = 54(5 \cdot 729 + 1).$$

The equality $196884 = 1 + 196883$ separates the trivial representation and the smallest nontrivial irreducible representation of the Monster. The other two equalities are exact integer decompositions; they neither replace this graded structure nor are used to select the corridor retrospectively.

The finite stage up to N_α starts from a declared dodecad, alignment, origin and chamber. The calculation proves that N_α is even, unimodular and rootless. The classical classification and orbifold theorems are applied to that output: the orbifold is $V^\natural$, its automorphism group is $\mathbb{M}$ and its graded character is J_{Mon}. The composition thus preserves the provenance of each arrow without reducing the corridor to a coincidence of coefficients.

21.9.11 Quotient space of 243 syndromes

Puncturing one coordinate of C_W produces

$$G_{11} = [11, 6, 5]_3.$$

The ternary ball of radius two has

$$1 + 22 + 220 = 243$$

elements. Since

$$|G_{11}| \cdot 243 = 3^6 \cdot 3^5 = 3^{11},$$

and the minimum distance is five, these balls are disjoint and cover all of $\mathbb{F}_3^{11}$. Each vector admits a unique decomposition

$$x = c + e, \qquad c \in G_{11}, \quad \mathrm{wt}(e) \le 2.$$

The linear quotient is

$$\mathbb{F}_3^{11}/G_{11} \cong \mathbb{F}_3^5, \qquad |\mathbb{F}_3^{11}/G_{11}| = 243.$$

Thus, a quotient space of 243 syndromes is obtained in an ambient space of eleven coordinates and quotient dimension five. The catalogue of 243 words w_6 and this quotient have the same cardinality, but are objects of different types; the direct encoder sends code words to the zero syndrome. The proved double projection uses the common flag, not an unstructured cardinality bijection.

21.9.12 Finite compatibility of the arithmetic and exceptional evaluations

Theorem 21.51 (Finite compatibility of the two projections)**.** *Consider the vector K and the signed dodecaphase state constructed in the section 30.12; the four catalogue words defined in the chapter 9; and the matrix A_W constructed in the section 21.2. The construction fixes a single calibration $c_{\mathrm{exc}} \in \mathscr{C}_{\mathrm{exc}}$ and transports it with the state; this calibration types the coordinates of the exceptional codomain and does not act as a generating input. The following statements hold:*

1. *Archimedean evaluation obtains α_{12} through dodecaphase carrying;*
2. *the Archimedean and exceptional support maps produce the same flag $B_K \subset H_\alpha^-$;*
3. *the marked frame recovers the origin $o_* = 1$;*
4. *the matrix A_W constructs W_{12}, and the 495 star involutions generate a group of order* 95040*, identified with M_{12};*
5. *the explicit discriminant realization constructs $N(A_2^{12})$, and the origin, together with the positive chamber, selects v_α; its 3-neighbor is even, unimodular and rootless.*

The support identities and the origin rule are equivariant under a simultaneous permutation of the twelve coordinates. The calibration transforms the incidence data simultaneously and does not alter their isomorphism class.

Proof. The first statement is the dodecaphase reconstruction of the section 30.12. Equations (21.121) and (21.122) prove the second by direct evaluation of the two maps. The set-theoretic calculation in the preceding section gives $o_* = 1$. Finally, the enumerator, the 132 weight-six supports, the 495 involutions and the group order, together with the 3-neighbor theorem, prove the last statement. □

Corollary 21.52 (Compatibility with the HMT–Moonshine corridor)**.** *The finite data of the exceptional projection construct the same N_α that enters into the theorem 21.49; therefore, finite evaluation is compatible with $V_{\mathrm{HMT}}^\natural$, its $\mathbb{M}$ action and its character J_{Mon}.*

The finite flag is obtained by two distinct operations applied to coordinates of the same enriched state, and the origin is derived after fixing that flag. This proves a typed internal identity and preserves the common provenance without promoting calibration to a causal input. The lattice construction preserves the type distinction. The composition from the data of α to Λ_{24} factors through the code, the gluing A_2^{12}, the marked origin, the radial chamber and the 3-neighbor. The branch $W_{12} \to W_{24}$ continues separately and is determined for every choice of a dodecad D and an incidence isomorphism $\ell : W_{12}^{\mathrm{HMT}} \to \mathcal{H}(D)$. The proved equivariance means that those choices coordinate the representation without altering the generated isomorphism class or the closure of the double projection.

21.10 From spectral jump 4 to Monster symmetries: APP unfolding $2 \to 6 \to 54$, the Leech lattice, $V^\natural$, and the Moonshine corridor

The corridor is not a sequence of numerical coincidences. It begins at the central block of APP, preserves the sum–product orientation, branches into the APP–Fock and APP–Witt couplings, and is coordinated anew through the grading. The binding causal order is

$$\begin{aligned} B_c = 9P_+ + 5P_- &\longrightarrow 4 \longrightarrow 2 \longrightarrow 6 \longrightarrow 54 \\ &\longrightarrow \begin{cases} \text{Fock degree two and } [q]t_3 = 54, \\ \text{APP–Witt alignment and } N_\alpha \cong \Lambda_{24} \end{cases} \\ &\longrightarrow V^\natural \longrightarrow \big(\mathrm{Aut}, \mathrm{ch}, g \mapsto T_g\big) \longrightarrow \text{Moonshine}. \end{aligned}$$

The two intermediate branches have distinct codomains. The common key 54 is a graded invariant transported by the corridor; it is not a linear map from a scalar into a vertex operator algebra.

21.10.1 Typed hierarchy and 2 realizations of index 54

Theorem 21.53 (Spectral Hierarchy and APP Unfolding)**.** *Let $B_c = 7I + 2R = 9P_+ + 5P_-$ be the central block of APP. If M_Π, M_Σ are the defined modular compressions, then*

$$9 - 5 = 4, \qquad (B_c)_{i \neq j} = 2, \qquad \sum M_\Pi - \sum M_\Sigma = 51 - 45 = 6,$$

and the deployment over the nine positions gives

$$9 \cdot 6 = 459 - 405 = 54.$$

The four integers pertain, respectively, to the spectral gap, the local coupling, modular compression, and two-dimensional integration.

Proof. The spectral decomposition of B_c gives 9 and 5, whereas $7I + 2R$ fixes the nondiagonal coefficient. The two aggregate sums are 51 and 45. Each compressed entry represents nine positions, so that the unfolding multiplies the difference by nine. None of the four integers is obtained by retrospectively identifying its types. □

Once the orientation line $o_{\Sigma\Pi}$, leaf parity, and the triangular normalization have been fixed, the oriented coupling

$$\mathcal{H}^{(m)}_{\Sigma,\Pi} : M_{\mathrm{bal}}^{C_3,-} \longrightarrow \mathrm{End}\big(\mathcal{F}_2(\mathcal{V}_m)\big) \otimes o_{\Sigma\Pi}$$

satisfies

$$\mathrm{Tr}_{o,\mathcal{F}_2}\Big(\mathcal{H}^{(m)}_{\Sigma,\Pi}(\nu)\Gamma_2(g_m)\Big) = -\frac{3m\, c(\nu)}{2}.$$

For $m = 12$ and $c(\delta) = -3$, the trace equals 54. On the other hand,

$$t_3(q) = q^{-1} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots,$$

from which $[q]t_3 = 54$.

Theorem 21.54 (Common Index Compatibility Cone)**.** *With the starting structures of each branch preserved, it holds that*

$$\boxed{D_{\mathrm{APP}} = \mathrm{Tr}_{o,\mathcal{F}_2}\left(\mathcal{H}^{(12)}_{\Sigma,\Pi}(\delta)\Gamma_2(g_{12})\right) = [q]t_3 = v_\alpha^2 = \frac{196884}{5\cdot 729+1} = 54.}$$

This equality constitutes a cone of evaluations toward the same integer. It does not identify W_{APP}, the Fock space, the neighboring lattice, and $V^\natural$.

Proof. The APP census yields $459 - 405 = 54$; the oriented trace yields 54; expansion of the cyclotomic product yields $[q]t_3 = 54$; and the radial vector of the neighbor satisfies $v_\alpha^2 = 4^2 \cdot 2 + 11 \cdot 2 = 54$. Finally, $5 \cdot 729 + 1 = 3646$ and $54 \cdot 3646 = 196884$. The equalities are compared only after each object has been constructed and therefore do not numerically select the corridor. □

Exact status of the hierarchy 4→2→6→54 and of the lattice identification. The hierarchy $4 \to 2 \to 6 \to 54$, the APP–Fock trace, and the extraction $[q]t_3$ are exact internal identities. Identification of the neighbor with Leech uses the declared chamber, neighboring vector, and lattice classification.

21.11 Exceptional prolongation: from dodecaphasic incidence to Moonshine

The numerical expression does not exhaust the state that generated it. In the preceding construction, APP preserves the two sheets and division with remainder and quotient; TRIT determines the local regime and its orientation; TPK composes selection, transport, carry, memory and return. The Archimedean reading contracts compatible cylinders. The reading now studied instead preserves the incidence of positions and its transport between frames. Both start from the same arithmetic state with trajectory memory. No exceptional geometry is reconstructed from the final decimals of π, φ, e or α.

This point makes the meaning of the prolongation $\alpha/K \longrightarrow$ exceptional incidence precise. The arrow does not assert that an isolated real number determines a code, lattice or group. It transports the dodecaphasic register and signed data that entered into the determination of α, together with the words and frames arising from APP–TRIT–TPK. In particular, the ordered register K can be recovered from its rational constant κ with the base, length and origin conventions already fixed. Projection onto a support, by contrast, preserves only the selected incidences. Meanwhile, K_{ph} denotes another reading, with reduced memory, subsequent to the holonomy Γ_9.

The exposition separates three mathematical operations: constructing the finite objects and their maps; prolonging them to a lattice and a vertex operator algebra; subsequently recognizing the resulting objects through the relevant classical theorems. The names Paley, Witt, Mathieu, Golay, Leech and Monster denote those recognitions and the explicit realizations making them verifiable. They are not retrospective selectors of the seeds or coefficients of generation.

The argument starts with compatibility of prefixes and frames, constructs the ternary code and determines the flag through K and the signed register of α. Marked incidence then selects the lattice origin and Leech neighbor. The final step realizes the vertex algebra and its automorphisms. At each stage the structure preserved will be specified: linear combinations, supports, discriminant classes, bilinear form or graded product. Explanations of the function of K, normalization and the origin of norm 54 accompany their respective constructions in Sections 21.11.3 and 21.11.9.

21.11.1 Compatibility of the Archimedean and incidence realizations

Let X_n^{cal} be the space of admissible prefixes of length n of the arithmetic state with trajectory memory, with truncations $p_{n,m} : X_n^{\mathrm{cal}} \to X_m^{\mathrm{cal}}$ for $m \le n$. The superscript recalls that the declared initial frame and its transport are preserved, not that a parameter is fitted against an experimental value. We write (w_j, f_j) for the visible word of six trits and the frame at step j. The frames satisfy a causal law

$$f_{j+1} = g_j(x) f_j,$$

where $g_j(x)$ depends on the prefix already constructed. Consequently, a prolongation does not alter earlier frames.

The chain

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

is preserved in this reading. Phase return resets neither the frame nor the state memory. Likewise, the census of 468 decimal emissions, the 243 visible words of six trits and the ambient space $\mathbb{F}_3^6$, of 729 words, remain distinct. The ambient space will be used to construct a linear code; it does not replace the admissible domain of emissions.

For a block b of six trits, the Archimedean reading takes its integer address $\nu(b) \in \{0, \dots, 728\}$. A prefix determines

$$q_n = m + \sum_{j=0}^{n-1} \frac{\nu(b_j)}{729^{j+1}}, \qquad I_n = [q_n, q_n + 729^{-n}].$$

Prefix compatibility gives nested cylinders whose diameter tends to zero. Their Cauchy class belongs first to the internal completion $\mathbb{R}_{\mathrm{HMT}}$; its subsequent identification with the usual real line does not enter into the choice of blocks.

For the incidence reading we introduce, on the same prefix, the graph map

$$\gamma_A : \mathbb{F}_3^6 \longrightarrow \mathbb{F}_3^{12}, \qquad w \longmapsto (w, wA). \tag{21.123}$$

Words are written as row vectors. If $A^f = fAf^{-1}$, the change of frame satisfies the concrete identity

$$\gamma_{A^f}(wf^{-1}) = \gamma_A(w)(f^{-1} \oplus f^{-1}). \tag{21.124}$$

The calibrated codomain preserves f together with the encoded word. We then define

$$Q_n(x) = \big((f_j, \gamma_{f_j A_W f_j^{-1}}(w_j))\big)_{0 \le j < n}. \tag{21.125}$$

Proposition 21.55 (Compatibility and prolongation of the incidence reading)**.** *If $r_{n,m}$ truncates the encoded sequences, then*

$$r_{n,m} Q_n = Q_m p_{n,m}.$$

Therefore, the Q_n determine a unique map Q_∞ between the respective inverse limits. In each frame, the map preserves exactly the visible word, since $\mathrm{pr}_1 \gamma_A = \mathrm{id}$.

Proof. Two compatible prefixes have the same words and the same transport operators up to index $m - 1$. By induction, they have the same frames at those indices. The first m components of (21.125) coincide, proving the square. The universal property of the inverse limit gives Q_∞. The recovery assertion is projection onto the first six coordinates of each graph. □

This local injectivity has a precise domain. It does not prove that Q_∞ recovers all the deep memory of the TPK state if only the sequence of visible words and frames has been retained. Still less does it prove injectivity after passing from words to supports. Moreover, a general change of basis in $\mathrm{GL}_6(\mathbb{F}_3)$ does not

by itself preserve ordinary Hamming weight. In a general chart, the incidence and metric of the initial chart are also transported. The support calculations that follow are performed in the declared Paley chart; monomial relabelings directly preserve their coordinate interpretation.

21.11.2 The finite realization and the ternary code

The elliptic TRIT operator admits the following finite realization in the six-position chart. These coordinatize the six units $\{1, 2, 4, 5, 7, 8\}$ modulo nine, preserved by modular transport. On $\mathbb{P}^1(\mathbb{F}_5)$, once the order $\infty, 0, 1, 2, 3, 4$ is declared, let C be the matrix with zero diagonal, $C_{\infty,a} = C_{a,\infty} = 1$ and $C_{a,b} = \chi(b - a)$ in the five finite positions. Here $\chi(1) = \chi(4) = 1$, $\chi(2) = \chi(3) = -1$ and $\chi(0) = 0$. This is a coordinate realization of the already transported quadratic structure; identifying the six positions with the projective line is a chart datum, not a new numerical input into the generator.

The quadratic sum identities give $C^2 = 5I_6$. Reducing modulo three yields

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}, \qquad A_W^2 = 2I_6 = -I_6. \tag{21.126}$$

The quadratic equality realizes the elliptic regime; it does not identify the field $\mathbb{F}_3$ with an Archimedean realization of the imaginary unit. These are distinct realizations of a common operator relation, with their corresponding domains.

Definition 21.56 (Code of the dodecaphasic chart)**.** The ternary code associated with (21.126) is

$$C_W = \{(w, wA_W) : w \in \mathbb{F}_3^6\} \subset \mathbb{F}_3^{12}.$$

Its set of hexads is

$$\mathcal{H} = \{\operatorname{supp}(c) : c \in C_W, \operatorname{wt}(c) = 6\}.$$

Proposition 21.57 (Self-duality, distance and Witt design)**.** *The code C_W is self-dual with parameters $[12, 6, 6]_3$. Its weight enumerator is*

$$\sum_{c \in C_W} z^{\operatorname{wt}(c)} = 1 + 264z^6 + 440z^9 + 24z^{12}. \tag{21.127}$$

The set $\mathcal{H}$ has 132 *elements and constitutes a system $S(5, 6, 12)$: each set of five positions is contained in a unique hexad.*

Proof. The generator matrix $[I_6 \mid A_W]$ has rank six and, by symmetry of A_W, satisfies

$$[I_6 \mid A_W][I_6 \mid A_W]^{\mathsf{T}} = I_6 + A_W^2 = 0.$$

The code is self-orthogonal with dimension half its length and is therefore self-dual. Finite evaluation of the 3^6 words gives (21.127); this is an enumeration over the explicit matrix, without real values or external targets. In particular, the minimum distance is six.

If two words of weight six have the same support, among their six nonzero coordinate ratios one of the signs $1, -1$ appears at least three times. Subtracting the corresponding multiple would yield a nonzero word of weight at most three, impossible. Thus a support corresponds exactly to the pair $\{c, -c\}$ and there are $264/2 = 132$ supports. If two distinct supports shared five positions, the same argument would

cancel at least three coordinates of a union of size seven, producing weight at most four. A quintuple therefore belongs to at most one hexad. Finally,

$$132\binom{6}{5} = 792 = \binom{12}{5},$$

so it belongs to one and only one. □

The subsequent recognition is the extended ternary Golay code and the small Witt design [161]. The preceding proof explains which object is recognized. It does not replace the APP–TRIT–TPK genealogy with a search among known codes.

21.11.3 Dodecaphasic flag associated with K and α

Articulation of the regional coordinates and closure incidence. The function of this prolongation is understood through a distinction between three operations: preserving a register, evaluating a coordinate and extracting an incidence relation. All three act on information produced by APP–TRIT–TPK. Their articulation makes explicit the structural thesis of the article: a numerical realization has an operator provenance, and certain data from that provenance also admit a combinatorial and lattice realization. The equations allow both paths to be followed with their domains and the information remaining in each.

The starting point is the terminal state with its compatible prolongations. It preserves the residues and quotients of the two APP sheets, the TRIT regime and orientation, and TPK transport with its memory. The closure, propagation and self-scale regions are determined in that domain before their readers establish the coordinates π, e, φ. At the same time, the oriented register of the twelve windows determines the signed vector U. The subsequent appearance of K comes from the integral transformation proved in §11.4.8:

$$U = \mathcal{H}_{12}K, \qquad K = \frac{1}{4}\mathcal{H}_{12}U, \qquad \mathcal{H}_{12}^2 = 4I_{12}. \tag{21.128}$$

The congruence defining $\mathcal{L}_H$ guarantees integrality of the inverse. In this way, K constitutes a reversible coordinatization of the signed register in the relevant sublattice. Its positions preserve phase order; its differences D_3K, D_4K preserve transverse relations; the sum $Q(K)$ determines the uniform component. This structure explains why the register participates both in numerical composition and in selection of a boundary configuration.

The periodic evaluation

$$K \longmapsto \kappa_{\mathrm{per}} = \frac{\sum_{m=1}^{12} K_m 1000^{12-m}}{1000^{12} - 1}$$

keeps the twelve blocks recoverable when base, length and phase origin are fixed. Extracting a support performs a different operation: it preserves membership of each position in a class defined by a threshold and groups registers having the same support. The distinction between these two maps is decisive. The scalar precision of κ_{per} and the incidence of B_K are two specific mathematical contents, related through the complete register from which they arise.

In the frame inherited from the dodecaphasic register, the data are

$$K = (234, 543, 140, 729, 659, 824, 621, \mathtt{058}, 914, 794, 146, 601), \tag{21.129}$$
$$w_\pi = 010211, \qquad w_e = 201101,$$
$$w_\varphi = 121200, \qquad w_{\mathrm{APP}} = 022020.$$

Applying γ_{A_W} yields the following incidences:

$$P_\pi = \{2, 4, 5, 6, 7, 8, 9, 10, 11\},$$
$$H_e = \{1, 3, 4, 6, 9, 10\},$$

$$H_{\varphi} = \{1, 2, 3, 4, 7, 9\},$$
$$H_{\mathrm{APP}} = \{2, 3, 5, 10, 11, 12\}.$$

The first is the support of a word of weight nine; the other three are hexads. Through its high-block reading, the register provides

$$B_K = \{i : K_i \geq 729\} = \{4, 6, 9, 10\} = H_e \cap P_{\pi}. \tag{21.130}$$

The integer 729 here marks a boundary of the declared block format. It is not identified merely by cardinality with the ternary ambient space used in (21.56). In this specific register, all integer thresholds between 660 and 729 produce the same support: the support does not recover the threshold or the twelve blocks.

Before carry, the arithmetic route to α preserves the signed vector

$$Z_0 = (7, 297, 353, -430, -715, -1199, -3, 286, -894, -528, 380, 663). \tag{21.131}$$

Its negative support is

$$H_{\alpha}^{-} = \{4, 5, 6, 7, 9, 10\}. \tag{21.132}$$

These signs are not extracted from the decimal expansion of the scalar α; they are preserved in the state preceding its numerical expression.

Alpha normalization and its signed configuration. The coordinate of α is determined in the positional path through composition of the regional blocks and dodecaphasic register. Before positional division, the oriented combination has components $Z_j = P_j + E_j - \Phi_j - K_j^{\mathrm{per}}$ and the balance with incoming quotient is $s_j = Z_j + c_{j+1}$. Normalization satisfies

$$A_j = s_j - 1000c_j = Z_j + c_{j+1} - 1000c_j, \qquad 0 \leq A_j < 1000. \tag{21.133}$$

This identity simultaneously preserves the normalized block and the contribution of the transported quotient. The limit of compatible prefixes determines the scalar coordinate of the closure. The signed configuration, in turn, preserves which positions of the combination before normalization have a negative defect. In the initial window, that configuration is the vector Z_0 of (21.131), and its negative support is H_{α}^{-}.

Two contents of the same operation are thus defined. Positional normalization determines a real coordinate through its compatible remainders and quotients; the negative support determines a configuration of positions in the cycle of twelve components. The sign refers to the register balance before normalization. Its incidence reading remains available because the state preserves that balance together with the normalized result. This articulation corresponds to the proved positional path; comparison with the analytic vacancy operators retains the precise scope established in the chapter on α.

Proposition 21.58 (Agreement of the two flag selectors)**.** *Within $\mathcal{H}$, the support* (21.132) *is the unique hexad H satisfying*

$$B_K \subset H \subset P_{\pi}, \qquad (|H \cap H_e|, |H \cap H_{\varphi}|, |H \cap H_{\mathrm{APP}}|) = (4, 3, 2).$$

Thus, the signed reading and incidence reading select the same flag $B_K \subset H_{\alpha}^{-}$.

Proof. The four hexads containing B_K are obtained by adding, respectively, the pairs

$$\{1, 3\}, \qquad \{2, 11\}, \qquad \{5, 7\}, \qquad \{8, 12\}.$$

Only the second and third pairs are contained in P_π. For the second, the intersection with H_φ has size three and with H_{APP} size three; it fails the last condition. For the third, the three intersections have sizes $4, 3, 2$. This last one produces precisely the negative support of (21.131). □

Both the flag and its marked frame should be retained:

$$\mathcal{I}_* = (B_K \subset H_\alpha^-), \qquad \widetilde{\mathcal{I}}_* = (\mathcal{I}_*; P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}).$$

Union, intersection and difference operations are equivariant under simultaneous relabeling of the design. The marked class, not the position numbers taken in isolation, is the transported object.

Lemma 21.59 (Origin selected by marked incidence)**.** *For the preceding frame,*

$$o_* = (H_e \cap H_\varphi) \setminus (H_\alpha^- \cup H_{\mathrm{APP}}) = \{1\}.$$

The rule is equivariant under every automorphism applied simultaneously to the data of $\widetilde{\mathcal{I}}_*$.

Proof. The first intersection is $\{1, 3, 4, 9\}$. The union subtracted contains $3, 4, 9$ and does not contain 1. Equivariance follows because a bijection commutes with set operations. □

This origin will select a direction of the lattice neighbor when the metric A_2 and positive chamber are declared. Incidence alone does not contain that metric. The lattice step will explicitly preserve both data.

From ternary encoding to the marked flag. The regions also provide the codes w_π, w_e, w_φ and w_{APP} in the inherited frame. The map

$$\gamma_{A_W} : w \longmapsto (w, wA_W)$$

preserves the six-component word as its first coordinate and adds its transform by A_W. The relation $A_W^2 = -I_6$ fixes the quadratic compatibility of this realization. The next step, $c \mapsto \mathrm{supp}(c)$, preserves the nonzero positions. For words of weight six, the support identifies exactly the pair $\{c, -c\}$, as proved by the minimum distance of the code. In this way, the quotient by sign produces the hexads, while the complete code remains available for operations requiring its symbols.

In this chart, the two constructions of the tetrad coincide:

$$\{i : K_i \geq 729\} = H_e \cap P_\pi = B_K = \{4, 6, 9, 10\}. \tag{21.134}$$

The left-hand side comes from an integer comparison of the components of K; the right-hand side, from the intersection of the encoded propagation and closure supports. The threshold belongs to the declared block chart and remains explicit in the reader's definition. The complete register preserves the values on which it acts, even when different thresholds produce the same subset. The equality therefore expresses compatibility between specified maps.

The support H_α^- completes that tetrad to a hexad. The condition of membership in the support P_π, together with the intersection sizes $(4, 3, 2)$ relative to $H_e, H_\varphi, H_{\mathrm{APP}}$, selects a unique hexad. The following proofs combine the two determinations: that obtained through the sign of Z_0 and that obtained through incidence. The result is organized as

$$\widetilde{\mathcal{I}}_* = \big(B_K \subset H_\alpha^-; P_\pi, H_e, H_\varphi, H_{\mathrm{APP}}\big). \tag{21.135}$$

The inclusion is the flag; the four additional supports constitute its marked frame. Simultaneous permutations transport the frame and preserve its inclusions and intersections. The relevant information resides in this transported configuration and its isomorphism class.

The five regions of π here recover their internal differentiation. They share w_π as a visible ternary code, but preserve distinct emissions, signatures and multiplicities. In the binary realization on a marked dodecad, the transverse region corresponds to the octad whose intersection with the dodecad is the tetrad; the other four regions correspond to the lifts of the four hexads of its star. The negative region is distinguished by H_α^- and the chart order individualizes the three positive regions. This correspondence preserves regional roles and the distribution $432 + 4 \cdot 144 = 1008$, while also realizing the incidence partition $1 + 4$.

21.11.4 Isometric intertwining of the incidence representations

Incidence defines a linear map whose action can be checked position by position:

$$I : \mathbb{R}^{12} \longrightarrow \mathbb{R}^{\mathcal{H}}, \qquad (Iv)(H) = \sum_{p \in H} v_p. \tag{21.136}$$

Let $V_{11} = \mathbf{1}^\perp \subset \mathbb{R}^{12}$. The two Euclidean realizations are here subsequent languages for the same finite design.

Proposition 21.60 (Isometry of the dodecaphasic screen)**.** *We have*

$$I^{\mathsf{T}} I = 36 I_{12} + 30 J_{12},$$

where J_{12} is the all-ones matrix. Consequently,

$$U_W = \frac{1}{6} I\big|_{V_{11}} : V_{11} \xrightarrow{\sim} E_{\mathrm{inc}} := I(V_{11})$$

is an equivariant isometry for the permutation actions of the design automorphisms.

Proof. Each point belongs to $r = \binom{11}{4}/\binom{5}{4} = 66$ hexads, and each pair to $\lambda_2 = \binom{10}{3}/\binom{4}{3} = 30$. These are, respectively, the diagonal and off-diagonal entries of $I^{\mathsf{T}} I$. On $\mathbf{1}^\perp$, the J_{12} term vanishes, leaving $36I$. Finally, if g is an automorphism, $p \in H$ is equivalent to $g(p) \in g(H)$; hence $I \rho_{12}(g) = \rho_{\mathcal{H}}(g) I$. □

Incidence information also has a specific spectral reading. Define

$$G_{H,H'} = \binom{|H \cap H'|}{4}.$$

Lemma 21.61 (Action of the intersection kernel)**.** *If $J_{132,12}$ is the rectangular all-ones matrix,*

$$G I = 30 I + 15 J_{132,12}.$$

Thus G acts by the scalar 30 *on E_{inc}.*

Proof. The entry (H, p) of GI counts pairs (T, H') with $T \subset H \cap H'$, $|T| = 4$ and $p \in H'$. If $p \in H$, there are ten tetrads T containing p, each contained in four hexads, and five not containing it, each with a unique extension of the quintuple $T \cup \{p\}$. The total is $10 \cdot 4 + 5 = 45$. If $p \notin H$, the fifteen tetrads of H give one extension each: the total is 15. Hence the identity. The rectangular term vanishes on V_{11}. □

Here a material intertwiner does exist: it has a determined domain, codomain, entries and normalization. For example, any orthogonal projector P already constructed on V_{11} is transported to $Q = U_W P U_W^*$ on E_{inc}, with $U_W P = Q U_W$. This assertion does not identify all operators acting on those spaces by their trace alone.

21.11.5 The direction selected by the dodecaphasic register

The register K has a geometric function complementing its rational evaluation and support reading. Once the representation of the twelve positions is constructed, its components determine a direction in the space of zero-mean variations. The reduction $12 \to 11$ removes the uniform mode; the next reduction $11 \to 10$ removes the direction selected by the register itself. The two operations therefore have different antecedents.

To declare the chart used completely, consider the group A_5 of even permutations of five objects and the subgroup $C_5 = \langle (1\,2\,3\,4\,5) \rangle$. The twelve left cosets $r_p C_5$ are ordered by these representatives, written as lists of images:

p	r_p	p	r_p
1	$(4,3,5,2,1)$	7	$(5,4,3,2,1)$
2	$(4,2,1,3,5)$	8	$(1,3,4,2,5)$
3	$(1,2,4,5,3)$	9	$(4,2,3,5,1)$
4	$(2,5,3,4,1)$	10	$(3,2,5,4,1)$
5	$(4,3,1,5,2)$	11	$(4,5,2,3,1)$
6	$(5,1,2,3,4)$	12	$(5,3,2,4,1)$.

The action by left multiplication defines an orthogonal representation $\rho : A_5 \to O(\mathbb{R}^{12})$: $\rho(a) e_p = e_q$ when $a r_p C_5 = r_q C_5$. This representation chart acts on the register already obtained; the group characters are not used to choose its twelve values.

Let χ_3 be the values of the three-dimensional character

class	1	2^2	3	5_a	5_b
χ_3	3	-1	0	$(1+\sqrt{5})/2$	$(1-\sqrt{5})/2$.

The class 5_a contains the displayed generator of C_5, and 5_b contains its square. This convention distinguishes the two conjugate three-dimensional sectors of the representation. Define

$$P_3 = \frac{3}{60} \sum_{a \in A_5} \chi_3(a^{-1}) \rho(a), \qquad P_{11} = I_{12} - \frac{1}{12} J_{12}. \tag{21.137}$$

Both matrices are determined by finite sums in $\mathbb{Q}(\sqrt{5})$. The appearance of this quadratic field belongs to the realization of the representation, subsequent to regional generation of φ.

Lemma 21.62 (Projection of the register onto the three-dimensional sector)**.** *We have*

$$P_3 = P_3^{\mathsf{T}} = P_3^2, \quad P_3 \mathbf{1} = 0, \quad \operatorname{tr} P_3 = 3, \qquad P_3 P_{11} = P_{11} P_3 = P_3.$$

For the register (21.129)*, the vector*

$$u_K = P_3 P_{11} K \tag{21.138}$$

is nonzero. Its exact norm is

$$\|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0. \tag{21.139}$$

Proof. The character sum in (21.137) is the isotypic projector. The real character and substitution $a \mapsto a^{-1}$ give symmetry. The multiplicity of the sector in the action on A_5/C_5 is the dimension of its vectors fixed by C_5,

$$\frac{1}{5}\left(3 + 2\frac{1+\sqrt{5}}{2} + 2\frac{1-\sqrt{5}}{2}\right) = 1.$$

Hence the rank is three. Its orthogonality to the trivial character gives $P_3\mathbf{1} = 0$ and both compositions with P_{11}. These identities can also be verified by multiplying the matrices of the finite sum.

Finally, $\sum K_p = 6263$ and substitution of the twelve components into that same sum gives

$$\|u_K\|^2 = K^{\mathsf{T}} P_3 K = \frac{1}{20} \sum_{a \in A_5} \chi_3(a^{-1}) K^{\mathsf{T}} \rho(a) K = \frac{6638585 + 2275584\sqrt{5}}{20}.$$

This is an exact evaluation of sixty specified terms, reproduced by the attached certificate with quadratic rational arithmetic. The two positive coefficients prove nonvanishing. □

Definition 21.63 (Dodecaphasic direction and transverse complement)**.** The direction selected by K in the declared chart is $\ell_K = \mathbb{R}u_K$. Its transverse complement within $V_{11} = \mathbf{1}^{\perp}$ is

$$V_{10}(K) = V_{11} \cap u_K^{\perp}.$$

Proposition 21.64 (Orthogonal reduction determined by K)**.** *The operator*

$$P_{10}(K) = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2} \tag{21.140}$$

is the orthogonal projector of rank ten onto $V_{10}(K)$. We have

$$V_{11} = \ell_K \oplus^{\perp} V_{10}(K), \qquad P_{10}P_{11} = P_{10}, \quad P_{10}u_K = 0.$$

Proof. Let $E_K = u_K u_K^{\mathsf{T}}/\|u_K\|^2$. The proved nonvanishing guarantees that it is defined. It is symmetric, $E_K^2 = E_K$, has rank one and, since $u_K \in V_{11}$, $P_{11}E_K = E_K P_{11} = E_K$. Hence

$$(P_{11} - E_K)^2 = P_{11} - 2E_K + E_K = P_{11} - E_K.$$

Its image is $V_{11} \cap u_K^{\perp}$ and its trace is $11 - 1 = 10$. The decomposition and remaining identities are obtained by projection onto the two orthogonal summands. □

This result makes precise a role of K not exhausted by its designation as a register: besides reversibly representing oriented data and selecting the tetrad B_K, it determines a linear polarization. The direction depends on the complete register through P_3K, not merely on the four points of its support. The order of register, representation, direction, and dimensional reduction has thus been retained (Proposition 21.64).

The transformation has a precise covariance law. If the chart is changed simultaneously by an orthogonal permutation matrix S, $K' = SK$ and $P_3' = SP_3S^{-1}$, then

$$u'_{K'} = Su_K, \qquad P'_{10}(K') = SP_{10}(K)S^{-1}.$$

On the other hand, replacing u_K with au_K, with $a \neq 0$, does not change E_K. The direction retains a polarization and does not by itself allow recovery of either the amplitude of u_K or the complete register. Reversibility of $\kappa \leftrightarrow K$ remains in its own domain.

The geometric realization established here is a reduction of spaces with an inner product. Its subsequent use as a compact direction requires transporting this line to the corresponding physical realization. Section 21.11.17 presents the algebraic map keeping this reduction and the lattice screen coordinated.

21.11.6 The Witt star and the generation of M_{12}

Definition 21.65 (Star on a tetrad)**.** For $B \in \binom{[12]}{4}$, the Witt star is the family of the four hexads containing B. Its petals are the pairs $H \setminus B$. The permutation σ_B fixes B and exchanges the two points of each petal.

The existence of four hexads follows from

$$\lambda_4 = \frac{\binom{8}{1}}{\binom{2}{1}} = 4.$$

Two petals cannot share a point, since two hexads would then contain the same five-element set. They are therefore four disjoint pairs partitioning $[12] \setminus B$. This description is neither a five-pointed star nor a geometric metaphor: it is a four-to-one incidence of the design.

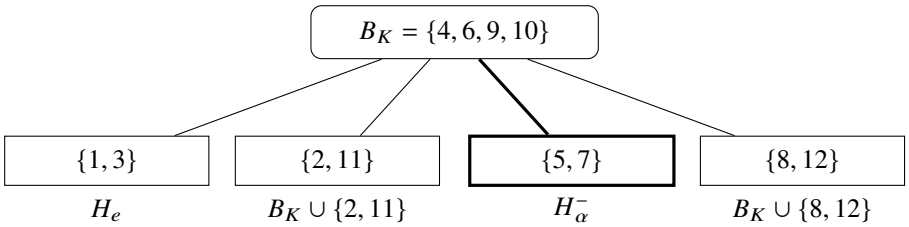

Figure 21.4: The concrete star of the dodecaphasic flag. Each line indicates the union of the central four-element set with the pair at its endpoint; the thick line marks the hexad also selected by the signs preceding the carry of α. The four pairs exhaust the eight outer positions.

Proposition 21.66 (The family of stars)**.** *The* $\binom{12}{4} = 495$ *permutations* σ_B *preserve* $\mathcal{H}$*. The group they generate has order* 95040 *and is the Mathieu group* M_{12} *in its action on the small Witt design.*

Proof. The preservation assertion is a finite check on the 132 hexads of (21.56): for each tetrad the four petals are constructed and $\{\sigma_B(H) : H \in \mathcal{H}\} = \mathcal{H}$ is verified. Closure under composition of these permutations produces 95040 elements. In lexicographic enumeration it suffices to add successively six stars not yet contained in the group; the intermediate orders are $2, 6, 18, 360, 7920, 95040$, and the 495 stars belong to the final group. The procedure, the six permutations written as their lists of images and the closure recurrence are developed in 25.18.2. Finally, recognition of the automorphism group of $S(5, 6, 12)$ as M_{12}, whose order is $12 \cdot 11 \cdot 10 \cdot 9 \cdot 8 = 95040$, is applied. □

An individual star generates a cyclic group of order two. It does not by itself generate M_{12}, still less the Monster. Nor does the existence of 495 generators of a permutation group prove that each is the transport of a specific TPK loop. That assertion requires the corresponding loop map; the result established here is the finite incidence action.

Remark 21.67 (Equality of traces does not identify operators). On V_{11}, a star has spectrum $+1$ with multiplicity seven and -1 with multiplicity four. Its normalized trace is $3/11$. A rank-three projector on the same space also has normalized trace $3/11$, but spectrum $1^3, 0^8$. They are not conjugate: their minimal polynomials and spectra differ. The intertwiner (21.136) transports defined operators; it does not turn this scalar coincidence into an equivalence of operators.

21.11.7 The binary residue and the five regions of π

The next recognition uses the extended binary Golay code G_{24}, with parameters $[24, 12, 8]_2$. Its weights are $0, 8, 12, 16, 24$, and the weight-eight supports form the design $S(5, 8, 24)$. Fix a dodecad D, the support of a word of weight twelve. This datum and the incidence isomorphism to be declared below belong to the realization chart; they are not used to generate or select the decimals of π.

Proposition 21.68 (Residue of a dodecad and lifting of hexads)**.** *The set*

$$\mathcal{H}(D) = \{O \cap D : O \text{ is an octad},\ |O \cap D| = 6\}$$

is an $S(5, 6, 12)$ system on D. Each of its hexads has a unique lift to an octad. For any four-element set $B \subset D$, the five octads containing it split into four residual lifts and a unique octad $O_B^{\perp}$ with $O_B^{\perp} \cap D = B$.

Proof. A quintuple $A \subset D$ belongs to a unique octad O. If $j = |O \cap D|$, the binary word given by the sum of O and D has weight $20 - 2j$. Among the allowed weights, and with $0 \le j \le 8$, only $j = 2, 4, 6$ are possible. Since $A \subset O \cap D$, we have $j \ge 5$ and therefore $j = 6$. This gives existence and uniqueness of the residual hexad, as well as uniqueness of its lift on choosing five of its points. Furthermore,

$$\lambda_4(S(5, 8, 24)) = \frac{\binom{20}{1}}{\binom{4}{1}} = 5, \qquad \lambda_4(S(5, 6, 12)) = 4.$$

The four residual hexads on B give four distinct octads. The fifth cannot meet D in six points, since it would be another residual hexad; as it contains B, its intersection has size four and coincides with B. □

A chart $\ell : [12] \to D$ preserving hexads identifies $\mathcal{H}$ with $\mathcal{H}(D)$. Its existence is recognition of the already constructed design as the small Witt design; a specific choice of ℓ fixes the relabeling. The lift

$$\iota_D : \mathcal{H} \longrightarrow \{\text{octads of } G_{24}\}, \qquad H \longmapsto O \text{ such that } O \cap D = \ell(H),$$

is injective because intersection with D recovers $\ell(H)$. The domain of this injectivity is the hexads, not the register K.

The relation to the five regions of π preserves richer data than the number five. The emissions and their signatures are:

Region	Multiplicity	Emission U_6	Signature
$\perp$	432	$(501, 614, 498, 169, 272, 272)$	555555
$++_1$	144	$(810, 923, 870, 169, 272, 272)$	339555
$++_2$	144	$(810, 983, 810, 169, 272, 272)$	393555
$++_3$	144	$(870, 923, 810, 169, 272, 272)$	933555
$--$	144	$(870, 923, 810, 418, 674, 521)$	933717

In each three-digit decimal block, the signature uses the modular difference of the first two digits. The five emissions have the same visible tritic word $w_\pi = 010211$, but not the same regional genealogy. The three positive regions preserve the tail 169|272|272; the negative region changes it to 418|674|521; the transverse region has constant signature and greater multiplicity.

The marked extension of the regional chart sends the transverse region to $O^{\perp}_{\ell(B_K)}$, the negative region to $\iota_D(H_\alpha^-)$ and the three positive regions to the other three lifts of the star. This realizes the partition $4 + 1$ of the five octads on $\ell(B_K)$. The individual correspondence between the three positive names and the three remaining petals requires a chart order; incidence does not determine it without that datum. The precise assertion is therefore a marked correspondence of regions, compatible with their roles and with the flag, not a canonical bijection inferred from cardinality five.

The identity $432 + 4 \cdot 144 = 1008$ preserves the regional multiplicities. Also $1008 = 36 \cdot 28$ and an octad has $\binom{8}{2} = 28$ pairs. These equalities are arithmetic catalogue checks, not substitutes for the map ι_D or the regional chart.

21.11.7.1 Pentadic representation of the microfiber and its incidence

The arrangement of the five regions allows simultaneous visualization of the unity of the ternary quotient and the differentiation preserved by the catalogue. The relevant map is the restriction

$$\Psi\big|_{\mathscr{R}_\pi^{\mathrm{micro}}} : \mathscr{R}_\pi^{\mathrm{micro}} \longrightarrow \{010211\}, \qquad \Psi(U) = (-U) \bmod 3.$$

Its five antecedents are the vectors U_6 in the preceding table. Figure 21.5 recovers their radial organization, preserving chart order, signatures and catalogue multiplicities (equation (10.37)).

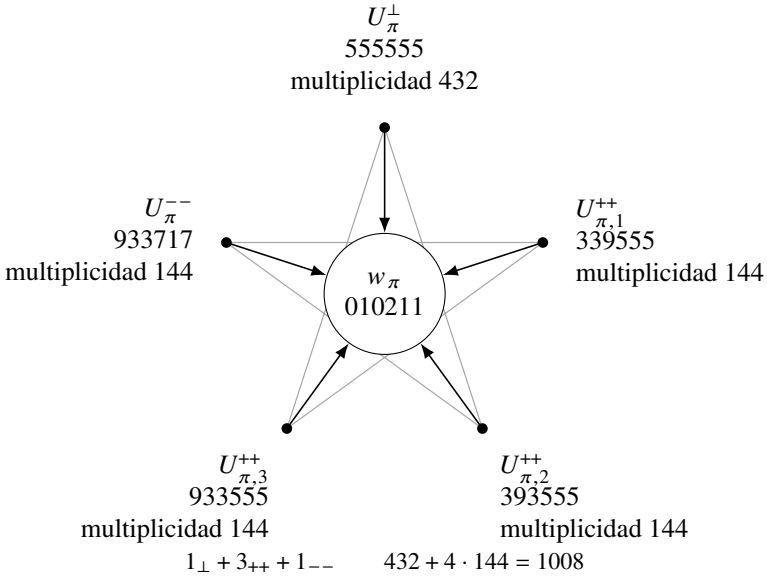

Figure 21.5: The five regions of π in a pentadic arrangement. Each position preserves its multiplicative signature and multiplicity; the radial arrows represent the common projection $\Psi(U) = 010211$. The star-shaped outline organizes the five positions of the chart. Their realization in the five Witt octads is carried out through regional alignment and the decomposition $4 + 1$ in the text.

Projection onto the center identifies the five ternary images; the register of the outer positions retains the regional information making the incidence realization possible. The distribution $1_\perp + 3_{++} + 1_{--}$ specifies one transverse region, three positive regions and one negative region. Their normalized weights are $3/7$ and $1/7$ for each of the other four: the transverse multiplicity is triple, even though the five images under Ψ coincide.

The link to the Witt star is formulated through the flag $B_K \subset H_\alpha^-$, alignment ℓ and lift ι_D already constructed. The five regional positions are realized in the five octads on $\ell(B_K)$:

$$\begin{aligned} U_\pi^{\perp} &\longmapsto O^{\perp}_{\ell(B_K)}, \\ U_\pi^{--} &\longmapsto \iota_D(H_\alpha^-), \\ \{U_{\pi,1}^{++}, U_{\pi,2}^{++}, U_{\pi,3}^{++}\} &\longmapsto \{\iota_D(B_K \cup P) : P \in \mathcal{P}_+\}, \\ \mathcal{P}_+ &= \big\{\{1,3\},\{2,11\},\{8,12\}\big\}. \end{aligned}$$

Assignment of the three positive positions to the three pairs is performed in an ordered chart. The transverse row and negative row are distinguished by their regional predicates and the flag.

The two figures are thus articulated: Figure 21.4 shows the four hexads of the small Witt design on B_K; Figure 21.5 shows the five regions that, under alignment, occupy the four residual octads and the transverse octad of the binary design. The law $4 + 1$, proved in Proposition 21.68, specifies the incidence change. In this composition, K determines the marked tetrad and the signature of α distinguishes one of its hexads. In addition to their common ternary value, the regions preserve the structure needed for that transport toward the exceptional realization.

21.11.8 From the ternary code to the Niemeier lattice

The passage to dimension twenty-four does not require first going through the binary code. It is realized directly from C_W by gluing discriminants. Two compatible prolongations are thus distinguished: one preserves the residue $W_{12} \subset W_{24}$; the other constructs the lattice on which the vertex operator algebra will be realized.

Let $A_2 = \mathbb{Z}a_1 \oplus \mathbb{Z}a_2$ have Gram matrix

$$\begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad \rho = a_1 + a_2, \qquad \rho^2 = 2.$$

We represent the three classes of A_2^*/A_2 by

$$\varpi_0 = 0, \qquad \varpi_1 = \frac{2a_1 + a_2}{3}, \qquad \varpi_2 = \frac{a_1 + 2a_2}{3}.$$

The map $j \mapsto \varpi_j + A_2$ additively identifies $\mathbb{F}_3$ with that discriminant. For $c \in C_W$, write $\phi(c) = (\varpi_{c_1}, \dots, \varpi_{c_{12}})$ and define

$$N(C_W) = \bigcup_{c \in C_W} \big(A_2^{12} + \phi(c)\big). \tag{21.141}$$

Theorem 21.69 (Ternary gluing)**.** *The object* (21.141) *is a positive, even, unimodular lattice of rank* 24*. Its root system is exactly* A_2^{12}*; it is therefore recognized as the Niemeier lattice with that root system.*

Proof. Linearity of the code makes the union of classes stable under addition. Self-orthogonality annuls the discriminant pairing: it is a multiple of $c \cdot d/3$ modulo $\mathbb{Z}$. Thus the lattice is integral. The norm of a gluing class is $2\,\mathrm{wt}(c)/3$ modulo $2\mathbb{Z}$. The weights of (21.127) are multiples of three, so it is even.

The index of A_2^{12} in $N(C_W)$ is $|C_W| = 3^6$. Consequently,

$$\det N(C_W) = \frac{3^{12}}{(3^6)^2} = 1.$$

Positivity comes from the orthogonal sum of the twelve metrics A_2. In a nonzero class of A_2^*/A_2 the minimum norm is $2/3$; every nonzero word has at least six nonzero positions. Therefore a vector in a nontrivial gluing class has norm at least $6 \cdot 2/3 = 4$. No norm-two roots appear outside A_2^{12}. Inside it, the roots are precisely those of its twelve components. □

21.11.9 Incidence selection of the rootless unimodular neighbor

From the incidence origin to the lattice modification. The marked flag determines a position through an equivariant set-theoretic operation:

$$o_* = (H_e \cap H_\varphi) \setminus (H_\alpha^- \cup H_{\mathrm{APP}}) = \{1\}.$$

Its function is to distinguish one component among the twelve involved in the lattice realization. The complete ternary code acts as a gluing code in the discriminant module $(A_2^*/A_2)^{12}$. Its preimage defines $N(C_W)$, and the self-duality, weights and distance of the code translate, respectively, into integrality and

determinant properties, parity and norm bounds on the gluing classes. Here the symbolic information of the code serves a function that the isolated support no longer performs.

The metric A_2 and positive radial chamber are fixed in the lattice development. Within that chamber, the congruence required for an even neighbor of index three has twelve realizations of minimum norm 54, permuted by changing the distinguished component. The origin o_* selects

$$v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v_\alpha^2 = 2(4^2 + 11) = 54.$$

The coefficient 4 belongs to that solution of the congruence in the declared chamber. The subscript α records the incidence provenance of the selection: its content is the frame involved in closure and now individualizing a lattice direction.

Pairing with v_α determines the sublattice $N_{\alpha,0}$ of index three, and adding the class $v_\alpha/3$ produces the neighbor N_α of (21.143). This modification preserves rank and recovers unimodularity and parity; selection by congruence removes the previous roots, and local bounds exclude roots in the new classes. Identification with Leech appears after these verifications. The binary realization of the five regions and this lattice construction are two prolongations of the common frame: the latter directly receives the ternary code as gluing data.

The label $o_* = 1$ of the flag is now realized as one of the twelve components A_2. This operation declares the preceding metric and the positive radial chamber

$$v(a) = \sum_{i=1}^{12} a_i \rho_i, \qquad a_i = 1 + 3b_i, \quad b_i \in \mathbb{Z}_{\geq 0}.$$

The evenness requirement for the index-three neighbor is $v(a)^2 \equiv 0 \pmod{18}$. Since

$$v(a)^2 = 2 \sum_i (1 + 3b_i)^2,$$

that congruence is equivalent to $\sum_i b_i \equiv 1 \pmod 3$. The smallest norm value in the chamber is obtained with a single $b_i = 1$ and all the others zero; it is 54. The marked origin selects

$$v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v_\alpha^2 = 54. \tag{21.142}$$

The word “smallest” refers to this positive chamber. It does not assert minimality in the entire residue class: the vector $(a_1 - 2a_2, \rho, \ldots, \rho)$ represents the same class modulo three and has norm $14 + 11 \cdot 2 = 36$. The chamber restriction is part of the construction data, not an omissible conclusion.

Let $N = N(C_W)$. We define

$$N_{\alpha,0} = \{x \in N : \langle x, v_\alpha \rangle \equiv 0 \pmod 3\}, \qquad N_\alpha = N_{\alpha,0} + \mathbb{Z}\frac{v_\alpha}{3}. \tag{21.143}$$

Theorem 21.70 (Leech neighbor determined by the marked flag)**.** *With the declared metric and chamber, N_α is a positive, even, unimodular lattice of rank* 24*, with no vectors of norm two. By the corresponding classification theorem, it is isometric to the Leech lattice Λ_{24}.*

Proof. The character $x \mapsto \langle x, v_\alpha \rangle$ mod 3 is nonzero: a simple root of one component pairs with $a_i\rho_i$ to give $a_i \equiv 1 \pmod 3$. Hence $[N : N_{\alpha,0}] = 3$ and $\det N_{\alpha,0} = 9$. Moreover, $v_\alpha/3 \in N_{\alpha,0}^*$ and $v_\alpha \in N_{\alpha,0}$. If $v_\alpha/3$ belonged to N, integrality of N would make all pairings with v_α divisible by three, contradicting the nonzero character. The class of $v_\alpha/3$ therefore has order three. We deduce

$$[N_\alpha : N_{\alpha,0}] = 3, \qquad \det N_\alpha = 9/3^2 = 1.$$

The extension is integral, and for $x \in N_{\alpha,0}$,

$$\left(x + m\frac{v_\alpha}{3}\right)^2 = x^2 + 2m\frac{\langle x, v_\alpha\rangle}{3} + 6m^2 \in 2\mathbb{Z}.$$

Hence it is even.

It remains to exclude the roots, which is the decisive step. The roots of N belong to A_2^{12}. Their pairings with v_α are congruent to ± 1 or ± 2 modulo three; none belongs to $N_{\alpha,0}$. For the other two classes of the neighbor, each component belongs to one of the local classes

$$A_2 + \varpi_j \pm \rho/3, \qquad j = 0, 1, 2.$$

Since $4\rho/3 \equiv \rho/3 \pmod{A_2}$, this description also holds in the distinguished component. Writing a local vector as $(ua_1 + va_2)/3$, its norm is $2(u^2 - uv + v^2)/9$. The six preceding classes have nonzero residues and minimum $2/9$: representatives minimizing the quadratic form are $(\pm 1, 0)$, $(0, \pm 1)$, $(1, 1)$, $(-1, -1)$ in the appropriate residues. A vector in a new class therefore has norm at least $12 \cdot 2/9 = 8/3 > 2$. There are no roots in any of the three classes. The classification of positive even unimodular lattices of rank twenty-four identifies the unique rootless case with Λ_{24}. □

The argument does not recognize Leech through a coincidence of dimension. It constructs the gluing, proves integrality, parity and determinant, and removes the roots through a local bound. Only then does it apply the classification theorem. Dependence on α is preserved in the flag selecting o_* and in the vector (21.142); the scalar value of the constant is not turned into a lattice length.

21.11.10 The vertex operator algebra and the Monster

Let $\Lambda = N_\alpha$, already recognized as Leech. The next step uses its integral lattice, not a decimal expansion. The lattice vertex operator algebra construction is written

$$V_\Lambda = M(1) \otimes \mathbb{C}_\varepsilon[\Lambda].$$

Here $M(1)$ is the Heisenberg oscillator space in rank twenty-four; $\mathbb{C}_\varepsilon[\Lambda]$ is the group algebra twisted by the cocycle of the lattice's central extension. The cocycle and lift of the isometries are part of the construction: a bare vector sum does not determine the vertex products.

Negation $\lambda \mapsto -\lambda$ admits the standard lift θ. With its twisted module and the compatible parity choice, the Frenkel–Lepowsky–Meurman construction produces

$$V_{\mathrm{HMT}}^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+. \tag{21.144}$$

The sign + denotes the even part of the lifted action. The expression includes the orbifold vertex product; it is not merely a sum of graded spaces.

Theorem 21.71 (Prolongation to the Moonshine module)**.** *The algebra* (21.144)*, constructed on the neighbor* (21.143)*, is a realization of the Moonshine algebra $V^\natural$. It has central charge* 24*, zero weight-one component, and automorphism group isomorphic to the Monster $\mathbb{M}$. Its graded character is*

$$\mathrm{Tr}_{V_{\mathrm{HMT}}^\natural}\, q^{L_0 - 1} = J(\tau) = j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \cdots, \qquad q = e^{2\pi i\tau}. \tag{21.145}$$

Proof. Theorem 21.70 verifies the lattice hypotheses: positivity, parity, unimodularity, rank twenty-four and absence of roots. The construction and theorem of Frenkel–Lepowsky–Meurman for the Leech lattice are then applied. They identify the orbifold with $V^\natural$ and establish its character and automorphism group. Composition of the flag, neighbor and VOA construction functor gives the realization indicated here. The group is not inferred from the coefficient 196884. □

The theorem used is a subsequent classical recognition with verified hypotheses, not a new proof in this article of the FLM construction [159]. Moreover, the notation $q = e^{2\pi i\tau}$ is the conventional Fourier variable used to recognize the character. It introduces neither π nor e as inputs to the coinductive generator that has already determined them.

Part of the trace mechanism can be seen before the orbifold. Only the zero lattice vector is fixed by negation; each oscillator contributes with alternating sign. Hence

$$\mathrm{Tr}_{V_\Lambda}\,\theta q^{L_0-1} = t_2(\tau) := q^{-1}\prod_{n\geq 1}(1+q^n)^{-24}.$$

This trace in the lattice algebra must not be confused with the character without insertion of $V^\natural$. Nor does it by itself identify a conjugacy class of the Monster: the space, insertion and lift must be specified before functions are compared.

Grading, unit and automorphisms. The Frenkel–Lepowsky–Meurman construction is applied to the lattice N_α once its properties have been verified. It incorporates the oscillator space, central extension of the lattice, vertex product and sector twisted by the lift of negation. The result is the algebra $V^\natural_{\mathrm{HMT}}$ of (21.144), whose automorphism group is isomorphic to the Monster. Its action domain is thus fixed by an algebraic structure with grading and product. Borcherds's Moonshine theorem subsequently determines the graded traces with insertion of these automorphisms [159, 160].

Unity acquires a precise realization at this level: the weight-zero component is the vacuum line and contributes the coefficient 1 of q^{-1} in the graded character. At the cylindrical level, the refinement maps preserve the constant function by precomposition. Each conservation assertion therefore has its object and map. Developing the proofs makes this continuity of construction visible, from arithmetic operations and memory to incidence, metric and vertex products.

This articulation places K and the closure of α in the main argument. K reversibly preserves an integral coordinate of the history; normalization of α composes the regional registers with that coordinate; the signed configuration determines a flag; and the marked flag selects the lattice modification on which Moonshine is realized. The following proofs develop these maps, distinguishing reversible equivalences, information quotients and realizations adding metric or algebraic structure. A provable relation between structure, equation and value is thus expressed, preserving the attribution of each construction and the scope of its theorems.

21.11.11 State-based construction of the twelve cyclotomic fibres

On the APP marks, multiplication $a : r \mapsto 4r$ in $\mathbb{Z}/9\mathbb{Z}$ satisfies $a^3 = 1$. The sheets satisfy

$$S(ax, ay) = aS(x, y), \qquad P(ax, ay) = a^{-1}P(x, y),$$

since $16 \equiv 7 \equiv 4^{-1} \pmod 9$. The ordered unit orbits are $O_0 = (1, 4, 7)$, $O_1 = (2, 8, 5)$. In each, the augmentation module $A(O) = \ker(\mathbb{Z}[O] \xrightarrow{\Sigma} \mathbb{Z})$ inherits the inner product making the e_r orthonormal. In the basis $b_1 = e_r - e_{4r}$, $b_2 = e_{4r} - e_{7r}$, its matrices are

$$G_{A_2} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad C^{\mathsf{T}} G_{A_2} C = G_{A_2}.$$

The lattice form therefore originates in the orbits of the marks. For the pairs $(1, 2)$, $(2, 3)$, $(3, 1)$ and sheets $\mu \in \{\Sigma, \Pi\}$, we obtain

$$W_{\mathrm{APP}} = \bigoplus_{(i,j)} \bigoplus_{\mu} \bigoplus_{\varepsilon=0}^{1} A(O_\varepsilon), \qquad \ell^{\Sigma}_{ij}(x) = x_i + x_j, \quad \ell^{\Pi}_{ij}(x) = x_i x_j \pmod 9.$$

Each summand preserves pair, sheet, and orbit. The state map is

$$\Psi : (\mathbb{Z}/9\mathbb{Z})^3 \longrightarrow W_{\mathrm{APP}}, \qquad \Psi(x)_{ij,\mu,\varepsilon} = \beta_\varepsilon(\ell_{ij}^{\mu}(x)), \quad \beta_\varepsilon(r) = \begin{cases} e_r - e_{4r}, & r \in O_\varepsilon, \\ 0, & r \notin O_\varepsilon. \end{cases}$$

Proposition 21.72 (Equivariance and rank of the state module)**.** *The action of C on the six additive fibres and of C^{-1} on the six multiplicative fibres satisfies $\Psi(ax) = \rho(a)\Psi(x)$. The images span $W_{\mathrm{APP}} \otimes \mathbb{Q}$, of dimension twenty-four.*

Proof. The sheet identities and $\beta(4r) = C\beta(r)$ prove equivariance. For rank, order the coordinates by the three stated pairs, by Σ, Π, by O_0, O_1, and by b_1, b_2. In each orbit, β takes successive values $(1,0), (0,1), (-1,-1)$. The matrix of the images of the following states, read row by row, has determinant 9:

$$\begin{array}{cccc} (0,0,1) & (0,0,2) & (0,0,4) & (0,0,5) \\ (0,1,0) & (0,1,1) & (0,1,2) & (0,1,3) \\ (0,1,4) & (0,1,5) & (0,1,6) & (0,2,0) \\ (0,2,2) & (0,2,3) & (0,4,0) & (0,5,0) \\ (1,0,1) & (1,0,2) & (1,0,4) & (1,0,5) \\ (1,1,0) & (1,2,0) & (1,4,0) & (1,5,0). \end{array}$$

Successive elimination, reducing each row by its predecessors and normalizing its first nonzero coefficient, gives pivot columns numbered from zero

$$(8, 10, 9, 11, 0, 12, 14, 16, 13, 15, 17, 2, \\ 18, 19, 1, 3, 20, 22, 21, 23, 4, 6, 5, 7)$$

and pivots

$$(1, 1, 1, -1, 1, 1, 1, 1, 1, -1, 3, 1, 1, 3, 1, -1, 1, 1, 1, -1, 1, 1, 1, -1).$$

Their product, multiplied by the sign of the column permutation, is 9. The invertible minor establishes full rank. □

21.11.12 Dodecaphasic alignment with the Witt positions

The pair index is $i \in \mathbb{Z}/3\mathbb{Z}$, the sheet index is $\mu \in \{0,1\}$, and the orbit index is $\varepsilon \in \{0,1\}$. With the dodecaphasic origin fixed, $\lambda(i,\mu,\varepsilon) = 4i + 2\mu + \varepsilon \pmod{12}$ is bijective: the four values for each i form a block, and the three blocks are disjoint. Let $R = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. Multiplication proves $RCR = C^{-1}$ and $R^{\mathsf{T}} G_{A_2} R = G_{A_2}$. For the trivializations ι_b and frames P_b transported jointly with Witt incidence, set

$$g_b = \iota_b^{-1} P_b C P_b^{-1} \iota_b, \qquad T_{i\mu\varepsilon} = \iota_{\lambda(i,\mu,\varepsilon)}^{-1} P_{\lambda(i,\mu,\varepsilon)} R^{\mu}.$$

Then

$$g_{\lambda(i,\mu,\varepsilon)} T_{i\mu\varepsilon} = T_{i\mu\varepsilon} C^{(-1)^{\mu}}.$$

The direct sum is a C_3-equivariant isomorphism between the twelve state fibres and the twelve lattice positions. It preserves pair, sheet, orbit, and form under simultaneous transport of origin, order, and orientation. These data persist in the lattice gluing and passage to the neighbour constructed below.

21.11.13 Ternary orientation of the Leech neighbor

The order-two presentation constructed above uses negation of the Leech lattice. The same lattice, obtained from the incidence marked by K and the dodecaphasic support of α, admits a second presentation compatible with the ternary character of the construction. To make this continuity explicit, the gluing is retained, its order-three isometry is constructed, and preservation of the already selected neighbour is verified. This step requires no alteration of K, its rational reading, or the preceding definition of α. The order-three prolongation is developed here, including the lattice operations and the precise conditions of the classical theorems used.

We work in the simple-root basis of each factor A_2, with

$$B_2 = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \qquad \mathsf{C} = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}, \qquad \mathsf{R} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \rho = \begin{pmatrix} 1 \\ 1 \end{pmatrix}. \tag{21.146}$$

The multiplication gives

$$\mathsf{C}^3 = I_2, \quad \mathsf{C}^2 + \mathsf{C} + I_2 = 0, \quad \mathsf{C}^{\mathsf{T}} B_2 \mathsf{C} = B_2, \quad \mathsf{R}\mathsf{C}\mathsf{R} = \mathsf{C}^{-1}, \quad \mathsf{R}^{\mathsf{T}} B_2 \mathsf{R} = B_2.$$

These identities fix both the metric and the orientation of the action. In the discriminant $A_2^*/A_2 \cong \mathbb{F}_3$ we take as generator the class of $\varpi = (2,1)^{\mathsf{T}}/3$. We have $\mathsf{C}\varpi - \varpi = (-1,0)^{\mathsf{T}}$, so C acts trivially on the discriminant; the reflection R changes its sign.

The already constructed Paley–Witt matrix produces an element of full support through the following operation:

$$\begin{aligned} q_* &= (1,1,1,1,1,1), \qquad q_* A_W = (2,1,1,1,1,1), \\ c_* &= (q_*, q_* A_W) = (1,1,1,1,1,1,2,1,1,1,1,1) \in C_W. \end{aligned} \tag{21.147}$$

Every coordinate of c_* is nonzero. For the twelve positions, define the frames and the isometry

$$P_b(c_*) = \begin{cases} \mathsf{R}, & (c_*)_b = 1, \\ I_2, & (c_*)_b = 2, \end{cases} \qquad g_c = \bigoplus_{b=1}^{12} P_b(c_*)\mathsf{C}P_b(c_*)^{-1}. \tag{21.148}$$

The symbol $P_b(c_*)$ here denotes an invertible frame of an A_2 factor, not the regional projector P_3.

Proposition 21.73 (Order-three isometry on the marked neighbor)**.** *The operator g_c is an order-three isometry without nonzero fixed vectors. It preserves the Niemeier lattice $N = N(C_W)$ and the neighbor N_α constructed in* (21.143)*.*

Proof. Each block of g_c is C or C^{-1}; its minimal polynomial is $X^2 + X + 1$. This proves the order and absence of fixed vectors. Both blocks act trivially on the discriminant, so they preserve each gluing class and therefore the lattice N.

Write $v = v_\alpha = 4\rho_{o_*} + \sum_{b \neq o_*} \rho_b$, with the frames and incidence origin already fixed. Its radial coefficients are $a_{o_*} = 4$ and $a_b = 1$ for $b \neq o_*$. All satisfy $a_b \equiv 1 \pmod 3$. In one factor,

$$(\mathsf{C} - I_2)\rho = (-2,-1)^{\mathsf{T}}, \qquad (\mathsf{C}^{-1} - I_2)\rho = (-1,-2)^{\mathsf{T}}.$$

After division by three, their discriminant classes are, respectively, 2 and 1. Consequently, the vectors

$$y = \frac{g_c v - v}{3}, \qquad z = \frac{g_c^{-1} v - v}{3} \tag{21.149}$$

have discriminant words c_* and $-c_*$, both in C_W. Hence $y, z \in N$. The local product is

$$\left\langle \frac{(\mathsf{C}^{\pm 1} - I_2) a_b \rho}{3}, a_b \rho \right\rangle = -a_b^2,$$

and their sum gives $\langle y, v\rangle = \langle z, v\rangle = -(16+11) = -27$. Thus, $y, z \in N_0 = \{x \in N : \langle x, v\rangle \equiv 0 \pmod 3\}$. For $x \in N_0$,

$$\langle g_c x, v\rangle = \langle x, g_c^{-1} v\rangle = \langle x, v\rangle + 3\langle x, z\rangle \equiv 0 \pmod 3.$$

The argument applied to g_c^{-1} proves $g_c N_0 = N_0$. Finally, $g_c(v/3) = v/3 + y$ preserves the class generating $N_\alpha = N_0 + \mathbb{Z}(v/3)$. We obtain $g_c N_\alpha = N_\alpha$. □

The proof preserves more than the lattice dimension: it uses the gluing code, its orientation, the origin of the flag and the congruence of the radial vector. These data explain why the second presentation remains linked to the dodecaphasic register from which the construction began.

21.11.14 Ternary trace, twisted weight and order-three extension

Let $\Lambda = N_\alpha$ and let $\widehat{g}_c$ be the standard lift of g_c to the lattice algebra $V_\Lambda = M(1) \otimes \mathbb{C}_\varepsilon[\Lambda]$, with the central extension and cocycle already declared. Odd order allows this lift to be chosen of order three. Each complex factor A_2 contributes eigenvalues ζ_3 and ζ_3^2, where $\zeta_3^2 + \zeta_3 + 1 = 0$.

Proposition 21.74 (Graded trace and type of the lift)**.** *For $j = 1, 2$,*

$$\operatorname{Tr}_{V_\Lambda}\big(\widehat{g}_c^{\,j} q^{L_0 - 1}\big) = t_3(\tau) := q^{-1} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-12}. \tag{21.150}$$

The minimum weight of the nontrivial twisted modules is $4/3$, and the lift is of type zero.

Proof. In the lattice part of the trace only the zero vector contributes, because g_c and g_c^2 have no nonzero fixed vectors. In each oscillator degree, the trace of symmetric powers is the inverse of the determinant $I - g_c^j q^n$. Each factor A_2 contributes $1 + q^n + q^{2n}$, proving (21.150).

The twisted-vacuum weight formula for an order-three lattice automorphism, applied to the two twelve-dimensional eigenspaces, gives

$$\rho_{\widehat{g}_c} = \frac{1}{4 \cdot 3^2}\big(1 \cdot 2 \cdot 12 + 2 \cdot 1 \cdot 12\big) = \frac{4}{3}.$$

The type is the class of $3^2 \rho_{\widehat{g}_c} = 12$ modulo three, which is zero. The weight formula is a result of twisted-module theory; the multiplicities and isometry feeding into it have been constructed here. □

Theorem 21.75 (Second presentation of the Moonshine algebra)**.** *The type-zero cyclic extension*

$$V_{(3)} = \operatorname{Orb}_{\mathbb{Z}/3}(V_\Lambda, \widehat{g}_c) \tag{21.151}$$

is isomorphic to the vertex operator algebra $V^\natural$.

Proof. Theorem 21.70 provides a positive, even, unimodular, rootless lattice of rank twenty-four. Proposition 21.73 constructs an order-three fixed-point-free isometry on that same lattice; Proposition 21.74 verifies the lift and its type. The Chen–Lam–Shimakura theorem on the order-three orbifold of the Leech lattice algebra then applies [165, Teorema 1.1]. This identification is also covered by the uniform treatment of Abe–Lam–Yamada [166, Teorema 4.4 y secciones 2–4]. This application follows construction of the lattice data; equality of characters does not replace the hypotheses of the theorem used. □

To make the dual symmetry precise, write $V_{(3)} = W_0 \oplus W_1 \oplus W_2$, where W_i is the integral sector selected in the $\widehat{g}_c^{\,i}$-twisted module. The product satisfies $Y(W_i, z)W_j \subset W_{i+j \bmod 3}((z))$. Hence

$$g^\vee|_{W_i} = \zeta_3^i I \tag{21.152}$$

defines an automorphism of order three. Indeed, the factor on a product is $\zeta_3^{i+j} = \zeta_3^i \zeta_3^j$, and the vacuum and conformal vector belong to W_0. The classical identification of this automorphism in the Monster is

class $3B$, with series $T_{3B} = t_3 + 12$ [167, 160]. This normalization can be checked in the construction. The lattice character is $\operatorname{ch} V_\Lambda = J + 24$: its initial pole is q^{-1}, its weight-one space has dimension 24 and the weight-zero modular character is determined by these data. If F is the character of the fixed subspace and H that of each integral twisted sector, projection onto invariants and conjugation of the two sectors give

$$F = \frac{J + 24 + 2t_3}{3}, \qquad F + 2H = J, \qquad \operatorname{Tr} g^\vee q^{L_0 - 1} = F - H = t_3 + 12.$$

Its domain is the extended algebra, whereas $\widehat{g}_c$ acts on the preceding lattice algebra.

21.11.15 Equivalence of the order-two and order-three presentations

Denote by

$$V_{(2)} = (V_\Lambda)^+ \oplus (V_\Lambda^T)^+$$

the FLM presentation of (21.144). Both presentations preserve the same Leech neighbor as antecedent. Their extensions use different automorphisms and vertex products determined through the respective lifting data.

Theorem 21.76 (Graded equivalence and transport of automorphisms)**.** *With vertex operator algebra isomorphisms fixed*

$$\phi_2 : V_{(2)} \xrightarrow{\cong} V^\natural, \qquad \phi_3 : V_{(3)} \xrightarrow{\cong} V^\natural,$$

the composition

$$\Phi_{23} = \phi_2^{-1}\phi_3 : V_{(3)} \xrightarrow{\cong} V_{(2)} \tag{21.153}$$

preserves the vacuum, conformal vector, grading and vertex product. Conjugation by Φ_{23} identifies the automorphism groups and preserves their graded traces.

Proof. Composition of the two isomorphisms preserves the declared structures. In particular,

$$\Phi_{23} Y_{(3)}(a, z)b = Y_{(2)}(\Phi_{23}a, z)\Phi_{23}b, \qquad \Phi_{23} L_0^{(3)} = L_0^{(2)} \Phi_{23}.$$

If h is an automorphism of $V_{(3)}$, then $h' = \Phi_{23} h \Phi_{23}^{-1}$ is an automorphism of $V_{(2)}$. Equality of traces on each finite-dimensional homogeneous component gives

$$\operatorname{Tr}_{V_{(3)}} h q^{L_0 - 1} = \operatorname{Tr}_{V_{(2)}} h' q^{L_0 - 1}.$$

□

The choice of ϕ_2 and ϕ_3 is part of the statement; Φ_{23} is not presented as a canonical identification independent of those choices. Nor does it transform an order-three automorphism into the order-two involution: conjugation preserves order. Its content is that two distinct extensions realize the same graded structure, with explicit transport of their products, representations and traces.

21.11.16 Eta functions, Fricke involution and vacuum normalization

For $\operatorname{Im} \tau > 0$, the traces of the two lattice automorphisms admit the expressions

$$\eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n), \qquad t_2 = \left(\frac{\eta(\tau)}{\eta(2\tau)} \right)^{24}, \qquad t_3 = \left(\frac{\eta(\tau)}{\eta(3\tau)} \right)^{12}. \tag{21.154}$$

They follow directly from the factorizations $1 - q^{2n} = (1 - q^n)(1 + q^n)$ and $1 - q^{3n} = (1 - q^n)(1 + q^n + q^{2n})$. The order in q of the level-three quotient, before raising it to the twelfth power, is

$$\frac{1}{24} - \frac{3}{24} = -\frac{1}{12}; \qquad 12 \left(-\frac{1}{12} \right) = -1.$$

Here $-1/12$ denotes the exact difference between the initial exponents of two eta functions. The operation is specified and does not require interpreting a divergent sum as a convergent one. Agreement with other normalized defects in the corpus preserves their respective realizations; it does not identify their operators through equality of the scalar.

Proposition 21.77 (Fricke involution on the order-two trace)**.** *Let* $w_2\tau = -1/(2\tau)$. *Then*

$$t_2(w_2\tau) = \frac{2^{12}}{t_2(\tau)}, \qquad T_{2A} = t_2 + 24 + \frac{2^{12}}{t_2} \tag{21.155}$$

y $T_{2A}(w_2\tau) = T_{2A}(\tau)$.

Proof. The transformation law $\eta(-1/\tau) = (-i\tau)^{1/2}\eta(\tau)$ gives

$$\frac{\eta(-1/(2\tau))}{\eta(-1/\tau)} = \sqrt{2}\,\frac{\eta(2\tau)}{\eta(\tau)}.$$

The twenty-fourth power produces the first identity. Substitution exchanges the two variable terms of T_{2A} and leaves the constant term fixed. Recognition of this expression as the McKay–Thompson series of class $2A$ corresponds to the level-two symmetrization of Conway–Norton [167, §§4 y 6, tabla 3] and the Moonshine theorem [160]. □

The modular uniformizations of levels two and three, in the preceding normalizations, are

$$j = \frac{(t_2 + 256)^3}{t_2^2}, \tag{21.156}$$

$$J = j - 744 = t_3 + 12 + \frac{10 \cdot 3^9}{t_3} + \frac{4 \cdot 3^{14}}{t_3^2} + \frac{3^{18}}{t_3^3}. \tag{21.157}$$

They are used as classical modular identities on the already constructed traces, not as rules for selecting the code or neighbor. The second is also written $j = (t_3 + 27)(t_3 + 243)^3/t_3^3$. Direct expansion of the product of (21.150) begins with

$$t_3 = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + 1188q^4 + O(q^5).$$

In particular, $[q]J = 54 + 10 \cdot 3^9 = 196884$; this is a consequence of the traces and uniformization. The construction of $V^\natural$ retains its lattice and orbifold proof, independently of this check of the first coefficient.

The three operations appearing in this prolongation have distinct domains. The dual symmetry $g^\vee$ acts on sectors of the vertex algebra; Fricke acts on the modular parameter and its function; radius duality exchanges momentum and winding in the compact lattice sector. Their reciprocity formulas can be coordinated through the corresponding maps, but the name “duality” does not replace those maps. This distinction allows the construction to continue toward dimensional screens while preserving incidence, grading and the origin of each operation.

21.11.17 Exceptional incidence and coordination of the screens

The direction selected by K and the Leech lattice arise from distinct representations of the constructed incidence. The first determines the orthogonal reduction $12 \to 11 \to 10$; the second enters into the isotropic reduction $26 \to 24$. Coordination preserves the prior space, its relations and the information transmitted by each projection.

Sections 24.4 and 25.14 develop this coordination jointly. The former brings together the involution of integer coordinates, unitary conjugation with its domains and the change of residual section retaining the quotient memory. The latter constructs the morphism $\mathcal{R}_M^{\mathrm{alg}}$ of (25.7) and proves the isomorphism of

the quotient presentations in Theorem 25.28. The graph preserves the coordinate in V_{11} together with its projection in V_{10}, while the isotropic quotient recovers the Leech lattice. The respective kernels and codomains are thereby preserved.

The action ellipse is constructed before duality is applied and fixes its dimensionless radius together with the reciprocal radius (Section 24.3). The compact sector then connects exceptional incidence with a determined quadratic form. The fields, action and operators of the subsequent physical realization are presented in their own domain, preserving this algebraic antecedent and its internal proofs.

21.11.18 Graded Moonshine traces and representation of the Monster

For $g \in \mathrm{Aut}(V^{\natural}_{\mathrm{HMT}})$, the trace with insertion is

$$T_g(\tau) = \mathrm{Tr}_{V^{\natural}_{\mathrm{HMT}}}\, g q^{L_0 - 1}.$$

The monstrous Moonshine theorem identifies these series as Hauptmoduln of the corresponding genus-zero groups [160, teorema 1.1]. The character J, group $\mathbb{M}$ and family $g \mapsto T_g$ are realizations of the already constructed algebra. They do not form a causal sequence in which one first guesses J and then infers the Monster.

Unity has a precise algebraic location here. The weight-zero subspace is the vacuum line, $V^{\natural}_0 = \mathbb{C}\mathbf{1}$, and the coefficient of q^{-1} in J is therefore 1. In weight one the dimension is zero, which accounts for the absence of a constant term in $J = j - 744$. A vertex algebra morphism preserves the vacuum vector. This property provides the technical meaning of preservation of unity at this level; the unit of cylindrical observables is preserved by the precomposition proved earlier. The relation between the two levels must follow the construction maps with their units.

In weight two, the equality

$$196884 = 1 + 196883 = 196560 + 324 = 54(5 \cdot 729 + 1).$$

The first separation corresponds to the trivial conformal line and the irreducible component of dimension 196883 of the Monster representation. The other expressions have lattice or arithmetic readings. Their equality does not automatically identify their summands with TPK regions, words or routes. Doing so would require presenting the maps between these spaces and proving that they respect the relevant actions.

In particular, an isometry $N_\alpha \simeq \Lambda_{24}$ induces a realization of (21.144), and a choice of isomorphism with $V^{\natural}$ transports its automorphism group. This has not constructed an action of the Monster on the digits of π, on the blocks of K or on all TPK histories. Such an additional assertion would require a representation ρ_{TPK} and a map F with an explicit square

$$F\rho_{\mathrm{TPK}}(g) = \rho_{V^{\natural}}(g)F,$$

including domain, codomain and preserved information. The absence of that step in the present assertion does not withdraw the incidence intertwiner U_W, flag or neighbor already constructed; it only delimits a distinct promotion, to action on the source state.

The chain established in this section can be summarized, keeping its transport data visible, as

$$\begin{aligned}
&\text{APP–TRIT–TPK and arithmetic state with trajectory memory} \longrightarrow (w_j, f_j; K, Z_0)\\
&\longrightarrow (C_W, \mathcal{H}; B_K \subset H^-_\alpha, P_\pi, H_e, H_\varphi, H_{\mathrm{APP}})\\
&\longrightarrow \big(N(C_W), o_*, \text{metric and chamber}\big) \longrightarrow N_\alpha \longrightarrow V^{\natural}_{\mathrm{HMT}}.
\end{aligned}$$

At the incidence level, the stars generate M_{12} and the residual chart realizes the regional structure $4 + 1$ in W_{24}. At the lattice and VOA level, the construction gives Leech and the Moonshine module. They are

prolongations of the same marked source, with different objects and maps. Causal continuity does not require identifying their codomains or erasing the explicit choices of frame, chamber and lift.

The result of this section is therefore an assembled derivation: the finite and lattice proofs make the passage from dodecaphasic incidence to the hypotheses of the recognition theorems effective. The conclusion comprises the structures and transports specified in the preceding propositions, with their explicit domains and choices. Comparison of constants and experimental validation concern assertions distinct from this algebraic construction.

21.11.19 Full-support orientations and lattice equivariance

The weight enumerator of (21.127) contains $24y^{12}$. Therefore, the set

$$C_W^{\times} := \{u \in C_W : u_b \in \{1, 2\} \text{ for every } b\}$$

has 24 elements. For each $u \in C_W^{\times}$, we define

$$P_b(u) = \begin{cases} \mathsf{R}, & u_b = 1, \\ I, & u_b = 2, \end{cases} \qquad g_u := \bigoplus_{b=0}^{11} P_b(u)\mathsf{C}P_b(u)^{-1}.$$

Proposition 21.78 (Robustness of Full Support Orientations)**.** *For every $u \in C_W^{\times}$,*

$$\frac{g_u v - v}{3}, \quad \frac{g_u^{-1} v - v}{3} \in N_0.$$

In particular, each g_u preserves the neighbor constructed with the transported orientation.

Proof. In simple root coordinates,

$$\mathsf{C}\rho - \rho = (-2, -1), \qquad \mathsf{C}^{-1}\rho - \rho = (-1, -2).$$

The discriminant classes of the two displacements are u and $-u$. For the radial coefficient $a_b \in \{4, 1\}$,

$$\left\langle \frac{(\mathsf{C}^{\pm 1} - I)a_b\rho}{3}, a_b\rho \right\rangle = -a_b^2.$$

The sum over the twelve factors again gives -27. The proof of proposition 21.73 is applied component by component. □

To type the recalibration, let $h \in \mathrm{Aut}(C_W)$ be monomial: a permutation σ of the twelve coordinates followed by multipliers $\epsilon_b \in \{1, 2\}$. We define its lattice lift

$$\widetilde{h} := P_\sigma \circ \bigoplus_{b=0}^{11} \mathsf{R}^{\nu_b}, \qquad \nu_b = \begin{cases} 0, & \epsilon_b = 1, \\ 1, & \epsilon_b = 2. \end{cases} \tag{21.158}$$

Its action on the discriminant is exactly h. If the change simultaneously transports the code, flag, incidence origin, vector v, neighbor, and frames, then

$$g_{hu} = \widetilde{h}\, g_u\, \widetilde{h}^{-1}. \tag{21.159}$$

The ternary matrix h does not act without a lift on A_2^{12} or on the Leech lattice.

21.12 Finite holonomy, Schläfli configuration and symmetry E_6

The Witt branch does not exhaust the exceptional structures accessible from APP. The parallel branch of this chapter starts from the two mixed sum–product and product–sum polarizations, together with a plaquette orientation and a declared central section. The calculated curvature determines the alternating form; this defines the central extension. An extension is not inferred from cardinality 27 alone.

21.12.1 Ordered system of incidences and radial camera orientation

On $T_9 = (\mathbb{Z}/9\mathbb{Z})^2$, with $S(x, y) = x + y$ and $P(x, y) = xy$, let

$$\Delta_x f = f(x + 1, y) - f(x, y), \qquad \Delta_y f = f(x, y + 1) - f(x, y).$$

Mixed connections are

$$A^{SP} = (\Delta_x S, \Delta_y P) = (1, x), \qquad A^{PS} = (\Delta_x P, \Delta_y S) = (y, 1).$$

Its discrete curvature is

$$F_A = \Delta_x A_y - \Delta_y A_x.$$

Proposition 21.79 (Oriented opposite curvatures)**.**

$$F_{A^{SP}} = 1, \qquad F_{A^{PS}} = -1 \pmod 9.$$

The circulation over an oriented rectangle of sides r, s is, respectively, rs and $-rs$.

Proof. $\Delta_x x - \Delta_y 1 = 1$ and $\Delta_x 1 - \Delta_y y = -1$. A rectangle contains rs plaquettes; upon summing, the interior edges cancel and the boundary circulation remains. □

For displazamientos $u = (a, b)$, $v = (c, d)$, the class alternante is

$$\sigma(u, v) = ad - bc \pmod 9. \tag{21.160}$$

The orientation fixes the sign of σ. The central section used below belongs to the gauge of this realization; replacing it with a coboundary produces an isomorphic extension, not a new invariant.

21.12.2 Central extension and ternary reduction

We define the nonadic Heisenberg group

$$\mathcal{H}_9 = \{(a, b, z) : a, b, z \in \mathbb{Z}/9\mathbb{Z}\}, \quad (a, b, z)(c, d, w) = (a + c, b + d, z + w + bc). \tag{21.161}$$

The commutator of two horizontal shifts is

$$[(a, b, 0), (c, d, 0)] = (0, 0, bc - ad),$$

which records $-\sigma(u, v)$. Reducing each coordinate modulo three gives

$$H_3 = \{(a, b, z) : a, b, z \in \mathbb{F}_3\}, \qquad |H_3| = 27, \tag{21.162}$$

with the same law. The nucleo of $\mathcal{H}_9 \to H_3$ is $(3\mathbb{Z}/9\mathbb{Z})^3$, of cardinal 27.

21.12.3 Construction of the radial character and determination of its congruence kernel

The nonadic extension admits an explicit unitary realization. Let

$$\zeta_9 := \exp(2\pi i/9), \qquad \mathscr{H}_9^{\mathrm{Sch}} := \mathbb{C}^9,$$

based on $\{|n\rangle : n \in \mathbb{Z}/9\mathbb{Z}\}$. We define

$$X|n\rangle := |n+1\rangle, \qquad Z|n\rangle := \zeta_9^n |n\rangle. \tag{21.163}$$

We have

$$ZX = \zeta_9 XZ$$

and, by multiplication,

$$(X^a Z^b)(X^c Z^d) = \zeta_9^{bc} X^{a+c} Z^{b+d}. \tag{21.164}$$

Theorem 21.80 (Faithful Weyl–Heisenberg Representation)**.** *The map*

$$\rho_{\mathrm{WH}} : \mathcal{H}_9 \longrightarrow U(\mathscr{H}_9^{\mathrm{Sch}}), \qquad \rho_{\mathrm{WH}}(a,b,z) := \zeta_9^z X^a Z^b, \tag{21.165}$$

is a faithful unitary representation. For $u = (a,b)$ and $v = (c,d)$, its commutator satisfies

$$[\rho_{\mathrm{WH}}(u,0), \rho_{\mathrm{WH}}(v,0)] = \zeta_9^{bc-ad} I = \zeta_9^{-\sigma(u,v)} I. \tag{21.166}$$

Proof. The identity (21.164) reproduces the term bc of (21.161); hence the homomorphism property. If $\zeta_9^z X^a Z^b = I$, the action on the basis successively forces $a = 0$, $b = 0$, and $z = 0$. This proves faithfulness. Comparing the products in the two orders gives ζ_9^{bc-ad}, which is the alternating phase of (21.160). □

The representation distinguishes two conjugate observables. Let

$$Q_{\mathrm{H}} := \mathrm{diag}(0,1,\dots,8), \qquad F_{jk} := \frac{1}{3}\zeta_9^{jk}, \qquad P_{\mathrm{H}} := F^\dagger Q_{\mathrm{H}} F.$$

The eigenbases of Q_{H} and P_{H} are mutually unbiased, since $|F_{jk}|^2 = 1/9$. For every unit vector $\psi \in \mathscr{H}_9^{\mathrm{Sch}}$,

$$\mathrm{Var}_\psi(Q_{\mathrm{H}})\,\mathrm{Var}_\psi(P_{\mathrm{H}}) \geq \frac{1}{4}\,|\langle \psi, [Q_{\mathrm{H}}, P_{\mathrm{H}}]\psi\rangle|^2\,, \tag{21.167}$$

$$H_{Q_{\mathrm{H}}}(\psi) + H_{P_{\mathrm{H}}}(\psi) \geq \log 9. \tag{21.168}$$

Here $H_{Q_{\mathrm{H}}}$ and $H_{P_{\mathrm{H}}}$ are the Shannon entropies of the Born distributions in the respective eigenbases, with natural logarithm and convention $0\log 0 = 0$. These operators are dimensionless. A physical units chart is a subsequent realization and does not enter into the central extension.

21.12.4 Action of 10 displacements on the Cayley graph

For a linear functional $\ell(a,b) = pa + qb$, set

$$D_\ell(a,b) = \left(a, b, \frac{ab}{2} + \ell(a,b)\right), \qquad Z = (0,0,1),$$

where $2^{-1} = 2$ in $\mathbb{F}_3$. The inverse-closed set

$$S_\ell = \{D_\ell(v) : v \in \mathbb{F}_3^2 \setminus \{0\}\} \cup \{Z, Z^{-1}\} \tag{21.169}$$

has ten elements and does not contain the identity.

Theorem 21.81 (Independence of the linear scale)**.** *The nine functionals ℓ produce isomorphic Cayley graphs. The nine sets S_ℓ form a single orbit under* $\mathrm{Aut}(H_3)$.

Proof. The map

$$\phi_\ell(a,b,z) = (a,b,z+\ell(a,b))$$

is a central automorphism and satisfies $\phi_\ell(S_0) = S_\ell$. To write the complete family in the polarized coordinates of equation (21.161), let $c(v,w) = bc$ for $v = (a,b)$, $w = (c,d)$. Given $M \in \mathrm{GL}(2,3)$, the defect

$$B_M(v,w) = c(Mv,Mw) - \det(M)c(v,w)$$

is symmetric, because the alternating parts of the two terms coincide. We define the quadratic correction

$$q_M(v) = 2B_M(v,v), \qquad q_M(v+w) - q_M(v) - q_M(w) = B_M(v,w), \tag{21.170}$$

where $2 = 2^{-1}$ in $\mathbb{F}_3$. The complete family of automorphisms is then written

$$(v,t) \longmapsto \big(Mv, \det(M)t + q_M(v) + \ell(v)\big), \qquad M \in \mathrm{GL}(2,3),\ \ell \in (\mathbb{F}_3^2)^*. \tag{21.171}$$

The polar identity of equation (21.170) directly proves that the central product is preserved. The family has $48 \cdot 9 = 432$ elements. Exhaustive enumeration of the $\binom{13}{5} = 1287$ inverse-closed subsets of cardinality ten finds exactly those nine with the parameters derived below. □

Write $\underline{S} = \sum_{s\in S} s$ in $\mathbb{Z}[H_3]$. Counting ordered products gives

$$\underline{S}^{\,2} = 10e + \underline{S} + 5(\underline{H_3} - e - \underline{S}) = 5\underline{H_3} + 5e - 4\underline{S}. \tag{21.172}$$

Indeed, the identity receives ten factorizations; an element of S receives one; each of the other sixteen receives five.

Theorem 21.82 (Graph of the twenty-seven lines)**.** *The matrix of adjacency A_ℓ of $\Gamma_\ell = \mathrm{Cay}(H_3, S_\ell)$ satisfies*

$$A_\ell^2 = 5I - 4A_\ell + 5J. \tag{21.173}$$

Therefore,

$$\Gamma_\ell = \mathrm{srg}(27,10,1,5), \qquad \mathrm{Spec}(A_\ell) = \{10^1, 1^{20}, (-5)^6\}.$$

It is isomorphic to the intersection graph of the twenty-seven lines of a smooth cubic surface.

Proof. The regular representation of equation (21.172) produces equation (21.173). Its entries state that every vertex has ten neighbors, that an adjacent pair has one common neighbor, and a nonadjacent pair has five. On the constant line, A_ℓ acts by 10; on its complement, $J = 0$ and $(A_\ell - I)(A_\ell + 5I) = 0$. Zero trace fixes the multiplicities 20 and 6.

In the model of a cubic obtained by blowing up six points of $\mathbb{P}^2$, the 27 classes are

$$E_i, \qquad L_{ij} = H - E_i - E_j, \qquad Q_i = 2H - \sum_{j\neq i} E_j.$$

With $H^2 = 1$, $E_i^2 = -1$, $H \cdot E_i = 0$, and $E_i \cdot E_j = 0$ for $i \neq j$, the adjacency matrix defined by intersection between distinct classes has the same parameters. The complete intersection matrix has diagonal -1. Identification with the classical configuration uses the uniqueness theorem for this realization of the 27 lines [173], with the domain and action specified there. □

The isomorphism assertion can be made fully effective by means of a computed bijection. The labeling is not absolute: another linear section or an automorphism of the surface produces another table in the same class.

Table 21.3: Explicit bijection between H_3 and the twenty-seven classes of lines.

$a\ b\ z$	class of line
0 0 0	E_1
0 0 1	L_{12}
0 0 2	Q_2
0 1 0	L_{13}
0 1 1	Q_1
0 1 2	E_3
0 2 0	Q_3
0 2 1	E_2
0 2 2	L_{23}
1 0 0	L_{14}
1 0 1	L_{35}
1 0 2	L_{26}
1 1 0	L_{36}
1 1 1	L_{24}
1 1 2	L_{15}
1 2 0	L_{25}
1 2 1	L_{16}
1 2 2	L_{34}
2 0 0	Q_4
2 0 1	L_{46}
2 0 2	E_6
2 1 0	E_5
2 1 1	Q_6
2 1 2	L_{56}
2 2 0	L_{45}
2 2 1	E_4
2 2 2	Q_5

As a local control, the ten neighbors of $e = (0,0,0)$ are the elements of S_0. The table transforms them into the ten classes that intersect E_1: the five L_{1j} and the five Q_j, with $2 \le j \le 6$. The complete verification compares all 729 entries of both adjacency matrices.

The complement $B_\ell = J - I - A_\ell$ satisfies

$$B_\ell^2 = 8I + 2B_\ell + 8J, \qquad \operatorname{srg}(27, 16, 10, 8), \qquad \operatorname{Spec}(B_\ell) = \{16^{1}, 4^{6}, (-2)^{20}\}. \tag{21.174}$$

This is the Schläfli graph in the convention of complementary adjacency; A_ℓ is the intersection graph with parameters $(27, 10, 1, 5)$.

Each edge belongs to a unique triangle, since $\lambda = 1$. The number of triangles is

$$\frac{27 \cdot 10}{6} = 45.$$

The full automorphism group has order

$$27 \cdot 1920 = 51840$$

and, through its action on the line configuration, is identified with $W(E_6)$, not merely by equality of orders [173].

21.12.5 The root lattice realizing E_6

To make explicit the object on which that group acts, let

$$\mathrm{Pic}(X) = \mathbb{Z}H \oplus \bigoplus_{i=1}^{6} \mathbb{Z}E_i, \qquad H^2 = 1, \qquad E_i^2 = -1, \qquad H \cdot E_i = E_i \cdot E_j = 0 \ (i \neq j), \tag{21.175}$$

the Picard lattice of the blow-up of six general points of $\mathbb{P}^2$. Its canonical class is

$$K_X = -3H + E_1 + \cdots + E_6.$$

The orthogonal complement

$$L_{E_6} = K_X^{\perp} \subset \mathrm{Pic}(X), \qquad (x, y)_{E_6} := -x \cdot y, \tag{21.176}$$

is positive definite of rank six. A simple root basis is

$$\begin{aligned} &\alpha_1 = E_1 - E_2, \quad \alpha_2 = E_2 - E_3, \quad \alpha_3 = E_3 - E_4, \\ &\alpha_4 = E_4 - E_5, \quad \alpha_5 = E_5 - E_6, \quad \alpha_6 = H - E_1 - E_2 - E_3. \end{aligned} \tag{21.177}$$

Each α_i is orthogonal to K_X, has norm two, and its products are -1 exactly for adjacent pairs of the diagram E_6: the chain $1 - 2 - 3 - 4 - 5$, with node 6 joined to node 3. Therefore, its Gram matrix is the Cartan matrix of E_6.

Proposition 21.83 (The seventy-two roots and their reflections)**.** *The roots of L_{E_6} are*

$$\begin{aligned} &E_i - E_j && (i \neq j), \\ &\pm (H - E_i - E_j - E_k) && (1 \leq i < j < k \leq 6), \\ &\pm (2H - E_1 - \cdots - E_6), \end{aligned} \tag{21.178}$$

in total $30 + 40 + 2 = 72$*. For each root α,*

$$s_\alpha(x) = x + (x \cdot \alpha)\alpha \tag{21.179}$$

preserves the intersection and K_X. The six simple reflections generate $W(E_6)$ and act faithfully by permutations on the 27 classes E_i, L_{ij}, Q_i in theorem 21.82.

Proof. Substituting each class of equation (21.178) into equation (21.175) gives $K_X \cdot \alpha = 0$ and $\alpha^2 = -2$. The class count is as stated. The reflection formula is the orthogonal reflection for the form $-(\cdot)$; it preserves K_X because $K_X \cdot \alpha = 0$. The simple system of equation (21.177) generates all roots, and its Coxeter group is $W(E_6)$. Its action on the 27 classes of exceptional curves preserves intersection, and therefore coincides with the action on the already constructed graph [173]. □

21.12.6 Stratification of the 729 Words

We write a six-trit word as

$$w = (\ell_1, h_1, \ell_2, h_2, \ell_3, h_3),$$

and we define two elements of H_3,

$$L(w) = (\ell_1, \ell_2, \ell_3), \qquad H(w) = (h_1, h_2, h_3),$$

using the central law in their products. According to $L(w)^{-1}H(w)$, the 729 words are divided into

$$\begin{aligned} \mathcal{D}_\ell &= \{w : L(w)^{-1}H(w) = e\}, \\ \mathcal{I}_\ell &= \{w : L(w)^{-1}H(w) \in S_\ell\}, \\ \mathcal{S}_\ell &= \{w : L(w)^{-1}H(w) \notin \{e\} \cup S_\ell\}. \end{aligned}$$

Theorem 21.84 (Hensel–Schläfli Partition)**.**

$$729 = 27 + 270 + 432, \tag{21.180}$$

corresponding to diagonal, incidence, and warping.

Proof. For each one of the 27 values of $L(w)$, there is a unique value of $H(w)$ with identity difference, ten with difference in S_ℓ and sixteen remaining ones. 27 is multiplied by $1, 10, 16$. □

The cardinal 432 of the warped stratum numerically coincides with the multiplicity of the transverse region of π in Figure 21.5. The two objects are not thereby identified: here one counts words classified by $L(w)^{-1}H(w)$, whereas there one counts preimages of a register U_6. Without an explicit and equivariant intertwiner between those domains, $432 = 432$ is only a cardinal control.

21.12.7 Necessity of the central phase

Enumerating all inverse-closed subsets of cardinality ten in the five groups of order 27 gives

group	abelian	$\#\,\mathrm{srg}(27, 10, 1, 5)$
C_{27}	yes	0
$C_9 \times C_3$	yes	0
C_3^3	yes	0
$C_9 \rtimes C_3$	no	9
H_3	no	9.

Thus, retaining 27 labels while abelianizing composition destroys the configuration. Neither cardinality nor degree suffices.

If $\mathcal{T}$ is the conjunto of 45 triangulos, the cubico

$$C_\Gamma(x_1, \dots, x_{27}) = \sum_{\{i,j,k\} \in \mathcal{T}} x_i x_j x_k$$

recovers adjacency, because every edge lies in a unique triangle. Its permutation stabilizer is exactly

$$\mathrm{Aut}(\Gamma_\ell) \cong W(E_6).$$

For the following diagram we write $\Gamma_{27} = \Gamma_\ell$ and $\mathcal{T}_{45} = \mathcal{T}$.

Comparison Criterion 21.85 (Falsification criteria for branch E_6)**.** The branch is refuted if the curvatures are not opposite, if the central cocycle is erased, if the quadratic correction (21.170) does not preserve the

$$\text{APP curvatures } \pm 1 \longrightarrow \sigma \longrightarrow \mathcal{H}_9 \longrightarrow H_3,$$
$$H_3 \longrightarrow \Gamma_{27} \longrightarrow \mathcal{T}_{45} \longrightarrow W(E_6).$$

Figure 21.6: Causal chain of the mixed-holonomy branch. It is parallel to $C_W \to W_{12} \to M_{12}$ and not a link of it.

product, if (21.172) does not produce the coefficients $(10, 1, 5)$, if an abelian group produces the same configuration, if the partition does not sum to 729, if the table 21.3 does not intertwine the adjacency matrices, or if $W(E_6)$ is identified only by its order and not by its action on the twenty-seven classes and the 72 roots.

21.13 Generation and locality of fields on the incidence lattice

The lattice construction is carried out after the selection of the dodecaphase register and its incidences. The marked origin, the integral product and the parity form used by the state space arise from that construction. The operations producing the fields, their coefficients and their locality relations are made explicit below. The same lattice enters into state generation, products on the vacuum and commutators of all integer modes.

21.13.1 Location of the marked origin and persistence of incidence

Write K_i, $0 \le i < 12$, for the coordinates of the selected register. The two support readings are

$$T_K = \{i : K_i \ge 729\}, \qquad H_K = \{i : p_i + e_i - f_i - K_i < 0\}, \tag{21.181}$$

where p_i, e_i, f_i are the regional blocks used by the pre-carry reader. The upper support uses the integer threshold 729; the negative support uses the sign of the pre-carry before reduction. Two different operations on the same register are thus preserved.

The selection already established gives

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601),$$

as the evaluation of the register, and produces the flag $T_K \subset H_K$, with $|T_K| = 4$, $|H_K| = 6$. The regional propagation and self-scaling incidences, together with the APP support, determine the set

$$O_K = (E_{\mathrm{inc}} \cap F_{\mathrm{inc}}) \setminus (H_K \cup A_{\mathrm{inc}}).$$

The incidence construction proves that O_K is a singleton. Its unique element, o, fixes the marked origin preserved throughout what follows.

In the concrete Golay realization, the support T_K corresponds to $\{4, 6, 8, 14\}$. The four hexads incident to this support have four octadic lifts; the complete octadic star has five elements. Their difference is a single additional octad. The support H_K, in turn, has a unique octadic lift in the same realization. These properties arise from the concrete residual realization and preserve the regional origin of the selected support.

The marked lattice neighbour Λ_o obtained from that incidence has rank 24, an integral even bilinear form, integral self-duality and quadratic minimum 4. The radial vector used by the marked construction has square 54. We denote by $\langle x, y\rangle \in \mathbb{Z}$ the integral form of Λ_o. The theorems of this section use precisely that lattice and that form, already constructed.

21.13.2 Parity cocycle and twisted lattice algebra

Choose an integral basis $(b_i)_{i=1}^{r}$ of Λ_o, with $r = 24$. This choice presents the coordinates of a lattice already obtained. Its Gram matrix is $G_{ij} = \langle b_i, b_j \rangle$. For $x = \sum_i x_i b_i$, $y = \sum_i y_i b_i$, define

$$\tau(x, y) = \sum_{i<j} x_i G_{ij} y_j \pmod 2, \qquad \varepsilon(x, y) = (-1)^{\tau(x,y)}. \tag{21.182}$$

Proposition 21.86 (Cocycle identity and parity commutator)**.** *The following hold*

$$\varepsilon(x, y)\varepsilon(x + y, z) = \varepsilon(y, z)\varepsilon(x, y + z), \tag{21.183}$$

$$\varepsilon(x, y)\varepsilon(y, x) = (-1)^{\langle x,y \rangle}, \tag{21.184}$$

$$\varepsilon(0, x) = \varepsilon(x, 0) = 1. \tag{21.185}$$

Proof. The bilinearity of τ in $\mathbb{F}_2$ gives $\tau(x, y)+\tau(x+y, z) = \tau(y, z)+\tau(x, y+z)$, and applying $a \mapsto (-1)^a$ yields (21.183). The symmetry of G, together with the evenness of its diagonal, allows the two triangular sums to be combined:

$$\tau(x, y) + \tau(y, x) = \sum_{i,j} x_i G_{ij} y_j = \langle x, y \rangle \pmod 2.$$

This proves (21.184). The identities involving zero follow directly from (21.182). □

The twisted complex algebra $\mathbb{C}_\varepsilon[\Lambda_o]$ consists of finite linear combinations of symbols $\mathbf{e}^x$, with product

$$\mathbf{e}^x \mathbf{e}^y = \varepsilon(x, y)\mathbf{e}^{x+y}. \tag{21.186}$$

The cocycle identity proves associativity, and $\mathbf{e}^0$ is the unit. The notation $\mathbf{e}^x$ denotes the basic element of charge x and preserves the full lattice label.

21.13.3 Oscillator space and Heisenberg representation

Let $\mathfrak{h} = \mathbb{C} \otimes_{\mathbb{Z}} \Lambda_o$. The algebraic oscillator space is

$$\mathfrak{h}_- = \bigoplus_{n \geq 1} \mathfrak{h}\, t^{-n}, \qquad M(1) = \mathrm{Sym}_{\mathbb{C}}(\mathfrak{h}_-).$$

The support of each vector is finite, whereas the set of available frequencies includes all positive integers. The state space that simultaneously preserves oscillator occupation and lattice charge is

$$V_{\Lambda_o} = M(1) \otimes_{\mathbb{C}} \mathbb{C}_\varepsilon[\Lambda_o], \qquad \mathbf{1} = 1 \otimes \mathbf{e}^0. \tag{21.187}$$

For $x \in \Lambda_o$ and $n \geq 1$, the operator $x(-n)$ multiplies by the generator $x\, t^{-n}$. The operator $x(n)$ is the derivation of $M(1)$ determined by

$$x(n)(y\, t^{-m}) = n\, \delta_{n,m} \langle x, y \rangle. \tag{21.188}$$

Both act as the identity on the second factor of (21.187). The zero mode acts on the charge through

$$x(0)(v \otimes \mathbf{e}^y) = \langle x, y \rangle v \otimes \mathbf{e}^y.$$

Theorem 21.87 (Commutation relations and non-emptiness)**.** *For $m, n \geq 1$,*

$$[x(n), y(-m)] = n\delta_{n,m}\langle x, y \rangle I, \tag{21.189}$$

$$[x(-n), y(-m)] = 0, \qquad [x(n), y(m)] = 0. \tag{21.190}$$

Moreover, $x(n)\mathbf{1} = 0$ *and* $\mathbf{1} \neq 0$.

Proof. If D is a derivation and M_a multiplication by a, the Leibniz rule gives $[D, M_a](v) = D(a)v$. Applied to (21.188), it yields (21.189). The multiplication operators commute because the symmetric algebra is commutative; the coordinate derivations commute on the generators and, by Leibniz, on all monomials. Annihilation of the vacuum follows by differentiating the unit. Finally, the functional extracting the coefficient of the empty monomial and zero charge takes the value 1 on $\mathbf{1}$, so the vacuum is nonzero. Extension by tensor product preserves all the identities. □

Each oscillator monomial has an integer weight $\mathrm{wt}(a) = \sum_{n,i} n a_{n,i}$, where $a_{n,i}$ are its occupations. This grading provides finite bounds for the sums occurring in the field coefficients.

21.13.4 Creation and annihilation coefficients in all degrees

The two formal operator series are constructed

$$E_x^-(z) = \exp\left(\sum_{n\geq 1} \frac{x(-n)}{n} z^n\right) = \sum_{d\geq 0} C_x(d) z^d, \tag{21.191}$$

$$E_x^+(s) = \exp\left(-\sum_{n\geq 1} \frac{x(n)}{n} s^n\right) = \sum_{r\geq 0} A_x(r) s^r. \tag{21.192}$$

These exponentials are formal operations on the modes already constructed. Each coefficient is defined by a finite sum. In particular, if $P_x(z) = \sum_{n\geq 1} x(-n) z^n / n$, then

$$C_x(d) = \sum_{q=0}^{d} \frac{1}{q!} [z^d] P_x(z)^q, \tag{21.193}$$

and the analogous formula for $A_x(r)$ is obtained by substituting the annihilation potential. The composition order of the endomorphisms is preserved in every power.

Lemma 21.88 (Stabilization of the coefficients)**.** *For any formal potential* P *with zero constant term,* $[z^d]P^q = 0$ *when* $q > d$. *Therefore, extending the upper bound of* (21.193) *to any* $N \geq d$ *preserves its value. Moreover,*

$$C_x(0) = A_x(0) = I, \qquad A_x(r)1 = 0 \quad (r > 0).$$

If v *has weight at most* N, *then* $A_x(r)v = 0$ *for* $r > N$.

Proof. Each factor of P has degree at least one, so a product of q factors has degree at least q. This argument uses only the grading and also applies to noncommutative coefficients. The degree-zero identities come from the empty power. Every nonempty composition of annihilation modes annihilates the unit. Finally, a term of degree r in the annihilation potential reduces the oscillator weight by r. A reduction exceeding the initial weight gives zero; by linearity, the conclusion holds throughout the subspace of weight at most N. □

The first coefficients illustrate the normalization:

$$C_x(1) = x(-1), \qquad C_x(2) = \tfrac{1}{2}\big(x(-1)^2 + x(-2)\big),$$
$$A_x(1) = -x(1), \qquad A_x(2) = \tfrac{1}{2}\big(x(1)^2 - x(2)\big).$$

Each denominator arises from the frequency or the order of the formal power. The Gram form entering the commutators remains the integral form of the marked lattice.

21.13.5 Charge field and Laurent truncation bound

The field associated with a charge $x \in \Lambda_o$ is written

$$Y_x(z) = E_x^-(z)E_x^+(z^{-1})\, e_x z^{x(0)}, \qquad Y_x(z) = \sum_{k\in\mathbb{Z}} Y_x[k] z^k, \tag{21.194}$$

where $e_x \mathbf{e}^y = \varepsilon(x,y)\mathbf{e}^{x+y}$. The following formula defines its coefficients on a monomial basis and makes the finiteness of each operation explicit.

Definition 21.89 (Field coefficient on a charged state)**.** If v is a monomial of weight N, define

$$Y_x[k](v \otimes \mathbf{e}^y) = \varepsilon(x,y) \sum_{j=0}^{N} C_x\big(k - \langle x,y\rangle + j\big) A_x(j) v \otimes \mathbf{e}^{x+y}, \tag{21.195}$$

with the convention $C_x(d) = 0$ for $d < 0$. It extends linearly to V_{Λ_o}.

Theorem 21.90 (Stability, truncation and creation of charge states)**.** *The formula* (21.195) *is independent of any weight bound greater than N. We have*

$$k < \langle x,y\rangle - N \quad \Longrightarrow \quad Y_x[k](v \otimes \mathbf{e}^y) = 0. \tag{21.196}$$

Each state therefore admits a lower Laurent bound. On the vacuum,

$$Y_x[k]\mathbf{1} = \begin{cases} C_x(k) 1 \otimes \mathbf{e}^x, & k \geq 0, \\ 0, & k < 0. \end{cases} \tag{21.197}$$

In particular, $Y_x[0]\mathbf{1} = 1 \otimes \mathbf{e}^x$.

Proof. Extending the bound adds terms $A_x(j)v$ with $j > N$, which vanish by Lemma 21.88. If the inequality in (21.196) holds, all indices $k - \langle x,y\rangle + j$, with $j \leq N$, are negative; every summand vanishes. A finite linear combination of monomials retains the smallest of its bounds, proving the assertion for any state. On $\mathbf{1}$, only $j = 0$ remains, and $\varepsilon(x,0) = 1$, $\langle x,0\rangle = 0$. We obtain (21.197). □

Theorem 21.91 (Generation of the entire lattice state space)**.** *The subspace generated from the vacuum by finite compositions of the operators $Y_x[0]$, $x \in \Lambda_o$, and all creation modes $b_i(-n)$, $n \geq 1$, is V_{Λ_o}.*

Proof. By (21.197), applying $Y_x[0]$ to the vacuum produces the ground state of any charge x. The creation operators multiply by the generators of the symmetric algebra; finite compositions of them produce all monomials on that ground state. Oscillator monomials multiplied by the elements $\mathbf{e}^x$ constitute an algebraic basis of (21.187). Their linear span is therefore the entire space. The argument covers every frequency, finite occupation and lattice charge. □

Corollary 21.92 (Determination of intertwiners by the vacuum)**.** *Two endomorphisms of V_{Λ_o} that commute with all generators of the preceding theorem and agree on the vacuum are equal.*

Proof. Commutation transports equality on the vacuum to every finite composition of generators. Total generation and linearity extend that equality to the entire space. □

21.13.6 Scalar contraction and normal ordering of products

The integer product $p = \langle x, y\rangle$ fixes a scalar sequence by the recurrence

$$s_p(0) = 1, \qquad (r+1)s_p(r+1) = (r-p)s_p(r). \tag{21.198}$$

The recurrence determines each coefficient from the preceding one. Its closed expression is $s_p(r) = (-1)^r \binom{p}{r}$, using the generalized integer binomial coefficient. The first terms are

$$1, \quad -p, \quad \frac{p(p-1)}{2}, \quad -\frac{p(p-1)(p-2)}{6}.$$

Proposition 21.93 (Formal contraction factor)**.** *The series $S_p(u) = \sum_{r\ge 0} s_p(r)u^r$ satisfies*

$$(1-u)S_p'(u) = -pS_p(u), \qquad S_p(0) = 1. \tag{21.199}$$

It is the unique formal solution of these conditions. Moreover,

$$S_{p+q} = S_pS_q, qquadS_0 = 1, qquadS_1 = 1-u, qquadS_pS_{-p} = 1.$$

For $p \ge 0$, $S_p(u) = (1-u)^p$, and its coefficients of degree greater than p vanish.

Proof. Comparing the coefficient of u^r in (21.199) reproduces exactly (21.198). Since $r+1 \neq 0$, the coefficients are determined inductively. The Leibniz rule shows that S_pS_q satisfies the same equation as S_{p+q} and has the same constant term; uniqueness gives the multiplicative identity. The cases 0, 1 are verified directly. The inverse identity follows from the case $q = -p$, and natural powers are obtained by induction. If p is natural, step $r = p$ of the recurrence produces zero and subsequent steps preserve that zero. □

Theorem 21.94 (Normal ordering in all degrees)**.** *The series constructed from the modes satisfy*

$$E_x^+(s)E_y^-(z) = S_{\langle x,y\rangle}(sz), E_y^-(z)E_x^+(s). \tag{21.200}$$

In coefficients, for $r, d \ge 0$,

$$A_x(r)C_y(d) = \sum_{i=0}^{\min(r,d)} s_{\langle x,y\rangle}(i), C_y(d-i)A_x(r-i). \tag{21.201}$$

Proof. Let $Q_x(s) = -\sum_{n\ge 1} x(n)s^n/n$ and $P_y(z) = \sum_{m\ge 1} y(-m)z^m/m$. By (21.189),

$$[Q_x(s), P_y(z)] = -\langle x, y\rangle \sum_{n\ge 1} \frac{(sz)^n}{n} I.$$

The commutator is central. The exponential identity for two potentials with central commutator is proved here coefficient by coefficient: commuting a power of Q_x through a power of P_y adds the scalar terms of that commutator; the sums in each bidegree are finite by Lemma 21.88. The resulting scalar factor has constant term one and satisfies (21.199), with $p = \langle x, y\rangle$; by the uniqueness in Proposition 21.93, it is $S_p(sz)$. This proves (21.200). Extracting the coefficient $s^r z^d$ gives (21.201); the contraction factor consumes the same degree i in both variables, which yields the bound $i \le \min(r, d)$. □

Theorem 21.95 (Exact contraction of states created from the vacuum)**.** *For every pair of charges x, y and all degrees r, d,*

$$A_x(r)C_y(d)1 = \begin{cases} s_{\langle x,y\rangle}(r), C_y(d-r)1, & r \le d, \\ 0, & r > d. \end{cases} \tag{21.202}$$

On the diagonal $r = d$, the result is $s_{\langle x,y\rangle}(r)1$. If $\langle x, y\rangle = p \geq 0$, it also vanishes for $r > p$.

Proof. We evaluate (21.201) on 1. Lemma 21.88 annihilates all summands with $r - i > 0$. Only $i = r$ remains, provided that $r \leq d$. For $r = d$, $C_y(0) = I$. The final vanishing follows from the polynomial bound of S_p. □

For example, $A_x(1)C_y(1)1 = -\langle x, y\rangle 1$. For $p = -1$, the recurrence gives $s_{-1}(r) = 1$ in all degrees; for $p = 2$, it gives $(1, -2, 1, 0, \ldots)$. These two evaluations exhibit, respectively, a contraction of unbounded order and a finite polynomial cancellation, both determined by the same integral lattice form.

21.13.7 Mixed commutator in all integer modes

For $x \in \Lambda_o$, write $H_x(m) = x(m)$, with $m \in \mathbb{Z}$, including negative creation modes, the zero charge mode and positive annihilation modes.

Theorem 21.96 (Integral mixed commutator)**.** *For all charges x, y and all integers m, k,*

$$[H_x(m), Y_y[k]] = \langle x, y\rangle, Y_y[k - m]. \tag{21.203}$$

Proof. We treat the three signs of m separately, preserving in each case the field coefficients of (21.195).

If $m > 0$, the Heisenberg relation gives

$$[x(m), C_y(d)] = \begin{cases} \langle x, y\rangle C_y(d - m), & d \geq m, \\ 0, & d < m. \end{cases}$$

Positive modes commute with the annihilation coefficients and with the charge shift. Commuting term by term in (21.195) decreases the creation degree by m, which amounts to replacing k by $k - m$. The weight cutoff remains valid because annihilation decreases the weight.

If $m = 0$, the field shifts the charge z to $y + z$. The difference between the zero-mode eigenvalues is $\langle x, y + z\rangle - \langle x, z\rangle = \langle x, y\rangle$. Oscillator operators preserve charge, yielding (21.203) with $k - m = k$.

Finally, let $m = -a$, with $a > 0$. Creation modes commute with one another, whereas the relation derived from (21.189) and (21.192) is

$$[x(-a), A_y(j)] = \begin{cases} \langle x, y\rangle A_y(j - a), & j \geq a, \\ 0, & j < a. \end{cases}$$

If the initial state has weight at most N, after creating mode $-a$ it has weight at most $N + a$. We use this common cutoff in both terms of the commutator. Summands with $j < a$ vanish; we reindex the remaining ones by $j = r + a$, $0 \leq r \leq N$. The creation degree becomes $k - \langle y, z\rangle + r + a$, exactly the field coefficient with index $k + a = k - m$. The identity is proved on charged monomial states and extends by linearity to the whole space. □

The shift of the field index correctly distinguishes the orientation of the modes: a positive mode subtracts its frequency, a negative mode adds it and the zero mode preserves the index. The three cases realize a single identity in $\mathbb{Z}$.

21.13.8 Mixed locality by coefficientwise cancellation

Consider the Heisenberg field $H_x(z) = \sum_{m\in\mathbb{Z}} H_x(m)z^{-m-1}$. For a bivariate series with coefficients $F(a, b)$, multiplication by $z - w$ acts as

$$(CF)(a, b) = F(a - 1, b) - F(a, b - 1). \tag{21.204}$$

The ordered compositions of the two fields have coefficients

$$F(a,b) = H_x(-a-1)Y_y[b], \qquad G(a,b) = Y_y[b]H_x(-a-1).$$

Theorem 21.97 (Mixed locality of order one)**.** *The constructed fields satisfy*

$$(z-w)H_x(z)Y_y(w) = (z-w)Y_y(w)H_x(z). \tag{21.205}$$

The equality is an identity of endomorphism coefficients on all of V_{Λ_o}.

Proof. By (21.204), coefficient (a,b) of the difference is

$$[H_x(-a), Y_y[b]] - [H_x(-a-1), Y_y[b-1]].$$

Theorem 21.96 turns both terms into $\langle x,y\rangle Y_y[a+b]$. Their difference is zero for all integers a,b. The identity holds in the endomorphisms, hence simultaneously for all states. □

21.13.9 Locality of charged fields and preservation of the origin

Normal ordering also proves locality for two charge fields. Let $p = \langle x,y\rangle$ and $N_p = \max(0,-p)$. The contraction factor for the two orders is expanded in the formal regions w/z and z/w; their relative parity is fixed by (21.184).

Theorem 21.98 (Uniform locality of charged fields)**.** *For arbitrary $x, y \in \Lambda_o$,*

$$(z-w)^{N_p}Y_x(z)Y_y(w) = (z-w)^{N_p}Y_y(w)Y_x(z), \qquad N_p = \max(0,-\langle x,y\rangle). \tag{21.206}$$

The exponent depends on the charges and is valid for all states.

Proof. On a state of bounded weight, products of field coefficients are expressed through (21.201), charge shifts and the cocycle. The sums for each coefficient are finite: annihilation has a weight cutoff, and the two variables of the ordered product have a lower bound. The cocycle identity combines the shifts into the same charge element $x+y$, and the commutator identity supplies the factor $(-1)^p$ between the two orders.

The resulting scalar factors are the two expansions of $(z-w)^p$. If $p \geq 0$, both are the same polynomial and agree without additional multiplication. If $p < 0$, multiplication by $(z-w)^{-p}$ transforms both expansions into the factor one. Formally, each application of C raises the exponent of both expansions by one; after $-p$ applications the exponent reaches zero. This cancellation is independent of the chosen weight cutoff and of the charge of the state on which the fields act. Thus (21.206) holds on every charged monomial state, and linearity extends it to V_{Λ_o}. □

Theorem 21.99 (Conservative composition of incidence, generation and locality)**.** *With the origin o produced by the incidence of the selected register fixed, the same space V_{Λ_o} jointly satisfies: generation from the vacuum in Theorem 21.91, products in all degrees in Theorem 21.95, charged locality in* (21.206) *and mixed locality in* (21.205)*. Its integral form, cocycle, vacuum and charge operators are those defined from Λ_o in this section.*

Proof. All the preceding statements are quantified over the same lattice and the same integral form. When specialized to the origin o already selected, their objects coincide by definition: the cocycle uses the basis of Λ_o, the oscillators use its Gram form, the fields use those oscillators and that cocycle, and the products use those same field coefficients. The conjunction of the theorems therefore preserves the incidence flag of (21.181) and all dependencies that determined the origin. No specialization introduces a new lattice choice. □

The demonstrative chain precisely distinguishes its operations: regional blocks determine prefixes, cylinders and signatures; dodecaphase selection and incidence produce the lattice origin; the lattice

determines the integral form and cocycle; these fix the modes, fields and their products. The resulting field structure is thus endowed with total generation and locality identities in the full algebraic space. The chapters devoted to reconstructing the vertex-operator structure, the twisted sector and the exceptional realization use these results with their respective additional hypotheses, preserving this same generative provenance.

Chapter 22

Vertex operator algebra $V^\natural$, modular function J, and monstrous Moonshine: graded action of the Monster, McKay–Thompson series, and replicability

22.1 Alineamiento ciclotomico, orbifold of order 3 and Monstrous Moonshine

The Leech lattice constructed in theorem 21.32 makes it possible to pass from finite incidence to an infinite graded structure. This transition will not be effected through a chain of names. The following will be constructed, in typed order:

1. the intertwining of the twelve fibres A_2;
2. a fixed-point-free lattice isometry of order three;
3. its graded trace and its type-zero lift;
4. the cyclic orbifold and its dual automorphism of class $3B$;
5. the moonshine vertex operator algebra;
6. through distinct publications, its automorphism group, its graded character, and the McKay–Thompson series.

Moonshine sera the theorem that coordina the action and the series. is not usara the atajo not tipado $V^\natural \to \mathbb{M} \to$ Moonshine.

22.1.1 Alignment of the 12 APP and Witt fibers

The twelve fibers of $W_{\mathrm{APP}} \cong A_2^{12}$ carry three independent labels:

$$i \in \mathbb{Z}/3\mathbb{Z} \quad \text{(coordinate pair)}, \qquad \mu \in \{0,1\} \quad \text{(sheet)}, \qquad \varepsilon \in \{0,1\} \quad \text{(cyclotomic orbit)}.$$

Fixing the dodecaphasic origin constructed on the TPK, we define

$$\lambda(i,\mu,\varepsilon) := 4i + 2\mu + \varepsilon \pmod{12}. \tag{22.1}$$

Lemma 22.1 (Bijectivity of the alignment)**.** *The map λ from (22.1) is a bijection onto $\mathbb{Z}/12\mathbb{Z}$.*

Proof. For each i, the four values $4i + 2\mu + \varepsilon$ form the block $\{4i, 4i+1, 4i+2, 4i+3\}$. The three blocks for $i = 0, 1, 2$ are disjoint and cover the twelve classes. □

Let C be the Coxeter element of A_2 and let R be the reflection that satisfies

$$\mathsf{R} C \mathsf{R} = C^{-1}. \tag{22.2}$$

Once the trivializations ι_b and the oriented frames P_b have been fixed, we set

$$g_b := \iota_b^{-1} P_b C P_b^{-1} \iota_b, \tag{22.3}$$

$$T_{i\mu\varepsilon} := \iota_{\lambda(i,\mu,\varepsilon)}^{-1} P_{\lambda(i,\mu,\varepsilon)} \mathsf{R}^{\mu}. \tag{22.4}$$

Theorem 22.2 (APP Entanglement–Witt)**.** *For each terna (i,μ,ε),*

$$g_{\lambda(i,\mu,\varepsilon)} T_{i\mu\varepsilon} = T_{i\mu\varepsilon} C^{(-1)^{\mu}}. \tag{22.5}$$

The direct sum defines a C_3-equivariant isomorphism

$$T_\lambda : W_{\mathrm{APP}} \otimes \mathbb{C} \xrightarrow{\cong} W_c := \bigoplus_{b=0}^{11} (A_{2,b} \otimes \mathbb{C}). \tag{22.6}$$

Proof. For $\mu = 0$, the definition of g_b directly gives conjugation by C. For $\mu = 1$, one inserts $\mathsf{R}C\mathsf{R} = C^{-1}$. The lemma 22.1 guarantees that the direct sum uses every Witt position exactly once and preserves the pair, sheet, and orbit. □

The theorem is relative to the simultaneous transport of the order of pairs, leaves, and orbits, of the Witt origin, of the frames, and of the orientation. Changing a single one of these coordinates does not define the same functor.

22.1.2 Graded trace of the action of the ternary generator on $V^\natural$

Let

$$\rho_W := \bigoplus_{b=0}^{11} g_b$$

and consider the bosonic envelope

$$\mathcal{H}_{\mathrm{bos}}(W_c) := \mathrm{Sym}\left(\bigoplus_{n \geq 1} W_c[n] \right). \tag{22.7}$$

If N is the degree operator, we define

$$Z_{\mathrm{Fock}}(q) := q^{-1} \operatorname{Tr}_{\mathcal{H}_{\mathrm{bos}}(W_c)} \left(\Gamma_{\mathrm{bos}}(\rho_W) q^N \right). \tag{22.8}$$

Proposition 22.3 (Cyclotomic polynomial of level three)**.** *As a formal Laurent series,*

$$\boxed{Z_{\mathrm{Fock}}(q) = q^{-1} \prod_{n \geq 1} (1 + q^n + q^{2n})^{-12} =: t_3(q).} \tag{22.9}$$

Its expansion begins with

$$t_3(q) = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + 1188q^4 + O(q^5). \tag{22.10}$$

Proof. Each g_b is conjugate to C, whence

$$\det(I - g_b q^n) = 1 + q^n + q^{2n}.$$

The identity

$$\sum_{k \geq 0} \operatorname{Tr}(\mathrm{Sym}^k \rho_W) t^k = \det(I - \rho_W t)^{-1}$$

applied in each degree produces the product. Formal multiplication through degree five gives the expansion. In particular, the coefficient of q is obtained as

$$[q^2]\, (1 + q + q^2)^{-12} (1 + q^2 + q^4)^{-12} = 66 - 12 = 54.$$

□

The value 54 appears here as the coefficient of a trace constructed from twelve fibers. Unit U030 also obtained it as the oriented index of the APP aggregate and proved that twelve is the unique positive solution of cyclotomic–radial rigidity. The equality of the two values is a compatibility between two realizations; neither uses the coefficient of J as input.

22.1.3 Isometry Without Fixed Points Induced by the Ternary Word of Full Support

Let

$$q_* = (1, 1, 1, 1, 1, 1) \in \mathbb{F}_3^6.$$

Multiplication by the Paley–Witt matrix gives

$$q_* A_W = (2, 1, 1, 1, 1, 1). \tag{22.11}$$

Therefore,

$$c_* := (q_*, q_* A_W) = (1, 1, 1, 1, 1, 1, 2, 1, 1, 1, 1, 1) \in C_W \tag{22.12}$$

and all its coordinates are non-zero.

For each position b, we fix

$$P_b(c_*) = \begin{cases} \mathsf{R}, & (c_*)_b = 1, \\ I, & (c_*)_b = 2, \end{cases} \qquad g_c := \bigoplus_{b=0}^{11} P_b(c_*) C P_b(c_*)^{-1}. \tag{22.13}$$

Proposition 22.4 (Order, absence of fixed points and gluing)**.** *The operator g_c has order three, has no nonzero fixed vectors, and preserves the Niemeier lattice $N(A_2^{12})$ constructed in U021.*

Proof. Each block is conjugate to the Coxeter C, whose minimal polynomial is $X^2 + X + 1$. Hence it has order three and has no eigenvalue one. The direct sum preserves both properties. The Coxeter acts trivially on A_2^*/A_2; therefore each block preserves the discriminant class and the union of lateral classes that defines the gluing. □

22.1.4 Preservation of the Leech Neighbor

Write

$$v := v_{\mathcal{F}_*} = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v^2 = 54,$$

for the vector selected by the incidence origin of (21.82). Let

$$N := N(A_2^{12}), \qquad N_0 := \ker(\langle \cdot, v \rangle \bmod 3), \qquad N_v := N_0 + \mathbb{Z}\frac{v}{3} \cong \Lambda_{24}.$$

Theorem 22.5 (Neighbor-Oriented Preservation)**.** *The displacements*

$$y_* := \frac{g_c v - v}{3}, \qquad z_* := \frac{g_c^{-1} v - v}{3} \tag{22.14}$$

belong to N_0. Consequently,

$$g_c N_0 = N_0, \qquad g_c N_v = N_v.$$

Proof. The discriminant words of y_* and z_* are c_* and $-c_*$, both in C_W; hence $y_*, z_* \in N$. Computation in each factor A_2 gives

$$\langle y_*, v \rangle = \langle z_*, v \rangle = -(4^2 + 11) = -27 \equiv 0 \pmod 3. \tag{22.15}$$

Thus both lie in N_0. For $x \in N_0$,

$$\langle g_c x, v \rangle = \langle x, g_c^{-1} v \rangle = \langle x, v \rangle + 3\langle x, z_* \rangle \equiv 0 \pmod 3.$$

The same count with g_c^{-1} gives equality of the kernel. Finally,

$$g_c(v/3) = v/3 + y_*,$$

so that the class generated by the neighbor is preserved. □

22.1.5 24 orientations and lattice naturality

The weight enumerator of (21.18) contains $24y^{12}$. Therefore, the set

$$C_W^{\times} := \{u \in C_W : u_b \in \{1, 2\} \text{ for every } b\}$$

has 24 elements. For each $u \in C_W^{\times}$, we define

$$P_b(u) = \begin{cases} \mathsf{R}, & u_b = 1, \\ I, & u_b = 2, \end{cases} \qquad g_u := \bigoplus_{b=0}^{11} P_b(u) C P_b(u)^{-1}.$$

Proposition 22.6 (Robustness of Full Support Orientations)**.** *For every $u \in C_W^{\times}$,*

$$\frac{g_u v - v}{3}, \quad \frac{g_u^{-1} v - v}{3} \in N_0.$$

In particular, each g_u preserves the neighbor constructed with the transported orientation.

Proof. In simple root coordinates,

$$C\rho - \rho = (-2, -1), \qquad C^{-1}\rho - \rho = (-1, -2).$$

The discriminant classes of the two displacements are u and $-u$. For the radial coefficient $a_b \in \{4, 1\}$,

$$\left\langle \frac{(C^{\pm 1} - I) a_b \rho}{3}, a_b \rho \right\rangle = -a_b^2.$$

The sum over the twelve factors again gives -27. The proof of theorem 22.5 is applied component by component. □

To type the recalibration, let $h \in \mathrm{Aut}(C_W)$ be monomial: a permutation σ of the twelve coordinates followed by multipliers $\epsilon_b \in \{1, 2\}$. We define its lattice lift

$$\widetilde{h} := P_\sigma \circ \bigoplus_{b=0}^{11} \mathsf{R}^{\nu_b}, \qquad \nu_b = \begin{cases} 0, & \epsilon_b = 1, \\ 1, & \epsilon_b = 2. \end{cases} \tag{22.16}$$

Its action on the discriminant is exactly h. If the change simultaneously transports the code, flag, incidence origin, vector v, neighbor, and frames, then

$$g_{hu} = \widetilde{h}\, g_u\, \widetilde{h}^{-1}. \tag{22.17}$$

The ternary matrix h does not act without a lift on A_2^{12} or on the Leech lattice.

22.1.6 Lattice trace and computation of type 0

Let $\widehat{g}_c$ be the standard lift of g_c to the lattice VOA

$$V_{N_v} = M(1) \otimes \mathbb{C}_\varepsilon[N_v].$$

For $j = 1, 2$, the oscillator–lattice decomposition produces

$$\begin{aligned} Z_{0,j}(\tau) &:= \operatorname{Tr}_{V_{N_v}}\left(\widehat{g}_c^{\,j} q^{L_0-1}\right) \\ &= q^{-1}\left(\sum_{\lambda\in N_v^{g_c^j}} \varepsilon_j(\lambda) q^{\langle\lambda,\lambda\rangle/2}\right)\prod_{n\geq 1}\det(I-g_c^j q^n)^{-1}. \end{aligned} \tag{22.18}$$

Proposition 22.7 (Trace of the nontrivial sectors)**.** *We have*

$$Z_{0,1}(\tau) = Z_{0,2}(\tau) = t_3(\tau).$$

Proof. The absence of fixed points implies

$$N_v^{g_c} = N_v^{g_c^2} = \{0\},$$

so that the lattice sum in (22.18) equals one. In each factor, g_c^j has eigenvalues ζ_3, ζ_3^2; therefore,

$$\det(I - g_c^j q^n) = 1 + q^n + q^{2n}.$$

The twelve factors reproduce (22.9). □

Theorem 22.8 (Twisted weight and type of the lift)**.** *The standard lift has order three, twisted weight*

$$\rho_{g_c} = \frac{4}{3} \tag{22.19}$$

and type zero.

Proof. In $\mathfrak{h} = N_v \otimes_{\mathbb{Z}} \mathbb{C}$, each of the twelve factors contributes one eigenvector with eigenvalue ζ_3 and another with eigenvalue ζ_3^2. Therefore,

$$\dim \mathfrak{h}_{\zeta_3} = \dim \mathfrak{h}_{\zeta_3^2} = 12.$$

The formula for the weight of the twisted vacuum of order three gives

$$\rho_{g_c} = \frac{1}{4\cdot 3^2}\left(1\cdot 2\cdot 12 + 2\cdot 1\cdot 12\right) = \frac{4}{3}.$$

For a lattice isometry of odd order, the standard elevation preserves the order. The type is the class of

$$3^2\rho_{g_c} = 12 \equiv 0 \pmod 3.$$

Thus, the two initially independent hypotheses are calculated here. □

22.1.7 Cyclic orbifold and dual class $3B$

Theorem 22.9 (Triadic orbifold of the Leech neighbor)**.** *The classical cyclic-orbifold theorems, applied to the standard lift in theorem 22.8, yield*

$$\operatorname{Orb}_{\mathbb{Z}/3}(V_{N_v}, \widehat{g}_c) \cong V^\natural. \tag{22.20}$$

The dual automorphism belongs to the class $3B$ and its series is

$$T_{3B}(\tau) = t_3(\tau) + 12. \tag{22.21}$$

Proof. The isometry is fixed-point-free of order three; the twisted weight and type zero were calculated, not assumed. The cyclic-orbifold theorems identify the holomorphic extension with the Moonshine module and classify the dual automorphism as $3B$ [27, 2, 23]. The identification uses these theorems after constructing the lattice object; it is not deduced solely from an equality of series. □

If $V^{(i)}$ is the $\widehat{g}_c^{\,i}$-twisted module and

$$Z_{i,j}(\tau) := \mathrm{Tr}_{V^{(i)}}\left(\phi_i(\widehat{g}_c)^j q^{L_0-1}\right),$$

the character of the orbifold is the average of the nine sectors:

$$\mathrm{ch}_{V^\natural}(\tau) = \frac{1}{3}\sum_{i,j\in\mathbb{Z}/3} Z_{i,j}(\tau) = J(\tau). \tag{22.22}$$

The level three rational identity is

$$J = t_3 + 12 + \frac{10\,3^9}{t_3} + \frac{4\,3^{14}}{t_3^2} + \frac{3^{18}}{t_3^3}. \tag{22.23}$$

Since $t_3^{-1} = q + O(q^2)$,

$$[q]J = 54 + 10\cdot 3^9 = 196884 = 54(5\cdot 729 + 1). \tag{22.24}$$

This is a graded compatibility within the constructed corridor, not a scalar morphism $54 \to V^\natural$.

22.1.8 Lattice construction of order 2

The preceding route of order three and the classical construction of Frenkel–Lepowsky–Meurman produce two presentations of the same moonshine VOA. To declare the second, we fix the central extension

$$1 \longrightarrow \{\pm 1\} \longrightarrow \widehat{\Lambda}_{24} \longrightarrow \Lambda_{24} \longrightarrow 1 \tag{22.25}$$

with commutator $(-1)^{\langle\lambda,\mu\rangle}$, and a cocycle $\varepsilon(\lambda,\mu)$ that represents it. The twisted group algebra is $\mathbb{C}_\varepsilon[\Lambda_{24}]$, and

$$V_\Lambda := M(1)\otimes \mathbb{C}_\varepsilon[\Lambda_{24}] \tag{22.26}$$

is the lattice VOA of central charge 24.

The negation $\lambda \mapsto -\lambda$ has a lift θ compatible with (22.25). Its trace is

$$t_2(\tau) := \mathrm{Tr}_{V_\Lambda}(\theta q^{L_0-1}) = q^{-1}\prod_{n\geq 1}(1+q^n)^{-24}. \tag{22.27}$$

Indeed, negation pairs e^λ with $e^{-\lambda}$, and the absence of torsion leaves only $\lambda = 0$ in the lattice trace; each of the 24 oscillators contributes $(1+q^n)^{-1}$.

Let V_Λ^T the modulo irreducible torcido by θ, and $(V_\Lambda^T)^+$ its sector of signo positive. The construction FLM is

$$V^\natural = (V_\Lambda)^+ \oplus (V_\Lambda^T)^+. \tag{22.28}$$

The route $\mathbb{Z}/2$ of (22.28) and the route $\mathbb{Z}/3$ of (22.20) are parallel constructions identified by classical theorems; neither replaces the other.

22.1.9 Automorphism group, character, and graded series

eleven constructed $V^\natural$, appear two publications distinct:

$$\mathrm{Aut}(V^\natural) \cong \mathbb{M}, \tag{22.29}$$

$$\mathrm{ch}_{V^\natural}(\tau) = J(\tau) = j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \cdots . \tag{22.30}$$

The former identifies the symmetry group; the latter counts graded dimensions. The vacuum line is

$$(V^\natural)_0 = \mathbb{C}\mathbf{1},$$

and the absence of roots in Λ_{24} gives

$$(V^\natural)_1 = 0.$$

In degree two,

$$196884 = 1 + 196883 = 196560 + 324 = 54(5 \cdot 729 + 1).$$

Only the first equality is a decomposition into dimensions of representations of the Monster; the others are arithmetic controls.

For $g \in \mathbb{M}$, the McKay–Thompson series is defined

$$T_g(\tau) := \mathrm{Tr}_{V^\natural}\left(g q^{L_0 - 1}\right). \tag{22.31}$$

Theorem 22.10 (Monstrous Moonshine)**.** *The graded action of $\mathbb{M}$ on $V^\natural$ produces the family $\{T_g\}_{g\in\mathbb{M}}$. The Moonshine theorems identify these series with genus-zero modular functions and prove their replicability identities [28, 15, 50].*

This theorem has as input the pair

$$\left(V^\natural, \mathrm{Aut}(V^\natural)\right)$$

and its grading. It is not the consequence of an arrow whose domain is the abstract group $\mathbb{M}$.

For $J = T_{1A}$, let P_n be the Faber polynomials normalized by

$$P_n(J) = q^{-n} + O(q).$$

The Hecke–Faber identity is

$$P_n(J) = n\, T_n J. \tag{22.32}$$

It controls all degrees; the coefficient 196884 is only the first nontrivial manifestation.

22.1.10 Paley–Witt–Golay–Leech–Moonshine Runner Dependency Graph

Comparison Criterion 22.11 (Refutation criteria for the moonshine corridor)**.** The construction is refuted if any of the following facts occurs:

1. λ is not bijective or (22.5) falla;
2. $c_* \notin C_W$, g_c has fixed points or does not preserve the neighbor;
3. the displacements of (22.14) do not belong to N_0;
4. the lattice lift $\widetilde{h}$ does not realize the monomial automorphism h on the discriminant;
5. the twisted weight is not $4/3$ or the lift is not of type zero;
6. the orbifold is identified with $V^\natural$ without verifying the hypotheses of the classical theorem;
7. W_{24} is used as a constructor of the Leech lattice;

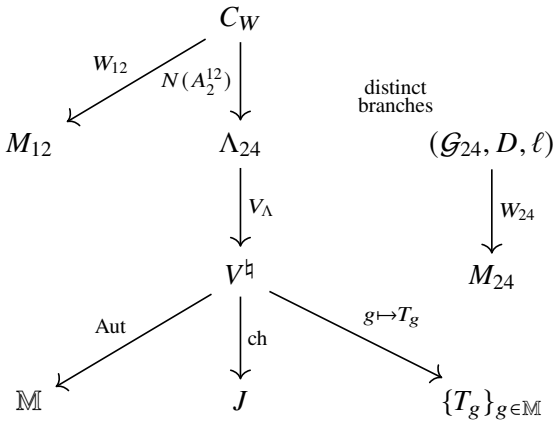

Figure 22.1: Exceptional bifurcation and three publications of $V^\natural$. The binary input $(\mathcal{G}_{24}, D, \ell)$ is independent; there is no arrow $W_{24} \to \Lambda_{24}$.

8. an equality of dimensions is presented as a construction of $\mathbb{M}$;
9. the publications Aut, ch, and $g \mapsto T_g$ are improperly serialized.

22.2 Theta control of the Leech lattice: identity $\Theta_\Lambda = E_4^3 - 720\Delta$ and separation between arithmetic coincidence and structural morphism

From Λ_{24}, the string

$$\Lambda_{24} \longrightarrow V^\natural \longrightarrow \mathbb{M} \longrightarrow \text{Moonshine}$$

is classical mathematics: vertex operator algebra, the Monster group, and McKay–Thompson functions. The contribution verified here lies in the finite input, the selection of the boundary, and the rootless 3-neighbor, not in claiming those theorems anew.

Three numerical identities accompany this chain:

$$\Theta_\Lambda = E_4^3 - 720\Delta,$$

$$196884 = 196560 + 324,$$

$$196884 = 54(3645 + 1) = 54(5 \cdot 729 + 1).$$

They are exact arithmetic identities, but without a morphism or a character decomposition, they do not by themselves constitute mathematical signals of compatibility. None replaces the construction of $V^\natural$ or provides a direct action of the Monster on HMT decimal words.

22.3 Lattice VOA, canonical involution and order-two Moonshine branch

The incidence branch first constructs the Leech lattice Λ_{24}. From that datum, the classical theory of vertex operator algebras provides a canonical prolongation. If $\mathfrak{h} = \Lambda_{24} \otimes_{\mathbb{Z}} \mathbb{C}$ and $M(1)$ is the Fock module of its Heisenberg algebra, the lattice VOA is

$$V_\Lambda = M(1) \otimes \mathbb{C}[\Lambda_{24}], \tag{22.33}$$

with central charge 24. For $\alpha \in \Lambda_{24}$, its vertex operators are written

$$Y(e^\alpha, z) = E^-(-\alpha, z)E^+(-\alpha, z)e^\alpha z^{\alpha_0}.$$

The absence of roots in Λ_{24} implies the vanishing of the weight-one sector in the Moonshine orbifold.

The involution

$$\theta : \Lambda_{24} \longrightarrow \Lambda_{24}, \qquad \theta(\lambda) = -\lambda,$$

is intrinsic and prolongs to V_Λ. Its graded trace is obtained by direct counting of the oscillator modes.

Theorem 22.12 (Trace of the negation involution)**.**

$$t_2(\tau) := \mathrm{Tr}_{V_\Lambda}\big(\theta q^{L_0-1}\big) = q^{-1}\prod_{n\geq 1}(1+q^n)^{-24}. \tag{22.34}$$

Proof. The involution pairs e^λ with $e^{-\lambda}$; since the lattice is torsion-free, only $\lambda = 0$ contributes to the trace of the lattice sector. Each one of the twenty-four energy oscillators n contributes $\sum_{k\geq 0}(-1)^k q^{nk} = (1+q^n)^{-1}$. The vacuum displacement produces the factor q^{-1}. □

The Fricke completion associated with this trace is

$$T_{2A}(\tau) = t_2(\tau) + 24 + \frac{2^{12}}{t_2(\tau)} = q^{-1} + 4372q + 96256q^2 + 1240002q^3 + \cdots. \tag{22.35}$$

The term 24 cancels the constant term of t_2; the factor 2^{12} is the degeneracy of the twisted sector of twenty-four bosons. The same boundary series determines the modular invariant through

$$\boxed{j(\tau) = \frac{(t_2(\tau)+256)^3}{t_2(\tau)^2}}. \tag{22.36}$$

Equations (22.34)– (22.36) construct the canonical branch of order two without continuous parameters.

The Frenkel–Lepowsky–Meurman orbifold is defined by

$$V^\natural = (V_\Lambda)^+ \oplus (V_\Lambda^T)^+.$$

It is a holomorphic VOA of central charge 24, satisfies $(V^\natural)_1 = 0$, and has character

$$\mathrm{ch}_{V^\natural}(\tau) = j(\tau) - 744$$

and its automorphism group is the Monster group [50, 28, 15]. In this chain, HMT fixes the Leech lattice and the involution θ; the classical VOA and FLM theorems identify the resulting prolongation with $V^\natural$ and its automorphism group. The assertion does not require an action of the Monster on the digits: the Archimedean evaluation and the exceptional branch descend from a common HMT preimage and preserve different invariants.

The neighboring function $T_{3A} = t_3 + 12 + 729/t_3$ belongs to the classical theory of Hauptmoduln of order three. The active HMT realization in the tritic corridor is the class $3B$; an identification with $3A$ requires declaration of the specific lift that changes the class.

22.3.1 APP–Witt intertwining, Leech neighbor, and orbifold of order 3

The twelve fibers bear the labels

$$(i,\mu,\varepsilon) \in \mathbb{Z}/3\mathbb{Z} \times \{0,1\} \times \{0,1\}, \qquad \lambda(i,\mu,\varepsilon) = 4i + 2\mu + \varepsilon \pmod{12}.$$

The map λ is bijective and, once trivializations and frames are fixed, the intertwiners satisfy

$$g_{\lambda(i,\mu,\varepsilon)} T_{i\mu\varepsilon} = T_{i\mu\varepsilon} C^{(-1)^\mu}.$$

Its direct sum is an C_3-equivariant isomorphism

$$T_\lambda : W_{\mathrm{APP}} \otimes \mathbb{C} \xrightarrow{\cong} \bigoplus_{b=0}^{11} (A_{2,b} \otimes \mathbb{C}).$$

Let $N = N(A_2^{12})$, let $v = v_\alpha$ the vector radial of norm 54, and definamos

$$N_0 = \ker\big(\langle \cdot, v\rangle \bmod 3\big), \qquad N_v = N_0 + \mathbb{Z}\frac{v}{3}.$$

The lattice calculation verifies that $N_v \cong \Lambda_{24}$, that the isometry g_c has order three and has no nonzero fixed points, and that

$$\frac{g_c v - v}{3}, \quad \frac{g_c^{-1} v - v}{3} \in N_0.$$

Hence $g_c N_v = N_v$. Its standard lift to the lattice VOA has twisted weight $4/3$ and type zero. The classical cyclic-orbifold theorems give

$$V_{(3)} := \mathrm{Orb}_{\mathbb{Z}/3}(V_{N_v}, \widehat{g_c}) \cong V^\natural, \qquad T_{3B} = t_3 + 12.$$

The character is recovered by the average of the nine sectors and by the level three uniformization:

$$\mathrm{ch}_{V_{(3)}} = \frac{1}{3} \sum_{i,j \in \mathbb{Z}/3} Z_{i,j} = J,$$

$$J = t_3 + 12 + \frac{10\,3^9}{t_3} + \frac{4\,3^{14}}{t_3^2} + \frac{3^{18}}{t_3^3}.$$

In particular,

$$[q]J = 54 + 10 \cdot 3^9 = 196884 = 54(5 \cdot 729 + 1).$$

22.3.2 Constructions of orders 2 and 3 of the vertex operator algebra $V^\natural$

Fix the central extension and the Leech cocycle.

$$1 \longrightarrow \{\pm 1\} \longrightarrow \widehat{\Lambda}_{24} \longrightarrow \Lambda_{24} \longrightarrow 1, \qquad V_\Lambda = M(1) \otimes \mathbb{C}_\varepsilon[\Lambda_{24}].$$

The negation $\lambda \mapsto -\lambda$ lifts to θ, and

$$t_2(\tau) = \mathrm{Tr}_{V_\Lambda}\left(\theta q^{L_0 - 1}\right) = q^{-1} \prod_{n \geq 1} (1 + q^n)^{-24}.$$

The FLM presentation is

$$V_{(2)} := (V_\Lambda)^+ \oplus (V_\Lambda^T)^+ \cong V^\natural.$$

Theorem 22.13 (Typed equivalence of the presentations of orders 3 and 2)**.** *Let*

$$\phi_3 : V_{(3)} \xrightarrow{\cong} V^\natural, \qquad \phi_2 : V_{(2)} \xrightarrow{\cong} V^\natural$$

the graded isomorphisms provided by the orbifold theorems applied to the preceding data. Then

$$\boxed{\Phi_{23} := \phi_2^{-1} \circ \phi_3 : V_{(3)} \xrightarrow{\cong} V_{(2)}}$$

is a graded isomorphism of vertex operator algebras. Moreover,

$$a \longmapsto \Phi_{23} a \Phi_{23}^{-1}$$

identifies its automorphism groups and preserves the graded traces.

Proof. The composition of VOA isomorphisms is a VOA isomorphism and preserves the vacuum, the conformal vector, the vertex operators, and the grading by L_0. Conjugation transports automorphisms. For every automorphism a, invariance of the trace under conjugation gives equality of the corresponding graded series. □

The isomorphism Φ_{23} depends on the identifications ϕ_2 and ϕ_3; absolute canonicity is not asserted. The order-two construction also preserves the exclusive content

$$T_{2A} = t_2 + 24 + \frac{2^{12}}{t_2}, \qquad \boxed{j = \frac{(t_2+256)^3}{t_2^2}},$$

which completes the modular uniformization of order two.

Once $V^\natural$ has been constructed, the three publications are stated without unduly serializing them:

$$\mathrm{Aut}(V^\natural) \cong \mathbb{M}, \qquad \mathrm{ch}_{V^\natural} = J, \qquad g \longmapsto T_g(\tau) = \mathrm{Tr}_{V^\natural}\left(g q^{L_0-1}\right).$$

The Moonshine theorem coordinates the graded action with genus-zero functions and their replicability identities. The Monster action resides in $V^\natural$; the fact that it is not a pointwise permutation of digits is a final type control, not the thesis of the corridor.

22.4 Continuous evidentiary chain of the exceptional publication: from the APP unfolding to Paley–Witt, $V^\natural$ and Moonshine

The exceptional publication starts from the incidence reader $\mathfrak{E}_{\mathrm{exc}}$ of (2). It does not take an already given code, lattice or exceptional group as input: it takes the boundary, orientation, sheet and memory of an enriched history and expresses them in the projective gauge fixed by nonadic holonomy. Only afterwards are the classical theorems of codes, lattices and vertex operator algebras applied to the produced objects.

22.4.1 APP unfolding and graded cone of the index 54

Let R be the involution exchanging the APP sheets and let $P_+ = (I+R)/2$, $P_- = (I-R)/2$ be its projectors. The central block

$$B_c = 7I + 2R = 9P_+ + 5P_- \tag{22.37}$$

produces four objects of distinct types:

$$9-5=4, \qquad (B_c)_{i\neq j} = 2, \qquad \sum M_\Pi - \sum M_\Sigma = 51-45 = 6, \qquad 9\cdot 6 = 459-405 = 54. \tag{22.38}$$

The 4 is the spectral jump between sheets, the 2 the local coupling, the 6 the difference of the modular compressions and the 54 the integration of that difference over the nine positions. Therefore, $4 \to 2 \to 6 \to 54$ designates a hierarchy of morphisms and evaluations, not a chain of equalities between objects.

With the orientation $o_{\Sigma\Pi}$, sheet parity and triangular normalization fixed, the Fock branch has the coupling

$$\mathcal{H}^{(m)}_{\Sigma,\Pi} : M_{\mathrm{bal}}^{C_3,-} \longrightarrow \mathrm{End}\big(\mathcal{F}_2(\mathcal{V}_m)\big) \otimes o_{\Sigma\Pi}, \tag{22.39}$$

and its oriented trace satisfies

$$\mathrm{Tr}_{o,\mathcal{F}_2}\big(\mathcal{H}^{(m)}_{\Sigma,\Pi}(\nu)\Gamma_2(g_m)\big) = -\frac{3m\,c(\nu)}{2}. \tag{22.40}$$

For $m = 12$ and $c(\delta) = -3$, 54 holds. Independently, the cyclotomic product

$$t_3(q) = q^{-1}\prod_{n\geq 1}(1+q^n+q^{2n})^{-12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots \tag{22.41}$$

gives $[q]t_3 = 54$.

Theorem 22.14 (Typed cone of the common index)**.** *Once the APP census, the Fock branch, the cyclotomic product, the lattice neighbor of equation (22.52) and the lunar module of equation (22.58) have been constructed separately, their readers satisfy*

$$D_{\mathrm{APP}} = \mathrm{Tr}_{o,\mathcal{F}_2}\big(\mathcal{H}^{(12)}_{\Sigma,\Pi}(\delta)\Gamma_2(g_{12})\big) = [q]t_3 = v^2 = \frac{196884}{5\cdot 729+1} = 54. \tag{22.42}$$

The equality gathers evaluations in a cone toward $\mathbb{Z}$; it does not identify their domains or use 196884 *to select the corridor.*

Proof. The first three equalities are (22.38), (22.40) and (22.41). For the radial vector $v = 4\rho_1+\rho_2+\cdots+\rho_{12}$ of (22.51), orthogonality of the factors A_2 gives $v^2 = 4^2\cdot 2 + 11\cdot 2 = 54$. Finally, $5\cdot 729+1 = 3646$ and $54\cdot 3646 = 196884$. Each identity is proved in its own codomain before they are compared. □

22.4.2 Paley form and internal quadratic root of $-I_6$

Let

$$\mathcal{U}_9 = (\mathbb{Z}/9\mathbb{Z})^{\times} = \{1,2,4,8,7,5\},$$

in the order of the powers of 2, and let

$$\theta : \mathcal{U}_9 \xrightarrow{\sim} \mathbb{P}^1(\mathbb{F}_5), \qquad \begin{array}{c|cccccc} u & 1 & 2 & 4 & 8 & 7 & 5 \\ \hline \theta(u) & \infty & 0 & 1 & 2 & 3 & 4 \end{array}. \tag{22.43}$$

This bijection is a coordinate gauge of the reader; it is not used as a homomorphism. For the quadratic character $\chi : \mathbb{F}_5 \to \{-1,0,1\}$, define

$$C_P = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & -1 & -1 & 1 \\ 1 & 1 & 0 & 1 & -1 & -1 \\ 1 & -1 & 1 & 0 & 1 & -1 \\ 1 & -1 & -1 & 1 & 0 & 1 \\ 1 & 1 & -1 & -1 & 1 & 0 \end{pmatrix}, \tag{22.44}$$

where the finite off-diagonal entries are $\chi(x-y)$ and the entries incident with ∞ are one.

Lemma 22.15 (Quadratic correlation)**.** *If $a \neq b$ in $\mathbb{F}_5$, then*

$$\sum_{t\in\mathbb{F}_5}\chi(t-a)\chi(t-b) = -1.$$

Proof. The substitution $u = (t-a)/(b-a)$ reduces the sum to $\sum_u \chi(u(u-1))$. For $u = 0,1,2,3,4$, the summands are $0,0,1,-1,-1$. □

Proposition 22.16 (Conference identity and ternary reduction)**.** *The matrix C_P is symmetric and satisfies*

$$C_P C_P^{\mathsf{T}} = 5I_6.$$

Its reduction $A_W = C_P \bmod 3$ satisfies

$$\boxed{A_W^2 = -I_6 \quad \text{in } M_6(\mathbb{F}_3).} \tag{22.45}$$

Proof. Each row of C_P has squared norm five. Two distinct finite rows have inner product $1 - 1 = 0$ by the lemma 22.15; the sum of a nontrivial character also proves orthogonality with the row of ∞. Reducing modulo three yields $A_W A_W^{\mathsf{T}} = 5I_6 = 2I_6 = -I_6$. Since A_W is symmetric, (22.45) follows. □

The identity (22.45) constructs the finite complex structure of the corridor. Indeed,

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1), \qquad P_{\pm\iota} = \frac{1}{2}(I \mp \iota A_W)$$

are complementary rank-three projectors and endow $\mathbb{F}_3^6$ with a rank-three $\mathbb{F}_9$-module structure. The action is explicit:

$$(a + b\iota) \cdot v = av + b(vA_W). \tag{22.46}$$

Therefore, $3^6 = 9^3$ is not used as a cardinal substitute for an action.

22.4.3 Self-dual ternary code and Witt system

Define

$$c : \mathbb{F}_3^6 \longrightarrow \mathbb{F}_3^{12}, \qquad c(q) = (q, qA_W), \qquad C_W := \operatorname{im} c. \tag{22.47}$$

Theorem 22.17 (Ternary code produced by incidence)**.** *The map c is injective and*

$$C_W = C_W^{\perp}, \qquad W_{C_W}(y) = 1 + 264y^6 + 440y^9 + 24y^{12}. \tag{22.48}$$

In particular, C_W has parameters $[12, 6, 6]_3$.

Proof. The first projection of $c(q)$ is q, so c is injective. With $G_W = (I_6 \mid A_W)$,

$$G_W G_W^{\mathsf{T}} = I_6 + A_W A_W^{\mathsf{T}} = 0$$

in $\mathbb{F}_3$. Thus $C_W \subseteq C_W^{\perp}$, and equality of dimensions gives self-duality. The enumerator is the exact finite sum

$$\sum_{q \in \mathbb{F}_3^6} y^{\mathrm{wt}(q)+\mathrm{wt}(qA_W)}.$$

Evaluating the $3^6 = 729$ rows of the explicit matrix (22.44) gives, respectively, the counts $1, 264, 440, 24$ at weights $0, 6, 9, 12$, and zero at the others. The sum of the four counts is 729, so no word remains outside the finite certificate. □

The 264 weight-six vectors occur in pairs $\{x, -x\}$; their 132 supports form the Steiner system

$$W_{12} = S(5, 6, 12). \tag{22.49}$$

This is the recognition, after constructing C_W, of the extended ternary Golay code and its Witt design [91, 34]. The design is not introduced to select the matrix A_W.

The binary prolongation remains separate. If $\mathcal{G}_{24} \subset \mathbb{F}_2^{24}$ is the extended binary Golay code, D a dodecad and $\ell : \{1, \ldots, 12\}_{\mathrm{HMT}} \to D$ a design isomorphism, the weight-eight supports form $W_{24} = S(5, 8, 24)$. For a fixed tetrad,

$$\lambda_4(W_{12}) = 4, \qquad \lambda_4(W_{24}) = 5,$$

so that four octads lift the four incident hexads and a fifth is transversal. The datum $(\mathcal{G}_{24}, D, \ell)$ belongs to the binary codomain; there is no canonical arrow $W_{24} \to \Lambda_{24}$.

22.4.4 Ternary gluing and Leech neighbor

Let $Q = A_2^{12}$, with $\det Q = 3^{12}$. The discriminant of each factor A_2 is $\mathbb{F}_3$, and the gluing defined by (22.47) is

$$N := \{x \in Q^* : x \bmod Q \in C_W\}. \tag{22.50}$$

Theorem 22.18 (Niemeier lattice produced by the code)**.** *The lattice N is positive definite, even and unimodular of rank twenty-four, and its root system is A_2^{12}. Consequently, $N \cong N(A_2^{12})$.*

Proof. Self-duality of C_W makes the gluing integral. All its weights are multiples of three, which makes the extension even. Moreover, $[N : Q] = |C_W| = 3^6$, and therefore

$$\det N = \frac{\det Q}{[N : Q]^2} = \frac{3^{12}}{3^{12}} = 1.$$

A nonzero discriminant class of A_2 has minimum norm $2/3$. Since every nonzero word of C_W has weight at least six, every gluing vector outside Q has norm at least four. The norm-two vectors are exactly the roots of the twelve factors A_2. The classification of even unimodular lattices of rank twenty-four identifies the indicated type [34]. □

Let ρ_i be the highest root of the factor $A_2^{(i)}$, normalized by $\rho_i^2 = 2$, and define

$$v = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v^2 = 54. \tag{22.51}$$

The ordered frame of the exceptional reader fixes which of the twelve fibers occupies the first position; no Archimedean value intervenes in this selection. Set

$$\chi_v(x) = \langle x, v\rangle \bmod 3, \quad N_0 = \ker \chi_v, \quad N_v = N_0 + \mathbb{Z}\frac{v}{3}. \tag{22.52}$$

Lemma 22.19 (Structure of the neighbor)**.** *The character χ_v is surjective, $[N : N_0] = 3$, $v/3 \in N_0^*$, and N_v is even and unimodular.*

Proof. For every root of a factor A_2, the product with the highest root is ± 1 or ± 2; the coefficients of v are congruent to one modulo three. Therefore, no root belongs to N_0 and χ_v is nontrivial, hence surjective. The definition of the kernel gives index three and $\det N_0 = 9$. For $x \in N_0$, $\langle x, v/3\rangle \in \mathbb{Z}$, while $(v/3)^2 = 6$. Thus the extension by $v/3$ is integral and even. Since $[N_v : N_0] = 3$, $\det N_v = 9/3^2 = 1$. □

Lemma 22.20 (Minimum of the new classes)**.** *Each coordinate of a local class appearing in $N_0 \pm v/3$ has minimum norm $2/9$. Consequently,*

$$\|x \pm v/3\|^2 \geq 12 \cdot \frac{2}{9} = \frac{8}{3} \qquad (x \in N_0).$$

Proof. Writing a coordinate of A_2^* in the simple-root basis, the six relevant oriented classes are the shifts of $\pm\rho/3$ by the three discriminant classes. Completing squares in the Gram form $\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$ gives minimum $2/9$ in all six classes. The orthogonal sum of the twelve coordinates gives the inequality. □

Theorem 22.21 (Construction of the Leech lattice)**.** *The neighbor N_v of (22.52) is isometric to the Leech lattice:*

$$\boxed{N_v \cong \Lambda_{24}.} \tag{22.53}$$

Proof. The roots of N do not belong to N_0, and the two new classes contain no norm-two vectors by the lemma 22.20. The lemma 22.19 proves that N_v is positive definite, even, unimodular and of rank twenty-four. The uniqueness of the lattice with these properties and no roots identifies it with Λ_{24} [34]. □

22.4.5 Order-three isometry, orbifold and lunar module

The Coxeter rotation of each factor A_2 induces an order-three isometry g_c. Stability of the code C_W proves that $g_c N = N$. For the oriented frame fixing v, the shifts

$$y_* := \frac{g_c v - v}{3}, \qquad z_* := \frac{g_c^{-1} v - v}{3} \tag{22.54}$$

belong to N_0: their discriminant words are a pair $c_*, -c_* \in C_W$, and $\langle y_*, v\rangle = \langle z_*, v\rangle = -27$. Therefore,

$$g_c N_v = N_v. \tag{22.55}$$

The action has no fixed points in $N_v \otimes \mathbb{R}$, since each factor A_2 has the two primitive eigenvalues of order three.

Let $\widehat{g}_c$ be the standard lift to the lattice VOA $V_{\Lambda_{24}}$. Its two nontrivial eigenspaces have dimension twelve. The vacuum energy of the twisted module is therefore

$$\rho_{g_c} = \frac{1}{4 \cdot 3^2} \sum_{k=1}^{2} k(3-k) \dim \mathfrak{h}_{(k)} = \frac{4}{3}. \tag{22.56}$$

The congruence $3^2 \rho_{g_c} = 12 \equiv 0 \pmod 3$ proves that the lift is of type zero.

Theorem 22.22 (Triadic orbifold)**.** *The cyclic orbifold of the preceding lift satisfies*

$$\mathrm{Orb}_{\mathbb{Z}/3}(V_{\Lambda_{24}}, \widehat{g}_c) \cong V^\natural. \tag{22.57}$$

The dual automorphism belongs to the class $3B$.

Proof. The three hypotheses that cannot be replaced by an equality of series have been verified: fixed-point-free order-three isometry, preservation of the neighbor and type zero. The cyclic orbifold theorems then identify the holomorphic extension with the lunar module and classify the dual automorphism [27, 2, 23]. □

The order-two construction is a parallel realization. For the lift θ of negation on Λ_{24},

$$V^\natural = (V_{\Lambda_{24}})^+ \oplus (V_{\Lambda_{24}}^T)^+. \tag{22.58}$$

The order-two and order-three routes are identified by the VOA theorems; they are not causally serialized one inside the other [50].

Theorem 22.23 (Publications of the lunar module)**.** *Once $V^\natural$ has been constructed, one obtains*

$$\mathrm{Aut}(V^\natural) \cong \mathbb{M}, \tag{22.59}$$

$$\mathrm{ch}_{V^\natural}(\tau) = J(\tau) = j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \cdots, \tag{22.60}$$

$$T_g(\tau) = \mathrm{Tr}_{V^\natural}\big(g q^{L_0 - 1}\big), \qquad g \in \mathbb{M}. \tag{22.61}$$

The series T_g are the genus-zero modular functions of the Moonshine theorem and satisfy the replicability identities.

Proof. The first identification and the graded construction come from the FLM realization. The coordination between the graded action, the McKay–Thompson series and their modular properties is the Moonshine theorem of Conway–Norton and Borcherds [50, 28, 15]. In particular, $(V^\natural)_0 = \mathbb{C}\mathbf{1}$ and $(V^\natural)_1 = 0$; the coefficient $196884 = 1 + 196883$ is the first nontrivial decomposition into dimensions of Monster representations. □

Falsification criterion 22.24 (Exceptional corridor)**.** The publication is refuted if any of the effective steps fails: (22.38), the trace (22.40), the coefficient $[q]t_3 = 54$, $C_P C_P^{\mathsf{T}} = 5I_6$, $A_W^2 = -I_6$, self-duality or the enumerator of C_W, evenness or unimodularity of the gluing, absence of roots of the neighbor, its preservation by g_c, the twisted weight $4/3$ or type zero. A narrative is also refuted if it uses W_{24} to construct Λ_{24}, confuses the two sets of 243 on account of their cardinality, or makes the Monster act directly on digits and routes. The action of $\mathbb{M}$ resides in $V^\natural$.

Chapter 23

Hilbertian realization of the genealogical state and von Neumann continuous dimension: nonadic UHF tower, trace and hyperfinite factor II_1

23.1 From the internal complex structure to the projective geometry of Bloch

The internal square root of minus the identity has two coordinated realizations. In Part I, Paley–Witt incidence constructs $J_W^2 = -I$ over $\mathbb{F}_3^6$, organizes the ternary code, and realizes the structure $\mathbb{F}_9^3$; in an analytic realization, an orthogonal operator J_E with $J_E^2 = -I$ turns a real space of even dimension into a complex space. This second arrow adds topology, norm, and completion: it preserves the quadratic relation but does not identify the scalar fields.

The complete transition is fully characterized by

$$\boxed{\begin{array}{c} C_P \longrightarrow J_W^2 = -I_6 \longrightarrow \mathbb{F}_3^6 \simeq \mathbb{F}_9^3, \\ (E_4, J_E), \quad \dim_{\mathbb{R}} E_4 = 4, \longrightarrow \mathbb{P}(\mathcal{H}_J) \simeq \mathbb{CP}^1 \longrightarrow S^2, \\ \mathrm{SU}(2) \longrightarrow \mathrm{PSU}(2) \simeq \mathrm{SO}(3) \subset \mathrm{PSL}(2,\mathbb{C}) \cong \mathrm{M\ddot{o}b}^+(S^2), \\ 2A_5 = \pi^{-1}(A_5) \subset \mathrm{SU}(2). \end{array}} \tag{23.1}$$

The first line retains its proofs in the section 21.2 y theorem 3.21; the two projective lines are constructed here.

23.1.1 Phase and ray space realification

Let (E, g) a space euclideo real of dimension par and let $J_E \in \mathrm{End}(E)$ such that

$$J_E^2 = -I, \qquad g(J_E u, J_E v) = g(u, v).$$

Then $J_E^{\mathsf{T}} = -J_E$ and

$$R_J(\theta) := e^{\theta J_E} = \cos\theta\, I + \sin\theta\, J_E$$

is orthogonal, with $R_J(\theta)R_J(\phi) = R_J(\theta + \phi)$. The action $(a + ib)u := au + bJ_E u$ realizes the complex chart without using the scalar i as antecedent of the operator.

Now let $E_4 \subseteq E$ be a J_E-stable subspace of real dimension four and let $\mathcal{H}_J = (E_4, J_E)$ be the resulting Hilbert space, of complex dimension two. A unit vector

$$\psi = \begin{pmatrix} z_0 \\ z_1 \end{pmatrix}, \qquad |z_0|^2 + |z_1|^2 = 1,$$

determines to ray $[\psi] \in \mathbb{CP}^1$. Definamos

$$r_1 = 2\,\mathrm{Re}(\bar{z}_0 z_1), \qquad r_2 = 2\,\mathrm{Im}(\bar{z}_0 z_1), \qquad r_3 = |z_0|^2 - |z_1|^2. \tag{23.2}$$

Theorem 23.1 (Projective Bloch Identification)**.** *The map*

$$\mathcal{B} : \mathbb{CP}^1 \longrightarrow S^2, \qquad [\psi] \longmapsto (r_1, r_2, r_3),$$

is a smooth bijection. The rank one projector associated with the ray is

$$\rho_\psi = |\psi\rangle\langle\psi| = \frac{1}{2}\big(I_2 + r_1\sigma_1 + r_2\sigma_2 + r_3\sigma_3\big), \tag{23.3}$$

where $\sigma_1, \sigma_2, \sigma_3$ are the Pauli matrices.

Proof. The global phase leaves the three coordinates invariant and

$$r_1^2 + r_2^2 + r_3^2 = 4|z_0|^2|z_1|^2 + (|z_0|^2 - |z_1|^2)^2 = 1.$$

Conversely, each $\boldsymbol{r} \in S^2$ determines the positive projector $\rho = (I + \boldsymbol{r} \cdot \boldsymbol{\sigma})/2$, which satisfies $\rho^2 = \rho$ and $\operatorname{tr} \rho = 1$; its image is a single ray. The affine charts of $\mathbb{CP}^1$ make the map and its inverse [12] smooth. □

The Hopf sequence

$$S^1 \longrightarrow S^3 \longrightarrow S^2 \tag{23.4}$$

exhibits the loss published by projectivization: the normalized vector belongs to S^3, the projective observable publishes a point of S^2, and the fiber S^1 preserves the common phase that the chart identifies [63]. This is a precise realization of the HMT distinction between enriched state and visible coordinate.

23.1.2 Rotations, Möbius transformations and spinor lifting

Every element of $\mathrm{SU}(2)$ can be written

$$U = \begin{pmatrix} \alpha & \beta \\ -\overline{\beta} & \overline{\alpha} \end{pmatrix}, \qquad |\alpha|^2 + |\beta|^2 = 1.$$

Theorem 23.2 (Spinorial action on the Bloch sphere)**.** *For each $U \in \mathrm{SU}(2)$ there exists a unique rotation $R_U \in \mathrm{SO}(3)$ such that*

$$U(\boldsymbol{r} \cdot \boldsymbol{\sigma})U^\dagger = (R_U \boldsymbol{r}) \cdot \boldsymbol{\sigma}.$$

The map $U \mapsto R_U$ is a surjective homomorphism with kernel $\{\pm I_2\}$.

Proof. Conjugation preserves the three-dimensional real space of traceless Hermitian matrices and the inner product $\langle A, B\rangle = \frac{1}{2}\operatorname{tr}(AB)$, and therefore induces a rotation. If it acts trivially, U commutes with the three Pauli matrices and is scalar; the unit-determinant condition leaves $U = \pm I_2$. The axis–angle representation provides the two preimages of each rotation. □

In the affine chart $z = z_0/z_1$ of $\mathbb{CP}^1$, the same action is the Möbius transformation

$$z \longmapsto \frac{\alpha z + \beta}{-\overline{\beta} z + \overline{\alpha}}.$$

The Bloch rotation and the fractional transformation are two coordinates of a single projective action: the first acts on Hermitian projectors and the second on the Riemann sphere.

The rotational group of the icosahedron is $A_5 \subset \mathrm{SO}(3)$. Its preimage defines the binary icosahedral group

$$2A_5 := \pi^{-1}(A_5) \subset \mathrm{SU}(2),$$

and produces the exact sequence

$$1 \longrightarrow \{\pm I_2\} \longrightarrow 2A_5 \longrightarrow A_5 \longrightarrow 1. \tag{23.5}$$

In particular, $|2A_5| = 120$. For a rotation of odd order n, the half-angle lift has order $2n$, whereas its opposite has order n. Icosahedral rotations of orders three and five therefore admit pairs of lifts of orders $(6, 3)$ and $(10, 5)$, respectively. This specialization links the projective geometry of two-level states with the McKay branch and the exceptional symmetries, whose modules and lattices remain in their reference constructions in Part I.

Provenance and scope of the projective chain

The Paley–Witt identity, structure $\mathbb{F}_3^6 \simeq \mathbb{F}_9^3$, action $\mathrm{SU}(2) \to \mathrm{SO}(3)$, the Mobius realization, and extension $2A_5$ are results demonstrated in their domains. Chain (23.1) is a unified functorial realization: it explicitly declares the realization that changes scalars and does not convert the finite root J_W into an analytic operator without that additional datum.

23.2 Projective realization of Bloch from the internal complex structure

23.2.1 Matrix realization of each depth

For $d \geq 1$, define

$$C_9^{(d)} = (\mathbb{Z}/9\mathbb{Z})^d, \qquad H_d = \ell^2(C_9^{(d)}), \qquad A_d = B(H_d) \cong M_{9^d}(\mathbb{C}).$$

The canonical basis $\{\delta_x : x \in C_9^{(d)}\}$ preserves the discrete label of each state. The uniform measure induces the normalized trace

$$\tau_d(a) = \frac{1}{9^d}\,\mathrm{Tr}(a).$$

The factorization

$$C_9^{(d+1)} = C_9^{(d)} \times \mathbb{Z}/9\mathbb{Z}$$

produce a unitary identification

$$H_{d+1} \cong H_d \otimes \mathbb{C}^9.$$

This is the exact input to the operator tower. This does not identify $(\mathbb{Z}/9)^3$ with $\mathbb{F}_3^6$ as groups: they share 729 elements, but their operations and carry cocycles are distinct.

23.2.2 Weyl–Heisenberg Representation of Phase and Displacement on the Triadic Fiber

Let $\omega = e^{2\pi i/9}$. On $H_1 = \ell^2(\mathbb{Z}/9\mathbb{Z})$, we define

$$(Xf)(r) = f(r-1), \qquad (Zf)(r) = \omega^r f(r).$$

Then

$$X^9 = Z^9 = I, \qquad ZX = \omega XZ.$$

The group generated by $X, Z, \omega I$ is the finite Heisenberg group of order $9^3 = 729$.

Theorem 23.3 (Stone–von Neumann finite)**.** *Every irreducible unitary representation of the finite Heisenberg group in which the center acts by means of the primitive character ωI is unitarily equivalent to the preceding representation.*

Proof. Let v be an eigenvector of Z. The vectors

$$v, Xv, \ldots, X^8 v$$

have eigenvalues distinct from Z, since $ZX^k v = \omega^k X^k Z v$. They are orthogonal and span an invariant subspace. By irreducibility, they form a basis of the entire representation. In that basis, X is the cyclic shift and Z the diagonal phase. □

Structural obstruction

Uniqueness fails if the primitive central character is not fixed or if reducible representations are allowed. This finite theorem must not be confused with the continuous version for the canonical commutation relations.

23.2.3 Aritmetic Projectors and Incompatibility

The additive and multiplicative sheets of APP define information subspaces and their orthogonal projectors $P_{\Sigma,d}, P_{\Pi,d}$. The constructed identities satisfy

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}.$$

Noncommutativity is not deduced from a quantum analogy: it is a finite matrix theorem. Its "pre-Heisenberg" reading is subsequent to that calculation.

Proposition 23.4. *The preceding projectors do not jointly belong to the same Boolean subalgebra of projections.*

Proof. In an abelian subalgebra all projectors commute. The displayed commutators are nonzero. □

23.2.4 Hilbertian structure of the matrix publication and preserved genealogical memory

Hilbert space provides linear superposition, orthogonal projection, and spectral calculus. HMT supplies the genealogical index of the basis and distinguishes which operator represents a transition, a measurement, or a shadow. The realization does not replace TPK: it represents it.

Premises and derivation

The APP projectors and the Weyl–Heisenberg pair are part of the preceding construction. The organization H_d, A_d and the uniqueness proof are established here by applying the corresponding classical theorem to the HMT objects.

23.3 The 9 phases of the TPK and continuous geometry

23.3.1 Typed separation between the UHF lift of nonadic ranks and the geometric prolongation of the marked branch

Let $p_j = |e_j\rangle\langle e_j|$ be the projector onto a marked gate. The factorization $H_{d+1} \cong H_d \otimes \mathbb{C}^9$ admits two lifts:

$$\iota_d(a) = a \otimes I_9, \qquad j_{d,j}(a) = a \otimes p_j.$$

Proposition 23.5 (Unit and trace)**.** *For all $a \in A_d$,*

$$\tau_{d+1}(\iota_d(a)) = \tau_d(a), \qquad \iota_d(I) = I,$$

while

$$\tau_{d+1}(j_{d,j}(a)) = \frac{1}{9}\tau_d(a), \qquad j_{d,j}(I) \neq I.$$

Proof. Since $\mathrm{Tr}(I_9) = 9$ and $\mathrm{Tr}(p_j) = 1$,

$$\tau_{d+1}(a \otimes I_9) = \frac{\mathrm{Tr}(a)\,9}{9^{d+1}} = \tau_d(a),$$

and

$$\tau_{d+1}(a \otimes p_j) = \frac{\mathrm{Tr}(a)}{9^{d+1}} = \frac{\tau_d(a)}{9}.$$

The identity identities are immediate. □

Scientific reading

"Looking at the nine phases of the TPK" means preserving the identity operator on the complete fiber. An isolated gate preserves a marked history; the nine together also preserve the unit and the global normalization.

23.3.2 The UHF limit

Theorem 23.6 (UHF nonadic closure)**.** *The unital inductive limit*

$$A_{9^\infty} := \varinjlim (A_d, \iota_d) \cong \bigotimes_{n=1}^{\infty} M_9(\mathbb{C})$$

is the UHF algebra of supernatural type $9^\infty = 3^\infty$*. It has a product trace* τ *compatible with all the* τ_d*.*

Proof. The inclusions are injective, unital, and trace-preserving. The algebraic union consists of nested finite matrices; its norm closure is, by definition, a UHF algebra. The product trace is the only trace compatible with the matrix traces of all the factors [54]. □

Theorem 23.7 (Hyperfinite factor)**.** *Let* $(\pi_\tau, \mathcal{H}_\tau, \Omega_\tau)$ *be the GNS representation of the trace. Then*

$$\pi_\tau(A_{9^\infty})'' \cong \mathcal{R}_{\mathrm{hyp}},$$

the hyperfinite factor of type II_1*.*

Proof. The closure is finite because $\tau(I) = 1$. Extremality of the trace makes it a factor. It is hyperfinite because the increasing union of the matrices $\pi_\tau(A_d)$ is weakly dense. Uniqueness of the separable hyperfinite factor II_1 completes the identification [93, 33]. □

23.3.3 Corner immersion of a marked phase: compact ideal $\mathcal{K}(\mathcal{H}_\infty)$ and factor $\mathcal{B}(\mathcal{H}_\infty)$ of type I_∞

Let $V_{d,j} : H_d \to H_{d+1}$, $V_{d,j}\xi = \xi \otimes e_j$. Then

$$j_{d,j}(a) = V_{d,j} a V_{d,j}^*.$$

In the limit of the spaces, the union of the corners contains the finite-rank operators. Its norm closure is $\mathcal{K}(H_\infty)$, and its natural bicommutant is $B(H_\infty)$, of type I_∞.

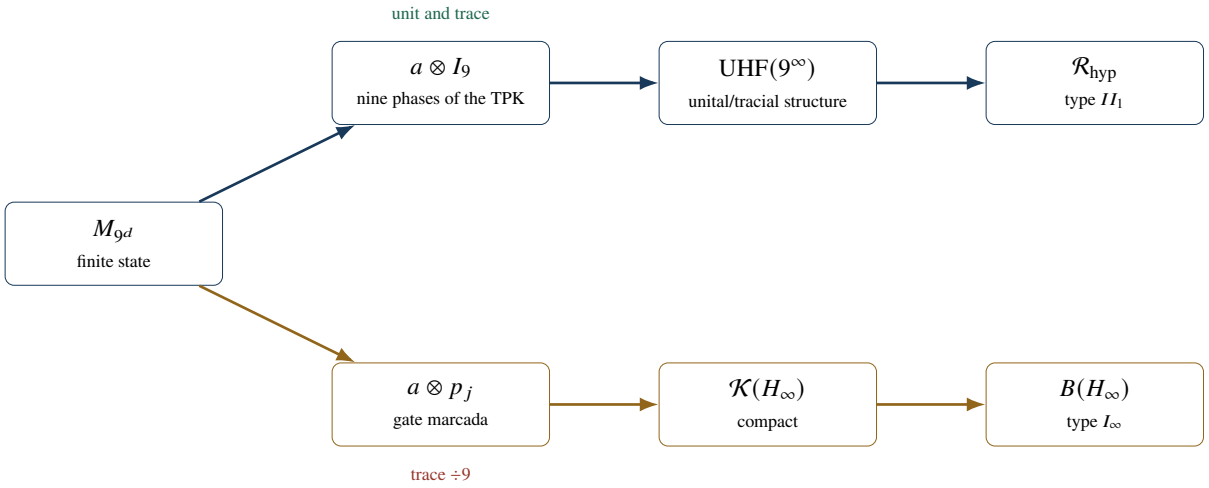

Figure 23.1: A marked door and the nine phases of the TPK produce closures of distinct types.

23.3.4 Continuous dimension from nonadic ranges

For a projection $P \in M_{9^d}$,

$$d_d(P) = \tau_d(P) = \frac{\operatorname{rank}(P)}{9^d}.$$

The values belong to $\mathbb{Z}[1/9] \cap [0,1]$, a dense set in $[0,1]$.

Theorem 23.8 (Discrete Continuous Geometry)**.** *For each $t \in [0,1]$ there exists to projection $P_t \in \mathcal{R}_{\text{hyp}}$ with $\tau(P_t) = t$. Moreover,*

$$P \sim Q \quad \Longleftrightarrow \quad \tau(P) = \tau(Q),$$

where $\sim$ denotes Murray–von Neumann equivalence.

Proof. Let $m_d = \lfloor 9^d t \rfloor$. Since $0 \le m_{d+1} - 9m_d \le 8$, nested projections of rank m_d can be chosen. Their strong limit P_t satisfies, by normality of the trace,

$$\tau(P_t) = \lim_d \frac{m_d}{9^d} = t.$$

The classification of projections in a finite factor gives the final equivalence. □

Continuous dimension is not fractional cardinality. It measures equivalence of subspaces in the closure. Each approximant preserves integer rank; the continuity appears when the entire unital genealogy is closed.

Result

Holographic conservation of the unit becomes a falsifiable operator-theoretic criterion: replacing I_9 by p_j divides the trace and changes the type of the limit. The set of gates is not a census; it is the condition for unital, trace-preserving inclusion.

23.4 Profinite dynamical system: translation, logical algebra, and state space

23.4.1 The 2nd route to the hyperfinite factor

The HMT construction produces the compact group

$$K_\infty \cong C_4 \times \mathbb{Z}_3$$

as a limit of Pell norm kernels, together with a minimal and uniquely ergodic translation $T_u(x) = x + u$ for the Haar measure μ_H. We consider

$$M_{\mathrm{clk}} = L^\infty(K_\infty, \mu_H) \rtimes_{T_u} \mathbb{Z}.$$

Theorem 23.9 (Clock factor)**.** *If T_u is free, ergodic, and Haar-preserving, then*

$$M_{\mathrm{clk}} \cong \mathcal{R}_{\mathrm{hyp}}.$$

Proof. The free and ergodic p.m.p. action produces a finite trace factor.

$$\tau_{\mathrm{clk}}\left(\sum_n f_n V^n\right) = \int f_0 \, d\mu_H.$$

Amenability of $\mathbb{Z}$ makes the orbit relation hyperfinite; therefore, the factor is the hyperfinite II_1. □

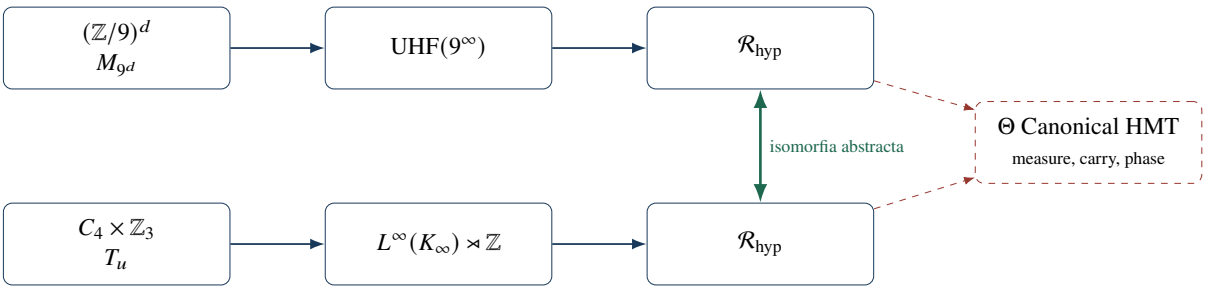

Figure 23.2: Two abstract routes toward $\mathcal{R}_{\mathrm{hyp}}$. HMT causal conjugation is an additional problem.

The coincidence of weak closures does not identify the antecedents C^*. The UHF branch and the odometer crossed product may have distinct K-theoretic invariants. A canonical HMT identification requires a map Θ with

$$\Theta_* \mu_{\mathrm{APP}} = \mu_H, \qquad \Theta S_{\mathrm{carry}} = T_u \Theta,$$

and preservation of diagonals, phase, orientation, and projectors. That intertwiner remains as boundary.

23.4.2 theorem ergodico medio of von Neumann for the odometro of Haar in K_∞

Let $Uf = f \circ T_u^{-1}$ in $L^2(K_\infty, \mu_H)$. The theorem ergodico medio of von Neumann [130] gives

$$\frac{1}{N} \sum_{j=0}^{N-1} U^j f \longrightarrow P_{\mathrm{Fix}(U)} f.$$

The ergodicity identifies the limit with

$$\left(\int f \, d\mu_H\right) \mathbf{1}.$$

The clock has pure point spectrum and zero entropy, but its temporal averages converge to the Haar average. Mixing is not required.

23.4.3 Orthomodular Lattice of Projections and the Logic of Closed Subspaces

The lattice $\mathrm{Proj}(\mathcal{R}_{\mathrm{hyp}})$, with

$$P^{\perp} = I - P, \qquad P \wedge Q, \qquad P \vee Q = (P^{\perp} \wedge Q^{\perp})^{\perp},$$

is complete and orthomodular. It is not distributive. The noncommuting APP projectors embed into $\mathcal{R}_{\mathrm{hyp}}$ and provide a finite witness of that nondistributivity [21].

Each Abelian subalgebra selects a Boolean context. Classical logic does not disappear: it occupies the commutative contexts. What fails globally is the possibility of gathering all the incompatible observables into a single Boolean algebra.

23.4.4 Density matrices and entropy

In M_{9^d}, to normal state is written

$$\varphi_\rho(a) = \mathrm{Tr}(\rho a), \qquad \rho \geq 0, \quad \mathrm{Tr}\,\rho = 1.$$

In $\mathcal{R}_{\mathrm{hyp}}$, a normal density is

$$h \in L^1(\mathcal{R}_{\mathrm{hyp}}, \tau)_+, \qquad \tau(h) = 1,$$

and $\varphi_h(a) = \tau(ha)$. Its entropy relative to the trace is

$$S_\tau(h) = -\tau(h \log h).$$

If $h = 9^d \rho$, then

$$S_\tau(h) = S_{\mathrm{vN}}(\rho) - d \log 9.$$

The canonical extension

$$\rho_{d+1} = \rho_d \otimes \frac{I_9}{9}$$

adds $\log 9$ to the matrix entropy, but leaves $S_\tau(h)$ invariant. The first quantity records an additional uniform fiber; the second uses the holographic normalization of the tower.

Structural obstruction

Tr and τ will not be used interchangeably. Nor will $\tau(P)$ be interpreted as a cardinality of points, or every vector in a representation be called pure. A diffuse factor II_1 has no minimal projections.

23.4.5 Operator types and modular boundary

The classification constructed so far is:

object	type
M_{9^d}	I_{9^d}
marked branch	I_∞
tracial UHF branch	II_1
p.m.p. clock	II_1.

A type III would require a quasi-invariant measure with nontrivial Radon–Nikodym cocycle or a KMS state whose GNS representation were not semifinite. The mere presence of the word “KMS” does not select the type.

Mathematical extensions

The completion of the total memory groupoid of TPK requires a topology or Borel structure, measure, closure under inversion, amenability, ergodicity, and control of isotropy. The clock subgroupoid satisfies those hypotheses; the total groupoid is not promoted by analogy.

23.5 Hilbert-space realization of the nonadic phase and preservation of the unit

The construction of Triadic Modular Holography first provides the states, their transitions, and the restriction maps. The Hilbert-space realization adds a linear structure and an inner product to their discrete coordinates. This order determines what each operator represents: the basis labels arise from the nonadic construction; linear operations subsequently act on those labels. Genealogical memory remains in the TPK state and accompanies the projections used to represent it.

23.5.1 Phase fiber, labeled basis, and inner product

For an integer depth $d \geq 1$, let

$$C_{9,d} = (\mathbb{Z}/9\mathbb{Z})^d, \qquad \mathcal{H}_d = \ell^2(C_{9,d}), \qquad \mathcal{A}_d = B(\mathcal{H}_d). \tag{23.6}$$

The inner product is $\langle f, g\rangle = \sum_x \overline{f(x)}g(x)$. The functions δ_x form an orthonormal basis labeled by the phase coordinates. Thus $\dim \mathcal{H}_d = 9^d$ and $\mathcal{A}_d \cong M_{9^d}(\mathbb{C})$. The matrix algebra represents this finite fiber; routes, quotients, and memory omitted by a phase projection still belong to the starting state.

Coordinate factorization induces the unitary map

$$\mathcal{H}_{d+1} \longrightarrow \mathcal{H}_d \otimes \mathbb{C}^9, \qquad \delta_{(x,r)} \longmapsto \delta_x \otimes \delta_r. \tag{23.7}$$

Define the normalized trace $\tau_d(a) = 9^{-d}\,\mathrm{Tr}(a)$. Finite counting and normalization are distinguished: $\mathrm{Tr}(I) = 9^d$, whereas $\tau_d(I) = 1$. Likewise, the group $(\mathbb{Z}/9\mathbb{Z})^3$ and the vector space $\mathbb{F}_3^6$ both have 729 elements, but retain different algebraic laws. Realization of a phase fiber does not replace the ternary encoding of APP emissions.

23.5.2 Translation and phase: finite Weyl representation

In the complex realization subsequent to the constructions of π and the structure $\mathrm{i}^2 = -1$, fix $\omega = \exp(2\pi\mathrm{i}/9)$. On $\mathcal{H}_1$, let

$$(Xf)(r) = f(r-1), \qquad (Zf)(r) = \omega^r f(r). \tag{23.8}$$

The first operation shifts the phase coordinate; the second evaluates it through a character. Both are unitary and satisfy

$$X^9 = Z^9 = I, \qquad ZX = \omega XZ. \tag{23.9}$$

Indeed, $(ZXf)(r) = \omega^r f(r-1)$, whereas $(XZf)(r) = \omega^{r-1} f(r-1)$. The character appears here as a realization of the phase already constructed and does not select the TPK numerical registers.

23.5.2.1 Oriented area and central extension of translations

The translation support is $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$. The mixed APP curvature constructed in Section 4.3.4 assigns $+1$ to the oriented plaquette of the sum–product pair and -1 to the pair in the opposite order. Its bilinear extension to two displacements $u = (a, b)$ and $v = (c, d)$ is the alternating form

$$\sigma_{\mathrm{ar}}(u, v) = ad - bc \quad \text{in } \mathbb{Z}/9\mathbb{Z}. \tag{23.10}$$

Indeed, alternation makes the evaluation on two displacements along the same axis vanish. The values on the oriented basis are $\sigma_{\mathrm{ar}}((1,0),(0,1)) = 1$ and $\sigma_{\mathrm{ar}}((0,1),(1,0)) = -1$; distributing both arguments gives (23.10). The same formula is the sum of plaquettes of any oriented cellular chain realizing that

parallelogram: the interior edges cancel. Changing an integer representative by a multiple of nine preserves its publication in $\mathbb{Z}/9\mathbb{Z}$.

The order $X^a Z^b$ of the already defined operators fixes a section of the central extension. Denote its composition factor by

$$c_{\mathrm{W}}(u, v) = bc \quad \text{in } \mathbb{Z}/9\mathbb{Z}. \tag{23.11}$$

This cocycle preserves the order of the two operations, while σ_{ar} preserves the orientation of the parallelogram.

Proposition 23.10 (Central extension and commutator sign)**.** *The set $\mathfrak{H}_9 = (\mathbb{Z}/9\mathbb{Z})^3$, with product*

$$(a, b, t)(c, d, s) = (a + c, b + d, t + s + bc), \tag{23.12}$$

is a group of order 729*. The map*

$$\varrho(a, b, t) = \omega^t X^a Z^b$$

is a faithful unitary representation on $\mathcal{H}_1$. With the convention $[g, h] = ghg^{-1}h^{-1}$, one has

$$[\varrho(a, b, 0), \varrho(c, d, 0)] = \omega^{bc-ad} I = \omega^{-\sigma_{\mathrm{ar}}((a,b),(c,d))} I. \tag{23.13}$$

The center and the translation group form the exact sequence

$$0 \longrightarrow \mathbb{Z}/9\mathbb{Z} \xrightarrow{t \mapsto (0,0,t)} \mathfrak{H}_9 \xrightarrow{(a,b,t) \mapsto (a,b)} X_9 \longrightarrow 0.$$

Proof. For $w = (e, f)$, the cocycle identity reads

$$c_{\mathrm{W}}(u, v) + c_{\mathrm{W}}(u + v, w) = bc + (b + d)e = de + b(c + e) = c_{\mathrm{W}}(v, w) + c_{\mathrm{W}}(u, v + w).$$

It proves associativity of (23.12); the identity is $(0, 0, 0)$, and the inverse of (a, b, t) is $(-a, -b, -t + ab)$. The three residues are free, giving order $9^3 = 729$. From $ZX = \omega XZ$ it follows that

$$(X^a Z^b)(X^c Z^d) = \omega^{bc} X^{a+c} Z^{b+d},$$

which proves the representation property. If $\omega^t X^a Z^b = I$, its action on δ_r first forces $a = 0$. Evaluation at $r = 0$ gives $t = 0$, and evaluation at $r = 1$ gives $b = 0$, since ω has order nine. The representation is therefore faithful. Comparing the products in both orders gives the factor $bc - ad$. A central element must satisfy $bc - ad = 0$ for every (c, d). Taking successively $(c, d) = (1, 0), (0, 1)$ yields $b = a = 0$. This identifies the center and proves exactness. □

The Wilson phase for the orientation (23.10) is $\omega^{\sigma_{\mathrm{ar}}(u,v)}$; the commutator of the ordered section $X^a Z^b$ publishes its inverse. In particular, $c_{\mathrm{W}}(u, v) - c_{\mathrm{W}}(v, u) = -\sigma_{\mathrm{ar}}(u, v)$. This identity relates two specified conventions, without identifying the polarized cocycle with the alternating form. The extension belongs to the translation group of the APP support. Its representation acts on the phase fibre; the path register and carries retain their residence in the TPK state that produced that fibre. The order 729 of the group and the cardinality 729 of the ternary ambient space retain the distinct types established in (23.6). The centre $\mathbb{Z}/9\mathbb{Z}$ of this extension records the phase of the commutator. The memory C_{12} of the sequence $0 \to C_{12} \to C_{108} \to C_9 \to 0$, constructed in proposition 11.31, belongs to the dodecaphase calendar. Each extension retains its own composition law and projection.

Proposition 23.11 (Algebra generated by phase and translation)**.** *The* 81 *operators $X^a Z^b$, with $0 \le a, b <$ 9, form a basis of $\mathcal{A}_1 = M_9(\mathbb{C})$. In particular, the representation* (23.8) *is irreducible.*

Proof. If $a \neq 0 \pmod 9$, the matrix $X^a Z^b$ has no diagonal entries. If $a = 0$, its trace is $\sum_{r=0}^{8} \omega^{br}$, equal to 9 for $b = 0$ and 0 otherwise. By (23.9), the product $(X^a Z^b)^* X^{a'} Z^{b'}$ is a factor of modulus one times $X^{a'-a} Z^{b'-b}$. Therefore,

$$\tau_1\big((X^a Z^b)^* X^{a'} Z^{b'}\big) = \delta_{a,a'}\delta_{b,b'}.$$

These are 81 linearly independent matrices in a space of dimension 81. They generate the whole matrix algebra, whose commutant consists of scalars; irreducibility follows. □

Theorem 23.12 (Uniqueness with fixed primitive central character)**.** *Every irreducible unitary representation of the group presented by $X^9 = Z^9 = c^9 = I$, c central, and $ZX = cXZ$, in which c acts as ωI, is unitarily equivalent to* (23.8)*.*

Proof. Let $v \neq 0$ be an eigenvector of Z, with eigenvalue λ. Since $Z^9 = I$, λ is a power of ω. The vectors $X^k v$, $0 \leq k < 9$, have eigenvalues $\omega^k \lambda$, distinct because the character is primitive. They are orthogonal, and their span is invariant under X, Z, and the center. Irreducibility forces it to be the entire space. Reordering the basis to begin with eigenvalue 1, Z is diagonal with entries $1, \omega, \ldots, \omega^8$, and X is cyclic translation. Normalizing the basis produces the asserted unitary equivalence. □

Primitivity of the character and irreducibility are part of the statement. At depth d, operators acting on different factors commute, and tensor products of the preceding bases generate $\mathcal{A}_d$. The phase structure is thus represented at each level without identifying phase return with return of the complete genealogical state.

23.5.3 Two lifts and two different normalizations

Factorization (23.7) permits preserving the entire new fiber or fixing one of its labels. For $p_j = |\delta_j\rangle\langle\delta_j|$, define

$$\iota_d(a) = a \otimes I_9, \qquad \jmath_{d,j}(a) = a \otimes p_j. \tag{23.14}$$

Proposition 23.13 (Preservation of unit and trace)**.** *The inclusion ι_d is unital and preserves normalized trace. The inclusion $\jmath_{d,j}$ is a corner embedding and satisfies*

$$\tau_{d+1}(\iota_d(a)) = \tau_d(a), \quad \iota_d(I) = I, \qquad \tau_{d+1}(\jmath_{d,j}(a)) = \frac{\tau_d(a)}{9}, \quad \jmath_{d,j}(I) = I \otimes p_j.$$

Proof. The trace of a tensor product is the product of the traces. Since $\mathrm{Tr}(I_9) = 9$ and $\mathrm{Tr}(p_j) = 1$, dividing by 9^{d+1} produces both formulas. The images of the identity are read directly from (23.14). □

The unital inclusion preserves the set of 9 phases and its global normalization. The corner preserves a marked continuation and its support projector. Both operations are legitimate, but transmit different data to the next depth.

23.5.4 Inductive closure and tracial realization

Theorem 23.14 (Nonadic uniformly hyperfinite algebra)**.** *The norm closure of the union through the inclusions ι_d is*

$$\mathcal{A}_{9^\infty} = \varinjlim(\mathcal{A}_d, \iota_d) \cong \bigotimes_{n=1}^{\infty} M_9(\mathbb{C}).$$

It is a UHF algebra of type $9^\infty = 3^\infty$, with a unique normalized trace τ, whose restriction to $\mathcal{A}_d$ is τ_d.

Proof. The inclusions are injective and unital. The closure of the increasing union of matrix algebras is precisely the UHF construction. The compatibility in Proposition 23.13 defines τ on the union; positivity and norm one allow its extension to the closure. Every normalized trace on the limit restricts to the unique normalized trace on each matrix algebra. Since the union is dense, those restrictions determine the trace uniquely. □

Let $\mathcal{H}_\tau$ be the completion of $\mathcal{A}_{9^\infty}$ for $\langle a, b\rangle_\tau = \tau(a^*b)$, and let π_τ be its representation by left multiplication. The vector defined by the identity is denoted Ω_τ.

Theorem 23.15 (Tracial factor of complete refinement)**.** *The weak closure $\mathcal{R}_9 = \pi_\tau(\mathcal{A}_{9^\infty})''$ is a hyperfinite factor of type II_1. The nonadic inclusions preserve its unit and normalized trace.*

Proof. The product trace extends to a faithful finite normal trace in the tracial representation. To see that the center is trivial, let E_d be the tracial expectation onto $\pi_\tau(\mathcal{A}_d)$. On a tensor of length $n > d$, it takes the trace of the last $n - d$ factors. These maps extend continuously to the corresponding orthogonal projections in L^2. If z is central, $E_d(z)$ commutes with $\pi_\tau(\mathcal{A}_d)$, by bimodularity of E_d. It is therefore scalar and equal to $\tau(z)I$. Density of the matrix union implies $E_d(z) \to z$ in L^2, hence $z = \tau(z)I$. The algebra is thus a finite factor. It contains unital matrix algebras of unbounded sizes 9^d, so it is not a finite matrix factor. It is of type II_1. It is hyperfinite because the same union of matrices is weakly dense. Preservation of unit and trace follows from each finite inclusion and persists upon taking closures. □

23.5.5 Integer ranks and continuous tracial dimension

In $\mathcal{A}_d$, a projection P has normalized dimension $\tau_d(P) = \mathrm{rank}(P)/9^d$. Ranks remain integers at every finite depth. Their compatible normalizations allow the following passage to the limit.

Proposition 23.16 (Realization of each tracial dimension)**.** *For each $t \in [0, 1]$, there exists a projection $P_t \in \mathcal{R}_9$ with $\tau(P_t) = t$.*

Proof. Let $m_d = \lfloor 9^d t \rfloor$. Then $0 \le m_{d+1} - 9m_d \le 8$. After choosing a diagonal projection of rank m_d, its inclusion has rank $9m_d$; add $m_{d+1} - 9m_d$ diagonal positions in its complement. This yields an increasing sequence of projections within $\mathcal{R}_9$. Its strong limit is a projection P_t, and normality of the trace gives

$$\tau(P_t) = \lim_{d\to\infty} \frac{\lfloor 9^d t \rfloor}{9^d} = t.$$

□

Here t denotes the dimension coordinate represented in the closure, not an input to the APP generator. The assertion describes the scope of the resulting tracial realization. To compare it with a particular observable, it remains necessary to identify the projection and the genealogical information it preserves.

By contrast, the isometries $V_{d,j}\xi = \xi \otimes \delta_j$ realize $\jmath_{d,j}(a) = V_{d,j} a V_{d,j}^*$. In the limit of a marked route, the finite spaces are dense. The corners approximate all finite-rank operators; their norm closure is $\mathcal{K}(\mathcal{H}_\infty)$, and their bicommutant is $B(\mathcal{H}_\infty)$, of type I_∞. This difference preserves the operational content of the two choices in (23.14): selection of one continuation and unital prolongation of the entire fiber have different limits.

The Hilbert-space realization, its phase operators, and the tracial closure are thus constructed in this section, with their inclusion choices explicit. They constitute the operator-theoretic support to be used subsequently for coordinate interchange and the compact Hamiltonian.

23.6 Two-dimensional refinement of APP and carry cocycle

The realization of APP on a torus of nine positions per coordinate and its expansion to twenty-seven positions are related through Euclidean division. The expansion preserves two independent directions and assigns an additional ternary digit to each coordinate. Thus each position of the initial APP has nine lifts in the expanded support. The two additional digits preserve the position within the fiber, while the direction of transport and the regime of the TRIT reader remain as distinct coordinates of the enriched state.

For $m \geq 1$, we write

$$T_m = (\mathbb{Z}/m\mathbb{Z})^2.$$

In the calculations of this section the representatives $0, \ldots, m-1$ are chosen. The nonadic presentation $1, \ldots, 9$ prints the zero class using the sign 9. This convention allows the APP table to be read and integer divisions to be performed with a single residue rule.

23.6.1 Projection, fibers and ternary refinement coordinates

The projection and the section of representatives are

$$p : T_{27} \longrightarrow T_9, \qquad p(x, y) = (x \bmod 9, y \bmod 9),$$

$$s : T_9 \longrightarrow T_{27}, \qquad s(r, t) = (r, t), \quad 0 \leq r, t < 9.$$

The projection is a surjective homomorphism of additive groups. Its kernel is

$$\ker p = \{(9a, 9b) : a, b \in \mathbb{F}_3\} \simeq \mathbb{F}_3^2.$$

The coordinate map

$$\Psi : T_9 \times \mathbb{F}_3^2 \longrightarrow T_{27}, \qquad \Psi((r, t), (a, b)) = (r + 9a, t + 9b) \tag{23.15}$$

uses representatives $0 \leq a, b < 3$.

Proposition 23.17 (Unique decomposition of the expanded positions)**.** *The map Ψ is bijective. Each fiber of p contains nine positions and the entire support satisfies*

$$|T_{27}| = 27^2 = 9^2 \cdot 3^2 = 729.$$

The two coordinates of $\mathbb{F}_3^2$ are the two positional trits that describe the refinement of the two APP coordinates.

Proof. For $0 \leq x, y < 27$, the Euclidean divisions

$$x = r + 9a, \qquad y = t + 9b, \quad 0 \leq r, t < 9, \quad 0 \leq a, b < 3$$

exist and are unique. These formulas construct the inverse of Ψ. With r, t fixed, the nine pairs (a, b) are distinct and exhaust the fiber. The census results from multiplying the 81 residual positions by their nine lifts. □

For example, the position $(5, 5)$ has the fiber

$$\{(5 + 9a, 5 + 9b) : 0 \leq a, b < 3\}.$$

The row of this fiber with $b = 1$ is $(5, 14), (14, 14), (23, 14)$. Each position preserves the same residual pair $(5, 5)$ and a different pair of quotients. Multiplicity nine expresses two independent ternary choices. The topological and temporal reading of TRIT additionally preserves its own operator domain.

23.6.2 Additive composition and memory of modular crossing

For $r, t \in \{0, \ldots, 8\}$, define

$$r \oplus t = (r + t) \bmod 9, \qquad c_9(r, t) = \left\lfloor \frac{r + t}{9} \right\rfloor.$$

Transported by Ψ, addition in one coordinate of $\mathbb{Z}/27\mathbb{Z}$ is

$$(r,a) \boxplus (t,b) = \big(r \oplus t,\ a+b+c_9(r,t) \pmod 3\big). \tag{23.16}$$

In two coordinates, the same formula is applied separately to each axis.

Proposition 23.18 (Cocycle of the positional extension)**.** *The carry satisfies*

$$c_9(r,t) + c_9(r \oplus t, u) = c_9(t,u) + c_9(r, t \oplus u) = \left\lfloor \frac{r+t+u}{9} \right\rfloor. \tag{23.17}$$

Therefore, (23.16) *is associative and exactly reproduces the additive group of the expanded support.*

Proof. The equality $r + t = (r \oplus t) + 9c_9(r,t)$ gives

$$\left\lfloor \frac{r+t+u}{9} \right\rfloor = c_9(r,t) + \left\lfloor \frac{(r \oplus t)+u}{9} \right\rfloor.$$

The grouping $r + (t+u)$ provides the other side. Substituting $x = r + 9a$ and $y = t + 9b$ into $x + y$ proves (23.16); reducing its second component modulo three corresponds to reducing $x + y$ modulo twenty-seven. The cocycle identity directly proves the associativity of this notation by residues and quotients. □

In particular, $8 + 1 = 0 + 9 \cdot 1$ shows the elementary crossing: the residue returns to the zero class, printed as 9 in the nonadic table, and the first quotient increases by one. If only the residue is preserved, the datum distinguishing 0, 9 and 18 in the expanded support is lost; the lifted state distinguishes these three positions.

The extension

$$0 \longrightarrow \mathbb{Z}/3\mathbb{Z} \xrightarrow{a \mapsto 9a} \mathbb{Z}/27\mathbb{Z} \longrightarrow \mathbb{Z}/9\mathbb{Z} \longrightarrow 0$$

is nonsplit as an extension of groups. Indeed, any lift of the class 1 is $1 + 9a$, of order twenty-seven. A homomorphic section would have to send an element of order nine to one whose order divides nine. The section of representatives instead has the exact defect $9c_9$, which the preceding formula preserves.

23.6.3 Compatibility of the multiplicative sheet

The same decomposition preserves the second APP operation. For one coordinate, we define

$$r \odot t = rt \bmod 9, \qquad m_9(r,t) = \left\lfloor \frac{rt}{9} \right\rfloor.$$

The lifted product is

$$(r,a) \boxtimes (t,b) = \big(r \odot t,\ m_9(r,t) + rb + ta \pmod 3\big). \tag{23.18}$$

Proof. The integer expansion provides

$$(r + 9a)(t + 9b) = rt + 9(rb + ta) + 81ab.$$

The last term vanishes modulo twenty-seven. Substituting $rt = (r \odot t) + 9m_9(r,t)$ gives the formula. Uniqueness of Euclidean division proves that its two components recover the residual product and its refinement quotient. □

For example, $8 \cdot 8 = 64 \equiv 10 \pmod{27}$ is represented by $(1,1)$: the residue is 1 and $m_9(8,8) = 7 \equiv 1 \pmod 3$. Thus sum and product preserve their respective carries within the same expanded support.

23.6.4 Directions and realization of transport

Let $\mathcal{D} = \{N, S, E, O\}$ be the direction register and $\delta_d \in \mathbb{Z}^2$ the unit displacement associated with d. On the support with direction we define

$$S_m(z, d) = (z + \delta_d \pmod m, d).$$

The projection explicitly preserves the direction, $p_{\mathcal{D}}(z, d) = (p(z), d)$, and satisfies

$$p_{\mathcal{D}} S_{27} = S_9 p_{\mathcal{D}}. \tag{23.19}$$

The quotient calculation uses, for an integer displacement v,

$$c_9(r; v) = \left\lfloor \frac{r + v}{9} \right\rfloor, \qquad r' = r + v - 9c_9(r; v), \qquad a' = a + c_9(r; v) \pmod 3.$$

The formula includes negative displacements. For example, $r = 0, v = -1$ gives $r' = 8, c_9 = -1$; the reverse return restores the quotient.

Proposition 23.19 (Conjugation of displacement in fiber coordinates)**.** *The coordinate change Ψ transforms S_{27} into the residual displacement S_9 accompanied by the update of the two quotients just defined. This transformation is bijective and preserves direction. Its powers preserve the same identity for any finite length of transport.*

Proof. On each axis, $x = r + 9a$ is substituted into $x + v$ and Euclidean division is performed. Direction remains fixed in the definition of S_m. The inverse uses $-v$ and the cocycle, thereby recovering the initial state. Composing the identity once per transition proves the statement for all powers. □

The Hilbert realization preserves this decomposition. On the position bases, the operator

$$\mathcal{U}\delta_{\Psi(z,a),d} = \delta_{z,d} \otimes \delta_a$$

defines a surjective isometry

$$\ell^2(T_{27} \times \mathcal{D}) \simeq \ell^2(T_9 \times \mathcal{D}) \otimes \ell^2(\mathbb{F}_3^2).$$

The conjugated shift is the permutation operator with carry described in the proposition. An additional internal factor E remains intact when tensoring with I_E. If a phase reader depends only on the projection and a directional operator acts with the same matrix at all positions, their compatibility squares also commute. A reader using the quotient is realized precisely in the preserved fiber factor. These conditions make explicit the relation between the expanded support and the factors of the operator on the torus, with the internal actions declared in its construction.

23.6.5 Six ternary digits and distinct algebraic structures

Each coordinate of T_{27} has three base-three digits. Their joint notation defines a bijection of sets

$$T_{27} \longleftrightarrow \mathbb{F}_3^6.$$

This bijection publishes six positional digits. Addition on the torus contains carries between digits and vector addition in $\mathbb{F}_3^6$ is performed componentwise. For example, the positional sum $2 + 1 = 3$ transforms $(2, 0, 0)$ into $(0, 1, 0)$, whereas ternary vector addition would give $(0, 0, 0)$. The torus contains elements of order twenty-seven; the ternary vector space has exponent three. The two objects share a finite encoding, with different typed operations. The fiber of ternary words, the position support and the lines of a cubic surface thus preserve their specific constructions and maps.

23.7 Genealogical path kernels: finite composition, unitary realization and cylindrical limit

The matrix composition proved in this section establishes exactly that each entry of U^R is the sum of the ordered weights of routes of length R. The next step preserves the information that a visible route does not publish and organizes finite refinements into a compact space of genealogies. This distinguishes three results: the finite combinatorial identity, the cylindrical integral over the path limit and the realization of that integral as the propagator of a specific physical system.

23.7.1 Route category and functorial weight

Let $\mathsf{P}_{\mathrm{TPK}}$ be the free category generated by the admissible TPK transitions. Its objects are enriched boundary states and its morphisms are composable sequences of transitions. Composition is concatenation, and the empty path is the identity. Let P_X be the category of visible routes obtained by applying the reader to the objects and transitions; its compositions are visible concatenations. The map

$$q_{\mathrm{vis}} : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathsf{P}_X$$

publishes the observable route and preserves in its fiber the differences of sheet, orientation, carry, block, boundary, and memory.

Definition 23.20 (Genealogical weight)**.** Let $\mathcal{B}$ be a normed real algebra, possibly noncommutative, and let $\mathbf{B}_{\mathcal{B}}$ be the category with a single object $*$ whose endomorphism monoid is $\mathrm{End}(*) = (\mathcal{B}, \cdot, 1)$. A genealogical weight is a functor

$$W : \mathsf{P}_{\mathrm{TPK}} \longrightarrow \mathbf{B}_{\mathcal{B}}$$

such that

$$W(\mathrm{id}_x) = 1, \qquad W(\gamma_2 \circ \gamma_1) = W(\gamma_2)W(\gamma_1).$$

The product order agrees with the causal order of the route.

For enriched states $\widetilde{i}, \widetilde{f}$, the kernel at depth R is

$$\mathcal{K}_R(\widetilde{f}, \widetilde{i}) = \sum_{\substack{\gamma \in \mathsf{P}_{\mathrm{TPK}}(\widetilde{i}, \widetilde{f}) \\ |\gamma| = R}} W(\gamma). \tag{23.20}$$

Two routes with the same visible word remain distinct summands when they belong to different genealogical fibers.

Proposition 23.21 (Composition through an enriched cut)**.** *If every route of length $R + S$ has a unique cut after R transitions, then*

$$\mathcal{K}_{R+S}(\widetilde{f}, \widetilde{i}) = \sum_{\widetilde{x}} \mathcal{K}_S(\widetilde{f}, \widetilde{x})\mathcal{K}_R(\widetilde{x}, \widetilde{i}).$$

The formula preserves the causal order of the factors when $\mathcal{B}$ is noncommutative.

Proof. The set of complete routes is partitioned by the enriched state $\widetilde{x}$ reached at the cut. The functorial factorization of the weight turns the sum over each class into the product of the partial kernels. Uniqueness of the cut ensures that each route appears exactly once. □

23.7.2 Construction of the internal phase through the real action character on genealogical routes

Let (E, J_E) be a real Euclidean space equipped with an orthogonal endomorphism J_E such that $J_E^2 = -I$. If $\mathcal{A}_* : \mathsf{P}_{\mathrm{TPK}} \to \mathbb{R}$ is additive under concatenation, the phase

$$\Phi_J(\gamma) := \exp[-J_E \mathcal{A}_*(\gamma)] = \cos \mathcal{A}_*(\gamma)\, I - \sin \mathcal{A}_*(\gamma)\, J_E \tag{23.21}$$

is multiplicative. Fix a nonzero positive section $\hbar_{\mathrm{int}}$ of the action line $\mathcal{L}_S$ constructed earlier; the section $\hbar_{\mathrm{ret}}$ of the declared profile may be used. For a dimensional action $S_{\mathrm{int}}(\gamma) = \hbar_{\mathrm{int}} \mathcal{A}_*(\gamma)$, this expression internally realizes the phase $\exp[-J_E\, S_{\mathrm{int}}(\gamma)/\hbar_{\mathrm{int}}]$. The scalar symbol i appears only when choosing a complex chart for the pair (E, J_E).

Proposition 23.22 (Phase functor)**.** *The map Φ_J satisfies*

$$\Phi_J(\mathrm{id}_x) = I, \qquad \Phi_J(\gamma_2 \circ \gamma_1) = \Phi_J(\gamma_2)\Phi_J(\gamma_1).$$

Proof. The action of the empty path is zero. For composable routes, additivity of $\mathcal{A}_*$ and commutativity of multiples of the same endomorphism J_E allow the exponential of the summed value to be separated. □

23.7.3 Unitary realization on the chronological register 27×27

Before passing to the cylindrical limit, a finite kernel admits an explicit unitary realization. Let

$$\mathbb{T}^2_{27} := (\mathbb{Z}/27\mathbb{Z})^2, \qquad \mathcal{D} := \{\mathrm{N}, \mathrm{S}, \mathrm{E}, \mathrm{W}\},$$

and consider the real space

$$\mathcal{H}^{\mathbb{R},\mathrm{reg}}_{27} := \ell^2(\mathbb{T}^2_{27}; \mathbb{R}) \otimes \mathbb{R}^{\mathcal{D}} \otimes E.$$

The endomorphism J_E is extended as the identity on the position and direction factors, and the same notation is retained for that extension.

In the ordered basis $(\mathrm{N}, \mathrm{S}, \mathrm{E}, \mathrm{W})$, the directional mixer is

$$C_4 := \frac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}, \qquad C_4^{\mathsf{T}} C_4 = I_4. \tag{23.22}$$

Here C_4 denotes exclusively the Walsh–Hadamard mixer on the directional fiber; when it acts on $\mathcal{H}^{\mathbb{R},\mathrm{reg}}_{27}$ it is understood as $C_4 \otimes I_E$.

Fix a translational chart in which the action of an elementary edge γ_d depends only on its direction:

$$s_d := S_{\mathrm{int}}(\gamma_d) \in \mathcal{L}_S, \qquad a_d := \frac{s_d}{\hbar_{\mathrm{int}}} \in \mathbb{R}.$$

The real diagonal phase operator is

$$D_J := \mathrm{diag}\left(e^{-J_E a_{\mathrm{N}}}, e^{-J_E a_{\mathrm{S}}}, e^{-J_E a_{\mathrm{E}}}, e^{-J_E a_{\mathrm{W}}}\right).$$

The conditional shift transports each component in its direction:

$$\begin{aligned} (S\psi)(x, y, \mathrm{N}) &= \psi(x, y-1, \mathrm{N}), & (S\psi)(x, y, \mathrm{S}) &= \psi(x, y+1, \mathrm{S}), \\ (S\psi)(x, y, \mathrm{E}) &= \psi(x-1, y, \mathrm{E}), & (S\psi)(x, y, \mathrm{W}) &= \psi(x+1, y, \mathrm{W}), \end{aligned}$$

with all coordinates taken modulo 27. The elementary step and its composition of twelve steps are

$$U_{\mathrm{micro}} := SD_J C_4, \qquad U_{12}^{\mathrm{reg}} := U_{\mathrm{micro}}^{12}. \tag{23.23}$$

The superscript reg preserves the type: this operator acts on the directional torus 27×27 and is not identified with the other dodecaphasic objects of the construction or with the temporal endomorphism of order 108.

Proposition 23.23 (Unitarity and exact path sum in the register)**.** *The operator U_{micro} is orthogonal on the realification and unitary in the complex chart determined by J_E. In particular, U_{12}^{reg} is unitary. If $\Xi := \mathbb{T}_{27}^2 \times \mathcal{D}$, then, for every $n \geq 0$ and $\xi_i, \xi_f \in \Xi$,*

$$\left(U_{\mathrm{micro}}^n\right)_{\xi_f, \xi_i} = \sum_{\substack{\gamma : \xi_i \to \xi_f \\ |\gamma| = n}} W_{U_{\mathrm{micro}}}(\gamma),$$

where, for $\gamma = (\xi_0, \ldots, \xi_n)$,

$$W_{U_{\mathrm{micro}}}(\gamma) := (U_{\mathrm{micro}})_{\xi_n, \xi_{n-1}} \cdots (U_{\mathrm{micro}})_{\xi_1, \xi_0}.$$

The sum ranges over exactly the paths permitted by the nonzero blocks of the operator.

Proof. Since J_E is orthogonal and $J_E^2 = -I$, we have $J_E^{\mathsf{T}} = -J_E$. Thus, each block $e^{-J_E a_d}$ is an orthogonal rotation and D_J is orthogonal. The operator S permutes an orthonormal basis, and (23.22) proves that C_4 is orthogonal. Consequently,

$$U_{\mathrm{micro}}^{\mathsf{T}} U_{\mathrm{micro}} = C_4^{\mathsf{T}} D_J^{\mathsf{T}} S^{\mathsf{T}} S D_J C_4 = I.$$

All three factors commute with the extension of J_E; hence U_{micro} is complex-linear in the chart $J_E \leftrightarrow \mathrm{i}$, and its real orthogonality is equivalent to unitarity. Every power, in particular U_{12}^{reg}, preserves this property.

For $n \geq 1$, block multiplication gives

$$\left(U_{\mathrm{micro}}^n\right)_{\xi_f, \xi_i} = \sum_{\xi_1, \ldots, \xi_{n-1}} (U_{\mathrm{micro}})_{\xi_f, \xi_{n-1}} \cdots (U_{\mathrm{micro}})_{\xi_1, \xi_i}.$$

Each choice of intermediate states determines a path of length n, and each path determines a unique ordered product. For $n = 0$, the sole term is the empty path and its weight is the identity. □

Translation invariance decomposes the problem into blocks of four directional components, tensored with E. For

$$k_x = \frac{2\pi a}{27}, \qquad k_y = \frac{2\pi b}{27}, \qquad 0 \leq a, b < 27,$$

we adopt the realified Fourier convention

$$\chi_{a,b}(x, y) := \exp[-J_E(k_x x + k_y y)].$$

Direct substitution into the conditional shift produces

$$S(k_x, k_y) = \mathrm{diag}\left(e^{J_E k_y}, e^{-J_E k_y}, e^{J_E k_x}, e^{-J_E k_x}\right),$$

and, since D_J and C_4 do not depend on position,

$$\begin{aligned} U_{\mathrm{micro}}(k_x, k_y) &= S(k_x, k_y) D_J C_4, \\ U_{12}^{\mathrm{reg}}(k_x, k_y) &= U_{\mathrm{micro}}(k_x, k_y)^{12}. \end{aligned} \tag{23.24}$$

Consequently,

$$\operatorname{Spec} U_{12}^{\mathrm{reg}} = \bigcup_{a,b=0}^{26} \operatorname{Spec} U_{12}^{\mathrm{reg}} \left(\frac{2\pi a}{27}, \frac{2\pi b}{27} \right).$$

The matrix power enumerates paths, and the Fourier decomposition publishes the quasienergies of the same finite dynamics.

Fix an elementary duration $\delta t > 0$, and let $\Delta t_{12} := 12\,\delta t$. In each unitary block, choose a spectral branch $\mathfrak{b}$ of the logarithm. The operator $\operatorname{Log}_{\mathfrak{b}} U_{12}^{\mathrm{reg}}(k_x, k_y)$ is skew-adjoint and commutes with J_E. Define

$$\begin{aligned} H_{\mathrm{eff}}(k_x, k_y) &:= \frac{\hbar_{\mathrm{int}}}{\Delta t_{12}} J_E \operatorname{Log}_{\mathfrak{b}} U_{12}^{\mathrm{reg}}(k_x, k_y), \\ U_{12}^{\mathrm{reg}}(k_x, k_y) &= \exp\left[-\frac{J_E \Delta t_{12}}{\hbar_{\mathrm{int}}} H_{\mathrm{eff}}(k_x, k_y) \right]. \end{aligned} \tag{23.25}$$

The first line is self-adjoint in the complex chart. The second follows from $-J_E^2 = I$ and proves that the exponential recovers the propagator exactly. The branch $\mathfrak{b}$ fixes the quasienergy zone.

This realization constructs a finite propagator, its exact path sum and its effective generator. Identifying it with a continuous physical Hamiltonian still requires verification of the representation, action and limit hypotheses stated below.

23.7.4 Cylindrical limit on the space of genealogies

With endpoints fixed, let $\mathcal{P}_n$ be finite sets of paths at resolution n, with surjective restriction maps. The space

$$\Omega_{fi}^{\mathrm{path}} := \varprojlim_n \mathcal{P}_n$$

is compact and totally disconnected. A compatible family of probability measures μ_n on the cylinders determines a Borel measure μ on $\Omega_{fi}^{\mathrm{path}}$.

Let Π_n be the partition into level-n cylinders. For $C \in \Pi_n$, choose a representative γ_C, an approximate action $S_n(C)$ and the weight $\mu_n(C)$. For $F : \Omega_{fi}^{\mathrm{path}} \to \operatorname{End}(E)$, define

$$\mathcal{I}_n(F) := \sum_{C \in \Pi_n} \mu_n(C) F(\gamma_C) \exp\left[-J_E \frac{S_n(C)}{\hbar_{\mathrm{int}}} \right]. \tag{23.26}$$

Theorem 23.24 (Genealogical path integral)**.** *Suppose that:*

1. *the cylinder measures μ_n are projectively compatible;*
2. *F is continuous and bounded;*
3. *there exists a continuous action $S : \Omega_{fi}^{\mathrm{path}} \to \mathcal{L}_S$ for which*

$$\max_{C \in \Pi_n} \sup_{\gamma \in C} \left\| \frac{S_n(C) - S(\gamma)}{\hbar_{\mathrm{int}}} \right\| \longrightarrow 0;$$

4. *the mesh of Π_n tends to zero.*

Then $\mathcal{I}_n(F)$ converges in operator norm, the limit is independent of the representatives, and it defines the Bochner integral

$$\int_{\Omega_{fi}^{\mathrm{path}}} F(\gamma) \exp\left[-J_E \frac{S(\gamma)}{\hbar_{\mathrm{int}}} \right] \mathrm{d}\mu(\gamma). \tag{23.27}$$

Proof. Compatibility of the finite measures constructs μ on the cylinder algebra and, by extension, on the Borel sigma-algebra. The function

$$G(\gamma) = F(\gamma)\exp[-J_E\, S(\gamma)/\hbar_{\mathrm{int}}]$$

is continuous on a compact space and is therefore uniformly continuous and bounded. Orthogonality of J_E gives the estimate

$$\|e^{-J_E a} - e^{-J_E b}\| \le |a-b|.$$

Uniform approximation of the action and contraction of the mesh make the cylindrical sums converge to the Bochner integral of G [174]. □

The theorem constructs a rigorous integral on the compact space of genealogies. Its realization as a Feynman oscillatory integral for a specific Hamiltonian is obtained when the finite kernels, action and cylinder measure satisfy these convergence hypotheses. The finite matrix expansion, genealogical integral and physical propagator are thus related by explicit morphisms, without being identified by abbreviation.

23.7.5 Reading of the value and memory of the fiber

Let $\mathrm{Val}_{\mathrm{path}} : \Omega_{fi}^{\mathrm{path}} \to \mathcal{Y}_{\mathrm{val}} \subset \mathbb{R}$ be a Borel-measurable path reader, where $\mathcal{Y}_{\mathrm{val}}$ carries its standard Borel structure, and let $\nu = (\mathrm{Val}_{\mathrm{path}})_*\mu$. For every function factoring through the value, $F = \widehat{F} \circ \mathrm{Val}_{\mathrm{path}}$, we have

$$\int_{\Omega_{fi}^{\mathrm{path}}} F\,\mathrm{d}\mu = \int_{\mathcal{Y}_{\mathrm{val}}} \widehat{F}(x)\,\mathrm{d}\nu(x).$$

Since $\Omega_{fi}^{\mathrm{path}}$ is compact metrizable and μ is a Borel probability measure, there exists a family of regular conditional probabilities $(\mu_x)_{x\in\mathcal{Y}_{\mathrm{val}}}$, defined for ν-almost every x. For a general genealogical integrand, the disintegration of μ takes the form

$$\int_{\Omega_{fi}^{\mathrm{path}}} G(\gamma)\,\mathrm{d}\mu(\gamma) = \int_{\mathcal{Y}_{\mathrm{val}}} \left[\int_{\mathrm{Val}_{\mathrm{path}}^{-1}(x)} G(\gamma)\,\mathrm{d}\mu_x(\gamma)\right] \mathrm{d}\nu(x). \tag{23.28}$$

The inner integral preserves the distinct histories that publish the same coordinate. This is the precise link between the sum over all paths, real evaluation, and the thesis that the continuum is a projection of a richer genealogical domain.

Domain of the genealogical path integral: cylindrical compactness, projective consistency, kernel convergence and disintegration over fibers The finite expansion, unitary realization on $\mathbb{T}_{27}^2$ and its Fourier reduction are exact on their finite domains. The construction of H_{eff} is exact once the complex structure, elementary translational action, duration and spectral branch have been declared; it does not by itself select a continuous physical Hamiltonian. The enriched route category and internal phase precede the cylindrical assembly. theorem 23.24 is exact under the four declared premises. Realizing a specific continuous quantum model requires verifying those premises for its action and Hamiltonian.

23.8 Hilbert-space realization of the nonadic phase and preservation of the unit

The construction of Triadic Modular Holography first provides the states, their transitions, and the restriction maps. The Hilbert-space realization adds a linear structure and an inner product to their discrete coordinates. This order determines what each operator represents: the basis labels arise from the nonadic construction; linear operations subsequently act on those labels. Genealogical memory remains in the TPK state and accompanies the projections used to represent it.

23.8.1 Phase fiber, labeled basis, and inner product

For an integer depth $d \geq 1$, let

$$C_{9,d} = (\mathbb{Z}/9\mathbb{Z})^d, \qquad \mathcal{H}_d = \ell^2(C_{9,d}), \qquad \mathcal{A}_d = B(\mathcal{H}_d). \tag{23.29}$$

The inner product is $\langle f, g\rangle = \sum_x \overline{f(x)}g(x)$. The functions δ_x form an orthonormal basis labeled by the phase coordinates. Thus $\dim \mathcal{H}_d = 9^d$ and $\mathcal{A}_d \cong M_{9^d}(\mathbb{C})$. The matrix algebra represents this finite fiber; routes, quotients, and memory omitted by a phase projection still belong to the starting state.

Coordinate factorization induces the unitary map

$$\mathcal{H}_{d+1} \longrightarrow \mathcal{H}_d \otimes \mathbb{C}^9, \qquad \delta_{(x,r)} \longmapsto \delta_x \otimes \delta_r. \tag{23.30}$$

Define the normalized trace $\tau_d(a) = 9^{-d}\,\mathrm{Tr}(a)$. Finite counting and normalization are distinguished: $\mathrm{Tr}(I) = 9^d$, whereas $\tau_d(I) = 1$. Likewise, the group $(\mathbb{Z}/9\mathbb{Z})^3$ and the vector space $\mathbb{F}_3^6$ both have 729 elements, but retain different algebraic laws. Realization of a phase fiber does not replace the ternary encoding of APP emissions.

23.8.2 Translation and phase: finite Weyl representation

In the complex realization subsequent to the constructions of π and the structure $\mathrm{i}^2 = -1$, fix $\omega = \exp(2\pi\mathrm{i}/9)$. On $\mathcal{H}_1$, let

$$(Xf)(r) = f(r-1), \qquad (Zf)(r) = \omega^r f(r). \tag{23.31}$$

The first operation shifts the phase coordinate; the second evaluates it through a character. Both are unitary and satisfy

$$X^9 = Z^9 = I, \qquad ZX = \omega XZ. \tag{23.32}$$

Indeed, $(ZXf)(r) = \omega^r f(r-1)$, whereas $(XZf)(r) = \omega^{r-1} f(r-1)$. The character appears here as a realization of the phase already constructed and does not select the TPK numerical registers.

23.8.2.1 Oriented area and central extension of translations

The translation support is $X_9 = (\mathbb{Z}/9\mathbb{Z})^2$. The mixed APP curvature constructed in Section 4.3.4 assigns $+1$ to the oriented plaquette of the sum–product pair and -1 to the pair in the opposite order. Its bilinear extension to two displacements $u = (a, b)$ and $v = (c, d)$ is the alternating form

$$\sigma_{\mathrm{ar}}(u, v) = ad - bc \quad \text{in } \mathbb{Z}/9\mathbb{Z}. \tag{23.33}$$

Indeed, alternation makes the evaluation on two displacements along the same axis vanish. The values on the oriented basis are $\sigma_{\mathrm{ar}}((1,0),(0,1)) = 1$ and $\sigma_{\mathrm{ar}}((0,1),(1,0)) = -1$; distributing both arguments gives (23.33). The same formula is the sum of plaquettes of any oriented cellular chain realizing that parallelogram: the interior edges cancel. Changing an integer representative by a multiple of nine preserves its publication in $\mathbb{Z}/9\mathbb{Z}$.

The order $X^a Z^b$ of the already defined operators fixes a section of the central extension. Denote its composition factor by

$$c_{\mathrm{W}}(u, v) = bc \quad \text{in } \mathbb{Z}/9\mathbb{Z}. \tag{23.34}$$

This cocycle preserves the order of the two operations, while σ_{ar} preserves the orientation of the parallelogram.

Proposition 23.25 (Central extension and commutator sign)**.** *The set $\mathfrak{H}_9 = (\mathbb{Z}/9\mathbb{Z})^3$, with product*

$$(a, b, t)(c, d, s) = (a + c, b + d, t + s + bc), \tag{23.35}$$

is a group of order 729*. The map*

$$\varrho(a,b,t) = \omega^t X^a Z^b$$

is a faithful unitary representation on $\mathcal{H}_1$. With the convention $[g,h] = ghg^{-1}h^{-1}$, one has

$$[\varrho(a,b,0), \varrho(c,d,0)] = \omega^{bc-ad} I = \omega^{-\sigma_{\mathrm{ar}}((a,b),(c,d))} I. \tag{23.36}$$

The center and the translation group form the exact sequence

$$0 \longrightarrow \mathbb{Z}/9\mathbb{Z} \xrightarrow{t\mapsto(0,0,t)} \mathfrak{H}_9 \xrightarrow{(a,b,t)\mapsto(a,b)} X_9 \longrightarrow 0.$$

Proof. For $w = (e,f)$, the cocycle identity reads

$$c_{\mathrm{W}}(u,v) + c_{\mathrm{W}}(u+v,w) = bc + (b+d)e = de + b(c+e) = c_{\mathrm{W}}(v,w) + c_{\mathrm{W}}(u,v+w).$$

It proves associativity of (23.35); the identity is $(0,0,0)$, and the inverse of (a,b,t) is $(-a,-b,-t+ab)$. The three residues are free, giving order $9^3 = 729$. From $ZX = \omega XZ$ it follows that

$$(X^a Z^b)(X^c Z^d) = \omega^{bc} X^{a+c} Z^{b+d},$$

which proves the representation property. If $\omega^t X^a Z^b = I$, its action on δ_r first forces $a = 0$. Evaluation at $r = 0$ gives $t = 0$, and evaluation at $r = 1$ gives $b = 0$, since ω has order nine. The representation is therefore faithful. Comparing the products in both orders gives the factor $bc - ad$. A central element must satisfy $bc - ad = 0$ for every (c,d). Taking successively $(c,d) = (1,0), (0,1)$ yields $b = a = 0$. This identifies the center and proves exactness. □

The Wilson phase for the orientation (23.33) is $\omega^{\sigma_{\mathrm{ar}}(u,v)}$; the commutator of the ordered section $X^a Z^b$ publishes its inverse. In particular, $c_{\mathrm{W}}(u,v) - c_{\mathrm{W}}(v,u) = -\sigma_{\mathrm{ar}}(u,v)$. This identity relates two specified conventions, without identifying the polarized cocycle with the alternating form. The extension belongs to the translation group of the APP support. Its representation acts on the phase fibre; the path register and carries retain their residence in the TPK state that produced that fibre. The order 729 of the group and the cardinality 729 of the ternary ambient space retain the distinct types established in (23.29). The centre $\mathbb{Z}/9\mathbb{Z}$ of this extension records the phase of the commutator. The memory C_{12} of the sequence $0 \to C_{12} \to C_{108} \to C_9 \to 0$, constructed in proposition 11.31, belongs to the dodecaphase calendar. Each extension retains its own composition law and projection.

Proposition 23.26 (Algebra generated by phase and translation)**.** *The* 81 *operators $X^a Z^b$, with $0 \le a, b < 9$, form a basis of $\mathcal{A}_1 = M_9(\mathbb{C})$. In particular, the representation* (23.31) *is irreducible.*

Proof. If $a \neq 0 \pmod 9$, the matrix $X^a Z^b$ has no diagonal entries. If $a = 0$, its trace is $\sum_{r=0}^{8} \omega^{br}$, equal to 9 for $b = 0$ and 0 otherwise. By (23.32), the product $(X^a Z^b)^* X^{a'} Z^{b'}$ is a factor of modulus one times $X^{a'-a} Z^{b'-b}$. Therefore,

$$\tau_1\big((X^a Z^b)^* X^{a'} Z^{b'}\big) = \delta_{a,a'}\delta_{b,b'}.$$

These are 81 linearly independent matrices in a space of dimension 81. They generate the whole matrix algebra, whose commutant consists of scalars; irreducibility follows. □

Theorem 23.27 (Uniqueness with fixed primitive central character)**.** *Every irreducible unitary representation of the group presented by $X^9 = Z^9 = c^9 = I$, c central, and $ZX = cXZ$, in which c acts as ωI, is unitarily equivalent to* (23.31).

Proof. Let $v \neq 0$ be an eigenvector of Z, with eigenvalue λ. Since $Z^9 = I$, λ is a power of ω. The vectors $X^k v$, $0 \le k < 9$, have eigenvalues $\omega^k \lambda$, distinct because the character is primitive. They are orthogonal, and their span is invariant under X, Z, and the center. Irreducibility forces it to be the entire space.

Reordering the basis to begin with eigenvalue 1, Z is diagonal with entries $1, \omega, \dots, \omega^8$, and X is cyclic translation. Normalizing the basis produces the asserted unitary equivalence. □

Primitivity of the character and irreducibility are part of the statement. At depth d, operators acting on different factors commute, and tensor products of the preceding bases generate $\mathcal{A}_d$. The phase structure is thus represented at each level without identifying phase return with return of the complete genealogical state.

23.8.3 Two lifts and two different normalizations

Factorization (23.30) permits preserving the entire new fiber or fixing one of its labels. For $p_j = |\delta_j\rangle\langle\delta_j|$, define

$$\iota_d(a) = a \otimes I_9, \qquad \jmath_{d,j}(a) = a \otimes p_j. \tag{23.37}$$

Proposition 23.28 (Preservation of unit and trace)**.** *The inclusion ι_d is unital and preserves normalized trace. The inclusion $\jmath_{d,j}$ is a corner embedding and satisfies*

$$\tau_{d+1}(\iota_d(a)) = \tau_d(a), \quad \iota_d(I) = I, \qquad \tau_{d+1}(\jmath_{d,j}(a)) = \frac{\tau_d(a)}{9}, \quad \jmath_{d,j}(I) = I \otimes p_j.$$

Proof. The trace of a tensor product is the product of the traces. Since $\mathrm{Tr}(I_9) = 9$ and $\mathrm{Tr}(p_j) = 1$, dividing by 9^{d+1} produces both formulas. The images of the identity are read directly from (23.37). □

The unital inclusion preserves the set of 9 phases and its global normalization. The corner preserves a marked continuation and its support projector. Both operations are legitimate, but transmit different data to the next depth.

23.8.4 Inductive closure and tracial realization

Theorem 23.29 (Nonadic uniformly hyperfinite algebra)**.** *The norm closure of the union through the inclusions ι_d is*

$$\mathcal{A}_{9^\infty} = \varinjlim(\mathcal{A}_d, \iota_d) \cong \bigotimes_{n=1}^{\infty} M_9(\mathbb{C}).$$

It is a UHF algebra of type $9^\infty = 3^\infty$, with a unique normalized trace τ, whose restriction to $\mathcal{A}_d$ is τ_d.

Proof. The inclusions are injective and unital. The closure of the increasing union of matrix algebras is precisely the UHF construction. The compatibility in Proposition 23.28 defines τ on the union; positivity and norm one allow its extension to the closure. Every normalized trace on the limit restricts to the unique normalized trace on each matrix algebra. Since the union is dense, those restrictions determine the trace uniquely. □

Let $\mathcal{H}_\tau$ be the completion of $\mathcal{A}_{9^\infty}$ for $\langle a, b\rangle_\tau = \tau(a^*b)$, and let π_τ be its representation by left multiplication. The vector defined by the identity is denoted Ω_τ.

Theorem 23.30 (Tracial factor of complete refinement)**.** *The weak closure $\mathcal{R}_9 = \pi_\tau(\mathcal{A}_{9^\infty})''$ is a hyperfinite factor of type II_1. The nonadic inclusions preserve its unit and normalized trace.*

Proof. The product trace extends to a faithful finite normal trace in the tracial representation. To see that the center is trivial, let E_d be the tracial expectation onto $\pi_\tau(\mathcal{A}_d)$. On a tensor of length $n > d$, it takes the trace of the last $n - d$ factors. These maps extend continuously to the corresponding orthogonal projections in L^2. If z is central, $E_d(z)$ commutes with $\pi_\tau(\mathcal{A}_d)$, by bimodularity of E_d. It is therefore scalar and equal to $\tau(z)I$. Density of the matrix union implies $E_d(z) \to z$ in L^2, hence $z = \tau(z)I$. The algebra is thus a finite factor. It contains unital matrix algebras of unbounded sizes 9^d, so it is not a finite matrix factor. It is of type II_1. It is hyperfinite because the same union of matrices is weakly dense. Preservation of unit and trace follows from each finite inclusion and persists upon taking closures. □

23.8.5 Integer ranks and continuous tracial dimension

In $\mathcal{A}_d$, a projection P has normalized dimension $\tau_d(P) = \operatorname{rank}(P)/9^d$. Ranks remain integers at every finite depth. Their compatible normalizations allow the following passage to the limit.

Proposition 23.31 (Realization of each tracial dimension)**.** *For each $t \in [0,1]$, there exists a projection $P_t \in \mathcal{R}_9$ with $\tau(P_t) = t$.*

Proof. Let $m_d = \lfloor 9^d t \rfloor$. Then $0 \le m_{d+1} - 9m_d \le 8$. After choosing a diagonal projection of rank m_d, its inclusion has rank $9m_d$; add $m_{d+1} - 9m_d$ diagonal positions in its complement. This yields an increasing sequence of projections within $\mathcal{R}_9$. Its strong limit is a projection P_t, and normality of the trace gives

$$\tau(P_t) = \lim_{d\to\infty} \frac{\lfloor 9^d t \rfloor}{9^d} = t.$$

□

Here t denotes the dimension coordinate represented in the closure, not an input to the APP generator. The assertion describes the scope of the resulting tracial realization. To compare it with a particular observable, it remains necessary to identify the projection and the genealogical information it preserves.

By contrast, the isometries $V_{d,j}\xi = \xi \otimes \delta_j$ realize $\jmath_{d,j}(a) = V_{d,j} a V_{d,j}^*$. In the limit of a marked route, the finite spaces are dense. The corners approximate all finite-rank operators; their norm closure is $\mathcal{K}(\mathcal{H}_\infty)$, and their bicommutant is $B(\mathcal{H}_\infty)$, of type I_∞. This difference preserves the operational content of the two choices in (23.37): selection of one continuation and unital prolongation of the entire fiber have different limits.

Proposition 23.26 realizes the matrix algebra through the phase operators. Theorems 23.29 and 23.30 establish the unital inductive closure and its tracial realization, with their explicit choices of inclusion. This is the operator support that will subsequently be used for the exchange of coordinates and the compact Hamiltonian.

23.9 Arithmetic–geometric coupling and bilateral recovery

The dodecaphase register of section 11.4 admits arithmetic, incidence and operator readings. We call *holographic constant of arithmetic-geometric coupling* the generated register K, preserving the order of its twelve windows, the phase origin and orientation. Its rational reading $\kappa = K_{\mathrm{int}}/(1000^{12} - 1)$ is an encoding of that register; it does not replace its types or the enriched history that produces it. Hadamard inversion recovers its signed coordinate; the incidence reading determines the Witt tetrad. The following constructions make two further functions explicit: identifying operators on its cyclic carrier and preserving information between two isometric realizations. These are operations subsequent to the realization of the continuum, not rules introducing conventional constants into APP–TRIT–TPK.

23.9.1 Exact encoding and cyclic reference

Proposition 23.32 (Recovery of the record from its rational reading)**.** *With base $b = 1000$, length twelve, origin, and orientation fixed, the map*

$$(k_1, \dots, k_{12}) \longmapsto \kappa = \frac{\sum_{j=1}^{12} k_j b^{12-j}}{b^{12} - 1}, \qquad 0 \le k_j < b,$$

is injective. From κ, one recovers the integer $n = (b^{12} - 1)\kappa$ and, by successive Euclidean divisions, the twelve blocks, including leading zeros. An absolute error strictly smaller than $1/[2(b^{12} - 1)]$ permits the same recovery by rounding.

Proof. The fixed-length integer expansion in base b is unique. Two distinct integers are separated by at least one; their rational readings are separated by at least $1/(b^{12}-1)$. The strict bound places the approximate datum within the rounding cell of a unique integer. □

Now consider $K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601)$, the cyclic shift S of its positions, and $O_K = (K, SK, \dots, S^{11}K)$ on $\mathbb{R}^{12}$. The shift of positions is identified neither with the entire enriched evolution nor, solely by virtue of its periodicity, with an exceptional symmetry.

Theorem 23.33 (Invertibility of the orbital reference)**.** *The matrix O_K is invertible, and*

$$589609\|c\|^2 \le \|O_K c\|^2 \le 6263^2\|c\|^2.$$

Its centred orbit has rank eleven.

Proof. The Gram matrix $O_K^* O_K$ is circulant. Its first row, obtained from the twelve inner products $\langle K, S^j K\rangle$, is

$$(4251257, 2999323, 3163385, 3287920, 3216553, 3344743,$$
$$2950064, 3344743, 3216553, 3287920, 3163385, 2999323).$$

Evaluation at the twelve characters of the cycle yields the eigenvalues

$$6263^2, \quad 697225, \quad 589609\ (2), \quad 1407529\ (2), \quad 1053157\ (2),$$
$$(1248025 - 345420\sqrt{3})\ (2), \qquad (1248025 + 345420\sqrt{3})\ (2),$$

where parentheses indicate multiplicities. The smallest value is 589609: for the only comparison that is not immediate, $658416 > 345420\sqrt{3}$, as is seen by squaring both sides. The triangle inequality for the Fourier transform and $K_j \ge 0$ give the maximum $(\sum K_j)^2 = 6263^2$. Positivity of every mode proves invertibility and the bounds. Centring the record removes only the uniform mode. □

Corollary 23.34 (Identification of an operator from its responses)**.** *A linear operator $T : \mathbb{R}^{12} \to \mathbb{R}^{12}$ is determined by $Y = (TK, TSK, \dots, TS^{11}K)$, through $T = YO_K^{-1}$. If $TS = ST$, the complete vector response $y = TK$ suffices, since $T = O_y O_K^{-1}$. For a perturbation E of Y, $\|\widehat{T} - T\| \le \|E\|/\sqrt{589609}$.*

Proof. We have $Y = TO_K$. Under commutation, $TS^jK = S^j y$, hence $Y = O_y$. The bound follows from $\|O_K^{-1}\| = 1/\sqrt{589609}$. The norms are the Euclidean norm and its induced operator norm. □

The response y contains twelve components. The statement does not attribute the recovery of an arbitrary operator to a single scalar: it specifies the observation and commutation condition that make identification possible.

23.9.2 Conservation and reconstruction of two channels

Let H, H' be Hilbert spaces, and let $\mathcal{B}, C : H \to H'$ be bounded linear isometries. For $a > 0$, define

$$p = a^2 + a + 1, \qquad N = (2a+1)p = (a+1)^3 + a^3, \qquad Q_- = a\mathcal{B} - C, \quad Q_+ = (a+1)\mathcal{B} + C.$$

Theorem 23.35 (Bilateral balance and recovery)**.** *The following hold*

$$(a+1)Q_-^*Q_- + aQ_+^*Q_+ = NI_H, \qquad W_a v = \frac{1}{\sqrt{N}}\begin{pmatrix}\sqrt{a+1}\,Q_- v\\ \sqrt{a}\,Q_+ v\end{pmatrix}, \qquad W_a^* W_a = I_H.$$

The data $x = Q_- v$, $y = Q_+ v$ determine

$$\mathcal{B}v = \frac{x+y}{2a+1}, \qquad Cv = \frac{ay - (a+1)x}{2a+1}, \qquad v = \mathcal{B}^*\frac{x+y}{2a+1}.$$

Proof. Setting $X = \mathcal{B}^*C + C^*\mathcal{B}$, one obtains

$$Q_-^*Q_- = (a^2+1)I - aX, \qquad Q_+^*Q_+ = ((a+1)^2+1)I + (a+1)X.$$

The weights cancel X, and the remaining coefficient is $2a^3 + 3a^2 + 3a + 1 = N$. Normalization gives the isometry. Adding the two channels recovers $(2a+1)\mathcal{B}v$; the combination $ay - (a+1)x$ recovers $(2a+1)Cv$. Finally, $\mathcal{B}^*\mathcal{B} = I_H$. □

The balance also holds in infinite dimension: only bounded operators are composed. The image of W_a is closed, and its orthogonal projector is $W_aW_a^*$. Thus a normalized pair has an input precisely when it belongs to that image; its orthogonal component measures the compatibility defect.

The factorization

$$W_a = R_aE_a, \qquad E_av = \frac{1}{\sqrt{p}}\begin{pmatrix}\sqrt{a(a+1)}\,\mathcal{B}v\\ Cv\end{pmatrix}, \quad R_a = \frac{1}{\sqrt{2a+1}}\begin{pmatrix}\sqrt{a} & -\sqrt{a+1}\\ \sqrt{a+1} & \sqrt{a}\end{pmatrix}$$

is verified by block multiplication; R_a acts on $H' \oplus H'$, with each scalar entry multiplying $I_{H'}$. In the nonadic partition $a = 8$, the weights are $72/73$ and $1/73$; the factor $73 = 8 \cdot 9 + 1$ follows from the general law $a(a+1)+1$, rather than being an additional primitive datum. The corresponding balance is $9\|Q_-v\|^2 + 8\|Q_+v\|^2 = 17 \cdot 73\,\|v\|^2$.

23.9.3 Transport of observables and incoming memory

Theorem 23.36 (Observables common to both channels)**.** *For a bounded self-adjoint operator F on H',*

$$W_a^*\,\mathrm{diag}(F,F)W_a = \frac{a(a+1)\mathcal{B}^*F\mathcal{B} + C^*FC}{p}.$$

If $\mathcal{B}$ is unitary and $C = \mathcal{B}R$, with R unitary, and $G = \mathcal{B}^*F\mathcal{B}$, the observable is preserved if and only if $GR = RG$.

Proof. Expanding $(a+1)Q_-^*FQ_- + aQ_+^*FQ_+$ cancels the cross terms. The other two coefficients are $a(a+1)(2a+1)$ and $2a+1$. Dividing by N gives the formula. In the stated case, equality with G is equivalent to $R^*GR = G$; unitarity makes this equivalent to $GR = RG$. □

The norm is obtained by taking $F = I$. A general observable requires the commutation condition: preserving the norm does not mean preserving every observable without transformation.

Theorem 23.37 (Unitary extension with memory)**.** *If $H' = H$, $\mathcal{B} = I$, and $C = U$ is unitary, set*

$$A = \frac{\sqrt{a+1}}{\sqrt{N}}Q_-, \qquad D = \frac{\sqrt{a}}{\sqrt{N}}Q_+, \qquad \mathscr{R}_a = \begin{pmatrix}A & -D^*\\ D & A^*\end{pmatrix}.$$

Then $\mathscr{R}_a$ is unitary on $H \oplus H$, its first column is W_a, and it preserves $\|v\|^2 + \|m\|^2$ for every input (v,m). The inverse is

$$v = A^*z_1 + D^*z_2, \qquad m = -Dz_1 + Az_2.$$

Proof. The operators A, D are normal and commute with each other and with their adjoints, since they are polynomials in U, U^*. The balance gives $A^*A + D^*D = I$, and normality gives $AA^* + DD^* = I$. The cross terms in both products $\mathscr{R}_a^*\mathscr{R}_a$ and $\mathscr{R}_a\mathscr{R}_a^*$ vanish; the diagonal blocks are the identity. Applying the adjoint to (z_1, z_2) yields the inverse. □

Recovery of the register, orbital identification and unitary extension specify three distinct levels of information. The first preserves the blocks with their chart; the second identifies operators under the

stated hypotheses; the third transports state and memory jointly. This hierarchy allows the same generated structure to be used without confusing a reduced reading with the state in its entirety.

Chapter 24

T-duality of residual memory: unitary equivalence between momentum and winding for reciprocal radii

24.1 Involution between the residue and quotient coordinates

The Euclidean division used in $\mathcal{A}_9^{\#}$ writes, for an integer in the nonadic chart,

$$n = 9Q + r, \qquad r \in \{1, \dots, 9\}.$$

The coordinate r is the observable representative, and Q records the number of boundary crossings. To formulate an involution interchanging the two coordinates, one must pass to an extension stable under the interchange. Denote by $\bar{r} \in \{0, \dots, 8\}$ the residual class, with $\bar{r} = 0$ when the representative is $r = 9$, and consider

$$\mathscr{D}_{\mathrm{dual}} = \mathbb{Z}^2 \times \mathbb{R}_{>0}.$$

The two integers of $\mathscr{D}_{\mathrm{dual}}$ are not restricted to the canonical section of representatives; this enlargement is necessary because a quotient Q may fall outside the interval $0, \dots, 8$ when occupying the first coordinate.

Definition 24.1 (Radial energy form)**.** For $R_0 > 0$ and $(m, w) \in \mathbb{Z}^2$, define

$$E_{R_0}(m, w) = \frac{m^2}{R_0^2} + w^2 R_0^2.$$

The duality transformation is

$$\mathsf{T}(m, w, R_0) = (w, m, R_0^{-1}).$$

Theorem 24.2 (Residue–Quotient Duality)**.** *The map* T *is an involution of* $\mathscr{D}_{\mathrm{dual}}$ *and preserves the energy form in the sense*

$$E_{R_0}(m, w) = E_{R_0^{-1}}(w, m).$$

Proof. The second map of T exchanges of new m, w e invierte by second time R_0, by lo that

$$\mathsf{T}^2(m, w, R_0) = (m, w, R_0).$$

Moreover,

$$E_{R_0^{-1}}(w, m) = \frac{w^2}{R_0^{-2}} + m^2 R_0^{-2} = w^2 R_0^2 + \frac{m^2}{R_0^2} = E_{R_0}(m, w). \qquad \square$$

The insertion of a nonadic state into the extended domain is

$$(r, Q) \longmapsto (\bar{r}, Q, R_0).$$

The transform $(Q, \bar{r}, R_0^{-1})$ need not belong to the section $0 \le \bar{r} \le 8$. For this reason, T is an exact involution of the enlarged domain, not an endomorphism of the residual atlas of 81 positions. The fixed point of the parameter transformation is $R_0 = 1$; there the exchange of the two coordinates preserves the same quadratic form.

The identity admits an operatorial realization. Let $\mathcal{H}_{\mathrm{lat}} = \ell^2(\mathbb{Z}^2)$, with orthonormal basis $\{|m, w\rangle\}$. Define the diagonal operator

$$H(R_0)|m,w\rangle = E_{R_0}(m,w)|m,w\rangle$$

in its natural domain, and the unitary operator

$$U_T|m,w\rangle = |w,m\rangle.$$

Corollary 24.3 (Unitary Equivalence of Reciprocal Radii)**.** *For every $R_0 > 0$,*

$$U_T H(R_0) U_T^{-1} = H(R_0^{-1}).$$

Proof. On a basis vector,

$$U_T H(R_0) U_T^{-1}|m,w\rangle = E_{R_0}(w,m)|m,w\rangle.$$

The theorem 24.2 gives $E_{R_0}(w,m) = E_{R_0^{-1}}(m,w)$, which is the action of $H(R_0^{-1})$. □

This conjugation has the mathematical form of radius duality in a circular compactification, in units in which the string scale has been normalized to one [57]. The further physical identification assigns m to the momentum number, w to the winding number, and R_0 to the compactification radius. The theorem does not introduce oscillators, fields, supersymmetry, or a string tension; it proves the lattice involution and the unitary equivalence of the declared diagonal operators.

24.2 HMT reading duality: duality T, block 243, ternary Golay code, and mass routes

The T duality of strings is realized as the continuous projection of a prior HMT duality: the exchange between visible value and boundary memory. Every integer admits the reading

$$n = 9Q + r,$$

where r is the visible value of the nonadic wheel and Q preserves boundary-crossing memory. The same structure appears in lifted APP, in the decomposition $1215 = 54 + 9 \cdot 129$, in the stratified dimensional unit $1000 = 729 + 243 + 27 + 1$, and in the reading of mass as a route with visible advance and counterangular winding. This duality links the block 243, the perfect ternary ball $V_3(11,2) = 243$, the punctured ternary Golay code $[11,6,5]_3$, the channels of π, e, φ, α, the hinge 744, the dimension $11 = 6 + 5 = 3 + 8$, and the involution

$$(r,Q;R) \longmapsto (Q,r;R^{-1}).$$

In string-theoretic language, the visible value is published as a vibrational mode or momentum, whereas boundary memory is published as winding. In Dimensional Mechanics these two modes appear as $n_A A_{\mathrm{rad}}$ and $(s_C/6)C^*_{\mathrm{rad}}$: visible advance and counterangular memory.

HMT does not take the continuum as a primary object. It starts from a discrete cell with boundary memory. The real line, Moonshine, and dimensional physics are different readings of that same cell. Consequently, the chain

$$\text{lifted APP} \longrightarrow \text{value and memory} \longrightarrow \text{duality } T \longrightarrow 243/\text{Golay} \longrightarrow \text{mass routes}$$

does not import duality from string theory: it shows that its structure exists in HMT before continuous geometrization.

24.2.1 Operational extension of APP: visible modes and memory modes

For every positive integer n, let be defined

$$r_9(n) = 1 + ((n-1) \bmod 9), \qquad Q_9(n) = \frac{n - r_9(n)}{9}.$$

Then

$$n = 9Q_9(n) + r_9(n).$$

The ordinary reading preserves the residue. The enriched reading preserves the complete pair.

$$n \longmapsto (r, Q).$$

This pair is the minimal structure of a compact reading: one component is published inside the wheel and the other preserves how many times its boundary was traversed.

Principle 24.4 (Duality between visible value and boundary memory)**.** The HMT cell admits two conjugate readings. The first publishes r as phase, value, or vibration; the second publishes Q as memory, winding, or number of boundary crossings.

24.2.2 Completion 1000=729+243+27+1 and stratification of the unit

Let $R > 0$. The functional

$$E_R(r, Q) = \frac{r^2}{R^2} + Q^2 R^2$$

satisfies

$$E_R(r, Q) = E_{1/R}(Q, r),$$

for

$$E_{1/R}(Q, r) = \frac{Q^2}{(1/R)^2} + r^2(1/R)^2 = Q^2R^2 + \frac{r^2}{R^2}.$$

Therefore,

$$(r, Q; R) \longleftrightarrow (Q, r; R^{-1}).$$

The continuous string expression contains terms of the form

$$\frac{n^2}{R^2} + \frac{w^2R^2}{\alpha'^2}.$$

Before that continuous realization, HMT supplies the visible residue, boundary memory, and scale inversion. The duality T is the geometric projection of this reading involution.

24.2.3 Operatorial extension of APP: separation between visible modes and memory modes

For the sum and product over the same support one writes

$$i + j = 9Q_{ij}^{+} + R_{ij}^{+}, \qquad ij = 9Q_{ij}^{\times} + R_{ij}^{\times}.$$

The raised APP is

$$\mathcal{A}_9^{\sharp} = (R^{+}, Q^{+}; R^{\times}, Q^{\times}),$$

where $R^{+}, R^{\times}$ are the visible modes and $Q^{+}, Q^{\times}$ the memory modes. The complete discrepancy is

$$ij - (i + j) = (R_{ij}^{\times} - R_{ij}^{+}) + 9(Q_{ij}^{\times} - Q_{ij}^{+}).$$

When summing over $1 \le i, j \le 9$,

$$\sum R^{+} = 405, \quad \sum R^{\times} = 459, \quad \sum Q^{+} = 45, \quad \sum Q^{\times} = 174.$$

From here, one obtains

$$\Delta_{\text{visible}} = 459 - 405 = 54, \qquad \Delta_{\text{memoria}} = 174 - 45 = 129,$$

and

$$\sum ij - \sum (i + j) = 2025 - 810 = 1215 = 54 + 9 \cdot 129.$$

Normalization by the wheel produces

$$\frac{1215}{9} = 135 = 6 + 129 = 120 + 15.$$

Thus, 54 is the visible defect, 129 the memory defect, 135 the normalized total defect, 120 the constitutive octadic channel, and 15 the internal pair of the hexad.

24.2.4 Decomposition 243=1+22+90+120+10 and typing of its components

The Extreme and Mean Holographic Ratio possesses the cubic completion

$$10^3 = 9^3 + 3 \cdot 9^2 + 3 \cdot 9 + 1,$$

that is,

$$1000 = 729 + 243 + 27 + 1.$$

The four summands represent, respectively, the discrete volume of dimension 3, the boundary of codimension 1, the boundary of codimension 2, and the return of codimension 3. The active corona is refined as

$$270 = 243 + 27 = 3 \cdot 9^2 + 3 \cdot 9.$$

The unit is thus decomposed into interior, stratified active boundary, and return. The passage $9 \to 10$ opens a complete dimensional layer, and the boundary of one level becomes a propagation channel of the next level.

24.2.5 Derivation of the constant channels from the decomposition of block 243

The same block is obtained as a ternary Hamming ball of radius 2 and length 11:

$$V_3(11, 2) = \sum_{k=0}^{2} \binom{11}{k} 2^k = 1 + 22 + 220 = 243.$$

The punctured perfect ternary Golay code has parameters

$$G_{11} = [11, 6, 5]_3, \qquad |G_{11}| = 3^6 = 729,$$

and satisfies

$$729 \cdot 243 = 3^{11}.$$

Therefore, G_{11} tiles $\mathbb{F}_3^{11}$ by ternary balls of radius 2. The number 243 is simultaneously

$$3 \cdot 9^2, \qquad V_3(11, 2), \qquad 3^5, \qquad 1 + 22 + 220.$$

This identity joins dimensional boundary, perfect correction, dimension 11, Witt–Golay incidence and the structural reading of M-theory.

24.2.6 Construction of dimension 11 via compatible residual readers

The ball admits the decomposition

$$243 = 1 + 22 + 90 + 120 + 10.$$

Here 1 is the center and return; $22 = 2 \cdot 11$, the first Hamming shell and the electronic reading of the block; $90 = 6\binom{6}{2}$, the hexadic channel; $120 = 8\binom{6}{2}$, the octadic channel; and $10 = 9 + 1$, closure of the monodromy $9 \to 1$. Thus, the return, component 22, channels 90/120, and monodromy are contained in the same perfect ball.

24.2.7 Constant channels derived from the block 243

With $B = 243$, one obtains the channels

$$C_\alpha = 3B = 729, \qquad C_e = B + 27 + 1 = 271,$$

$$C_\pi = B + 72 = 315, \qquad C_\varphi = B - 81 - 1 = 161.$$

The channel of α is the triple block 243; that of e is the block 243 with the boundary 27 and the return; that of π is the block with the channel 72; and that of φ is the block after removing the subsquare 81 and the return. The hinge is reconstructed as

$$C_\pi + C_e + C_\varphi - 3 = 315 + 271 + 161 - 3 = 744 = 729 + 15.$$

The reduced trace of the three characters therefore combines the triple block 243 with the internal pair of the hexad.

24.2.8 Closure of the genealogical register under the T-duality involution

The punctured perfect ternary code produces

$$11 = 6 + 5,$$

where 6 is the dimension of G_{11} and 5 is the correction depth $3^5 = 243$. The same dimension decomposes as

$$11 = 3 + 8,$$

where 3 corresponds to TRIT and 8 to the internal octad. Taken together,

$$11 = 6 + 5 = 3 + 8, \qquad 12 = 11 + 1.$$

The dimension reading 11 thus coordinates code and correction, TRIT and octad, and the identity $729 \cdot 243 = 3^{11}$.

24.2.9 Dimensional realization of duality

The local action of a route is expressed as

$$E_0(P) = n_A(P) A_{\mathrm{rad}} + \frac{s_C(P)}{6} C^*_{\mathrm{rad}}.$$

The first term is the visible advance or vibration mode; the second is the boundary or contra-angular winding mode. The local mass is

$$m_{\mathrm{HMT}}(P) = m_e \exp(E_0(P)).$$

The refined tower adds the boundary memory:

$$E(P) = E_0(P) + k(P)\Delta_4 + \nu_{120}(P)s_{120} + \nu_{270}(P)\zeta_{270},$$

where Δ_4 is the minimal torsion, s_{120} the hexad–octad selector, and

$$\zeta_{270} = 135\Delta_4^2$$

the quadratic memory of the crown. The abstract duality of route is

$$E_{A,C}(n,w) = nA_{\text{rad}} + wC^*_{\text{rad}}, \qquad E_{A,C}(n,w) = E_{C,A}(w,n).$$

In the physical sector, A and C^* are polarized, and the genealogical register selects the realization. Mass is the exponential of a closure route with visible advance, boundary winding, and torsion.

24.2.10 Compatibility between leaves and closure of the genealogical record

In a closed string, compatibility between the left- and right-moving modes is expressed schematically by

$$N_L - N_R = nw.$$

In the HMT reading, the left-hand member measures the difference of excitation between sheets, whereas the right-hand member measures the coupling between the visible phase and boundary memory. The adjustment of levels thus constitutes a closure of the bidirectional genealogical record. In the readings CP, T, and CPT, an asymmetry of orientation is compensated through bidirectional inversion in order to close the record.

24.2.11 T-Duality, Modularity and J Function

In the complex torus,

$$q = e^{2\pi i\tau},$$

and the modular transformation

$$\tau \longmapsto -\frac{1}{\tau}$$

interchanges its cycles. The duality T interchanges large and small radii; both realizations publish the interchange between the visible cycle and the boundary cycle. The modular function J, the Sommerfeld action, and the duality T constitute distinct closures of the same primary boundary structure with memory.

24.2.12 Dimensional Consequences for Photon, Electron, Mass, and Statistics

The observable photon is associated with the central TPK mode:

$$L_{\text{TPK}} = 3(I - P_0), \qquad \text{Spec}(L_{\text{TPK}}) = \{0,3,3\}.$$

The zero mode is an extended null propagation with no compactified memory of its own. The electron appears as the compact closure of the conjugate zero modes,

$$e^- = \text{compact closure of } P_+ + P_-,$$

and constitutes the minimal physical winding with stable memory. Mass measures the cost of stabilizing that compact memory. Pauli exclusion is interpreted as saturation of the genealogical register: two identical fermions do not occupy the same boundary because their winding closure is already saturated. Bosons publish shareable modes of unfolded memory, whereas fermions publish compactified memory.

24.2.13 Exact identities of involution, modularity, and residual conservation

The construction satisfies jointly the identities

1. $1000 = 729 + 243 + 27 + 1$;
2. $V_3(11, 2) = 1 + 22 + 220 = 243$;
3. $729 \cdot 243 = 3^{11}$;
4. $243 = 1 + 22 + 90 + 120 + 10$;
5. $C_\alpha, C_e, C_\pi, C_\varphi = 729, 271, 315, 161$;
6. $315 + 271 + 161 - 3 = 744$;
7. $1215 = 54 + 9 \cdot 129$;
8. $E_R(r, Q) = E_{1/R}(Q, r)$;
9. $11 = 6 + 5 = 3 + 8$, $12 = 11 + 1$, $26 = 2 + 24$ y $10 = 2 + 8$.

The duality T is therefore recognized as the geometric realization of the exchange between residue and quotient. Winding is not introduced first as an external property of a compact string, but as boundary memory of the decomposition $n = 9Q + r$. The block 243 brings this duality together with ternary Golay, dimension 11, channels 90/120, generation of constants, mass routes, and M-theory. In its most general form, HMT reads mass, string, and dimension as publications of a single boundary with memory.

24.2.14 Common core of the 3 formulations of T-duality

Let us define the stable domain

$$\mathscr{D}_0 = \mathbb{Z}^2 \times \mathbb{R}_{>0}, \qquad E_{R_0}(m, w) = \frac{m^2}{R_0^2} + w^2 R_0^2,$$

and the involution

$$\mathsf{T}_0(m, w, R_0) = (w, m, R_0^{-1}).$$

Theorem 24.5 (Residual ambient core equivalence–quotient)**.** *After prolonging the variables r, Q to the stable domain $\mathbb{Z}^2$, the three formulations are identified by means of*

$$I_F(r, Q, R) = (m, w, R_0) = (r, Q, R), \qquad I_{16\to 02} = \mathrm{id}_{\mathscr{D}_0}.$$

These maps intertwine the involutions and the quadratic forms:

$$I_F \mathsf{T}_F = \mathsf{T}_0 I_F, \qquad E_R^F = E_{R_0} \circ I_F, \qquad \mathsf{T}_0^2 = \mathrm{id}, \qquad E_{R_0} = E_{R_0^{-1}} \circ \mathrm{swap}.$$

Proof. The two maps are renamings of the same three coordinates. Moreover,

$$\mathsf{T}_0^2(m, w, R_0) = (m, w, R_0)$$

and

$$E_{R_0^{-1}}(w, m) = \frac{w^2}{R_0^{-2}} + m^2 R_0^{-2} = w^2 R_0^2 + \frac{m^2}{R_0^2} = E_{R_0}(m, w).$$

The identities are the same after applying I_F or the identity between the two formulations. □

In $\mathcal{H}_{\mathrm{lat}} = \ell^2(\mathbb{Z}^2)$, let us define

$$H(R_0)|m, w\rangle = E_{R_0}(m, w)|m, w\rangle, \qquad U_T|m, w\rangle = |w, m\rangle.$$

Then U_T is unitary, $U_T^2 = I$, and the preceding scalar identity is equivalent, on the orthonormal basis, to

$$\boxed{U_T H(R_0) U_T^{-1} = H(R_0^{-1}).}$$

This is the second exact realization of the same core, not a new physical hypothesis.

24.2.15 Distinction of the 2 residual sections by their energy insertions and equivalence classes

The positive residual convention uses

$$r_9^+(n) = 1 + ((n-1) \bmod 9), \qquad Q_9^+(n) = \frac{n - r_9^+(n)}{9},$$

whereas the zero residual convention inserts the class $\bar{r}_9(n) \in \{0, \dots, 8\}$. The change of section that preserves the integer is

$$C(r, Q) = \big(\bar{r}, Q + \mathbf{1}_{\{r=9\}}\big).$$

Proposition 24.6 (Energy Obstruction of Section Change)**.** *The map C preserves $n = 9Q + r$, but in general it preserves neither the form E_R nor the exchange involution. Equivalence of the ambient kernel therefore does not imply equivalence of the two nonadic embeddings.*

Proof. For $n = 9$, the first convention gives $(r, Q) = (9, 0)$, whereas the change with carry gives $(\bar{r}, Q_0) = (0, 1)$. Their energies are

$$E_R(9, 0) = \frac{81}{R^2}, \qquad E_R(0, 1) = R^2,$$

which do not coincide for every $R > 0$. Insertion without correcting the carry would send this example to $(0, 0)$ and would likewise fail to preserve the integer. A unique section must be fixed, or a form covariant under change of section must be constructed, before this equivalence is promoted. □

Definition 24.7 (Quotient of section change and covariant energy)**.** Let

$$L_9 := \mathbb{Z}(9, -1) \subset \mathbb{Z}^2, \qquad S(x_1, x_2) = (x_2, x_1),$$

and let

$$q_R(x_1, x_2) = \frac{x_1^2}{R^2} + x_2^2 R^2.$$

On the quotients

$$\mathcal{Q}_9 = (\mathbb{Z}^2/L_9) \times \mathbb{R}_{>0}, \qquad \mathcal{Q}_9^\vee = (\mathbb{Z}^2/SL_9) \times \mathbb{R}_{>0},$$

we define

$$\mathcal{E}_R^{L_9}([x]_{L_9}) := \min_{\ell \in L_9} q_R(x + \ell)$$

and

$$\mathsf{T}_{\mathrm{cov}}([x]_{L_9}, R) := ([Sx]_{SL_9}, R^{-1}).$$

Theorem 24.8 (Covariant Equivalence of Nonary Sections)**.** *The energy $\mathcal{E}_R^{L_9}$ and the transformation $\mathsf{T}_{\mathrm{cov}}$ are well defined. The conventions $(9, 0)$ and $(0, 1)$, and in general the sections $1, \dots, 9$ and $0, \dots, 8$ with the corresponding carry, represent the same class of $\mathbb{Z}^2/L_9$. Moreover,*

$$\boxed{\mathcal{E}_{R^{-1}}^{SL_9}([Sx]_{SL_9}) = \mathcal{E}_R^{L_9}([x]_{L_9}).}$$

The inverse exchange, defined on $\mathcal{Q}_9^\vee$, returns the initial class; hence the two quotiented charts are T-dual.

Proof. If $x' = x + \ell_0$, the translation $\ell \mapsto \ell + \ell_0$ permutes L_9, so the minimum does not depend on the representative. It exists because $q_R(x + k(9, -1))$ is a coercive quadratic function of $k \in \mathbb{Z}$. The difference $(9, 0) - (0, 1) = (9, -1)$ belongs to L_9, and the same occurs under every change of section with carry. Finally,

$$\begin{aligned}\mathcal{E}^{SL_9}_{R^{-1}}([Sx]) &= \min_{\ell \in L_9} q_{R^{-1}}(Sx + S\ell) \\ &= \min_{\ell \in L_9} q_R(x + \ell) = \mathcal{E}^{L_9}_R([x]).\end{aligned}$$

Since $S^2 = I$, the second exchange recovers the original quotient and the radius R. □

Equivalence domain of the dual nucleus and nonequivalence of energy insertions. The equivalence of the kernels over $\mathscr{D}_0$ is exact. The two embeddings are not equivalent for the uncorrected energy; the covariant closure is the quotient and the energy of the preceding theorem.

24.2.16 Exact normalization of the string realization

Fix $\alpha' > 0$. In the domain $\mathscr{D}_{\alpha'} = \mathbb{Z}^2 \times \mathbb{R}_{>0}$, let

$$\mathsf{T}_{\alpha'}(m, w, R) = \left(w, m, \frac{\alpha'}{R}\right), \qquad \mathcal{N}_{\alpha'}(m, w, R) = \left(m, w, \frac{R}{\sqrt{\alpha'}}\right).$$

Theorem 24.9 (String scale conjugation)**.** *The normalization $\mathcal{N}_{\alpha'}$ is an exact conjugation:*

$$\boxed{\mathcal{N}_{\alpha'}\mathsf{T}_{\alpha'} = \mathsf{T}_0\mathcal{N}_{\alpha'}.}$$

For

$$E_{\mathrm{str}}(m, w, R) = \frac{m^2}{R^2} + \frac{w^2R^2}{\alpha'^2},$$

we have

$$E_{\mathrm{str}} = \alpha'^{-1}E_0 \circ \mathcal{N}_{\alpha'}.$$

Furthermore, if

$$p_L = \frac{m}{R} + \frac{wR}{\alpha'}, \qquad p_R = \frac{m}{R} - \frac{wR}{\alpha'},$$

then p_L remains fixed and $p_R \mapsto -p_R$.

Proof. We have

$$\mathcal{N}_{\alpha'}\mathsf{T}_{\alpha'}(m, w, R) = \left(w, m, \frac{\sqrt{\alpha'}}{R}\right) = \mathsf{T}_0\mathcal{N}_{\alpha'}(m, w, R).$$

The energy identity results from

$$E_0\left(m, w, \frac{R}{\sqrt{\alpha'}}\right) = \frac{\alpha' m^2}{R^2} + \frac{w^2R^2}{\alpha'} = \alpha' E_{\mathrm{str}}(m, w, R).$$

The substitution of $(m, w, R) \mapsto (w, m, \alpha'/R)$ in (p_L, p_R) gives, respectively, p_L and $-p_R$. □

Conjugation and spectral invariance with fixed oscillatory data are exact. The identification of m, w, R, α' with momentum, winding, physical radius, and inverse tension is a physical interface with its own premises.

24.2.17 Level separation, linear mass exchange, and modularity of the 3 realizations

The active string condition is

$$N_L - N_R = a_L - a_R - mw.$$

The schematic formula $N_L - N_R = nw$ coincides with it only after declaring $a_L = a_R$ and $n = -m$, or an equivalent reversal of leaf orientation. Without that dictionary, the two expressions are not the same formulation.

The linear symmetry of the action is typified in the extended space of coefficients and modes:

$$L(A, C; n, w) = nA + wC, \qquad \sigma(A, C; n, w) = (C, A; w, n).$$

Then

$$L \circ \sigma = wC + nA = L.$$

It is an exact identity under simultaneous exchange of parameters and coordinates. It is not equivalent to quadratic invariance of $H(R)$ on a sector with fixed physical parameters; such a promotion requires an additional intertwiner.

Finally, on the imaginary axis of the upper half-plane, let us define

$$\iota(R_0) = iR_0^2, \qquad S(\tau) = -\frac{1}{\tau}.$$

Then

$$\boxed{S \circ \iota(R_0) = \iota(R_0^{-1}).}$$

Since $J(S\tau) = J(\tau)$, one obtains $J(iR_0^2) = J(iR_0^{-2})$. This is an exact semiconjugacy of the radius parameter with the modular transformation S, proved from the explicit starting modular structure. It does not by itself identify target-space duality, the exchange of charges, or the construction of $V^{\natural}$.

24.3 Action ellipse and determination of the normalized radius

The angular reader and the action section preserve the same APP–TRIT–TPK antecedent. The form constructed below uses the publications (14.75) and a positive section $\hbar = \hbar_s$, with $s \in \{\mathrm{pre}, \mathrm{ret}\}$, of (14.71). The angular ratio will determine the form; the action section will preserve its common scale.

24.3.1 Domain and labelled semiaxes

For brevity, let $A = A_{\mathrm{deg}}$ and $C^* = C^*_{\mathrm{deg}}$. In the chart $A \neq 0$, $\hbar > 0$ and $|C^*/A| < 1$, we define

$$\xi = \frac{C^*}{A}, \qquad \eta_{\mathrm{el}} = \operatorname{artanh} \xi, \qquad a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}, \qquad b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}. \tag{24.1}$$

The semiaxes and the balanced coordinates Q, P have units of the square root of action. The axes remain labelled: the sign of η_{el} determines which is larger. The curve and the product of its semiaxes are

$$\gamma(\theta) = (a_S \cos\theta, b_S \sin\theta), \qquad \frac{Q^2}{a_S^2} + \frac{P^2}{b_S^2} = 1, \qquad a_S b_S = 2\hbar. \tag{24.2}$$

Proposition 24.10 (Membership of the publications in the elliptic chart)**.** *The positive branch of* (14.75)*, with the intervals* (14.62)*, satisfies $A > 0$, $0 < C^* < A$, and $\hbar_s > 0$. Reversal of the odd coordinate preserves $|C^*/A| < 1$.*

Proof. Proposition 14.22 gives $0 < \eta_{\mathrm{ret}} < H_5$ and positivity of both action sections. For an upper bound on H_5, (14.62) implies $\alpha < 1/125$ and $\varphi > 8/5$. Retaining only the positive terms of (14.64) yields

$$H_5 < \frac{\sqrt{5}}{2} + \frac{9}{16 \cdot 125^2} + \frac{7}{48 \cdot 125^4}.$$

Since $5 < 81/16$, one has $\sqrt{5}/2 < 9/8$. Moreover,

$$\frac{9}{16 \cdot 125^2} + \frac{7}{48 \cdot 125^4} = \frac{421882}{11718750000} < \frac{1}{1000}.$$

Thus $H_5 < 9/8 + 1/1000 < 2$. Using $\alpha > 7/1000$ now gives

$$0 < C^* = 2(\eta_{\mathrm{ret}} + \alpha) < 2\left(2 + \frac{1}{125}\right) = \frac{502}{125} < 7 < 1000\alpha = A.$$

The channel interchange in 14.26 replaces C^* by $-C^*$ and preserves A; it therefore preserves the absolute inequality. □

24.3.2 Parametric phase and oriented area

Proposition 24.11 (Area law and transport of angular coordinates)**.** *The parametric phase θ of γ and its polar angle ϕ, continuously lifted from zero, satisfy*

$$\phi(\theta) = \arg(a_S \cos\theta + i b_S \sin\theta), \qquad \frac{d\phi}{d\theta} = \frac{a_S b_S}{a_S^2 \cos^2\theta + b_S^2 \sin^2\theta} > 0. \tag{24.3}$$

In a chart where both tangents are defined, $\tan\phi = (b_S/a_S)\tan\theta$*. The oriented area swept out from phase zero is*

$$\mathcal{A}(\theta) = \frac{1}{2}\int_0^\theta (QP' - PQ')\,dt = \hbar\theta, \qquad \mathcal{A}(1) = \hbar, \quad \mathcal{A}(2\pi) = h_s. \tag{24.4}$$

Proof. The derivative of the argument of a nonzero vector is $(QP' - PQ')/(Q^2 + P^2)$. For the curve (24.2), the numerator equals $a_S b_S = 2\hbar$; this proves the derivative formula and its positivity. The quotient P/Q gives the tangent relation; the continuous lift preserves quadrants and turns. The integral equals $a_S b_S \theta/2 = \hbar\theta$. Finally, $h_s = 2\pi\hbar_s$ gives the identity for the complete turn. □

One radian of parametric phase sweeps an area $\hbar$. The polar angle retains its own derivative in (24.3). In polar coordinates, the equivalent law is

$$d\mathcal{A} = \frac{1}{2}\rho_\partial(\phi)^2\,d\phi, \qquad \rho_\partial(\phi) = \left(\frac{\cos^2\phi}{a_S^2} + \frac{\sin^2\phi}{b_S^2}\right)^{-1/2}.$$

The radial formula follows by substituting $(Q, P) = \rho(\cos\phi, \sin\phi)$ into (24.2). With the orientation of γ, the integral of the canonical one-form retains the sign

$$\oint_\gamma P\,dQ = -\pi a_S b_S = -h_s. \tag{24.5}$$

Indeed, $P\,dQ = -a_S b_S \sin^2\theta\,d\theta$, and the integral of $\sin^2\theta$ over one turn is π.

24.3.3 Shape reciprocity and symplectic orientation

Define the matrices

$$D(\eta) = \begin{pmatrix} e^{\eta} & 0 \\ 0 & e^{-\eta} \end{pmatrix}, \qquad S_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad J_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{24.6}$$

Proposition 24.12 (Quadratic form and action under reciprocity)**.** *Both transports satisfy $T^{\mathsf{T}} D(-\eta) T = D(\eta)$. For $\omega = dQ \wedge dP$, the interchange S_2 is antisymplectic and the rotation J_2 is symplectic:*

$$S_2^* \omega = -\omega, \qquad J_2^* \omega = \omega.$$

If $\mathcal{I}(\gamma) = \oint_\gamma P\, dQ$ on a closed curve, then

$$\mathcal{I}(S_2 \gamma) = -\mathcal{I}(\gamma), \qquad \mathcal{I}(J_2 \gamma) = \mathcal{I}(\gamma). \tag{24.7}$$

Proof. Matrix multiplication interchanges the two diagonal entries of D, proving both congruences. The determinants of S_2, J_2 are $-1, 1$; this gives the transformation of the area form. For $\lambda = P\, dQ$, direct calculation gives

$$S_2^* \lambda = d(PQ) - \lambda, \qquad J_2^* \lambda = \lambda - d(PQ).$$

The integral of the exact differential over the closed curve is zero, proving both action identities. □

Orientation distinguishes the two transports even though they express the same quadratic form, including in the circular case. The labelling of the axes and the sign of the action therefore belong to the data preserved in passing to the lattice representation.

24.3.4 Normalized radius and lattice-readout matrix

Proposition 24.13 (Determination and recoverability of the shape radius)**.** *The labelled ellipse determines a unique positive radius*

$$R_\star = \sqrt{\frac{b_S}{a_S}} = e^{-\eta_{\mathrm{el}}/2} = \left(\frac{A - C^*}{A + C^*} \right)^{1/4}, \qquad \tau_{\mathrm{el}} = i R_\star^2. \tag{24.8}$$

The angular ratio is recovered through

$$\frac{C^*}{A} = \frac{1 - R_\star^4}{1 + R_\star^4}, \qquad R_\star^4 = \frac{499\alpha - \eta_{\mathrm{ret}}}{501\alpha + \eta_{\mathrm{ret}}}. \tag{24.9}$$

Interchanging the semiaxes transforms $(\eta_{\mathrm{el}}, R_\star, \tau_{\mathrm{el}})$ into $(-\eta_{\mathrm{el}}, R_\star^{-1}, -1/\tau_{\mathrm{el}})$ and preserves $a_S b_S = 2\hbar$.

Proof. Dividing the semiaxes gives $b_S/a_S = e^{-\eta_{\mathrm{el}}}$. The map $R \mapsto R^2$ is bijective on the positive reals, so the positive root is unique. For $\xi = C^*/A \in (-1, 1)$,

$$2 \operatorname{artanh} \xi = \log \frac{1 + \xi}{1 - \xi};$$

hence $R_\star^4 = (1 - \xi)/(1 + \xi)$. Solving for ξ proves the first identity in (24.9). Substituting $A = 1000\alpha$ and $C^* = 2(\eta_{\mathrm{ret}} + \alpha)$ gives

$$\frac{A - C^*}{A + C^*} = \frac{998\alpha - 2\eta_{\mathrm{ret}}}{1002\alpha + 2\eta_{\mathrm{ret}}} = \frac{499\alpha - \eta_{\mathrm{ret}}}{501\alpha + \eta_{\mathrm{ret}}}.$$

The interchange inverts the semiaxis ratio and changes the sign of η_{el}. The identity $-1/(iR_\star^2) = iR_\star^{-2}$ gives the modular transport. The product of the semiaxes remains fixed. □

On the positive branch, $0 < R_\star < 1$; the chart of the reversed form publishes $R_\star^{-1} > 1$. The angular ratio is recovered from the radius, while the absolute angles and their history remain in the enriched state. The circular form corresponds to $C^*/A = 0$, with $R_\star = 1$. Changing the positive action section while retaining the angular pair changes the common scale of the semiaxes and preserves their ratio.

Proposition 24.14 (Lattice form determined by the ellipse)**.** *The matrix of normalized squared semiaxes is*

$$D(\eta_{\mathrm{el}}) = \frac{1}{2\hbar}\begin{pmatrix} a_S^2 & 0 \\ 0 & b_S^2 \end{pmatrix} = \begin{pmatrix} R_\star^{-2} & 0 \\ 0 & R_\star^2 \end{pmatrix}. \tag{24.10}$$

Its evaluation on an integer pair produces

$$E_\star(m, w) = \begin{pmatrix} m & w \end{pmatrix} D(\eta_{\mathrm{el}}) \begin{pmatrix} m \\ w \end{pmatrix} = \frac{m^2}{R_\star^2} + w^2 R_\star^2. \tag{24.11}$$

The equation of the ellipse multiplied by $2\hbar$ uses, instead, the inverse matrix $D(-\eta_{\mathrm{el}})$.

Proof. The squares of the semiaxes in (24.1), divided by $2\hbar$, are $e^{\eta_{\mathrm{el}}}$ and $e^{-\eta_{\mathrm{el}}}$. By (24.8), these are $R_\star^{-2}$ and $R_\star^2$. Multiplication by the integer vector proves (24.11). Finally, $2\hbar/a_S^2 = e^{-\eta_{\mathrm{el}}}$ and $2\hbar/b_S^2 = e^{\eta_{\mathrm{el}}}$, identifying the matrix of the elliptic equation. □

The radius $R_\star$ is a dimensionless publication of the labelled form. The polar radius ρ_∂ belongs to the square-root-of-action line. Representation by a spatial radius requires its subsequent dimensional chart; this preserves the form already determined and the independence of its construction from a prescribed length.

24.3.5 Inductive–capacitive realization of the action form

The action form already constructed admits an electrical realization in a chart equipped with a clock $\omega > 0$ and a reference impedance $Z_* > 0$. These two quantities preserve their units and accompany the shape parameter η. One defines

$$L_\eta = \frac{Z_*}{\omega} e^{-\eta}, \qquad C_\eta = \frac{e^{\eta}}{Z_* \omega}, \qquad Z_\eta = \sqrt{L_\eta / C_\eta}. \tag{24.12}$$

Here C_η denotes capacitance, distinct from the counterangle C^*.

Proposition 24.15 (Conservation of the dynamical product)**.** *The realization* (24.12) *satisfies*

$$L_\eta C_\eta = \omega^{-2}, \qquad \frac{Z_\eta}{Z_*} = e^{-\eta} = \frac{b_S}{a_S}, \tag{24.13}$$

where $a_S = \sqrt{2\hbar}\, e^{\eta/2}$ and $b_S = \sqrt{2\hbar}\, e^{-\eta/2}$ are the semiaxes of equation (24.1)*. With $Q = \sqrt{Z_*}\, q$ and $P = \Phi/\sqrt{Z_*}$, the energy takes the form*

$$H_{LC} = \frac{q^2}{2C_\eta} + \frac{\Phi^2}{2L_\eta} = \frac{\omega}{2}(e^{-\eta} Q^2 + e^{\eta} P^2).$$

On $(Q, P) = (a_S \cos\theta, b_S \sin\theta)$, the electric and magnetic contributions are $\hbar\omega \cos^2\theta$ and $\hbar\omega \sin^2\theta$; the total energy is $\hbar\omega$.

Proof. Multiplying L_η and C_η cancels the factors Z_* and $e^{\pm\eta}$, whereas their ratio is $Z_*^2 e^{-2\eta}$. The positive square root proves the impedance identity. Substitution of $q = Q/\sqrt{Z_*}$ and $\Phi = \sqrt{Z_*}\, P$ gives the form of H_{LC}. The squared semiaxes cancel the remaining shape factors; the sum uses $\cos^2\theta + \sin^2\theta = 1$. □

The Hamiltonian convention $\dot{Q} = \partial_P H$, $\dot{P} = -\partial_Q H$ assigns $\dot{\theta} = -\omega$ to this parametrization. The form, the clock and the dimensional chart remain distinct. The constitutive response of the vacuum and the impedance Z_η are related by the channel inversion of proposition 118.4; each preserves its definition and its normalization.

24.4 T-duality: integer coordinates, change of section, and operator equivalence

The arithmetic decomposition of APP preserves the residual representative and its quotient. TPK evolution also transports its orientation and the memory of boundary crossings. Interchanging the two coordinates requires preserving this distinction and specifying the domain on which the operation is again defined. An arithmetic involution is first constructed on that domain; its quadratic form subsequently admits a representation by self-adjoint operators.

24.4.1 Stable domain of the interchange

In the positive residual section,

$$r_9^+(n) = 1 + ((n-1) \bmod 9), \qquad Q_9^+(n) = \frac{n - r_9^+(n)}{9}, \qquad n = r_9^+(n) + 9Q_9^+(n). \tag{24.14}$$

An interchange can place an arbitrary quotient in the first coordinate. Its stable domain is therefore $\mathscr{D}_0 = \mathbb{Z}^2 \times \mathbb{R}_{>0}$, not merely the section $1 \le r \le 9$. Extending the domain makes it possible to define a total operation; the admissibility of a pair as the readout of a TPK route separately retains its selection rules.

Definition 24.16 (Normalized compact form and interchange)**.** For $d = (m, w, R_0) \in \mathscr{D}_0$, let

$$E_{R_0}(m, w) = \frac{m^2}{R_0^2} + w^2 R_0^2, \qquad \mathsf{T}_0(m, w, R_0) = (w, m, R_0^{-1}). \tag{24.15}$$

The symbols m, w name the two transported integer coordinates; R_0 is the positive dimensionless scale of the form. Their interpretation through momentum, winding, and physical radius is established by a subsequent realization map.

Theorem 24.17 (Involution and preservation of the quadratic form)**.** *The map T_0 is an involution of $\mathscr{D}_0$, and*

$$E_{R_0^{-1}}(w, m) = E_{R_0}(m, w).$$

Proof. Two interchanges restore (m, w), and two inversions restore R_0. Moreover,

$$E_{R_0^{-1}}(w, m) = w^2 R_0^2 + \frac{m^2}{R_0^2} = E_{R_0}(m, w).$$

□

The equivalence holds for each radius and its reciprocal. At $R_0 = 1$, the radius remains fixed and the operation acts on the same form. A specific pair is fixed by the full involution precisely when, in addition, $m = w$.

24.4.2 Compact Hamiltonian and self-adjoint domain

Let $\mathcal{H}_{\mathrm{lat}} = \ell^2(\mathbb{Z}^2)$, with orthonormal basis $\{|m, w\rangle\}$. Define

$$H(R_0)|m, w\rangle = E_{R_0}(m, w)|m, w\rangle, \tag{24.16}$$

$$D(H(R_0)) = \left\{ \psi : \sum_{m,w \in \mathbb{Z}} E_{R_0}(m, w)^2 |\psi_{m,w}|^2 < \infty \right\}. \tag{24.17}$$

Finitely supported vectors belong to the domain and form a core for the diagonal operator. The associated quadratic form has domain

$$D(H(R_0)^{1/2}) = \left\{ \psi : \sum_{m,w} E_{R_0}(m,w)|\psi_{m,w}|^2 < \infty \right\}.$$

Proposition 24.18 (Self-adjointness and compact resolvent)**.** *The operator $H(R_0)$ is self-adjoint and nonnegative. Its eigenvalues are $E_{R_0}(m,w)$, counted with multiplicity, and $(H(R_0)+I)^{-1}$ is compact.*

Proof. A multiplication operator defined by a real sequence is symmetric on (24.17). If η belongs to the domain of the adjoint, testing the adjoint identity against each vector $|m,w\rangle$ forces its image to have coordinates $E_{R_0}(m,w)\eta_{m,w}$. Membership in ℓ^2 is exactly condition (24.17); hence the adjoint has the same domain and the same action. Nonnegativity follows by summing the nonnegative weights.

With $c_{R_0} = \min(R_0^{-2}, R_0^2) > 0$, we have $E_{R_0}(m,w) \geq c_{R_0}(m^2+w^2)$. Outside increasing finite sets, the coefficients $(1+E_{R_0}(m,w))^{-1}$ tend uniformly to zero. Truncating the resolvent to those sets produces finite-rank operators converging in norm, which proves its compactness. The diagonal basis determines the stated spectrum. □

Theorem 24.19 (Unitary conjugation, including domains)**.** *The interchange $U_T|m,w\rangle = |w,m\rangle$ is unitary, $U_T^2 = I$, and satisfies*

$$U_T D(H(R_0)) = D(H(R_0^{-1})), \qquad U_T H(R_0) U_T^{-1} = H(R_0^{-1}). \tag{24.18}$$

It also transports the quadratic-form domains.

Proof. The interchange is an involutive permutation of the orthonormal basis. For a sequence ψ, the identity in Theorem 24.17 gives

$$\sum_{m,w} E_{R_0^{-1}}(m,w)^2 |(U_T\psi)_{m,w}|^2 = \sum_{m,w} E_{R_0}(m,w)^2 |\psi_{m,w}|^2.$$

Equality of the domains is established. On each coordinate, $U_T H(R_0) U_T^{-1}$ multiplies by $E_{R_0}(w,m) = E_{R_0^{-1}}(m,w)$. The same sum, with the first power of the weight, proves the result for the quadratic forms. □

The scalar equality and the operator equality are two realizations of the same involution. The second preserves the domains that allow the first to be interpreted as spectral equivalence, not merely as an equality on finitely supported vectors.

24.4.3 Specialization to the radius of the action ellipse

The radius $R_\star$ determined in section 24.3 fixes the realization of this family that corresponds to the angular publications of the state. The symbol R_0 allows the transport results to be expressed for the entire positive family; composition with the ellipse evaluates that family at $R_0 = R_\star$ and also preserves its reciprocal image.

Corollary 24.20 (Elliptic family stable under duality)**.** *The set*

$$\mathscr{D}_{\mathrm{el}} = \mathbb{Z}^2 \times \{R_\star, R_\star^{-1}\}$$

is stable under T_0. Its Hamiltonians are self-adjoint, nonnegative, and have compact resolvent. The interchange U_T transports the domain of $H(R_\star)$ onto that of $H(R_\star^{-1})$, including their form domains.

Proof. The positivity of $R_\star$ and its unique determination are established in section 24.3. Inversion permutes $R_\star$ and $R_\star^{-1}$, while interchange preserves $\mathbb{Z}^2$. Proposition 24.18 and theorem 24.19 apply on these two fibres. If $R_\star = 1$, the two fibres coincide; in every other case, the operator intertwines two distinct fibres of the same family. □

The common action scale determines the area of the ellipse; its semiaxis ratio determines $R_\star$. This separation makes it possible to preserve the area and the common action scale while interchanging the semiaxes and obtaining the reciprocal radius. The index interchange on $\ell^2(\mathbb{Z}^2)$ and the transports of the action plane act on different spaces; their respective properties are proved on their own domains.

24.4.4 Change of representative and quotient memory

The zero section uses $\bar{r} \in \{0, \dots, 8\}$. The change that preserves the integer in (24.14) is

$$C(r, Q) = (\bar{r}, Q + \mathbf{1}_{\{r=9\}}). \tag{24.19}$$

The modification of the quotient is part of the operation. For $n = 9$, the two pairs are $(9, 0)$ and $(0, 1)$. Their uncorrected energies are $81/R_0^2$ and R_0^2. Representing the same integer therefore does not imply equality of those two insertions into a form that distinguishes the coordinates.

The equivalence relation is preserved by defining

$$L_9 = \mathbb{Z}(9, -1), \qquad S(x_1, x_2) = (x_2, x_1), \qquad q_{R_0}(x) = \frac{x_1^2}{R_0^2} + x_2^2 R_0^2.$$

For $x \in \mathbb{Z}^2$, let

$$\mathcal{E}_{R_0}^{L_9}([x]) = \min_{k \in \mathbb{Z}} q_{R_0}(x + k(9, -1)). \tag{24.20}$$

This construction operates on classes. The memory distinguishing individual representatives remains in the TPK state preceding the quotient; the function in (24.20) determines the invariant evaluation of the chosen class.

Theorem 24.21 (Covariant duality of sections)**.** *The energy in* (24.20) *is well defined. The transformation*

$$\mathsf{T}_{\mathrm{cov}}([x]_{L_9}, R_0) = ([Sx]_{SL_9}, R_0^{-1})$$

is a bijection between $(\mathbb{Z}^2/L_9) \times \mathbb{R}_{>0}$ *and* $(\mathbb{Z}^2/SL_9) \times \mathbb{R}_{>0}$*, with inverse given by the second interchange, and*

$$\mathcal{E}_{R_0^{-1}}^{SL_9}([Sx]) = \mathcal{E}_{R_0}^{L_9}([x]).$$

Proof. Replacing x by $x + k_0(9, -1)$ reindexes the candidates for the minimum. The minimum exists: the function of k is quadratic and has leading coefficient $81/R_0^2 + R_0^2 > 0$. The change $(9, Q) \mapsto (0, Q + 1)$ has difference in L_9, so it represents the same class. Interchange transports the equivalence relation to SL_9, and

$$\min_{\ell \in L_9} q_{R_0^{-1}}(Sx + S\ell) = \min_{\ell \in L_9} q_{R_0}(x + \ell).$$

Finally, $S^2 = I$ recovers the initial quotient and radius. □

The minimum can be evaluated exactly using two candidates. If $x = (m, w)$, the real minimum of the quadratic occurs at

$$k_* = \frac{wR_0^4 - 9m}{81 + R_0^4}.$$

The integer minimum is attained at $\lfloor k_* \rfloor$ or $\lceil k_* \rceil$. This formula does not alter the equivalence; it makes its finite evaluation explicit and allows the effect of changing section to be checked without discarding the quotient.

24.4.5 Radius normalization in the string realization

Let $\alpha' > 0$ be a scale of the string realization. This symbol denotes the string scale and is kept distinct from the fine-structure constant α. Define

$$\mathsf{T}_{\alpha'}(m, w, R) = \left(w, m, \frac{\alpha'}{R}\right), \qquad \mathcal{N}_{\alpha'}(m, w, R) = \left(m, w, \frac{R}{\sqrt{\alpha'}}\right). \tag{24.21}$$

Theorem 24.22 (Exact conjugation by the scale)**.** *Normalization satisfies*

$$\mathcal{N}_{\alpha'}\mathsf{T}_{\alpha'} = \mathsf{T}_0\mathcal{N}_{\alpha'}.$$

If

$$E_{\mathrm{str}}(m, w, R) = \frac{m^2}{R^2} + \frac{w^2R^2}{\alpha'^2},$$

then $E_{\mathrm{str}} = \alpha'^{-1}E \circ \mathcal{N}_{\alpha'}$. *The combinations*

$$p_L = \frac{m}{R} + \frac{wR}{\alpha'}, \qquad p_R = \frac{m}{R} - \frac{wR}{\alpha'}$$

transform as $p_L \mapsto p_L$ *and* $p_R \mapsto -p_R$.

Proof. Both compositions in the first equality give $(w, m, \sqrt{\alpha'}/R)$. On the other hand,

$$E_{R/\sqrt{\alpha'}}(m, w) = \frac{\alpha' m^2}{R^2} + \frac{w^2R^2}{\alpha'} = \alpha' E_{\mathrm{str}}(m, w, R).$$

Substituting $(w, m, \alpha'/R)$ into the expressions for p_L, p_R gives the two asserted transformations, respectively. □

Conjugation fixes what it means to express the same result in a dimensional chart. In the elliptic family, the radii are

$$R = \sqrt{\alpha'}R_\star, \qquad R^\vee = \sqrt{\alpha'}R_\star^{-1}.$$

Their product is α'. The internal determination of the dimensionless semiaxis ratio and the length-squared scale of the realization serve different functions: the former fixes the shape; the latter expresses its radii in a dimensional unit.

The preceding normalization allows the same result to be expressed with normalized or physical radius. Assigning a tension and a unit to α' belongs to the realization map and has its own origin; it is not a datum entering the production of APP–TRIT–TPK registers.

24.4.6 Relationship with the modular transformation

Radius inversion has a precise representation on the imaginary axis of the upper half-plane. Let $\iota(R_0) = \mathrm{i}R_0^2$ and $\mathsf{S}(\tau) = -1/\tau$. Then

$$\mathsf{S} \circ \iota(R_0) = \iota(R_0^{-1}). \tag{24.22}$$

The equality follows from $-1/(\mathrm{i}R_0^2) = \mathrm{i}R_0^{-2}$. For the modular function $J = j - 744$, whose invariance is preserved in the Moonshine development, it follows that $J(\mathrm{i}R_0^2) = J(\mathrm{i}R_0^{-2})$.

The map ι expresses a semiconjugacy of parameters. The interchange U_T acts on the coordinates of $\ell^2(\mathbb{Z}^2)$; S acts on the upper half-plane; the dual automorphism of an orbifold acts on its graded sectors. Writing out their domains makes it possible to compose specific relationships between them

while preserving the information of each representation. The results assembled here establish coordinate interchange with explicit operator domains and proofs.

24.5 Action ellipse and determination of the normalized radius

The angular reader and the action section preserve the same APP–TRIT–TPK antecedent. The form constructed below uses the publications (14.75) and a positive section $\hbar = \hbar_s$, with $s \in \{\mathrm{pre}, \mathrm{ret}\}$, of (14.71). The angular ratio will determine the form; the action section will preserve its common scale.

24.5.1 Domain and labelled semiaxes

For brevity, let $A = A_{\mathrm{deg}}$ and $C^* = C^*_{\mathrm{deg}}$. In the chart $A \neq 0$, $\hbar > 0$ and $|C^*/A| < 1$, we define

$$\xi = \frac{C^*}{A}, \qquad \eta_{\mathrm{el}} = \operatorname{artanh} \xi, \qquad a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}, \qquad b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}. \tag{24.23}$$

The semiaxes and the balanced coordinates Q, P have units of the square root of action. The axes remain labelled: the sign of η_{el} determines which is larger. The curve and the product of its semiaxes are

$$\gamma(\theta) = (a_S \cos\theta, b_S \sin\theta), \qquad \frac{Q^2}{a_S^2} + \frac{P^2}{b_S^2} = 1, \qquad a_S b_S = 2\hbar. \tag{24.24}$$

Proposition 24.23 (Membership of the publications in the elliptic chart)**.** *The positive branch of* (14.75)*, with the intervals* (14.62)*, satisfies $A > 0$, $0 < C^* < A$, and $\hbar_s > 0$. Reversal of the odd coordinate preserves $|C^*/A| < 1$.*

Proof. Proposition 14.22 gives $0 < \eta_{\mathrm{ret}} < H_5$ and positivity of both action sections. For an upper bound on H_5, (14.62) implies $\alpha < 1/125$ and $\varphi > 8/5$. Retaining only the positive terms of (14.64) yields

$$H_5 < \frac{\sqrt{5}}{2} + \frac{9}{16 \cdot 125^2} + \frac{7}{48 \cdot 125^4}.$$

Since $5 < 81/16$, one has $\sqrt{5}/2 < 9/8$. Moreover,

$$\frac{9}{16 \cdot 125^2} + \frac{7}{48 \cdot 125^4} = \frac{421882}{11718750000} < \frac{1}{1000}.$$

Thus $H_5 < 9/8 + 1/1000 < 2$. Using $\alpha > 7/1000$ now gives

$$0 < C^* = 2(\eta_{\mathrm{ret}} + \alpha) < 2\left(2 + \frac{1}{125}\right) = \frac{502}{125} < 7 < 1000\alpha = A.$$

The channel interchange in 14.26 replaces C^* by $-C^*$ and preserves A; it therefore preserves the absolute inequality. □

24.5.2 Parametric phase and oriented area

Proposition 24.24 (Area law and transport of angular coordinates)**.** *The parametric phase θ of γ and its polar angle ϕ, continuously lifted from zero, satisfy*

$$\phi(\theta) = \arg(a_S \cos\theta + i b_S \sin\theta), \qquad \frac{d\phi}{d\theta} = \frac{a_S b_S}{a_S^2 \cos^2\theta + b_S^2 \sin^2\theta} > 0. \tag{24.25}$$

In a chart where both tangents are defined, $\tan\phi = (b_S/a_S)\tan\theta$*. The oriented area swept out from phase zero is*

$$\mathcal{A}(\theta) = \frac{1}{2}\int_0^\theta (QP' - PQ')\,dt = \hbar\theta, \qquad \mathcal{A}(1) = \hbar, \quad \mathcal{A}(2\pi) = h_s. \tag{24.26}$$

Proof. The derivative of the argument of a nonzero vector is $(QP' - PQ')/(Q^2 + P^2)$. For the curve (24.24), the numerator equals $a_S b_S = 2\hbar$; this proves the derivative formula and its positivity. The quotient P/Q gives the tangent relation; the continuous lift preserves quadrants and turns. The integral equals $a_S b_S \theta/2 = \hbar\theta$. Finally, $h_s = 2\pi\hbar_s$ gives the identity for the complete turn. □

One radian of parametric phase sweeps an area $\hbar$. The polar angle retains its own derivative in (24.25). In polar coordinates, the equivalent law is

$$d\mathcal{A} = \frac{1}{2}\rho_\partial(\phi)^2\,d\phi, \qquad \rho_\partial(\phi) = \left(\frac{\cos^2\phi}{a_S^2} + \frac{\sin^2\phi}{b_S^2}\right)^{-1/2}.$$

The radial formula follows by substituting $(Q, P) = \rho(\cos\phi, \sin\phi)$ into (24.24). With the orientation of γ, the integral of the canonical one-form retains the sign

$$\oint_\gamma P\,dQ = -\pi a_S b_S = -h_s. \tag{24.27}$$

Indeed, $P\,dQ = -a_S b_S \sin^2\theta\,d\theta$, and the integral of $\sin^2\theta$ over one turn is π.

24.5.3 Shape reciprocity and symplectic orientation

Define the matrices

$$D(\eta) = \begin{pmatrix} e^\eta & 0 \\ 0 & e^{-\eta} \end{pmatrix}, \qquad S_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad J_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{24.28}$$

Proposition 24.25 (Quadratic form and action under reciprocity)**.** *Both transports satisfy $T^\mathsf{T} D(-\eta) T = D(\eta)$. For $\omega = dQ \wedge dP$, the interchange S_2 is antisymplectic and the rotation J_2 is symplectic:*

$$S_2^*\omega = -\omega, \qquad J_2^*\omega = \omega.$$

If $\mathcal{I}(\gamma) = \oint_\gamma P\,dQ$ on a closed curve, then

$$\mathcal{I}(S_2\gamma) = -\mathcal{I}(\gamma), \qquad \mathcal{I}(J_2\gamma) = \mathcal{I}(\gamma). \tag{24.29}$$

Proof. Matrix multiplication interchanges the two diagonal entries of D, proving both congruences. The determinants of S_2, J_2 are $-1, 1$; this gives the transformation of the area form. For $\lambda = P\,dQ$, direct calculation gives

$$S_2^*\lambda = d(PQ) - \lambda, \qquad J_2^*\lambda = \lambda - d(PQ).$$

The integral of the exact differential over the closed curve is zero, proving both action identities. □

Orientation distinguishes the two transports even though they express the same quadratic form, including in the circular case. The labelling of the axes and the sign of the action therefore belong to the data preserved in passing to the lattice representation.

24.5.4 Normalized radius and lattice-readout matrix

Proposition 24.26 (Determination and recoverability of the shape radius)**.** *The labelled ellipse determines a unique positive radius*

$$R_\star = \sqrt{\frac{b_S}{a_S}} = e^{-\eta_{\mathrm{el}}/2} = \left(\frac{A - C^*}{A + C^*}\right)^{1/4}, \qquad \tau_{\mathrm{el}} = iR_\star^2. \tag{24.30}$$

The angular ratio is recovered through

$$\frac{C^*}{A} = \frac{1 - R_\star^4}{1 + R_\star^4}, \qquad R_\star^4 = \frac{499\alpha - \eta_{\mathrm{ret}}}{501\alpha + \eta_{\mathrm{ret}}}. \tag{24.31}$$

Interchanging the semiaxes transforms $(\eta_{\mathrm{el}}, R_\star, \tau_{\mathrm{el}})$ *into* $(-\eta_{\mathrm{el}}, R_\star^{-1}, -1/\tau_{\mathrm{el}})$ *and preserves* $a_S b_S = 2\hbar$*.*

Proof. Dividing the semiaxes gives $b_S/a_S = e^{-\eta_{\mathrm{el}}}$. The map $R \mapsto R^2$ is bijective on the positive reals, so the positive root is unique. For $\xi = C^*/A \in (-1, 1)$,

$$2\,\operatorname{artanh}\xi = \log\frac{1+\xi}{1-\xi};$$

hence $R_\star^4 = (1-\xi)/(1+\xi)$. Solving for ξ proves the first identity in (24.31). Substituting $A = 1000\alpha$ and $C^* = 2(\eta_{\mathrm{ret}} + \alpha)$ gives

$$\frac{A - C^*}{A + C^*} = \frac{998\alpha - 2\eta_{\mathrm{ret}}}{1002\alpha + 2\eta_{\mathrm{ret}}} = \frac{499\alpha - \eta_{\mathrm{ret}}}{501\alpha + \eta_{\mathrm{ret}}}.$$

The interchange inverts the semiaxis ratio and changes the sign of η_{el}. The identity $-1/(iR_\star^2) = iR_\star^{-2}$ gives the modular transport. The product of the semiaxes remains fixed. □

On the positive branch, $0 < R_\star < 1$; the chart of the reversed form publishes $R_\star^{-1} > 1$. The angular ratio is recovered from the radius, while the absolute angles and their history remain in the enriched state. The circular form corresponds to $C^*/A = 0$, with $R_\star = 1$. Changing the positive action section while retaining the angular pair changes the common scale of the semiaxes and preserves their ratio.

Proposition 24.27 (Lattice form determined by the ellipse)**.** *The matrix of normalized squared semiaxes is*

$$D(\eta_{\mathrm{el}}) = \frac{1}{2\hbar}\begin{pmatrix} a_S^2 & 0 \\ 0 & b_S^2 \end{pmatrix} = \begin{pmatrix} R_\star^{-2} & 0 \\ 0 & R_\star^2 \end{pmatrix}. \tag{24.32}$$

Its evaluation on an integer pair produces

$$E_\star(m, w) = \begin{pmatrix} m & w \end{pmatrix} D(\eta_{\mathrm{el}}) \begin{pmatrix} m \\ w \end{pmatrix} = \frac{m^2}{R_\star^2} + w^2 R_\star^2. \tag{24.33}$$

The equation of the ellipse multiplied by $2\hbar$ *uses, instead, the inverse matrix* $D(-\eta_{\mathrm{el}})$*.*

Proof. The squares of the semiaxes in (24.23), divided by $2\hbar$, are $e^{\eta_{\mathrm{el}}}$ and $e^{-\eta_{\mathrm{el}}}$. By (24.30), these are $R_\star^{-2}$ and $R_\star^2$. Multiplication by the integer vector proves (24.33). Finally, $2\hbar/a_S^2 = e^{-\eta_{\mathrm{el}}}$ and $2\hbar/b_S^2 = e^{\eta_{\mathrm{el}}}$, identifying the matrix of the elliptic equation. □

The radius $R_\star$ is a dimensionless publication of the labelled form. The polar radius ρ_∂ belongs to the square-root-of-action line. Representation by a spatial radius requires its subsequent dimensional chart; this preserves the form already determined and the independence of its construction from a prescribed length.

24.6 T-duality: integer coordinates, change of section, and operator equivalence

The arithmetic decomposition of APP preserves the residual representative and its quotient. TPK evolution also transports its orientation and the memory of boundary crossings. Interchanging the two coordinates requires preserving this distinction and specifying the domain on which the operation is again defined. An arithmetic involution is first constructed on that domain; its quadratic form subsequently admits a representation by self-adjoint operators.

24.6.1 Stable domain of the interchange

In the positive residual section,

$$r_9^+(n) = 1 + ((n-1) \bmod 9), \qquad Q_9^+(n) = \frac{n - r_9^+(n)}{9}, \qquad n = r_9^+(n) + 9Q_9^+(n). \tag{24.34}$$

An interchange can place an arbitrary quotient in the first coordinate. Its stable domain is therefore $\mathscr{D}_0 = \mathbb{Z}^2 \times \mathbb{R}_{>0}$, not merely the section $1 \le r \le 9$. Extending the domain makes it possible to define a total operation; the admissibility of a pair as the readout of a TPK route separately retains its selection rules.

Definition 24.28 (Normalized compact form and interchange)**.** For $d = (m, w, R_0) \in \mathscr{D}_0$, let

$$E_{R_0}(m, w) = \frac{m^2}{R_0^2} + w^2 R_0^2, \qquad \mathsf{T}_0(m, w, R_0) = (w, m, R_0^{-1}). \tag{24.35}$$

The symbols m, w name the two transported integer coordinates; R_0 is the positive dimensionless scale of the form. Their interpretation through momentum, winding, and physical radius is established by a subsequent realization map.

Theorem 24.29 (Involution and preservation of the quadratic form)**.** *The map T_0 is an involution of $\mathscr{D}_0$, and*

$$E_{R_0^{-1}}(w, m) = E_{R_0}(m, w).$$

Proof. Two interchanges restore (m, w), and two inversions restore R_0. Moreover,

$$E_{R_0^{-1}}(w, m) = w^2 R_0^2 + \frac{m^2}{R_0^2} = E_{R_0}(m, w).$$

□

The equivalence holds for each radius and its reciprocal. At $R_0 = 1$, the radius remains fixed and the operation acts on the same form. A specific pair is fixed by the full involution precisely when, in addition, $m = w$.

24.6.2 Compact Hamiltonian and self-adjoint domain

Let $\mathcal{H}_{\mathrm{lat}} = \ell^2(\mathbb{Z}^2)$, with orthonormal basis $\{|m, w\rangle\}$. Define

$$H(R_0)|m, w\rangle = E_{R_0}(m, w)|m, w\rangle, \tag{24.36}$$

$$D(H(R_0)) = \left\{ \psi : \sum_{m,w \in \mathbb{Z}} E_{R_0}(m, w)^2 |\psi_{m,w}|^2 < \infty \right\}. \tag{24.37}$$

Finitely supported vectors belong to the domain and form a core for the diagonal operator. The associated quadratic form has domain

$$D(H(R_0)^{1/2}) = \left\{ \psi : \sum_{m,w} E_{R_0}(m, w) |\psi_{m,w}|^2 < \infty \right\}.$$

Proposition 24.30 (Self-adjointness and compact resolvent)**.** *The operator $H(R_0)$ is self-adjoint and nonnegative. Its eigenvalues are $E_{R_0}(m,w)$, counted with multiplicity, and $(H(R_0)+I)^{-1}$ is compact.*

Proof. A multiplication operator defined by a real sequence is symmetric on (24.37). If η belongs to the domain of the adjoint, testing the adjoint identity against each vector $|m,w\rangle$ forces its image to have coordinates $E_{R_0}(m,w)\eta_{m,w}$. Membership in ℓ^2 is exactly condition (24.37); hence the adjoint has the same domain and the same action. Nonnegativity follows by summing the nonnegative weights.

With $c_{R_0} = \min(R_0^{-2}, R_0^2) > 0$, we have $E_{R_0}(m,w) \geq c_{R_0}(m^2+w^2)$. Outside increasing finite sets, the coefficients $(1+E_{R_0}(m,w))^{-1}$ tend uniformly to zero. Truncating the resolvent to those sets produces finite-rank operators converging in norm, which proves its compactness. The diagonal basis determines the stated spectrum. □

Theorem 24.31 (Unitary conjugation, including domains)**.** *The interchange $U_T|m,w\rangle = |w,m\rangle$ is unitary, $U_T^2 = I$, and satisfies*

$$U_T D(H(R_0)) = D(H(R_0^{-1})), \qquad U_T H(R_0) U_T^{-1} = H(R_0^{-1}). \tag{24.38}$$

It also transports the quadratic-form domains.

Proof. The interchange is an involutive permutation of the orthonormal basis. For a sequence ψ, the identity in Theorem 24.29 gives

$$\sum_{m,w} E_{R_0^{-1}}(m,w)^2 |(U_T\psi)_{m,w}|^2 = \sum_{m,w} E_{R_0}(m,w)^2 |\psi_{m,w}|^2.$$

This gives equality of domains. On each coordinate, $U_T H(R_0) U_T^{-1}$ multiplies by $E_{R_0}(w,m) = E_{R_0^{-1}}(m,w)$. The same sum, with the first power of the weight, proves the result for the quadratic forms. □

The scalar equality and the operator equality are two realizations of the same involution. The second preserves the domains that allow the first to be interpreted as spectral equivalence, not merely as an equality on finitely supported vectors.

24.6.3 Specialization to the radius of the action ellipse

The radius $R_\star$ determined in section 24.5 fixes the realization of this family that corresponds to the angular publications of the state. The symbol R_0 allows the transport results to be expressed for the entire positive family; composition with the ellipse evaluates that family at $R_0 = R_\star$ and also preserves its reciprocal image.

Corollary 24.32 (Elliptic family stable under duality)**.** *The set*

$$\mathscr{D}_{\mathrm{el}} = \mathbb{Z}^2 \times \{R_\star, R_\star^{-1}\}$$

is stable under T_0. Its Hamiltonians are self-adjoint, nonnegative, and have compact resolvent. The interchange U_T transports the domain of $H(R_\star)$ onto that of $H(R_\star^{-1})$, including their form domains.

Proof. The positivity of $R_\star$ and its unique determination are established in section 24.5. Inversion permutes $R_\star$ and $R_\star^{-1}$, while interchange preserves $\mathbb{Z}^2$. Proposition 24.30 and theorem 24.31 apply on these two fibres. If $R_\star = 1$, the two fibres coincide; in every other case, the operator intertwines two distinct fibres of the same family. □

The common action scale determines the area of the ellipse; its semiaxis ratio determines $R_\star$. This separation makes it possible to preserve the area and the common action scale while interchanging the semiaxes and obtaining the reciprocal radius. The index interchange on $\ell^2(\mathbb{Z}^2)$ and the transports of the action plane act on different spaces; their respective properties are proved on their own domains.

24.6.4 Change of representative and quotient memory

The zero section uses $\bar{r} \in \{0, \dots, 8\}$. The change that preserves the integer in (24.34) is

$$C(r, Q) = (\bar{r}, Q + \mathbf{1}_{\{r=9\}}). \tag{24.39}$$

The modification of the quotient is part of the operation. For $n = 9$, the two pairs are $(9, 0)$ and $(0, 1)$. Their uncorrected energies are $81/R_0^2$ and R_0^2. Representing the same integer therefore does not imply equality of those two insertions into a form that distinguishes the coordinates.

The equivalence relation is preserved by defining

$$L_9 = \mathbb{Z}(9, -1), \qquad S(x_1, x_2) = (x_2, x_1), \qquad q_{R_0}(x) = \frac{x_1^2}{R_0^2} + x_2^2 R_0^2.$$

For $x \in \mathbb{Z}^2$, let

$$\mathcal{E}_{R_0}^{L_9}([x]) = \min_{k \in \mathbb{Z}} q_{R_0}(x + k(9, -1)). \tag{24.40}$$

This construction operates on classes. The memory distinguishing individual representatives remains in the TPK state preceding the quotient; the function in (24.40) determines the invariant evaluation of the chosen class.

Theorem 24.33 (Covariant duality of sections)**.** *The energy in* (24.40) *is well defined. The transformation*

$$\mathsf{T}_{\mathrm{cov}}([x]_{L_9}, R_0) = ([Sx]_{SL_9}, R_0^{-1})$$

is a bijection between $(\mathbb{Z}^2/L_9) \times \mathbb{R}_{>0}$ *and* $(\mathbb{Z}^2/SL_9) \times \mathbb{R}_{>0}$*, with inverse given by the second interchange, and*

$$\mathcal{E}_{R_0^{-1}}^{SL_9}([Sx]) = \mathcal{E}_{R_0}^{L_9}([x]).$$

Proof. Replacing x by $x + k_0(9, -1)$ reindexes the candidates for the minimum. The minimum exists: the function of k is quadratic and has leading coefficient $81/R_0^2 + R_0^2 > 0$. The change $(9, Q) \mapsto (0, Q + 1)$ has difference in L_9, so it represents the same class. Interchange transports the equivalence relation to SL_9, and

$$\min_{\ell \in L_9} q_{R_0^{-1}}(Sx + S\ell) = \min_{\ell \in L_9} q_{R_0}(x + \ell).$$

Finally, $S^2 = I$ recovers the initial quotient and radius. □

The minimum can be evaluated exactly using two candidates. If $x = (m, w)$, the real minimum of the quadratic occurs at

$$k_* = \frac{wR_0^4 - 9m}{81 + R_0^4}.$$

The integer minimum is attained at $\lfloor k_* \rfloor$ or $\lceil k_* \rceil$. This formula does not alter the equivalence; it makes its finite evaluation explicit and allows the effect of changing section to be checked without discarding the quotient.

24.6.5 Radius normalization in the string realization

Let $\alpha' > 0$ be a scale of the string realization. This symbol denotes the string scale and is kept distinct from the fine-structure constant α. Define

$$\mathsf{T}_{\alpha'}(m, w, R) = \left(w, m, \frac{\alpha'}{R}\right), \qquad \mathcal{N}_{\alpha'}(m, w, R) = \left(m, w, \frac{R}{\sqrt{\alpha'}}\right). \tag{24.41}$$

Theorem 24.34 (Exact conjugation by the scale)**.** *Normalization satisfies*

$$\mathcal{N}_{\alpha'}\mathsf{T}_{\alpha'} = \mathsf{T}_0\mathcal{N}_{\alpha'}.$$

If

$$E_{\mathrm{str}}(m, w, R) = \frac{m^2}{R^2} + \frac{w^2R^2}{\alpha'^2},$$

then $E_{\mathrm{str}} = \alpha'^{-1}E \circ \mathcal{N}_{\alpha'}$*. The combinations*

$$p_L = \frac{m}{R} + \frac{wR}{\alpha'}, \qquad p_R = \frac{m}{R} - \frac{wR}{\alpha'}$$

transform as $p_L \mapsto p_L$ *and* $p_R \mapsto -p_R$*.*

Proof. Both compositions in the first equality give $(w, m, \sqrt{\alpha'}/R)$. On the other hand,

$$E_{R/\sqrt{\alpha'}}(m, w) = \frac{\alpha' m^2}{R^2} + \frac{w^2R^2}{\alpha'} = \alpha' E_{\mathrm{str}}(m, w, R).$$

Substituting $(w, m, \alpha'/R)$ into the expressions for p_L, p_R gives the two asserted transformations, respectively. □

Conjugation fixes what it means to express the same result in a dimensional chart. In the elliptic family, the radii are

$$R = \sqrt{\alpha'}R_\star, \qquad R^\vee = \sqrt{\alpha'}R_\star^{-1}.$$

Their product is α'. The internal determination of the dimensionless semiaxis ratio and the length-squared scale of the realization serve different functions: the former fixes the shape; the latter expresses its radii in a dimensional unit.

The preceding normalization allows the same result to be expressed with normalized or physical radius. Assigning a tension and a unit to α' belongs to the realization map and has its own origin; it is not a datum entering the production of APP–TRIT–TPK registers.

24.6.6 Relationship with the modular transformation

Radius inversion has a precise representation on the imaginary axis of the upper half-plane. Let $\iota(R_0) = \mathrm{i}R_0^2$ and $\mathsf{S}(\tau) = -1/\tau$. Then

$$\mathsf{S} \circ \iota(R_0) = \iota(R_0^{-1}). \tag{24.42}$$

The equality follows from $-1/(\mathrm{i}R_0^2) = \mathrm{i}R_0^{-2}$. For the modular function $J = j - 744$, whose invariance is preserved in the Moonshine development, it follows that $J(\mathrm{i}R_0^2) = J(\mathrm{i}R_0^{-2})$.

The map ι expresses a semiconjugacy of parameters. The interchange U_T acts on the coordinates of $\ell^2(\mathbb{Z}^2)$; S acts on the upper half-plane; the dual automorphism of an orbifold acts on its graded sectors. Writing their domains allows specific relations between them to be composed while preserving the information of each representation. Theorems 24.31, 24.33 and 24.34 establish, respectively, unitary conjugation, change of residual section and scale normalization, with the declared operator domains.

Chapter 25

Coordination of the Moonshine corridor and the M-theory screens: shared grading, lattice transport and double realization of the HMT state

The integers 10, 11, 24, and 26 arise in the construction through different algebraic procedures: the length of a code, the dimension of a module, the rank of a lattice, and the dimension of an orthogonal quotient. The purpose of this section is to reconstruct those procedures and the maps that relate them. Equality between integers will not suffice to identify the objects they enumerate.

We shall call an *algebraic screen* a subspace or quotient accompanied by the map that selects it. This denomination does not introduce a new class of spaces: it abbreviates the pair formed by the linear object and its projector or quotient map. With this convention, the reductions

$$12 \longrightarrow 11 \longrightarrow 10, \qquad 26 \longrightarrow 24$$

are statements about defined maps, not numerological decompositions. The first chain arises from a representation of A_5 marked by the dodecaphasic vector K; the second, from an isotropic reduction of a Lorentzian lattice. Both rely on the exceptional branch constructed in the preceding sections, but they are not the same mechanism.

25.1 The perfect quotient of 11 coordinates

Let

$$C_W = [12, 6, 6]_3$$

the extended ternary Golay code. Puncturing a coordinate produces the ternary Golay code

$$G_{11} = [11, 6, 5]_3 \subset \mathbb{F}_3^{11}$$

[91]. The length eleven belongs here to the ambient space of the code; it is not introduced through a physical interpretation.

Definition 25.1 (Ternary ball)**.** For $x \in \mathbb{F}_3^n$ and $t \geq 0$, the Hamming ball of radius t centered at x is

$$B_t(x) = \{y \in \mathbb{F}_3^n : d_H(x, y) \leq t\}.$$

Its cardinality, independent of x, is

$$V_3(n, t) = \sum_{j=0}^{t} \binom{n}{j} 2^j.$$

Theorem 25.2 (Perfection of G_{11})**.** *The Hamming balls of radius two centered at the words of G_{11} constitute a partition of $\mathbb{F}_3^{11}$. In particular,*

$$V_3(11, 2) = 243, \qquad |G_{11}|\, V_3(11, 2) = 3^{11}.$$

Proof. The minimum distance of G_{11} is five. If two balls of radius two, centered at distinct words $c, c' \in G_{11}$, had a common element y, the triangle inequality would give

$$d_H(c, c') \leq d_H(c, y) + d_H(y, c') \leq 4,$$

in contradiction with $d_H(c, c') \geq 5$. The balls are therefore disjoint. Their cardinality is

$$V_3(11,2) = \binom{11}{0} + 2\binom{11}{1} + 2^2\binom{11}{2} = 1 + 22 + 220 = 243 = 3^5.$$

Since G_{11} has dimension six, it contains 3^6 words. In consequence,

$$3^6 V_3(11,2) = 3^6 \cdot 3^5 = 3^{11} = |\mathbb{F}_3^{11}|.$$

The disjoint union of the balls has the cardinality of the ambient space and therefore coincides with it. □

Perfect decoding assigns to each received word a unique codeword at distance at most two. Equivalently, the syndrome space has $3^{11-6} = 243$ elements. This occurrence of 243 must be distinguished from the cubic layer

$$3 \cdot 9^2 = 243$$

of the completion $1000 = 729 + 243 + 27 + 1$. One quantity enumerates syndromes of a code; the other enumerates positions in a boundary layer. Equality of cardinalities authorizes a comparison, but does not provide a canonical bijection between the two realizations.

It is also convenient to separate the metric partition

$$243 = 1 + 22 + 220$$

of the typed identity

$$243 = 1 + 22 + 90 + 120 + 10.$$

In the second expression, $90 = 6\binom{6}{2}$ and $120 = 8\binom{6}{2}$ count families of incidences in the hexad–octad extension, whereas 10 will be the dimension of a linear screen. They are not subsets of weights $0, 1, 2$ of the same Hamming ball. The construction of designs underpinning that extension belongs to the classical theory of Witt systems [1].

25.2 Dimensional reduction 26→24→11→10 and coordination with M-theory screens

Length eleven is not the only rank that descends from C_W. The same code intervenes in the gluing of the root lattice A_2^{12}, whose rank is twenty-four. After fixing the chamber data and the neighborhood vector constructed in the exceptional branch, the index-three rootless neighbor is the Leech lattice Λ_{24}. The dependency structure is

$$\begin{aligned} C_W &\xrightarrow{\text{puncturing}} G_{11} \subset \mathbb{F}_3^{11}, \\ C_W &\xrightarrow{\text{gluing}} N(A_2^{12}) \xrightarrow{\text{neighbor with index 3}} \Lambda_{24}. \end{aligned} \tag{25.1}$$

The first arrow is a code morphism; the second line belongs to lattice theory. The common ternary source explains the coexistence of ranks eleven and twenty-four without identifying them. In particular, 11 is not a subdimension of 24, nor is 24 obtained by completing the punctured code.

Proposition 25.3 (Range bifurcation)**.** *The construction* (25.1) *produces two invariants of different types:*

$$\operatorname{length}(G_{11}) = 11, \qquad \operatorname{rank}(\Lambda_{24}) = 24.$$

Their common provenance is the code C_W; neither equality implies an isomorphism between the coordinate space of the code and the real space generated by the lattice.

Proof. Puncturing removes one of the twelve positions and does not alter the code's dimension six, whence length eleven. Each copy of A_2 has rank two; therefore, A_2^{12}, its finite-index gluings, and its full-rank neighbors have rank twenty-four. The objects live, respectively, in the categories of codes over $\mathbb{F}_3$ and integral lattices. An isomorphism between them would not even be well typed without an additional functor. □

25.3 Coordination of exact screens with the physical realization of M theory

Reduction $12 \to 11 \to 10$ proceeds from a second realization of the number twelve. Let $V_{12} = \mathbb{R}^{12}$ be the permutation module of A_5 on the twelve vertices of an icosahedron. Denote this representation by ρ and its character by χ_{12}. To fix unambiguously the correspondence with the twelve dodecaphasic positions, we realize the vertices as left cosets A_5/H, where A_5 acts on $\{0,1,2,3,4\}$ and

$$H = \langle (0\ 1\ 2\ 3\ 4) \rangle \cong C_5.$$

The position j is identified with the coset $r_j H$, for the following representatives, written in image notation:

j	r_j	j	r_j	j	r_j
1	$(3,2,4,1,0)$	5	$(3,2,0,4,1)$	9	$(3,1,2,4,0)$
2	$(3,1,0,2,4)$	6	$(4,0,1,2,3)$	10	$(2,1,4,3,0)$
3	$(0,1,3,4,2)$	7	$(4,3,2,1,0)$	11	$(3,4,1,2,0)$
4	$(1,4,2,3,0)$	8	$(0,2,3,1,4)$	12	$(4,2,1,3,0)$

This table is the orientation datum that allows a projector of A_5 to be applied to the vector K; without it, a coordinate norm would depend on an unspecified permutation. In the order of conjugacy classes

$$1A, \quad 2A, \quad 3A, \quad 5A, \quad 5B,$$

the sizes of the classes and the number of fixed points are

	$1A$	$2A$	$3A$	$5A$	$5B$
$\lvert C\rvert$	1	15	20	12	12
χ_{12}	12	0	0	2	2.

Indeed, rotations of orders two and three fix no vertices, whereas each rotation of order five fixes the two vertices of its axis. Write

$$\phi = \frac{1+\sqrt{5}}{2}, \qquad \phi' = \frac{1-\sqrt{5}}{2}, \qquad \phi + \phi' = 1.$$

The relevant part of the character table of A_5 is

	$1A$	$2A$	$3A$	$5A$	$5B$
χ_1	1	1	1	1	1
χ_3	3	-1	0	ϕ	ϕ'
$\chi_{3'}$	3	-1	0	ϕ'	ϕ
χ_4	4	0	1	-1	-1
χ_5	5	1	-1	0	0.

Theorem 25.4 (Decomposition of the Icosahedral Module)**.** *The permutation representation on the twelve vertices decomposes as*

$$V_{12} \cong V_1 \oplus V_3 \oplus V_{3'} \oplus V_5.$$

The subspace orthogonal to the uniform vector is

$$V_{11} := \mathbf{1}^{\perp} \cong V_3 \oplus V_{3'} \oplus V_5$$

and has dimension eleven.

Proof. The multiplicity of an irreducible character χ in χ_{12} is

$$\langle \chi_{12}, \chi \rangle = \frac{1}{60} \sum_{C} |C| \chi_{12}(C) \chi(C).$$

Only $1A, 5A, 5B$ contribute. For the characters of dimensions one, three, three-prime, four, and five one obtains, respectively,

$$\frac{12 + 24 + 24}{60} = 1,$$

$$\frac{36 + 24(\phi + \phi')}{60} = 1, \qquad \frac{36 + 24(\phi' + \phi)}{60} = 1,$$

$$\frac{48 - 24 - 24}{60} = 0, \qquad \frac{60}{60} = 1.$$

Therefore, the multiplicities are $(1, 1, 1, 0, 1)$. The only vector fixed by all permutations is the uniform vector $\mathbf{1} = (1, \dots, 1)$. Its orthogonal complement contains the three nontrivial summands and has dimension $3 + 3 + 5 = 11$. □

The orthogonal projector onto V_{11} is explicit:

$$P_{11} = I_{12} - \frac{1}{12} J_{12},$$

where J_{12} is the matrix all of whose entries are one. Thus, the first reduction is the map

$$\mathbb{R}^{12} \longrightarrow V_{11}, \qquad x \longmapsto x - \frac{1}{12} \Big(\sum_{j=1}^{12} x_j \Big) \mathbf{1}.$$

This formula specifies which information is eliminated: exclusively the uniform component. The equality $12 = 1 + 11$ is a consequence of the decomposition of the module, not a dimensional convention.

25.4 Polarization of the three-dimensional sector determined by K

Consider the already obtained dodecaphasic vector,

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601), \qquad \sum_{j=1}^{12} K_j = 6263.$$

Its zero-sum component is

$$\widetilde{K} = P_{11} K = K - \frac{6263}{12} \mathbf{1}.$$

To select one of the two three-dimensional representations, we use the position–coset bijection fixed in the preceding table. The corresponding central projector is written

$$P_{\mathrm{ico},3} = \frac{3}{60} \sum_{g \in A_5} \chi_3(g^{-1}) \rho(g).$$

The sum contains permutation matrices and coefficients in $\mathbb{Q}(\sqrt{5})$; consequently, $P_{\mathrm{ico},3}$ is an exact operator over that field, satisfies $P_{\mathrm{ico},3}^2 = P_{\mathrm{ico},3} = P_{\mathrm{ico},3}^{\mathsf{T}}$, and has rank three.

Definition 25.5 (Polarizing Direction)**.** The icosahedral projection of the vector and the line that generates it are

$$u_K = P_{\mathrm{ico},3}\widetilde{K}, \qquad \ell_K = \mathbb{R}u_K.$$

Lemma 25.6 (No polarization degeneracy)**.** *For the vector K and the declared position–coset correspondence,*

$$\|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0.$$

In particular, ℓ_K is a well-defined line.

Proof. Upon substituting the expression for $P_{\mathrm{ico},3}$ into $\|u_K\|^2 = \widetilde{K}^{\mathsf{T}} P_{\mathrm{ico},3}\widetilde{K}$, the sum reduces to

$$\frac{3}{60}\sum_{g\in A_5} \chi_3(g^{-1})\, \widetilde{K}^{\mathsf{T}}\rho(g)\widetilde{K}.$$

Each scalar product is rational, since $\rho(g)$ is a permutation matrix and $\widetilde{K} \in \mathbb{Q}^{12}$. The separation of the two classes of order five leaves as the only irrational part a multiple of $\sqrt{5}$. The exact sum of the sixty terms is

$$\frac{6638585}{20} + \frac{2275584}{20}\sqrt{5}.$$

Both coefficients are positive and $\sqrt{5} > 0$; therefore, the norm does not vanish. □

Exact enumeration of the group and the twelve lateral classes reconstructs the projector onto $\mathbb{Q}(\sqrt{5})$, verifies its idempotence, and produces the preceding norm.

Theorem 25.7 (Polarized reduction $11 \to 10$)**.** *Let*

$$V_{10} := (V_3 \cap \ell_K^{\perp}) \oplus V_{3'} \oplus V_5.$$

Then

$$V_{11} = \ell_K \oplus V_{10}, \qquad \dim V_{10} = 10.$$

The projector onto the ten-dimensional screen is

$$P_{10} = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2}.$$

Proof. By the lemma 25.6, $u_K \neq 0$ and, by definition, $u_K \in V_3$. Hence

$$V_3 = \ell_K \oplus (V_3 \cap \ell_K^{\perp}).$$

Al anadir the sumandos orthogonal $V_{3'}$ and V_5, the theorem 25.4 gives

$$V_{11} = \ell_K \oplus \big((V_3 \cap \ell_K^{\perp}) \oplus V_{3'} \oplus V_5\big).$$

The dimension of the second summand is $2 + 3 + 5 = 10$. The formula for P_{10} subtracts from P_{11} the rank-one orthogonal projector onto ℓ_K, so its image is precisely V_{10}. □

Corollary 25.8 (Exact Decomposition 1 + 3 + 7)**.** *Let*

$$W_7(K) := (V_3 \cap \ell_K^{\perp}) \oplus V_5.$$

Then

$$\boxed{V_{11} = \ell_K \oplus V_{3'} \oplus W_7(K), \qquad \dim(\ell_K, V_{3'}, W_7) = (1, 3, 7),}$$

and

$$\boxed{V_{10} = V_{3'} \oplus W_7(K), \qquad 10 = 3 + 7.}$$

Proof. $\ell_K \subset V_3$ is a line, so that $\dim(V_3 \cap \ell_K^{\perp}) = 2$. Therefore, $\dim W_7 = 2 + 5 = 7$, and the two decompositions follow from the theorem 25.7. □

Remark 25.9 (Condition additional for the reading 1 + 3 + 6). The exact decompositions 1 + 3 + 7 and 3 + 7 do not by themselves select a time, an extended three-dimensional space, or a compact sector of rank six. A physical realization must choose a line $\ell_t \subset W_7(K)$, prove

$$W_7(K) = \ell_t \oplus W_6,$$

construct a full-rank lattice $\Lambda_6 \subset W_6$ that is stable under transport, interpret W_6/Λ_6 as the compact sector, and exhibit an intertwiner between the TRIT temporal reader, W_6, and that lattice. The same transport must separately preserve the three extended directions of the summand $V_{3'}$, without mixing them with ℓ_t or with the compact quotient. Only under those hypotheses are the decompositions obtained

$$\boxed{V_{11} = \ell_K \oplus \ell_t \oplus V_{3'} \oplus W_6, \qquad 11 = 1 + 1 + 3 + 6,}$$

$$\boxed{V_{10} = \ell_t \oplus V_{3'} \oplus W_6, \qquad 10 = 1 + 3 + 6.}$$

The absence of a natural choice of ℓ_t, stability of Λ_6, full rank, separation of the three extended directions, or the intertwiner would refute this realization, without altering the algebraic corollary 1 + 3 + 7.

The reduction is not A_5-equivariant in the absence of the marked datum. The submodule V_3 is irreducible and contains no A_5-invariant line; the direction ℓ_K appears after introducing K. The sequence

$$12 \longrightarrow 11 \longrightarrow 10$$

therefore has two distinct natures: the passage $12 \to 11$ is canonical for the permutation action, whereas $11 \to 10$ is a polarization relative to the vector K and to the declared position–lateral-class correspondence.

25.5 Operatorial representation of APP and supersymmetric spectral triple in dimension 11

Let U be the integral hyperbolic plane with basis e_+, e_- and Gram matrix

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

It is an even, unimodular lattice of signature $(1, 1)$. The lattice

$$L_{26} := \Lambda_{24} \oplus U$$

is even, unimodular, and of signature $(25, 1)$; by the classification of even unimodular indefinite lattices, it is identified with $II_{25,1}$ [34].

The adjective *Lorentzian* is used in an algebraic sense: it indicates the presence of a negative direction in the bilinear form. The terminology comes from Lorentz and Minkowski geometry [81, 89]; it does not by itself identify the lattice with a physical spacetime.

Theorem 25.10 (Null reduction)**.** *For the primitive isotropic vector $e_+ \in U$, there exists a canonical isomorphism, once the decomposition $L_{26} = \Lambda_{24} \oplus U$ has been fixed,*

$$e_+^\perp / \mathbb{Z}e_+ \cong \Lambda_{24}.$$

Proof. Every element of L_{26} can be written uniquely as $x = \lambda + ae_+ + be_-$, with $\lambda \in \Lambda_{24}$ and $a, b \in \mathbb{Z}$. Since the sum is orthogonal and $\langle e_-, e_+ \rangle = 1$,

$$\langle x, e_+ \rangle = b.$$

Therefore,

$$e_+^\perp = \Lambda_{24} \oplus \mathbb{Z}e_+.$$

The quotient by $\mathbb{Z}e_+$ removes the second summand and preserves the first, thereby defining the asserted isomorphism. □

The dimension decreases by two because the orthogonality condition eliminates one direction and the quotient eliminates the remaining null direction. This is not an orthogonal projection onto a positive complement: an isotropic line is contained in its own orthogonal complement. This is the algebraic reason why the correct procedure is $e_+^\perp / \mathbb{Z}e_+$.

The matrix of the plane U formally coincides with the matrix that exchanges the two sectors of bidirectional transport. Adopting it as a Gram form establishes a concrete lattice realization of that involutor. The reduction theorem 25.10 is then exact within that realization; the matrix coincidence, by itself, does not identify the lattice with a physical spacetime.

This ambient space is also the one used in the Borcherds construction: the central-charge twenty-four sector is combined with the rank-two Lorentzian plane before the reduction leading to the Monster Lie algebra [15]. The relation relevant here is the explicit lattice quotient; vertex operator algebra theory follows the classical corridor described above.

25.6 Icosahedral McKay correspondence and type E_8

Three occurrences of the integer eight are involved near this boundary:

$$8_{\mathrm{oct}} = |O_H|, \qquad V_8 := V_{3'} \oplus V_5, \qquad \mathrm{rank}(E_8) = 8.$$

The first is the cardinality of an octad in the Witt system; the second is a real module of A_5; the third is the rank of a root system. They are not instances of a single object. The relevant classical bridge passes through the binary icosahedral group:

$$A_5 \longleftarrow 2A_5 \subset SU(2) \xrightarrow{\text{McKay}} \widetilde{E}_8$$

[88]. In the McKay correspondence, the vertices of the affine diagram encode irreducible representations of $2A_5$, and the edges describe the decomposition of the tensor product with the natural two-dimensional representation. This construction explains why the icosahedron and E_8 are related; it does not identify a Witt octad with the module V_8, or either of them with the lattice E_8.

Proposition 25.11 (Categorical separation of three value-eight invariants)**.** *No equality among the three preceding invariants defines an interlinker by itself. To relate two of them one needs, respectively, a map*

from incidence sets to modules, from modules of A_5 to modules of $2A_5$, or from representations to lattice data.

Proof. The cardinality of a set, the dimension of a vector space, and the rank of a lattice are invariants in different categories. An isomorphism in one of them is not defined for objects in the others. The McKay correspondence provides one of the intermediate functors, but not the remaining ones; the coincidence of the integer eight is therefore insufficient. □

25.7 Dimensional reduction and the context of M-theory

The preceding constructions produce two exact occurrences of eleven. The first is the length of the perfect code G_{11}; the second is the dimension of the active module $V_{11} = \mathbf{1}^{\perp}$. These objects are not identified: one is defined over $\mathbb{F}_3$ and the other over $\mathbb{R}$. Reduction to ten belongs exclusively to the latter and depends on the marked line ℓ_K.

Eleven-dimensional supergravity and the network of dualities that led to the formulation of M-theory provide the physical context in which an eleventh-dimensional direction can be compactified and produce ten-dimensional theories [26, 64, 135, 124]. The dimensional correspondence suggested by the HMT construction is organized in the following dictionary:

Objeto algebraico	**Dato requerido en una realización física**
$V_{11} = \ell_K \oplus V_{10}$	una dirección compacta y una pantalla de diez dimensiones con un mapa de campos definido
$(m, w, R_0) \mapsto (w, m, R_0^{-1})$	sectores de momento y enrollamiento, radio físico y escala de cuerda
$\Lambda_{24} \oplus U \cong II_{25,1}$	una interpretación dinámica del sector reticular lorentziano
$C_W \to G_{11}$ y $C_W \to \Lambda_{24}$	un entrelazador que preserve incidencia, acción y espectro

In eleven-dimensional supergravity, a complete realization must include, at least, the metric field g_{MN}, the three-form C_{MNP}, the gravitino ψ_M, its action, and its supersymmetry transformations. For the screen $V_{11} = \ell_K \oplus V_{10}$ to represent a physical compactification, a map is required that sends those fields to data on ℓ_K and V_{10} and that preserves the dynamics and the low-energy limit. None of those fields enters as a hypothesis in the theorems 24.2, 25.2, 25.7 y 25.10.

Consequently, the interface has two clearly differentiated levels. At the algebraic level, perfection of the code, the decomposition $12 = 1 + 3 + 3' + 5$, the polarization $11 = 1 + 10$, the isotropic reduction $26 \to 24$, and the radius involution are proved. At the physical level, these structures provide a domain and compatibility equations for constructing a dictionary with M-theory. The second task adds fields and dynamics; it neither modifies nor is used to prove the first level.

25.8 Quotient Diagrams and Rank Reductions

The rank diagram can be summarized without losing its types:

$$\begin{array}{ccc} & C_W = [12,6,6]_3 & \\ \swarrow & & \searrow \\ G_{11} \subset \mathbb{F}_3^{11} & & N(A_2^{12}) \longrightarrow \Lambda_{24} \end{array}$$

$$\begin{array}{c} V_{12} = \mathbb{R}^{12} \\ \downarrow P_{11} \\ V_{11} = V_3 \oplus V_{3'} \oplus V_5 \\ \downarrow P_{10}(K) \\ V_{10} \end{array}$$

$$\begin{array}{c} II_{25,1} = \Lambda_{24} \oplus U \\ \downarrow \ e_+^{\perp}/\mathbb{Z}e_+ \\ \Lambda_{24}. \end{array}$$

The arrow P_{11} eliminates the uniform mode; $P_{10}(K)$ eliminates the direction selected by K; the null reduction eliminates an isotropic pair by means of orthogonal complement and quotient. The involution T acts on an enlarged lattice domain and relates reciprocal radii. These are the mathematical mechanisms supporting the dimensional interface. Their explicit formulation makes it possible to distinguish precisely the rank theorems from the physical interpretations that may be built upon them.

25.9 From exact screens to the physical interface of M-theory

The first part constructed, in explicit mathematical domains, the reductions

$$12 \longrightarrow 11 \longrightarrow 10, \qquad 26 \longrightarrow 24,$$

and the moment, winding, and radius involutions

$$(m, w, R) \longleftrightarrow (w, m, R^{-1}).$$

These results are not yet a physical theory of strings nor an action of supergravity. They constitute the screens and equivalences that a dimensional realization must respect.

The interface is typed via a map declared

$$\mathcal{R}_M : \mathcal{X}_{\mathrm{HMT}}^{\mathrm{enr}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}},$$

whose codomain must carry, at a minimum, the metric field g_{MN}, the three-form C_{MNP}, the gravitino ψ_M, its action, and the supersymmetry transformations. A specialization to strings further requires identification of the physical radius, tension, momentum and winding sectors, and the state space on which T-duality is realized. A conformal or CFT reading requires its own operator algebra, grading, and state–operator correspondence.

The positive connection with the exceptional branch is not a bare arrow Monster→M-theory. Both prolongations preserve data from the same enriched state—phase, grading, orientation, sewing, and memory— but employ distinct functors. In the exceptional branch, those data reach $V^\natural$, the Monster, and Moonshine; in the dimensional branch they feed the screens and, only through $\mathcal{R}_M$, a possible realization of fields and strings.

Definition 25.12 (Internal Admissibility of a Compactification)**.** A candidate compactification is represented by a triple

$$(x_\infty, \kappa, \mathcal{U}),$$

where $x_\infty \in \mathcal{X}_{\mathrm{HMT}}^{\mathrm{enr}}$ is a surviving section,

$$\kappa : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \dashrightarrow \mathcal{M}$$

is the possibly partial map into a declared moduli space $\mathcal{M}$, and $\mathcal{U}$ transports metric, orientation, register and boundary data. We define

$$\mathrm{Adm}_{\mathrm{HMT}}(x_\infty, \kappa, \mathcal{U}) = 1$$

if the following four conditions hold:

1. the section has a compatible extension to every depth;
2. the declared dualities are compatible at the point considered:

$$\kappa(\mathsf{T}_{\mathrm{HMT}} x_\infty) = \mathsf{T}_{\mathcal{M}}(\kappa(x_\infty)),$$

   when both sides are defined;
3. the spectrum descends to the compactification quotient;
4. the observables preserve their domains, codomains, and types under $\mathcal{U}$.

This predicate is an internal admissibility criterion and not an automatic identification with the physical *Swampland*. The distance, tower, weak-gravity, and absence-of-global-symmetries criteria, as well as the geometric conditions of a specific compactification, are subsequently evaluated on $\mathrm{im}\,\kappa$ and require the corresponding metric maps, fields, and scales. The preceding definition fixes the interface that a realization must preserve; it does not by itself prove the existence of a physical compactification or a Swampland conjecture.

Status of the interface

The screens, the quotients, and the T-dual involution are exact mathematical results. The complete dictionary toward $(g_{MN}, C_{MNP}, \psi_M)$, the action, supersymmetry, and a physical CFT is a typed interface that must be verified in each realization. This boundary neither diminishes the mathematical result nor authorizes its presentation as already completed physical dynamics.

25.10 Polyakov Action, T Duality, and Compactification of the HMT State in M-Theory Branes

25.10.1 Extended persistence and world surface

A physical string is an extended one-dimensional object whose evolution sweeps out a worldsheet. Each point of the string has an internal coordinate, and each instant adds a temporal coordinate; their combination forms the domain on which the induced metric, tension, and background fields live. A closed string has a circular spatial section. An open string has endpoints subject to boundary conditions. Its vibrations organize states, and its tension converts the area traversed by the worldsheet into action.

A brane of dimension p is an extended object whose history forms a worldvolume of dimension $p + 1$. Branes receive string endpoints, carry fields on their volume, and may wrap cycles of a compact space. This definition fixes three different data: the dimension of the object, the dimension of its history, and the conditions governing its boundary. The tension, charges, and spectrum belong to the dynamical realization that completes those geometric data.

HMT reaches this boundary from an architecture of persistent routes. A route preserves the orientation, sheet, phase, quotient, carry, and memory of the crossings that have prolonged it. The passage to an extended object assigns that genealogy to a section distributed over an internal coordinate. The composition of routes is then effected by sewing segments; the boundary memory records windings and intersections; the action measures the complete persistence over the traversed surface. This map preserves the causal order: first the enriched state is constructed, and its realization as a string, brane, or field is declared thereafter.

The Polyakov action provides a precise form for the physical codomain:

$$S_{\mathrm{P}}[X,h] = -\frac{T}{2}\int d^2\sigma\,\sqrt{-h}\,h^{ab}g_{MN}(X)\partial_a X^M\partial_b X^N.$$

Here T is the tension, h_{ab} the worldsheet metric and X^M the map into the target space. An HMT string realization must produce these objects, their state space and their symmetries from a typed map; the route structure supplies the genealogical domain on which that map acts.

25.10.2 Exact screens in dimensions 11, 10, 26 and 24

The first screen starts from the extended ternary code $C_W = [12,6,6]_3$. Puncturing one coordinate produces the code $G_{11} = [11,6,5]_3$. Its Hamming balls of radius two have cardinality

$$V_3(11,2) = 1 + 22 + 220 = 243 = 3^5,$$

and the 3^6 codewords satisfy

$$3^6 V_3(11,2) = 3^{11}.$$

Therefore, these balls partition the ambient space exactly. The integer eleven here measures the length of a perfect code and retains its combinatorial type.

A second screen uses the real permutation module V_{12} associated with the twelve icosahedral vertices. The complement of the uniform vector decomposes as

$$V_{11} = V_3 \oplus V_{3'} \oplus V_5.$$

The dodecaphase state K polarizes a line $\ell_K \subset V_3$ and determines the projector

$$P_{10} = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2}.$$

From it descend the exact decompositions.

$$V_{11} = \ell_K \oplus V_{10}, \qquad V_{10} = V_{3'} \oplus W_7(K),$$

with dimensions $11 = 1 + 3 + 7$ and $10 = 3 + 7$. The step $12 \to 11$ eliminates the uniform mode; the step $11 \to 10$ eliminates the direction marked by K. A physical compactification adds a temporal line, a stable rank-six lattice, and the transport that preserves the three extended directions.

The third screen starts from the lattice

$$L_{26} = \Lambda_{24} \oplus U \cong II_{25,1},$$

where U is the integral hyperbolic plane. For a primitive isotropic vector e_+, the reduction

$$e_+^{\perp}/\mathbb{Z}e_+ \cong \Lambda_{24}$$

is exact. The orthogonality condition removes one direction and the quotient removes the null direction contained in its orthogonal complement; the result is rank twenty-four. Code, real module, and lattice belong to distinct categories. Their explicit maps make it possible to relate their ranks while preserving the provenance of each.

The incidence between the six faces and the eight vertices of the cube also provides a screen of spatial and temporal signature. If M is its incidence matrix, then

$$MM^{\mathsf{T}} = 12P_u + 4P_-.$$

The quotient by the kernel has rank four and decomposes as $1 \oplus 3$. Upon declaring the uniform line to be the temporal direction, the normalized form becomes $\mathrm{diag}(-1, 1, 1, 1)$. The incidence proves the rank and the spectral ratio; the declared orientation fixes the signature.

25.10.3 Moment, winding and reciprocal radius

In a compact coordinate of radius R, the integer m records momentum and the integer w records winding. The form

$$E_R(m, w) = \frac{m^2}{R^2} + w^2 R^2$$

has the involution

$$\mathsf{T}(m, w, R) = (w, m, R^{-1}), \qquad E_R(m, w) = E_{R^{-1}}(w, m).$$

In $\ell^2(\mathbb{Z}^2)$, the exchange $U_T|m, w\rangle = |w, m\rangle$ provides the unitary equivalence

$$U_T H(R) U_T^{-1} = H(R^{-1}).$$

This is the algebraic residence of radius duality: momentum and winding are two reciprocal readings of the same lattice sector. The realization as T-duality incorporates the string scale, the oscillators and the action on the physical state space. At the self-dual radius both readings share the same scale and the exchange acts within the same spectrum.

25.10.4 Interface in dimension 11: spectral triple, supersymmetry and operator $Q^2 = H$

M-theory organizes an eleven-dimensional physical codomain with metric g_{MN}, three-form C_{MNP}, gravitino ψ_M, action, and supersymmetry transformations. The bridge is written as a map

$$\mathfrak{R}_M : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \longrightarrow \mathcal{X}^{\mathrm{phys}}_{11}.$$

Its source preserves phase, orientation, sewing and memory; its codomain adds the fields and the eleven-dimensional dynamics. The compactification of one direction must transport these fields to a ten-dimensional screen, preserve the low-energy limit and intertwine the declared dualities.

A candidate compactification is typed by a triple $(x_\infty, \kappa, \mathcal{U})$. Section x_∞ represents a prolongable persistence; κ carries it to a moduli space; $\mathcal{U}$ transports metric, orientation, register, and boundary. Its admissibility requires prolongation to every depth, commutation with duality, descent of the spectrum to the quotient, and preservation of the domains and codomains of the observables. These conditions convert an analogy of ranks into a verifiable mathematical problem.

Strings appear after compactifying the eleven-dimensional sector; branes appear as extended realizations coupled to the three-form and its duals. The exceptional branch that reaches Λ_{24}, $V^\natural$, and the Monster preserves the same enriched source through another functor. The dimensional and exceptional interfaces are distinct prolongations of a common genealogy, each with its own codomain.

Result

The perfection of G_{11}, the polarization $11 \to 10$, the isotropic reduction $26 \to 24$, the cubic screen of signature $(3, 1)$ and the radius involution are proven algebraic results. Together they form the exact residence of ranks, quotients and dualities on which the interface toward strings, branes and M-theory is built.

Physical realization

An extended history preserves position, winding, orientation, and boundary within a single persistence. Compactification determines which directions appear as macroscopic extension and which act as

internal degrees. The string reads that persistence on a worldsheet; the brane reads it on a worldvolume; M-theory coordinates both readings through eleven-dimensional fields.

Boundary of validity

The realization is falsified if the map $\mathfrak{R}_M$ alters the types of the screens, if the duality ceases to act unitarily on the spectrum, if the compactification loses prolongation, or if the fields fail to satisfy the action and supersymmetry. Physical closure requires tension, oscillators, amplitudes, controlled anomalies, and a coherent gravitational limit for each declared compactification.

25.11 operatorial extension of APP and spectral triad of the supersymmetric interface in dimension 11

The screens $11 \to 10$, the isotropic reduction $26 \to 24$, and the involution between momentum and winding provide the exact algebraic support of the interface. The physical dynamics adds a state space, a Hamiltonian, and a supercharge. These data are assembled into the triple

$$\mathfrak{M} = \big(\mathcal{H}_{\text{phys}}, H, Q\big),$$

where $\mathcal{H}_{\text{phys}}$ is a $\mathbb{Z}_2$-graded Hilbert space,

$$\mathcal{H}_{\text{phys}} = \mathcal{H}_+ \oplus \mathcal{H}_-,$$

H is a nonnegative self-adjoint operator compatible with the transports, and Q is an odd operator. The supercharge relation is

$$Q^2 = H, \qquad [H, Q] = 0. \tag{25.2}$$

The equality implies that Q exchanges the graded sectors and that the Hamiltonian preserves each of them.

25.11.1 Operatorial extension of the APP–TRIT–TPK state toward the triad $(\mathcal{H}_{\text{phys}}, H, Q)$

Enriched APP simultaneously preserves the residues and quotients of the additive and multiplicative sheets:

$$\mathcal{A}_9^\sharp = \big(R^+, Q^+; R^\times, Q^\times\big).$$

TRIT adds temporal orientation and the Topological Phase Kernel preserves phase, route, carry, boundary, and memory. Let $\mathcal{H}_{\text{HMT}}$ be the linear space generated by these enriched states. A compatible operatorial realization is a map

$$W : \mathcal{H}_{\text{HMT}} \longrightarrow \mathcal{H}_{\text{phys}}$$

which preserves the grading, transports the residue and quotient observables, and intertwines the bidirectional involution with radius duality. For the operators defined on both domains, compatibility requires

$$W\, U_T^{\text{HMT}} = U_T^{\text{phys}}\, W, \qquad W\, H_{\text{HMT}} = H\, W.$$

This arrow does not identify the two spaces by decree: it specifies the datum that the genealogy must preserve when passing from the discrete construction to its physical realization.

25.11.2 Compaction and undecadimensional physical codomain

The realization in dimension 11 has as codomain a space

$$\mathcal{X}_{11}^{\mathrm{phys}}$$

equipped with a metric g_{MN}, a 3-form C_{MNP}, a gravitino ψ_M, an action, and supersymmetry transformations. The gluing ℓ_K produces the exact decomposition

$$V_{11} = \ell_K \oplus V_{10},$$

and the compactification must induce on $\mathcal{H}_{\mathrm{phys}}$ the corresponding spectral decomposition. The duality T also requires

$$U_T H(R) U_T^{-1} = H(R^{-1}).$$

The string worldsheet and brane worldvolumes then provide the extended realizations of the same genealogical antecedent.

25.11.3 Spectral compatibility of $(\mathcal{H}_{\mathrm{phys}}, H, Q)$ with $Q^2 = H$, T-duality, and $11 \to 10$ compactification

A realization satisfies the interface when it jointly preserves:

1. the grading of $\mathcal{H}_{\mathrm{phys}}$ and the identity $Q^2 = H$;
2. the Polyakov action and the boundary conditions of the worldsheet;
3. the polarization $11 \to 10$ and the isotropic reduction $26 \to 24$;
4. the exchange of momentum and winding under $R \leftrightarrow R^{-1}$;
5. the descenso of the campos g_{MN}, C_{MNP} and ψ_M to the limite compactificado;
6. the phase, route, orientation, carry, and boundary memory of the APP–TRIT–TPK state.

The screen identities and the radius involution are exact in their algebraic domains. The ternary $(\mathcal{H}_{\mathrm{phys}}, H, Q)$, the action, and the eleven-dimensional fields fix, separately and explicitly, the data of the physical interface.

25.12 Boundary systems, dimensional range, and action functional

In Dimensional Mechanics, dimension is obtained from the number of independent channels available at a boundary. It is not appended as an external label to the state space: it is computed as the rank of a module of prolongations subject to its relations. A change in dimension then corresponds to a variation in rank during transport.

25.12.1 Constraint systems and boundary data

Let

$$\cdots \longrightarrow \mathcal{S}_{n+1} \xrightarrow{r_{n+1,n}} \mathcal{S}_n \longrightarrow \cdots$$

an inverse system of surviving states. The boundary structure at level n is the pair

$$\mathcal{F}_n = (r_{n+1,n}, \beta_n),$$

where β_n preserves the minimum datum necessary to decide the compatibility of a prolongation. Its coordinates may include the arithmetic type, the orientation, the carry cocycle, and the incidence class.

Lemma 25.13 (Compatibility of successive constraints)**.** *Suppose*

$$r_{n+2,n} = r_{n+1,n} \circ r_{n+2,n+1}, \qquad \beta_n \circ r_{n+1,n} = b_{n+1,n} \circ \beta_{n+1}.$$

Then every compatibility condition expressed through β_{n+1} induces a compatible condition at level n.

Proof. For $x \in \mathcal{S}_{n+2}$, equality of compositions identifies the direct restriction with the two consecutive restrictions. The second equality transports the boundary datum through the same diagram. The condition at level n is therefore the image of the deeper condition. □

25.12.2 Module of channels and dimensional range

Fixing a field $\mathbb{K}_n$, let $M_n(x)$ be the module generated by the prolongation channels of x, and let $\mathcal{R}_n(x)$ be the submodule of relations among them.

Definition 25.14 (Dimensional screen)**.** The screen associated with x at level n is

$$\Sigma_n(x) = (\mathbb{K}_n, M_n(x), \beta_n(x), \mathcal{R}_n(x)),$$

and its effective dimension is

$$d_{\Sigma_n}(x) = \dim_{\mathbb{K}_n} \frac{M_n(x)}{\mathcal{R}_n(x)}.$$

If $M_n(x) \cong \mathbb{K}_n^{g_n}$ and the columnas of a matrix $R_n(x)$ generate $\mathcal{R}_n(x)$, then

$$d_{\Sigma_n}(x) = g_n - \operatorname{rank}_{\mathbb{K}_n} R_n(x).$$

When a complement is fixed and $P_n(x)$ denotes the projector whose image is isomorphic to the quotient, the same dimension is $d_{\Sigma_n}(x) = \operatorname{rank}_{\mathbb{K}_n} P_n(x)$.

Proposition 25.15 (Invariance under equivalence of presentations)**.** *The screen dimension is invariant under invertible changes of basis in the generators and in the relations.*

Proof. A change of bases transforms the relation matrix R into URV, with U and V invertible. Since $\operatorname{rank}(URV) = \operatorname{rank} R$, the number $g - \operatorname{rank} R$ does not change. Equivalently, two projectors presenting the same quotient have isomorphic images and therefore the same rank. □

For a transport $T_\gamma : \mathcal{S}_n \to \mathcal{S}_m$, define

$$\Delta d(\gamma; x) = d_{\Sigma_m}(T_\gamma x) - d_{\Sigma_n}(x).$$

A dimensional transition simultaneously transports the state and its channel module; fixed-rank dynamics is the case $\Delta d = 0$.

25.12.3 Inherited arithmetic and lattice screens of HMT

The ranks that occur below are not labels appended to the equations. They arise from distinct linear constructions and preserve their selection maps. The punctured ternary Golay code

$$G_{11} = [11, 6, 5]_3 \subset \mathbb{F}_3^{11}$$

is perfect of radius two [91], since the balls centered at its 3^6 words are disjoint and

$$V_3(11, 2) = 1 + 2\binom{11}{1} + 2^2\binom{11}{2} = 1 + 22 + 220 = 243, \qquad 3^6 \cdot 243 = 3^{11}.$$

Here 243 is the cardinal of the syndrome space. It is not identified by mere numerical equality with the layer of 243 cells of the cubic completion of APP.

The second chain starts from the permutation module $V_{12} = \mathbb{R}^{12}$ of A_5 on the twelve vertices of the icosahedron. To fix the gauge, we let A_5 act on $\{0,1,2,3,4\}$, take $H = \langle (0\ 1\ 2\ 3\ 4) \rangle \cong C_5$ and identify the position j with the left coset $r_j H$. In image notation, the twelve representatives are

j	r_j	j	r_j	j	r_j
1	$(3,2,4,1,0)$	5	$(3,2,0,4,1)$	9	$(3,1,2,4,0)$
2	$(3,1,0,2,4)$	6	$(4,0,1,2,3)$	10	$(2,1,4,3,0)$
3	$(0,1,3,4,2)$	7	$(4,3,2,1,0)$	11	$(3,4,1,2,0)$
4	$(1,4,2,3,0)$	8	$(0,2,3,1,4)$	12	$(4,2,1,3,0)$.

We denote by $5A$ the conjugacy class containing the generator $g_5 = (0\ 1\ 2\ 3\ 4)$ of H, and by $5B$ the class containing g_5^2. In the class order $1A, 2A, 3A, 5A, 5B$, the permutation character is $\chi_{12} = (12, 0, 0, 2, 2)$. For $\phi = (1+\sqrt{5})/2$ and $\phi' = (1-\sqrt{5})/2$, we choose the irreducible character

$$\chi_3 = (3, -1, 0, \phi, \phi').$$

The scalar product of characters gives the exact decomposition.

$$V_{12} \cong V_1 \oplus V_3 \oplus V_{3'} \oplus V_5.$$

The projector

$$P_{11} = I_{12} - \frac{1}{12} J_{12}$$

eliminates exclusively the uniform vector and has image

$$V_{11} = \mathbf{1}^{\perp} \cong V_3 \oplus V_{3'} \oplus V_5.$$

For the dodecaphasic state

$$K = (234, 543, 140, 729, 659, 824, 621, 58, 914, 794, 146, 601), \qquad \sum_j K_j = 6263,$$

let $\widetilde{K} = P_{11} K$. The preceding position–coset correspondence defines the permutation matrices $\rho(g)$, and the central projector

$$P_3 = \frac{3}{60} \sum_{g \in A_5} \chi_3(g^{-1}) \rho(g)$$

satisfies $P_3^2 = P_3 = P_3^{\mathsf{T}}$ and has rank three. Exact evaluation at $\mathbb{Q}(\sqrt{5})$ produces

$$u_K = P_3 \widetilde{K}, \qquad \|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0.$$

Consequently, the line $\ell_K = \mathbb{R} u_K$ is well defined and

$$V_{10} := (V_3 \cap \ell_K^{\perp}) \oplus V_{3'} \oplus V_5, \qquad V_{11} = \ell_K \oplus V_{10}, \qquad \dim V_{10} = 10.$$

The chain $12 \to 11 \to 10$ means, respectively, removing the uniform component and the line polarized by K. The finite set of sixty elements is divided into twelve classes; its enumeration reconstructs the projector and norm exactly.

The reduction $26 \to 24$ belongs to another category. Let U be the integral hyperbolic plane with Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, y sea

$$L_{26} = \Lambda_{24} \oplus U.$$

With the hyperbolic summand fixed, this is the standard presentation of the even unimodular Lorentzian lattice $II_{25,1}$ [34]. For a primitive isotropic vector $e_+ \in U$,

$$e_+^\perp = \Lambda_{24} \oplus \mathbb{Z}e_+, \qquad e_+^\perp/\mathbb{Z}e_+ \cong \Lambda_{24}.$$

The decrease of rank by two comes from imposing orthogonality and then quotienting by the null line. It is not the reduction $11 \to 10$ repeated with other numbers.

25.12.4 Involution between residual data and Euclidean quotient

The decomposition $n = 9Q + r$ suggests two coordinates of different kinds: the residual representative r and the quotient Q. To formulate their exchange on a stable domain, we consider

$$\mathcal{D} = \mathbb{Z}^2 \times \mathbb{R}_{>0}, \qquad E_R(m, w) = \frac{m^2}{R^2} + w^2R^2,$$

and we define

$$\mathsf{T}(m, w, R) = (w, m, R^{-1}).$$

Proposition 25.16 (Residual–Euclidean Duality)**.** T *is an involution and*

$$E_R(m, w) = E_{R^{-1}}(w, m).$$

On $\ell^2(\mathbb{Z}^2)$*, the unitary* $U_T|m, w\rangle = |w, m\rangle$ *satisfies*

$$U_T H(R) U_T^{-1} = H(R^{-1}), \qquad H(R)|m, w\rangle = E_R(m, w)|m, w\rangle.$$

Proof. The second map again exchanges the coordinates and inverts R twice. The energy identity is obtained by direct substitution; the operatorial identity is checked on the orthonormal basis. □

The proposition is an exact lattice duality. The physical reading as momentum, winding, and compactification radius requires an additional map to the state space of a string theory; it does not follow from the algebraic involution [57].

25.12.5 Typed interface with undecadimensional reduction

The screen $V_{11} = \ell_K \oplus V_{10}$ and the involution $(m, w, R) \mapsto (w, m, R^{-1})$ provide the two algebraic data that motivate comparison with the M-theory context: a marked reduction from eleven to ten coordinates and an equivalence of reciprocal radii. For that comparison to be a physical realization, a morphism must be specified

$$\mathcal{R}_M : (\mathcal{X}_{\mathrm{TPK}}, V_{11}, \ell_K, \mathsf{T}) \longrightarrow (\mathcal{H}_M, \mathcal{F}_{10}, R_{\mathrm{phys}}, \alpha', Q_{\mathrm{susy}}),$$

where the codomain includes a state space, ten-dimensional fields, physical radius, string tension, and supersymmetric charges [135]. The algebraic decomposition fixes the domain of $\mathcal{R}_M$; it does not by itself introduce oscillators, branes, supersymmetry, or the supergravity equations.

This separation preserves the depth of the correspondence without altering the types. The reduction $11 \to 10$, the involution of radii, and the quotient $26 \to 24$ are theorems of the objects defined. The assertion that a concrete dynamical theory is their image requires exhibiting $\mathcal{R}_M$ and proving that it intertwines actions, restrictions, and observables.

25.12.6 Dimensional state and simultaneous transport

The state on which Dimensional Mechanics acts is written

$$\mathfrak{x} = (x, \Sigma_n(x), \beta_n(x), [\gamma]),$$

where $x \in \mathcal{X}_{\mathrm{TPK}}$, $\Sigma_n(x)$ is its screen, $\beta_n(x)$ is the boundary datum, and $[\gamma]$ is the class of paths compatible with that datum. A transport does not act only on x: it consists of

$$(T_\gamma, F_\gamma) : (x, \Sigma_n, \beta_n) \longrightarrow (T_\gamma x, \Sigma_m, \beta_m),$$

where $F_\gamma : M_n(x) \to M_m(T_\gamma x)$ maps relations to relations and satisfies the compatibility diagram with β_n, β_m. The dimensional jump is the change in rank of the induced morphism

$$\overline{F}_\gamma : M_n(x)/\mathcal{R}_n(x) \longrightarrow M_m(T_\gamma x)/\mathcal{R}_m(T_\gamma x).$$

This formulation prevents assigning a dimension to the isolated point: the dimension belongs to the system of channels that accompanies the state and its transport.

25.12.7 Descent to a dynamics on point states

Let $q_{\mathrm{pt}} : \mathcal{X}_{\mathrm{TPK}} \to Z$ be a projection that eliminates the genealogy of the state, and define

$$Y_{\mathrm{pt}} := \mathrm{im}(q_{\mathrm{pt}}).$$

Let, moreover, $U : \mathcal{X}_{\mathrm{TPK}} \to \mathcal{X}_{\mathrm{TPK}}$ a evolution complete.

Theorem 25.17 (Fiberwise Descent Criterion)**.** *There exists a unique map $\overline{U} : Y_{\mathrm{pt}} \to Y_{\mathrm{pt}}$ such that $q_{\mathrm{pt}}U = \overline{U}q_{\mathrm{pt}}$ if and only if*

$$q_{\mathrm{pt}}(x) = q_{\mathrm{pt}}(y) \Longrightarrow q_{\mathrm{pt}}(Ux) = q_{\mathrm{pt}}(Uy).$$

Proof. Necessity results by applying $\overline{U}$ to two representatives of one and the same fiber. For sufficiency, one defines

$$\overline{U}(q_{\mathrm{pt}}(x)) = q_{\mathrm{pt}}(Ux).$$

The condition guarantees that the definition does not depend on the representative. Since the codomain has been fixed equal to the image of q_{pt}, the surjectivity required for uniqueness is automatic. □

When the condition fails, a single point class has distinct images; the descended evolution is then multivalued. Retaining the memory datum, restricting the domain, or working with a correspondence are three distinct mathematical modifications.

25.12.8 Additive functional on oriented trajectories

To avoid a hidden path-composition term, the state of an edge is extended by the direction and arithmetic type of the preceding edge. If $\widetilde{e}_j = (e_j, d_{j-1}, t_{j-1})$, define the local weights

$$w_{\mathrm{giro}}(\widetilde{e}_j) = \mathbf{1}_{d_j \neq d_{j-1}}, \qquad w_{\mathrm{tipo}}(\widetilde{e}_j) = \mathbf{1}_{t_j \neq t_{j-1}}.$$

The data (d_0, t_0) form part of the initial boundary condition. For an augmented trajectory $\widetilde{\gamma} = (\widetilde{e}_1, \ldots, \widetilde{e}_R)$, let

$$N_{\mathrm{giro}}(\widetilde{\gamma}) = \sum_{j=1}^{R} w_{\mathrm{giro}}(\widetilde{e}_j), \qquad N_{\mathrm{tipo}}(\widetilde{\gamma}) = \sum_{j=1}^{R} w_{\mathrm{tipo}}(\widetilde{e}_j).$$

We define

$$\mathbf{I}(\widetilde{\gamma}) = (N_{\mathrm{giro}}(\widetilde{\gamma}), N_{\mathrm{tipo}}(\widetilde{\gamma})).$$

The composition is allowed only when the preceding datum of the second path coincides with the terminal datum of the first. With this convention, the partition of the sum into the two edge intervals proves

$$\mathbf{I}(\widetilde{\gamma}\widetilde{\eta}) = \mathbf{I}(\widetilde{\gamma}) + \mathbf{I}(\widetilde{\eta}),$$

so that $\mathbf{I}$ is a cocycle with values in $\mathbb{N}^2$. For $\lambda > 0$, the combination

$$I_\lambda(\widetilde{\gamma}) = N_{\mathrm{giro}}(\widetilde{\gamma}) + \lambda N_{\mathrm{tipo}}(\widetilde{\gamma})$$

is a scalar functional over the path space.

In the ordinary Lagrangian formulation, the action functional is defined on curves in a previously selected configuration space. Here the order is prior: I_λ quantifies changes in direction and arithmetic law in the category of augmented trajectories itself. A realization map may subsequently transport this cocycle into a continuous action. The additivity proved above is the property that permits that comparison without identifying the two functionals in advance.

Principle 25.18 (Minimal interaction)**.** Among admissible trajectories with fixed endpoints and boundary data, the selected evolution minimizes I_λ.

Proposition 25.19 (Finite Existence of Minimizers)**.** *If $\Gamma(a, b)$ is finite and nonempty, I_λ attains a minimum in $\Gamma(a, b)$.*

Proof. The image of a non-empty finite set under a real function has a minimum element. □

The mass character of chapter 90 constitutes another functional on trajectories: it transforms an integer cocycle into a positive ratio. The functional and the mechanism selecting the trajectory are distinct objects; their composition will be specified before introducing a unit of mass.

25.13 Coordinated projections of the HMT state: algebraic equivalence of screens and physical realization in dimension 11

Let $\mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}}$ be the domain preserving phase, orientation, quotient, carry, boundary, incidence, grading, and memory. Its exceptional and screen components are extracted by the canonical projections

$$\varepsilon_{\mathrm{exc}} : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \longrightarrow \mathscr{X}_{\mathrm{exc}}, \qquad \varepsilon_{\mathrm{scr}} : \mathcal{X}^{\mathrm{enr}}_{\mathrm{HMT}} \longrightarrow \mathcal{S}_{\mathrm{HMT}}.$$

The former feeds the already proved construction $\mathcal{P}_{\mathrm{exc}} : \mathscr{X}_{\mathrm{exc}} \to V^{\natural}$. The latter will feed the algebraic morphism $\mathcal{R}^{\mathrm{alg}}_{M}$ constructed below. The joint realization is

$$\mathcal{P}^{M}_{\mathrm{joint}}(x) = \left(\mathcal{P}_{\mathrm{exc}}\varepsilon_{\mathrm{exc}}(x), \mathcal{R}^{\mathrm{alg}}_{M}\varepsilon_{\mathrm{scr}}(x)\right).$$

This map preserves the common antecedent and keeps the codomains distinct.

25.13.1 Exact equivalence of lattice screens and conditions for the realization of undecadimensional structures

The real screen starts from

$$V_{12} \cong V_1 \oplus V_3 \oplus V_{3'} \oplus V_5, \qquad P_{11} = I_{12} - \frac{1}{12}J_{12}.$$

The state K produces $u_K = P_3P_{11}K \neq 0$, the line $\ell_K = \mathbb{R}u_K$, and

$$V_{11} = \ell_K \oplus V_{10}, \qquad \dim V_{11} = 11, \qquad \dim V_{10} = 10.$$

The step $12 \to 11$ removes the uniform mode, and the step $11 \to 10$ removes the line polarized by K.

The lattice screen belongs to another category. For

$$L_{26} = \Lambda_{24} \oplus U \cong II_{25,1}$$

and a primitive isotropic vector $e_+ \in U$,

$$e_+^\perp = \Lambda_{24} \oplus \mathbb{Z}e_+, \qquad \boxed{e_+^\perp/\mathbb{Z}e_+ \cong \Lambda_{24}.}$$

Orthogonality and the quotient eliminate two directions. This theorem is not a repetition of $11 \to 10$ nor an automatic identification with a physical spacetime.

25.13.2 Algebraic screen morphism and quotient equivalence

Let

$$P_{10} := P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2}, \qquad \mathcal{G}_K := \{(v_{11}, v_{10}) \in V_{11} \times V_{10} : v_{10} = P_{10} v_{11}\}.$$

The decomposition $e_+^\perp = \Lambda_{24} \oplus \mathbb{Z}e_+$ defines

$$q_{24} : e_+^\perp \longrightarrow \Lambda_{24}, \qquad q_{24}(\lambda + ae_+) = \lambda.$$

Take

$$\mathcal{S}_{\mathrm{HMT}} := V_{12} \times \mathscr{D}_0 \times e_+^\perp, \qquad \mathcal{S}_M^{\mathrm{alg}} := \mathcal{G}_K \times \mathscr{D}_0 \times \Lambda_{24}.$$

Definition 25.20 (Algebraic screen morphism M)**.** For $d = (m, w, R_0) \in \mathscr{D}_0$, we define

$$\boxed{\mathcal{R}_M^{\mathrm{alg}}(v, d, y) := \big((P_{11}v, P_{10}v), d, q_{24}(y)\big).}$$

Theorem 25.21 (Algebraic Equivalence of Quotient Screens)**.** *The preceding morphism induces an isomorphism*

$$\boxed{\overline{\mathcal{R}}_M^{\mathrm{alg}} : (V_{12}/V_1) \times \mathscr{D}_0 \times (e_+^\perp/\mathbb{Z}e_+) \xrightarrow{\cong} \mathcal{S}_M^{\mathrm{alg}}.}$$

If

$$\tau_{\mathrm{src}}([v], d, [y]) = ([v], \mathsf{T}_0 d, [y])$$

and

$$\tau_{\mathrm{tar}}((v_{11}, v_{10}), d, \lambda) = ((v_{11}, v_{10}), \mathsf{T}_0 d, \lambda),$$

then

$$\overline{\mathcal{R}}_M^{\mathrm{alg}} \tau_{\mathrm{src}} = \tau_{\mathrm{tar}} \overline{\mathcal{R}}_M^{\mathrm{alg}}.$$

The compact energy $E_{R_0}(m, w)$ is preserved under this intertwining and under reciprocal radii.

Proof. The projector P_{11} has kernel V_1 and image V_{11}. Since $P_{10}P_{11} = P_{10}$, the map

$$[v] \longmapsto (P_{11}v, P_{10}v)$$

is an isomorphism of V_{12}/V_1 onto the graph $\mathcal{G}_K$. The map q_{24} is surjective and its kernel is $\mathbb{Z}e_+$, hence it induces the isomorphism $e_+^\perp/\mathbb{Z}e_+ \cong \Lambda_{24}$. The factor $\mathscr{D}_0$ is transported by the identity. The product of these three isomorphisms is $\overline{\mathcal{R}}_M^{\mathrm{alg}}$.

The projectors and q_{24} do not act on d, whereas the two involutions act only through T_0. The square commutes by direct substitution. The energetic invariance is the theorem 24.5. □

The mathematical reduction map, and not merely a correspondence of ranks, is thus constructed. The screen $11 \to 10$, the quotient $26 \to 24$, and radius duality appear as distinct factors of the same morphism.

25.13.3 Physical Recognition Undecadimensional

The interpretation as M-theory is separated by a recognition map.

$$\Xi_M : \mathcal{S}_M^{\mathrm{alg}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}},$$

whose codomain carries at least

$$g_{MN}, \qquad C_{MNP}, \qquad \psi_M,$$

the action and the supersymmetry transformations. An operator completion includes

$$\mathfrak{S}_M = (\mathcal{H}_{\mathrm{phys}}, H, Q), \qquad Q^2 = H,$$

and an isometry

$$W : \mathcal{H}_{\mathrm{HMT}} \longrightarrow \mathcal{H}_{\mathrm{phys}}$$

which, in its common domains, satisfies

$$W\widehat{H} = HW, \qquad W\widehat{Q} = QW, \qquad \widehat{Q}^2 = \widehat{H}.$$

Theorem 25.22 (Physically consistent recognition criterion)**.** *If Ξ_M preserves the inner product, transports the direction ℓ_K to the compact direction, intertwines the duality, and satisfies the preceding operator identities, then the compact physical spectrum is invariant under reciprocal radii and the transported supercharge satisfies $Q^2 = H$ on the image of W.*

Proof. The interlinking of Ξ_M with τ_{tar}, joined to theorem 25.21, transports the unitary involution to the compact sector. For the supercharge,

$$Q^2 W = W\widehat{Q}^2 = W\widehat{H} = HW.$$

The preservation of the inner product converts the transported operator into a unitary equivalence on the image. □

The isomorphism $\overline{\mathcal{R}}_M^{\mathrm{alg}}$ is mathematical and has been proved. Recognition by Ξ_M is a physical interface conditioned on the fields, action, gauge constraints, supersymmetry, oscillators, amplitudes, anomaly control, and low-energy limit of the selected realization. The physical codomain is not identified with $V^\natural$: both receive coordinated information from the same antecedent through distinct functors.

A literal action of $\mathbb{M}$ on digits is not postulated. This sentence is the typing control placed at the end; it does not replace the positive chain that reaches the deep action of $\mathbb{M}$ in $V^\natural$.

25.14 Dimensional screens and coordinated reduction of the state

The ranks appearing in exceptional prolongation and in compactification belong to different objects. To relate them, their presentation is preserved: generators, relations, inner product and selected direction. Dimension is then a consequence of the channel module and its relations. Its transport is formulated through maps acting on that module, in addition to acting on the state that determines it.

25.14.1 Channels, relations and effective dimension

Let $\mathcal{S}_n$ be the set of surviving states at depth n, with compatible restrictions $r_{m,n} : \mathcal{S}_m \to \mathcal{S}_n$, $m \geq n$. The boundary datum $\beta_n(x)$ preserves the information needed to decide the compatibility of a prolongation: sheet, orientation, quotient, memory and incidence class according to the reader considered. The restrictions satisfy

$$r_{\ell,n} = r_{m,n} r_{\ell,m}, \qquad \beta_n r_{m,n} = b_{m,n} \beta_m.$$

These equalities are the naturality conditions of the presentation and retain the same data when restricting in stages or directly.

Definition 25.23 (Channel screen)**.** Given a field $\mathbb{K}_n$, let $M_n(x)$ be the space generated by the prolongation channels and $\mathcal{R}_n(x)$ the subspace of relations. The screen is

$$\Sigma_n(x) = \big(\mathbb{K}_n, M_n(x), \beta_n(x), \mathcal{R}_n(x)\big),$$

and its effective dimension is

$$d_{\Sigma_n}(x) = \dim_{\mathbb{K}_n}\big(M_n(x)/\mathcal{R}_n(x)\big). \tag{25.3}$$

If $M_n(x) \cong \mathbb{K}_n^{g_n}$ and the columns of $R_n(x)$ generate the relations, then $d_{\Sigma_n}(x) = g_n - \operatorname{rank} R_n(x)$.

Proposition 25.24 (Invariance of presentation and transport)**.** *The dimension* (25.3) *is preserved under invertible changes of basis. For two screens over the same field $\mathbb{K}_n = \mathbb{K}_m = \mathbb{K}$, if the linear map $F_\gamma : M_n(x) \to M_m(T_\gamma x)$ sends $\mathcal{R}_n(x)$ into $\mathcal{R}_m(T_\gamma x)$, it uniquely induces a linear map between the screen quotients.*

Proof. A change of generators and relations transforms R into URV, with U, V invertible, and preserves its rank. For descent, define $\overline{F}_\gamma([v]) = [F_\gamma(v)]$. If two representatives differ by a relation, linearity implies that their images differ by a relation of the terminal screen; the map is well defined. Projection to the quotient is surjective and guarantees uniqueness. □

The dimensional change during transport is determined by

$$\Delta d(\gamma; x) = d_{\Sigma_m}(T_\gamma x) - d_{\Sigma_n}(x).$$

This expression preserves the state and its channel presentation. An isolated rank does not allow reconstruction of either the relations or the map that produced it.

25.14.2 Ternary puncturing and syndrome screen

The code $C_W = [12, 6, 6]_3$, constructed from exceptional incidence, produces another screen by puncturing one coordinate. Denote that map by $p : C_W \to \mathbb{F}_3^{11}$ and its image by $G_{11} = p(C_W)$.

Proposition 25.25 (Punctured code and perfect partition)**.** *The map p is injective. The code G_{11} has parameters $[11, 6, 5]_3$, and its Hamming balls of radius 2 partition $\mathbb{F}_3^{11}$.*

Proof. A vector in the kernel of p would have support contained in the single removed coordinate. The minimum distance 6 of C_W excludes any nonzero vector of that form. Thus, the dimension remains 6. Puncturing decreases the weight by at most one, so the minimum distance of the image is at least 5. The balls of radius 2 are therefore disjoint. Each contains

$$1 + 2\binom{11}{1} + 2^2\binom{11}{2} = 1 + 22 + 220 = 243$$

vectors. Since $|G_{11}| = 3^6$ and $3^6 \cdot 243 = 3^{11}$, the balls cover the ambient space. To check that the distance is exactly 5, take a vector of weight 3. Its decoding ball cannot have centre zero and has a centre of weight at most $3 + 2 = 5$; that centre must have weight at least 5. A word of weight 5 is thus obtained. □

The integer $243 = 3^{11-6}$ is here the number of classes of the syndrome quotient $\mathbb{F}_3^{11}/G_{11}$. Its function is fixed by the puncturing and distance of the code; equality of cardinality with another fibre does not replace the map between them. This combinatorial screen and the following real screen retain their own operations.

25.14.3 The dodecaphase direction and rank reduction

The construction of 21.11.5 starts from the register K already obtained by APP–TRIT–TPK and from the representation chart declared on $\mathbb{R}^{12}$. In that chart,

$$V_{11} = \mathbf{1}^{\perp}, \qquad P_{11} = I_{12} - \frac{1}{12}J_{12}, \qquad u_K = P_3 P_{11} K. \tag{25.4}$$

Here J_{12} is the all-ones matrix and P_3 is the isotypic projector specified by the action of A_5. The finite sum defining P_3, its representatives and the generation of K are preserved in the cited section of this same article. In particular,

$$\|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0.$$

The positive norm defines $\ell_K = \mathbb{R}u_K$, and the projector

$$P_{10} = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2} \tag{25.5}$$

has image $V_{10} = V_{11} \cap u_K^{\perp}$.

Proposition 25.26 (Two orthogonal reductions)**.** *The following hold*

$$\mathbb{R}^{12} = \mathbb{R}\mathbf{1} \oplus^{\perp} V_{11}, \qquad V_{11} = \ell_K \oplus^{\perp} V_{10}, \qquad \dim V_{10} = 10.$$

Moreover, $P_{10}P_{11} = P_{10}$, $P_{10}u_K = 0$, and P_{10} is an orthogonal projector.

Proof. Proposition 21.64, proved before constructing the screens, establishes idempotence, symmetry, rank and the two operator identities for this same u_K and this same P_{10}. The first decomposition follows from $P_{11} = I - J_{12}/12$; the second is the orthogonal decomposition of that proposition. This preserves the single proof of the reduction and makes its two stages explicit here. □

The first reduction removes only the uniform mode. The second removes the direction determined by K in the fixed representation. If the chart is simultaneously changed by an orthogonal matrix S, the vector transforms by $u_K \mapsto Su_K$ and the projector by $P_{10} \mapsto SP_{10}S^{-1}$. This covariance preserves the geometric operation, even though its coordinates change.

25.14.4 Lorentzian lattice screen

Let $\Lambda = N_\alpha$ be the Leech lattice constructed in 21.11.9. Consider the integral hyperbolic plane $U = \mathbb{Z}e_+ \oplus \mathbb{Z}e_-$, with

$$\langle e_+, e_+\rangle = \langle e_-, e_-\rangle = 0, \qquad \langle e_+, e_-\rangle = 1.$$

The lattice $L_{26} = \Lambda \oplus U$ is even and unimodular, with signature $(25, 1)$. Each vector is written $y = \lambda + ae_+ + be_-$. Since $\langle y, e_+\rangle = b$,

$$e_+^{\perp} = \Lambda \oplus \mathbb{Z}e_+, \qquad e_+^{\perp}/\mathbb{Z}e_+ \cong \Lambda. \tag{25.6}$$

The quotient map is $q_{24}(\lambda + ae_+) = \lambda$; it is surjective and has kernel $\mathbb{Z}e_+$. The decrease in rank by two comes from an orthogonality restriction followed by an isotropic quotient. It is therefore an operation of a different type from (25.5).

25.14.5 Joint screen morphism

With the domain $\mathscr{D}_0$ of 24.16, let

$$\mathscr{G}_K = \{(v_{11}, P_{10}v_{11}) : v_{11} \in V_{11}\},$$

$$\mathcal{S}_{\mathrm{HMT}} = \mathbb{R}^{12} \times \mathscr{D}_0 \times e_+^{\perp}, \qquad \mathcal{S}_M^{\mathrm{alg}} = \mathscr{G}_K \times \mathscr{D}_0 \times \Lambda.$$

Definition 25.27 (Algebraic map of coordinated screens)**.** It is defined

$$\mathcal{R}_M^{\mathrm{alg}}(v, d, y) = \big((P_{11}v, P_{10}v), d, q_{24}(y)\big). \tag{25.7}$$

Theorem 25.28 (Quotient isomorphism and duality intertwining)**.** *The map* (25.7) *induces an isomorphism*

$$\overline{\mathcal{R}}_M^{\mathrm{alg}} : (\mathbb{R}^{12}/\mathbb{R}\mathbf{1}) \times \mathscr{D}_0 \times (e_+^{\perp}/\mathbb{Z}e_+) \longrightarrow \mathcal{S}_M^{\mathrm{alg}}.$$

It intertwines the transformations acting by T_0 *on the factor* $\mathscr{D}_0$ *and by the identity on the other two factors. The form* $E_{R_0}(m, w)$ *is preserved under that duality.*

Proof. The map $[v] \mapsto P_{11}v$ is an isomorphism from $\mathbb{R}^{12}/\mathbb{R}\mathbf{1}$ onto V_{11}. Since $P_{10}P_{11} = P_{10}$, the map $[v] \mapsto (P_{11}v, P_{10}v)$ identifies that quotient with $\mathscr{G}_K$; its inverse takes the first component and its class. By (25.6), q_{24} induces the lattice isomorphism of the third factor. The second is transported by the identity. The product of the three maps proves the isomorphism.

The projectors and q_{24} do not modify d, whereas duality acts only on d. The two compositions are therefore identical. Preservation of the form is theorem 24.17. □

The graph $\mathscr{G}_K$ preserves the preceding coordinate v_{11} together with its projection. The theorem proves the equivalence of the quotient presentations; the isolated reduction $V_{11} \to V_{10}$ retains its kernel ℓ_K. This clarification establishes what information the isomorphism retains and what information each projection composing it removes.

Corollary 25.29 (Screens over the elliptic family)**.** *The same morphism restricts to an isomorphism*

$$(\mathbb{R}^{12}/\mathbb{R}\mathbf{1}) \times \mathscr{D}_{\mathrm{el}} \times (e_+^{\perp}/\mathbb{Z}e_+) \;\cong\; \mathscr{G}_K \times \mathscr{D}_{\mathrm{el}} \times \Lambda,$$

and preserves the duality intertwining.

Proof. The morphism and its inverse preserve the second factor exactly. Corollary 24.20 proves that duality preserves $\mathscr{D}_{\mathrm{el}}$. Thus both the bijection and the already proved intertwining square restrict. □

25.14.6 Coordination with the exceptional realization

On the domain $\mathcal{X}_{\mathrm{HMT}}$, with phase, orientation, quotient, boundary, incidence, grading and memory, the readings $\varepsilon_{\mathrm{exc}}$ and $\varepsilon_{\mathrm{scr}}$ extract the exceptional and screen data. The corridor constructs the graded algebra $\mathfrak{V}(x) \cong V^{\natural}$, with its vertex product and automorphisms; $\mathfrak{S}_M(x)$ brings together the preceding screens, quotients and operators. The joint assignment $x \mapsto (\mathfrak{V}(x), \mathfrak{S}_M(x))$ therefore has an algebra as its first component and a family of spaces and maps as its second. The Monster action belongs to the first; the reduction directed by K and compact duality belong to the second. The two readings fix the common provenance and each construction preserves its type. The isomorphism of this section establishes the correspondence of screens with its explicit factors and proof.

25.15 Action on trajectories and eleven-dimensional dynamical realization

Extending the structure to dimensional dynamics requires joint transport of the state, channels and boundary data. This section begins with a functional defined on TPK trajectories and its exact composition law. The worldsheet and eleven-dimensional codomain are introduced afterwards, with the maps that must preserve that composition and the operators already constructed.

25.15.1 Descent of an evolution and sufficiency of the observed datum

Let $q : \mathcal{X}_{\mathrm{HMT}} \to Y$ be a surjective readout of states with memory, and let $U : \mathcal{X}_{\mathrm{HMT}} \to \mathcal{X}_{\mathrm{HMT}}$ be a complete evolution. An evolution on observed values exists precisely when the datum preserved by q suffices to determine the next observed value.

Theorem 25.30 (Exact criterion for descent along fibres)**.** *There exists a unique map $\overline{U} : Y \to Y$ satisfying $qU = \overline{U}q$ if and only if*

$$q(x) = q(y) \quad \Longrightarrow \quad q(Ux) = q(Uy). \tag{25.8}$$

Proof. If $\overline{U}$ exists, applying the same function to $q(x) = q(y)$ proves the condition. Conversely, define $\overline{U}(q(x)) = q(Ux)$. Condition (25.8) guarantees independence of the representative. Surjectivity of q defines the map on all of Y and proves uniqueness. □

The theorem determines what memory a readout must preserve. When two representatives have different observed images, the retained datum may be enlarged, the domain restricted, or a multivalued correspondence used. These are distinct mathematical choices. In particular, return of a phase coordinate does not authorize identification of the evolutions of two histories retaining different memories.

25.15.2 Cocycle of directional and arithmetic changes

An admissible TPK trajectory carries, on each edge e_j, a direction d_j and an arithmetic type t_j. To count changes in a concatenation, the preceding datum is also preserved. The augmented edge is $\widetilde{e}_j = (e_j, d_{j-1}, t_{j-1})$; the pair (d_0, t_0) belongs to the initial boundary. Define

$$w_{\mathrm{giro}}(\widetilde{e}_j) = \mathbf{1}_{\{d_j \neq d_{j-1}\}}, \qquad w_{\mathrm{tipo}}(\widetilde{e}_j) = \mathbf{1}_{\{t_j \neq t_{j-1}\}}.$$

For $\widetilde{\gamma} = (\widetilde{e}_1, \dots, \widetilde{e}_R)$, let

$$\mathbf{I}(\widetilde{\gamma}) = \left(\sum_{j=1}^{R} w_{\mathrm{giro}}(\widetilde{e}_j), \sum_{j=1}^{R} w_{\mathrm{tipo}}(\widetilde{e}_j) \right) = \big(N_{\mathrm{giro}}, N_{\mathrm{tipo}}\big). \tag{25.9}$$

Two trajectories compose when their endpoints agree and the preceding datum of the second agrees with the terminal datum of the first.

Proposition 25.31 (Additivity with preserved boundary)**.** *For every composable pair,*

$$\mathbf{I}(\widetilde{\gamma}\widetilde{\eta}) = \mathbf{I}(\widetilde{\gamma}) + \mathbf{I}(\widetilde{\eta}). \tag{25.10}$$

Thus, $\mathbf{I}$ is an additive cocycle with values in $\mathbb{N}^2$ on the category of augmented trajectories. For every $\lambda > 0$, the functional

$$I_\lambda(\widetilde{\gamma}) = N_{\mathrm{giro}}(\widetilde{\gamma}) + \lambda N_{\mathrm{tipo}}(\widetilde{\gamma})$$

is also additive.

Proof. Concatenation does not change the preceding datum of any edge: for the first edge of $\widetilde{\eta}$, the composition condition makes it agree with the terminal datum of $\widetilde{\gamma}$. The sum over all edges splits exactly into the two sums in (25.10). Applying the linear functional $(a, b) \mapsto a + \lambda b$ proves the last statement. □

Boundary information is an effective part of the proof. If two one-edge segments are evaluated separately while ignoring the connection between them, both may have zero turn count even though their directions differ. The concatenated path then contains a turn. Preserving (d_{j-1}, t_{j-1}) records that term on the first edge of the second segment and restores additivity.

For fixed endpoints and boundary data, the corpus's minimum-interaction principle selects minimizers of I_λ among admissible routes. The principle is a selection rule, whereas the following result establishes a finite-existence property.

Proposition 25.32 (Finite Existence of Minimizers)**.** *If the set $\Gamma(a, b)$ of admissible trajectories with the fixed boundary is finite and nonempty, there exists $\gamma_* \in \Gamma(a, b)$ such that $I_\lambda(\gamma_*) \le I_\lambda(\gamma)$ for all $\gamma \in \Gamma(a, b)$.*

Proof. The image of $\Gamma(a, b)$ under I_λ is a nonempty finite set of real numbers, which has a minimum element and at least one preimage. □

The proposition does not select the value of λ, nor does it confuse existence with uniqueness. The value and selection rule used in a particular realization must be part of its declared data. The additive functional recovered here quantifies changes of the path itself; its transport to a dimensional action is a later operation.

25.15.3 Extended persistence and world surface

Realization of a route as an extended object distributes its genealogy along an internal coordinate. For a string, the history has two local coordinates σ^a: one internal spatial coordinate and one temporal coordinate. A realization is described by a map $X : \Sigma \to \mathcal{M}$, a metric h_{ab} on the worldsheet and background fields in the target space. Conditions on $\partial\Sigma$ belong to the variational domain. For a brane of spatial dimension p, the history is a worldvolume of dimension $p + 1$.

The string variational codomain used by the corpus is the Polyakov action

$$S_{\mathrm{P}}[X, h] = -\frac{T_{\mathrm{s}}}{2} \int_\Sigma d^2\sigma \, \sqrt{-h}\, h^{ab} g_{MN}(X) \partial_a X^M \partial_b X^N, \tag{25.11}$$

where T_{s} is tension. The notation T_{s} distinguishes it from duality T_0, cardinal transport T_d and complete evolution U.

Composition of augmented trajectories already has the property proved in 25.31. A continuous realization of that composition must specify the map from paths to configurations, its transport of boundary conditions and the normalization comparing I_λ with the continuous action. Integral (25.11) specifies the codomain and its fields; its parameters do not retrospectively select TPK emissions or registers.

25.15.4 Eleven-dimensional realization and graded operators

The reduction directed by K provides $V_{11} = \ell_K \oplus V_{10}$, and Theorem 25.28 coordinates this reduction with the lattice screen and duality. The physical realization is typed through

$$\Xi_M : \mathcal{S}_M^{\mathrm{alg}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}}.$$

The codomain carries a metric g_{MN}, a three-form C_{MNP}, a gravitino ψ_M, an action, gauge constraints and supersymmetry transformations. An operator realization includes

$$\mathfrak{S}_M = (\mathcal{H}_{\mathrm{phys}}, H, Q), \qquad \mathcal{H}_{\mathrm{phys}} = \mathcal{H}_+ \oplus \mathcal{H}_-.$$

The grading is expressed through an involution Γ, equal to $+I$ on $\mathcal{H}_+$ and $-I$ on $\mathcal{H}_-$. The supercharge is odd, $\Gamma Q = -Q\Gamma$, and the Hamiltonian is nonnegative. The relation $Q^2 = H$ is understood as an equality of operators, including their domains.

Let $\mathcal{H}_{\mathrm{HMT}}$ be a Hilbert-space realization of the relevant genealogical states, with operators $\widehat{H}, \widehat{Q}$. An isometry $W : \mathcal{H}_{\mathrm{HMT}} \to \mathcal{H}_{\mathrm{phys}}$ must transport domains, grading and observables. The operator conditions are written

$$W\widehat{H} = HW, \qquad W\widehat{Q} = QW, \qquad WU_T^{\mathrm{HMT}} = U_T^{\mathrm{phys}}W. \tag{25.12}$$

Theorem 25.33 (Compatible transport of the supercharge)**.** *Suppose $\widehat{Q}^2 = \widehat{H}$, $WD(\widehat{Q}) \subset D(Q)$, and the intertwining relations of* (25.12) *hold on their domains. Then, for $\psi \in D(\widehat{H}) = D(\widehat{Q}^2)$,*

$$W\psi \in D(Q^2), \qquad Q^2W\psi = HW\psi.$$

If physical transport of the radii also respects (24.18)*, the transported compact sector preserves its spectrum under reciprocal radii.*

Proof. Since $\psi \in D(\widehat{Q}^2)$, both ψ and $\widehat{Q}\psi$ belong to $D(\widehat{Q})$. Thus, $W\psi \in D(Q)$ and $QW\psi = W\widehat{Q}\psi \in D(Q)$. One may apply Q again, and

$$Q^2W\psi = W\widehat{Q}^2\psi = W\widehat{H}\psi = HW\psi.$$

Spectral equality of the compact sector is transported by the isometry and the unitary T-intertwiner; on the closed image of W, this is a unitary equivalence of the corresponding realizations. □

The theorem explicitly preserves the operators and the domain on which the identity is proved. The grading organizes two sectors; construction of fermionic fields and their occupation relations has its own structure. Thermal distributions and the species catalogue are not used in the proof of the screens or in the compact duality of this article.

25.15.5 Compatible compactification and conclusion of the development

A compactification of the state is described through a prolongable section x_∞, a map κ_{comp} to the chosen moduli space and a transport $\mathcal{U}$ of the metric, orientation, boundary and memory data. The subscript distinguishes this map from the rational readout κ of the dodecaphasic register. Its compatibility requires four concrete properties:

1. the finite restrictions of x_∞ belong to admissible TPK prolongations;
2. the compactification map intertwines the dualities, $\kappa_{\mathrm{comp}}\mathsf{T} = \mathsf{T}_M\kappa_{\mathrm{comp}}$;
3. observables and the spectrum descend to the chosen quotients according to criterion 25.30;
4. the realization transports the direction ℓ_K, boundary conditions and operator domains, and preserves the declared action and supersymmetry equations.

The preceding proofs provide the phase Hilbert-space realization, tracial closure, screens with their quotient maps, radius involution, its unitary equivalence and the additive trajectory cocycle. The eleven-dimensional realization specifies the fields and compatibilities it uses when receiving that structure. Its complete physical identification also retains the conditions on tension, oscillators, amplitudes, anomalies and the low-energy limit enumerated by the corpus. These conditions do not alter the proved algebraic identities: they delimit the subsequent claim obtained by transporting them.

The exceptional and dimensional prolongations remain linked by their common origin. The Monster acts on the graded construction $V^\natural$; the compact Hamiltonian and screens receive data from other maps of the same state. This formulation preserves the positive content of the dual realization, with its operations, proofs and the information transmitted at each stage (Theorem 25.33).

25.16 Dimensional screens and coordinated reduction of the state

The ranks appearing in exceptional prolongation and in compactification belong to different objects. To relate them, their presentation is preserved: generators, relations, inner product and selected direction. Dimension is then a consequence of the channel module and its relations. Its transport is formulated through maps acting on that module, in addition to acting on the state that determines it.

25.16.1 Channels, relations and effective dimension

Let $\mathcal{S}_n$ be the set of surviving states at depth n, with compatible restrictions $r_{m,n} : \mathcal{S}_m \to \mathcal{S}_n$, $m \geq n$. The boundary datum $\beta_n(x)$ preserves the information needed to decide the compatibility of a prolongation: sheet, orientation, quotient, memory and incidence class according to the reader considered. The restrictions satisfy

$$r_{\ell,n} = r_{m,n} r_{\ell,m}, \qquad \beta_n r_{m,n} = b_{m,n} \beta_m.$$

These equalities are the naturality conditions of the presentation and retain the same data when restricting in stages or directly.

Definition 25.34 (Channel screen)**.** Given a field $\mathbb{K}_n$, let $M_n(x)$ be the space generated by the prolongation channels and $\mathcal{R}_n(x)$ the subspace of relations. The screen is

$$\Sigma_n(x) = \big(\mathbb{K}_n, M_n(x), \beta_n(x), \mathcal{R}_n(x)\big),$$

and its effective dimension is

$$d_{\Sigma_n}(x) = \dim_{\mathbb{K}_n}\big(M_n(x)/\mathcal{R}_n(x)\big). \tag{25.13}$$

If $M_n(x) \cong \mathbb{K}_n^{g_n}$ and the columns of $R_n(x)$ generate the relations, then $d_{\Sigma_n}(x) = g_n - \operatorname{rank} R_n(x)$.

Proposition 25.35 (Invariance of presentation and transport)**.** *The dimension* (25.13) *is preserved under invertible changes of basis. For two screens over the same field $\mathbb{K}_n = \mathbb{K}_m = \mathbb{K}$, if the linear map $F_\gamma : M_n(x) \to M_m(T_\gamma x)$ sends $\mathcal{R}_n(x)$ into $\mathcal{R}_m(T_\gamma x)$, it uniquely induces a linear map between the screen quotients.*

Proof. A change of generators and relations transforms R into URV, with U, V invertible, and preserves its rank. For descent, define $\overline{F}_\gamma([v]) = [F_\gamma(v)]$. If two representatives differ by a relation, linearity implies that their images differ by a relation of the terminal screen; the map is well defined. Projection to the quotient is surjective and guarantees uniqueness. □

The dimensional change during transport is determined by

$$\Delta d(\gamma; x) = d_{\Sigma_m}(T_\gamma x) - d_{\Sigma_n}(x).$$

This expression preserves the state and its channel presentation. An isolated rank does not allow reconstruction of either the relations or the map that produced it.

25.16.2 Ternary puncturing and syndrome screen

The code $C_W = [12, 6, 6]_3$, constructed from exceptional incidence, produces another screen by puncturing one coordinate. Denote that map by $p : C_W \to \mathbb{F}_3^{11}$ and its image by $G_{11} = p(C_W)$.

Proposition 25.36 (Punctured code and perfect partition)**.** *The map p is injective. The code G_{11} has parameters $[11, 6, 5]_3$, and its Hamming balls of radius 2 partition $\mathbb{F}_3^{11}$.*

Proof. A vector in the kernel of p would have support contained in the single removed coordinate. The minimum distance 6 of C_W excludes any nonzero vector of that form. Thus, the dimension remains 6.

Puncturing decreases the weight by at most one, so the minimum distance of the image is at least 5. The balls of radius 2 are therefore disjoint. Each contains

$$1 + 2\binom{11}{1} + 2^2\binom{11}{2} = 1 + 22 + 220 = 243$$

vectors. Since $|G_{11}| = 3^6$ and $3^6 \cdot 243 = 3^{11}$, the balls cover the ambient space. To check that the distance is exactly 5, take a vector of weight 3. Its decoding ball cannot have centre zero and has a centre of weight at most $3 + 2 = 5$; that centre must have weight at least 5. A word of weight 5 is thus obtained. □

The integer $243 = 3^{11-6}$ is here the number of classes of the syndrome quotient $\mathbb{F}_3^{11}/G_{11}$. Its function is fixed by the puncturing and distance of the code; equality of cardinality with another fibre does not replace the map between them. This combinatorial screen and the following real screen retain their own operations.

25.16.3 The dodecaphase direction and rank reduction

The construction of 21.11.5 starts from the register K already obtained by APP–TRIT–TPK and from the representation chart declared on $\mathbb{R}^{12}$. In that chart,

$$V_{11} = \mathbf{1}^{\perp}, \qquad P_{11} = I_{12} - \frac{1}{12}J_{12}, \qquad u_K = P_3 P_{11} K. \tag{25.14}$$

Here J_{12} is the all-ones matrix and P_3 is the isotypic projector specified by the action of A_5. The finite sum defining P_3, its representatives and the generation of K are preserved in the cited section of this same article. In particular,

$$\|u_K\|^2 = \frac{6638585 + 2275584\sqrt{5}}{20} > 0.$$

The positive norm defines $\ell_K = \mathbb{R}u_K$, and the projector

$$P_{10} = P_{11} - \frac{u_K u_K^{\mathsf{T}}}{\|u_K\|^2} \tag{25.15}$$

has image $V_{10} = V_{11} \cap u_K^{\perp}$.

Proposition 25.37 (Two orthogonal reductions)**.** *The following hold*

$$\mathbb{R}^{12} = \mathbb{R}\mathbf{1} \oplus^{\perp} V_{11}, \qquad V_{11} = \ell_K \oplus^{\perp} V_{10}, \qquad \dim V_{10} = 10.$$

Moreover, $P_{10}P_{11} = P_{10}$, $P_{10}u_K = 0$, and P_{10} is an orthogonal projector.

Proof. Proposition 21.64, proved before constructing the screens, establishes idempotence, symmetry, rank and the two operator identities for this same u_K and this same P_{10}. The first decomposition follows from $P_{11} = I - J_{12}/12$; the second is the orthogonal decomposition of that proposition. This preserves the single proof of the reduction and makes its two stages explicit here. □

The first reduction removes only the uniform mode. The second removes the direction determined by K in the fixed representation. If the chart is simultaneously changed by an orthogonal matrix S, the vector transforms by $u_K \mapsto Su_K$ and the projector by $P_{10} \mapsto SP_{10}S^{-1}$. This covariance preserves the geometric operation, even though its coordinates change.

25.16.4 Lorentzian lattice screen

Let $\Lambda = N_\alpha$ be the Leech lattice constructed in 21.11.9. Consider the integral hyperbolic plane $U = \mathbb{Z}e_+ \oplus \mathbb{Z}e_-$, with

$$\langle e_+, e_+\rangle = \langle e_-, e_-\rangle = 0, \qquad \langle e_+, e_-\rangle = 1.$$

The lattice $L_{26} = \Lambda \oplus U$ is even and unimodular, with signature $(25, 1)$. Each vector is written $y = \lambda + ae_+ + be_-$. Since $\langle y, e_+\rangle = b$,

$$e_+^\perp = \Lambda \oplus \mathbb{Z}e_+, \qquad e_+^\perp/\mathbb{Z}e_+ \cong \Lambda. \tag{25.16}$$

The quotient map is $q_{24}(\lambda + ae_+) = \lambda$; it is surjective and has kernel $\mathbb{Z}e_+$. The decrease in rank by two comes from an orthogonality restriction followed by an isotropic quotient. It is therefore an operation of a different type from (25.15).

25.16.5 Joint screen morphism

With the domain $\mathscr{D}_0$ of 24.28, let

$$\mathscr{G}_K = \{(v_{11}, P_{10}v_{11}) : v_{11} \in V_{11}\},$$

$$\mathcal{S}_{\mathrm{HMT}} = \mathbb{R}^{12} \times \mathscr{D}_0 \times e_+^\perp, \qquad \mathcal{S}_M^{\mathrm{alg}} = \mathscr{G}_K \times \mathscr{D}_0 \times \Lambda.$$

Definition 25.38 (Algebraic map of coordinated screens)**.** It is defined

$$\mathcal{R}_M^{\mathrm{alg}}(v, d, y) = \big((P_{11}v, P_{10}v), d, q_{24}(y)\big). \tag{25.17}$$

Theorem 25.39 (Quotient isomorphism and duality intertwining)**.** *The map* (25.17) *induces an isomorphism*

$$\overline{\mathcal{R}}_M^{\mathrm{alg}} : (\mathbb{R}^{12}/\mathbb{R}\mathbf{1}) \times \mathscr{D}_0 \times (e_+^\perp/\mathbb{Z}e_+) \longrightarrow \mathcal{S}_M^{\mathrm{alg}}.$$

It intertwines the transformations acting by T_0 *on the factor* $\mathscr{D}_0$ *and by the identity on the other two factors. The form* $E_{R_0}(m, w)$ *is preserved under that duality.*

Proof. The map $[v] \mapsto P_{11}v$ is an isomorphism from $\mathbb{R}^{12}/\mathbb{R}\mathbf{1}$ onto V_{11}. Since $P_{10}P_{11} = P_{10}$, the map $[v] \mapsto (P_{11}v, P_{10}v)$ identifies that quotient with $\mathscr{G}_K$; its inverse takes the first component and its class. By (25.16), q_{24} induces the lattice isomorphism of the third factor. The second is transported by the identity. The product of the three maps proves the isomorphism.

The projectors and q_{24} do not modify d, whereas duality acts only on d. The two compositions are therefore identical. Preservation of the form is theorem 24.29. □

The graph $\mathscr{G}_K$ preserves the preceding coordinate v_{11} together with its projection. The theorem proves the equivalence of the quotient presentations; the isolated reduction $V_{11} \to V_{10}$ retains its kernel ℓ_K. This clarification establishes what information the isomorphism retains and what information each projection composing it removes.

Corollary 25.40 (Screens over the elliptic family)**.** *The same morphism restricts to an isomorphism*

$$(\mathbb{R}^{12}/\mathbb{R}\mathbf{1}) \times \mathscr{D}_{\mathrm{el}} \times (e_+^\perp/\mathbb{Z}e_+) \;\cong\; \mathscr{G}_K \times \mathscr{D}_{\mathrm{el}} \times \Lambda,$$

and preserves the duality intertwining.

Proof. The morphism and its inverse preserve the second factor exactly. Corollary 24.32 proves that duality preserves $\mathscr{D}_{\mathrm{el}}$. Thus both the bijection and the already proved intertwining square restrict. □

25.16.6 Coordination with the exceptional realization

On the domain $\mathcal{X}_{\mathrm{HMT}}$, with phase, orientation, quotient, boundary, incidence, grading and memory, the readings $\varepsilon_{\mathrm{exc}}$ and $\varepsilon_{\mathrm{scr}}$ extract the exceptional and screen data. The corridor constructs the graded algebra $\mathfrak{B}(x) \cong V^{\natural}$, with its vertex product and automorphisms; $\mathfrak{S}_M(x)$ brings together the preceding screens, quotients and operators. The joint assignment $x \mapsto (\mathfrak{B}(x), \mathfrak{S}_M(x))$ therefore has an algebra as its first component and a family of spaces and maps as its second. The Monster action belongs to the former; the reduction directed by K and compact duality belong to the latter. The two readings fix the common provenance and each construction retains its type. Theorem 25.39 gives the isomorphism factor by factor; its proof identifies the inverses, kernels and operations preserved by each component.

25.17 Action on trajectories and eleven-dimensional dynamical realization

Extending the structure to dimensional dynamics requires joint transport of the state, channels and boundary data. This section begins with a functional defined on TPK trajectories and its exact composition law. The worldsheet and eleven-dimensional codomain are introduced afterwards, with the maps that must preserve that composition and the operators already constructed.

25.17.1 Descent of an evolution and sufficiency of the observed datum

Let $q : \mathcal{X}_{\mathrm{HMT}} \to Y$ be a surjective readout of states with memory, and let $U : \mathcal{X}_{\mathrm{HMT}} \to \mathcal{X}_{\mathrm{HMT}}$ be a complete evolution. An evolution on observed values exists precisely when the datum preserved by q suffices to determine the next observed value.

Theorem 25.41 (Exact criterion for descent along fibres)**.** *There exists a unique map $\overline{U} : Y \to Y$ satisfying $qU = \overline{U}q$ if and only if*

$$q(x) = q(y) \quad \Longrightarrow \quad q(Ux) = q(Uy). \tag{25.18}$$

Proof. If $\overline{U}$ exists, applying the same function to $q(x) = q(y)$ proves the condition. Conversely, define $\overline{U}(q(x)) = q(Ux)$. Condition (25.18) guarantees independence of the representative. Surjectivity of q defines the map on all of Y and proves uniqueness. □

The theorem determines what memory a readout must preserve. When two representatives have different observed images, the retained datum may be enlarged, the domain restricted, or a multivalued correspondence used. These are distinct mathematical choices. In particular, return of a phase coordinate does not authorize identification of the evolutions of two histories retaining different memories.

25.17.2 Cocycle of directional and arithmetic changes

An admissible TPK trajectory carries, on each edge e_j, a direction d_j and an arithmetic type t_j. To count changes in a concatenation, the preceding datum is also preserved. The augmented edge is $\widetilde{e}_j = (e_j, d_{j-1}, t_{j-1})$; the pair (d_0, t_0) belongs to the initial boundary. Define

$$w_{\mathrm{giro}}(\widetilde{e}_j) = \mathbf{1}_{\{d_j \neq d_{j-1}\}}, \qquad w_{\mathrm{tipo}}(\widetilde{e}_j) = \mathbf{1}_{\{t_j \neq t_{j-1}\}}.$$

For $\widetilde{\gamma} = (\widetilde{e}_1, \dots, \widetilde{e}_R)$, let

$$\mathbf{I}(\widetilde{\gamma}) = \left(\sum_{j=1}^{R} w_{\mathrm{giro}}(\widetilde{e}_j), \sum_{j=1}^{R} w_{\mathrm{tipo}}(\widetilde{e}_j) \right) = \big(N_{\mathrm{giro}}, N_{\mathrm{tipo}}\big). \tag{25.19}$$

Two trajectories compose when their endpoints agree and the preceding datum of the second agrees with the terminal datum of the first.

Proposition 25.42 (Additivity with preserved boundary)**.** *For every composable pair,*

$$\mathbf{I}(\widetilde{\gamma\eta}) = \mathbf{I}(\widetilde{\gamma}) + \mathbf{I}(\widetilde{\eta}). \tag{25.20}$$

Thus, $\mathbf{I}$ *is an additive cocycle with values in* $\mathbb{N}^2$ *on the category of augmented trajectories. For every* $\lambda > 0$*, the functional*

$$I_\lambda(\widetilde{\gamma}) = N_{\mathrm{giro}}(\widetilde{\gamma}) + \lambda N_{\mathrm{tipo}}(\widetilde{\gamma})$$

is also additive.

Proof. Concatenation does not change the preceding datum of any edge: for the first edge of $\widetilde{\eta}$, the composition condition makes it agree with the terminal datum of $\widetilde{\gamma}$. The sum over all edges splits exactly into the two sums in (25.20). Applying the linear functional $(a, b) \mapsto a + \lambda b$ proves the last statement. □

Boundary information is an effective part of the proof. If two one-edge segments are evaluated separately while ignoring the connection between them, both may have zero turn count even though their directions differ. The concatenated path then contains a turn. Preserving (d_{j-1}, t_{j-1}) records that term on the first edge of the second segment and restores additivity.

For fixed endpoints and boundary data, the minimum-interaction principle selects minimizers of I_λ among admissible routes. The principle is a selection rule, whereas the following result establishes a finite-existence property.

Proposition 25.43 (Finite Existence of Minimizers)**.** *If the set* $\Gamma(a, b)$ *of admissible trajectories with the fixed boundary is finite and nonempty, there exists* $\gamma_* \in \Gamma(a, b)$ *such that* $I_\lambda(\gamma_*) \le I_\lambda(\gamma)$ *for all* $\gamma \in \Gamma(a, b)$*.*

Proof. The image of $\Gamma(a, b)$ under I_λ is a nonempty finite set of real numbers, which has a minimum element and at least one preimage. □

The proposition does not select the value of λ, nor does it confuse existence with uniqueness. The value and selection rule used in a particular realization must be part of its declared data. The additive functional recovered here quantifies changes of the path itself; its transport to a dimensional action is a later operation.

25.17.3 Extended persistence and world surface

Realization of a route as an extended object distributes its genealogy along an internal coordinate. For a string, the history has two local coordinates σ^a: one internal spatial coordinate and one temporal coordinate. A realization is described by a map $X : \Sigma \to \mathcal{M}$, a metric h_{ab} on the worldsheet and background fields in the target space. Conditions on $\partial\Sigma$ belong to the variational domain. For a brane of spatial dimension p, the history is a worldvolume of dimension $p + 1$.

The variational realization of the string is expressed by the Polyakov action

$$S_{\mathrm{P}}[X, h] = -\frac{T_{\mathrm{s}}}{2} \int_\Sigma d^2\sigma \, \sqrt{-h}\, h^{ab} g_{MN}(X) \partial_a X^M \partial_b X^N, \tag{25.21}$$

where T_{s} is tension. The notation T_{s} distinguishes it from duality T_0, cardinal transport T_d and complete evolution U.

Composition of augmented trajectories already has the property proved in 25.42. A continuous realization of that composition must specify the map from paths to configurations, its transport of boundary conditions and the normalization comparing I_λ with the continuous action. Integral (25.21) specifies the codomain and its fields; its parameters do not retrospectively select TPK emissions or registers.

25.17.4 Eleven-dimensional realization and graded operators

The reduction directed by K provides $V_{11} = \ell_K \oplus V_{10}$, and Theorem 25.39 coordinates this reduction with the lattice screen and duality. The physical realization is typed through

$$\Xi_M : \mathcal{S}_M^{\mathrm{alg}} \longrightarrow \mathcal{X}_{11}^{\mathrm{phys}}.$$

The codomain carries a metric g_{MN}, a three-form C_{MNP}, a gravitino ψ_M, an action, gauge constraints and supersymmetry transformations. An operator realization includes

$$\mathfrak{S}_M = (\mathcal{H}_{\mathrm{phys}}, H, Q), \qquad \mathcal{H}_{\mathrm{phys}} = \mathcal{H}_+ \oplus \mathcal{H}_-.$$

The grading is expressed through an involution Γ, equal to $+I$ on $\mathcal{H}_+$ and $-I$ on $\mathcal{H}_-$. The supercharge is odd, $\Gamma Q = -Q\Gamma$, and the Hamiltonian is nonnegative. The relation $Q^2 = H$ is understood as an equality of operators, including their domains.

Let $\mathcal{H}_{\mathrm{HMT}}$ be a Hilbert-space realization of the relevant genealogical states, with operators $\widehat{H}, \widehat{Q}$. An isometry $W : \mathcal{H}_{\mathrm{HMT}} \to \mathcal{H}_{\mathrm{phys}}$ must transport domains, grading and observables. The operator conditions are written

$$W\widehat{H} = HW, \qquad W\widehat{Q} = QW, \qquad WU_T^{\mathrm{HMT}} = U_T^{\mathrm{phys}}W. \tag{25.22}$$

Theorem 25.44 (Compatible transport of the supercharge)**.** *Suppose $\widehat{Q}^2 = \widehat{H}$, $WD(\widehat{Q}) \subset D(Q)$, and the intertwining relations of* (25.22) *hold on their domains. Then, for $\psi \in D(\widehat{H}) = D(\widehat{Q}^2)$,*

$$W\psi \in D(Q^2), \qquad Q^2W\psi = HW\psi.$$

If physical transport of the radii also respects (24.38)*, the transported compact sector preserves its spectrum under reciprocal radii.*

Proof. Since $\psi \in D(\widehat{Q}^2)$, both ψ and $\widehat{Q}\psi$ belong to $D(\widehat{Q})$. Thus, $W\psi \in D(Q)$ and $QW\psi = W\widehat{Q}\psi \in D(Q)$. One may apply Q again, and

$$Q^2W\psi = W\widehat{Q}^2\psi = W\widehat{H}\psi = HW\psi.$$

Spectral equality of the compact sector is transported by the isometry and the unitary T-intertwiner; on the closed image of W, this is a unitary equivalence of the corresponding realizations. □

The theorem explicitly preserves the operators and the domain on which the identity is proved. The grading organizes two sectors; construction of fermionic fields and their occupation relations has its own structure. Thermal distributions and the species catalogue are not used in the proof of the screens or in the compact duality of this article.

25.17.5 Compatible compactification and conclusion of the development

A compactification of the state is described through a prolongable section x_∞, a map κ_{comp} to the chosen moduli space and a transport $\mathcal{U}$ of the metric, orientation, boundary and memory data. The subscript distinguishes this map from the rational readout κ of the dodecaphasic register. Its compatibility requires four concrete properties:

1. the finite restrictions of x_∞ belong to admissible TPK prolongations;
2. the compactification map intertwines the dualities, $\kappa_{\mathrm{comp}}\mathsf{T} = \mathsf{T}_M\kappa_{\mathrm{comp}}$;
3. observables and the spectrum descend to the chosen quotients according to criterion 25.41;
4. the realization transports the direction ℓ_K, boundary conditions and operator domains, and preserves the declared action and supersymmetry equations.

The preceding proofs provide the phase Hilbert-space realization, tracial closure, screens with their quotient maps, radius involution, its unitary equivalence and the additive trajectory cocycle. The eleven-dimensional realization specifies the fields and compatibilities it uses when receiving that structure.

Conditions for physical identification. Complete physical identification must additionally specify the tension and action normalization, construct the oscillator sector and its amplitudes, control anomalies and establish a consistent low-energy gravitational limit for each stated compactification. The string action and change of scale used here are expressed in (25.21) and (24.41), respectively. Theorem 25.44 proves the supercharge identity on the image of W, under the domains and intertwining relations in its statement. The conditions for complete physical identification do not alter this identity or the other algebraic proofs: they delimit the physical realization to which those results are transported.

The exceptional and dimensional prolongations remain linked by their common origin. The Monster acts on the graded construction $V^{\natural}$; the compact Hamiltonian and screens receive data from other maps of the same state. This formulation preserves the positive content of the dual realization, with its operations, proofs and the information transmitted at each stage: Theorem 21.71 establishes the exceptional identification, and Theorems 24.31 and 25.39 establish compact equivalence and screen coordination.

25.18 Finite enumerations of emissions and Witt stars

The two enumerations in this appendix concern distinct objects. The first classifies the cursor signatures of APP emission; the second computes the group generated by the stars of the Witt design. Their domains and rules are retained so that each table can be reproduced without being used as an input to the calculation.

25.18.1 Initial-condition indices and signature recurrence

Let $i, j \in \{0, \dots, 8\}$ and $a \in \{0, 1, 2, 3\}$, with direction order (N, E, S, O) and vectors

$$v_N = (-1, 0), \quad v_E = (0, 1), \quad v_S = (1, 0), \quad v_O = (0, -1).$$

The index

$$\mathrm{id}(i, j, a) = 4(9i + j) + a$$

ranges over exactly $\{0, \dots, 323\}$. Its inverse is obtained from $a = \mathrm{id} \bmod 4$, $j = \lfloor \mathrm{id}/4 \rfloor \bmod 9$ and $i = \lfloor \mathrm{id}/36 \rfloor$. Two indices, one per sheet, enumerate the 324^2 joint conditions in (4.29); this domain is not identified with the 81 positions.

For each index, the cursor starts at (i, j), with vector v_a. The instants $t = 1, \dots, 54$ are traversed in six windows of nine instants. Write $r_t = 1 + ((t - 1) \bmod 9)$. The rule is:

1. On the additive sheet, an operation occurs when $r_t \in \{1, 4, 7\}$: $\rho_9(i + j + 2)$ is added to the window accumulator, and the cursor moves by v_a, modulo nine.
2. On the multiplicative sheet, an operation occurs when $r_t \in \{2, 5, 8\}$: $\ell_9(\rho_9((i + 1)(j + 1)))$ is added, and the cursor moves by v_a, modulo nine. The extension of ℓ_9 by zero outside the units, stated in Section 4.3, is retained.
3. At all other instants, that cursor does not move. After instants 27 and 54, v_a is replaced by $-v_a$.
4. At the end of each window, its accumulator is recorded modulo ten, and only the accumulator is reset; neither position nor orientation is reset.

This defines two functions on the 324 indices,

$$s : \{0, \dots, 323\} \longrightarrow \{0, \dots, 9\}^6, \qquad e : \{0, \dots, 323\} \longrightarrow \{0, \dots, 9\}^6.$$

The multiplicity of a signature is the number of indices with that image. The witness index in each table is the least index in its fibre. Complete preimages are recovered by applying the recurrence to all 324 indices and retaining those that produce the stated signature.

Table 25.1: Additive signatures: image of s, multiplicity and witness index.

Class	Signature	Multiplicity	Witness index
1	122564	18	17
2	122898	18	24
3	212645	18	5
4	212988	18	0
5	221456	18	29
6	221889	18	12
7	456221	18	28
8	465898	18	21
9	546988	18	9
10	564122	18	16
11	645212	18	4
12	654889	18	33
13	889221	18	13
14	889654	18	32
15	898122	18	25
16	898465	18	20
17	988212	18	1
18	988546	18	8

Table 25.2: Multiplicative signatures: image of e, multiplicity and witness index.

Class	Signature	Multiplicity	Witness index
1	000000	108	8
2	177393	8	1
3	177555	8	54
4	177771	8	11
5	339555	8	6
6	339771	8	15
7	339933	8	59
8	393177	8	0
9	393393	8	45
10	393555	8	40
11	555177	8	52
12	555339	8	4
13	555393	8	41
14	555555	24	84
15	555717	8	14
16	555771	8	18
17	555933	8	24
18	717555	8	12
19	717717	8	21

Class	Signature	Multiplicity	Witness index
20	717933	8	19
21	771177	8	9
22	771339	8	13
23	771555	8	16
24	933339	8	57
25	933555	8	26
26	933717	8	17

The sums of multiplicities are $18 \cdot 18 = 324$ and $24 \cdot 8 + 24 + 108 = 324$. Joint emission is obtained by applying (4.31) to every pair of signatures. The inverse through hundreds and tens proved in Section 4.3 identifies the 468 emissions and gives their multiplicities as the product of the two fibres. The subsequent map (4.32) produces the 243 visible words. The initial domain, emission, its fibres and the ternary quotient are thus specified separately.

25.18.2 Explicit generators and closure of the stars

The matrix A_W of (21.126) is retained, and the following words are formed in lexicographic order:

$$c(w) = (w, wA_W), \qquad w \in \mathbb{F}_3^6.$$

They are grouped by weight and the supports of weight six are retained. This produces the enumerator (21.127) and the 132 hexads of $\mathcal{H}$. For each quadruple $B \subset \{1, \dots, 12\}$, the four pairs $H \setminus B$, with $B \subset H \in \mathcal{H}$, define σ_B: it fixes B and interchanges the two points of each pair. This gives the family of 495 stars of proposition 21.66.

The six generators used in its closure are expressed by their lists of images of $1, \dots, 12$:

	1	2	3	4	5	6	7	8	9	10	11	12
g_1	1	2	3	4	12	11	9	10	7	8	6	5
g_2	1	2	3	12	5	10	11	9	8	6	7	4
g_3	1	2	3	11	10	6	8	7	12	5	4	9
g_4	1	2	12	4	5	9	8	7	6	11	10	3
g_5	1	12	3	4	5	8	10	6	11	7	9	2
g_6	12	2	3	4	5	7	6	11	10	9	8	1

Each row is verified to be a star by comparison with the σ_B already constructed. For $j = 1, \dots, 6$, the closure is computed by

$$G_j^{(0)} = \{\mathrm{id}\}, \qquad G_j^{(n+1)} = G_j^{(n)} \cup \{g_i \circ p : 1 \le i \le j,\ p \in G_j^{(n)}\}.$$

The increasing sequence stabilizes in the finite set $\mathrm{Sym}(12)$. Since the generators are involutions, its stable value is exactly the group G_j they generate. With the convention $(g_i \circ p)(a) = g_i(p(a))$, their orders are

j	1	2	3	4	5	6
$\lvert G_j \rvert$	2	6	18	360	7920	95040.

Finally, one checks that each of the 495 stars belongs to G_6 and that they all preserve $\mathcal{H}$. The first inclusion, together with membership of the six generators in the family, makes the two generated groups equal. Preservation is checked through $\{\sigma_B(H) : H \in \mathcal{H}\} = \mathcal{H}$. This is the finite enumeration used in the proof of 21.66; subsequent recognition as M_{12} retains the external reference declared there.

Chapter 26

Completely positive systems and matrix genealogy of the continuum: convexity, Choi matrices, Stinespring dilation, and De les Coves–Netzer bridge

26.1 Matrix range of APP: exact classification of the sum–product algebra and free interval

The qutrit squares of section 26.3 provide an operatorial input. There exists a second input, more internal to APP: the two partitions induced by sum and product generate noncommutative orthogonal projections. The language of operator systems makes it possible to study them without forcing a grid.

26.1.1 Pair of conditional expectations associated with the additive and multiplicative partitions of APP

Let

$$\mathcal{H}_d = \ell^2(\{1,\dots,9\}^d),$$

and let us define

$$\Sigma_d(x) = \mathrm{dr}(x_1 + \cdots + x_d), \qquad \Pi_d(x) = \mathrm{dr}(x_1 \cdots x_d). \tag{GMC-6.1}$$

Let $P_{\Sigma,d}$ and $P_{\Pi,d}$ be the orthogonal projections onto the functions constant on the fibres of Σ_d and Π_d. The preceding bridge proves

$$\|[P_{\Sigma,2}, P_{\Pi,2}]\| = \frac{\sqrt{2}}{3}, \qquad \|[P_{\Sigma,3}, P_{\Pi,3}]\| = \frac{\sqrt{3}}{4}, \tag{GMC-6.2}$$

and

$$\operatorname{Ran} P_{\Sigma,d} \cap \operatorname{Ran} P_{\Pi,d} = \mathbb{C}\mathbf{1} \qquad (2 \le d \le 15). \tag{GMC-6.3}$$

APP therefore contains a noncommutative operator package prior to any QLS or QMS designation.

We define

$$\mathcal{S}_d = \mathrm{span}\{I, P_{\Sigma,d}, P_{\Pi,d}\}, \qquad \mathfrak{C}_d^{\mathrm{APP}} = C^*(P_{\Sigma,d}, P_{\Pi,d}). \tag{GMC-6.4}$$

$\mathcal{S}_d$ is a system of operators and its rango matrix is

$$\mathcal{W}_s(\mathrm{APP}_d) = \left\{(\Phi(P_{\Sigma,d}), \Phi(P_{\Pi,d})) : \Phi : \mathfrak{C}_d^{\mathrm{APP}} \to M_s \text{ UCP}\right\}. \tag{GMC-6.5}$$

The tower $\bigsqcup_s \mathcal{W}_s$ is matricially convex. Unlike a general label of "quantumness," (GMC-6.5) makes it possible to compute extreme points, compressions, dilations, and invariants.

26.1.2 Classification of the sum–product algebra at depth 2

Place $P = P_{\Sigma,2}$ and $Q = P_{\Pi,2}$ on $\mathcal{H}_2$, of dimension 81. The nine fibres of Σ_2 have size nine. The fibres of Π_2 have sizes

$$6, 6, 12, 6, 6, 12, 6, 6, 21. \tag{GMC-6.6}$$

Let u_a and v_b be the normalized indicator vectors of those fibres, and $C = (\langle u_a, v_b\rangle)_{a,b=1}^{9}$ their cross-Gram matrix. The exact intersection count yields

$$\chi_{CC^*}(t) = t^5(t-1)\left(t - \frac{5}{7}\right)\left(t - \frac{1}{3}\right)^2. \tag{GMC-6.7}$$

Moreover,

common subspace	dimension
$\ker P \cap \ker Q$	64
$\mathrm{Ran}\, P \cap \mathrm{Ran}\, Q$	1
$\mathrm{Ran}\, P \cap \ker Q$	5
$\ker P \cap \mathrm{Ran}\, Q$	5

(GMC-6.8)

Theorem 26.1 (Sum–product algebra of APP in $d = 2$)**.** *There is an isomorphism of finite-dimensional C^*-algebras*

$$\boxed{\mathfrak{C}_2^{\mathrm{APP}} \cong \mathbb{C}^4 \oplus M_2(\mathbb{C}) \oplus M_2(\mathbb{C}).} \tag{GMC-6.9}$$

In particular, $\dim \mathfrak{C}_2^{\mathrm{APP}} = 12$.

Proof. The canonical Halmos decomposition for two projections separates the four subspaces of (GMC-6.8) and a generic sector for each principal angle $0 < \lambda < 1$. Equation (GMC-6.7) shows that the only distinct generic values are $5/7$ and $1/3$. In each case, the pair is unitarily equivalent to

$$P_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad Q_\lambda = \begin{pmatrix} \lambda & \sqrt{\lambda(1-\lambda)} \\ \sqrt{\lambda(1-\lambda)} & 1-\lambda \end{pmatrix}, \tag{GMC-6.10}$$

which generates M_2. The multiplicity of $\lambda = 1/3$ amplifies the same representation but does not create another simple summand. The four sectors $0/1$ simultaneously produce $\mathbb{C}^4$. □

Specifically,

$$Q_{5/7} = \begin{pmatrix} 5/7 & \sqrt{10}/7 \\ \sqrt{10}/7 & 2/7 \end{pmatrix}, \qquad Q_{1/3} = \begin{pmatrix} 1/3 & \sqrt{2}/3 \\ \sqrt{2}/3 & 2/3 \end{pmatrix}. \tag{GMC-6.11}$$

The norm of the commutator is the maximum of $\sqrt{\lambda(1-\lambda)}$ and recovers $\sqrt{2}/3$.

Corollary 26.2 (Complete parameterization of the matrix range)**.** *A pair (X, Y) belongs to $\mathcal{W}_s(\mathrm{APP}_2)$ if and only if there exist effects $E_{00}, E_{11}, E_{10}, E_{01} \succeq 0$ and CP maps $\Psi_{5/7}, \Psi_{1/3} : M_2 \to M_s$ such that*

$$E_{00} + E_{11} + E_{10} + E_{01} + \Psi_{5/7}(I) + \Psi_{1/3}(I) = I_s, \tag{GMC-6.12}$$

$$X = E_{11} + E_{10} + \Psi_{5/7}(P_0) + \Psi_{1/3}(P_0), \tag{GMC-6.13}$$

$$Y = E_{11} + E_{01} + \Psi_{5/7}(Q_{5/7}) + \Psi_{1/3}(Q_{1/3}). \tag{GMC-6.14}$$

Proof. Every CP map from a direct sum decomposes into CP maps on its summands. The four scalar summands produce the effects E_{ab}; the two matrix summands produce Ψ_λ. Unitality is (GMC-6.12); the coordinates of P and Q in (GMC-6.9) give (GMC-6.13)–(GMC-6.14). The argument is reversible. □

Matrix bridge result

The classification (GMC-6.9) provides the operator-theoretic realization of the bridge. It converts the sum–product incompatibility into a fully computable operator object: four classical sectors and two irreducible matrix blocks. The value $1/3$ reappears here as a principal operator angle, not merely as an MUB overlap; $5/7$ is the second generic value of PQP in the sum–product sector. Neither should be identified with the contraction $5/9$ of the central block B_c. They are invariants of distinct objects, coordinated without being identified by decimal similarity.

26.1.3 Spectral separation 4 and free matrix interval

For the block of (GMC-2.4), $B_c = 7I + 2R$ with $R = R^*$ nonscalar, $R^2 = I$ and $\mathrm{Spec}(R) = \{-1, +1\}$, $C^*(B_c) = C^*(R) \cong \mathbb{C}^2$. Its matrix rank at level s is

$$\mathcal{W}_s(B_c) = \{\Phi(B_c) : \Phi : C^*(B_c) \to M_s \text{ UCP}\}.$$

Theorem 26.3 (Free interval of the central block)**.** *For every $s \geq 1$,*

$$\boxed{\mathcal{W}_s(B_c) = \{Y = Y^* : 5I_s \preceq Y \preceq 9I_s\}.} \tag{GMC-6.15}$$

Proof. A UCP map sends the symmetry R to a self-adjoint contraction $-I_s \preceq X \preceq I_s$ and, therefore, $\Phi(B_c) = 7I_s + 2X$ belongs to the interval. Conversely, given such an X, the effects $(I_s \pm X)/2$ define a UCP map from $\mathbb{C}^2$ that sends R to X. □

Thus, 7 is the center, 2 the operatorial radius, and 4 the spectral diameter of the free interval. The positive boundary, the boundary of the matrix interval, and the determinant-one hyperbola of (GMC-2.6) are three distinct notions that can now be coordinated without being conflated.

The double projection does not reside in this early classification. Its formulation from a common spectral antecedent is published, with its hypotheses and limits, in the dedicated section of the governing chapter on double projection.

26.1.4 Common antecedent of readers: spectral refinement and joint dilation limit

Let X_m be a finite set of histories and let

$$R_m : X_m \to \mathcal{A}_m, \qquad Q_m : X_m \to \mathcal{E}_m \tag{GMC-6.16}$$

two readers: for example, one Archimedean and the other exceptional. Each one defines a PVM in $C(X_m)$ by means of the characteristic functions of its fibers.

Proposition 26.4 (Common spectral predecessor)**.** *The two* PVM *of* (GMC-6.16) *commute and possess the common refinement*

$$P_{a,e} = 1_{\{R_m = a\}} 1_{\{Q_m = e\}} = 1_{\{x : R_m(x) = a,\ Q_m(x) = e\}}. \tag{GMC-6.17}$$

If the readers are compatible with the truncations, the refinements are compatible in m and determine two readers on $C(X_\infty)$ with a common cylindrical PVM*.*

Proof. All functions belong to the same commutative algebra. The product of the indicators is the indicator of the intersection. Summing in e recovers the PVM of R_m, and summing in a recovers that of Q_m. The compatibility passes to the limit by the Theorem 26.11. □

This result formalizes the common antecedent of the double projection. It does not prove that the pair of readers is jointly injective: for that purpose, it must separate points of X_∞. Nor does it automatically construct a common noncommutative antecedent.

Proposition 26.5 (Incompatibility of Two Mutually Unbiased Projective Measurements)**.** *Two mutually unbiased qutrit* PVM *do not admit a joint sharp measurement in $M_3(\mathbb{C})$.*

Proof. Two finite PVM are jointly measurable by a common PVM if and only if they commute. Projectors from distinct MUB contexts have overlap $1/3$ and do not commute. □

The HMT double projection must therefore not be identified with two sharp MUB contexts on the same qutrit. It can be realized on the common diagonal of histories, through noisy effects, or in a larger

noncommutative antecedent with two UCP channels. The last possibility requires inclusion of matrix ranges, Choi positivity and equivariance with respect to TPK dynamics.

Mathematical extensions

The noncommutative antecedent is constructed in Section 17.9: the system $\mathcal{S}_\infty$ and the UCP maps Φ_{arq} and Φ_{exc} simultaneously reproduce the two HMT projections and intertwine the TPK dynamics on the declared equivariant domain. The Proposition 26.4 provides its diagonal antecedent.

26.2 Genealogical matrix convexity: objects, domains, and typed dictionary

26.2.1 Construction of 4 cyclic quantum Latin squares in an elementary operator class

The question organizing the work of De las Cuevas–Netzer is how a collection of local measurements can compose a two-dimensional object and to what extent that object is the compression of an ideal totality. An isolated measurement —a POVM— admits a Naimark or Stinespring dilation. However, a grid simultaneously contains one POVM in every row and every column. Requiring a common dilation that makes all those measurements projective is a much stronger global condition. There are quantum magic squares that do not satisfy it, even at the smallest relevant noncommutative matrix level [36].

HMT formulates another problem of parts and wholes. The visible coordinate of a state does not necessarily preserve the route that produced it. APP distinguishes the sum and product evaluations on a common support; TRIT preserves orientation and carry; TPK preserves path composition, return, holonomy, and memory. The continuum arises by coherently prolonging finite histories, and the double projection publishes two different shadows of the same enriched state. Both theories therefore ask what is lost under compression. The difference is that one organizes loss by matrix level and the other by genealogical depth.

Scientific reading

De las Cuevas asks: «Can I view this imperfect grid as the compression of a larger projective grid?». HMT asks: «What complete history was compressed to produce this output?». The bridge answers that both questions can be formulated on the same family, with two independent indices: depth m and observation dimension s.

26.2.2 Quantum Squares, Operator Systems, and Matrix Convexity

Let $n, s \geq 1$. A quantum magic square of exterior size n and interior size s is a matrix

$$A = (A_{ij})_{i,j=0}^{n-1} \in \mathrm{Mat}_n(\mathrm{Her}_s(\mathbb{C}))$$

such that

$$A_{ij} \succeq 0, \qquad \sum_{j=0}^{n-1} A_{ij} = I_s, \qquad \sum_{i=0}^{n-1} A_{ij} = I_s. \tag{GMC-1.1}$$

Each row and each column is a POVM. If all entries are projections, A is a quantum permutation matrix; if, moreover, those projections commute, A is a commutative quantum permutation matrix [36, 39].

To QMS is *semiclasico* if there exists to POVM $\{Q_\sigma\}_{\sigma \in S_n}$ such that

$$A = \sum_{\sigma \in S_n} P_\sigma \otimes Q_\sigma, \tag{GMC-1.2}$$

where P_σ is the classical permutation matrix associated with σ. The formula does not require the effects Q_σ to commute. It states that the entire grid is obtained by reordering a single primary measurement.

A quantum Latin square of order n is a grid of unit vectors $v_{ij} \in \mathbb{C}^n$ whose rows and columns are orthonormal bases. The rank-one projectors

$$P_{ij} = |v_{ij}\rangle\langle v_{ij}|$$

form a projective QMS. The easy-class QLS are those produced by a classical Latin square and a fixed orthonormal basis. De las Cuevas, Netzer, and Valentiner-Branth prove that the semiclassical QLS are exactly those of the easy class and that the matrix convex hull of the QLS contains more than the semiclassical squares [39].

The elementary convex matrix operation is

$$X = \sum_{r=1}^{k} V_r^* X^{(r)} V_r, \qquad \sum_{r=1}^{k} V_r^* V_r = I_s. \tag{GMC-1.3}$$

It permits objects of different internal sizes to be combined. In operator language, compressions and direct sums are organized by unital completely positive maps. The set of all matrix values of an operator system is its matrix range.

Antecedent theorem

The governing results used are: a QMS dilates to a quantum permutation matrix with commuting entries if and only if it is semiclassical; for $n \geq 3$ and $s \geq 2$ there exist nonsemiclassical QMS, and for every $n \geq 3$ there exist QMS on $M_2(\mathbb{C})$ that do not dilate to any quantum permutation matrix [36]. Simultaneous dilatability is therefore a substantive property, not an automatic consequence of each row and column dilating separately.

26.2.3 Typed correspondence between the HMT–MD genealogical state and operator systems: depth, truncation, monodromy, and reading

In HMT, a visible output does not exhaust the state. A finite section carries, according to the domain, data of the form

$$x_m = (\text{prefix}, \text{sheet}, \text{orientation}, \text{carry}, \text{boundary}, \text{route}, \text{memory}, \text{gauge}). \tag{GMC-1.4}$$

The depth m is not a Hilbert-space dimension. It counts how much of the genealogy has been resolved. Two states may share a visible coordinate and differ in m, in leaf, or in memory.

APP provides the nonadic orthogram and the sum and product sheets. TRIT records the ternary orientation and the local carry. TPK is the topological phase kernel and the category of routes that composes those data. In a finite realization, the routes act by operators on a Hilbert space, but the representation does not replace the genealogy: it transports it.

The language of HMT also contains three operations that are absent from the bare definition of a QMS:

1. *truncation*: forgetting the continuation beyond depth m, preserving the prefix and aggregating its prolongations;
2. *monodromy*: returning to the same visible phase with nontrivial memory;
3. *reading*: publishing a mathematical or physical coordinate without identifying it with the complete section.

26.2.4 Realization of 3 operator contexts in a quantum square (9,3)

Matrix language	Lenguaje HMT	Correspondencia tipada
Outer size n	published grid	number of rows and columns of the magic object; it is not depth nor internal dimension
Internal size s	carta operatorial	dimension of the effects or of the matrix compression
Profundidad m	genealogy	new index that does not reduce to n or s
POVM	family of positive readers	effects that sum to the unit; the sum expresses normalization, not complete memory
PVM	contexto espectral	family of orthogonal projections that resolves the identity
UCP	matrix reader	map that preserves unitarity and positivity at all levels
Compression $V^*(\cdot)V$	shadow	step from a higher realization to an observational chart lower
Dilation	antecedente operatorio	common multiplicative representation before compressing
Semiclassicality	a single reordered primary POVM	formal property; does not equivalent to commutativity of all cells
No semiclasicidad	genuinely two-dimensional composition	cannot be reduced to the reordering of a common primary POVM
System of operators	space of readers	self-adjoint subspace with the unit that organizes all the UCP cards
Rango matricial	set of shadows to all the s	free family of internal evaluations
Inductive limit	closure of operatorial refinements	conservation of the unit through the entire nonadic filtration
Inverse limit	infinite section compatible	history that preserves all its prefixes

26.2.5 Representation of the complete genealogical atlas in a quantum square (12,3)

The magic-square formalism separates (n, s). HMT adds m. The total object must be written

$$\mathfrak{M}_{m,s}^{(n)}, \tag{GMC-1.5}$$

and not simply $\mathfrak{M}_n$ or $\mathfrak{M}_s$. Each index answers a different question:

Index	Question	Associated operation
m	How much history is preserved?	refinement and truncation
n	How is the grid composed?	rows, columns and permutations
s	From which matrix level is it observed?	direct sum and compression UCP

For APP, $n = 9$ is fixed. Then the family $\{\mathfrak{M}^{(9)}_{m,s}\}_{m,s}$ is bigraded by (m, s). If APP, the four QLS of order three, and the atlas of twelve directions are compared, the index n varies once more, and the correct structure is trigraded.

Structural obstruction

Calling it a "bigrading (m, s)" does not erase n: it means that a family with fixed exterior size is being studied. Calling APP "9×9" likewise does not fix the interior size of its operators. The internal matrices 6×6, the qutrit chart $s = 3$, and the exterior grid $n = 9$ are objects of distinct types.

26.2.6 Bidirectionality of Mathematical Exchange

The De las Cuevas–Netzer ⟶ HMT direction contributes criteria that HMT had not formulated with this degree of separation: cellwise positivity, normalization of all rows and columns, semiclassicality, the boundary of the matrix convex hull, simultaneous dilation, and Arveson extreme points. The result is a set of tests and falsifiers for any claim of a «quantum square».

The HMT ⟶ De las Cuevas–Netzer direction adds structure to the object being compressed: depth, route, nonsplitting of the carry, monodromy, dynamics, gauge, double projection, and metrological readers. The problem ceases to ask only whether a dilation exists and instead asks whether a *genealogically faithful* dilation exists: one that does not identify two distinct routes merely because they produce the same visible effect.

Matrix bridge result

The new notion organizing the article is the *simultaneous genealogical dilation*: a common multiplicative representation that dilates not only several rows and columns at fixed depth, but all compatible depths, and that specifies which part of memory remains in the representation and which part is lost in compression. The exact theorem is proved in Section 26.4.

26.3 Operator systems of incidence: quantum Latin squares, qutrit contexts, and common genealogical dilation

The outer APP object has order nine, but the number nine does not suffice to make it a quantum magic square. One must exhibit 81 positive effects and verify 18 operator normalizations. This chapter performs that task for two shadows of APP and for the complete atlas of twelve directions. It also determines its exact class in the De las Cuevas–Netzer taxonomy.

26.3.1 Cyclic classification of 4 quantum Latin squares into an elementary operator class

Let

$$\mathcal{P}_a = \{P_{a,0}, P_{a,1}, P_{a,2}\}, \qquad a \in \mathbb{P}^1(\mathbb{F}_3), \tag{GMC-4.1}$$

the four qutrit PVM of the Weyl system. For each a, choose unit vectors $v_{a,k}$ with $P_{a,k} = |v_{a,k}\rangle\langle v_{a,k}|$ and define

$$L^{(a)}_{ij} = v_{a,i+j \bmod 3}. \tag{GMC-4.2}$$

Each row and each column traverses the basis $(v_{a,0}, v_{a,1}, v_{a,2})$ once. Therefore, $L^{(a)}$ is a QLS of order three. Since it is obtained from the cyclic Latin table and from a fixed orthonormal basis, it is of easy class and its projective QMS is semiclassical [39].

Proposition 26.6 (MUB Obstruction to Latin Stacking)**.** *Two rows from distinct contexts $\mathcal{P}_a$ and $\mathcal{P}_b$, $a \neq b$, cannot be taken as rows of the same* QLS *of order three while preserving their aligned columns.*

Proof. The column condition of a QLS would require orthogonality between the two vectors of a column. But mutual unbiasedness gives

$$|\langle v_{a,k}, v_{b,\ell}\rangle|^2 = \mathrm{Tr}(P_{a,k}P_{b,\ell}) = \frac{1}{3}$$

for every k, ℓ. The overlap is not zero. □

The obstruction does not deny quantum compatibility of the four bases. It determines that the operator structure appropriate for using them simultaneously is not a QLS of rank one: one must pass to weighted effects and to a QMS.

26.3.2 Bigraduation of the genealogical-matrix family

Lemma 26.7 (Cyclic square associated with a POVM)**.** *Let $E = (E_0, \dots, E_{n-1})$ be a* POVM *on $\mathbb{C}^s$. Then*

$$A_{ij} = E_{i+j \bmod n}, \qquad 0 \le i, j < n, \tag{GMC-4.3}$$

is a QMS *of sizes (n, s). It is also semiclassical and admits a simultaneous dilation to a commutative* QPM.

Proof. Each entry is positive. Every row and every column is a permutation of the n effects, so that its sum is I_s. For $t \in \mathbb{Z}/n\mathbb{Z}$, let $\sigma_t(i) = t - i$ and P_{σ_t} be its permutation matrix. Then

$$A = \sum_{t=0}^{n-1} P_{\sigma_t} \otimes E_t, \tag{GMC-4.4}$$

which is an explicit semiclassical decomposition. If $E_t = V^* Q_t V$ is a Naimark dilation of the POVM to a PVM $(Q_t)_t$, the entries $\widehat{A}_{ij} = Q_{i+j}$ form a commutative QPM and $A_{ij} = V^* \widehat{A}_{ij} V$ simultaneously for the n^2 cells. □

This construction belongs to the class of Latin families associated with POVMs (*POVM Latin-square friends*) of De las Cuevas and Netzer [39]. The novelty of the bridge lies not in the abstract lemma, but in the POVM furnished by HMT, their nonadic calibration, and the exact separation between what each square preserves and what it still compresses.

26.3.3 Additive APP representation of sizes $(9, 3)$ and its incidence codomain

Fix one of the four contexts, for example $\mathcal{P}_0 = \{P_{0,0}, P_{0,1}, P_{0,2}\}$. For $t \in \mathbb{Z}/9\mathbb{Z}$ define

$$E_t^{\Sigma} = \frac{1}{3} P_{0,t \bmod 3}, \qquad A_{ij}^{\Sigma} = E_{i+j \bmod 9}^{\Sigma}. \tag{GMC-4.5}$$

Each projection appears three times, then

$$\sum_{t=0}^{8} E_t^{\Sigma} = \frac{1}{3} \sum_{k=0}^{2} 3P_{0,k} = I_3.$$

By Lemma 26.7, A^{Σ} is a semiclassical QMS of sizes $(9, 3)$. It is a direct transduction of the Latin law $\Sigma(i, j) = i + j \bmod 9$ into a qutrit reading. It preserves the outer size and the additive leaf; it deliberately does not distinguish the three Hensel lifts of the same ternary class.

26.3.4 3 contexts in a square $(9, 3)$

Elijamos three of the four PVM qutrit, indexadas by $a = 0, 1, 2$, and ordenemos their projectors by means of $t = 3a + k$:

$$E^{(9)}_{3a+k} = \frac{1}{3} P_{a,k}, \qquad a, k \in \mathbb{Z}/3\mathbb{Z}. \tag{GMC-4.6}$$

Since

$$\sum_{a,k} E^{(9)}_{3a+k} = \frac{1}{3} \sum_{a=0}^{2} \sum_{k=0}^{2} P_{a,k} = I_3,$$

the formula

$$A^{(9)}_{ij} = E^{(9)}_{i+j \bmod 9} \tag{GMC-4.7}$$

produce otro QMS of sizes $(9, 3)$.

Theorem 26.8 (Qutrit square of outer order nine)**.** *The square $A^{(9)}$ of* (GMC-4.7) *satisfies:*

1. *its 81 cells are positive effects of rank one and trace $1/3$;*
2. *all rows and columns sum to I_3;*
3. *contains entries that do not commute;*
4. *is semiclassical by means of*
$$A^{(9)} = \sum_{t=0}^{8} P_{\sigma_t} \otimes E^{(9)}_t; \tag{GMC-4.8}$$
5. *admits a simultaneous commutative dilation of its 81 entries.*

Proof. The first two points and the decomposition follow from Lemma 26.7. If $a \neq b$, two rank-one MUB projectors do not commute unless they coincide or are orthogonal, both of which are impossible because their overlap is $1/3$; hence some $[E^{(9)}_{3a+k}, E^{(9)}_{3b+\ell}]$ are nonzero. The last assertion is the dilation constructed in the proof of the lemma. □

Matrix bridge result

This theorem closes an existence that the preliminary bridge had left open: there already are 81 explicit effects with $n = 9$, $s = 3$ and exact normalizations. At the same time it proves a fertile conceptual separation:

$$\text{noncommutative cells} \quad \not\Longrightarrow \quad \text{no semiclassicality}.$$

Here the cells do not commute, but the entire grid arises by reordering a single primary POVM.

26.3.5 The atlas complete in a cuadrado $(12, 3)$

The projective line over the nonadic ring has twelve points:

$$|\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})| = 12. \tag{GMC-4.9}$$

Reduction modulo three induces

$$r : \mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \longrightarrow \mathbb{P}^1(\mathbb{F}_3), \tag{GMC-4.10}$$

with four fibers of cardinality three. Fixing a calibration

$$\Xi : \mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \xrightarrow{\sim} \{(a, k) : a \in \mathbb{P}^1(\mathbb{F}_3),\ k \in \mathbb{F}_3\} \tag{GMC-4.11}$$

that respects the fibre of r, each direction ℓ is assigned the projector $P_{\Xi(\ell)}$. Ordering the twelve directions as $t = 0, \dots, 11$, let

$$F_t = \frac{1}{4} P_{\Xi(\ell_t)}, \qquad B_{ij} = F_{i+j \bmod 12}. \tag{GMC-4.12}$$

Theorem 26.9 (Square qutrit of the complete nonadic atlas)**.** *The matrix B is a* QMS *of tamanos* $(12, 3)$*, contains the twelve projectors calibrados of the four contextos qutrit and is semiclasica:*

$$B = \sum_{t=0}^{11} P_{\sigma_t} \otimes F_t. \tag{GMC-4.13}$$

It admits a simultaneous dilation to a commutative QPM*.*

Proof. Each of the four contexts sums to I_3, so $\sum_t F_t = (1/4) \cdot 4 I_3 = I_3$. The Lemma 26.7 applies. □

The factor $1/4$ is not decorative. The atlas contains four resolutions of the identity and, without that normalization, the sum would be $4I_3$. The complete atlas is therefore a twelve-outcome measurement, not a fifth orthonormal basis.

26.3.6 Operatorial theorems and genealogical fidelity criterion APP–TPK

The three previous constructions have an exact status:

Object	Closed theorem	HMT Structure Not Yet Transported
A^{Σ}, $(9, 3)$	sheet sum, positivity, normalization and semiclassicality	product sheet, quotient and paths
$A^{(9)}$, $(9, 3)$	three contexts, noncommutativity and common dilation	fourth context, Hensel incidence, gnomon and TPK memory
B, $(12, 3)$	complete atlas $12 \to 4 \times 3$ and common dilation	equivariance of calibration, dynamics, and monodromy

Neither of the final two squares is a QLS or a QPM: their cells are projectors scaled by $1/3$ or $1/4$, not projections. They are quantum magic squares under the orthodox definition, and they do possess a simultaneous dilation. This formulation resolves the terminological ambiguity and preserves the mathematical difference between an effect and a projection.

Mathematical extensions

The next objective is not to prove again that a QMS of order nine exists. It is to construct an *APP–TPK-faithful* one: in addition to (GMC-4.3), it must simultaneously carry Σ, Π, quotient, orientation, and route, and it must satisfy an equivariance equation with the TPK action. A candidate that does not satisfy that equation will remain a valid shadow, but not the total object.

26.4 Genealogical–matrix bigrading at fixed outer size and trigrading (m, n, s): truncation, compression, and simultaneous dilation

The De las Cuevas–Netzer separation between outer size n and matrix level s resolves an ambiguity in the language of grids. HMT requires a second separation: depth m is not an inner size. This chapter proves that the m and s directions are compatible and that a family coherent at every depth possesses a common dilation.

26.4.1 Inverse system of histories and direct system of observables

Let $(X_m, p_m)_{m\geq 0}$ be a system of nonempty finite sets with surjective maps

$$p_m : X_{m+1} \longrightarrow X_m. \tag{GMC-3.1}$$

In HMT, X_m may be the complete set of nonadic prefixes of length m or a set of survivors, provided that the restriction maps are surjective on the declared domain. The inverse limit

$$X_\infty = \varprojlim_m X_m$$

is the compact space of compatible histories. Each $x \in X_m$ determines the clopen cylinder

$$[x]_m = \{\xi \in X_\infty : \xi_m = x\}. \tag{GMC-3.2}$$

By duality, the diagonal algebras

$$D_m = C(X_m)$$

form an inductive system through

$$\jmath_m : D_m \longrightarrow D_{m+1}, \qquad \jmath_m(f) = f \circ p_m. \tag{GMC-3.3}$$

Its uniform limit is $C(X_\infty)$: the cylinder functions form a unital self-adjoint subalgebra that separates points and are dense by Stone–Weierstrass.

26.4.2 The family at 2 degrees

For $s \geq 1$, define the matrix state space

$$\mathcal{K}_{m,s} = \mathrm{UCP}(D_m, M_s(\mathbb{C})). \tag{GMC-3.4}$$

If $e_x \in D_m$ is the characteristic function of $x \in X_m$, every $\Phi \in \mathcal{K}_{m,s}$ is equivalent to a POVM

$$E_x^{(m)} = \Phi(e_x) \succeq 0, \qquad \sum_{x\in X_m} E_x^{(m)} = I_s. \tag{GMC-3.5}$$

The genealogical restriction is

$$\rho_m^s : \mathcal{K}_{m+1,s} \longrightarrow \mathcal{K}_{m,s}, \qquad \rho_m^s(\Phi) = \Phi \circ \jmath_m. \tag{GMC-3.6}$$

In terms of effects,

$$E_x^{(m)} = \sum_{y\in p_m^{-1}(x)} E_y^{(m+1)}. \tag{GMC-3.7}$$

It is exactly the operation "forget the continuation but sum all its prolongations." It is neither an average nor an elimination of mass: it preserves the unit.

In the matrix direction, if $d \geq 0$, $\Phi_r \in \mathcal{K}_{d,s_r}$ and $V_r : \mathbb{C}^s \to \mathbb{C}^{s_r}$ satisfy $\sum_r V_r^* V_r = I_s$, their matrix convex combination is

$$\mathrm{mc}_V(\Phi_1,\dots,\Phi_k)(f)=\sum_{r=1}^{k} V_r^*\Phi_r(f)V_r\in\mathcal{K}_{d,s}. \tag{GMC-3.8}$$

Theorem 26.10 (Genealogy Switching and Matrix Convexity)**.** *For every family $\Phi_r\in\mathcal{K}_{m+1,s_r}$ and every compression as in* (GMC-3.8)*,*

$$\rho_m^s(\mathrm{mc}_V(\Phi_1,\dots,\Phi_k))=\mathrm{mc}_V\left(\rho_m^{s_1}(\Phi_1),\dots,\rho_m^{s_k}(\Phi_k)\right). \tag{GMC-3.9}$$

Proof. For $f\in D_m$, both sides are equal to

$$\sum_r V_r^*\Phi_r(J_m f)V_r.$$

The equality is functorial, not numerical: it holds simultaneously for all matrix levels and for any system of truncations. □

Matrix bridge result

Equation (GMC-3.9) is the core of the bigrading (m,s). Refining the history and then compressing produces exactly the same shadow as compressing each reader and then forgetting the continuation. Depth and matrix level are independent, but form a commutative square.

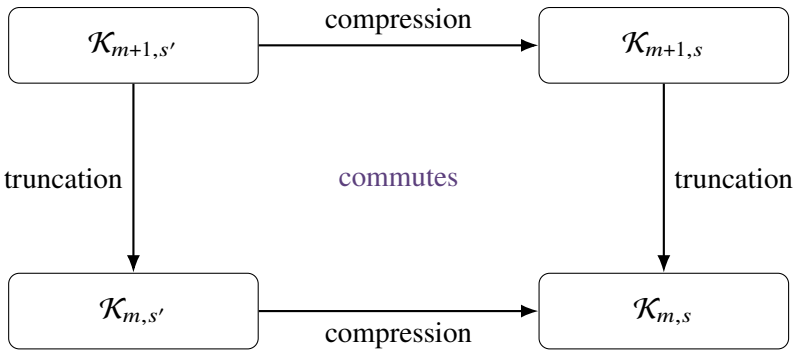

Figure 26.1: The two independent directions of the bigraduation. The symbol s' may represent a direct sum of several internal levels.

26.4.3 Uniform dilation compatible with all depths of the projective system

A family $(\Phi_m)_{m\geq 0}$ is compatible if

$$\Phi_m=\Phi_{m+1}\circ J_m. \tag{GMC-3.10}$$

This is equivalent to requiring the aggregation law (GMC-3.7) for all prefixes.

Theorem 26.11 (Simultaneous genealogical dilation, diagonal corridor)**.** *Every compatible family $\Phi_m\in\mathrm{UCP}(C(X_m),M_s)$ determines a unique map*

$$\Phi_\infty : C(X_\infty)\longrightarrow M_s \tag{GMC-3.11}$$

which coincides with Φ_m on each cylindrical algebra. There exist a Hilbert space $\mathcal{K}$, an isometry $V:\mathbb{C}^s\to\mathcal{K}$, a representation $\pi : C(X_\infty)\to B(\mathcal{K})$, and its associated projective spectral measure P on X_∞ such that

$$\Phi_\infty(f)=V^*\left(\int_{X_\infty} f(\xi)\,dP(\xi)\right)V. \tag{GMC-3.12}$$

In particular, for every m and $x \in X_m$,

$$E_x^{(m)} = V^* P([x]_m) V. \tag{GMC-3.13}$$

A common PVM *simultaneously dilates all finite* POVM *of the genealogy. If the Stinespring dilation is chosen to be minimal, the triple $(\pi, \mathcal{K}, V)$ is unique up to unitary equivalence; once π is fixed, its spectral measure P is unique.*

Proof. Compatibility defines a unital positive map on the union of the cylindrical algebras. Because the domain is commutative, positivity implies complete positivity, and the map is contractive. By density it extends uniquely to $C(X_\infty)$. The Stinespring theorem yields $\Phi_\infty(f) = V^*\pi(f)V$ and guarantees that its minimal realization is unique up to unitary equivalence. Every representation of a commutative algebra is the integral with respect to a unique PVM P associated with that representation. Applying the formula to the characteristic function of the cylinder $[x]_m$ gives (GMC-3.13). □

Corollary 26.12 (Fidelity environmental realization)**.** *The representation of Theorem 26.11 may be chosen faithful on $C(X_\infty)$ without changing any finite compression.*

Proof. If $(\pi, \mathcal{K}, V)$ is a dilation and $\pi_f : C(X_\infty) \to B(\mathcal{K}_f)$ a faithful representation, take $\pi \oplus \pi_f$ and the isometry $V \oplus 0$. The compression remains Φ_∞, and the ambient representation no longer identifies two distinct cylindrical functions. □

The final construction types the phrase "preserve the genealogy." The minimal dilation preserves exactly what the reader sees; the faithful ambient dilation additionally preserves all distinctions of the algebra before compression. The fidelity of a TPK dynamics, however, also requires intertwining its arrows and does not follow solely from the fidelity of the diagonal representation.

26.4.4 Noncommutative UHF Tower and Matrix Compatibility

The nonadic UHF tower, its trace, and its factorial closures are proved in chapter 23. Here they are taken as an explicit starting structure to prove a different result: the simultaneous prolongation of a compatible family of UCP maps and their common dilation.

Let

$$\mathcal{A}_m = M_{9^m}(\mathbb{C}), \qquad \iota_m(a) = a \otimes I_9, \qquad \mathcal{A}_\infty = \varinjlim(\mathcal{A}_m, \iota_m). \tag{GMC-3.14}$$

Theorem 26.13 (Simultaneous dilation on the UHF limit)**.** *If $\Psi_m : \mathcal{A}_m \to M_s$ are UCP maps and*

$$\Psi_m = \Psi_{m+1} \circ \iota_m, \tag{GMC-3.15}$$

there exists a unique UCP map $\Psi_\infty : \mathcal{A}_\infty \to M_s$ that prolongs them. There exists a representation $\pi : \mathcal{A}_\infty \to B(\mathcal{K})$ and an isometry $V : \mathbb{C}^s \to \mathcal{K}$ such that

$$\Psi_m(a) = V^*\pi(\iota_{m,\infty}(a))V \quad \textit{for every } m. \tag{GMC-3.16}$$

The representation can be made faithful by direct sum with a faithful representation of the UHF limit.

Proof. Compatibility defines Ψ_∞ on the algebraic inductive limit. UCP maps are completely contractive, so it extends to the completion C^*. Stinespring gives (GMC-3.16); the direct sum proves the last assertion. □

Restricting Theorem 26.13 to the canonical diagonals recovers the complete nonadic case $X_m = (\mathbb{Z}/9\mathbb{Z})^m$ of the Theorem 26.11; this restriction does not by itself cover an arbitrary system of survivors. In the canonical nonadic UHF system of (GMC-3.14), the GNS representation of its unique trace has weak

closure isomorphic to $\mathcal{R}_{\mathrm{hyp}}$. Thus, the bigrading is not a combinatorial appendix: it joins the cylinders of histories, the finite matrix charts, and the operatorial continuum of the von Neumann realization.

26.4.5 Trigraduation and Levels of Simultaneity

When a grid appears, the exterior size n is incorporated:

$$\mathfrak{M}_{m,s}^{(n)}. \tag{GMC-3.17}$$

The structure is trigraded if n varies and bigraded by (m, s) if n is fixed. 'Simultaneous' can denote three increasingly stringent requirements:

1. *by rows and columns*: a common dilation of the $2n$ POVM of a magic square;
2. *by depth*: a common dilation of all levels m, proved in Theorems 26.11 and 26.13;
3. *by dynamic genealogy*: in addition, an intertwiner preserving the route, monodromy, and TPK composition.

The first two have exact theorems within their respective domains. The third is the strongest notion that HMT contributes to the De las Cuevas–Netzer framework. The construction of the common operator system and its equivariance equation are proved in Section 17.9; the static dilation constitutes only one of its antecedents.

Structural obstruction

The theorem does not claim that every disconnected collection of effects at different depths has a common dilation. The decisive hypothesis is the compatibility (GMC-3.10) or (GMC-3.15). In HMT, that compatibility is the operator form of "each prefix is exactly the restriction of its continuations".

26.5 Matrix representation of the genealogical composition APP–TRIT–TPK

The recent program of De les Coves, van der Eyden, and Netzer extends operator systems to conic systems defined over more general categories [41]. The framework does not turn every category into a quantum theory: it requires choosing suitable cones, dualities, compressions, and completely positive maps. HMT provides an especially rich testbed in which to make that choice.

26.5.1 Realizations in systems of ordinary operators

The following families are entirely within the standard formalism:

- $\mathcal{S}_d = \mathrm{span}\{I, P_{\Sigma,d}, P_{\Pi,d}\}$ and its matrix ranks;
- the diagonal algebras $C(X_m)$ and the UHF tower $M_{9^m} \hookrightarrow M_{9^{m+1}}$;
- the readers UCP, POVM, PVM, channels CPTP and dilatacionis of Stinispring;
- the bigraded families $\mathcal{K}_{m,s}$.

No broader categorical formalism is required here in order to assert positivity, dilation, or matrix convexity. Indeed, the classification (GMC-6.9) shows that a substantial part of APP can be resolved by exact finite-dimensional operator theory.

26.5.2 Genealogical extension of operator systems for TPK routes

A TPK route is not merely an operator between two spaces: it carries source, target, sheet, orientation, length, carry, and a composition law. If those labels are forgotten and only the matrix representing the route is retained, distinct arrows may collapse. To incorporate the complete type, one proposes a category $\mathsf{C}_{\mathrm{HMT}}$ whose objects are register profiles and whose arrows are admissible transports. To each type c one would associate a cone of positive readers $A(c)$, and to each transformation a compatible action on those cones.

In the language of *Beyond Operator Systems*, the objective is to construct a S-system: a functorial extension of the tensor product by the base object to a family of cones, with CP maps defined as natural transformations level by level. The theory provides minimal and maximal systems, duality, generalized Choi–Kraus theorems, representations as intersections of S-hedra, and a $*$-autonomous category [41].

Mathematical extensions

The intrinsic S-system of the TPK remains to be constructed. At a minimum, the cone functor, the dualizing object, the evaluations and coevaluations, and the proof that TPK composition preserves positivity in every type are lacking. The fact that the TPK is monoidal in its finite realization does not by itself prove that it is $*$-autonomous.

26.5.3 Genealogical HMT Cones and Extension of the Conical Theory

The classical examples start from a base cone and study its minimal and maximal systems. HMT suggests a base cone with stratified memory:

$$C_m^{\mathrm{HMT}} = \mathrm{cone}\{\text{positive readers of histories at depth } m\}. \tag{GMC-8.1}$$

The truncations induce positive maps $C_{m+1}^{\mathrm{HMT}} \to C_m^{\mathrm{HMT}}$, while the compressions generate the matrix levels. The new phenomenon to study is whether the minimal and maximal systems remain separate upon taking the limit in m, and what part of that separation measures loss of genealogy rather than mere noncommutativity.

This proposes three invariants for the general program:

1. *separation depth*: the smallest m at which the minimal and maximal systems differ;
2. *matrix detection level*: the least s exhibiting that difference;
3. *memory defect*: the minimal route information that must be added in order to lift a point from the maximal system to the minimal system.

The first two refine the separation (m, s); the third is genuinely HMT. They are proposed definitions and must first be studied in $\mathfrak{C}_2^{\mathrm{APP}}$, where (GMC-6.9) permits exact computations.

26.5.4 TPK as a category of routes with selection, transport, memory, and return.

The paper on Latin squares proposes the development of quantum magic cubes. The cyclic lemma admits an immediate extension.

Definition 26.14 (Quantum Magic Cube)**.** A family $C = (C_{ijk})_{0\le i,j,k<n}$ of effects in M_s is a quantum magic cube if every line parallel to any of the three axes sums to I_s.

Theorem 26.15 (Cyclic cube of a POVM)**.** *For every* POVM $(E_t)_{t\in\mathbb{Z}/n\mathbb{Z}}$,

$$C_{ijk} = E_{i+j+k \bmod n} \tag{GMC-8.2}$$

is a quantum magic cube of exterior size n and interior size s.

Proof. Once two coordinates are fixed, as the third varies the index $i + j + k$ traverses $\mathbb{Z}/n\mathbb{Z}$ once. Each line therefore sums to $\sum_t E_t = I_s$. Positivity is inherited from POVM. □

Applying the theorem to $E^{(9)}$ of (GMC-4.6) and to F of (GMC-4.12) yields explicit qutrit cubes of orders nine and twelve. The former may assign the third axis to a phase coordinate; the latter uses the complete nonadic atlas. To convert that axis into genuine HMT depth, the layers must also satisfy

$$\rho_m(C^{m+1}_{ijk}) = C^m_{ijk}, \tag{GMC-8.3}$$

and intertwine the TPK. The cyclic construction closes the operatorial cube; genealogical fidelity remains an additional condition.

26.5.5 Completely positive compositions compatible with the genealogical-matricial bidegree

Another open direction of the theory consists in transferring the magic conditions to completely positive maps through Choi–Jamiołkowski. If $J(\Phi_{ij}) \succeq 0$ are the Choi matrices of a grid of CP maps, the conditions

$$\sum_j J(\Phi_{ij}) = J(\mathrm{id}), \qquad \sum_i J(\Phi_{ij}) = J(\mathrm{id}) \tag{GMC-8.4}$$

are a linear version of the magic normalizations. HMT provides channels of reading, updating, and transport; the problem is to decompose them into a grid that simultaneously preserves normalization, sheet, and route. The generalized conic formalism can treat codomains that are not simply matrix PSD cones.

26.5.6 Universality criterion in the genealogical domain

The framework of Gonda, Reinhart, Stengele, and De les Coves defines a simulator in a *target–context* category by means of

$$s : P \otimes C \longrightarrow T \otimes C, \tag{GMC-8.5}$$

with a functional compiler $s_T : P \to T$ and a context reduction. Universality is the existence of a lax reduction to the trivial simulator, not the mere richness or recurrence of the system [58].

An HMT instance may take:

- P: prefixes, route programs, or seeds;
- T: mathematical and physico-metrological observables intended to be realized;
- C: gauge, leaf, boundary conditions, and reading apparatus;
- s_T: transformation of a genealogy into an output;
- s_C: transport of the context and residual memory.

Proving universality would require constructing those data and the lax reduction. A monotone of the contextual preorder suffices to refute a proposal. The framework's impossibility theorem states, in particular, that if the functional image of the compiler has a supremum strictly below the target space for some compatible monotone, the simulator is not universal.

Matrix bridge result

HMT suggests a stronger version: *genealogically faithful universality*. In addition to reproducing the behavior of the target, the reduction must lift to a functor between categories of routes and preserve composition, return, and the enriched chronological register. Two behaviorally equivalent simulators may cease to be equivalent when preservation of provenance is required. This distinction offers a new and nontrivial instance for the categorical program.

The metrological unification demonstrated by HMT and categorical universality are distinct claims. The former derives readers and relations within the system; the latter requires the ability to simulate a declared class of targets and contexts. Typing them separately strengthens both: it avoids requiring from metrology a property that it does not need and turns universality into a falsifiable theorem.

26.5.7 Contextuality and Nonsemiclassicality

The cyclic squares of Section 26.3 are semiclassical. They therefore do not resolve the open direction concerning contextuality or nonsemiclassical QMS. APP, however, contains the noncommuting pair P_Σ, P_Π and algebra (GMC-6.9). The correct route is to construct cell effects that depend on both operators and prove that they admit no decomposition (GMC-4.4) with a POVM on S_n.

The verification is a semidefinite problem: find $Q_\sigma \succeq 0$, $\sum_\sigma Q_\sigma = I$, and

$$A_{ij} = \sum_{\sigma:\, \sigma(i)=j} Q_\sigma. \tag{GMC-8.6}$$

Feasibility certifies semiclassicality; infeasibility must be accompanied by a dual witness. A noncommutative matrix or a visual graph does not replace that certificate.

26.6 Genealogical structure of APP–TRIT–TPK at the matrix level

This chapter isolates the structures involved in the transduction and keeps their types explicit. The order is deliberate: support, sum–product difference, ternary memory, category of routes, quantum realization, operatorial closure, and metrological reading. Only afterward will it be asked which of these structures form a magic square or an operator system.

26.6.1 Common support of APP and dual evaluation via sum and product sheets

Let

$$X_9 = (\mathbb{Z}/9\mathbb{Z})^2, \qquad \mathscr{D} = \{(1,0),(0,1),(-1,0),(0,-1)\}.$$

The Cayley graph $\mathrm{Cay}(X_9, \mathscr{D})$ has 81 vertices and four oriented cardinal edges from every vertex. The APP architecture contains all finite paths in that graph. The acronym is retained as a technical name and is not used here to fix a historical expansion. At length r there are exactly $81 \cdot 4^r$ paths if returns and backtracking are allowed. There are not independent additive and multiplicative tables: there is a single support and two evaluations of the same point,

$$\Sigma(i,j) = \mathrm{dr}(i+j), \qquad \Pi(i,j) = \mathrm{dr}(ij), \qquad \mathrm{dr}(a) = 1 + ((a-1) \bmod 9). \tag{GMC-2.1}$$

The table of Σ is a classical Latin square of order nine, because every translation permutes $\mathbb{Z}/9\mathbb{Z}$. The table of Π is not: only its rows and columns indexed by the six units $\{1,2,4,5,7,8\}$ are permutations; $3, 6, 9$ fold classes.

Result

APP already contains an exact Latin structure, but APP is not exhausted by it. The sum leaf is Latin; the product leaf records the defect of Latinity of the local ring; the paths preserve the consultation order, and the residue–quotient lift preserves what modular reduction would conceal.

For each cell, the residue and quotient are retained:

$$i + j = R^+_{ij} + 9q^+_{ij}, \qquad ij = R^\times_{ij} + 9q^\times_{ij}. \tag{GMC-2.2}$$

The certified totals are

$$\sum R^+ = 405, \quad \sum R^\times = 459, \quad \sum q^+ = 45, \quad \sum q^\times = 174,$$

and therefore

$$2025 - 810 = 1215 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129. \tag{GMC-2.3}$$

The visible difference 54 and the quotient difference 129 are not two names for the same datum. One resides in the published residues; the other, in the memory required to recompose the integer value.

26.6.2 Posterior metrological realization of the double projection of the enriched state

The central block of APP takes the form

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 7I + 2R = 9P_+ + 5P_-, \qquad R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad P_\pm = \frac{I \pm R}{2}. \tag{GMC-2.4}$$

From this one obtains exactly the typed hierarchy induced by the preceding spectral decomposition:

$$\underbrace{9-5}_{4}\,;\quad \underbrace{2}_{\text{off-diagonal coupling}}\quad;\ \underbrace{51-45}_{6}\,;\ \underbrace{9\cdot 6}_{54}\,. \tag{GMC-2.5}$$

The first figure is the primordial spectral gap; the second, the coupling of the block; the third, the aggregate excess of the nonunitary sector; the fourth, its transport to the global scale of the table. They must not be collapsed on account of their arithmetic kinship.

Since $\det B_c = 45$, the normalization has determinant one and belongs to the connected hyperbolic group:

$$\frac{B_c}{\sqrt{45}} = \exp(\eta R), \qquad \eta = \frac{1}{2}\log\frac{9}{5}, \qquad \frac{5}{9} = e^{-2\eta}. \tag{GMC-2.6}$$

The same spectral pair thus admits a contractive reading and a Lorentzian reading. This is the precise connection with convexity and the hyperbolic interior that the bridge must preserve: the contraction $5/9$ is the shadow of the separation of the two idempotents $P_\pm$, not a verbal analogy with curvature.

26.6.3 TRIT: visible state, orientation, carry, and genealogical memory

TRIT is the oriented signature $\{-1, 0, +1\}$ obtained from $\mathbb{F}_3$ through $0 \mapsto 0$, $1 \mapsto +1$, $2 \mapsto -1$. To type its local lift, we define the lifted alphabet

$$\mathcal{L}_1 = \{\nu = r + 3c : r, c \in \{-1, 0, +1\}\} = \{-4, -3, \dots, 4\}, \qquad \widehat{\tau}(\nu) = (r, c). \tag{GMC-2.7}$$

The decomposition $\nu = r + 3c$ is unique in $\mathcal{L}_1$; r is the visible residue and c the carry. The symbol ν is a lifted amplitude and is not identified, in the absence of further data, with the sum of two visible trits. In particular, the amplitudes $3, 0, -3$ publish the same zero residue and yield three distinct antecedents,

$$0^+ = (0, +1), \qquad 0^0 = (0, 0), \qquad 0^- = (0, -1). \tag{GMC-2.8}$$

The complete state may contain

$$x = (t, \mu, o, h, c, \sigma, \lambda, g), \tag{GMC-2.9}$$

where t is the visible signature, μ the leaf, o the orientation, h the extension, c the carry, σ the boundary, λ the route, and g the nonadic phase. The projection $x \mapsto t$ eliminates all the other coordinates. This is the structural point that HMT contributes to the theory of dilations: two equal observable effects may possess distinct genealogies.

The three signatures admit the real algebras

$$\mathbb{A}_\tau = \mathbb{R}[J]/(J^2 + \bar{\tau}),$$

of elliptic type ($J^2 = -I$), parabolic type ($J^2 = 0$), and hyperbolic type ($J^2 = +I$). In the last case, $P_\pm = (I \pm J)/2$ separate two eigendirections. The TRIT is not merely the sign: it is the minimal observable of a transport that preserves the label, orientation, and memory.

26.6.4 TPK: category of memoryful paths

TPK, *Topological Phase Kernel*, resides on the free path category of APP and on its bivariate sum–product reading. Two paths that end in the same cell may differ in cardinal word, winding, sheet, quotient, and holonomy. TPK preserves that difference and composes routes associatively. The carry cocycle

$$\kappa_9(a, b) = \frac{\mathrm{dr}(a) + \mathrm{dr}(b) - \mathrm{dr}(a + b)}{9}$$

satisfies

$$\kappa_9(a, b) + \kappa_9(a + b, c) = \kappa_9(b, c) + \kappa_9(a, b + c), \tag{GMC-2.10}$$

and guarantees that the recovery does not depend on how a concatenation is parenthesized.

The quotient phase–length has objects $(b, r) \in \mathbb{Z}/12\mathbb{Z} \times \{0, \dots, 8\}$ and arrows

$$(b, r) \xrightarrow{\ell} \left(b + \left\lfloor \frac{r + \ell}{9} \right\rfloor , r + \ell \bmod 9 \right). \tag{GMC-2.11}$$

After nine unit iterations ($\ell = 1$), r returns and one dodecaphasic phase advances; after $108 = 9 \cdot 12$ unit iterations, the quotient returns. The enriched state of TPK may not have returned, because it preserves additional memory. The minimal predictive quotient of the published observables has 36 states and fibers of cardinality three. This fact makes visible the difference between equality of output and equivalence of history.

Scientific reading

A magic square simultaneously organizes rows and columns. TPK simultaneously organizes position, sheet, phase, and composition. The correct translation does not consist in calling every HMT table "quantum," but in constructing a positive reader that preserves the APP identities and declaring, coordinate by coordinate, which memory it preserves and which memory it compresses.

26.6.5 Hilbertian realization and quantum structure

The finite quantum closure of HMT constructs, for each depth d, the space

$$\mathcal{H}_d = \ell^2((\mathbb{Z}/9\mathbb{Z})^d), \qquad \mathcal{A}_d = B(\mathcal{H}_d) \cong M_{9^d}(\mathbb{C}). \tag{GMC-2.12}$$

For $u, v \in (\mathbb{Z}/9\mathbb{Z})^d$, the nonadic translations and phases act by means of

$$X_u|x\rangle = |x + u\rangle, \qquad Z_v|x\rangle = \omega^{v \cdot x}|x\rangle, \qquad \omega = e^{2\pi i/9},$$

and satisfy

$$Z_v X_u = \omega^{u \cdot v} X_u Z_v.$$

The complete family—equivalently, the d coordinate pairs X_j, Z_j—generates $\mathcal{A}_d$ and acts irreducibly. For the primitive central character fixed by ω, the finite Heisenberg representation is determined up to unitary equivalence. In this realization, states, self-adjoint observables, spectral measures, Born probabilities, unitary dynamics, and Kraus channels are constructed; the composition of registers is transported monoidally to the tensor product. The finite Hilbert-space representation is not presupposed: it is constructed explicitly and transports the genealogy of the system.

In the qutrit quotient there appear four maximal abelian subalgebras of the three-dimensional Weyl system. Their four spectral bases are mutually unbiased:

$$\operatorname{Tr}(P_{a,k}P_{b,\ell}) = \begin{cases} \delta_{k\ell}, & a = b, \\ 1/3, & a \neq b, \end{cases} \qquad a, b \in \mathbb{P}^1(\mathbb{F}_3). \tag{GMC-2.13}$$

The twelve minimal projectors $P_{a,k}$ are the operatorial atlas that is later calibrated with the twelve directions of $\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})$.

26.6.6 From the nonadic tower to the operatorial continuum

The unital inclusion, the marked branch, the UHF limit, and the closures of types I_∞ and II_1 are constructed in chapter 23. Their formulas are premises of the matrix bridge and determine the bigrading.

The operatorial tower prolongs the finite charts through the unital inclusions preserving the normalized trace

$$\iota_d : M_{9^d}(\mathbb{C}) \longrightarrow M_{9^{d+1}}(\mathbb{C}), \qquad a \longmapsto a \otimes I_9. \tag{GMC-2.14}$$

Indeed, if $\tau_n = \operatorname{Tr}/n$, then $\tau_{9^{d+1}} \circ \iota_d = \tau_{9^d}$; the ordinary trace, by contrast, is multiplied by nine. Its inductive limit is the UHF algebra of type $9^\infty = 3^\infty$. The closure in the GNS representation of the unique trace is the hyperfinite factor $\mathcal{R}_{\text{hyp}}$ of type II_1. The marked inclusions $a \mapsto a \otimes p_j$ follow one branch and lead to the corridor of compact operators, of type I_∞. The result therefore distinguishes preserving all branches simultaneously from selecting a particular history.

In the diagonal corridor, the finite sets of prefixes form an inverse system $X_{m+1} \to X_m$. The space of infinite histories is $X_\infty = \varprojlim X_m$, while its function algebras form the opposite inductive system. This duality of directions —inverse for histories, direct for observables— will be the exact support of the new bigraduation.

26.6.7 Double projection and metrology

HMT does not identify the published real number with the state that generates it. A compatible family of cylinders produces an Archimedean reading; another projection organizes the exceptional output and its symmetries. Numerical reality appears as the shadow of a double projection of a richer state. The monodromic generation theorems for π, e, φ, and α, the action and gravitation readers, the mass law, the mixing and CP-violation sectors, and the exceptional genealogy apply in their declared domains. The bridge makes explicit the operator objects that transport their conclusions.

The Planck identity uses the same block B_c, its transport in $SO^+(1,1)$, and the self-dual identity of the mass line. The decisive mathematical fact for this translation is that ‘physical observable’ and ‘generating history’ are different types. A UCP map can publish the former; the coordinate m and the TPK category preserve the latter.

Premises and derivation

The premises of the bridge are the unital inclusion $a \mapsto a \otimes I_9$, the block $B_c = 9P_+ + 5P_-$, the self-dual identity of the mass line, and periodicity of order 108. Each is used with the domain and hypotheses of its theorem; the matrix conclusions are deduced by means of the maps written in this chapter.

26.7 Genealogical Limits, Transfer Channels and Stinespring Memory

The HMT continuum and the continuum limit of matrix product states (MPS) answer different questions. The former prolongs finite histories and then reads them; the latter refines a tensor network and requires its transfer channel to admit compatible roots. The comparison is fruitful only if the channel connecting them is constructed.

26.7.1 Typed separation of the genealogical limit and the MPS limit

In the HMT corridor, an infinite history is an element of $X_\infty = \varprojlim X_m$. Under the finiteness, surjectivity, nested-compactum, contraction, and coherent-covering conditions proved in the continuum appendix, the quotient by the Archimedean reading reconstructs the declared real compactum. The complete state and its real value remain distinct objects.

For a translationally invariant MPS, a tensor $A = \{A^i \in M_D\}_{i=1}^d$ determines the transfer channel

$$E_A = \sum_i A^i \otimes \overline{A^i}. \tag{GMC-7.1}$$

De las Cuevas, Schuch, Pérez-García, and Cirac prove that an MPS in irreducible form has a continuum limit if and only if E_A is infinitely divisible; equivalently, there exist a projector channel P and a Lindblad generator L such that

$$E_A = Pe^L, \qquad P^2 = P, \qquad PLP = PL. \tag{GMC-7.2}$$

It has a coarse continuous limit if some power E_A^r is infinitely divisible [40].

Structural obstruction

The existence of the HMT inverse limit does not imply (GMC-7.2). To apply the MPS theorem, one must exhibit a uniform local tensor, identify its transfer channel, and verify infinite divisibility. Conversely, (GMC-7.2) does not by itself preserve sheet, carry, route, or monodromy.

26.7.2 Symplectic decomposition 12→4×3 of the phase coordinates

In the tower $\mathcal{A}_{m+1} = \mathcal{A}_m \otimes M_9$, the conditional expectation

$$\mathbb{E}_m = \mathrm{id} \otimes \tau_9 : \mathcal{A}_{m+1} \longrightarrow \mathcal{A}_m, \qquad \tau_9(b) = \frac{1}{9}\,\mathrm{Tr}(b), \tag{GMC-7.3}$$

is UCP and satisfies

$$\mathbb{E}_m(a \otimes I_9) = a. \tag{GMC-7.4}$$

On the diagonal, $D_{m+1} = C(X_m \times \mathbb{Z}_9)$ reduces to the uniform average over the last digit. The branch evaluation

$$\kappa_{m,a}(f)(x) = f(x, a) \tag{GMC-7.5}$$

is another retraction, this time multiplicative on the diagonal. Averaging all branches and selecting one branch are distinct operations, parallel to the inclusions $a \otimes I_9$ and $a \otimes p_a$ of the operatorial closure.

The expectation (GMC-7.3) has a dilation with an explicit record. Let

$$W_a\psi = \frac{1}{3}\,\psi \otimes e_a, \qquad a = 0, \dots, 8.$$

Then

$$\mathbb{E}_m(X) = \sum_{a=0}^{8} W_a^* X W_a. \tag{GMC-7.6}$$

In Stinespring form,

$$\pi(X) = X \otimes I_9, \qquad V\psi = \frac{1}{3}\sum_{a=0}^{8}(\psi \otimes e_a) \otimes e_a, \qquad \mathbb{E}_m(X) = V^*\pi(X)V. \tag{GMC-7.7}$$

The final auxiliary system (*ancilla*) labels exactly the digit discarded by averaging.

Matrix bridge result

The formula (GMC-7.7) is a canonical nonadic memory in the sense of Stinespring: what is lost when applying $\mathbb{E}_m$ remains orthogonally registered. It is not yet identified with TPK memory. That identification requires an intertwiner that also transports route, leaf, and dynamics.

26.7.3 Stinespring's Memoir and Non-Uniform Growth

The Theorem 26.13 provides a common, generally infinite-dimensional representation for every compatible family. A fixed finite ancillary system that purifies all levels cannot in general be required. Indeed, the compatible family of normalized traces on M_{9^m} has rank 9^m at level m, and any purification of the corresponding state requires an ancillary dimension of at least 9^m. Therefore,

$$\text{UCP compatibility at every depth} \quad \not\Longrightarrow \quad \text{uniform finite auxiliary memory.} \tag{GMC-7.8}$$

Memory growth is not a defect of the construction: it quantifies the amount of genealogy that one requires to be preserved.

The dynamic fidelity of this memory and its comparison with the limit of matrix product states are developed in section 26.7.4, without repeating the UHF tower or the Stinespring dilation demonstrated here.

26.7.4 Dynamic fidelity equation

The trace-preserving expectation $\mathrm{id} \otimes \tau_9$, its Stinespring dilation, and the general impossibility of a uniform finite auxiliary memory have been constructed in sections 26.7.2 y 26.7.3. On that operatorial premise, and without abbreviating its proofs, the additional condition of genealogical fidelity is now formulated.

Let T_m^{TPK} be the transport between records at depth m, and let J_m be the encoding of those records in the dilation space. The Stinespring memory is TPK-faithful if there exists a transport $\widetilde{T}_m$ in the ambient space such that

$$J_{m+1}T_m^{\mathrm{TPK}} = \widetilde{T}_m J_m \tag{GMC-7.9}$$

and the observational compressions satisfy the corresponding naturality. If two distinct histories are identified under J_m, the dilation may be operatorially valid but not genealogically faithful.

The equation (GMC-7.9) is falsifiable: it suffices to have a pair of routes that TPK distinguishes and the environment identifies, or a composition whose image does not coincide with the composition of the images.

26.7.5 Compatibility Criterion for Product State Limits

To apply (GMC-7.2) to the HMT continuum, five steps must be completed:

1. choose a uniform local cell and construct matrices $A^i \in M_D$;
2. prove that nonadic cell blocking intertwines the evolution with a refinement isometry;
3. compute the channel E_A and its irreducible form;
4. resolve whether E_A or some power E_A^r is infinitely divisible;
5. transport the leaf, carry cocycle, and monodromy to the limit, rather than preserving only the tensor state.

If the channel were unitary, $E_A = \mathrm{Ad}_U$, it would have unitary roots of every order by functional calculus. But it would still be necessary to prove that this channel is the transfer channel associated with an HMT tensor and that its roots respect the genealogical refinement. If a projective part P appeared, HMT memory would offer a concrete interpretation of the sectors that survive scale grouping.

26.7.6 Tensorial decompositions with symmetry

The work of De las Cuevas with Netzer and collaborators on approximate tensor decompositions and on simplicial complexes provides another point of entry [38, 37]. APP supplies a finite complex with an action of translations; TPK supplies labels and compatibilities along routes. An HMT tensor decomposition should state:

- which tensor encodes a cell or a transition;
- which group preserves the labels and which part acts only after reduction;
- whether the factorization is exact, approximate, or only asymptotic;
- which rank remains stable as m increases.

The bidirectional opportunity is concrete. Its formalism provides criteria of factorization, invariance, and limit; HMT provides a refinement system with fibers, carry, and monodromy that can produce examples in which a visible factorization exists but no genealogically faithful factorization preserves the route.

Mathematical extensions

A subsequent paper may study "infinite divisibility with root memory": not only whether $E = E_k^k$, but whether a coherent tower of roots $E_{k\ell}^{\ell} = E_k$ equipped with TPK records can be chosen. This condition is stronger than divisibility of the bare channel and constitutes a natural extension of the MPS problem from HMT.

26.8 Completely positive matrix realization of the nonadic fibration of observables

Symplectic geometry is not part of the published theorems on De las Cuevas–Netzer magic squares. The legitimate link passes through a neighboring, standard route: Weyl operators, discrete phase space and mutually unbiased bases [52, 100]. In HMT, that route acquires a nonadic lift and fiber memory.

26.8.1 The alternating form and the Weyl commutation

On $V_3 = \mathbb{F}_3^2$ we define

$$\langle (q,p),(q',p')\rangle_{\mathrm{sp}} = qp' - pq'. \tag{GMC-5.1}$$

If $X|k\rangle = |k+1\rangle$, $Z|k\rangle = \omega^k|k\rangle$, and $\omega = e^{2\pi i/3}$, the operators $W_{q,p} = X^q Z^p$ satisfy, under these conventions,

$$W_u W_v = \omega^{-\langle u,v\rangle_{\mathrm{sp}}} W_v W_u. \tag{GMC-5.2}$$

Therefore, two operators commute exactly when their labels are orthogonal for the alternating form. In dimension two, the maximal isotropic sublines are the four points of

$$\mathbb{P}^1(\mathbb{F}_3) = \{[1:0],[0:1],[1:1],[1:2]\}. \tag{GMC-5.3}$$

Each generates a maximal abelian context of $M_3(\mathbb{C})$; its spectral projectors constitute a PVM. Contexts associated with distinct lines produce the four MUB bases of (GMC-2.13).

Proposition 26.16 (Qutrit decomposition by directions)**.** *Let $\mathcal{D}_a$ be the four diagonal subalgebras determined by the lines of* (GMC-5.3) *and $\mathcal{D}_a^0$ their traceless parts. Then*

$$M_3(\mathbb{C}) = \mathbb{C}I \oplus \bigoplus_{a\in\mathbb{P}^1(\mathbb{F}_3)} \mathcal{D}_a^0 \tag{GMC-5.4}$$

as an orthogonal sum for the Hilbert–Schmidt product. The dimension count is $9 = 1 + 4 \cdot 2$.

Proof. Each $\mathcal{D}_a^0$ has dimension two. Unbiasedness implies $\mathrm{Tr}(A^*B) = 0$ for $A \in \mathcal{D}_a^0$ and $B \in \mathcal{D}_b^0$, $a \neq b$. All are orthogonal to I. The dimensions sum to nine, the dimension of $M_3(\mathbb{C})$. □

This identity explains why the twelve projections are not twelve arbitrary independent pieces: they are four resolutions of the identity whose centered parts decompose the entire qutrit operator space.

26.8.2 The lift $12 \to 4 \times 3$

On the modulo nonadic $V_9 = (\mathbb{Z}/9\mathbb{Z})^2$ it preserves the forma alternante

$$\langle (a,b),(c,d)\rangle_9 = ad - bc \pmod 9. \tag{GMC-5.5}$$

The projective line $\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})$ consists of the primitive vectors modulo multiplication by a unit. It can be represented as

$$\{[1:t] : t \in \mathbb{Z}/9\mathbb{Z}\} \sqcup \{[3u:1] : u \in \mathbb{Z}/3\mathbb{Z}\}, \tag{GMC-5.6}$$

and has $9 + 3 = 12$ points. Reduction modulo three gives the diagram

$$\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \xrightarrow{r} \mathbb{P}^1(\mathbb{F}_3), \qquad |r^{-1}(a)| = 3. \tag{GMC-5.7}$$

The basis a of a qutrit context and the outcome k of its PVM likewise form a set 4×3. A *calibration* is a bijection

$$\Xi : \mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}) \longrightarrow \{P_{a,k} : a \in \mathbb{P}^1(\mathbb{F}_3),\ k \in \mathbb{F}_3\} \tag{GMC-5.8}$$

that sends each fiber of r to the three outcomes of the context lying over a.

Structural obstruction

The fibration is canonical; assigning the internal order of each fiber to the three outputs k is a gauge. A bijection is not yet an equivariance. To promote Ξ to an intertwiner, one must prove that the relevant linear, projective, and antiunitary actions are transported in every fiber. The preliminary gauge fails an antiunitary check in one fiber; that failure is preserved as a falsifier, not concealed.

26.8.3 Depth, carry, and memory over the discrete phase space

The Weyl geometry over $\mathbb{F}_3^2$ explains commutation, contexts, and MUB. HMT adds three levels that are not recovered from the symplectic form by itself:

1. the lift of a ternary direction to three points of $\mathbb{P}^1(\mathbb{Z}/9\mathbb{Z})$;
2. the sheet, carry and orientation that distinguish states with the same reduction;
3. the TPK route that transports those coordinates and can return to the phase without returning to the state.

The potential contribution to the qutrit literature is not "another construction of four MUBs," which is already known. It is a geometry of *context roots*: each ternary context has three nonadic antecedents, and those antecedents may carry dynamics and monodromy. The order-twelve square of Theorem 26.9 is the first normalized shadow of that atlas.

26.8.4 Typed separation between the qutrit overlap $1/3$ and the HMT reader $1/\pi$

In a pair of MUB qutrit bases,

$$\mathrm{Tr}(P_{a,k}P_{b,\ell}) = \frac{1}{3}. \tag{GMC-5.9}$$

In the HMT reader defined here, the relation between a real sheet and a volumetric reading can take the quotient

$$\frac{\pi}{\pi^2} = \frac{1}{\pi}. \tag{GMC-5.10}$$

The two expressions are not interchangeable: $1/3$ is an overlap between projectors in dimension three; $1/\pi$ is a scalar weight of another reader. The difference does not prevent their coordination. For a fixed PVM $\{P_0, P_1, P_2\}$, we define a measurement with nine effects:

$$F_k^{(\pi)} = \frac{3}{\pi}P_k \quad (k = 0, 1, 2), \qquad F_r^{(\pi)} = \frac{1 - 3/\pi}{6}I_3 \quad (r = 3, \ldots, 8). \tag{GMC-5.11}$$

It is a POVM because $3/\pi < 1$ and

$$\sum_{r=0}^{8} F_r^{(\pi)} = \frac{3}{\pi}I_3 + \left(1 - \frac{3}{\pi}\right) I_3 = I_3. \tag{GMC-5.12}$$

If Q is a rank-one projector of a distinct MUB context,

$$\mathrm{Tr}(QF_k^{(\pi)}) = \frac{3}{\pi}\,\mathrm{Tr}(QP_k) = \frac{3}{\pi}\cdot\frac{1}{3} = \frac{1}{\pi}. \tag{GMC-5.13}$$

Matrix bridge result

The formula (GMC-5.11) exactly transforms the MUB probability $1/3$ into the reader $1/\pi$ through the gauge $3/\pi$, without identifying the two numbers. The six residual effects preserve the unit and complete a POVM of nine outcomes, from which another cyclic QMS $(9, 3)$ is obtained. This construction does not yet identify the geometric provenance of the residual mass; it fixes the exact operator type that it must have.

26.8.5 Symplectic group and equivariance equation

In dimension two over $\mathbb{F}_3$, the symplectic group coincides with $SL(2, \mathbb{F}_3)$ and permutes the four lines. Its action lifts projectively, by means of the Clifford group, on the PVM qutrits. Let G_{HMT} be a group or groupoid of transformations of the nonadic atlas and U_g the candidate unitary or antiunitary operator in the qutrit chart. The condition that turns a calibration into a dynamical bridge is

$$\Xi(g \cdot \ell) = U_g\,\Xi(\ell)\,U_g^*, \qquad g \in G_{\mathrm{HMT}}, \quad \ell \in \mathbb{P}^1(\mathbb{Z}/9\mathbb{Z}). \tag{GMC-5.14}$$

If g is an arrow and not merely a global symmetry, the equation must include the source and target and is formulated as a natural transformation. The verification of (GMC-5.14) is the step that separates a fortunate labeling from a structural transduction.

Premises and derivation

The symplectic and MUB identities rely on the finite-phase literature [52, 100]. They are not attributed to the papers on magic squares by De las Cuevas–Netzer. The nonadic fibration, calibration, and route readers constitute the original contribution of the HMT construction studied here.

26.9 Nonsemiclassical quantum magic square in a corner APP

En $\mathbb{C}^4$, with base e_1, e_2, e_3, e_4, considerese the arreglo of vectors

$$\begin{array}{cccc} e_1 & e_2 & e_3 & e_4 \\ e_2 & e_1 & e_4 & e_3 \\ (e_3+e_4)/\sqrt{2} & (e_3-e_4)/\sqrt{2} & (e_1+e_2)/\sqrt{2} & (e_1-e_2)/\sqrt{2} \\ (e_3-e_4)/\sqrt{2} & (e_3+e_4)/\sqrt{2} & (e_1-e_2)/\sqrt{2} & (e_1+e_2)/\sqrt{2}. \end{array}$$

Let P_{ij} be the rank-one projector onto the vector located in cell (i, j). Each row and each column is an orthonormal basis, hence

$$\sum_j P_{ij} = I_4, \qquad \sum_i P_{ij} = I_4. \tag{26.1}$$

To realize it in the APP fiber of dimension 9, fix

$$A_{ij} := P_{ij} \oplus \frac{1}{4} I_5 \in M_9(\mathbb{C}). \tag{26.2}$$

Theorem 26.17 (No certified semiclassicality)**.** *The matrix $A = (A_{ij})_{i,j=1}^4$ is a quantum magic square and does not admit a semiclassical decomposition*

$$A_{ij} = \sum_{\pi:\, \pi(i)=j} Q_\pi, \qquad Q_\pi \succeq 0, \qquad \sum_\pi Q_\pi = I_9.$$

Proof. The row and column identities follow from (26.1); four copies of $I_5/4$ sum to I_5. If a semiclassical decomposition existed, its compression to the corner $\mathbb{C}^4$ would be a joint measurement of the PVM defined by the rows $(P_{ij})_j$. Jointly measurable projective measurements commute. However,

$$\left[|e_1\rangle\langle e_1|, \left|\frac{e_1+e_2}{\sqrt{2}}\right\rangle\left\langle\frac{e_1+e_2}{\sqrt{2}}\right| \right] = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \oplus 0_2 \neq 0.$$

The contradiction proves nonsemiclassicality. The compression simultaneously provides an analytic witness to the infeasibility of the semidefinite problem. □

Each row defines a UCP channel.

$$\Phi_i : \ell_4^\infty \to M_9, \qquad \Phi_i(\delta_j) = A_{ij},$$

and each column defines another. Thus, the magic normalizations translate into completely positive maps with explicit domain and codomain; a symbol $J(\mathrm{id})$ is not used without first fixing those types.

26.10 Conical route system and internal genealogical universality

For each finite profile c, let G_c be the finite groupoid of TPK routes with that profile and let $A(c) = C^*(G_c)$. At matrix level s, one takes the cone

$$C_s(c) = M_s(A(c))_+.$$

A route $r : c \to d$, represented by the partial isometry v_r, induces the CP map

$$T_r(a) = v_r^* a v_r.$$

Theorem 26.18 (Functorial conic system of TPK paths)**.** *The assignments $c \mapsto (C_s(c))_{s\geq 1}$ and $r \mapsto T_r$ respect identity, composition, matrix amplification, and genealogical truncation. The CPM category generated by the finite fibers is compact monoidal: the dual of a fiber is its conjugate space, and the*

coevaluations and evaluations are the canonical cups and caps. The projective limit of these systems preserves all compatible CP maps.

Proof. The complete positivity of $a \mapsto v_r^* a v_r$ is immediate from its Kraus form. For composable routes, $v_{r_2 r_1} = v_{r_2} v_{r_1}$, hence $T_{r_2 r_1} = T_{r_1} T_{r_2}$ with the declared variance. The inclusions and conditional expectations of the finite levels are UCP and form commuting squares. The compactification of CPM in finite dimension is the standard construction by conjugate spaces; truncation compatibility permits passage to the limit coordinate by coordinate. □

Let $\mathsf{P}_{\mathrm{HMT}}$ the set countable of codigos of routes finite and let $\mathsf{C}_{\mathrm{HMT}}$ the space of states with its contexto complete. The evaluation

$$\mathrm{Ev}(\ulcorner r \urcorner, x) = T_r(x)$$

preserves origin, destination, sheet, orientation, carry, boundary, and word of route.

Corollary 26.19 (Genealogically faithful universality in the HMT domain)**.** *The evaluator* Ev *is universal for the declared class of finite TPK transports and their compatible limits: every transport in that class has a code, composition is performed by concatenating codes, and reduction preserves the complete genealogy. This internal universality is not extended by decree to an untyped external class of targets.*

26.11 Identification of the Stinespring memory with the local record TPK

In the nonadic expectation, the Stinespring dilation retains the discarded digit in a basis $\{e_a\}_{a=0}^{8}$. For a TPK state x, let $\lambda(x, a)$ be the complete label of the continuation by the digit a. Define the isometry

$$W_x : e_a \longmapsto e_{\lambda(x,a)}$$

from the memory minima of Stinespring toward the record local TPK. Let $F_x e_{\lambda(x,a)} = e_a$ the forgetful functor restringido to its imagen.

Theorem 26.20 (The TPK memory refines the minimal memory of Stinespring)**.** *For every x,*

$$W_x^* W_x = I_9, \qquad F_x W_x = I_9.$$

The family $(W_x)_x$ intertwines the inclusion of a new digit with the truncations. At depth m, the tensor product of these isometries identifies the ancilla $(\mathbb{C}^9)^{\otimes m}$ with the TPK subregister that preserves the sequence of extensions; the additional sheet, carry, boundary, and route coordinates explain why TPK memory is a refinement rather than a second copy of the ancilla.

Proof. Continuations with distinct digits have orthogonal labels, so W_x is isometric. The definition of F_x proves the second identity. Composition of extensions concatenates the labels in the same order as the tensor product of the ancillas; hence naturality under truncation and the assertion at arbitrary depth. □

From the surviving sections to the fundamental constants

The genealogical continuum already constructed does not publish mere decimal expansions: it publishes compatible sections that preserve orientation, boundary, carry, and memory. A fundamental constant is the stable evaluation of one of those sections under a typed reader. Part III therefore reconstructs the object, the map, and the proof that precede each value; Archimedean or metrological comparisons appear only after the internal output.

In the sense fixed by the tesis inaugural, the nonadic reading does not act again as a threshold or restart the continuum. The joint nonadic connection and the prolongation

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

constitute, with the changes and invariants fixed in the TPK threshold architecture, the first certified segment of the uniform law that constructs a unique enriched coinductive state. Among its correlated outputs, which form the minimal kernel of its typed nonadic image, are $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}$ and α_{HMT}. Unity of origin does not flatten their types: angular closure, propagation, autoscale and coupling have their own readers; the coordinate α is published through the signed record, reversible seal and dodecaphasic closure. Only after these outputs are published do complex realization, modular memory, the action scale and angular geometry open, with separate domains. The common state is not exhausted by these four coordinates: its typed readers also publish invariants, aggregates, mirror relations and derived mathematical and physical constants.

Part III

Genealogy of the fundamental constants: coinductive generation and dodecaphasic closure

The order of the following chapters is expository, not causal. The nonadic connection and the complete prolongation

$$w_{6} \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_{9}$$

stabilize a unique coinductive APP–TRIT–TPK state. From that state, π, e, φ and α are published correlatively: the successive chapters separate their readers so that they can be studied precisely, but do not turn that typographical separation into serial generation. The closure of π, the propagation of e, the self-scaling of φ and the signed, dodecaphasic publication of α retain their respective statuses within the same correlated coinductive generation.

Chapter 27

Algebra and genealogical classification of the fundamental constants

The Euclidean residue–quotient extension of APP contains two local maps: the additive map normalizes collisions, and the multiplicative map produces partial products. In this section, the global multiplication of words is constructed using exclusively both maps. The correspondence with integer multiplication will be a consequence of the intertwiner, not the definition of the operation.

27.1 Euclidean coordinates of the local cell

Definition 27.1 (Additive and multiplicative applications on the same support)**.** Let $D_9 = \{1, \dots, 9\}$. For $a, b \in D_9$ they are defined by Euclidean division with remainder in D_9:

$$a + b = 9q^{+}(a, b) + R^{+}(a, b), \tag{27.1}$$

$$ab = 9q^{\times}(a, b) + R^{\times}(a, b). \tag{27.2}$$

In particular, the zero remainder is represented by 9 and the quotient is reduced by one unit. The quadruple

$$C_9^{\mathrm{rq}}(a, b) = (R^{+}(a, b), q^{+}(a, b); R^{\times}(a, b), q^{\times}(a, b))$$

is the local arithmetic extension by residue and quotient.

Aggregation by the three classes modulo three of the visible table $R^{\times}$ defines a matrix distinct from the local maps:

$$(M_\Pi)_{rs} = \frac{1}{9} \sum_{\substack{a \equiv r \ (3) \\ b \equiv s \ (3)}} R^{\times}(a, b), \qquad r, s \in \{1, 2, 0\},$$

and, in that order of classes,

$$M_\Pi = \begin{pmatrix} 4 & 5 & 6 \\ 5 & 4 & 6 \\ 6 & 6 & 9 \end{pmatrix}.$$

Thus, q^{+} and $q^{\times}$ are quotient coordinates of a cell, whereas M_Π is an aggregate operator on residual classes.

The 81 cells satisfy exactly

	$\sum R$	$\sum q$	$\sum(9q + R)$
$+$	405	45	810
$\times$	459	174	2025

and therefore

$$2025 - 810 = (459 - 405) + 9(174 - 45) = 54 + 9 \cdot 129 = 1215.$$

The quotient $q^{\times}$ is necessary for reconstruction. For example,

$$2 \cdot 5 = 9 \cdot 1 + 1.$$

If only $R^{\times}$ is preserved, the product 10 is conflated with the visible value 1.

27.1.1 Cocycles of associativity and distributivity

The coherence of the transducer can already be decided in the cell. For every $a, b, c \in D_9$ the three identities are verified

$$q^{+}(a,b) + q^{+}(R^{+}(a,b),c) = q^{+}(b,c) + q^{+}(a,R^{+}(b,c)), \tag{27.3}$$

$$q^{\times}(R^{\times}(a,b),c) + c\,q^{\times}(a,b) = q^{\times}(a,R^{\times}(b,c)) + a\,q^{\times}(b,c), \tag{27.4}$$

$$\begin{aligned} q^{\times}(a,R^{+}(b,c)) + a\,q^{+}(b,c) &= q^{+}(R^{\times}(a,b),R^{\times}(a,c)) \\ &\quad + q^{\times}(a,b) + q^{\times}(a,c). \end{aligned} \tag{27.5}$$

Theorem 27.2 (Local coherence of the Euclidean extension)**.** *The identities* (27.3)–(27.5)*, together with the corresponding equalities of residues, express respectively additive associativity, multiplicative associativity, and distributivity in the residue–quotient extension. The three families have zero discrepancies in the* $9^3 = 729$ *triples.*

Proof. Expanding $(a + b) + c$ through (27.1), the coefficient of nine is the left-hand side of (27.3); expanding $a + (b + c)$ yields the right-hand side. Uniqueness of division with remainder in D_9 equates both residues and quotients. The same argument applied to $(ab)c = a(bc)$ gives (27.4). Finally, the two expansions of $a(b + c) = ab + ac$ produce (27.5). Direct enumeration of the 729 cases of each identity confirms the algebraic calculation. □

27.2 Bijectivity of numbering

The symbol 9 is not identified with zero. In C_9^{rq}, 9 represents a complete crossing of the nonadic boundary. Replacing it with the digits $0, \dots, 8$ would eliminate the Euclidean quotient that intervenes in the intertwining.

Definition 27.3 (Canonical words)**.** Let

$$\mathscr{W}_9^{+} = \bigsqcup_{\ell \geq 1} D_9^{\ell}, \qquad \mathscr{W}_9 = \{\varnothing\} \sqcup \mathscr{W}_9^{+}.$$

Words are written from the least significant digit. We define

$$\mathrm{ev}_9(u_0, \dots, u_{\ell-1}) = \sum_{j=0}^{\ell-1} u_j 9^j, \qquad \mathrm{ev}_9(\varnothing) = 0.$$

Theorem 27.4 (Uniqueness of the normal form)**.** *The evaluation* ev_9 *is a bijection from* $\mathscr{W}_9^{+}$ *onto* $\mathbb{N}_{\geq 1}$*, and from* $\mathscr{W}_9$ *onto* $\mathbb{N}_0$*.*

Proof. The words of length ℓ cubren the intervalo

$$\frac{9^{\ell} - 1}{8} \leq \mathrm{ev}_9(u) \leq 9\,\frac{9^{\ell} - 1}{8}.$$

The minimum of the next interval is one unit greater than the maximum of the preceding one. Within each interval, division of $n - 1$ by nine uniquely determines the digit

$$d = (n - 1) \bmod 9 + 1$$

and the quotient that is encoded recursively. The process terminates because the quotient strictly decreases. □

Examples:

$$9 \longleftrightarrow (9), \qquad 10 \longleftrightarrow (1,1), \qquad 81 \longleftrightarrow (9,8), \qquad 1000 \longleftrightarrow (1,3,3,1).$$

27.3 Fibers of the residual projections on the integral liftings

For this block, we distinguish two alphabets. The normal form $\mathscr{W}_9$ uses the digits $\{1,\dots,9\}$, written from the least significant. By contrast, $\mathscr{B}_9$ denotes the conventional positional representations in base nine, with digits $\{0,\dots,8\}$ and the most significant on the left. The two types are not identified.

Let

$$\mathscr{W}_{10}^{(2)} = \{0,\dots,9\}^2, \qquad \rho_{10}(a,b) = (b,a), \qquad \mathrm{ev}_{10}(a,b) = 10a + b,$$

and let $q_9 : \mathbb{N} \to \mathbb{Z}/9\mathbb{Z}$ be the residual reduction.

Lemma 27.5 (Residual descent of decimal reversal)**.** *Reversion on decimal words of length two is involutive and its shadow modulo nine is the identity:*

$$\rho_{10}^2 = I, \qquad q_9(\mathrm{ev}_{10}(\rho_{10}(a,b))) = q_9(\mathrm{ev}_{10}(a,b))\,.$$

Fixed length preserves the initial zeros.

Proof. The doble permutation recovers (a,b). Ifnce $10 \equiv 1 \pmod 9$,

$$10b + a \equiv a + b \equiv 10a + b \pmod 9.$$

A word whose double reversal were not itself, or whose digit sum changed modulo nine, would refute the lemma. □

Lemma 27.6 (Residual Square Descent)**.** *The map $s(n) = n^2$ induces the residual endomap*

$$[n]_9 \longmapsto [n]_9^2, \qquad q_9(s(n)) = q_9(n)^2.$$

Proof. The compatibility of a congruence with the product gives $n \equiv m \pmod 9 \Rightarrow n^2 \equiv m^2 \pmod 9$. An integer for which $q_9(n^2) \neq q_9(n)^2$ would refute the statement. □

Proposition 27.7 (Residual fibers of the full reversal)**.** *The residual shadow does not reconstruct the integral lift $\widehat{\rho}_{10} = \mathrm{ev}_{10} \circ \rho_{10}$. Indeed,*

$$18 \equiv 27 \pmod 9, \qquad \widehat{\rho}_{10}(1,8) = 81 \neq 72 = \widehat{\rho}_{10}(2,7).$$

Proof. Both integers belong to residue class zero, but their reversals are distinct. Therefore, there is no $\overline{\rho} : \mathbb{Z}/9\mathbb{Z} \to \mathbb{N}$ that simultaneously factors those two values. □

Proposition 27.8 (Residual fibres of the entire square)**.** *The same shadow likewise does not reconstruct the integer square:*

$$18 \equiv 27 \pmod 9, \qquad 18^2 = 324 \neq 729 = 27^2.$$

Proof. A function $\overline{s} : \mathbb{Z}/9\mathbb{Z} \to \mathbb{N}$ that factorized s would have to assign the two values 324 and 729 to the same zero class, which is impossible. □

Corollary 27.9 (Cross-witness 27–72–729)**.**

$$\widehat{\rho}_{10}(2,7) = 72, \qquad 27^2 = 729 = 9^3 = 3^6,$$

and, in the alfabeto convencional $\mathscr{B}_9$*,*

$$27 = 30_9, \qquad 72 = 80_9, \qquad 729 = 1000_9.$$

The three integers have residual shadow zero and positive digital root nine.

Proof. The two operations are computed directly; successive divisions by nine produce the three expressions. The result would fail if $\mathscr{B}_9$ were confused with $\mathscr{W}_9$, if any of the expressions were incorrect, or if it were claimed that faithful residual descent reconstructs the operation and its complete genealogy. □

27.4 Native adder and quotient propagation

Algorithm 27.10 (Word addition)**.** Two words are traversed by positions, with initial carry $c_0 = 0$. If there are two digits at a position, (27.1) is applied; if there is only one, that digit is taken as the provisional residue and the provisional quotient is zero. When $c_j \neq 0$, a second additive cell is applied to the provisional residue and to c_j. The new residue is published, and the sum of the quotients is transported to the next position. If a nonzero carry remains upon completion, it is published as the final digit. In this manner, the local cells never receive the absent symbol 0, which does not belong to D_9.

Lemma 27.11 (Adder Invariant)**.** *If* $u \boxplus_{\#} v$ *is the word produced by the preceding algorithm,*

$$\mathrm{ev}_9(u \boxplus_{\#} v) = \mathrm{ev}_9(u) + \mathrm{ev}_9(v).$$

The intermediate carry lies in $\{0, 1, 2\}$.

Proof. After processing the positions $0, \ldots, k-1$, let c_k be the pending quotient. The local identities imply

$$\sum_{j<k} (u_j + v_j) 9^j = \sum_{j<k} w_j 9^j + c_k 9^k,$$

including the absent digits as zero. Each new cell preserves this equality. The local maximum is $9 + 9 + 2 = 20$, so that $c_{k+1} \leq 2$. At the end the last quotient is published, and the global identity remains. □

27.5 Multiplication by a digit

Algorithm 27.12 (Scalar transducer)**.** With $d \in D_9$ fixed, each digit u_j produces

$$u_j d = 9q_j + r_j, \qquad (r_j, q_j) = \big(R^{\times}(u_j, d), q^{\times}(u_j, d)\big).$$

Let $c_j \in \{0, \ldots, 9\}$ be the incoming quotient. Since $0 \notin D_9$, the transition is defined by branches:

$$(w_j, c_{j+1}) = \begin{cases} (r_j, q_j), & c_j = 0, \\ \big(R^{+}(r_j, c_j), q_j + q^{+}(r_j, c_j)\big), & c_j \in D_9. \end{cases}$$

Thus, no local map is evaluated outside its domain. The first branch expresses the absence of a pending quotient; the second normalizes the collision by means of the additive map.

Lemma 27.13 (Scalar invariant)**.** *The word $d \odot_{\#} u$ produced by the transducer satisfies*

$$\mathrm{ev}_9(d \odot_{\#} u) = d\,\mathrm{ev}_9(u).$$

The multiplicative quotient belongs to $\{0, \dots, 9\}$.

Proof. The argument is that of the adder, replacing each local summand by $u_j d$. If $c_j = 0$, the identity $u_j d = 9q_j + r_j$ directly preserves the partial equality. If $c_j \in D_9$, the second Euclidean division gives

$$r_j + c_j = 9q^+(r_j, c_j) + R^+(r_j, c_j),$$

and preserves the same equality after transporting $q_j + q^+(r_j, c_j)$. The maximum $9 \cdot 9 + 9 = 90$ and the remainder form in D_9 keep the quotient within the declared bound. The last quotient is published as a digit. □

27.6 Global product by Horner

Definition 27.14 (Native product)**.** Let $v = (v_0, \dots, v_{m-1})$. Partiendo of $a_m = \varnothing$, is defined for $j = m-1, \dots, 0$

$$a_j = (9 \odot_{\#} a_{j+1}) \boxplus_{\#} (v_j \odot_{\#} u).$$

The result is

$$u \boxtimes_{\#} v := a_0.$$

This definition does not contain

$$\mathrm{dec}_9(\mathrm{ev}_9(u)\,\mathrm{ev}_9(v)).$$

The evaluation will appear only in the proof of entanglement.

Theorem 27.15 (Native multiplicativity)**.** *For all words $u, v \in \mathscr{W}_9$,*

$$\boxed{\mathrm{ev}_9(u \boxtimes_{\#} v) = \mathrm{ev}_9(u)\,\mathrm{ev}_9(v).} \tag{27.6}$$

The empty word is absorbing, and (1) *is the unit.*

Proof. By the two previous lemmas,

$$\mathrm{ev}_9(a_j) = 9\,\mathrm{ev}_9(a_{j+1}) + v_j\,\mathrm{ev}_9(u).$$

Horner's iteration gives

$$\mathrm{ev}_9(a_0) = \mathrm{ev}_9(u) \sum_{j=0}^{m-1} v_j 9^j.$$

The last factor is $\mathrm{ev}_9(v)$. The uniqueness of the normal form identifies the resulting word. □

Corollary 27.16 (Multiplicative monoid of words)**.** *The structure*

$$\mathfrak{W}_9^{\times} = (\mathscr{W}_9, \boxtimes_{\#}, (1))$$

is a commutative monoid; the empty word is its absorbing element. Its construction does not use global multiplication of integers.

The shortest boundary example is

$$(9) \boxtimes_{\#} (9) = (9, 8), \qquad 9 + 8 \cdot 9 = 81.$$

The 17 local cells of multiplication produce

$$(9, 8) \boxtimes_{\#} (9, 8) = (9, 8, 8, 8), \qquad \mathrm{ev}_9(9, 8, 8, 8) = 6561.$$

27.7 Matrix linearization of the genealogical state and construction of the completely positive entangler

Definition 27.17 (Hilbert Sectors)**.** Let

$$\mathcal{K}_{\#}^{+} = \ell^2(\mathscr{W}_9^{+}), \qquad \mathcal{H}_{+} = \ell^2(\mathbb{N}_{\geq 1}).$$

We define on the canonical bases

$$W_{\times} e_u = e_{\mathrm{ev}_9(u)}.$$

In $\mathcal{H}_{+}$, the number operator is denoted by

$$\mathsf{N} e_n = n e_n, \qquad \mathrm{Spec}(\mathsf{N}) = \mathbb{N}_{\geq 1}.$$

The vacuum may be added separately as a vacuum vector e_0; it is not confused with $\mathcal{H}_{+}$, whose spectrum begins at one.

Theorem 27.18 (Unitarity and multiplicative square)**.** *$W_{\times}$ is unitary. In the algebraic kernel $\mathbb{C}[\mathscr{W}_9^{+} \times \mathscr{W}_9^{+}]$, let*

$$\mu_{\#}(e_u \otimes e_v) = e_{u \boxtimes_{\#} v}, \qquad \mu_{\mathbb{N}}(e_a \otimes e_b) = e_{ab}.$$

Then the square holds.

$$\begin{array}{ccc} \mathcal{K}_{\#}^{+} \otimes_{\mathrm{alg}} \mathcal{K}_{\#}^{+} & \xrightarrow{W_{\times} \otimes W_{\times}} & \mathcal{H}_{+} \otimes_{\mathrm{alg}} \mathcal{H}_{+} \\ \downarrow{\scriptstyle \mu_{\#}} & & \downarrow{\scriptstyle \mu_{\mathbb{N}}} \\ \mathcal{K}_{\#}^{+} & \xrightarrow[W_{\times}]{} & \mathcal{H}_{+} \end{array}$$

and therefore, the square commutes.

Proof. The bijection of normal forms sends one orthonormal basis to another and proves unitarity. On a basic tensor, both paths produce $e_{\mathrm{ev}_9(u)\,\mathrm{ev}_9(v)}$ by (27.6). Linearity gives the equality on the kernel. □

The maps $\mu_{\#}$ and $\mu_{\mathbb{N}}$, initially defined on the respective algebraic kernels, are densely defined and unbounded. For $c = (c_{u,v}) \in \ell^2(\mathscr{W}_9^{+} \times \mathscr{W}_9^{+})$, each sum over a product fiber is finite. The adjoint of $\mu_{\#}$ contains all finite-support vectors in its domain, so that $\mu_{\#}$ is closable. The domain of its closure is

$$\mathrm{Dom}(\overline{\mu_{\#}}) = \left\{ c \in \ell^2(\mathscr{W}_9^{+} \times \mathscr{W}_9^{+}) : \sum_{w \in \mathscr{W}_9^{+}} \left| \sum_{u \boxtimes_{\#} v = w} c_{u,v} \right|^2 < \infty \right\}.$$

Each fiber is finite because ev_9 identifies it with the ordered pairs of divisors of an integer. The same description holds for $\overline{\mu_{\mathbb{N}}}$ after applying $W_{\times} \otimes W_{\times}$, and $W_{\times}$ intertwines the graphs of both closures.

27.8 Native coproduct and native antipode

The multiplicative opening is now defined before looking at the codomain:

$$\Delta_{\#} e_w = \sum_{u \boxtimes_{\#} v = w} e_u \otimes e_v .$$

The sum is obtained by enumerating products of the transducer. One does not ask whether one ordinary integer divides another. In the integer sector define, on the corresponding algebraic kernel,

$$\Delta_{\times} e_n = \sum_{\substack{a,b \in \mathbb{N}_{\geq 1} \\ ab = n}} e_a \otimes e_b .$$

Both coproducts enumerate ordered pairs.

Theorem 27.19 (Native coassociativity)**.** *In the algebraic core,*

$$(\Delta_{\#} \otimes I)\Delta_{\#} = (I \otimes \Delta_{\#})\Delta_{\#}.$$

Moreover,

$$(W_{\times} \otimes W_{\times})\Delta_{\#} = \Delta_{\times} W_{\times}.$$

Proof. Both sides of the first equality enumerate every native triple $a \boxtimes_{\#} b \boxtimes_{\#} c = w$ exactly once. The second equality follows from the bijection between fibers induced by (27.6). □

Theorem 27.20 (Complete arithmetic coproduct)**.** *In the algebraic kernel $c_{00}(\mathbb{N}_{\geq 1}) \subset \ell^2(\mathbb{N}_{\geq 1})$, let*

$$\Delta_{\times} e_n = \sum_{ab = n} e_a \otimes e_b .$$

Its closure has domain

$$\operatorname{Dom}(\overline{\Delta_{\times}}) = \left\{ x = (x_n) : \sum_{n \geq 1} d(n) |x_n|^2 < \infty \right\},$$

is coassociative on the kernel and, for $Q e_n = n e_n$, satisfies

$$(\log Q \otimes I + I \otimes \log Q)\Delta_{\times} = \Delta_{\times} \log Q.$$

Proof. The supports of $\Delta_{\times} e_n$ are orthogonal for distinct integers, and their squared norm is the number $d(n)$ of divisors, which yields the weighted domain of the closure. The two coassociativity relations reindex the same sum over $abc = n$. Finally, $\log a + \log b = \log n$ in each term proves the intertwining. A triple factorization counted differently, or failure of this identity, would falsify the theorem. □

Theorem 27.21 (Reduced coproduct and irreducible selector)**.** *In the sector integer, the coproducto reducido*

$$\Delta_{\times}^{\mathrm{red}} e_n = \sum_{\substack{ab = n \\ a,b > 1}} e_a \otimes e_b$$

is closable. The operator

$$N_{\times}^{\mathrm{red}} = \left(\overline{\Delta_{\times}^{\mathrm{red}}}\right)^{*} \overline{\Delta_{\times}^{\mathrm{red}}}$$

is positive self-adjoint and diagonal:

$$N_{\times}^{\mathrm{red}} e_n = d_{\mathrm{red}}(n) e_n .$$

Its kernel is generated by e_1 and by the e_p with p irreducible; therefore,

$$P_{\mathfrak{I}} = \mathbf{1}_{\{0\}}(N_{\times}^{\mathrm{red}}) - |e_1\rangle\langle e_1|$$

select the irreducibles and exclude the unit.

In the native sector, the corresponding coproduct is

$$\widetilde{\Delta}_{\#} e_w = \sum_{\substack{u \boxtimes_{\#} v = w \\ u,v \neq (1)}} e_u \otimes e_v .$$

The entrelazador $W_{\times}$ transports $\Delta_{\times}^{\mathrm{red}}$, $N_{\times}^{\mathrm{red}}$ and $P_{\mathfrak{I}}$ toward $\widetilde{\Delta}_{\#}$,

$$A_{\#} := \overline{(\widetilde{\Delta}_{\#})}^{*} \overline{\widetilde{\Delta}_{\#}}, \qquad P_{\mathfrak{I},\#} = (I - P_{(1)})\mathbf{1}_{\{0\}}(A_{\#}), \qquad P_{(1)} = |e_{(1)}\rangle\langle e_{(1)}|.$$

Proof. The supports of the images of two distinct basis vectors are orthogonal. The squared norm of $\Delta_{\times}^{\mathrm{red}} e_n$ is $d_{\mathrm{red}}(n)$, which vanishes exactly for $n = 1$ or n irreducible. This proves the diagonalization and the declared kernel; subtracting the projector of e_1 removes the unit. The multiplicativity of $W_{\times}$ identifies the integer fibers with the native fibers and transports the three operators. A composite in the kernel, an irreducible outside it, or inclusion of the unit in $P_{\mathfrak{I}}$ would refute the theorem. □

Proposition 27.22 (Nonadic coincidence of primes and composites)**.** *Let* $\gcd(n, 90) = 1$, $\tau_n = \mathrm{ord}_n(10)$ *and*

$$M_n = \frac{10^{\tau_n} - 1}{n}.$$

Then $M_n \equiv 0 \pmod 9$, *both for primes and for composites. In particular, the nonadic closure and the isolated decimal period are not a selector of irreducibles.*

Proof. Because $9 \mid 10^{\tau_n} - 1$ and because n is invertible modulo nine, divisibility by nine survives passage to the quotient. The primes $7, 13$ and the composites $77, 91, 143$ share period six; the Carmichael numbers provide additional controls. The statement would be falsified only if the congruence or the period separated all primes from all composites in the declared domain. □

This statement is strictly arithmetic: it identifies factorization fibers and the operators they induce on the sector of normal forms.

27.9 Exhaustive enumeration and necessity of structural coordinates

The finite enumeration comprises:

Test	Result
Cells per local map	81
Reversible numbering paths	59050
Intertwiner pairs	532900
Intertwiner errors	0
Associative triples	531441
Associative errors	0
Coproduct window	1 to 500
Irreducibles obtained	95

Definition 27.23 (Multiplicative quotient)**.** Preserving only $R^{\times}$ transforms $2 \cdot 5 = 10$ into the visible value 1. Perturbing $q^{\times}(9, 9)$ from 8 to 7 transforms 81 into 72. The local quotient is necessary.

Definition 27.24 (Additive application)**.** The multiplicative map produces partial products, but does not resolve their collisions. Removing q^{+} breaks the global normalization; for example, it no longer reproduces the intermediate quotients of $10 \cdot 18 = 180$.

Definition 27.25 (Coordinates and boundary symbol)**.** Ordinary zero is not a digit of the construction. The empty word is 0, and the symbol 9 preserves its value and quotient. Mixing zero-indexed positional coordinates with the labels $1, \ldots, 9$ changes the cells.

Proposition 27.26 (Exact scope of the ablations and of the finite census)**.** *The preceding ablations prove, within the declared conventions:*

1. *without* $q^{\times}$, $2 \cdot 5 = 10$ *colapsa to the residue visible* 1*;*
2. *cambiar* $q^{\times}(9, 9) = 8$ *by* 7 *transforms* 81 *in* 72*;*
3. *without* q^{+}*, normalization of the additive collisions fails.*

The exhaustive enumeration comprises the $2 \cdot 81 = 162$ *cells of the two maps, the* 729 *local triples,* 532 900 *word pairs, and the* 95 *irreducibles no greater than* 500*. The indicated identities are proved on these finite domains, but the coinductive survival of every TPK history is not.*

Proof. The three counterexamples are computed directly with (27.1) and (27.2). The enumeration of the four finite domains produces the cardinals written in the statement and does not add any coinductive identity to those already proved in the monoid of words. □

27.10 Algebraic structure of the word monoid

The construction proves, in the monoid $\mathfrak{W}_9^{\times}$:

1. a unique normal form for each nonnegative integer;
2. global sum and product constructed solely from the two local maps;
3. symbolic conservation of the value under quotient propagation;
4. a unitary $W_{\times}$ and the exact multiplicative square;
5. a divisor coproduct and an irreducible selector defined natively;
6. the need to preserve the transport class when leaving the normal-form sector.

Passage to the enriched space now reduces to an existence problem: constructing a family $(\iota_n)_n$ compatible with the depth restrictions and proving that it satisfies the equation of the preceding section. This question is distinct from the exact intertwiner on $\mathfrak{W}_9^{\times}$, which is already determined by the normal form and the local maps.

27.11 Problem of determining the constants from the genealogical state

A physical constant is represented as a section of a magnitude line equipped with a rule of evaluation, orientation, and normalization. Its numerical coordinate depends on the chosen chart, whereas its genealogy remains invariant. Consequently, the determination problem comprises:

1. the identification of the antecedent HMT state;
2. the specification of the operator or character of selection;
3. determination of the conserved invariant;
4. the corresponding magnitude line;

5. the chart in which the terminal value is expressed.

The causal chain of the work is

$$\begin{aligned}\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow \text{internal realization} \longrightarrow \text{dimensionless invariant} \\ \longrightarrow \text{magnitude section} \longrightarrow \mathbb{R}.\end{aligned} \tag{27.7}$$

The term $\mathbb{R}$ in the chain represents the terminal evaluation of the section; it does not constitute the original domain from which the route is retrospectively reconstructed.

27.12 Antecedent chain APP–TRIT–TPK and domain of the extraction operators

APP supplies the geometry of positions, residues, quotients, and boundaries. TRIT incorporates orientation $(-1, 0, +1)$ and distinguishes opening, threshold, and return. TPK completes the state through carry, route, sheet, memory, and survival. In particular, transition $9 \to 1$ preserves phase and modifies the memory state; it therefore does not constitute a reinitialization devoid of genealogy.

The realizations developed below preserve that antecedent without replacing it. The vacuum is obtained through a spectral function of the bilayer operator; gravity selects a section through the chronological structure 108; criticality uses a dodecaphasic family; the Gaussian constants follow from the evaluation of cylinders; and the modular Hamiltonian is defined on a boundary that preserves the incidence $6 \to 8$. The production of scalar values does not establish functional identity among these realizations.

Proposition 27.27 (Insufficiency of the Scalar Coincidence)**.** *Let $F_1 : X_1 \to L_1$ and $F_2 : X_2 \to L_2$ be two typed functionals. Equality of coordinates $c_1(F_1(x_1)) = c_2(F_2(x_2))$ does not by itself induce either an identification $X_1 \simeq X_2$ or an intertwiner $F_2 I = J F_1$.*

In particular, a numerical proximity such as $I_{\mathrm{or}} \approx \gamma_{\mathrm{HMT}} a_0$ cannot be promoted to an identity without constructing the corresponding intertwiner.

27.13 Lines of magnitude, oriented letters and dimensional coordinate systems

Let L_Q be an oriented real line representing the magnitude Q. A unit $u_Q \in L_Q \setminus \{0\}$ determines a provisional coordinate $L_Q \simeq \mathbb{R}$, without replacing the intrinsic structure of the line. The constitutive relation

$$L_\mu = L_S L_C^{-1} L_Q^{-2}, \qquad L_\varepsilon = L_S^{-1} L_C^{-1} L_Q^{2}$$

precedes the SI choice. In the same way,

$$L_Z = L_S L_Q^{-2}, \qquad L_G = L_C^{5} L_T^{2} L_S^{-1}$$

type impedance and the gravitational constant before expressing their magnitudes in ohms or SI units. In this work we shall write

$$Q_{\mathrm{int}} = \widehat{Q}\, u_Q$$

to distinguish the dimensionless character $\widehat{Q}$ from the reference section u_Q.

27.14 Torsor of frames and covariance of dimensional evaluations

The admissible charts form a torsor and therefore none has a character that is canonical relative to the others. The frame change $u_Q \mapsto \lambda_Q u_Q$ induces the contragredient transformation of the coordinate. Physical identities must be homogeneous with respect to this action. For example,

$$\mu\varepsilon = c^{-2}, \qquad \frac{\mu}{\varepsilon} = Z^2$$

are valid in every compatible frame. Mathematical unification and dimensional unification do not eliminate units; rather, they reconstruct them through the covariance of the lines and allow the invariant to precede its coordinate expression.

27.15 Final metrological evaluation and prohibition of retrospective selection

Each entry of the final atlas adopts the form

$$\boxed{\text{antecedent} \longrightarrow \text{operator} \longrightarrow \text{invariant} \longrightarrow \text{meaning} \longrightarrow \text{terminal value.}} \tag{27.8}$$

This order expresses a causal dependency: the numerical value is only determined after fixing the antecedent, operator, invariant, and interpretation. Omission of any of these elements reduces the result to a reconstruction that is numerical, not a derivation that is genealogical.

27.16 Exact domain of the genealogical generation and its terminal metrical chart

The generation of π, e, φ, the dodecaphasic closure of α_{HMT}, the action section, and the Barbero–Immirzi output γ_{HMT} are adopted as initial results. The present development does not recalibrate those constructions; it determines the constants and invariants resulting from their application to the constitutive, thermal, gravitational, modular, and spectral realizations.

The electron mass is likewise not included as a governing problem, since it belongs to the General Mass Law. Every occurrence of m_e in an atomic identity is treated as a datum proceeding from that domain and not as a new selection of the present development.

Logical Scope and Domain of Validity

The APP–TRIT–TPK architecture and the dimensional lines constitute the starting structure. The uniform rule of five fields of the atlas makes explicit its causal discipline in each entry.

27.17 Operator classification of 114 numerical expressions by domain, generator, invariant, and codomain

Let the finite indexed set be

$$E_{114} = \{\varepsilon_1, \ldots, \varepsilon_{114}\}$$

of expresiones numericas and let O the space of readings of the reader triadico. The map

$$T : E_{114} \longrightarrow O, \qquad \varepsilon_i \longmapsto T_{\mathrm{tri}}(\varepsilon_i), \qquad |\operatorname{im} T| = 106,$$

classifies expressions according to their operatorial role. Each ε_i, including the compared targets, is fixed as input of T; therefore, this map does not generate the values that it evaluates. The functional partition is

functional family	entries
structural kernel	5
coupling and closure	1
bridges between modes	7
angular and closure	22
exponential–logarithmic	12
spectral and regularization	14
hyperbolic and modular	2
algebraic and metric	50
typed miscellany	1

$$\sum n_i = 114.$$

Network centrality, shortest paths, and communities computed on the graph induced by T describe connectivity within the classification; they do not establish mathematical causality or HMT genealogy.

Seven fibers of T gather fifteen expressions with a common reading. A shared fiber does not identify their values either. In particular, φ^{-1}, φ, and φ^2 are distinct real numbers that the map T groups into the same self-scaling orbit; the common projection preserves dynamic function and forgets the Archimedean coordinate that separates them.

The exhaustive enumeration traversed the 114 entries of E_{114}, four hundred sixty-eight direct candidates U_{12}, and one hundred four thousand nine hundred seventy-six weighted seeds without finding, within that finite domain, a rival that reproduced the oriented dodecaphasic correction of α_{HMT}. The search domain is thereby bounded by those three sets. The census proves that no rival appears in the enumerated class; it does not prove uniqueness among all possible functionals and does not enter as a premise of theorem α_{HMT}.

For each ε_i, the taxonomy assigns the quadruple (object, reader, domain, structural function) used in the enumeration.

27.18 Spectral, informational, and thermodynamic confluence of $\log 3$

The identity

$$\log 3 = C_1 + C_2 - 2C_0 = S_{\widehat{\mathbb{T}}}/k_B = E_P/(k_B\Theta_{\mathrm{clk}}),$$

relates three distinct realizations. The first member is a residual defect, the second an entropy of decision, and the third a ratio between energy and temperature. Their equality proves the conservation of the scalar under a change of realization, without identifying the state spaces.

The first equality is deduced from the three residual channels.

$$Z_r(s) = \sum_{\substack{n\geq 1\\ n\equiv r \pmod 3}} n^{-s}, \qquad r = 0, 1, 2.$$

Then

$$Z_0(s) = 3^{-s}\zeta(s), \quad Z_1(s) + Z_2(s) = (1 - 3^{-s})\zeta(s), \quad Z_1(s) - Z_2(s) = L(s, \chi_{-3}).$$

If C_r denotes the part finite of Z_r in $s = 1$, the expansion of 3^{-s} gives

$$C_0 + C_1 + C_2 = \gamma, qquad - 2C_0 + C_1 + C_2 = \log 3, qquad C_1 - C_2 = \frac{\pi}{3\sqrt{3}}. \tag{27.9}$$

The three covectors are linearly independent. From a single residual decomposition, they recover the total finite term, the dilation of the zero class, and the orientation between the two nonzero classes. $\log 3$ is therefore a scale-change invariant before being interpreted as entropy or temperature.

27.19 Epistemological classification of the derived constants

The chapter's contributions are classified into three categories:

1. assignment of an internal operator to a known constant, as in the Catalan case;
2. exact composed evaluation of two internal characters, such as $L(1, \chi_{12})$;
3. derivation of a constant from a field or a family constructed internally, such as $\gamma_{\mathbb{Q}(\sqrt{3})}$ or A_k.

Mathematical provenance determines the status of recovery or novelty; decimal proximity plays no role in that classification.

Remark 27.28 (Negative control). The character χ_{12} must have exactly the pattern $(+,-,-,+)$ in $(1,5,7,11)$; any other pattern invalidates equations (41.8) y (41.9). The identity equation (43.2) and the factorization equation (42.1) are independent controls.

Logical Scope and Domain of Validity

$J^2 = -I$, Catalan, χ_{12}, their values L, Euler–Kronecker, and the Bendersky–Glaisher tower: *Exact internal theorem*. The gathering in a lattice $3/4/12$ is *New formalization* that preserves the mathematical provenances.

All these results are joined because they turn the terminal value into the quantitative expression of a previously constructed structure. Numerical exactness accompanies a different conception of what a fundamental constant is. The nonadic connection does not first generate three constants and then add a fourth: the prolongation $w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$ stabilizes a common coinductive state from which π, e, φ and α are published in a correlated manner. Their readers distinguish closure, propagation, self-scaling and coupling; within this joint generation, coordinate α retains its signed, dodecaphasic realization and its two internal derivation routes.

In the usual description, a constant is commonly presented as a number placed before an equation: a quantity that the theory requires but whose value must be received from outside. In Triadic Modular Holography, the opposite occurs. The constant appears at the end, after the same state has been traversed by several readers and it has been determined which relation has survived all of them.

This is why the constants in the document are magnitudes endowed with genealogy: invariant remnants of a transformation. Each states what has been preserved when something has changed:

- to sheet has been inverted;
- a cycle has returned to its initial phase;
- a memory has crossed the seam;
- an interior description has been published on the boundary;
- a dimensionless magnitude has received a physical realization;
- a system has changed scale while fully preserving its genealogy.

Dimensional Mechanics subsequently adds the magnitude lines and the units. But the structure that selects the constant is prior. The real value appears at the end because $\mathbb{R}$ functions here as a terminal evaluation: it is the quantitative shadow of a construction that was already complete before becoming a decimal.

With that view, the nine developments considered form a single narrative on orientation, memory, geometry, information, and scale.

27.20 Joint theorem of coinductive generation and arbitrary depth

The starting structure of this theorem is not the bare set of nine symbols. It is the typed system

$$\mathfrak{H}_9 = \big(\mathrm{APP}, \mathrm{TRIT}, \mathrm{TPK}; \widehat{\mathcal{X}}^{\mathrm{enr}}, \mathcal{U}, \Gamma_9, \mathrm{Ext}, \mathrm{tr}\big),$$

constructed on the double positional and arithmetic realization of $\mathcal{D}_9 = \{1, \dots, 9\}$. APP accumulates and folds through its sheets Σ and Π, preserving residue and quotient; TRIT orients each transition in one of its three regimes; and TPK selects, transports, memorizes and returns on the enriched fiber. In particular,

$$M_{\mathrm{ph}} : \mathcal{D}_9 \longrightarrow \{+1, -1, 0\}, \qquad m_{\mathrm{ph}} := \big(M_{\mathrm{ph}}(1), \dots, M_{\mathrm{ph}}(9)\big)^{\mathsf{T}},$$

$$\mathrm{Tra}_t(y, d) := \mathrm{Lift}(T_d)(y), \qquad \mathrm{Upd}_t := \mathrm{Rec}_t \circ \mathrm{Mem}_t,$$

and, for all $x \in \widehat{\mathcal{X}}^{\mathrm{enr}}$,

$$\mathcal{U}_t(x) = \mathrm{Upd}_t\big(\mathrm{Tra}_t\big(\mathrm{Sel}_t\big(x, M_{\mathrm{ph}}(g(t))\big), d(t)\big)\big).$$

This composition is the effective dynamic datum: the nine-symbol chart is its finite support, not a substitute for the dynamics. In particular, $M_{\mathrm{ph}}(g(t))$ is the scalar value received by the selector, whereas m_{ph} is the vector of the nine values of the function; neither composes directly with a state operator.

For $r \in 6\mathbb{N}_{>0}$, let $\widehat{\mathcal{X}}_r^{\mathrm{enr}}$ be the truncated states with sheet, orientation, residue, quotient, carry, route, boundary and memory, and let

$$\mathrm{Ext}_{r+6,r} \subseteq \widehat{\mathcal{X}}_r^{\mathrm{enr}} \times \widehat{\mathcal{X}}_{r+6}^{\mathrm{enr}}, \qquad \mathrm{tr}_{r+6,r} : \widehat{\mathcal{X}}_{r+6}^{\mathrm{enr}} \longrightarrow \widehat{\mathcal{X}}_r^{\mathrm{enr}}$$

the admissible prolongation relation and truncation. For $x_r \in \widehat{\mathcal{X}}_r^{\mathrm{enr}}$, the local fiber

$$\mathrm{Ext}_{r+6,r}(x_r) := \{x_{r+6} : (x_r, x_{r+6}) \in \mathrm{Ext}_{r+6,r}\}$$

may contain several children. The correct compatibility is

$$(x_r, x_{r+6}) \in \mathrm{Ext}_{r+6,r} \Longrightarrow \mathrm{tr}_{r+6,r}(x_{r+6}) = x_r.$$

In R_{36}, the three recovered rows $222220, 021222, 102011$, transported to the active gauge by the permutation $p_0 = (0, 1, 2, 4, 5, 3)$ in zero-based indices —equivalently, $p_1 = (1, 2, 3, 5, 6, 4)$ in one-based indices—, carry, before any real realization, the internal characters of closure, propagation and self-scaling. Their triple, together with the signed register U_{12} and the seal K, carries the internal coordinate of α. For each $\chi \in \{\pi, \varphi, e, \alpha\}$, we write the state thus enriched as

$$x_r^{\chi} = (\widetilde{x}_r, \chi_{\mathrm{HMT}}, \varepsilon_r^{\chi}, N_r^{\chi}).$$

Here ε_r^{χ} is the internal residue produced by the APP quotient in the state, not $\mathrm{frac}(P_{\mathrm{ar}}(\chi))$. Internal Euclidean division fixes

$$d_r^{\chi} = \mathrm{Dig}_{729}(\varepsilon_r^{\chi}), \quad 0 \le d_r^{\chi} < 729, \quad \varepsilon_{r+6}^{\chi} = 729\varepsilon_r^{\chi} - d_r^{\chi}, \quad N_{r+6}^{\chi} = 729N_r^{\chi} + d_r^{\chi}.$$

Selection, transport and updating on the section χ are typed by

$$\mathrm{Sel}_r^{\chi}(x) := \mathrm{Sel}\big(x, M_{\mathrm{ph}}(\rho_9(r/6 + 1))\big), \qquad \mathrm{Tra}_r^{\chi}(y, d) := \mathrm{Lift}(T_d)(y), \qquad \mathrm{Upd}_r^{\chi} := \mathrm{Rec}_r^{\chi} \circ \mathrm{Mem}_r^{\chi}.$$

The complete transition is

$$\mathcal{U}_r^{\chi}(x) := \mathrm{Upd}_r^{\chi}\big(\mathrm{Tra}_r^{\chi}\big(\mathrm{Sel}_r^{\chi}(x), d_r^{\chi}\big)\big),$$

and reads only the preceding enriched state: internal phase, memory, carry, sheet, orientation, route, boundary, signature, register, character and residue. It does not read a future digit, P_{ar}, or a Machin, factorial or Perron bracket. We define the forward subrelation

$$\mathrm{Ext}^{\chi,\rightarrow}_{r+6,r} := \{(x^{\chi}_{r}, \mathcal{U}^{\chi}_{r}(x^{\chi}_{r}))\} \subseteq \mathrm{Ext}_{r+6,r}\,.$$

It is not the retrospective selection $\mathrm{Ext} \cap \{P_{\mathrm{ar}} = \chi\}$: the character is already a causal coordinate of x^{χ}_{36}. The preceding equations give $\lfloor N^{\chi}_{r+6}/729 \rfloor = N^{\chi}_{r}$ and preserve sheet, orientation, carry, boundary, route, signature, register and genealogy.

The complete relation Ext remains multivalued. The required uniqueness is that of each forward section over its produced R36 seed,

$$\#\Big\{(x^{\chi}_{r})_{r\geq 36} : x^{\chi}_{36} \text{ fixed},\ (x^{\chi}_{r}, x^{\chi}_{r+6}) \in \mathrm{Ext}^{\chi,\rightarrow}_{r+6,r}\Big\} = 1,$$

not the false equality $\#\,\mathrm{Ext}_{r+6,r}(x_r) = 1$ at each local gate. This compatibility extends to every level. The notation

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

designates these maps and their type changes, not a list of labels. The holonomy Γ_9 satisfies

$$g(k+9) = g(k), \qquad q^{(9)}(k+9) = q^{(9)}(k) + 1,$$

so that the phase returns while the quotient, the route and the memory of the state advance.

A generic canonical history based on $a_{(1,1)}$ and $t_j = M_{\mathrm{ph}}(\rho_9(j+1))$ establishes the nonemptiness of Ext; it does not by itself individualize the four preceding sections. These are joined by their internal R36 coordinates and by the forward rule just defined.

Theorem 27.29 (Inaugural construction from the seeds)**.** *Let*

$$I_9 = \{0, \ldots, 8\}, \qquad D = \{N, E, S, O\}, \qquad \mathcal{S} = I_9^2 \times D,$$

and let $\Omega_{\mathrm{seed}} = \mathcal{S}_{+} \times \mathcal{S}_{\times}$ *be the domain of the two cursors realizing the additive and multiplicative sheets of APP. Then*

$$|\Omega_{\mathrm{seed}}| = (9^2 \cdot 4)^2 = 104\,976,$$

and the 54*-step recurrence and ternary reduction define*

$$\Omega_{\mathrm{seed}} \xrightarrow{T^{\mathrm{seed}}_{54}} \mathcal{U}^{\mathrm{cat}}_{6} \xrightarrow{\rho_3} \mathcal{W}_6 \hookrightarrow \mathbb{F}^6_3,$$

with

$$|\mathcal{U}^{\mathrm{cat}}_{6}| = 468, \qquad |\mathcal{W}_6| = 243, \qquad |\mathbb{F}^6_3| = 729.$$

The fibers satisfy exactly

$$432 \cdot 144 + 18 \cdot 432 + 18 \cdot 1944 = 104\,976.$$

The TPK extension relation prolongs the surviving words to the family of compatible sections of arbitrary depth. The forward subrelations anchored in R36 individualize the correlated coinductive generation of π, φ, e *and* α*; the complete relation may continue to have several local prolongations. On that family, the Archimedean shadow and the exceptional realization of the theorem 27.30 are constructed jointly.*

Proof. The preceding Cartesian product exhaustively enumerates the positions and orientations of both cursors. The map T^{seed}_{54} is obtained by composing at each step sheet selection, cardinal transport, quotient updating and carry memory. Enumeration of its image contains 468 distinct sextets; the sum of the

cardinalities of its fibers is the displayed identity. The componentwise map ρ_3 contains 243 distinct words. Finally, nonemptiness at every horizon and compatibility of Ext with the truncations produce the inverse limit. Functionality of each $\mathrm{Ext}^{\chi,\to}$, starting from the R36 state that already carries χ_{HMT}, proves by induction the uniqueness of that global section without requiring each local fiber of Ext to be a singleton. Each statement is an internal identity or a consequence of projective compatibility; none uses a real number, a recognized constant or a decimal table as input. □

Theorem 27.30 (Governing thesis: one continuum and two projections)**.** *Let $\Omega_\Gamma^{\mathrm{cal}} \subset X_\infty^{\mathrm{cal}}$ be the space of surviving sections of the enriched turns of the TPK. The carry of the three turns $\gamma_-, \gamma_0, \gamma_+$ defines, without prior Archimedean evaluation, the homeomorphism*

$$\beta : \Omega_\Gamma^{\mathrm{cal}} \xrightarrow{\sim} (\mathbb{F}_3^6)^{\mathbb{N}} =: \mathcal{W}_\infty.$$

The normalized balanced forms

$$a_k + c_k = \rho_k + 3c_{k+1}, \qquad \rho_k \in \{-1, 0, +1\},$$

construct the ordered ring $\mathbb{Z}_{\mathrm{HMT}}$, its field of fractions $\mathbb{Q}_{\mathrm{HMT}}$ and the completion

$$\mathbb{R}_{\mathrm{HMT}} := \mathrm{Cau}(\mathbb{Q}_{\mathrm{HMT}})/\asymp.$$

The joint discrete structure is the fiber product

$$C_{\mathrm{cont}}^{\mathrm{disc}} = \left(\mathbb{Z}_{\mathrm{HMT}} \times \Omega_\Gamma^{\mathrm{cal}}\right) \times_{\mathcal{W}_\infty} X_\infty^{\mathrm{cal}}.$$

Its two natural maps are

$$P_{\mathrm{ar}} : \mathbb{Z}_{\mathrm{HMT}} \times \Omega_\Gamma^{\mathrm{cal}} \longrightarrow \mathbb{R}_{\mathrm{HMT}}, \qquad Q_\infty : X_\infty^{\mathrm{cal}} \longrightarrow (\mathscr{C}_W^{\mathrm{cal}})^{\mathbb{N}}.$$

If $\beta(\xi) = (b_q)_{q\geq 0}$, $\nu(b) = \sum_{i=1}^{6} b_i 3^{6-i}$ and

$$q_n(m, \xi) = m + \sum_{q=0}^{n-1} \frac{\nu(b_q)}{729^{q+1}},$$

then (q_n) is Cauchy and $P_{\mathrm{ar}}(m, \xi)$ is its class in $\mathbb{R}_{\mathrm{HMT}}$. The rational cylinders

$$I_n(m; b_0, \ldots, b_{n-1}) = [q_n, q_n + 729^{-n}]$$

are compatible, have diameter tending to zero and the recurrent partition into 729 subcylinders constructs, for every Cauchy class, a tape (b_q) representing it. Consequently,

$$P_{\mathrm{ar}} \text{ is surjective}, \qquad (\mathbb{Z}_{\mathrm{HMT}} \times \Omega_\Gamma^{\mathrm{cal}})/\!\sim_{\mathrm{ar}} \;\cong\; \mathbb{R}_{\mathrm{HMT}}.$$

Only after this internal construction does uniqueness of the complete Archimedean ordered field recognize $\mathbb{R}_{\mathrm{HMT}} \cong \mathbb{R}$.

The second projection preserves the calibrated incidence of each level; in the coordinates $x = ((w_j, f_j))_{j\geq 1}$ it acts by

$$Q_\infty(x) = \left(f_j, \Gamma_{f_j A_W f_j^{-1}}(w_j)\right)_{j\geq 1}.$$

Thus, $\mathbb{R}_{\mathrm{HMT}}$, subsequently recognized as $\mathbb{R}$, is the Archimedean shadow obtained by contracting the complete genealogy of cylinders. The exceptional projection preserves that genealogy as boundary incidence and admits the successive realization Paley–Witt–Golay–Leech–$V^\natural$–Monster. The two branches come from the same state and neither is retrospectively reconstructed from the other.

Proof. The three enriched turns exist after each prefix and their carry distinguishes them by $-1, 0, +1$. Concatenation and truncation are inverses, proving bijectivity and continuity of β. For a Cauchy class of $\mathbb{Q}_{\mathrm{HMT}}$, one first chooses its ordered unit cylinder and then, recursively, the unique half-open subcylinder of the internal partition into 729 pieces containing the class; at a common boundary, the two writings are identified by $\sim_{\mathrm{ar}}$. The sequence of left endpoints is precisely (q_n), converges to the given class and proves surjectivity without presupposing an expansion of $[0, 1]$ or a point of $\mathbb{R}$. Identification with the real field is the uniqueness theorem applied afterwards to $\mathbb{R}_{\mathrm{HMT}}$.

The subspaces satisfying the closure of a specific character are survival filters within the global capacity. Their function is to individualize the sections of π, e, φ, α; surjectivity of the continuum comes from the completion of $\mathbb{Q}_{\mathrm{HMT}}$. This separation of domains prevents turning a constant-selection condition into a premise of the coverage of $\mathbb{R}$.

In the second branch, compatibility $r_{n,m}Q_n = Q_m p_{n,m}$ allows passage to the limit and defines Q_∞. Conjugation by f_j transports the gauge without erasing incidence. The subsequent code, lattice and vertex-algebra functors realize the exceptional chain. Equality of the tapes in the fiber product constructs the joint source and preserves complementary information: Archimedean value in the first; incidence, boundary and genealogy in the second. □

Corollary 27.31 (Infinite expansion as a mathematical object)**.** *For each numerical character χ published by the coinductive state, the decimal reading is a complete sequence*

$$\mathrm{Dec}_\chi(x_\infty) = (d_{\chi,1}, d_{\chi,2}, \ldots) \in \{0, \ldots, 9\}^{\mathbb{N}}.$$

Its prefix of length N is the projection $\rho_N \mathrm{Dec}_\chi(x_\infty)$. Thus a thousand, ten thousand or a million digits are cuts of the same infinite object; generation does not consist in successively raising an experimental bound.

Theorem 27.32 (Correlated coinductive generation of π, φ, e and α)**.** *The complete profile of the system $\mathfrak{H}_9$ determines the correlated family of compatible forward sections*

$$\boldsymbol{x}_\infty = (x_\infty^\pi, x_\infty^\varphi, x_\infty^e, x_\infty^\alpha) \in \widehat{\Omega}_\pi \times_{R_{36}} \widehat{\Omega}_\varphi \times_{R_{36}} \widehat{\Omega}_e \times_{R_{36}} \widehat{\Omega}_\alpha, \qquad \widehat{\Omega}_\chi := \varprojlim_{r \geq 36} (\widehat{\mathcal{X}}_r^{\mathrm{enr},\chi}, \mathrm{Ext}_{r+6,r}^{\chi,\rightarrow}),$$

and four correlated characters

$$\big(\Pi_{\mathrm{cl}}, \Pi_{\mathrm{aut}}, \Pi_{\mathrm{prop}}, \Pi_{\mathrm{dod}}\big)(\boldsymbol{x}_\infty) = \big(\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}\big).$$

The first three characters come, respectively, from the unique closure orbit, the unique self-scaling orbit and the unique propagation orbit of the enriched catalog. The fourth comes from the signed primitive coordinate of the correlated terminal family and its dodecaphase closure. The four coordinates are therefore outputs of the correlated coinductive generation of arbitrary depth governed by the same APP–TRIT–TPK dynamics, with phase return, memory advance and genealogical preservation, even though their publication maps are distinct.

Proof. The exhaustive census $104,976 \to 468 \to 243 \subset \mathbb{F}_3^6$ decomposes the realized image into 43 dihedral orbits. The fiber invariants leave a single orbit in each of the closure, propagation and self-scaling classes; the internal gauge orients in them, without decimal consultation, the representatives

$$w_6^{\mathrm{cl}} = 010211, \qquad w_6^{\mathrm{prop}} = 201101, \qquad w_6^{\mathrm{aut}} = 121200.$$

The forward subrelations preserve the internal character and the predicates that define the three classes; Machin, the factorial recurrence and Perron do not choose any child of Ext. In the closure channel, the five-region composition with unit return produces the ratios $1/5$, $1/239$ and the relation $120/119$; the

Machin identity recognizes exactly the half-turn. In the propagation channel, the normalized semigroup law forces $(n+1)a_{n+1} = a_n$, hence $a_n = 1/n!$ and $P_1 = e$. In the self-scaling channel, the incidence

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$$

has a unique positive ray and its eigenvalue equation forces $x^2 - x - 1 = 0$, $x > 0$, that is, $x = \varphi$.

In the complete TPK profile, the terminal reading $x_{\mathrm{term}} \mapsto (B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}})$ simultaneously publishes the chart of the three channels and the signed primitive coordinate. The second is reversibly identified with the seal K and its dodecaphase differences. The Euclidean recurrence with carry

$$s_m = P_m + E_m - \Phi_m - K_m + c_{m+1}, \qquad A_m = s_m \bmod 1000, \qquad c_m = (s_m - A_m)/1000$$

produces α_{HMT} without receiving it as input. The independent analytic characterization begins with the finite kernel $E_{21/22}^{(9)}$, which determines a simple root ξ_9 in $(0, 10^{-2})$ without consulting the dodecaphase output. Iteration of the same graded reader produces the inverse system $E_{21/22}^{(6)} \leftarrow E_{21/22}^{(9)} \leftarrow E_{21/22}^{(12)} \leftarrow \cdots$. Its truncations commute with those of the dodecaphase route and both families determine at each depth the same surviving cylinder. Since their diameters tend to zero, the intersection is a singleton and one obtains exactly $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$. The equality $\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9(\alpha_{12}^{-1})$ is only the finite order-nine certificate of that identity of complete sections. Thus, separation of readers preserves the common origin of the four coordinates without introducing a pending prolongation or a target value. □

Proposition 27.33 (Dodecaphase register of the complete state prior to α)**.** *The enriched terminal state has the double publication*

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} (B_{\mathrm{term}}, U),$$

where

$$U = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997).$$

Upon ordering the coordinates by the three step-three orbits, the transform

$$\mathcal{H}_{12} = P_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)P_{\mathrm{orb}}, \qquad H_4^2 = 4I_4,$$

has inverse $\mathcal{H}_{12}/4$ on its integral image and determines uniquely

$$K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).$$

Therefore, within the complete TPK profile,

$$x_{\mathrm{term}} \xrightarrow{R_{\mathrm{sgn}}} U \xrightarrow{\mathcal{H}_{12}^{-1}} K$$

is an exact composition prior to the carry that publishes α. The visible matrix B_{term} and the signed register U are two coordinates of the same state; the second preserves the orientation, opposition, quotient and register fields that the first contracts. The composition

$$\Omega_{\mathrm{seed}} \longrightarrow \mathcal{U}_6^{\mathrm{cat}} \longrightarrow \widehat{\mathcal{X}}_{\mathrm{term}}^{\mathrm{enr}} \xrightarrow{R_{\mathrm{sgn}}} U \xrightarrow{\mathcal{H}_{12}^{-1}} K$$

constructs each coordinate through APP–TRIT–TPK and preserves their registers. Its inputs are the seeds, the sheets and the operator rules; U, K, their differences, α and the published expansions belong to the codomain of successive stages.

Theorem 27.34 (Bidirectional closure of the second route of α)**.** *Prolongation of the vacancy kernel to degrees* 7:9 *determines*

$$B_9(\alpha) := \log_{10}\!\left(\frac{10}{9}\right) + \frac{7}{4}\alpha^2 - \frac{\alpha^4}{20} + \frac{2\alpha^5}{21} + \frac{\alpha^6}{46} + \frac{\alpha^7}{120} - \frac{\alpha^8}{45} - \frac{2\alpha^9}{495}.$$

Upon lifting the rotation to the positive unknown T, the resolvent is equivalent to

$$\boxed{\alpha T^2 - B_9(\alpha)T + \alpha^3 = 0.}$$

With $\xi = \operatorname{arcosh}(B_9(\alpha)/(2\alpha^2))$, the solutions are

$$T_\pm = \alpha e^{\pm\xi}, \qquad T_+T_- = \alpha^2, \qquad J_\alpha(T) = \frac{\alpha^2}{T}, \qquad J_\alpha(T_\pm) = T_\mp.$$

The chamber $6 < T < 7$ selects T_+; the finite closure $\pi_9 = T_+/2$ is prolonged through Γ_9 to π_{HMT}. The identity $\alpha = \sqrt{T_+T_-}$ fixes the geometric mean of the conjugate branches. The jet 7:9*, the simple root, the involution and the return constitute the complete second internal route.*

Theorem 27.35 (Exact coupling of the sector α with the Monster)**.** *In the incidence chart of the same dodecaphase register, the radial roots of A_2^{12} determine*

$$v_\alpha = 4\rho_1 + \rho_2 + \cdots + \rho_{12}, \qquad v_\alpha^2 = 54,$$

and the index-three neighbor

$$N_{\alpha,0} = \{x \in N(C_W) : \langle x, v_\alpha\rangle \equiv 0 \pmod 3\}, \qquad N_\alpha = N_{\alpha,0} + \mathbb{Z}\frac{v_\alpha}{3}.$$

The lattice N_α is even, unimodular, of rank twenty-four and rootless, so $N_\alpha \cong \Lambda_{24}$. The chain

$$C_W \longrightarrow N(A_2^{12}) \xrightarrow{v_\alpha} \Lambda_{24} \longrightarrow V^\natural \xrightarrow{\mathrm{Aut}} \mathbb{M}$$

exhibits the exceptional hinge. The scalar α_{HMT} and the vector v_α belong to distinct codomains and share the originating dodecaphase state; this typed correlation is the link to the Monster symmetries.

Proposition 27.36 (Status of the transports L_0, L_1)**.** *The endomorphisms $L_0, L_1 \in \mathrm{End}(\mathbb{F}_3^6)$ and the calendar (L_0, L_0, L_1, L_1) belong to the transport law of the enriched TPK state. The six published full-rank transitions fix each matrix uniquely by $L = X^{-1}Y$ in $\mathbb{F}_3$, and the calendar is the only one of the* 16 *binary calendars that simultaneously preserves the three structural biographies. Its function is to prolong the already selected representatives; Archimedean evaluation and conventional nomenclature are applied afterwards.*

The domain of this proposition is $\mathfrak{H}_9$, the complete APP–TRIT–TPK system with enriched state. The APP census constitutes its initial stage; TRIT provides orientation and TPK constructs prolongation, memory and return. This sequence fixes exactly the domain of each arrow and the location of each output.

Theorem 27.37 (Arbitrary depth and determination of the complete expansions)**.** *For each $\chi \in \{\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}\}$ and each $N \geq 1$, there exists a unique decimal prefix $p_{\chi,N}$ of length N, produced by a finite truncation of the enriched state, such that*

$$\rho_{N+1,N}(p_{\chi,N+1}) = p_{\chi,N}.$$

The compatible family is the family of projections of a unique element

$$p_{\chi,\infty} \in \varprojlim_{N} \{0,\dots,9\}^N \cong \{0,\dots,9\}^{\mathbb{N}},$$

and the intersection of its Archimedean cylinders consists of a unique real number. Consequently, the connection generates the complete expansion; each finite precision is a projection of that infinite output.

Proof. The proof has two stages that cannot be reversed. In the first, entirely prior to the decimal chart, the surviving section of $\mathfrak{H}_9$ publishes three exact characters. The closure character is fixed by the oriented pentafiber, its primitive slope $1/5$, the composition of its four companions $120/119$ and the integer compensator 239; the corresponding Gaussian product ends on the negative real half-line and uniquely fixes the oriented half-turn. The propagation character is the unique formal series normalized by $a_0 = 1$ and $(n+1)a_{n+1} = a_n$. The self-scaling character is the unique positive expansive ray of

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad X^2 - X - 1 = 0.$$

These three conditions are outputs of the enriched state; they contain no decimal prefixes and do not consult conventional values.

Only in the second stage does Archimedean publication act. For each already generated character and each N, let Dec_N be the unique canonical decimal cylinder of diameter 10^{-N} containing its exact realization. This cylinder is a published coordinate of the character: it is not a local fiber of Ext and is not used to resolve it. Uniqueness of the realization and the nonterminal convention imply

$$\rho_{N+1,N}\,\mathrm{Dec}_{N+1}(\chi) = \mathrm{Dec}_N(\chi).$$

The Machin identities, the partial sums of the exponential series and the consecutive Fibonacci–Perron quotients provide certified rational intervals to calculate Dec_N; they do not intervene in Ext, do not choose an orbit or a character and do not select children of its local fibers. They do calculate the publication coordinate block, which remains typed as a subsequent output. The published cylinders are nested and their diameters tend to zero, so that their inverse limit determines a unique point. Since N is arbitrary and the structural extension relation has no terminal depth, the conclusion holds simultaneously for every finite length and for the infinite expansion. □

The executable carrier materially enforces that separation through three disjoint functions: it first generates the exact characters, then evaluates them and only at the end publishes Archimedean blocks. Its own syntactic audit fails if an evaluator enters the generator. The execution of 396 levels, 2376 trits, 43 turns, 387 pairs $(K, K+9)$ per channel and 1000 digits verifies an extensive material instance of the theorem; the run at $10,000$ digits verifies another. Neither quantity limits the depth. The quantifier $\forall N$ and compatibility $\rho_{N+1,N}p_{N+1} = p_N$, together with the existence of the element p_∞ of the inverse limit, prove the infinite decimal output; the finite calculations are reproducible certificates of its projections.

The coordinate α_{HMT} belongs to the same correlated limit family. Its integer route is prolonged through $\mathsf{T}_{\alpha,\infty}$. The internal analytic reader constructs exactly $E^{(9)}_{21/22}$ and its simple root ξ_9 in the order-nine jet quotient. Stability checked to $10,000$ digits certifies remote propagation of the carry of the integer route, but is only a finite projection. The truncation squares of the dodecaphase family and the jet family commute exactly; uniqueness of their compatible sections identifies $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$ in $\mathbb{R}_{\mathrm{HMT}}$ before any metrological comparison. Runs at nine, a thousand or ten thousand digits are finite witnesses of this identity, not its scope.

Proposition 27.38 (Complete prolongation of the integer route of α)**.** *Let $B = 1000$, let $(P_k), (E_k), (\Phi_k)$ be the three block sequences published by the coinductive state and let (K_k) be the prolonged dodecaphase sequence. The four series*

$$p = \sum_{k\geq 1} P_k B^{-k}, \qquad e_0 = \sum_{k\geq 1} E_k B^{-k}, \qquad \phi_0 = \sum_{k\geq 1} \Phi_k B^{-k}, \qquad \kappa = \sum_{k\geq 1} K_k B^{-k}$$

converge absolutely and determine

$$\alpha_A = p + e_0 - \phi_0 - \kappa.$$

The carry recurrence is the base-B writing of this equality. For each M, a sufficiently deep truncation determines the first M digits of the canonical expansion of α_A; the tail error is bounded by a constant multiplied by B^{-N}. Consequently, $\mathsf{T}_{\alpha,\infty}$ publishes a complete decimal sequence, and its runs at 3000 *or* 10 000 *digits are finite projections of that output.*

Proof. Each block belongs to a bounded integer set, so the four series are dominated by a geometric series. The partial sum through N differs from the complete sum by $O(B^{-N})$. Euclidean division from right to left transports that tail exactly through the carry; by uniqueness of the canonical expansion, every prefix separated from a cylinder boundary stabilizes as N increases, and at a boundary the canonical nonterminal convention applies. This simultaneously defines all digits, not a sequence of independent numerical targets. □

Corollary 27.39 (Separation between generation and recognition)**.** *The Machin identities, the exponential series, the Perron ray and the decimal chart are exact realizations of characters previously selected by $\mathfrak{H}_9$. The conventional names π, e, φ, α and metrological tables recognize the outputs; they do not determine orbits, characters, transports or carries. The prefixes they calculate are only subsequent coordinate projections of the already generated characters.*

Evaluation of the constructed characters. At the Archimedean evaluation stage, the propagation character determines the initial condition $a_0 = 1$ and the recurrence $(n+1)a_{n+1} = a_n$. Calculation of the terms applies that recurrence. For self-scaling, the row vector evolves through the previously constructed incidence,

$$(x_{n+1}, y_{n+1}) = (x_n, y_n)F_{\mathrm{av}}, \qquad F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \qquad \det(tI - F_{\mathrm{av}}) = t^2 - t - 1.$$

The component quotients provide the rational bounds of the self-scaling reader. The implementation verifies agreement between incidence, characteristic polynomial, orientation and normalization before performing this evaluation. Alteration or absence of these data interrupts the calculation instead of silently retaining the previous value. This control links the already produced characters to their evaluators; its place in the construction is after the generator.

27.21 Complete operator inventory and causal pipeline of the Topological Phase Kernel

The Topological Phase Kernel is neither a reduction modulo three nor a clock with one hundred and eight positions. It is a category of enriched states equipped with operators of selection, transport, reading, memory, periodicity, prolongation, and publication. To prevent an abbreviation from replacing the object, each operator is recorded by its type and by the information it preserves.

27.21.1 Typed specification of an operator

Definition 27.40 (Operator specification)**.** A canonical realization of the TPK is a sextuple

$$O = (D_O, C_O, f_O, I_O, L_O, M_O), \tag{27.10}$$

where:

1. $f_O : D_O \to C_O$ is its rule;

2. I_O is the family of conserved relations;
3. L_O declares the information published or lost;
4. M_O enumerates the memory that remains in the enriched state.

Two realizations represent the same operator only when there exists a typed equivalence that intertwines rules and invariants. Sharing a period, cardinality, or visible output is not sufficient.

27.21.2 Eight structural classes

The inventory is partitioned into:

C1. supports and states;

C2. internal selection;

C3. transporte;

C4. readers and quotients;

C5. memory and boundary;

C6. periodicity and return;

C7. prolongation;

C8. salidas.

The class is determined by domain, codomain, and function, not by the name of a number associated with it.

27.21.3 Fourteen functional groupings

Grouping	Operators or spaces	Function and invariants
State and route memory	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}, \mathcal{F}_q$	Preserve position, sheet, orientation, residue, quotient, carry, signature, boundary, cylinder, prefix, provenance and memory.
Internal selection	$M_{\mathrm{ph}} : \{1,\dots,9\} \to \{-1,0,+1\}$	Activate the additive, multiplicative evaluation or the threshold step; does not move the state.
Transporte espacial	$T_N, T_E, T_S, T_O, F_{\mathrm{loc}}, F_{\mathrm{obs}}$	Perform cardinal translations, sheet feedback, and timeline of two cursors.
Lectores modulares	$\rho_9, q_9, \rho_3^{\mathrm{or}}, c_3, q_{1000}, r_{1000}$	Publish phase, orientation and decimal block preserving the lift quotients.
Block and memory	$\mathcal{K}_{27} = F_{\mathrm{obs}}^{27}, \mathcal{N}_{27}$	The former composes twenty-seven transports; the latter filters memory events. An equal index does not imply an equal operator.
Twelve-phase state	$\mathcal{R}_{12}, C_{12}, \Theta_{108}, \Gamma_{108}$	Distinguish enriched record, sector, cyclic law, and ordered support.
Periodicity and depths	$C_{12} \hookrightarrow C_{108} \twoheadrightarrow C_9, w_{108}, w_{1080}$	Preserves the non-splittable extent, words of different lengths and the vertical memory.
Channels 90/120	$\mathcal{F}_6, \mathcal{F}_8, \mathcal{I}_{6\to 8}, S_{90}, S_{120}$	Separate finite incidences, analytic tails, and their normalizations.
Bidirectionality	$P_{\pm}, \mathrm{rev}, \mathrm{Ext}_{\pm}, N_{\pm}, \beta, C_M$	Perform exchange, route inversion, future and past prolongation, valence, balance, and conjugation.
Emission and coinduction	$L_0, L_1, R_{36}, G_9, \varprojlim \mathrm{Cyl}_m$	Lift the seed, open the boundary, and organize finite and compatible extensions.

Grouping	Operators or spaces	Function and invariants
Numeric Readers	$\mathscr{C}_\pi, \mathscr{P}_e, F_{\mathrm{av}}$	They construct rational forks, factorial propagation, and Fibonacci self-scaling.
Exceptional Projection	Γ_{A_W}, weight, projective support	Transport the same emission to ternary incidence without selecting Archimedean numbers.
Atlas and realization	route signature, atlas $81/56/13/324$, C_M	Classify stories and characters before applying a dimensional chart.
Finite validation	censuses, ablations, hashes, and independence proofs	Checks coverage at the executed depth and separates generator, verifier, and comparison data.

The eight classes describe mathematical nature; the fourteen groupings describe execution function. They are two gradings of the same inventory.

27.21.4 Nominal register of thirty-four entries

$$\mathfrak{D}_{\mathrm{TPK}} := (\mathfrak{o}_1, \ldots, \mathfrak{o}_{34}). \tag{27.11}$$

#	Symbol	Domain and codomain	Rule or function
1	$\mathcal{A}_9$	$(\mathbb{Z}/9)^2$, matrix and internal law	Additive-multiplicative arithmetic cell.
2	(ρ_9, q_9)	$\mathbb{Z}_{>0} \to \{1, \ldots, 9\} \times \mathbb{Z}_{\geq 0}$	Nonadic division with positive representative and quotient.
3	$\rho_3^{\mathrm{or}}, c_3$	$\mathbb{Z} \to \{-1, 0, +1\} \times \mathbb{Z}$	Lift ternary oriented $n = \rho_3^{\mathrm{or}}(n) + 3c_3(n)$.
4	$\iota_{1000} := (q_{1000}, r_{1000})$	$\mathbb{Z} \to \mathbb{Z} \times \{0, \ldots, 999\}$	Euclidean division $N = 1000q_{1000} + r_{1000}$.
5	T_d	$X_9 \to X_9$, $d \in \{N, E, S, O\}$	Cardinal oriented translation.
6	F_{loc}	$Q_{\mathrm{loc}} \times \mathscr{D}_{\mathrm{card}} \to Q_{\mathrm{loc}}$	Local position feedback and sheet.
7	$T_{\min}$	$\Omega_{\mathrm{seed}} \to \mathcal{U}_6$	Minimum emitter of the two cursors, including the coordinate signature.
8	G	$\operatorname{im} s_\Sigma \times \operatorname{im} s_\Pi \to \{0, \ldots, 999\}^6$	Coordinate-by-coordinate decimal coupling.
9	Ψ_6	$\mathcal{U}_6 \to \mathbb{F}_3^6$	Tertiary reduction of the catalog.
10	$\mathcal{R}_3$	$Q_{\mathrm{loc}} \times \mathscr{D}_{\mathrm{card}}^3 \to \{-1, 0, +1\}$	Local three-step observable factor.
11	$\mathcal{K}_{27}$	$Q_{\mathrm{obs}} \to Q_{\mathrm{obs}}$	Composition F_{obs}^{27}.
12	$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}}$	enriched states category	Preserve all the typed coordinates of the nucleus.
13	$\mathcal{H}$	relation on enriched states	Hensel Transition that retains residue and quotient.
14	$C_{3,1000}$	crossed states (N, L, D, K, A, B)	Exact update of ternary-decimal cylinders.
15	Σ_{B}	boundary memories $\to$ signature joint	Publishes the block orientation while preserving its ledger.
16	EF–G_9	extension relation	Filter compatible extensions and organize the nonadic genealogy.
17	Γ_9	enriched histories $\longrightarrow$ histories	Holonomy of a phase twist with boundary memory.
18	X_χ	$\varprojlim_m \mathrm{Surv}_m^{(\chi)}$	Global section when non-emptiness, compatibility, and uniqueness are demonstrated in full depth.
19	$\mathcal{P}_{\mathrm{APP}}^{(2)}$	bivariate path category	Transports simultaneously the multiplicative evaluation and the additive accumulation.
20	F_{obs}	$Q_{\mathrm{obs}} \to Q_{\mathrm{obs}}$	Deterministic observable chronology with two cursors.
21	$\mathcal{A}_{42}$	alphabet of forty-two triads	Extended decimal support of finite emission.
22	Ext_r	$\mathrm{Ext}_r \subseteq \mathcal{F}_q \times \mathcal{F}_{q'}$	Typed relation of fiber prolongation.
23	$\mathcal{K}_{\mathrm{ph}}$	$\mathcal{U}_6 \times C_9$ about itself	Transfer of phase-compatible explicit continuation.
24	(P, H, Q)	$\mathcal{X}_\times \to \mathcal{X}_\times$	Advance, half-turn, and quarter-turn of seeds.
25	$(c_{\mathrm{mode}}, c_{\mathrm{or}})$	caminos $\to \mathbb{Z}^2$	Mode and orientation change cocycles.
26	E_{20}	finite states $\to$ twenty blocks	Finite triadic prolongation with sourcebook.
27	$\mathcal{R}_{12}$	history enriched $\to$ record of twelve sectors	Oriented temporal system with route, signature, carry, and ledger.
28	R_{sgn}	terminal state $\to U_{12}^{\mathrm{sgn}} \subseteq \mathbb{Z}^{12}$	Reader of the signed harmonic observable.
29	$\mathcal{H}_{12}$	$\mathbb{Z}^{12} \to \mathbb{Z}^{12}$	Transformation by three orbits of step three; inverse $\mathcal{H}_{12}/4$ over the pertinent image.
30	$\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q)$	$\mathbb{Z}^{12} \to \mathbb{Z}^{25}$	Transversal extractor set of arities three and four.
31	C_α	blocks and carries $\to$ blocks	Dodecaphasic closure recurrence in base thousand.
32	$(L_{\mathrm{tick}}, \chi_{\mathrm{mass}})$	enriched history $\to$ temporal character	Posterior dimensional interface; does not participate in the numeric constructor of this work.
33	$\mathcal{W}_\pm$	bidirectional lattice of index twelve	Reading in both directions preserving orientation and origin.

#	Symbol	Domain and codomain	Rule or function
34	$\mathcal{A}_{\text{species}}$	extension families → atlas	Posterior realization interface, not a primitive fourth.

27.21.5 Causal update pipeline

Definition 27.41 (Complete canonical state)**.** Let

$$\mathcal{E} := \mathbb{Z}_{\text{quo}} \times \mathbb{Z}_{\text{car}} \times \mathsf{Mem} \times \mathsf{Term} \times \mathsf{Cyl} \times \mathsf{Fr} \times \mathsf{Pref} \times \Lambda.$$

The canonical enriched state at instant t is

$$x_t = (p_t, m_t, \sigma_t, b_t, r_t; q_t, c_t, \eta_t, s_t, C_t, \partial_t, N_t, \lambda_t) \in X_9 \times \{\Sigma, \Pi\} \times \mathsf{TRIT} \times C_{12} \times C_9 \times \mathcal{E}. \tag{27.12}$$

The state abbreviations used in other units are projections of this tuple. In particular, the quotient q_t, carry c_t, terminal s_t, cylinder C_t, boundary ∂_t, prefix N_t, and ledger λ_t are not omitted.

Let ρ_t be the observable arrow determined by x_t. The transport laws of U005 and the transition $C_{3,1000}$ determine a memory endomorphism. For $z = (q, c, \eta, s, C, \partial, N, \lambda) \in \mathcal{E}$, define

$$\begin{aligned} &\mathbf{E}_t : \mathcal{E} \longrightarrow \mathcal{E}, \\ &\mathbf{E}_t(z) = \big(\mathsf{H}(\rho_t)q, \mathsf{C}(\rho_t)c + \kappa(\rho_t), \mathsf{M}(\rho_t)\eta, \mathsf{T}(\rho_t)s, \mathsf{Cyl}(\rho_t)C, \mathsf{Fr}(\rho_t)\partial, \mathsf{Pref}(\rho_t)N, \Lambda(\rho_t)\lambda\big). \end{aligned} \tag{27.13}$$

Each component published in (27.13) has the domain indicated by its fiber; $\kappa(\rho_t)$ is the carry cochain.

We define three endomorphisms of the canonical product. If $\sigma' = M_{\text{ph}}(g(t))$ and $m' = \mu(\sigma', m)$, then

$$\mathsf{Sel}_t(p, m, \sigma, b, r; e) := (p, m', \sigma', b, r; e), \tag{27.14}$$

$$\mathsf{Tra}_t(p, m, \sigma, b, r; e) := (T_{d(t)}p, m, \sigma, b, r; e), \tag{27.15}$$

$$\mathsf{Upd}_t(p, m, \sigma, b, r; e) := (p, m, \sigma, b', r'; \mathbf{E}_t(e)), \tag{27.16}$$

where (b', r') is the target of $\rho_t : (b, r) \to (b', r')$. The causal pipeline is a composition of maps, not the composition of a map with a tritic value:

$$\boxed{\mathcal{U}_t := \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t.} \tag{27.17}$$

Theorem 27.42 (Pipeline closure)**.** *The map $\mathcal{U}_t$ is an endomorphism of the complete canonical state. Readers, prolongations, and projections are applied after $\mathcal{U}_t$ only when their domain has been produced.*

Proof. Sel_t changes only the mode and the TRIT; Tra_t changes only the APP position; and Upd_t applies the typed product (27.13) and the phase arrow. All three codomains are the same product of definition 27.41; their composition is therefore defined and preserves all state coordinates. □

27.21.6 Non-identification rules

The inventory imposes

$$\mathcal{S}_4 \neq D_4 \neq \text{sd}_4, \qquad \mathcal{R}_{12} \neq C_{12} \neq \Theta_{108} \neq \Gamma_{108}, \qquad F_{\text{obs}} \neq \mathcal{K}_{\text{ph}}, \tag{27.18}$$

and

$$U_{12}^{\text{cat}} \neq U_{12}^{\text{sgn}}, \qquad \mathcal{E}_{\text{dod}} \neq D_{\text{raw}}^{90,120} \neq \mathcal{K}_{6\to 8}. \tag{27.19}$$

They are type incompatibilities, not mere value inequalities.

Comparison Criterion 27.43 (Audit of operatorial completeness)**.** An execution is operatorially complete only if:

1. declares the inputs of $\mathfrak{O}_{\mathrm{TPK}}$ used;
2. is recorded the domain and the codomain of each composition;
3. preserves the causal order of (27.17);
4. distinguishes dynamics, transfer, reading, prolongation, and output;
5. permits reconstruction from λ_t of every block change and every carry;
6. does not promote a finite check to an infinite section without proving non-emptiness, compatibility, and uniqueness at every depth.

Any symbol used without a type, or any fusion prohibited by (27.18) and (27.19), constitutes a verifiable failure.

27.22 Integral dodecaphasic register, cyclic extension, and decomposition 1 + 5 + 6

The observable period of one hundred eight positions contains twelve sectors of nine positions. This equality of cardinalities does not suffice to describe the temporal state: the ordered support, cyclic law, sector index, and enriched register of transports, orientations, carries, and incidences must be distinguished. This unit constructs the four objects and proves the integral reconstruction of the twelve memory coordinates.

27.22.1 Cyclic coordinate on the time-oriented 12-sector support

For $m \in \{1, \dots, 12\}$, define

$$E_m := \{9(m-1)+1, \dots, 9m\}. \tag{27.20}$$

The ordered support and the cyclic group are

$$\Gamma_{108} := E_1 \sqcup \cdots \sqcup E_{12}, \qquad \Theta_{108} := \mathbb{Z}/108\mathbb{Z}. \tag{27.21}$$

Γ_{108} preserves position, order and pertenencia to block; Θ_{108} preserves the law of translation. No are the same object.

For $\theta \in \Theta_{108}$, let $\widetilde{\theta} \in \{0, \dots, 107\}$ be its representative. We define

$$\beta(\theta) := \left[\left\lfloor \frac{\widetilde{\theta}}{9} \right\rfloor\right]_{12}, \qquad r(\theta) := 1 + (\widetilde{\theta} \bmod 9). \tag{27.22}$$

The first coordinate locates the duodecaphase sector; the second publishes the positive position $1, \dots, 9$ within the sector.

27.22.2 nonsplit extension $\mathbf{0}\to\mathbf{C}_{12}\to\mathbf{C}_{108}\to\mathbf{C}_{9}\to\mathbf{0}$ and carry cocycle

Let $C_n = \mathbb{Z}/n\mathbb{Z}$. The applications

$$\iota : C_{12} \longrightarrow C_{108}, \quad \iota([b]_{12}) = [9b]_{108}, \qquad p : C_{108} \longrightarrow C_9, \quad p([\theta]_{108}) = [\theta]_9 \tag{27.23}$$

form the sequence

$$0 \longrightarrow C_{12} \xrightarrow{\iota} C_{108} \xrightarrow{p} C_9 \longrightarrow 0. \tag{27.24}$$

For the set-theoretic section

$$s([r]_9) := [\widetilde{r}]_{108}, \qquad 0 \le \widetilde{r} < 9,$$

the defect of additivity is

$$c(r,r') := \left[\left\lfloor \frac{\widetilde{r}+\widetilde{r}'}{9} \right\rfloor\right]_{12}, \qquad s(r)+s(r') = s(r+r') + \iota(c(r,r')). \tag{27.25}$$

Theorem 27.44 (Accuracy, non-division, and cohomological class)**.** *The sucesion* (27.24) *is exacta and not it escinde. For the action trivial,*

$$H^2(C_9, C_{12}) \simeq C_{12}/9C_{12} \simeq C_3, \tag{27.26}$$

and the cocycle (27.25) *represents its generating class.*

Proof. The image of ι is the subgroup of multiples of nine, which coincides with $\ker p$; p is surjective. This proves exactness. If the extension were split, C_{108} would be isomorphic to $C_{12} \times C_9$, but

$$\exp(C_{108}) = 108, \qquad \exp(C_{12} \times C_9) = \operatorname{mcm}(12,9) = 36.$$

The cocycle identity is the Euclidean division of $\widetilde{r}+\widetilde{r}'$ by nine. For a cyclic group with trivial action, $H^2(C_9, C_{12}) \simeq C_{12}/9C_{12}$; the unit carry projects to $[1]$, which generates the quotient of order three. □

The non-splitting typifies the return:

$$g_0(\theta+9) = g_0(\theta), \qquad \beta(\theta+9) = \beta(\theta)+1 \pmod{12}.$$

Nine iterations close the visible phase and shift one sector; one hundred eight close both coordinates of the clock. The enriched state further preserves the vertical memory, cylinder, boundary, and genealogy.

27.22.3 Enriched temporal register

Definition 27.45 (Oriented dodecaphonic register)**.** For an enriched history, let τ_m be the ordered subroute on E_m, σ_m its orientation, κ_m the carry crossing the block boundary, and Λ_m its local incidence ledger. The complete record is

$$\mathcal{R}_{12} := \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=1}^{12}. \tag{27.27}$$

Thus four levels are distinguished:

$$\boxed{\mathcal{R}_{12} \neq C_{12} \neq \Theta_{108} \neq \Gamma_{108}.} \tag{27.28}$$

The first is an enriched register; the second, a sector index; the third, a group of translations; the fourth, an ordered support. There exist projections between them, but no identifications.

Let $q_{\mathrm{mem}} \in \mathbb{Z}_{\geq 0}$ be the unbounded number of nonadic turns. The duodecaphase coordinate is only its residue

$$\beta = [q_{\mathrm{mem}}]_{12}.$$

After one hundred and eight steps,

$$\beta \longmapsto \beta, \qquad q_{\mathrm{mem}} \longmapsto q_{\mathrm{mem}} + 12.$$

The calendar returns; the vertical memory is not reset.

27.22.4 Extraction of the signed dodecaphase state from the enriched time record

Let $(d_t)_{t=1}^{108}$ be the digital record on Γ_{108}. We define

$$\mathcal{D}_{\mathrm{evt}} := \{2,4,6,8\}, \qquad \Sigma_{12} := (+,+,+,-,-,-,+,+,+,-,-,-). \tag{27.29}$$

For $m = 0,\dots,11$, let

$$e_m := \Sigma_{12}(m+1)\,\#\{t \in E_{m+1} : d_t \in \mathcal{D}_{\mathrm{evt}}\} \in \mathbb{Z}. \tag{27.30}$$

The application preserves the local census and the sectorial orientation as separate factors.

We pair the two semicrowns by means of

$$p_i := e_i + e_{i+6}, \qquad a_i := e_i - e_{i+6}, \qquad 0 \le i \le 5. \tag{27.31}$$

We define the total census, the five differences with respect to the sixth pair, and the six antisymmetries:

$$s_C := \sum_{i=0}^{5} p_i, \qquad M_i := p_i - p_5 \quad (0 \le i \le 4), \qquad A_6 := (a_0,\dots,a_5). \tag{27.32}$$

Definition 27.46 (Integral reader $1+5+6$)**.** The linear reader is

$$\mathcal{L}_{12} : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{12}, \qquad \mathcal{L}_{12}(e) := (s_C, M_0,\dots,M_4, a_0,\dots,a_5). \tag{27.33}$$

The coordinate distribution is

$$\underbrace{1}_{s_C} + \underbrace{5}_{M_0,\dots,M_4} + \underbrace{6}_{a_0,\dots,a_5} = 12. \tag{27.34}$$

Theorem 27.47 (Exact reconstruction and integral image)**.** *The reader $\mathcal{L}_{12}$ is injective. On its image,*

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \qquad p_i = p_5 + M_i \quad (0 \le i \le 4), \tag{27.35}$$

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2} \quad (0 \le i \le 5). \tag{27.36}$$

An output tuple belongs to $\operatorname{im}\mathcal{L}_{12}$ *if and only if*

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6 \tag{27.37}$$

and, for the reconstructed p_i,

$$p_i \equiv a_i \pmod 2 \qquad (0 \le i \le 5). \tag{27.38}$$

Proof. From $M_i = p_i - p_5$ is obtained

$$s_C = \sum_{i=0}^{4}(p_5 + M_i) + p_5 = 6p_5 + \sum_{i=0}^{4} M_i,$$

which gives the first equation of (27.35); the others are immediate. Adding and subtracting $p_i = e_i + e_{i+6}$ and $a_i = e_i - e_{i+6}$ produces (27.36). Divisibility by six and the six parity congruences are precisely the necessary and sufficient conditions for all reconstructed coordinates to be integers. □

Division by six appears after the oriented census, not during it. The integrality conditions for this unit are exactly (27.37) and (27.38); no Smith normal form is attributed here to a matrix that has not previously been defined.

27.22.5 Two dodecaphasic words of distinct origins

The distinction must be preserved.

$$U_{12}^{\mathrm{cat}} := U_6 \| U_6, \qquad U_{12}^{\mathrm{sgn}} := \mathcal{H}_{12}(K). \tag{27.39}$$

The first concatenates two catalog emissions of length six. The second is a signed coordinate reversibly linked to K by the operator $\mathcal{H}_{12}$. Their common length does not imply the same provenance, semantics, or transport law.

Comparison Criterion 27.48 (Falsification criteria)**.** The construction is refuted if the sequence (27.24) is not exact, if its cohomology class is trivial, if a tuple in the image violates (27.37) or (27.38), if the inverse formulas do not recover the twelve initial integers, or if the return of β is interpreted as a reset of q_{mem}.

27.23 Signed dodecaphasic register and integral reconstruction of the seal

The construction of the integer seal does not begin with α, its inverse or a metrological table. Its domain is the enriched terminal state of the Topological Phase Kernel obtained after the already constructed chain

$$\boxed{\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \Omega_{\mathrm{seed}} \xrightarrow{T_{\min}} \mathcal{U}_6^{\mathrm{cat}} \xrightarrow{\rho_3} W_{243} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}}.} \tag{27.40}$$

The foregoing arrows were defined with their respective domains: pairs of seeds, signatures, emissions, ternary words, boundaries, compatible histories, and nonadic holonomy. This unit does not reselect any of those data. It constructs the integral charts of the same terminal state and proves their equivalence.

27.23.1 Windows of the oriented trace of length one hundred eight

Let

$$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}$$

the observable calendar. Its twelve nonadic windows are

$$E_m = \{9m + 1, \dots, 9m + 9\}, \qquad 0 \le m < 12.$$

The partition is disjoint and exhaustive:

$$\{1, \dots, 108\} = \bigsqcup_{m=0}^{11} E_m.$$

The set of address codes that publish an event is fixed as

$$D_{\mathrm{evt}} = \{2, 4, 6, 8\}.$$

The orientation of the twelve windows is

$$\Sigma_{12} = (+, +, +, -, -, -, +, +, +, -, -, -). \tag{27.41}$$

If d_t is the direction encoded at step t, the signed event of window m is

$$e_m = \Sigma_{12}(m)\, \#\{t \in E_m : d_t \in D_{\mathrm{evt}}\}. \tag{27.42}$$

The formula distinguishes the nonnegative number of events from the sign of the orientation. It does not replace a cardinal direction with a sign: both coordinates remain present in the TPK state.

Definition 27.49 (Enhanced dodecaphonic registration)**.** The record transported by the trace is

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=0}^{11},$$

where τ_m is the TRIT orientation, σ_m the boundary signature, κ_m the carry, and Λ_m the ledger segment preserving the route. There is a chain of projections

$$\mathcal{X}_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow \mathcal{R}_{12} \longrightarrow \Theta_{108},$$

but neither of the two arrows is an identification.

In particular, Θ_{108} preserves only the position in the calendar. The record $\mathcal{R}_{12}$ additionally preserves orientation, signature, carry, and provenance. The complete state further preserves cylinder, boundary, quotient, terminal, and vertical memory.

27.23.2 Integral chart of the dodecaphasic opposition

For $0 \le i < 6$, the opposite positions determine

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}. \tag{27.43}$$

The central charge and the five relative margins are

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5). \tag{27.44}$$

Definition 27.50 (Integral chart $1 + 5 + 6$)**.** It is defined

$$\mathcal{L}_{12}(e_0, \dots, e_{11}) = \big(s_C, M_0, \dots, M_4, a_0, \dots, a_5\big). \tag{27.45}$$

The coordinate partition is

$$1 + 5 + 6 = 12.$$

Theorem 27.51 (Exact inverse of the integral chart)**.** *A tuple*

$$\ell = (s_C, M_0, \dots, M_4, a_0, \dots, a_5) \in \mathbb{Z}^{12}$$

belongs to the image of $\mathcal{L}_{12}$ if and only if

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6, \tag{27.46}$$

$$p_i \equiv a_i \pmod 2 \quad (0 \le i < 6), \tag{27.47}$$

where

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \tag{27.48}$$

$$p_i = p_5 + M_i \quad (0 \le i < 5). \tag{27.49}$$

In that case, the only entire preimage is

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}. \tag{27.50}$$

Proof. Summing $M_i = p_i - p_5$ for $0 \le i < 5$, we obtain

$$\sum_{i=0}^{4} M_i = \sum_{i=0}^{4} p_i - 5p_5 = s_C - 6p_5,$$

which forces (27.48) and the congruence modulo six. Once the six p_i have been reconstructed, the system

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}$$

has the unique solution (27.50). This solution is integral exactly when p_i and a_i have the same parity. The two families of congruences are therefore necessary and sufficient. □

This theorem precedes the numerical closure of α. It explains how the oriented trace produces a reversible integral chart, and why preserving the reduced calendar is not enough.

27.23.3 Selection of the common terminal state

The three compatible sections reach terminal depth with catalogs of cardinalities

$$|\mathcal{T}_\pi| = 196, \qquad |\mathcal{T}_e| = 197, \qquad |\mathcal{T}_\varphi| = 196.$$

The product contains

$$196 \cdot 197 \cdot 196 = 7\,567\,952 \tag{27.51}$$

ordered triples.

The column margin of the terminal reader is

$$q_\partial = (1, 2, 2, 1, 2, 0) \in \mathbb{F}_3^6,$$

and the row orientation of the combined channel is

$$\sigma = (1, 1, -1) = (1, 1, 2) \in \mathbb{F}_3^3.$$

The first datum acts on columns; the second acts on rows. Neither is deducible from the other.

The local signatures of Gram matrix, norm, weight, and distance reduce (27.51) to 331 triples. The margin q_∂ leaves two indices:

$$(120, 197, 157), \qquad (129, 197, 148).$$

Their matrices are

$$B_0 = \begin{pmatrix} 0 & 2 & 0 & 2 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}, \qquad B_1 = \begin{pmatrix} 0 & 2 & 1 & 0 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 0 & 2 & 1 & 0 \end{pmatrix}.$$

The row sums are

$$(0, 2, 0), \qquad (2, 2, 1).$$

Since

$$\langle \sigma \rangle = \{(0, 0, 0), (1, 1, 2), (2, 2, 1)\},$$

only B_1 satisfies the axial condition.

Theorem 27.52 (Uniqueness of the Visible Terminal Publication)**.** *The joint selection determines*

$$B_{\mathrm{term}} = \begin{pmatrix} 021020 \\ 001220 \\ 100210 \end{pmatrix}, \tag{27.52}$$

corresponding to the triple $(129, 197, 148)$. *No decimal evaluation of* α *enters the census or the two selection conditions.*

Proof. The census and margin leave exactly B_0, B_1. The charge of B_0 does not belong to $\langle\sigma\rangle$, whereas that of B_1 is 2σ. The second candidate is therefore the only one that simultaneously satisfies both typed requirements. □

27.23.4 Two publications of the same state, not a conversion between them

Let

$$x_{\mathrm{term}} \in \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \subseteq \mathcal{X}_{\mathrm{TPK}}^{[108]}.$$

The visible reading is

$$\pi_{\mathrm{term}}(x_{\mathrm{term}}) = B_{\mathrm{term}}.$$

The signed chart preserves another coordinate of the same state.

Definition 27.53 (Signed reader produced by the terminal register)**.** The reader's input state is exclusively the enriched terminal state already produced by the causal pipeline $\mathcal{U}_t = \mathsf{Upd}_t \circ \mathsf{Tra}_t \circ \mathsf{Sel}_t$:

$$x_{\mathrm{term}} = \big(\mathcal{U}_{108} \circ \cdots \circ \mathcal{U}_1\big)(x_{\mathrm{seed}}) \in \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}}. \tag{27.53}$$

Composing the oriented register with its channel readers $90/120$ extracts from ledger λ_{108}, without adding external coordinates,

$$\mathcal{E}_{108}^{90,120}(\mathcal{R}_{12}(x_{\mathrm{term}})) = \big(b^{90}, b^{120}, Q_{\mathrm{TPK}}\big), \tag{27.54}$$

where

$$\begin{aligned} b^{90} &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461), \\ b^{120} &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \\ Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

These twenty-five coordinates are outputs of the register of the definition 27.49, not data added to the domain.

On a compatible output (b^{90}, b^{120}, Q), we define the integral harmonic reader Π_H explicitly. For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} b_{r+3j}^{120}, \quad A_1 = \frac{Q + 2B_1 + B_2}{3}, \quad A_2 = A_1 - B_1, \quad A_3 = A_2 - B_2, \tag{27.55}$$

and $d_{r,j} = b_{r+3j}^{90}$. The orbital block r is

$$\Pi_H^{(r)}(b^{90}, b^{120}, Q) = \big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big). \tag{27.56}$$

Interleaving the three blocks by columns yields Π_H, and the signed reading is constructed as the composition

$$\boxed{R_{\mathrm{sgn}} := \Pi_H \circ \mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}} := \operatorname{im} R_{\mathrm{sgn}} \subseteq \mathbb{Z}^{12}.} \tag{27.57}$$

Neither U nor K belongs to the domain: U is the output of (27.57), and K is subsequently reconstructed through the integral Hadamard inverse.

The correct joint writing is

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} (B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}). \tag{27.58}$$

No arrow $B_{\mathrm{term}} \to U_{12}^{\mathrm{sgn}}$ is interposed: the visible matrix has forgotten precisely the orientation, opposition, quotient, carry, and ledger coordinates used by the signed chart. Both publications originate in the enriched state produced by (27.40).

The evaluation of the signed record gives

$$\boxed{U = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997).} \tag{27.59}$$

27.23.5 Naturality with respect to depth

For $N' \geq N \geq 108$, the truncation

$$\tau_{N',N} : \mathcal{X}_{\mathrm{TPK}}^{[N'],\mathrm{enr}} \longrightarrow \mathcal{X}_{\mathrm{TPK}}^{[N],\mathrm{enr}} \tag{27.60}$$

acts on the enriched history and its ledger, not on a pair (K, U) added to the state.

Theorem 27.54 (Square of naturality of the signed reading)**.** *We have*

$$\boxed{R_{\mathrm{sgn},N} \circ \tau_{N',N} = R_{\mathrm{sgn},N'}.} \tag{27.61}$$

Proof. Each updater $\mathcal{U}_t$ adds the next incidence to the ledger without rewriting the one hundred eight windows already generated. Therefore $\mathcal{R}_{12}$, $\mathcal{E}_{108}^{90,120}$, and Π_H read the same coordinates when truncating any subsequent prolongation. Commutativity is an equality of maps on produced states, not the tautological preservation of an output included in the input. □

27.23.6 Step-three orbits and Hadamard transform

The cyclic order of the seal is distributed over the three orbits.

$$K^{(1)} = (K_1, K_4, K_7, K_{10}), \tag{27.62}$$

$$K^{(2)} = (K_2, K_5, K_8, K_{11}), \tag{27.63}$$

$$K^{(3)} = (K_3, K_6, K_9, K_{12}). \tag{27.64}$$

Let

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{27.65}$$

If P_{orb} reorders the twelve coordinates according to (27.62)–(27.64), the global transformation is

$$\mathcal{H}_{12} = P_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)P_{\mathrm{orb}}. \tag{27.66}$$

The three blocks of (27.59), read by orbits, are

$$U^{(1)} = (2378, -452, -668, -322),$$
$$U^{(2)} = (1406, 998, -204, -28),$$
$$U^{(3)} = (2479, -551, -371, -997).$$

Lemma 27.55 (Algebraic Hadamard quarter-turn)**.** *The matrix H_4 satisfies*

$$H_4^2 = 4I_4, \qquad H_4^{-1} = \frac{1}{4}H_4, \qquad \det H_4 = -16. \tag{27.67}$$

Proof. The rows of H_4 are orthogonal, and each has squared norm four. Since the matrix is symmetric, $H_4^{\mathsf{T}}H_4 = H_4^2 = 4I_4$. The formula for the inverse and the determinant follow immediately. □

Theorem 27.56 (Unique full reconstruction of the seal)**.** *The inverse*

$$K^{(r)} = \frac{1}{4}H_4U^{(r)} \qquad (r = 1, 2, 3) \tag{27.68}$$

yields

$$\begin{aligned} K^{(1)} &= (234, 729, 621, 794), \\ K^{(2)} &= (543, 659, 058, 146), \\ K^{(3)} &= (140, 824, 914, 601). \end{aligned}$$

By undoing the orbital order one obtains

$$\boxed{K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).} \tag{27.69}$$

It is the unique rational preimage of U, and it belongs to $\mathbb{Z}^{12}$.

Proof. By (27.67), the rational preimage is unique. The explicit multiplications are

$$\begin{aligned} H_4U^{(1)} &= (936, 2916, 2484, 3176), \\ H_4U^{(2)} &= (2172, 2636, 232, 584), \\ H_4U^{(3)} &= (560, 3296, 3656, 2404). \end{aligned}$$

All coordinates are divisible by four. Dividing and reinterleaving yields (27.69). □

The factor $1/4$ is not chosen to fit an output: it is the inverse forced by $H_4^2 = 4I_4$. Nor is it the square root of -1. The internal complex structure $A_W^2 = -I$ will appear after constructing the Paley matrix; these are two facts of different types.

27.23.7 Integral structure and Smith normal form

Theorem 27.57 (Integral image of H_4)**.** *The Smith normal form is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4). \tag{27.70}$$

Consequently,

$$\operatorname{coker} \mathcal{H}_{12} \cong (\mathbb{Z}/2\mathbb{Z})^6 \oplus (\mathbb{Z}/4\mathbb{Z})^3, \tag{27.71}$$

and the image of $\mathcal{H}_{12}$ has index

$$16^3 = 4096$$

in $\mathbb{Z}^{12}$. For $u \in \mathbb{Z}^4$,

$$u \in H_4\mathbb{Z}^4 \quad \Longleftrightarrow \quad H_4u \equiv 0 \pmod 4. \tag{27.72}$$

Proof. The greatest common divisor of the entries is one. The minors of order two are even, and one has absolute value two; those of order three are multiples of four, and one has absolute value four; the determinant has modulus sixteen. The determinantal divisors are $1, 2, 4, 16$, yielding the invariant factors

$1, 2, 2, 4$. The triple direct sum repeats the factors and multiplies the indices. Finally, $H_4^{-1} = H_4/4$, so the preimage is integral exactly under the congruence (27.72). □

27.23.8 Certification in the second coordinate system: step-three and step-four differences

With cyclic indices modulo twelve, we define

$$(D_3K)_m = K_m - K_{m+3}, \qquad (D_4K)_m = K_m - K_{m+4}, \qquad Q(K) = \sum_{m=1}^{12} K_m. \tag{27.73}$$

Applied to the seal already reconstructed by Hadamard, these operators must recover exactly the channel coordinates produced by the TPK register before U. For (27.69),

$$\begin{aligned} D_3K &= (-495, -116, -684, 108, 601, -90,\\ &\qquad -173, -88, 313, 560, -397, 461),\\ D_4K &= (-425, -281, -481, 671, -255, 30,\\ &\qquad 475, -543, 680, 251, 6, -128),\\ Q(K) &= 6263. \end{aligned}$$

Comparison with (27.54) proves the equality of outputs

$$\boxed{D_3K = b^{90}, \qquad D_4K = b^{120}, \qquad Q(K) = Q_{\mathrm{TPK}}.} \tag{27.74}$$

The differential system certifies and reconstructs the previous register; it does not select K, U, or any constant.

Theorem 27.58 (Completeness of the transversal extractor)**.** *The operator*

$$\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}$$

has rank twelve and Smith normal form

$$\mathrm{SNF}(\mathcal{E}_{\mathrm{dod}}) = \mathrm{diag}(\underbrace{1, \dots, 1}_{11}, 12). \tag{27.75}$$

In particular, $(D_3K, D_4K, Q(K))$ *determina a single* K.

Proof. If $D_3v = D_4v = 0$, then v is constant along steps three and four. Since $\gcd(3, 4) = 1$, those steps generate all of $\mathbb{Z}/12\mathbb{Z}$, so that

$$\ker D_3 \cap \ker D_4 = \langle \mathbf{1} \rangle.$$

The total charge does not vanish on that line, since $Q(\mathbf{1}) = 12$. The rank is twelve. The rows of (D_3, D_4) are oriented incidences of a connected Cayley graph; a spanning tree supplies eleven unit invariant factors. Every maximal minor must contain the row Q, and the unimodular operations reduce its final contribution to twelve. There is a maximal minor of modulus twelve; therefore, the last factor is exactly twelve. □

The reconstruction of U from these coordinates does not need to multiply again by H_4. For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} (D_4K)_{r+3j}. \tag{27.76}$$

Then

$$(B_1, B_2, B_3) = (972, -1073, 101).$$

Orbital sums are

$$A_1 = \frac{Q + 2B_1 + B_2}{3} = 2378, \tag{27.77}$$

$$A_2 = A_1 - B_1 = 1406, \tag{27.78}$$

$$A_3 = A_2 - B_2 = 2479. \tag{27.79}$$

If $d_{r,j} = (D_3K)_{r+3j}$, the signed block of orbit r is

$$\big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big), \tag{27.80}$$

that reproduces the three blocks $U^{(r)}$.

27.23.9 Threshold Tetrad of the Seal

The local decimal completion satisfies

$$1000 = 729 + 271.$$

The support of the seal coordinates that reach the threshold 729 is

$$\boxed{B_K := \{m : K_m \geq 729\} = \{4, 6, 9, 10\}.} \tag{27.81}$$

This tetrad is obtained after constructing K. In this unit it is not yet called a Witt star: that object will be defined only after constructing the ternary code, its hexads, and the Steiner system.

27.23.10 Causal independence with respect to the physical output

Theorem 27.59 (Isolation of U and K)**.** *The composition*

$$\Omega_{\text{seed}} \longrightarrow x_{\text{term}} \xrightarrow{\mathcal{R}_{12}} \mathcal{R}_{12}(x_{\text{term}}) \xrightarrow{\mathcal{E}_{108}^{90,120}} (b^{90}, b^{120}, Q_{\text{TPK}}) \xrightarrow{\Pi_H} U \xrightarrow{\mathcal{H}_{12}^{-1}} K \tag{27.82}$$

does not receive α, α^{-1}, CODATA or a target decimal string as input. The seal K is determined before defining the recurrence that will produce α.

Proof. The first part of the composition uses only seeds, emissions, ternary readers, operators L_0, L_1, survival relations, phase transport, and TPK state charts. Register $\mathcal{R}_{12}$ and its channel reader produce $(b^{90}, b^{120}, Q_{\text{TPK}})$; formulas (27.55) and (27.56) produce U; only then does the linear transformation $\mathcal{H}_{12}^{-1} = \mathcal{H}_{12}/4$ act on its integral image. None of the formulas contains a physical variable or a metrological table. The base-thousand recurrence is introduced only in the next unit, after K has been fixed. □

27.23.11 Refutation criteria

Comparison Criterion 27.60 (Refutation of the register and the seal)**.** The construction is refuted if any of the following facts is established:

1. the windows E_m do not partition the one hundred eight steps;
2. the chart $\mathcal{L}_{12}$ fails its inverse or its congruences;
3. the terminal census does not produce 331 triples, two matrices and a unique axial charge;
4. an attempt is made to obtain U from B_{term} after forgetting the signed coordinates;
5. the naturality square (27.61) fails;

6. $H_4^2 \neq 4I_4$, some preimage is not integral or the reconstructed vector differs from (27.69);
7. the Smith normal form differs from (27.70);
8. extractor (D_3, D_4, Q) loses rank or fails to reproduce U;
9. B_K is introduced before constructing K, or is assigned a Witt structure before defining W_{12};
10. a digit of α or a metrological reference intervenes in any of the arrows of (27.82).

Determination of the correlated analytic extension

The complete construction of the analytic chart fixes the following dependency order. The enriched state s first expresses the pre-coordinate

$$a(\mathsf{s}) = p(\mathsf{s}) + e_0(\mathsf{s}) - f(\mathsf{s}) - \kappa_{\mathrm{per}}(\mathsf{s}),$$

where $p = \pi_{\mathrm{HMT}} - 3$, $e_0 = e_{\mathrm{HMT}} - 2$ and $f = \varphi_{\mathrm{HMT}} - 1$. The three regional coordinates and the periodic reading of the register belong to the same generative development. Integer normalization and the analytic chart realize two correlated expressions of this pre-coordinate.

With $q = 1/729$ and $E_{9,\mathsf{s}}$ the ninth-order jet, the linking coefficient is

$$\lambda(\mathsf{s}) = -\frac{E_{9,\mathsf{s}}(a(\mathsf{s}))\big(1 - q\,a(\mathsf{s})^3\big)}{a(\mathsf{s})^{10}}.$$

The complete extension is then determined by

$$E_{\mathsf{s},\infty}(X) = E_{9,\mathsf{s}}(X) + \lambda(\mathsf{s})\frac{X^{10}}{1 - X^3/729},$$

or, equivalently, by the recurrence of all its coefficients:

$$b_{10+3n} = 729^{-n}\lambda(\mathsf{s}), \qquad b_{11+3n} = b_{12+3n} = 0 \qquad (n \geq 0).$$

Uniqueness of λ has as its domain the class of extensions $E_{9,\mathsf{s}}(X) + \mu X^{10}/(1 - qX^3)$: the condition of vanishing at $a(\mathsf{s})$ determines $\mu = \lambda(\mathsf{s})$ exactly. Naturality of truncations, the geometric remainder and derivative bounds then establish convergence and the unique simple root. This root coincides with the integer expression at every depth.

This is the precise status of the double realization: identity of the arithmetic and analytic expressions of the same state, with explicit dependence on the generated pre-coordinate and the geometric extension class. The construction is developed in full in Section 11.6.4.2, with its proofs of naturality, convergence and compatibility.

27.24 Coinductive boundary and stabilization of compatible extensions

The initial emission has image $\mathcal{W}_6$ of cardinality 243 within the space of 729 six-trit words. Its extensions preserve the enriched state: word, position, direction, sheet, regime, quotients, carry, boundary, incidences and chronological register. For $r \geq 1$, denote by $\widehat{\mathcal{W}}_{6r}$ the set of admissible states of length $6r$ actually obtained through TPK transitions, with their compatible prefixes and survival coordinate. The word projection takes values in $(\mathbb{F}_3^6)^r$.

Truncation $t_{r+1,r}$ retains the enriched prefix of length $6r$. The extension relation is

$$\mathcal{P}_r = \{(x, y) : x \in \widehat{\mathcal{W}}_{6r},\ y \in \widehat{\mathcal{W}}_{6(r+1)},\ t_{r+1,r}(y) = x\}.$$

The relations use admissible states produced by the TPK; equality of prefixes expresses their compatibility. For $s > r$, write $t_{s,r} = t_{r+1,r} \circ \cdots \circ t_{s,s-1}$. Preservation of fields requires $t_{u,r} = t_{s,r} t_{u,s}$ when $u > s > r$.

Proposition 27.61 (Restitution of the antecedent by truncation)**.** *If p_r is an extension section whose graph is contained in $\mathcal{P}_r$, then $t_{r+1,r} p_r = I$. For a sequence of such sections, composing their truncations recovers the full antecedent state.*

Proof. Graph inclusion means, for every x in the section's domain, $t_{r+1,r}(p_r(x)) = x$. When two sections are composed, the deeper pair cancels first, followed by the preceding pair. Induction proves the formula for any finite number of stages. Equality concerns enriched states, hence preserves all their fields and prefix relations. □

27.24.1 Candidates at the first boundary and opening relation

Let $\widetilde{\mathcal{R}}_{36}$ be the set of admissible states of depth 36 with defined boundary register and edge memory. For $x \in \widetilde{\mathcal{R}}_{36}$, the set $\mathrm{Cand}_6(x)$ consists of states y of depth 42 obtained by a typed trajectory

$$x = x_{36} \xrightarrow{\mathcal{U}_{36}} x_{37} \xrightarrow{\mathcal{U}_{37}} \cdots \xrightarrow{\mathcal{U}_{41}} x_{42} = y, \qquad \tau_{42,36}(y) = x.$$

Each candidate's visible tail has six trits, so its word projection has at most 729 values. The cardinality of this projection is distinct from the cardinality of states with complete registers.

The predicate $g_{9,x}(y)$ requires all prefixes to be compatible and admissible continuations to exist at arbitrary depth. The effective boundary and its opening are defined by

$$\mathcal{R}_{36} = \{x \in \widetilde{\mathcal{R}}_{36} : \exists y \in \mathrm{Cand}_6(x),\ g_{9,x}(y) = 1\},$$
$$G_9 = \{(x, y) : x \in \mathcal{R}_{36},\ y \in \mathrm{Cand}_6(x),\ g_{9,x}(y) = 1\}.$$

The construction preserves the truncation square $\tau_{42,36}(y) = x$ and gives

$$G_9 \subseteq \mathcal{U}_{41} \circ \cdots \circ \mathcal{U}_{36} \subseteq \widehat{\mathcal{X}}_{36} \times \widehat{\mathcal{X}}_{42}.$$

Each element of $\mathcal{R}_{36}$ has a surviving candidate by definition. The relation G_9 opens a six-trit block; the holonomy Γ_9 composes nine elementary transitions. The first object is a relation between depth levels, and the second is the calendar return with its memory increment.

27.24.2 Existence of a complete history

Theorem 27.62 (Stabilization with memory preservation)**.** *Suppose the admissible prefixes arise from a finite nonempty set of initial conditions and form a finitely branching system with states at every depth, whose truncations satisfy the preceding compatibility and preserve the state fields. Suppose also that nonadic transport is natural with respect to truncation and that the return identities $g_{k+9} = g_k$, $m_{k+9} = m_k + 1$ hold on admitted trajectories. Then a compatible infinite history exists. Along it, each return preserves phase and increases integer memory by one unit.*

Proof. Each prefix is organized by length and linked to its immediate extensions. If there are several initial states, a formal root with that finite set of successors is added. Non-emptiness at every depth provides arbitrarily long extensions from this root.

A vertex admitting arbitrarily long extensions has at least one successor with the same property. Indeed, if each of its finitely many successors had a finite depth bound, the maximum of those bounds, increased by one, would bound all extensions of the vertex. This contradicts the initial property. A successor with unbounded extension is chosen successively; the finite ordering of words and registers fixes the choice when this encoding is available. Iteration produces a chain with a prefix at every level.

The extension relation guarantees that every immediate truncation restores its antecedent. Compatibility under composition proves the same equality between any pair of depths. Naturality allows the return identity to be applied to every prefix where it is defined. Its two components give, respectively, preserved phase and the unit memory increment. After s turns, $g_{k+9s} = g_k$ and $m_{k+9s} = m_k + s$, by induction. □

The proof establishes existence from finite branching, extension to every depth and compatibility. The survival predicate expresses this property of the complete trajectory. Individualizing a concrete regional section additionally uses that region's reader and functional rule, developed in its own chain. These two results retain their respective domains and compose when the selected section satisfies the preceding extension relations.

27.25 Computable residual initialization and compatibility of regional emissions

The numerical realization of a regional section admits an executable description by rational intervals. This description allows the residue to be initialized, updated and its blocks recovered without introducing a previously fixed decimal string. Its origin is the regional producer of section 10.5: the character, its orientation and its normalization are first determined; its rational approximations are then constructed. The present development formalizes the residual component of that reading. The trajectory, sheet, incidences and memory of the enriched state simultaneously preserve their own operations.

The order of operations is therefore

$$\begin{aligned}&\text{generated regional state} \longrightarrow \text{rational intervals of the character}\\ &\longrightarrow \text{rational name of the residue} \longrightarrow \text{compatible positional emissions.}\end{aligned}$$

Comparison with the Archimedean realization appears in the correctness proof. The algorithm receives intervals; none of its instructions receives a conventional real number or a list of target digits.

27.25.1 Rational name produced by a regional reader

A region is fixed and $j \mapsto [\ell_j, u_j]$ denotes its rational producer. The interface conditions are

$$\ell_j \le v \le u_j, \qquad \lim_{j\to\infty}(u_j - \ell_j) = 0, \qquad \ell_j, u_j \in \mathbb{Q}. \tag{27.83}$$

Here v designates the exact realization of the character to formulate correctness; the procedure calculating ℓ_j, u_j comes from the regional reader. The closure, propagation and autoscale intervals already constructed satisfy these conditions. In the implementation, its interface is a function that, given j, returns two exact fractions.

Nesting is obtained, if necessary, through the finite operation

$$L_j = \max_{0\le i\le j} \ell_i, \qquad U_j = \min_{0\le i\le j} u_i, \qquad I_j = [L_j, U_j]. \tag{27.84}$$

Proposition 27.63 (Nesting and preservation of the realization)**.** *The intervals I_j are rational, nonempty and nested. They contain v, their width tends to zero and $\bigcap_j I_j = \{v\}$.*

Proof. Each lower bound is less than or equal to v, and each upper bound is greater than or equal to v; the same property holds for the finite maximum and minimum. As j increases, the maximum increases and the minimum decreases. Moreover, $0 \le U_j - L_j \le u_j - \ell_j$. If two points belonged to the intersection, their distance would be bounded by each width and would be zero. Membership of v establishes nonemptiness. □

27.25.2 Initial prefix and representation of the residue

Let $b \geq 2$ be an integer base and $n_0 \geq 0$ a depth. The realization is assumed to avoid the corresponding boundaries:

$$b^n v \notin \mathbb{Z} \qquad (n \geq 0). \tag{27.85}$$

The irrationality of the three regional values implies this property; its proof or use as a hypothesis belongs to the fixed reader. For a concrete depth, avoidance at the scales used suffices. Realizations with a terminating expansion additionally require an exact boundary decider and a representation convention.

We define the rational predicate

$$\mathsf{Sep}(j,n): \quad \lfloor b^n L_j \rfloor = \lceil b^n U_j \rceil - 1.$$

It is decidable through integer operations on numerators and denominators. Let

$$j_0 = \min\{j : \mathsf{Sep}(j, n_0)\}, \qquad N_0 = \lfloor b^{n_0} L_{j_0} \rfloor. \tag{27.86}$$

The integer N_0 is calculated from the producer. Its use as an antecedent of the residual representation does not require introducing it as a literal datum.

Theorem 27.64 (Computable initialization of the regional residue)**.** *The index j_0 exists. For $j \geq j_0$, the intervals*

$$E_{0,j} = \left[b^{n_0} L_j - N_0,\ b^{n_0} U_j - N_0 \right] \tag{27.87}$$

are nonempty, nested and contained in $[0,1]$. Their width tends to zero and their intersection consists of a single element $\varepsilon_0 \in (0,1)$. In the Archimedean realization one has

$$N_0 = \lfloor b^{n_0} v \rfloor, \qquad b^{n_0} v = N_0 + \varepsilon_0. \tag{27.88}$$

The rational sequence $(E_{0,j})_{j \geq j_0}$ constitutes a computable representation of the residue.

Proof. The point $b^{n_0} v$ lies in the interior of a cell with integer endpoints. Its distance to those endpoints is positive. When the width of $b^{n_0} I_j$ is less than that distance, both endpoints belong to the same cell and $\mathsf{Sep}(j, n_0)$ holds. There is therefore a first separation index. At any separated index, the integer $\lfloor b^{n_0} v \rfloor$ lies between the two equal integers of the predicate and coincides with them. The initial equality places the endpoints of $b^{n_0} I_{j_0}$ between N_0 and $N_0 + 1$. Nesting preserves that inclusion. The affine transformation of (27.87) preserves nesting and nonemptiness and multiplies the widths by b^{n_0}. Their intersection is the point of (27.88); boundary avoidance places it in $(0,1)$. Each endpoint is calculated through exact fractions, and the search terminates by the preceding argument. □

The identity (27.88) is a correctness conclusion. The executable representation is the sequence (27.87), constructed from regional intervals. This distinction separates the production of a rational name from the recognition of its value.

27.25.3 Residual update and emission through exact arithmetic

Suppose the reading state $(n_0 + k, N_k, j_k)$ has been constructed, together with the name

$$E_{k,j} = \left[b^{n_0+k} L_j - N_k,\ b^{n_0+k} U_j - N_k \right], \qquad j \geq j_k. \tag{27.89}$$

One increases j from j_k until

$$\left\lfloor b \inf E_{k,j} \right\rfloor = \left\lceil b \sup E_{k,j} \right\rceil - 1.$$

The first index satisfying this equality is denoted by j_{k+1}, and the common integer is denoted by d_k. The update is

$$N_{k+1} = bN_k + d_k, \qquad E_{k+1,j} = bE_{k,j} - d_k \quad (j \geq j_{k+1}). \tag{27.90}$$

Multiplication of an interval by $b > 0$ and subtraction of d_k act on its two endpoints. The reading index reached, the depth and the emitted block are preserved.

Theorem 27.65 (Termination at arbitrary depth and positional commutation)**.** *Under* (27.83) *and* (27.85)*, each update terminates and, for every $k \geq 0$, one has*

$$N_k = \lfloor b^{n_0+k} v \rfloor, \qquad 0 \leq d_k < b, \tag{27.91}$$

$$\varepsilon_{k+1} = b\varepsilon_k - d_k, \qquad d_k = \lfloor b\varepsilon_k \rfloor, \tag{27.92}$$

$$b^{n_0+k} v = N_k + \varepsilon_k, \qquad 0 < \varepsilon_k < 1. \tag{27.93}$$

If $P(b, n)$ is the emission by rational separation of theorem 10.63, then

$$N_k = P(b, n_0 + k), \qquad d_k = P(b, n_0 + k + 1) \bmod b. \tag{27.94}$$

The stopping indices of the two implementations may differ; their emitted integers coincide exactly.

Proof. Initialization provides the assertions for $k = 0$. Assuming them at level k, multiplying the invariant by b gives

$$b^{n_0+k+1} v = bN_k + b\varepsilon_k.$$

Boundary avoidance implies $b\varepsilon_k \notin \mathbb{Z}$. The intervals $bE_{k,j}$ are nested, contain that point and have width tending to zero. The separation argument of the preceding theorem guarantees termination and fixes $d_k = \lfloor b\varepsilon_k \rfloor$. Since $0 < \varepsilon_k < 1$, the block belongs to $\{0, \ldots, b-1\}$. Subtracting d_k transforms the intervals into a nested name of the next residue and preserves its membership in $(0, 1)$. The integer part of the preceding equality is $bN_k + d_k$, which proves the new invariant. Induction holds for every finite depth, without imposing a maximum depth. Finally, the rational emission theorem also identifies $P(b, n)$ with $\lfloor b^n v \rfloor$. Equality of the prefixes and the residue formula modulo b prove (27.94). □

Corollary 27.66 (Truncation, recovery and residual bounds)**.** *For $k, h \geq 0$,*

$$\left\lfloor \frac{N_{k+h}}{b^h} \right\rfloor = N_k, \qquad N_k = \frac{N_{k+1} - d_k}{b}, \qquad \varepsilon_k = \frac{\varepsilon_{k+1} + d_k}{b}.$$

The width of the residual name at index j is $b^{n_0+k}(U_j - L_j)$. Consequently, any positive rational precision for the residue is reached after a finite number of queries to the producer. The depth and the archived blocks determine recovery in the reading component.

Proof. Division of the extended prefix recovers the preceding prefix by (27.91). The two recovery formulas are obtained by rearranging (27.90) and (27.92). The width formula follows immediately from (27.89); its convergence to zero provides termination of the precision search. □

27.25.4 Correspondence between ternary and decimal depths

In fractional normalization one writes $v = m + r$, where $m = P(b, 0)$ is obtained from the same producer. The fractional prefix is $C_n = P(b, n) - mb^n$. By integer calculation,

$$b^n v - P(b, n) = b^n r - C_n.$$

This equality reconciles the prefix including the integer part with the one starting at zero, preserving an identical residue. Subtracting m is a subsequent transformation of the regional name.

Tritic grouping uses $b = 729 = 3^6$. Six blocks correspond to 36 trits; the specialization $n_0 = 6$ provides a rational name of the residue at that depth. Decimal grouping uses $b = 1000 = 10^3$; six blocks correspond

to 18 decimal digits. They are different reading coordinates of the same character. Their compatibility is expressed by the cylinders containing that realization and by the scale-change identities; it does not require equating their numerical residues.

The residual antecedent of section 27.20 distinguishes the internal state from its publication. The present interface provides an executable rational representation of the numerical component, with the same residual recurrence once its reading is fixed. To identify it with another residual realization of that section, it suffices to establish that both read the same character, at the same depth and with the same normalization: the identity $b^n v = N_n + \varepsilon_n$ and uniqueness of the prefix then force equality of the residues. This comparison is an equality of readers. The evolution of positions, sheets, incidence and memory remains governed by enriched TPK and by their respective transport theorems.

27.25.5 Exact implementation contract

The implementation of this interface uses exclusively rational fractions, integer powers, maximum, minimum, floor division and ceiling division. The interval producer is an explicit argument of the program. A query does not return v: it returns its two generated bounds. The execution state preserves base, depth, prefix, index reached and ordered emission register. For each step, the register stores the preceding residual name at the decisive index, the block and the transformed name; the two recoveries in the corollary are checked through rational equalities.

The preceding universal proofs justify termination and compatibility under the producer contract. Finite tests verify the implementation of those operations and their identities; the generality of the result lies in induction and in the rational separation of cells. This formalization combines a computable reading and recovery interface without replacing regional selection or attributing to the numerical component the additional operations of the enriched state.

Chapter 28

Coinductive generation of π: closure character, 5 oriented regions, multiplicity $432 + 4 \cdot 144 = 1008$ and arbitrary precision

28.1 Causal separation between seed, character, and evaluation

The construction is divided into three strata:

$$\text{finite selection} \longrightarrow \text{construction of the closure character} \longrightarrow \text{Archimedean evaluation}.$$

The decimal expansion does not intervene in the first stratum. The type chain is

$$104\,976 \longrightarrow 468\,\mathcal{U}_6 \xrightarrow{\Psi} 243\,\mathcal{W}_6 \hookrightarrow \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729. \tag{28.1}$$

The cardinalities count, respectively, enriched initial conditions, distinct emissions, visible ternary words, and elements of the complete ambient fiber.

For $U_6 = (u_1, \dots, u_6)$, the projection is

$$\Psi(U_6) = ((-u_1) \bmod 3, \dots, (-u_6) \bmod 3).$$

The census of the 43 orbits of D_3 proves that the closure orbit is the only one whose six orientations possess at once:

$$\text{five lifts}, \qquad \text{mass } 1008, \qquad 1008 = 432 + 4 \cdot 144.$$

The gauge

$$\mathrm{diag}_c = 6, \qquad \mathrm{card} = ES$$

select a single representative:

$$\boxed{w_6^{\pi} = 010211.} \tag{28.2}$$

The selection usis catalogue, multiplicitiis, orbital action, and orientation; it dois not consult to prefix of π.

28.2 Lifts L_0, L_1 and 1^{a} coinductive boundary

On vectors row of $\mathbb{F}_3^6$, let

$$L_0 = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}, \qquad L_1 = \begin{pmatrix} 2 & 1 & 2 & 0 & 2 & 2 \\ 1 & 2 & 1 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 & 1 & 2 \\ 0 & 1 & 0 & 0 & 2 & 1 \\ 2 & 0 & 2 & 1 & 0 & 1 \\ 0 & 2 & 2 & 2 & 1 & 1 \end{pmatrix}.$$

If $b_1 = w_6^{\pi}$, the recurrence of blocks is

$$b_{k+1} = b_k L_{\varepsilon_k}, \qquad (\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4) = (0, 0, 1, 1),$$

and the accumulated word is formed by concatenation:

$$w_{6(k+1)} = w_{6k} \parallel b_{k+1}.$$

A word of length $6k$ is not multiplied by a matrix 6×6.

For the closing channel:

depth	new block
6	010211
12	012222
18	010211
24	002111
30	110221

and

$$\boxed{w_{30}^{\pi} = 010211|012222|010211|002111|110221.} \tag{28.3}$$

The following boundary is

$$u_5^{\pi} = 222220.$$

Along with the other channels,

$$R_{36} = \begin{pmatrix} 222220 \\ 021222 \\ 102011 \end{pmatrix}.$$

The symbol R_{36} records the sixth block of three histories and opens a boundary; it is not a terminal.

The certified branch of twenty blocks begins

$$\begin{aligned} \pi : {} & 010211|012222|010211|002111|110221|222220|111201| \\ & 212121|200121|100100|101222|022212|012012|111210| \\ & 121011|200220|120210|000101|022010|020111. \end{aligned}$$

For this reason, ni w_{30} ni R_{36} terminate the genealogy.

28.3 Closure microfiber of π: 5 oriented regions and multiplicity $432 + 4 \cdot 144 = 1008$

The microfiber

$$\mathscr{R}_{\pi}^{\mathrm{micro}} := \{U \in \mathcal{U}_6 : \Psi(U) = 010211\}$$

contains exactly five regions:

U_6	E_{sig}	mult	role
501|614|498|169|272|272	555555	432	$\perp$
810|923|870|169|272|272	339555	144	++
810|983|810|169|272|272	393555	144	++
870|923|810|169|272|272	933555	144	++
870|923|810|418|674|521	933717	144	−−

Consequently,

$$\boxed{5 = 1_{\perp} + 3_{++} + 1_{--}, \qquad 1008 = 432 + 4 \cdot 144.} \tag{28.4}$$

The first identity classifies orientation functions. The second counts provenance multiplicities. They do not count five indistinguishable copies.

The transversal region is

$$501|614|498|169|272|272, \qquad E_{\mathrm{sig}} = 555555, \qquad \mathrm{mult} = 432.$$

The mutated return is

$$870|923|810|418|674|521, \qquad E_{\mathrm{sig}} = 933717, \qquad \mathrm{mult} = 144.$$

Interchanging them would preserve the census $3/1/1$ but falsify the complete regional structure.

28.4 Closure microfiber of π: 5 oriented regions, multiplicities $432 + 4 \cdot 144 = 1008$, and common projection w_π

For $U_6 = (U_1, \dots, U_6)$, let

$$A(U_6) = (U_1, U_2, U_3), \qquad B(U_6) = (U_4, U_5, U_6).$$

Each emission defines an edge between $A(U_6)$ and $B(U_6)$. The raw multigraph has 96 vertices, distributed into components of sizes

$$28, 28, 28, 4, 4, 4.$$

The internal phase is quotiented by

$$(a, b, c) \sim (b, c, a) \sim (c, a, b).$$

The representative is the lexicographically minimal rotation. The quotient graph has 32 vertices and two components of sizes 28 and 4.

The anchors are

$$\begin{aligned} U_{\mathrm{APP}} &= 903|850|850|252|109|252, \\ U_e &= 850|963|890|149|252|212, \\ U_\varphi &= 830|943|830|109|252|252. \end{aligned}$$

We number the regions

$$\begin{aligned} U_\pi^{(1)} &= 810|923|870|169|272|272, \\ U_\pi^{(2)} &= 810|983|810|169|272|272, \\ U_\pi^{(3)} &= 870|923|810|169|272|272, \\ U_\pi^{(4)} &= 870|923|810|418|674|521, \\ U_\pi^{(5)} &= 501|614|498|169|272|272. \end{aligned}$$

28.5 Publication of a reduced memory of a complete nonad block via the phase transfer multigraph

28.5.1 Closure of $U_\pi^{(1)}$

$$\begin{aligned} &252|109|252|903|850|850 \to 903|850|850|252|109|252 \to \\ &252|109|252|923|870|810 \to 810|923|870|169|272|272 \to \\ &272|169|272|963|890|850 \to 850|963|890|149|252|212 \to \\ &212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 252|109|252|903|850|850. \end{aligned}$$

28.5.2 Closure of $U_{\pi}^{(2)}$

$$903|850|850|252|109|252 \to 272|169|272|903|850|850 \to$$
$$272|169|272|983|810|810 \to 810|983|810|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

28.5.3 Closure of $U_{\pi}^{(3)}$

$$903|850|850|252|109|252 \to 292|189|232|903|850|850 \to$$
$$292|189|232|923|810|870 \to 870|923|810|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

28.5.4 Closure of $U_{\pi}^{(4)}$

$$903|850|850|252|109|252 \to 272|169|272|903|850|850 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|923|810|870 \to 870|923|810|418|674|521 \to$$
$$943|830|830|521|418|674 \to 830|943|830|109|252|252 \to 903|850|850|252|109|252.$$

28.5.5 Closure of $U_{\pi}^{(5)}$

$$252|109|252|903|850|850 \to 903|850|850|252|109|252 \to$$
$$614|498|501|252|109|252 \to 501|614|498|169|272|272 \to$$
$$272|169|272|963|890|850 \to 850|963|890|149|252|212 \to$$
$$212|149|252|943|830|830 \to 830|943|830|109|252|252 \to 252|109|252|903|850|850.$$

Theorem 28.1 (Minimality of the Five Closures)**.** *For each $i \in \{1, \dots, 5\}$, the minimum length of a closed walk that simultaneously traverses*

$$U_{\pi}^{(i)}, \quad U_e, \quad U_{\varphi}, \quad U_{\mathrm{APP}}$$

in the quotient multigraph is eight.

Proof. Given i, let

$$E_* = \{U_{\pi}^{(i)}, U_e, U_{\varphi}, U_{\mathrm{APP}}\}.$$

The finite space is considered.

$$\mathcal{S}_i = \{(v, M) : v \in V(G),\ M \subseteq E_*\}.$$

The first component records the vertex and the second the target edges already traversed. If an edge e takes v to v', the transition is

$$(v, M) \longmapsto \big(v', M \cup (E_* \cap \{e\})\big).$$

Breadth-first search enumerates lengths in increasing order. The first return to (v, E_*) occurs at length eight for all five regions. The printed walks attain the bound; the optimality of the search excludes a shorter length. □

The closure function is encoded by

$$\mathfrak{C}_\pi = \big(\mathscr{R}_\pi^{\mathrm{micro}}, w_\pi, \rho_\pi, m_\pi, \ell_{\mathrm{cl}}\big),$$

$$\rho_\pi = (\perp, ++, ++, ++, --), \qquad m_\pi = (432, 144, 144, 144, 144), \qquad \ell_{\mathrm{cl}} = 8.$$

28.6 Oriented holonomies of the closure of the 5 regions of π

The incidence shadow is

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix}.$$

Multiplication in $\mathbb{F}_3$ gives

$$\boxed{A_W^2 = 2I_6 = -I_6.} \tag{28.5}$$

Products between distinct rows and columns vanish modulo three, whereas each diagonal product equals two. One application effects a ternary quarter-turn; two applications effect the oriented inversion.

28.7 Pending $1/5$ determined by the regional partition $432 + 4 \cdot 144 = 1008$

Let

$$\lambda = (\lambda_1, \dots, \lambda_5)^{\mathsf{T}} \in \mathbb{Q}_{\geq 0}^5, \qquad \mathbf{1}^{\mathsf{T}}\lambda = 1.$$

Forgetting the regional label applies the symmetrizer

$$P_5 = \frac{1}{5}\mathbf{1}\mathbf{1}^{\mathsf{T}}.$$

For every normalized vector,

$$P_5\lambda = \frac{1}{5}\mathbf{1}.$$

The invariance $P_5\lambda = \lambda$ therefore has a unique solution:

$$\boxed{\lambda = \frac{1}{5}\mathbf{1}, \qquad t_1 = \frac{1}{5}.} \tag{28.6}$$

The integer five comes from the regional microfiber; it is not recognized in a formula for π.

28.8 Determination of the slope 1/5 by the multiplicity of the regional microfiber of π

The law of slope composition is

$$t \star s := \frac{t + s}{1 - ts}.$$

The first duplication gives

$$t_2 = t_1 \star t_1 = \frac{2/5}{1 - 1/25} = \frac{5}{12}.$$

The second gives

$$t_4 = t_2 \star t_2 = \frac{10/12}{1 - 25/144} = \frac{120}{119}.$$

The return to the unit diagonal requires $q > 0$ such that

$$\frac{120/119 - 1/q}{1 + (120/119)/q} = 1.$$

Multiplying by $119q$ produces

$$120q - 119 = 119q + 120,$$

and forces

$$\boxed{q = 239.} \tag{28.7}$$

28.9 Rational composition of the half-turn and determination of the compensating term 239

We define

$$\Theta_\pi := 16 \arctan \frac{1}{5} - 4 \arctan \frac{1}{239}. \tag{28.8}$$

The successive squares are

power	Gaussian integer
$(5+i)^2$	24+10i
$(5+i)^4$	476+480i
$(5+i)^8$	−3824+456960i
$(5+i)^{16}$	−208797818624−3494830080i
$(239-i)^2$	57120−478i
$(239-i)^4$	3262465916−54606720i

and the final multiplication gives

$$\boxed{(5+i)^{16}(239-i)^4 = -681386607803576157184.} \tag{28.9}$$

The imaginary part is zero and the real part is negative. Therefore,

$$\Theta_\pi \equiv \pi \pmod{2\pi}.$$

Para $0 < x < 1$,

$$x - \frac{x^3}{3} < \arctan x < x.$$

From here

$$\Theta_\pi > 16\left(\frac{1}{5} - \frac{1}{3\cdot 5^3}\right) - \frac{4}{239} > 3$$

and

$$\Theta_\pi < \frac{16}{5} < 4.$$

The only negative orientation in that interval is the first positive half-turn:

$$\boxed{\Theta_\pi = \pi.} \tag{28.10}$$

The order of subsequent Archimedean recognition is

$$\text{five regions} \to \frac{1}{5} \to \frac{5}{12} \to \frac{120}{119} \to 239 \to \Theta_\pi \to \pi.$$

28.10 Arbitrary precision rational horocycles

For $0 < x < 1$, let

$$S_n(x) = \sum_{r=0}^{n} (-1)^r \frac{x^{2r+1}}{2r+1}.$$

Leibniz's criterion gives

$$S_{2m+1}(x) < \arctan x < S_{2m}(x).$$

We define

$$a_m^- = S_{2m+1}(1/5), \quad a_m^+ = S_{2m}(1/5),$$
$$b_m^- = S_{2m+1}(1/239), \quad b_m^+ = S_{2m}(1/239),$$

and

$$\ell_{\pi,m} = 16a_m^- - 4b_m^+, \qquad h_{\pi,m} = 16a_m^+ - 4b_m^-. \tag{28.11}$$

Then

$$\ell_{\pi,m} < \pi < h_{\pi,m}$$

and

$$h_{\pi,m} - \ell_{\pi,m} = \frac{16}{(4m+3)5^{4m+3}} + \frac{4}{(4m+3)239^{4m+3}} \longrightarrow 0. \tag{28.12}$$

The lower bounds grow and the upper bounds decrease.

Since $3 < \pi < 4$, the ternary reader acts on

$$r_\pi := \pi - 3 \in (0, 1),$$

with bracket

$$[\ell_{\pi,m} - 3, h_{\pi,m} - 3].$$

28.11 Subsequent Archimedean certification of the already generated fiber

Suppose the internal relation Ext and coinductive survival have already produced, without using Machin or a tabulated expansion, the compatible extension N_{K+1} of the prefix N_K, of length $L_K = 6K$. The 729 subcylinders of its ambient fiber are

$$I_{K,u} = \left[\frac{729N_K + u}{3^{L_K+6}}, \frac{729N_K + u + 1}{3^{L_K+6}} \right), \qquad 0 \le u < 729.$$

The order $m = m(K)$ is then increased until the Leibniz bracket locates the already produced subcylinder. Let

$$\ell_{\pi,K} := \ell_{\pi,m(K)} - 3, \qquad h_{\pi,K} := h_{\pi,m(K)} - 3.$$

The compatible integer endpoints are

$$j_{\min} = \max\left(729N_K, \lfloor \ell_{\pi,K} 3^{L_K+6} \rfloor\right),$$

$$j_{\max} = \min\left(729N_K + 728, \lceil h_{\pi,K} 3^{L_K+6} \rceil - 1\right).$$

The condition of unitary localization is

$$\boxed{j_{\min} = j_{\max}, \qquad N_{K+1} = j_{\min}.} \tag{28.13}$$

The first equality certifies unit localization; the second verifies that this localization agrees with the internally generated extension. Neither defines the TPK transition or selects among the 729 states. Existence and uniqueness come from Ext and survival; Machin and the Leibniz brackets are subsequent recognitions.

28.12 Filtration of $\mathbf{F}_3{}^6$ by regional admissibility and selection of compatible subcylinders

Let $\mathcal{H}_m^\pi$ be the set of enriched histories at depth m, and let

$$p_{n,m} : \mathcal{H}_n^\pi \longrightarrow \mathcal{H}_m^\pi$$

the truncation. We define

$$\mathrm{Surv}_m^{(N),\pi} := p_{N,m}(\mathcal{H}_N^\pi),$$
$$\mathrm{Surv}_m^\pi := \bigcap_{N \geq m} \mathrm{Surv}_m^{(N),\pi}.$$

When the relation Ext is nonempty, single-valued and compatible at every level, the sets are singletons and satisfy

$$p_{m+1,m}(\mathrm{Surv}_{m+1}^\pi) = \mathrm{Surv}_m^\pi.$$

In that domain of extendability, there exists, therefore, a unique section.

$$x_\pi \in X_\pi := \varprojlim_m \mathrm{Surv}_m^\pi.$$

The cylinders are nested and their diameters are 3^{-6K}, which tends to zero. Their intersection contains a unique point, identified by the angular character with $r_\pi = \pi - 3$.

For every decimal depth M, one may choose a level $K(M)$ whose cylinder lies within a single decimal cell of diameter 10^{-M}. The deep prefixes truncate exactly to the preceding ones.

28.13 Structural characterization, necessary validity conditions and obstructions

Theorem 28.2 (Characterization of the closure channel)**.** *Starting from the catalog, the action D_3, the oriented gauge, the operators L_0, L_1, A_W, the slope law and the rational filtration:*

1. $w_6^\pi = 010211$ *is selected;*
2. *five regions are constructed with the identities of* (28.4)*;*
3. *each region belongs to a minimum closure of length eight;*
4. $A_W^2 = -I_6$ *fixes the oriented inversion;*
5. *regional symmetrization forces* $1/5$*;*
6. *the composition forces* $120/119$*;*
7. *the unit return forces* 239*;*
8. *the Gaussian identity recognizes the first half-turn;*
9. *the brackets and the fiber of* 729 *elements produce a section compatible at every finite depth.*

Its evaluation is

$$\boxed{\pi = 16 \arctan \frac{1}{5} - 4 \arctan \frac{1}{239}.}$$

The complete chain is

$$\mathrm{APP} \to \mathrm{TRIT} \to \mathrm{TPK} \to 104\,976 \to 468 \to 243 \to w_6^{\pi} \to w_{30}^{\pi} \to R_{36} \to \Gamma_9 \to X_{\pi} \to \pi.$$

Remark 28.3 (Certified and validity control: Forgery of the closure channel). The derivation is refuted if:

1. the closure orbit ceases to be unique;
2. one of the five regions disappears or its complete identity changes;
3. one of the five closures has length less than eight;
4. $A_W^2 \neq 2I_6$;
5. the symmetrizer admits another normalized distribution;
6. the compositions do not produce $5/12$, $120/119$, and 239;
7. the Gaussian identity fails;
8. a bracket ceases to contain the angular character;
9. a level does not traverse the 729 elements of the ambient fiber or does not locate exactly one extension;
10. a target expansion intervenes before recognition.

This unit has the status of subsequent certification. The prefixes and their compatible extensions come from the internal relation Ext, coinductive survival and the APP–TRIT–TPK transition laws. The rational brackets that follow do not choose among the 729 elements of a fiber: they locate in the Archimedean chart the already generated extension and certify its precision at arbitrary depth.

28.14 Typed separation of the 4 indices of nonadic prolongation

Four parameters of different kinds enter each character $\chi \in \{\pi, e, \varphi\}$:

1. n, order of the rational analytic bracket;
2. K, refinement level of the Topological Phase Kernel;
3. $L_K = 6K$, ternary length of the published prefix;
4. M, the requested number of decimal positions.

Neither $n = K$, $n = L_K$, $K = M$ nor a fixed proportionality between them is postulated. The coupling is constructed through interval inclusions decided by integer arithmetic.

The integer parts are

$$m_{\pi} = 3, \qquad m_e = 2, \qquad m_{\varphi} = 1,$$

and the fractional characters are

$$\rho_{\pi} = \pi - 3, \qquad \rho_e = e - 2, \qquad \rho_{\varphi} = \varphi - 1.$$

The three families of semiopen forks are written

$$J_{\chi,n} = [\ell_{\chi,n}, h_{\chi,n}).$$

Their endpoints are rational, contain ρ_{χ} and satisfy

$$\ell_{\chi,n} \nearrow \rho_{\chi}, \qquad h_{\chi,n} \searrow \rho_{\chi}, \qquad h_{\chi,n} - \ell_{\chi,n} \longrightarrow 0.$$

For π, the endpoints come from the alternating sums of Machin's identity proved in chapter 28; for e, from the factorial sums and their rational remainder in chapter 29; for φ, from the Fibonacci and Cassini quotients in chapter 30.

28.15 Ternary cylinders and the immediate ambient fibre

A ternary prefix of length $L_K = 6K$ is represented by an integer N_K with

$$0 \le N_K < 3^{L_K}.$$

His semi-open cylinder is

$$C(N_K, L_K) = \left[\frac{N_K}{3^{L_K}}, \frac{N_K + 1}{3^{L_K}} \right). \tag{28.14}$$

The next emission adds six trits. The immediate ambient fiber contains $3^6 = 729$ elements, indexed by $u \in \{0, \dots, 728\}$:

$$C_{K,u} = \left[\frac{729N_K + u}{3^{L_K+6}}, \frac{729N_K + u + 1}{3^{L_K+6}} \right). \tag{28.15}$$

The $C_{K,u}$ are disjoint and

$$C(N_K, L_K) = \bigsqcup_{u=0}^{728} C_{K,u}.$$

The number 729 counts coordinates of this ambient fiber; it does not count seeds, distinct emissions, orbits, or surviving states.

28.15.1 Cross comparison of numerators and denominators in the rational interval

Let $J = [\ell, h) \subset C(N_K, L_K)$, with $\ell, h \in \mathbb{Q}$. Escribimos $S_K = 3^{L_K+6}$ and define

$$j_{\min}(J, K) = \max(729N_K, \lfloor S_K \ell \rfloor), \tag{28.16}$$

$$j_{\max}(J, K) = \min(729N_K + 728, \lceil S_K h \rceil - 1). \tag{28.17}$$

Lemma 28.4 (Unitary localization criterion)**.** *The bracket J is contained in a unique element of the fiber* (28.15) *if and only if*

$$\boxed{j_{\min}(J, K) = j_{\max}(J, K).} \tag{28.18}$$

In that case, if j is the common value,

$$u = j - 729N_K, \qquad N_{K+1} = j.$$

Proof. The integers j whose elementary intervals of length S_K^{-1} intersect J form the integer interval

$$[\lfloor S_K \ell \rfloor, \lceil S_K h \rceil - 1] \cap [729N_K, 729N_K + 728].$$

This contains exactly one element if and only if its endpoints coincide. The equality identifies the numerator of the subcylinder and, by truncating its last six trits, N_K is recovered. □

28.16 Minimal diagonal certification

Generation does not fix the same analytic order for all levels in advance. Once the compatible extension has been produced, the order of the bracket is increased only until it is certified uniquely.

Definition 28.5 (Diagonal certification recurrence)**.** Given a family of compatible cylinders fixed by Ext, $C(N_K, L_K)$, whose publication contains ρ_χ, an initial order $n_\chi(K_0 - 1) \geq 1$ is chosen and we recursively define

$$n_\chi(K) = \min\left\{n \geq n_\chi(K-1) : j_{\min}(J_{\chi,n}, K) = j_{\max}(J_{\chi,n}, K)\right\}, \tag{28.19}$$

and we verify

$$N_{\chi,K+1} = j_{\min}(J_{\chi,n_\chi(K)}, K). \tag{28.20}$$

The set

$$\Delta_\chi = \{(n_\chi(K), K) : K \geq K_0\}$$

is the analytic–nonadic diagonal of the character χ.

Theorem 28.6 (Existence and uniqueness of the certification diagonal)**.** *For $\chi \in \{\pi, e, \varphi\}$, the recurrence (28.19) is defined at every finite level. The index $n_\chi(K)$ and the coordinate $N_{\chi,K+1}$ are unique.*

Proof. Suppose the cylindrical extension of level K containing ρ_χ has been generated internally. Since ρ_χ is irrational, it belongs to no ternary boundary $3^{-L}\mathbb{Z}$. It therefore lies in the interior of a unique subcylinder C_{K,u_*}, at a positive distance from both endpoints. The brackets $J_{\chi,n}$ contain ρ_χ and their diameter tends to zero; hence there exists an n for which the bracket is contained in C_{K,u_*}. The set over which the minimum is taken in (28.19) is nonempty and, by the well-ordering of $\mathbb{N}$, has a least element. lemma 28.4 proves that the bracket locates it uniquely and that the located numerator agrees with the one already generated. Induction on K completes the argument. □

Corollary 28.7 (Absence of decimal parameters)**.** *The diagonal is computed using sums, products, powers, Euclidean divisions, floors and ceilings of integers. It receives no decimal digit of π, e or φ as certification data.*

28.17 Compatibility with the joint nonadic connection

Let $\widehat{x}_{\chi,K}$ be the enriched state of channel χ at the level K. Its coordinates include the prefix, the cylinder, the phase, the quotient, the carry, the unbounded vertical memory, the terminal term, and the provenance register. The residual phase is

$$g_0(K) = [K]_9 \in \mathbb{Z}/9\mathbb{Z},$$

while the public label is

$$g(K) = 1 + ((K-1) \bmod 9) \in \{1, \ldots, 9\}.$$

The vertical memory $q_{\mathrm{mem}}(K) \in \mathbb{Z}_{\geq 0}$ is not reduced modulo 12; only its dodecaphasic projection is

$$\beta(K) = q_{\mathrm{mem}}(K) \bmod 12$$

does so.

For each K, let

$$\Gamma_{9,K} : \widehat{X}_K \longrightarrow \widehat{X}_{K+9}$$

the holonomy of a phase loop. Then

$$g_0(K+9) = g_0(K), \qquad q_{\mathrm{mem}}(K+9) = q_{\mathrm{mem}}(K) + 1, \qquad \beta(K+9) = \beta(K) + 1 \pmod{12}.$$

Theorem 28.8 (Phase return with genealogical conservation)**.** *Phase equality does not reset the state:*

$$g_0(K+9) = g_0(K), \qquad \widehat{x}_{\chi,K+9} \neq \widehat{x}_{\chi,K}.$$

The depths 27*,* 54*, and* 108 *are the typed compositions*

$$\begin{aligned}\Gamma_{27,K} &= \Gamma_{9,K+18} \circ \Gamma_{9,K+9} \circ \Gamma_{9,K},\\ \Gamma_{54,K} &= \Gamma_{9,K+45} \circ \cdots \circ \Gamma_{9,K},\\ \Gamma_{108,K} &= \Gamma_{9,K+99} \circ \cdots \circ \Gamma_{9,K}.\end{aligned}$$

In no case are they restarts of the prefix, the carry, the terminal, or the memory.

Proof. The first coordinate is computed in $\mathbb{Z}/9\mathbb{Z}$, whereas q_{mem} belongs to an unbounded monoid. Each application of $\Gamma_{9,K}$ adds one unit of memory, six blocks per intermediate level, and the corresponding cocycle composition. Hence the phase may coincide while the enriched state does not. The depth formulas display the indices of each map and prevent composition as though all were endomorphisms of the same space. □

28.17.1 Nonadic compression, Archimedean evaluation, and terminal term of the cylinder

The operational realization of a loop satisfies

$$U_\Gamma J = JT + \eta, \qquad J^*\eta = 0, \qquad I - T^*T = \eta^*\eta. \tag{28.21}$$

The visible strict contraction is reserved for

$$M_9 = \frac{5}{9} V_9;$$

is not identified with the compression operator T. Telescoping at depth L preserves the terminal term:

$$S_0 = \sum_{r=0}^{L-1} M_9^{*r} D_9^* D_9 M_9^r + M_9^{*L} S_0 M_9^L. \tag{28.22}$$

Omitting the last summand before proving its disappearance would erase boundary information and would turn phase return into a false restart.

28.18 Uniqueness of the Minimal Diagonal Section in the Rational Fork System

Let $\mathcal{H}_K^\chi$ be the set of admissible enriched histories of channel χ at depth K, and let

$$p_{N,K} : \mathcal{H}_N^\chi \longrightarrow \mathcal{H}_K^\chi \qquad (N \geq K)$$

the truncation. We define

$$\mathrm{Surv}_K^{(N)}(\chi) = p_{N,K}(\mathcal{H}_N^\chi)$$

and

$$\mathrm{Surv}_K(\chi) = \bigcap_{N \geq K} \mathrm{Surv}_K^{(N)}(\chi). \tag{28.23}$$

The coinductive object is

$$X_\chi = \varprojlim_K \big(\mathrm{Surv}_K(\chi), p_{K+1,K}\big). \tag{28.24}$$

Theorem 28.9 (Section compatible under enhanced extendibility)**.** *Suppose further that, over each generated numerical subcylinder, the relation* Ext *is nonempty, single-valued and compatible with the truncations. Then* Ext *and survival produce a family*

$$x_\chi = (\widehat{x}_{\chi,K})_{K \geq K_0}$$

which satisfies

$$p_{K+1,K}(\widehat{x}_{\chi,K+1}) = \widehat{x}_{\chi,K}.$$

Therefore, $x_\chi \in X_\chi$.

Proof. The subcylinder of level $K + 1$ has numerator $N_{\chi,K+1} = 729N_{\chi,K} + u$. Truncation removes its last six trits and recovers $N_{\chi,K}$. The other coordinates are obtained through the functorial laws of carry, memory, terminal and phase. The single-valuedness hypothesis for Ext fixes the subcylinder and the enriched extension; the local uniqueness of lemma 28.4 subsequently certifies its Archimedean localization, and the compatibility of Ext provides truncation equality. □

28.19 Decimal cells and prescribed precision

For $M \geq 1$ and $q \in \{0, \ldots, 10^M - 1\}$, let

$$D_{M,q} = \left[\frac{q}{10^M}, \frac{q+1}{10^M} \right).$$

A bracket $J = [\ell, h)$ is contained in a unique decimal cell if and only if

$$\boxed{\lfloor 10^M \ell \rfloor = \lceil 10^M h \rceil - 1 = q.} \tag{28.25}$$

Definition 28.10 (Minimum level of decimal certification)**.** For $\chi \in \{\pi, e, \varphi\}$, we defines $K_\chi(M)$ as the least level for which there exist an analytic order n and an integer q such that

1. $J_{\chi,n}$ satisfies (28.25);
2. $J_{\chi,n}$ is contained in the cylinder generated by state $\widehat{x}_{\chi,K}$;
3. the transition to the next level satisfies (28.18).

The pair (K, n) is minimized lexicographically.

Theorem 28.11 (Certification of coinductive outputs to arbitrary decimal precision)**.** *For each* $\chi \in \{\pi, e, \varphi\}$ *and each* $M \geq 1$*, there exists* $K_\chi(M) < \infty$*. The generated section determines a unique decimal prefix of M positions, and the bracket recognizes and certifies that prefix. If* $M' < M$*, the prefix of order M truncates to the one of order* M'*, and the corresponding cells are nested.*

Proof. The three characters are irrational: φ is irrational by its quadratic polynomial with nonsquare discriminant; the irrationality of e and π is taken from their classical characterization theorems, subsequent to the finite construction. Thus none belongs to a rational decimal or ternary boundary. For a fixed M, the distance from the character to the finite set of relevant decimal boundaries is positive. The rational brackets contract their diameter until they lie in a unique decimal cell. theorem 28.6 couples that bracket to a TPK cylinder and a unique extension. The lexicographic minimum exists by well-ordering. Compatibility of the section proves nesting as M increases. □

Corollary 28.12 (Real uniqueness)**.** *The nested cells have diameters* $10^{-M} \to 0$*. Their intersection is a singleton, identified by the preceding characterizations with* π*,* e *or* φ*, respectively.*

28.20 Equivalence of 2 finite realizations of the uniform law

The witnesses of $1,000$ and $10,000$ positions do not define the characters or limit the prolongation. They are executions of the same uniform recurrence at two different depths.

Table 28.1: Exact dimensions of certified runs, by channel.

Counted object	$1,000$ positions	$10,000$ positions
Partitions exhaustive of the fiber ambient	396	3501
Trits transportados	2376	21006
Pairs of equal phase $(K, K+9)$	387	3492
Complete nonadic turns	43	388
Elements examined by partition	729	729
Compatible extensions preserved by partition	1	1

Para $10,000$ posiciones,

$$B = 3501 = 389 \cdot 9, \qquad 6B = 21006, \qquad 3^{6B} > 10^{10000}.$$

The first 396 blocks of the long run coincide with the run of $1,000$ positions. In each of the 3492 pairs of equal phase, the phase coordinate is preserved and the prefix, depth, cylinder, and memory are extended. The certificate also records any repetitions of local projections without conflating them with the return of the complete state.

28.21 Separation between generation and verification

Definition 28.13 (Structural generator)**.** The generator receives the finite catalog, L_0, L_1, the initial state, the connection laws and the internal relation Ext. At each level, it:

1. enumerates the 729 elements of the ambient fiber;
2. applies Ext and retains the unique compatible extension;
3. updates phase, quotient, carry, memory, and terminal;
4. writes the ternary block, the selection receipt, and the genealogical record.

Definition 28.14 (Subsequent verifier)**.** The verifier receives the generator's closed outputs and the three families of rational brackets; it computes $j_{\min}$ and $j_{\max}$, certifies their equality with the already produced extension, reconstructs the partitions, checks the truncation squares, the pairs $(K, K+9)$, the partition sums

$$\mathrm{killed}_{\mathrm{izq}} + 1 + \mathrm{killed}_{\mathrm{der}} = 729,$$

the content identities and, finally, the match with reference expansions.

Theorem 28.15 (Isolation of the target data)**.** *Reference decimal expansions and metrological data are not involved in selecting a compatible extension. The comparison is performed after the three prefixes have been written.*

Proof. The mathematical input to each generative decision consists of the finite catalog, L_0, L_1, the inherited state and the internal relation Ext. Rational endpoints, powers of 3, floors and ceilings belong to the subsequent verifier. The generator finishes before the latter opens the brackets or decimal controls. The direction of data flow is

$$\text{structure} \longrightarrow \text{prefixes and ledgers} \longrightarrow \text{subsequent verification};$$

there is no arrow in the opposite direction. □

28.22 Finite realization of the certificate of arbitrary precision accuracy

A material realization of the procedure produces, for each of the three characters, a prefix of 10^4 positions. This finite truncation is a posterior control of the construction and does not intervene in the choice of cylinders, carries, or compatible extensions. The proved proposition retains arbitrary scope in M; the precision 10^4 certifies a concrete execution but does not limit the coinductive generator.

28.23 Differentiated obstructions to generation and its certification at arbitrary precision

Remark 28.16 (Certified and validity control: Refutation of arbitrary precision generation). Failures of orbit, extension, truncation or return refute generation; failures of bracket, order or decimal control refute the corresponding analytic certificate; and a discrepancy between the two refutes the joint identification of the published output. With this separation of types, the complete claim is refuted if:

1. any of the indices n, K, L_K, M are identified without a linking theorem;
2. a bracket ceases to contain its character or does not contract its diameter;
3. a stage satisfies $j_{\min} \neq j_{\max}$ after the order declared to be minimal;
4. an extension does not truncate to the cylinder of the previous level;
5. the phase return resets the prefix, carry, terminal or memory;
6. the terminal term in (28.22) is omitted without proving that it vanishes;
7. the first 396 blocks of the long execution differ from the short execution;
8. a decimal or metrological control is read before the output is closed;
9. a certified digit differs from the material output of the generator;
10. the proof depends on the requested precision being $1,000$ or $10,000$, rather than an arbitrary M.

Chapter 29

Coinductive generation of e: exponential character, factorial semigroup, and phase return with state memory

29.1 Finite orbital selector: existence and uniqueness of compatible emission

Let $\mathcal{W} = \mathbb{F}_3^6$. For an emission $U = (u_1, \dots, u_6)$, the visible word is

$$\Psi(U) = ((-u_1) \bmod 3, \dots, (-u_6) \bmod 3).$$

On $\mathcal{W}$, the dihedral action is given by

$$r(u_1, u_2, u_3, u_4, u_5, u_6) = (u_3, u_1, u_2, u_5, u_6, u_4),$$
$$s(u_1, u_2, u_3, u_4, u_5, u_6) = (u_4, u_5, u_6, u_1, u_2, u_3).$$

For $w \in \mathcal{W}$, define

$$n(w) = \#\Psi^{-1}(w), \qquad M(w) = \sum_{U \in \Psi^{-1}(w)} \mathrm{mult}(U),$$

and

$$\nu(w) = \big(\#\{j : w_j = 0\}, \#\{j : w_j = 1\}, \#\{j : w_j = 2\}\big).$$

Theorem 29.1 (Structural selection of the exponential channel)**.** *Among the* 43 *orbits of the visible catalog, there is a unique orbit whose fibers simultaneously satisfy:*

$$n(w) = 1, \qquad M(w) = 144, \qquad \mathfrak{D}(w) = \{0, 3, 6\}, \qquad \nu(w) = (2, 3, 1).$$

The gauge

$$\mathrm{diag}_c = 6, \qquad \mathrm{card} = ES$$

select in it

$$\boxed{w_6^e = 201101.}$$

Proof. The four conditions are evaluated over the 243 words in the catalog, not over a sample. A single orbit satisfies the joint predicate. In that orbit, exactly one emission has both diagonal 6 and orientation ES. The enumeration uses only fields from the APP–TRIT catalog and does not consult an expansion of e. □

29.2 Block elevation and successive boundary compatibility

The recurrence L_0, L_0, L_1, L_1 produces

$$w_{30}^e = 201101|121221|102011|012222|102011,$$

and the joint boundary contributes

$$u_5^e = 021222.$$

The record of thirty-six trits remains

$$w_{36}^e = 201101|121221|102011|012222|102011|021222.$$

29.3 Exponential Section Prolongation via the Visible Block Chain

The initial reading of twelve digits is

$$\mathbf{d}_e^{(12)} = 718281828459 = 7\ \underbrace{1828\,1828}_{\text{local square}}\ 459.$$

The central equality is the concatenation

$$1828 \parallel 1828,$$

not an arithmetic product nor the supposed beginning of a period.

Definition 29.2 (Positional square)**.** A word $d_1 \cdots d_{12}$ contains a square of length ℓ at position p when

$$d_p \cdots d_{p+\ell-1} = d_{p+\ell} \cdots d_{p+2\ell-1}.$$

The position and the lateral contexts belong to the signature.

Table 29.1: Comprehensive census of squares in twelve-digit readings.

Length ℓ	1	2	3	4	5	6
Occurrences	240	21	3	2	0	0
Words that contain them	153	19	3	2	0	0

The other word with a square of length four is

$$575157518472 = \underbrace{5751\,5751}_{\text{initial position 1}}\ 8472.$$

Proposition 29.3 (Positional uniqueness)**.** *The reading of channel e is the only one that has a square of length four after a prefix of length one and with contexts* 7 *and* 459*.*

Proof. The census leaves only two words with squares of length four. One starts it at the first position; the other after the prefix 7. The position and contexts separate the two possibilities. □

29.4 Construction of the decimal signature and the positional square of the exponential section

In the elevation

$$201101|121221|102011|012222|102011$$

the third and the fifth blocks coincide:

$$B_3 = B_5 = 102011.$$

Their prestates modulo 27 are, however,

$$p_3 = (25, 11, 7, 17, 8, 16), \qquad p_5 = (7, 8, 4, 23, 26, 7),$$

and the subsequent quotients:

$$q_3 = (6, 13, 9, 2, 13, 1), \qquad q_5 = (15, 0, 3, 19, 23, 25).$$

$p_3 \neq p_5$ and $q_3 \neq q_5$ hold.

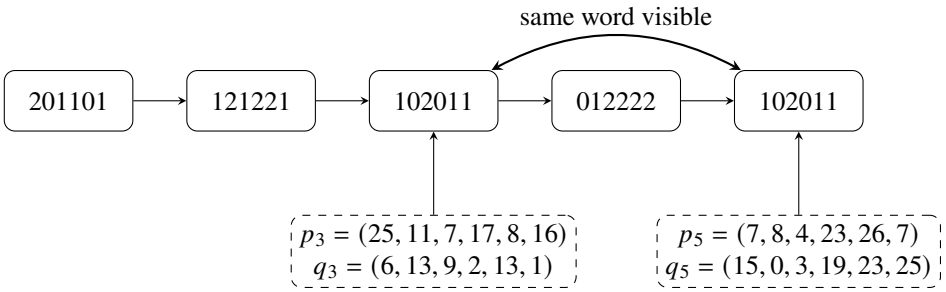

Figure 29.1: Visible return of 102011 with renewal of the prestate and the quotient.

Theorem 29.4 (Visible-phase return without periodicity of the state)**.** *$B_3 = B_5$ is a return of the visible projection, not a periodic orbit of the enriched state.*

Proof. The return of the complete state would require equality of all its coordinates. The prestate and quotient inequalities exclude it. Nor does 1828|1828 begin a decimal period: after the second block, 4 appears, whereas a periodic continuation would require 1. □

29.5 Subsequent factorial certification of the coinductive exponential section

Let $\mathcal{A}$ be a unital commutative algebra over $\mathbb{Q}$, and let $P_t \in \mathcal{A}[[t]]$ be the formal propagator. Temporal concatenation imposes

$$P_{s+t} = P_s P_t, \qquad P_0 = 1.$$

We write

$$P_t = \sum_{n=0}^{\infty} a_n t^n.$$

The unit fixes $a_0 = 1$, and normalized elementary transport fixes $a_1 = 1$.

Theorem 29.5 (Factorial recurrence)**.**

$$(n+1)a_{n+1} = a_n \qquad (n \geq 0),$$

and, therefore,

$$a_n = \frac{1}{n!}, \qquad P_t = \sum_{n=0}^{\infty} \frac{t^n}{n!}.$$

En $t = 1$,

$$\boxed{P_1 = e.}$$

Proof. The coefficient of $s^n t$ in P_{s+t} is

$$\binom{n+1}{n} a_{n+1} = (n+1)a_{n+1}.$$

In $P_s P_t$ it is $a_n a_1 = a_n$. Equality of series produces the recurrence. Induction from $a_0 = 1$ gives $a_n = 1/n!$. □

Corollary 29.6 (Differential equation)**.**

$$\frac{d}{dt} P_t = P_t, \qquad P_0 = 1.$$

Proof.

$$P_t' = \sum_{n\geq 0}(n+1)a_{n+1}t^n = \sum_{n\geq 0} a_n t^n = P_t.$$

□

29.6 Cofinal Forking of Rational Tangles and Convergence to the Published Value

Let

$$S_N = \sum_{n=0}^{N} \frac{1}{n!}.$$

Theorem 29.7 (Explicit factorial bound)**.** *For $N \geq 1$,*

$$\boxed{S_N < e < S_N + \frac{N+2}{(N+1)(N+1)!}.} \tag{29.1}$$

Proof. The rest is

$$R_N = \sum_{k=0}^{\infty} \frac{1}{(N+1+k)!} > 0.$$

Para $k \geq 0$,

$$(N+1+k)! \geq (N+1)!(N+2)^k.$$

Therefore,

$$R_N \leq \frac{1}{(N+1)!}\sum_{k=0}^{\infty}\frac{1}{(N+2)^k} = \frac{N+2}{(N+1)(N+1)!}.$$

The inequality is strict from $k = 2$ onward. □

We define

$$J_N^{(e)} = \left[S_N,\, S_N + \frac{N+2}{(N+1)(N+1)!}\right]$$

and, for the fractional part,

$$\widetilde{J}_N^{(e)} = J_N^{(e)} - 2.$$

The width converges to zero. For each M, there exists N such that

$$\operatorname{diam} J_N^{(e)} < 10^{-M}.$$

If the endpoints belong to the same decimal cell, the first M digits are certified by rational arithmetic.

29.7 Coinductive prolongation of the exponential section through ternary subcylinders of the Topological Phase Kernel

At level K, TPK and the relation Ext have already generated a unique compatible subcylinder. The smallest $N = N_e(K)$ for which the factorial bracket is contained in that subcylinder is taken. $N_e(K)$ is an order of analytic certification, not a generating index or a rule for selecting the fiber.

The TPK cylinders are compatible under truncation independently of the semigroup. The semigroup theorem subsequently identifies their Archimedean evaluation with $e - 2$; the integer part recovers e. If the orbit, Ext or truncation fails, generation fails; if the recurrence or the factorial bound fails, this analytic certificate fails, not the APP–TRIT–TPK genealogy.

29.8 Inductive prolongation of e via the nonadic holonomy Γ_9 of the TPK

Remark 29.8 (Certified and validity control: Falsification of the exponential channel). The construction is refuted if:

1. another orbit satisfies the complete finite predicate;
2. the signature 7[1828 1828]459 is not positionally unique;
3. the prestates or quotients of the two blocks 102011 coincide;
4. the semigroup does not force $(n + 1)a_{n+1} = a_n$;
5. the bound (29.1) fails;
6. a level does not locate a compatible extension uniquely;
7. a tabulated expansion intervenes before recognition.

Chapter 30

Coinductive generation of φ: modal incidence, positive Perron ray, and uniqueness of self-scaling

30.1 Finite Selection of the Self-Scaling Seed

Let $\mathcal{U}_6 \subset \{0,\dots,999\}^6$ be the catalog of the 468 distinct emissions constructed in section 8.2, and let

$$\Psi : \mathcal{U}_6 \longrightarrow \mathbb{F}_3^6, \qquad \Psi(U) = ((-U_j) \bmod 3)_{j=1}^6.$$

For $w \in \Psi(\mathcal{U}_6)$, we recall the invariants

$$n(w) = \#\Psi^{-1}(w), \qquad M(w) = \sum_{U \in \Psi^{-1}(w)} \mathrm{mult}(U),$$

and the occupation vector

$$\nu(w) = \big(\#\{j : w_j = 0\}, \#\{j : w_j = 1\}, \#\{j : w_j = 2\}\big).$$

Theorem 30.1 (Orbital selection of the self-scale)**.** *The dihedral action on $\Psi(\mathcal{U}_6)$ contains a unique orbit that satisfiis the self-scale predicate*

$$n(w) = 1, \qquad M(w) = 144, \qquad \nu(w) = (2,2,2).$$

The internal caliber

$$\mathrm{diag}_c = 6, \qquad \mathrm{card} = ES$$

select in that orbit the word

$$\boxed{w_6^{\varphi} = 121200.}$$

Its only emission is

$$\boxed{U_{\varphi} = (830, 943, 830, 109, 252, 252),}$$

of multiplicity 144*, multiplicative signature* 555933*, additive orientation ES, multiplicative support of cardinality six and residual type A.*

Proof. The direct projection gives

$$U_{\varphi} \bmod 3 = (2,1,2,1,0,0), \qquad -U_{\varphi} \bmod 3 = (1,2,1,2,0,0).$$

The enumeration is carried out over the 243 visible words and their 43 orbits, not over a selection of examples. The joint predicate $n = 1$, $M = 144$, $\nu = (2,2,2)$ leaves one orbit. Within it, the declared diagonal and orientation leave one emission. At this stage neither the equation $x^2 - x - 1 = 0$, nor a decimal table, nor the conventional name of the constant has been introduced. □

30.2 Blockwise lifting and 1^{a} coinductive boundary

Let $b_1 = w_6^{\varphi}$, and let $\varepsilon = (0, 0, 1, 1)$. With the matrices L_0, L_1 constructed in section 8.1, we define

$$b_{k+1} = b_k L_{\varepsilon_k} \pmod 3 \qquad (1 \le k \le 4),$$

and concatenate

$$w_{6(k+1)}^{\varphi} = w_{6k}^{\varphi} \parallel b_{k+1}.$$

Matrix calculus produces, block by block,

$$\begin{aligned} b_1 &= 121200, \\ b_2 &= 112202, \\ b_3 &= 121020, \\ b_4 &= 010210, \\ b_5 &= 010200, \end{aligned}$$

and, therefore,

$$\boxed{w_{30}^{\varphi} = 121200|112202|121020|010210|010200.} \tag{30.1}$$

The dual neutrality of the boundary adds

$$u_5^{\varphi} = 102011,$$

so that

$$\boxed{w_{36}^{\varphi} = 121200|112202|121020|010210|010200|102011.} \tag{30.2}$$

Remark 30.2 (Two distinct uses of a visible word). The word 102011 is also visible in the biography of e. The equality of a projection does not identify enriched states: the channel, prefix, quotient, carry, phase, and memory belong to the type of the object. This separation is mandatory before any real character is constructed.

30.3 Construction of the incidence multigraph from the triticale calendar

30.3.1 Primitive modal rule

The primitive triticale calendar is

$$(+1, -1, 0).$$

We fix two visible modis, Σ and Π, and the rule

$$+1 : m \longmapsto \Sigma, \qquad -1 : m \longmapsto \Pi, \qquad 0 : m \longmapsto m. \tag{30.3}$$

Under the cyclic closure condition, the modal orbit produced by (30.3) is

$$\boxed{(\Sigma, \Pi, \Pi).}$$

The three consecutive pairs are

$$\Sigma \longrightarrow \Pi, \qquad \Pi \longrightarrow \Pi, \qquad \Pi \longrightarrow \Sigma.$$

Definition 30.3 (Chronological incidence matrix)**.** For $i, j \in \{\Sigma, \Pi\}$, let

$$N_3(i, j) = \#\{r \in \mathbb{Z}/3\mathbb{Z} : (m_r, m_{r+1}) = (i, j)\}.$$

The subscript 3 counts instants of the primitive calendar; it does not denote a matrix power.

Theorem 30.4 (Necessary descent of modal incidence)**.** *In the order* (Σ, Π)*,*

$$\boxed{N_3 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{30.4}$$

By exact repetition of the calendar,

$$\boxed{N_9 = 3N_3, \qquad N_{27} = 9N_3, \qquad N_{108} = 36N_3.} \tag{30.5}$$

These three equalities are equalities of edge counts; they do not assert $N_9 = N_3^3$*,* $N_{27} = N_3^9$ *or* $N_{108} = N_3^{36}$*.*

Proof. $\Sigma \to \Sigma$ does not occur; each of the other three pairs occurs once. This determines the four entries of N_3. The calendars of lengths 9, 27, and 108 contain respectively 3, 9, and 36 copies of the primitive block. Each repetition multiplies all the counts by the same integer, which proves (30.5). □

30.3.2 Areal-volumetric publication

The modal label and the geometric sheet are distinct objects. The publication chart is

$$\mathfrak{g}_{\mathrm{av}}(\Sigma) = \mathscr{H}_{\mathrm{ar}}, \qquad \mathfrak{g}_{\mathrm{av}}(\Pi) = \mathscr{H}_{\mathrm{vol}}.$$

Transporting (30.4) through $\mathfrak{g}_{\mathrm{av}}$, we obtain the incidence operator

$$\boxed{F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.} \tag{30.6}$$

Thus, the two cross-transitions, the unique volumetric self-retention, and the absence of areal self-retention are derived from the calendar; they are not four independent inputs.

Remark 30.5 (Scope of the descent). Forgetting the elementary phase does not by itself produce a strong Markov quotient of the Topological Phase Kernel, because the visible mode does not determine which of the three internal operators will act at the next step. What does descend without an additional hypothesis is the edge multigraph of a complete block. Its minimal memory-one envelope has adjacency matrix F_{av}.

30.4 Construction of the modal incidence multigraph from the triticale calendar

Theorem 30.6 (Perron ray derived)**.** *The positive cone of* F_{av} *contains a unique eigenray. If we normalize it as* $v = (1, x)^{\mathsf{T}}$*, then*

$$x^2 - x - 1 = 0, \qquad x > 0,$$

and, therefore,

$$\boxed{x = \frac{1 + \sqrt{5}}{2} = \varphi.} \tag{30.7}$$

Proof. The equation $F_{\mathrm{av}} v = \lambda v$ gives, coordinate by coordinate,

$$x = \lambda, \qquad 1 + x = \lambda x.$$

Eliminating λ yields $x^2 - x - 1 = 0$. Its roots are $(1 \pm \sqrt{5})/2$, and only the positive root lies in the interior of the cone. The matrix F_{av} is primitive, since F_{av}^2 has all its entries positive; the Perron–Frobenius theorem ensures that this positive ray is simple and unique. The name φ is assigned only after this construction. □

Corollary 30.7 (Scalar Self-Similarity Equation)**.**

$$\varphi = 1 + \frac{1}{\varphi}, \qquad \varphi^2 = \varphi + 1, \qquad \varphi^{-1} = \varphi - 1.$$

Thi identitiis are consequencis of (30.7)*; they select neither the seed nor the matrix.*

30.5 Publication of the self-scale φ through Fibonacci powers and Diophantine convergence

Let $F_0 = 0$, $F_1 = 1$, and

$$F_{n+1} = F_n + F_{n-1} \qquad (n \geq 1).$$

Theorem 30.8 (Exact Powers of Incidence)**.** *For every $n \geq 1$,*

$$\boxed{F_{\mathrm{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}.} \tag{30.8}$$

Proof. For $n = 1$, the identity is the definition of F_{av}. If it holds for n, right multiplication by F_{av} gives

$$\begin{pmatrix} F_n & F_{n-1} + F_n \\ F_{n+1} & F_n + F_{n+1} \end{pmatrix} = \begin{pmatrix} F_n & F_{n+1} \\ F_{n+1} & F_{n+2} \end{pmatrix},$$

which is the case $n + 1$. □

Theorem 30.9 (Cassini's Identity)**.** *For every $n \geq 1$,*

$$\boxed{F_{n+1}F_{n-1} - F_n^2 = (-1)^n.} \tag{30.9}$$

Proof. The determinant of F_{av} is -1. Taking determinants in (30.8),

$$F_{n-1}F_{n+1} - F_n^2 = \det(F_{\mathrm{av}}^n) = (-1)^n.$$

□

We define $r_n = F_{n+1}/F_n$ for $n \geq 1$. From Cassini it follows that

$$r_n - r_{n-1} = \frac{F_{n+1}F_{n-1} - F_n^2}{F_nF_{n-1}} = \frac{(-1)^n}{F_nF_{n-1}}.$$

Therefore, the approximations alternate around the Perron ray.

Proposition 30.10 (Perron Rational Gaps)**.** *For $m \geq 1$,*

$$\frac{F_{2m+2}}{F_{2m+1}} < \varphi < \frac{F_{2m+1}}{F_{2m}}, \tag{30.10}$$

and the width is

$$\boxed{\frac{F_{2m+1}}{F_{2m}} - \frac{F_{2m+2}}{F_{2m+1}} = \frac{1}{F_{2m}F_{2m+1}}.} \tag{30.11}$$

Proof. The preceding alternation places the even quotients below and the odd ones above φ. The formula for the width is (30.9) with $n = 2m + 1$, after putting both fractions over a common denominator. Since $F_n \to \infty$, the width tends to zero. □

30.6 Memory incidence of order 1 and Parry measure of the symbolic envelope

Let X_{av} be the smallest subshift of finite type over $\{\mathscr{H}_{\mathrm{ar}}, \mathscr{H}_{\mathrm{vol}}\}$ that admits exactly the three pairs observed in the modal calendar. Its adjacency matrix is F_{av}.

Theorem 30.11 (Transition and Parry Measure)**.** *Let $r = (1, \varphi)^{\mathsf{T}}$. The Parry stochastic matrix is*

$$\boxed{P_{ij} = \frac{(F_{\mathrm{av}})_{ij} r_j}{\varphi r_i} = \begin{pmatrix} 0 & 1 \\ \varphi^{-2} & \varphi^{-1} \end{pmatrix}.} \tag{30.12}$$

The measure estacionaria of vertices is proporcional to $(1, \varphi^2)$, hence

$$\boxed{\frac{\mu_{\mathrm{ar}}}{\mu_{\mathrm{vol}}} = \varphi^{-2}.} \tag{30.13}$$

Proof. The sum of row i of P is

$$\frac{(F_{\mathrm{av}} r)_i}{\varphi r_i} = 1.$$

Since F_{av} is symmetric, the left and right eigenvectors coincide. The stationary weights are proportional to their coordinatewise products, that is, to $(1, \varphi^2)$. The ratio between the two weights is φ^{-2}. □

Remark 30.12 (Three measures that must not be confused). The chronological frequency of the primitive orbit is

$$\nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{ar}}) = \frac{1}{3}, \qquad \nu_{\mathrm{cyc}}(\mathscr{H}_{\mathrm{vol}}) = \frac{2}{3}.$$

The uniform measure τ_{468} lives on the emission catalog. The Parry measure lives on admissible histories of arbitrary length. The first counts instants, the second counts emissions, and the third weights dynamic cylinders. None is an approximation of the others.

30.7 Multiplicative character and cylindrical conservation

For an admissible route $\gamma : i \to j$ of length n, we define

$$\chi_P(\gamma) = \varphi^n \frac{r_i}{r_j}. \tag{30.14}$$

Proposition 30.13 (Concatenation multiplicativity)**.** *If $\gamma_1 : i \to j$ and $\gamma_2 : j \to k$, then*

$$\chi_P(\gamma_2 \circ \gamma_1) = \chi_P(\gamma_2)\chi_P(\gamma_1).$$

On to closed route of length n,

$$\chi_P(\gamma) = \varphi^n.$$

Proof. Length adds and the intermediate coordinate telescopes:

$$\varphi^{n_1+n_2} \frac{r_i}{r_k} = \left(\varphi^{n_1} \frac{r_i}{r_j}\right)\left(\varphi^{n_2} \frac{r_j}{r_k}\right).$$

If $i = k$, the quotient terminal is one. □

We normalize the left vector as

$$\ell = \frac{r}{1 + \varphi^2}, \qquad \ell^{\mathsf{T}} r = 1.$$

The measure of a cylinder is

$$\mu[x_0 \cdots x_n] = \ell_{x_0} r_{x_n} \varphi^{-n}.$$

Therefore,

$$V_n(x) := \frac{\mu[x_0]}{\mu[x_0 \cdots x_n]} = \varphi^n \frac{r_{x_0}}{r_{x_n}} = \chi_P(x_0 \cdots x_n). \tag{30.15}$$

For to typed dimension $D > 0$, the scale

$$a_n^{(D)}(x) = V_n(x)^{1/D}$$

satisfies the exact law

$$\boxed{\big(a_n^{(D)}(x)\big)^D \mu[x_0 \cdots x_n] = \mu[x_0].} \tag{30.16}$$

In three dimensions and over closed returns,

$$\frac{a_9}{a_0} = \varphi^3, \qquad \frac{a_{27}}{a_0} = \varphi^9, \qquad \frac{a_{108}}{a_0} = \varphi^{36}.$$

If $A_k = a_{9k}$, then

$$A_{k+1} - 2A_k + A_{k-1} = A_{k-1}(\varphi^3 - 1)^2 > 0. \tag{30.17}$$

This is convexity in return depth; it is not interpreted as a kinematic quantity without an additional duration chart.

30.8 Quadratic memory and contracted branch

The eigenvalues of F_{av} are

$$\varphi, \qquad -\varphi^{-1}.$$

The contracted branch changes orientation at each iteration. To preserve that sign before squaring, we pass to $\mathrm{Sym}^2(\mathbb{R}^2)$. In the basis $(x^2, 2xy, y^2)$,

$$\mathrm{Sym}^2(F_{\mathrm{av}}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}. \tag{30.18}$$

Theorem 30.14 (Spectrum of the second-order memory)**.**

$$\det\big(tI - \mathrm{Sym}^2(F_{\mathrm{av}})\big) = (t+1)(t^2 - 3t + 1),$$

and

$$\boxed{\mathrm{Spec}\big(\mathrm{Sym}^2(F_{\mathrm{av}})\big) = \{\varphi^2, -1, \varphi^{-2}\}.} \tag{30.19}$$

The only positive stable mode is φ^{-2}.

Proof. The eigenvalues of a degree-two symmetric power are the products λ_1^2, $\lambda_1\lambda_2$, and λ_2^2. With $\lambda_1 = \varphi$ and $\lambda_2 = -\varphi^{-1}$, one obtains φ^2, -1, and φ^{-2}. The first exceeds one, the second has modulus one, and the third belongs to $(0, 1)$. □

On a closed route with $V_n = \varphi^n$, the stable mode satisfies

$$\boxed{M_n = \varphi^{-2n} = V_n^{-2}.} \tag{30.20}$$

30.9 Normalized hyperbolic realization of the self-scale: $\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2$

Let

$$A = F_{\mathrm{av}}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}, \qquad J_h = \frac{2A - 3I}{\sqrt{5}}.$$

Then

$$J_h^2 = I, \qquad A = \frac{3}{2}I + \frac{\sqrt{5}}{2}J_h.$$

Since

$$\cosh(2\log\varphi) = \frac{3}{2}, \qquad \sinh(2\log\varphi) = \frac{\sqrt{5}}{2},$$

we obtain

$$\boxed{\exp(2\log\varphi\, J_h) = F_{\mathrm{av}}^2.} \tag{30.21}$$

The self-scaling constant is therefore simultaneously the Perron eigenvalue of the incidence and the exponential parameter of its normalized hyperbolic realization.

30.10 Characterization of self-similarity via rational forks and coinductive prolongation

The finite construction determines the positive ray of F_{av}. The subsequent analytic characterization is

$$x^2 - x - 1 = 0, \qquad x > 0.$$

The brackets (30.10) have rational endpoints and explicit width (30.11). For each nonadic level K, we choo the least $m = m_\varphi(K)$ who bracket remains contained in a single subcylinder among the 729 elements of the ambient fiber. Minimality converts localization into a function, not into to tacit choice.

The selected cylinders are compatible with the truncations, and their diameters tend to zero. Their intersection contains a unique real number; the theorem 30.6 identifies it with φ. The Fibonacci quotients are therefore rational certificates of localization, not decimal data used to decide the seed.

30.11 Characterization of φ by the Perron ray, fork embedding, and coinductive prolongation

Remark 30.15 (Certified and validity control: Refutation of the self-biography). The construction is refuted if any of the following events occurs:

1. the finite predicate selects more than one orbit or more than one emission;
2. the recurrence L_0, L_0, L_1, L_1 does not produce (30.1);
3. the calendar does not produce exactly the three pairs used in (30.4);
4. a count multiple N_9, N_{27}, N_{108} is confused with a power of N_3;
5. F_{av} has another positive eigenray;
6. (30.8) or Cassini's identity fails;
7. the rational brackets are not nested or do not contract their width;
8. the chronological frequency, the uniform measure on the catalog or the Parry measure are identified;
9. a decimal table is involved before the Perron ray is constructed;
10. a selected cylinder does not truncate to the previous cylinder.

30.12 The dodecaphase closure of α

This section establishes dodecaphase closure through integer arithmetic in base one thousand. The construction makes explicit the twelve recurrences, the propagated Euclidean quotients and the boundary conditions determining the output.

30.12.1 The terminal selector of the three channels

The closure brings together three already constructed generations, but does not identify them by their decimal name. At terminal depth, the catalogs of compatible tails have cardinalities

$$|\mathcal{T}_\pi| = 196, \qquad |\mathcal{T}_e| = 197, \qquad |\mathcal{T}_\varphi| = 196.$$

The selection object is therefore $\mathcal{T}_\pi \times \mathcal{T}_e \times \mathcal{T}_\varphi$, with

$$196 \cdot 197 \cdot 196 = 7\,567\,952$$

possible triples.

The coordinate boundary fixed by the terminal reader is

$$q = (1, 2, 2, 1, 2, 0) \in \mathbb{F}_3^6.$$

The channel law $\pi + e - \varphi$ has sign vector

$$\sigma = (1, 1, -1) = (1, 1, 2) \in \mathbb{F}_3^3$$

and nonzero dual line

$$\langle 2\sigma \rangle = \langle (2, 2, 1) \rangle.$$

The first datum acts on the boundary columns; the second, on its rows. They are not two interchangeable features.

Theorem 30.16 (Terminal matrix selector of α)**.** *In the preceding terminal catalog, the local signatures of Gram, norm, weight and Hamming distance reduce the* 7 567 952 *triples to* 331. *Requiring the column margin q leaves two candidates:*

$$(120, 197, 157), \qquad (129, 197, 148).$$

The condition that the row charge belong to the line of the channel $\langle \sigma \rangle$ selects exactly the second. Its blocks are

$$\boxed{b_\pi = 021020, \qquad b_e = 001220, \qquad b_\varphi = 100210.}$$

Proof. The two terminal matrices surviving the column margin are

$$B_0 = \begin{pmatrix} 0 & 2 & 0 & 2 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}, \qquad B_1 = \begin{pmatrix} 0 & 2 & 1 & 0 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 0 & 2 & 1 & 0 \end{pmatrix}.$$

Their row sums in $\mathbb{F}_3$ are, respectively,

$$(0, 2, 0), \qquad (2, 2, 1).$$

The first does not belong to $\langle (1, 1, 2) \rangle = \{0, (1, 1, 2), (2, 2, 1)\}$; the second does, since $(2, 2, 1) = 2\sigma$. Therefore only B_1 simultaneously satisfies the coordinate boundary and the channel charge. Its three rows are the blocks shown and correspond to the triple $(129, 197, 148)$. □

The theorem does not obtain q from the row charge: q is the coordinate datum of the terminal reader, and σ is the channel orientation. What is proved is that, once both boundaries of the same object are declared, the real branch is unique. This separation prevents a signature found a posteriori from being turned into a supposedly derived law.

Definition 30.17 (Two readings of the enriched terminal state)**.** Let

$$x_{\mathrm{term}} \in \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \subseteq \mathcal{X}_{\mathrm{TPK}}^{[108]}.$$

This state is the output

$$x_{\mathrm{term}} = (\mathcal{U}_{108} \circ \cdots \circ \mathcal{U}_1)(x_{\mathrm{seed}})$$

of the complete pipeline of TPK selection, transport and update. The preceding selector is the reading

$$\pi_{\mathrm{term}}(x_{\mathrm{term}}) = B_{\mathrm{term}} := \begin{pmatrix} 021020 \\ 001220 \\ 100210 \end{pmatrix}.$$

The oriented register and the reader of the channels of 90° and 120° produce, from the ledger of the same state,

$$\mathcal{E}_{108}^{90,120}(\mathcal{R}_{12}(x_{\mathrm{term}})) = (b^{90}, b^{120}, Q_{\mathrm{TPK}}), \tag{30.22}$$

with

$$\begin{aligned} b^{90} &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461), \\ b^{120} &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \\ Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} b_{r+3j}^{120}, \qquad A_1 = \frac{Q_{\mathrm{TPK}} + 2B_1 + B_2}{3}, \qquad A_2 = A_1 - B_1, \qquad A_3 = A_2 - B_2,$$

and $d_{r,j} = b_{r+3j}^{90}$. The harmonic reader Π_H forms the blocks

$$\Pi_H^{(r)} = \big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big) \tag{30.23}$$

and interleaves them by columns. The signed reading is therefore the produced composition

$$\boxed{R_{\mathrm{sgn}} := \Pi_H \circ \mathcal{E}_{108}^{90,120} \circ \mathcal{R}_{12} : \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}} \longrightarrow \mathcal{U}_{12}^{\mathrm{sgn}} := \operatorname{im} R_{\mathrm{sgn}}.} \tag{30.24}$$

Neither U nor K are coordinates added to the domain: U is the output of (30.24), and K will be its unique integral preimage under Hadamard. No factorization $B_{\mathrm{term}} \to U_{12}^{\mathrm{sgn}}$ is asserted: both outputs preserve distinct components of the same terminal state.

For $N' \geq N \geq 108$, the truncations act only on the enriched histories:

$$\tau_{N',N} : \mathcal{X}_{\mathrm{TPK}}^{[N'],\mathrm{enr}} \longrightarrow \mathcal{X}_{\mathrm{TPK}}^{[N],\mathrm{enr}}. \tag{30.25}$$

If $R_{\mathrm{sgn,N}}$ denotes the same composition at depth N, naturality is the concrete square

$$\boxed{R_{\mathrm{sgn,N}} \circ \tau_{N',N} = R_{\mathrm{sgn,N'}}.} \tag{30.26}$$

Theorem 30.18 (Reversible construction of the signed coordinate)**.** *The composite* (30.24)*, applied to the produced terminal state, gives exactly*

$$U = R_{\mathrm{sgn}}(x_{\mathrm{term}}) = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997). \quad (30.27)$$

Its inversion by three Hadamard blocks of order four then produces

$$\boxed{K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).}$$

The transformation is invertible; it satisfies the square (30.26) *under the truncations* (30.25)*; and it is independent of α, CODATA and every metrological figure.*

Proof. Formulas (30.22) and (30.23) give

$$(B_1, B_2, B_3) = (972, -1073, 101), \qquad (A_1, A_2, A_3) = (2378, 1406, 2479),$$

and produce the three signed blocks

$$\begin{aligned} U^{(1)} &= (2378, -452, -668, -322), \\ U^{(2)} &= (1406, 998, -204, -28), \\ U^{(3)} &= (2479, -551, -371, -997). \end{aligned}$$

Their interleaving is (30.27). Since $H_4^2 = 4I_4$ and $\det(H_4 \oplus H_4 \oplus H_4) = (-16)^3 = -4096$, we have

$$K = \mathcal{H}_{12}^{-1} U = \frac{1}{4} \mathcal{H}_{12} U \quad (30.28)$$

after undoing the orbit permutation. Indeed,

$$H_4 U^{(1)} = (936, 2916, 2484, 3176), \quad H_4 U^{(2)} = (2172, 2636, 232, 584),$$

and

$$H_4 U^{(3)} = (560, 3296, 3656, 2404).$$

The forced division by four gives the orbits $(234, 729, 621, 794)$, $(543, 659, 058, 146)$ and $(140, 824, 914, 601)$, whose interleaving is the declared seal.

As an independent check, the cyclic operators $(D_3K)_m = K_m - K_{m+3}$ and $(D_4K)_m = K_m - K_{m+4}$, together with $Q(K) = \sum_m K_m$, satisfy

$$\operatorname{rank}(D_3, D_4) = 11, \qquad \operatorname{rank}(D_3, D_4, Q) = 12. \quad (30.29)$$

Thus $(D_3K, D_4K, Q(K))$ reconstructs a unique seal; moreover, the calculation recovers exactly

$$D_3K = b^{90}, \qquad D_4K = b^{120}, \qquad Q(K) = Q_{\mathrm{TPK}},$$

which certifies the prior reader of the register, without turning its outputs into inputs. The truncation (30.25) does not rewrite the first one hundred and eight windows of the ledger; thus both sides of (30.26) read the same register and produce U. None of the matrices used contains α or an experimental datum. □

The observable 108-step calendar is a strictly poorer projection: resetting its cursors every 9 steps erases precisely the bidirectional coordinates that the enriched register preserves. Thus the raw register does not replace the enriched state and is not used to reconstruct R_{sgn}. The preceding selection theorem constructs B_{term}; theorem 30.18 constructs, separately, the second publication of the same state.

30.12.2 Dodecaphase state and reversible maps

The theorem in this section receives from theorem 30.18 the signed vector

$$U_{12}^{\mathrm{sgn}} = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997).$$

The typed route proved from that input is

$$U_{12}^{\mathrm{sgn}} \longleftrightarrow K,$$

$$K \longleftrightarrow (D_3K, D_4K, Q),$$

$$(P, E, \Phi, K, c_{13} = 0) \longleftrightarrow A = \alpha_{12}.$$

Direct evaluation does not receive α or a metrological value as input. It receives U_{12}^{sgn}, the three Archimedean representations and the boundary condition. The theorem 30.16 first constructs the selection of the three terminal blocks; the present layer begins with the signed vector that transports them to the dodecaphase closure. The reduced trace of a single positional coordinate does not enter into this determination.

Remark 30.19 (Two dodecaphase representations of different types).

$$U_{12}^{\mathrm{cat}} = U_6 \| U_6$$

is a periodic word from the catalogue, whereas

$$U_{12}^{\mathrm{sgn}} = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997)$$

is a signed integer vector in the full state space of TPK. The first belongs to a block representation and has period six. The second preserves orientation, is not a base-thousand word and does not have that period. They are not interchangeable.

30.12.3 The canonical vector and the three orbits

The dodecaphase vector is

$$\boxed{K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).}$$

Its sum is

$$Q(K) = 6263.$$

Step three divides C_{12} into three orbits of four sectors:

$$K^{(1)} = (K_1, K_4, K_7, K_{10}) = (234, 729, 621, 794),$$
$$K^{(2)} = (K_2, K_5, K_8, K_{11}) = (543, 659, 058, 146),$$
$$K^{(3)} = (K_3, K_6, K_9, K_{12}) = (140, 824, 914, 601).$$

Each orbit traverses four sectors separated by 90°. The cardinal labels north–east–south–west appear after fixing origin and orientation; the primary order is $(m, m+3, m+6, m+9)$.

30.12.4 First representation: Hadamard transform

Let

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}.$$

The action on the three orbits gives

$$\begin{aligned} H_4 K^{(1)} &= (2378, -452, -668, -322), \\ H_4 K^{(2)} &= (1406, 998, -204, -28), \\ H_4 K^{(3)} &= (2479, -551, -371, -997). \end{aligned}$$

Interleaving by columns recovers

$$\mathcal{H}_{12}(K) = U_{12}^{\mathrm{sgn}}.$$

Since

$$H_4^2 = 4I_4, \qquad \det H_4 = -16,$$

the global transformation is invertible over $\mathbb{Q}^{12}$:

$$K^{(r)} = \frac{1}{4} H_4 U^{(r)}, \qquad \det \mathcal{H}_{12} = (-16)^3 = -4096 \neq 0.$$

In the canonical representation, the inverse produces a unique integer vector in $[0, 999]^{12}$.

Theorem 30.20 (Integral structure of the Hadamard transformation)**.** *The Smith normal form of the block H_4, denoted by* $\mathrm{SNF}(H_4)$*, is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4).$$

Consequently, for the direct sum of the three blocks,

$$\operatorname{coker} \mathcal{H}_{12} \cong (\mathbb{Z}/2\mathbb{Z})^6 \oplus (\mathbb{Z}/4\mathbb{Z})^3,$$

and the image of $\mathbb{Z}^{12}$ has index 4096*. A vector $u \in \mathbb{Z}^4$ belongs to $H_4\mathbb{Z}^4$ exactly when*

$$H_4 u \equiv 0 \pmod 4.$$

Proof. The greatest common divisor of the entries of H_4 is one. The minors of order two are even and one has absolute value two; the minors of order three are multiples of four and one has absolute value four; finally, $|\det H_4| = 16$. The determinantal divisors are therefore $1, 2, 4, 16$, yielding the invariant factors $1, 2, 2, 4$. The direct sum of three blocks repeats these factors and has index $16^3 = 4096$. Since $H_4^{-1} = H_4/4$, the last congruence is equivalent to the integrality of the preimage. □

30.12.5 Relative cyclotomic transporter between sectors three and four

Let R be the regular rotation of the cycle C_{12} on $\mathbb{Q}^{12}$, and let

$$W_d^{\mathrm{cyc}} := \ker \Phi_d(\mathsf{R})$$

its cyclotomic sectors. The rational projectors onto the sectors of orders three and four can be written

$$\Pi_3 = \frac{1}{4}(I + \mathsf{R}^3 + \mathsf{R}^6 + \mathsf{R}^9) - \frac{1}{12} \sum_{k=0}^{11} \mathsf{R}^k,$$

$$\Pi_4 = \frac{1}{6}(I - \mathsf{R}^2 + \mathsf{R}^4 - \mathsf{R}^6 + \mathsf{R}^8 - \mathsf{R}^{10}).$$

To fix the coordinate order, let

$$\mathsf{P}_{\mathrm{orb}}(z_1, \dots, z_{12}) = \big((z_1, z_4, z_7, z_{10}), (z_2, z_5, z_8, z_{11}), (z_3, z_6, z_9, z_{12})\big).$$

The global transform used above is, in the natural order of C_{12},

$$\mathcal{H}_{12} := \mathsf{P}_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)\mathsf{P}_{\mathrm{orb}}.$$

That is, $H_4 \oplus H_4 \oplus H_4$ acts in the order of the three step-three orbits, not on three contiguous quadruples in the natural order. We then define the relative transporter

$$A_{34} := \Pi_4 \mathcal{H}_{12} \Pi_3|_{W_3^{\mathrm{cyc}}} : W_3^{\mathrm{cyc}} \longrightarrow W_4^{\mathrm{cyc}}.$$

Theorem 30.21 (Dodecaphase cyclotomic transporter)**.** *In the bases*

$$u_1 = (1, -1, 0)^{\times 4}, \qquad u_2 = (0, 1, -1)^{\times 4}$$

of W_3^{cyc}*, and*

$$v_1 = (1, 0, -1, 0)^{\times 3}, \qquad v_2 = (0, 1, 0, -1)^{\times 3}$$

of W_4^{cyc}*, we have*

$$A_{34}u_1 = \frac{2}{3}(v_1 - v_2), \qquad A_{34}u_2 = \frac{2}{3}(v_1 + v_2),$$

and, therefore,

$$\boxed{\det A_{34} = \frac{8}{9}}.$$

In particular, A_{34} *is a rational isomorphism between the two sectors.*

Proof. The four preceding periodic sequences are substituted into the expressions for Π_3, Π_4 and into the three Hadamard blocks. The matrix of A_{34} in the declared bases is

$$\begin{pmatrix} 2/3 & 2/3 \\ -2/3 & 2/3 \end{pmatrix},$$

whose determinant is $8/9$. □

The rational involution that exchanges W_3^{cyc} and W_4^{cyc} by means of A_{34} and A_{34}^{-1}, and fixes W_{12}^{cyc}, transports the sum $W_4^{\mathrm{cyc}} \oplus W_{12}^{\mathrm{cyc}}$ to $W_3^{\mathrm{cyc}} \oplus W_{12}^{\mathrm{cyc}}$. In this latter sum, the cyclotomic polynomial of the rotation is

$$\Phi_3(x)\Phi_{12}(x),$$

which coincides with the polynomial of the Coxeter element of type E_6. This is an exact spectral signature and prepares the subsequent geometric corridor.

Rational transport and integral continuation

The operator A_{34} realizes rational cyclotomic transport between the sectors of orders three and four. By fixing W_{12}^{cyc}, it places the dodecaphase in the exact spectral sector $\Phi_3\Phi_{12}$ of type E_6. The integral continuation is constructed through two subsequent and compatible sources: the theorem 20.3 provides the M_{12}-equivariant isometry to the Witt module, and the theorem 20.7 chains the three incidence projectors. On that integral realization, the theorem 21.38 constructs the graph of the

twenty-seven lines and the section 21.7 identifies its Weyl action. Thus, A_{34} fixes the rational stage of the genealogy and the Witt–Schläfli intertwiners realize its lattice and incidence extension.

The sign separation is

$$U_{12}^{+} = (2378, 1406, 2479, 0, 998, 0, 0, 0, 0, 0, 0, 0),$$

$$U_{12}^{-} = (0, 0, 0, 452, 0, 551, 668, 204, 371, 322, 28, 997),$$

and

$$U_{12}^{\mathrm{sgn}} = U_{12}^{+} - U_{12}^{-}.$$

30.12.6 Second representation: transverse differences

With indices in $\{1, \dots, 12\}$ and the cyclic convention

$$K_{m+r} := K_{1+((m+r-1) \bmod 12)},$$

we define

$$(D_3K)_m = K_m - K_{m+3}, \qquad (D_4K)_m = K_m - K_{m+4}.$$

The dodecaphase transverse extractor is the operator

$$\mathcal{E}_{\mathrm{dod}} := (D_3, D_4, Q).$$

The subscript "dod" declares its domain. Shifts three and four correspond to angular separations of 90° and 120° in the oriented cycle C_{12}, but $\mathcal{E}_{\mathrm{dod}}$ is not the hexad–octad incidence operator or the angular kernel subsequently used in the towers. The data are

$$\begin{aligned} D_3K = (&-495, -116, -684, 108, 601, -90,\\ &-173, -88, 313, 560, -397, 461),\\ D_4K = (&-425, -281, -481, 671, -255, 30,\\ &475, -543, 680, 251, 6, -128),\\ Q = &\ 6263. \end{aligned}$$

If $D_3v = D_4v = 0$, the vector is constant at steps three and four. Since $\gcd(3, 4) = 1$, those steps connect the entire cycle and

$$\ker D_3 \cap \ker D_4 = \langle \mathbf{1} \rangle.$$

Therefore

$$\operatorname{rank}(D_3, D_4) = 11.$$

The total charge eliminates the constant translation, because $Q(\mathbf{1}) = 12 \neq 0$. Therefore

$$\boxed{\operatorname{rank}(D_3, D_4, Q) = 12,}$$

and

$$K \longleftrightarrow (D_3K, D_4K, Q)$$

is an exact coordinate system.

Theorem 30.22 (Integral normal form of the transverse system)**.** *Let*

$$\mathcal{D} = (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}.$$

Its nonzero invariant factors are

$$\mathrm{SNF}(\mathcal{D}) = \mathrm{diag}(\underbrace{1, \dots, 1}_{11}, 12),$$

and, consequently,

$$\operatorname{coker} \mathcal{D} \cong \mathbb{Z}^{13} \oplus \mathbb{Z}/12\mathbb{Z}.$$

Proof. The rows of (D_3, D_4) are oriented incidences of the graph

$$\mathrm{Cay}\big(\mathbb{Z}/12\mathbb{Z}, \{\pm 3, \pm 4\}\big).$$

Since steps three and four generate $\mathbb{Z}/12\mathbb{Z}$, the graph is connected. The incidences of a spanning tree provide eleven unimodular reduced minors; the first eleven invariant factors are therefore equal to one.

Every minor of order twelve contains the row Q, since the incidence block has rank eleven. Adding the first eleven columns to the last, a unimodular operation, makes the last column vanish in the incidence rows and gives twelve in the row Q. All maximal minors are divisible by twelve. Choosing the eleven incidences of a tree gives a remaining minor of absolute value one and, therefore, a maximal determinant of absolute value twelve. The last invariant factor is exactly twelve. □

The component $\mathbb{Z}/12\mathbb{Z}$ records the condition of integral compatibility of the total charge with the reconstructed potential. In particular, the rational uniqueness proved by the rank is refined here into a statement about the integral lattice and its unique torsional obstruction.

The signed observable can also be reconstructed from these coordinates. For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} (D_4 K)_{r+3j}.$$

We obtain

$$(B_1, B_2, B_3) = (972, -1073, 101).$$

Orbital sums are

$$A_1 = \frac{Q + 2B_1 + B_2}{3} = 2378, \quad A_2 = A_1 - B_1 = 1406, \quad A_3 = A_2 - B_2 = 2479.$$

If $d_{r,j} = (D_3 K)_{r+3j}$ for $j = 0, 1, 2, 3$, with the same cyclic convention, the signed block of the orbit r is

$$(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}),$$

exactly the corresponding Hadamard block.

Remark 30.23 (Codomains of $\mathcal{H}_{12}$ and $\mathcal{E}_{\mathrm{dod}}$). The correct notation is

$$\mathcal{H}_{12}(K) = U_{12}^{\mathrm{sgn}}, \qquad \mathcal{E}_{\mathrm{dod}}(K) = (D_3 K, D_4 K, Q).$$

Both representations are compatible because they reconstruct the same vector, but no diagram between their codomains has been defined here. Their formulas and codomains are distinct. Sharing the steps $3/4$ or the indices $90/120$ does not authorize identifying them.

30.12.7 The three Archimedean coordinates

The vectors of twelve triads are

$$P = (141, 592, 653, 589, 793, 238, 462, 643, 383, 279, 502, 884),$$
$$E = (718, 281, 828, 459, 045, 235, 360, 287, 471, 352, 662, 497),$$
$$\Phi = (618, 033, 988, 749, 894, 848, 204, 586, 834, 365, 638, 117).$$

In concatenated form:

$$\iota(P) = 141592653589793238462643383279502884,$$
$$\iota(E) = 718281828459045235360287471352662497,$$
$$\iota(\Phi) = 618033988749894848204586834365638117.$$

P is the decimal coordinate shared by the five regions of π; the calculation does not assert that those regions are identical.

30.12.8 Base-thousand carry recurrence

We fix

$$c_{13} = 0$$

and calculate from right to left, $m = 12, 11, \ldots, 1$:

$$s_m = P_m + E_m - \Phi_m - K_m + c_{m+1},$$

$$A_m = s_m \bmod 1000, \qquad c_m = \frac{s_m - A_m}{1000}, \qquad 0 \le A_m < 1000.$$

The table is printed in increasing index order, but each carry comes from the row below.

Table 30.1: Complete dodecaphase closure in base thousand.

m	P_m	E_m	Φ_m	K_m	c_{m+1}	s_m	A_m	c_m
1	141	718	618	234	0	7	007	0
2	592	281	033	543	0	297	297	0
3	653	828	988	140	−1	352	352	0
4	589	459	749	729	−1	−431	569	−1
5	793	045	894	659	−2	−717	283	−1
6	238	235	848	824	−1	−1200	800	−2
7	462	360	204	621	0	−3	997	−1
8	643	287	586	058	−1	285	285	0
9	383	471	834	914	−1	−895	105	−1
10	279	352	365	794	0	−528	472	−1
11	502	662	638	146	0	380	380	0
12	884	497	117	601	0	663	663	0

The carries are

$$(c_1, \ldots, c_{13}) = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, 0).$$

Negative values of s_m are ordinary borrowings in base thousand. Euclidean division uniquely fixes the remainder and quotient.

The output is

$$\boxed{A = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663),}$$

and therefore

$$\boxed{\begin{aligned}\alpha_{12} &:= \frac{729735256928380099728510547238066 3}{10^{36}},\\ &= 0.007297352569283800997285105472380663.\end{aligned}}$$

This rational is the initial dodecaphase window of the compatible section generated by TPK transport. If $\rho_{N',N} : C^{\alpha}_{N'} \to C^{\alpha}_{N}$ are its truncations, the complete output is

$$\boxed{\alpha_{\mathrm{HMT}} := \varprojlim_{N} \alpha_N, \qquad \rho_{N',N}(\alpha_{N'}) = \alpha_N, \qquad \alpha_{36} = \alpha_{12}.}$$

Phase return extends the memory and narrows the surviving cylinders to arbitrary depth; it neither resets the state nor ends the construction at thirty-six digits.

30.12.9 The complete affine identity

Coordinate by coordinate,

$$\boxed{P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + 1000c_m.}$$

If

$$C = (c_1, \dots, c_{12}), \qquad C^{+} = (c_2, \dots, c_{13}),$$

the correct vector form is

$$\boxed{P + E - \Phi - K + C^{+} - 1000C = A.}$$

To avoid identifying the finite tails with the complete constants, we define

$$\tau_{36}(x) = 10^{-36} \left\lfloor 10^{36}\big(x - \lfloor x \rfloor\big) \right\rfloor, \qquad \kappa(K) = 10^{-36}\iota(K).$$

The exact decimal notation of the concatenated identity is then

$$\tau_{36}(\pi) + \tau_{36}(e) - \tau_{36}(\varphi) - \kappa(K) = \alpha_{12}.$$

Without the explicit truncation, the embedding κ and the cocycle $C^{+} - 1000C$, the coordinate equality would be false.

We define

$$\iota(v_1, \dots, v_{12}) = \sum_{m=1}^{12} v_m 1000^{12-m}.$$

Multiplying each recurrence by 1000^{12-m} and summing makes the carries telescope:

$$\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A) = 1000^{12}c_1 - c_{13}.$$

Since $c_1 = c_{13} = 0$:

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) = \iota(A).}$$

The two remaining integers are

$$\iota(K) = 234543140729659824621058914794146601,$$

$$\iota(A) = 007297352569283800997285105472380663.$$

30.12.10 Inversion and equivalence of the three representations

The recurrence is inverted by

$$K_m = P_m + E_m - \Phi_m + c_{m+1} - A_m - 1000c_m,$$

and the concatenated integer representation by

$$\iota(K) = \iota(P) + \iota(E) - \iota(\Phi) - \iota(A).$$

The complete diagram is

$$\boxed{K \longleftrightarrow U_{12}^{\mathrm{sgn}}, \qquad K \longleftrightarrow (D_3K, D_4K, Q), \qquad K \longleftrightarrow A \mid (P, E, \Phi, c_{13} = 0).}$$

The first two are linear representations; the third is a reversible affine map on the fiber conditioned by P, E, Φ and the boundary.

Remark 30.24 (Commutativity of the closure). The direct map obtains K from the signed representation and produces A. The inverse formula proves that the output and the boundary recover the same vector without residual freedom. Invertibility does not constitute independent statistical evidence; the commutativity of the three representations is an algebraic property of the closure.

Uniqueness is expressed at three levels of the same construction:

1. with the signed vector, P, E, Φ and the boundary fixed, the vector and the output are unique;
2. the representations are reversible and commutative;
3. the complete genealogy APP $\to$ TRIT $\to$ TPK produces those primitives before the local closure, and its compatible truncations extend the identity to the coinductive section α_{HMT}.

30.12.11 Dodecaphase boundary condition

The first dodecaphase window uses $c_{13} = 0$ and ends at

$$\ldots|380|663.$$

This boundary is part of the domain of the reversible affine map. The extension does not introduce another system: it iterates the same graded transport of the TPK on

$$w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9$$

and constructs the successive windows with phase return, memory advance and compatible terminal carry. The section 31.7 proves that the truncation squares of this route and of the analytic reader commute and that their surviving cylinders have singleton intersection.

30.12.11.1 Integral class of the carry

The terminal condition can be compared with the periodic problem. Let S be the cyclic shift on $\mathbb{Z}^{12}$ and, for an integer base $b \geq 2$, define

$$\partial_b = S - bI.$$

The periodic affine identity takes the form

$$A = P + E - \Phi - K + \partial_b C.$$

For every $h \in \mathbb{Z}^{12}$, the transformation

$$K \longmapsto K + \partial_b h, \qquad C \longmapsto C + h$$

preserves A. Thus, the choice of carries is a choice of representative within an integral class.

Proposition 30.25 (Periodic quotient of the carry)**.** *On a cycle of length twelve,*

$$\operatorname{coker}(S - bI) \cong \mathbb{Z}/(b^{12} - 1)\mathbb{Z}.$$

Concatenation in base b, taken modulo $b^{12} - 1$, determines the periodic class.

Proof. The cyclic module is identified with $\mathbb{Z}[t]/(t^{12} - 1)$. Imposing the relation $t = b$ produces $\mathbb{Z}/(b^{12} - 1)\mathbb{Z}$. Evaluation of the coefficient polynomial is concatenation in base b, with orientation fixed by the order of the twelve sectors. □

The closure of α does not use the periodic quotient: it uses an oriented chain with a right endpoint and requires $c_{13} = 0$. Euclidean division then selects a unique representative. This difference explains why the open boundary is part of the definition of the map and cannot be replaced by a cyclic identification of the carries.

30.12.12 Comparison with the metrological reference

After generation, the integer arithmetic of the first window verifies the recognition

$$\boxed{\alpha_{12} = 10^{-36} \left\lfloor \frac{10^{36}}{137.035999084} \right\rfloor .}$$

Its inverse is

$$\alpha_{12}^{-1} = 137.035999084000000000000000000000001066588\ldots,$$

and exactly reproduces the central string published in the 2018 adjustment by the Committee on Data for Science and Technology (CODATA) [122]:

$$\boxed{137.035999084.}$$

This is not a floating-point coincidence. The thirty-six digits of α_{12} constitute the exact truncation of the reciprocal of the printed central string. This finite check does not define α_{HMT} or limit its depth: the coinductive section already produced determines all its compatible windows, while CODATA only subsequently recognizes the prefix that its experimental resolution allows it to test.

Metrological recognition is not part of the recurrence. The mathematical result is the exact identity of the two routes

$$\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}},$$

whose dodecaphase windows are determined by the signed vector, the three generated words and the compatible boundaries. The CODATA table only subsequently compares an already fixed output.

Comparison with subsequent metrological adjustments is a separate external check. The HMT output remains frozen and can therefore be tested without modifying the generator.

30.12.13 Coordinate independence and rigidity

The closure tests distinguish deep modifications from local perturbations:

Variante	Result	What it controls
canonical right–left protocol	igualdad exacta	reference
use $U_6 \| U_6$ as K	fails macroscopically	type distinction
rotar K	breaks the closure	dodecaphase origin
reflejar K	reverses the boundary	orientation
left–right carry	changes the word	direction of transport
perturb K_i by one unit	the exact word fails	rigidez profunda

A local perturbation may alter only a deep digit; it remains a refutation of the exact equality. Structural variants produce larger failures and show that the closure is not invariant under arbitrary orders.

Remark 30.26 (Structure of the dodecaphase closure). The closure of α comprises an oriented cycle, two exact representations of the vector K, twelve typed inputs, a right-to-left recurrence, thirteen carries, a boundary condition and a telescoping integer identity. These data determine the output reproducibly.

30.13 Dodecaphasic closure and transversal dependencies of the state

30.14 Internal derivation of α_{HMT}: survival genealogy, dodecaphasic closure, two compatible constructions, and Witt bifurcation

Four strata of α_{HMT}.

1. The genealogical constructor is the enriched terminal state with its two parallel publications B_{term} and U_{12}^{sgn}.
2. The analytic characterization is the reversible chain $U_{12}^{\mathrm{sgn}} \leftrightarrow K \to A \to \alpha_{12}$, followed by its coinductive prolongation.
3. Being dimensionless, its common transduction introduces no unit: it fixes the angular chart $A_{\mathrm{deg}} = 1000\alpha_{\mathrm{HMT}}$ used by subsequent channels.
4. Comparison with CODATA begins only after obtaining α_{HMT}; it does not select K, the carry, or the prolongation.

The full genealogy explicitly preserves the input chain and reaches an enriched terminal state. Its two publications are parallel:

$$w_6 \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}} \xrightarrow{\pi_{\mathrm{term}}} B_{\mathrm{term}},$$
$$x_{\mathrm{term}} \xrightarrow{R_{\mathrm{sgn}}} U_{12}^{\mathrm{sgn}} \xleftrightarrow{\mathcal{H}_{12}} K \longrightarrow A \longrightarrow \alpha_{12}.$$

B_{term} does not generate U_{12}^{sgn}: both preserve different coordinates of the same state. The transformation $\mathcal{H}_{12}$ is invertible, and the extractor $(D_3K, D_4K, Q(K))$ has rank 12. In this domain of explicit terminal primitives, the chain receives neither α, CODATA, a mass, nor any other metrological coordinate as input. Archimedean evaluation forms $(P, E, \Phi, K, c_{13} = 0)$, applies the carry cocycle, and derives α_{HMT}. Incidence evaluation transports the same words and seal to $B_K \subset H_\alpha^-$, which becomes the input to the Witt–Golay branch. Construction E21/22 and the remote prolongation $\mathsf{T}_{\alpha,\infty}$ —called $T1$ in the original notation— preserve their own domains and maps as developments of the main dodecaphasic genealogy.

Chapter 31

Dodecaphasic closure of α_{HMT} and analytic reader $E^{(9)}_{21/22}$: reversible generation, simple root and typed comparator

31.1 Internal derivation of α_{HMT}: common terminal state, dodecaphase seal, and carry cocycle

The preceding generator reaches a terminal state enriched with two coordinated publications:

$$w_6 \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}} \xrightarrow{\pi_{\mathrm{term}}} B_{\mathrm{term}},$$
$$x_{\mathrm{term}} \xrightarrow{R_{\mathrm{sgn}}} U_{12}^{\mathrm{sgn}} \xleftrightarrow{\mathcal{H}_{12}} K \longrightarrow A \longrightarrow \alpha_{12}.$$

The two terminal arrows publish distinct coordinates of the same antecedent. The transform $\mathcal{H}_{12}$ is reversible; the transverse system $(D_3K, D_4K, Q(K))$ attains rank twelve; oriented Euclidean division preserves the carry cocycle and the boundary conditions. The chain uses the signed state, the seal, and the declared primitives, and obtains α_{HMT} before opening metrological recognition.

31.1.1 Dodecaphasic closure and compatible constructions

Dodecaphase closure provides the governing statement and proof. The E21/22 constructions and $\mathsf{T}_{\alpha,\infty}$ retain their own domains and functions within the principal genealogy.

31.2 Signed register, seal reconstruction, and integral carry

The signed register and the carry cocycle unfold the common terminal state, the Hadamard charts and transverse differences, the Smith normal form, the affine identity, the coinductive prolongation, and the boundaries 662/663.

31.3 Reversibility, independence, and non-circularity of the dodecaphasic closure

The state 108, the prospective constructor of K, the bidirectional Hadamard transform, integral carry, and infinite prolongation are articulated through explicit controls of reversibility, independence, and noncircularity. Each formulation preserves its domain and its refutation criterion.

31.4 Factorization of the signed dodecaphasic record and integral closure of the seal K

The construction of the integer seal does not begin with α, its inverse or a metrological table. Its domain is the enriched terminal state of the Topological Phase Kernel obtained after the already constructed chain

$$\boxed{\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \Omega_{\mathrm{seed}} \xrightarrow{T_{\min}} \mathcal{U}_6^{\mathrm{cat}} \xrightarrow{\rho_3} W_{243} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9 \longrightarrow x_{\mathrm{term}}.} \tag{31.1}$$

The foregoing arrows were defined with their respective domains: pairs of seeds, signatures, emissions, ternary words, boundaries, compatible histories, and nonadic holonomy. This unit does not reselect any of those data. It constructs the integral charts of the same terminal state and proves their equivalence.

31.4.1 Windows of the oriented trace of length 108

Let

$$\Theta_{108} = \mathbb{Z}/108\mathbb{Z}$$

the observable calendar. Its twelve nonadic windows are

$$E_m = \{9m + 1, \ldots, 9m + 9\}, \qquad 0 \le m < 12.$$

The partition is disjoint and exhaustive:

$$\{1,\dots,108\} = \bigsqcup_{m=0}^{11} E_m.$$

The set of address codes that publish an event is fixed as

$$D_{\mathrm{evt}} = \{2,4,6,8\}.$$

The orientation of the twelve windows is

$$\Sigma_{12} = (+,+,+,-,-,-,+,+,+,-,-,-). \tag{31.2}$$

If d_t is the direction encoded at step t, the signed event of window m is

$$e_m = \Sigma_{12}(m)\,\#\{t \in E_m : d_t \in D_{\mathrm{evt}}\}. \tag{31.3}$$

The formula distinguishes the nonnegative number of events from the sign of the orientation. It does not replace a cardinal direction with a sign: both coordinates remain present in the TPK state.

Definition 31.1 (Enhanced dodecaphonic registration)**.** The record transported by the trace is

$$\mathcal{R}_{12}(x) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)_{m=0}^{11},$$

where τ_m is the TRIT orientation, σ_m the boundary signature, κ_m the carry, and Λ_m the genealogical register segment that preserves the route. There is a chain of projections

$$\mathcal{X}^{\mathrm{enr}}_{\mathrm{TPK}} \longrightarrow \mathcal{R}_{12} \longrightarrow \Theta_{108},$$

but neither of the two arrows is an identification.

In particular, Θ_{108} preserves only the position in the calendar. The record $\mathcal{R}_{12}$ additionally preserves orientation, signature, carry, and provenance. The complete state further preserves cylinder, boundary, quotient, terminal, and vertical memory.

31.4.2 Integral chart of the dodecaphasic opposition

For $0 \le i < 6$, the opposite positions determine

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}. \tag{31.4}$$

The central charge and the five relative margins are

$$s_C = \sum_{i=0}^{5} p_i, \qquad M_i = p_i - p_5 \quad (0 \le i < 5). \tag{31.5}$$

Definition 31.2 (Integral chart $1+5+6$)**.** It is defined

$$\mathcal{L}_{12}(e_0,\dots,e_{11}) = \big(s_C, M_0,\dots,M_4, a_0,\dots,a_5\big). \tag{31.6}$$

The coordinate partition is

$$1+5+6 = 12.$$

Theorem 31.3 (Exact inverse of the integral chart)**.** *A tuple*

$$\ell = (s_C, M_0,\dots,M_4, a_0,\dots,a_5) \in \mathbb{Z}^{12}$$

belongs to the image of $\mathcal{L}_{12}$ if and only if

$$s_C - \sum_{i=0}^{4} M_i \equiv 0 \pmod 6, \tag{31.7}$$

$$p_i \equiv a_i \pmod 2 \quad (0 \le i < 6), \tag{31.8}$$

where

$$p_5 = \frac{s_C - \sum_{i=0}^{4} M_i}{6}, \tag{31.9}$$

$$p_i = p_5 + M_i \quad (0 \le i < 5). \tag{31.10}$$

In that case, the only entire preimage is

$$e_i = \frac{p_i + a_i}{2}, \qquad e_{i+6} = \frac{p_i - a_i}{2}. \tag{31.11}$$

Proof. Summing $M_i = p_i - p_5$ for $0 \le i < 5$, we obtain

$$\sum_{i=0}^{4} M_i = \sum_{i=0}^{4} p_i - 5p_5 = s_C - 6p_5,$$

which forces (31.9) and the congruence modulo six. Once the six p_i have been reconstructed, the system

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}$$

has the unique solution (31.11). This solution is integral exactly when p_i and a_i have the same parity. The two families of congruences are therefore necessary and sufficient. □

This theorem precedes the numerical closure of α. It explains how the oriented trace produces a reversible integral chart, and why preserving the reduced calendar is not enough.

31.4.3 Selection of the common terminal state

The three compatible sections reach terminal depth with catalogs of cardinalities

$$|\mathcal{T}_\pi| = 196, \qquad |\mathcal{T}_e| = 197, \qquad |\mathcal{T}_\varphi| = 196.$$

The product contains

$$196 \cdot 197 \cdot 196 = 7\,567\,952 \tag{31.12}$$

ordered triples.

The column margin of the terminal reader is

$$q_\partial = (1, 2, 2, 1, 2, 0) \in \mathbb{F}_3^6,$$

and the row orientation of the combined channel is

$$\sigma = (1, 1, -1) = (1, 1, 2) \in \mathbb{F}_3^3.$$

The first datum acts on columns; the second acts on rows. Neither is deducible from the other.

The local signatures of Gram matrix, norm, weight, and distance reduce (31.12) to 331 triples. The margin q_∂ leaves two indices:

$$(120, 197, 157), \qquad (129, 197, 148).$$

Their matrices are

$$B_0 = \begin{pmatrix} 0 & 2 & 0 & 2 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}, \qquad B_1 = \begin{pmatrix} 0 & 2 & 1 & 0 & 2 & 0 \\ 0 & 0 & 1 & 2 & 2 & 0 \\ 1 & 0 & 0 & 2 & 1 & 0 \end{pmatrix}.$$

The row sums are

$$(0, 2, 0), \qquad (2, 2, 1).$$

Since

$$\langle \sigma \rangle = \{(0, 0, 0), (1, 1, 2), (2, 2, 1)\},$$

only B_1 satisfies the axial condition.

Theorem 31.4 (Uniqueness of the Visible Terminal Publication)**.** *The joint selection determines*

$$B_{\mathrm{term}} = \begin{pmatrix} 021020 \\ 001220 \\ 100210 \end{pmatrix}, \tag{31.13}$$

corresponding to the triple $(129, 197, 148)$. *No decimal evaluation of α enters the census or the two selection conditions.*

Proof. The census and margin leave exactly B_0, B_1. The charge of B_0 does not belong to $\langle \sigma \rangle$, whereas that of B_1 is 2σ. The second candidate is therefore the only one that simultaneously satisfies both typed requirements. □

31.4.4 2 publications from the same state and absence of retroactive conversion

Let

$$x_{\mathrm{term}} \in \mathcal{X}^{\mathrm{term,enr}}_{\mathrm{TPK}} \subseteq \mathcal{X}^{[108]}_{\mathrm{TPK}}.$$

The visible reading is

$$\pi_{\mathrm{term}}(x_{\mathrm{term}}) = B_{\mathrm{term}}.$$

The signed chart preserves another coordinate of the same state.

Definition 31.5 (Terminal signed causal reading)**.** The domain incorporates neither K nor U as input coordinates. The state x_{term}, produced by the full composition APP $\to$ TRIT $\to$ TPK, contains the enriched terminal register, and the extractor of its twelve oriented windows is

$$R_{12} : \mathcal{X}^{\mathrm{term,enr}}_{\mathrm{TPK}} \longrightarrow \mathcal{R}^{\mathrm{or}}_{12}, \qquad R_{12}(x_{\mathrm{term}}) = \big((E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)\big)^{11}_{m=0}. \tag{31.14}$$

The ledger's channel reader $90/120$ emits, without receiving the result as data,

$$E^{90,120}_{108} : \mathcal{R}^{\mathrm{or}}_{12} \longrightarrow \mathbb{Z}^{12} \times \mathbb{Z}^{12} \times \mathbb{Z}, \qquad E^{90,120}_{108}\big(R_{12}(x_{\mathrm{term}})\big) = (b_{90}, b_{120}, Q_{\mathrm{TPK}}),$$

with

$$\begin{aligned} b_{90} &= (-495, -116, -684, 108, 601, -90, -173, -88, 313, 560, -397, 461), \\ b_{120} &= (-425, -281, -481, 671, -255, 30, 475, -543, 680, 251, 6, -128), \\ Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

For $r = 1, 2, 3$ and $j = 0, 1, 2, 3$, define

$$B_r = \sum_{j=0}^{3} b_{120,r+3j}, \qquad d_{r,j} = b_{90,r+3j},$$
$$A_1 = \frac{Q_{\mathrm{TPK}} + 2B_1 + B_2}{3}, \qquad A_2 = A_1 - B_1, \quad A_3 = A_2 - B_2.$$

The publication Π_H forms the three blocks

$$U^{(r)} = \big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big),$$

and reinterleaves them in dodecaphasic order, that is,

$$\Pi_H(b_{90}, b_{120}, Q_{\mathrm{TPK}}) := \mathrm{reint}_3\big(U^{(1)}, U^{(2)}, U^{(3)}\big) = U.$$

Let $\mathcal{H}_{12}$ be the integral transformation to be constructed in the next section. The publication module is

$$\mathcal{U}^{\mathrm{sgn}}_{12} := \mathrm{im}\big(\mathcal{H}_{12} : \mathbb{Z}^{12} \to \mathbb{Z}^{12}\big). \tag{31.15}$$

The signed reading is, causally, the composition

$$R_{\mathrm{sgn}} := \Pi_H \circ E^{90,120}_{108} \circ R_{12} : \mathcal{X}^{\mathrm{term,enr}}_{\mathrm{TPK}} \longrightarrow \mathcal{U}^{\mathrm{sgn}}_{12}, \qquad R_{\mathrm{sgn}}(x_{\mathrm{term}}) = U. \tag{31.16}$$

Only after this output is $K = \mathcal{H}_{12}^{-1}U$ reconstructed; the identity $U = \mathcal{H}_{12}K$ certifies that reconstruction and does not define the reader's domain.

The correct joint writing is

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} (B_{\mathrm{term}}, U^{\mathrm{sgn}}_{12}). \tag{31.17}$$

No arrow $B_{\mathrm{term}} \to U^{\mathrm{sgn}}_{12}$ is interposed: the visible matrix has forgotten precisely the orientation, opposition, quotient, carry, and genealogical record coordinates used by the signed chart. The source of both publications is the enriched state produced by (31.1).

The evaluation of the signed record gives

$$\boxed{U = (2378, 1406, 2479, -452, 998, -551, -668, -204, -371, -322, -28, -997).} \tag{31.18}$$

31.4.5 Naturality with respect to depth

For $N' \geq N \geq 108$, the truncations of the signed system are

$$\tau^{\mathrm{sgn}}_{N',N} x^{[N']}_{\mathrm{term}} = \tau_{N',N} x^{[N']}_{\mathrm{term}}. \tag{31.19}$$

Therefore, truncation acts only on the history and the enriched state; it does not carry either K or U as independent inputs.

Theorem 31.6 (Square of naturality of the signed reading)**.** *We have*

$$\boxed{R_{\mathrm{sgn},N} \circ \tau^{\mathrm{sgn}}_{N',N} = \mathrm{id}_{\mathcal{U}^{\mathrm{sgn}}_{12}} \circ R_{\mathrm{sgn},N'}.} \tag{31.20}$$

Proof. The naturality of the states literally preserves the first one hundred and eight windows of the ledger:

$$R_{12,N} \circ \tau^{\mathrm{sgn}}_{N',N} = R_{12,N'}.$$

Truncation can modify only the subsequent history. Since $E^{90,120}_{108}$ and Π_H depend exclusively on those windows, both sides return the same U. Commutativity is an equality of maps, not an analogy between diagrams. □

31.4.6 Orbits of step 3 and transform of Hadamard

The cyclic order of the seal is distributed over the three orbits.

$$K^{(1)} = (K_1, K_4, K_7, K_{10}), \tag{31.21}$$

$$K^{(2)} = (K_2, K_5, K_8, K_{11}), \tag{31.22}$$

$$K^{(3)} = (K_3, K_6, K_9, K_{12}). \tag{31.23}$$

Let

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{31.24}$$

If P_{orb} reorders the twelve coordinates according to (31.21)–(31.23), the global transformation is

$$\mathcal{H}_{12} = P_{\mathrm{orb}}^{-1}(H_4 \oplus H_4 \oplus H_4)P_{\mathrm{orb}}. \tag{31.25}$$

The three blocks of (31.18), read by orbits, are

$$U^{(1)} = (2378, -452, -668, -322),$$
$$U^{(2)} = (1406, 998, -204, -28),$$
$$U^{(3)} = (2479, -551, -371, -997).$$

Lemma 31.7 (Algebraic Hadamard quarter-turn)**.** *The matrix H_4 satisfies*

$$H_4^2 = 4I_4, \qquad H_4^{-1} = \frac{1}{4}H_4, \qquad \det H_4 = -16. \tag{31.26}$$

Proof. The rows of H_4 are orthogonal, and each has squared norm four. Since the matrix is symmetric, $H_4^{\mathsf{T}}H_4 = H_4^2 = 4I_4$. The formula for the inverse and the determinant follow immediately. □

Theorem 31.8 (Unique full reconstruction of the seal)**.** *The inverse*

$$K^{(r)} = \frac{1}{4}H_4U^{(r)} \qquad (r = 1, 2, 3) \tag{31.27}$$

yields

$$K^{(1)} = (234, 729, 621, 794),$$
$$K^{(2)} = (543, 659, 058, 146),$$
$$K^{(3)} = (140, 824, 914, 601).$$

By undoing the orbital order one obtains

$$\boxed{K = (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601).} \tag{31.28}$$

It is the unique rational preimage of U, and it belongs to $\mathbb{Z}^{12}$.

Proof. By (31.26), the rational preimage is unique. The explicit multiplications are

$$\begin{aligned} H_4U^{(1)} &= (936, 2916, 2484, 3176), \\ H_4U^{(2)} &= (2172, 2636, 232, 584), \\ H_4U^{(3)} &= (560, 3296, 3656, 2404). \end{aligned}$$

All coordinates are divisible by four. Dividing and reinterleaving yields (31.28). □

The factor $1/4$ is not chosen to fit an output: it is the inverse forced by $H_4^2 = 4I_4$. Nor is it the square root of -1. The internal complex structure $A_W^2 = -I$ will appear after constructing the Paley matrix; these are two facts of different types.

31.4.7 Integral structure and Smith normal form

Theorem 31.9 (Integral image of H_4)**.** *The Smith normal form is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4). \tag{31.29}$$

Consequently,

$$\operatorname{coker} \mathcal{H}_{12} \cong (\mathbb{Z}/2\mathbb{Z})^6 \oplus (\mathbb{Z}/4\mathbb{Z})^3, \tag{31.30}$$

and the image of $\mathcal{H}_{12}$ has index

$$16^3 = 4096$$

in $\mathbb{Z}^{12}$. For $u \in \mathbb{Z}^4$,

$$u \in H_4\mathbb{Z}^4 \quad \Longleftrightarrow \quad H_4 u \equiv 0 \pmod 4. \tag{31.31}$$

Proof. The greatest common divisor of the entries is one. The minors of order two are even, and one has absolute value two; those of order three are multiples of four, and one has absolute value four; the determinant has modulus sixteen. The determinantal divisors are $1, 2, 4, 16$, yielding the invariant factors $1, 2, 2, 4$. The triple direct sum repeats the factors and multiplies the indices. Finally, $H_4^{-1} = H_4/4$, so the preimage is integral exactly under the congruence (31.31). □

31.4.8 Certification and reconstruction by differences of steps 3 and 4

Once the ledger has emitted $(b_{90}, b_{120}, Q_{\mathrm{TPK}})$, Π_H has produced U and Hadamard has reconstructed K, the following coordinates act downstream as an independent certificate of those prior outputs. With cyclic indices modulo twelve, define

$$(D_3K)_m = K_m - K_{m+3}, \qquad (D_4K)_m = K_m - K_{m+4}, \qquad Q(K) = \sum_{m=1}^{12} K_m. \tag{31.32}$$

For (31.28), one verifies

$$\begin{aligned} D_3K = b_{90} = (&-495, -116, -684, 108, 601, -90, \\ &-173, -88, 313, 560, -397, 461), \\ D_4K = b_{120} = (&-425, -281, -481, 671, -255, 30, \\ &475, -543, 680, 251, 6, -128), \\ Q(K) = Q_{\mathrm{TPK}} &= 6263. \end{aligned}$$

Theorem 31.10 (Completeness of the transversal extractor)**.** *The operator*

$$\mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q) : \mathbb{Z}^{12} \longrightarrow \mathbb{Z}^{25}$$

has rank twelve and Smith normal form

$$\mathrm{SNF}(\mathcal{E}_{\mathrm{dod}}) = \mathrm{diag}(\underbrace{1, \ldots, 1}_{11}, 12). \tag{31.33}$$

In particular, $(D_3K, D_4K, Q(K))$ *determines a unique* K*. This uniqueness certifies and reconstructs the data already emitted by the ledger; it neither generates nor selects them.*

Proof. If $D_3 v = D_4 v = 0$, then v is constant along steps three and four. Since $\gcd(3, 4) = 1$, those steps generate all of $\mathbb{Z}/12\mathbb{Z}$, so that

$$\ker D_3 \cap \ker D_4 = \langle \mathbf{1} \rangle.$$

The total charge does not vanish on that line, since $Q(\mathbf{1}) = 12$. The rank is twelve. The rows of (D_3, D_4) are oriented incidences of a connected Cayley graph; a spanning tree supplies eleven unit invariant factors. Every maximal minor must contain the row Q, and the unimodular operations reduce its final contribution to twelve. There is a maximal minor of modulus twelve; therefore, the last factor is exactly twelve. □

The certifying reconstruction of U from these coordinates reproduces the prior publication of Π_H and does not require multiplying again by H_4. For $r = 1, 2, 3$, let

$$B_r = \sum_{j=0}^{3} (D_4 K)_{r+3j} = \sum_{j=0}^{3} b_{120, r+3j}. \tag{31.34}$$

Then

$$(B_1, B_2, B_3) = (972, -1073, 101).$$

Orbital sums are

$$A_1 = \frac{Q + 2B_1 + B_2}{3} = 2378, \tag{31.35}$$

$$A_2 = A_1 - B_1 = 1406, \tag{31.36}$$

$$A_3 = A_2 - B_2 = 2479. \tag{31.37}$$

If $d_{r,j} = (D_3 K)_{r+3j} = b_{90, r+3j}$, the signed block of orbit r is

$$\big(A_r, d_{r,1} - d_{r,3}, d_{r,0} + d_{r,2}, d_{r,0} - d_{r,2}\big), \tag{31.38}$$

which reproduces the three blocks $U^{(r)}$ already published by Π_H.

31.4.9 Threshold Tetrad of the Seal

The local decimal completion satisfies

$$1000 = 729 + 271.$$

The support of the seal coordinates that reach the threshold 729 is

$$\boxed{B_K := \{m : K_m \geq 729\} = \{4, 6, 9, 10\}.} \tag{31.39}$$

This tetrad is obtained after constructing K. In this unit it is not yet called a Witt star: that object will be defined only after constructing the ternary code, its hexads, and the Steiner system.

31.4.10 Causal independence with respect to the physical output

Theorem 31.11 (Isolation of U and K)**.** *The composition*

$$\Omega_{\mathrm{seed}} \longrightarrow x_{\mathrm{term}} \xrightarrow{R_{\mathrm{sgn}}} U \xrightarrow{\mathcal{H}_{12}^{-1}} K \tag{31.40}$$

does not receive α, α^{-1}, CODATA or a target decimal string as input. The seal K is determined before defining the recurrence that will produce α.

Proof. The first part of the composition uses only seeds, emissions, ternary readers, L_0, L_1 operators, survival relations, phase transport and the charts of the TPK state. The reading $R_{\mathrm{sgn}} = \Pi_H \circ E_{108}^{90,120} \circ R_{12}$ is the causal composition of the terminal register, and the last arrow is the linear transformation $\mathcal{H}_{12}^{-1} = \mathcal{H}_{12}/4$ on its integral image. None of the formulas contains a physical variable or a metrological table. The base-one-thousand recurrence is introduced only in the next unit, after K has been fixed. □

31.4.11 Obstructions of the dodecaphasic closure: seal, carry, reversibility and non-circularity

Remark 31.12 (Certificate and validity control: Refutation of the record and the seal). The construction is refuted if any of the following facts is verified:

1. the windows E_m do not partition the one hundred eight steps;
2. the chart $\mathcal{L}_{12}$ fails its inverse or its congruences;
3. the terminal census does not produce 331 triples, two matrices and a unique axial charge;
4. an attempt is made to obtain U from B_{term} after forgetting the signed coordinates;
5. the naturality square (31.20) fails;
6. $H_4^2 \neq 4I_4$, some preimage is not integral or the reconstructed vector differs from (31.28);
7. the Smith normal form differs from (31.29);
8. the certificate (D_3, D_4, Q) loses rank, does not match the ledger's prior emissions or does not reproduce U;
9. B_K is introduced before constructing K, or is assigned a Witt structure before defining W_{12};
10. a digit of α or a metrological reference intervenes in any of the arrows of (31.40).

31.5 Coinductive prolongation of the dodecaphase cocycle and compatibility of the boundary 662/663

31.5.1 Aritmetic closure domain

The construction receives four dodecaphasic coordinates obtained in the preceding units:

$$\begin{aligned} P &= (141, 592, 653, 589, 793, 238, 462, 643, 383, 279, 502, 884),\\ E &= (718, 281, 828, 459, 045, 235, 360, 287, 471, 352, 662, 497),\\ \Phi &= (618, 033, 988, 749, 894, 848, 204, 586, 834, 365, 638, 117),\\ K &= (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \end{aligned}$$

The first three vectors are the first twelve triads of the fractional Archimedean readings of π, e, and φ. The fourth is the dodecaphase coordinate of the enriched terminal state of the Topological Phase Kernel, constructed before the carry operation is opened.

We fix the base.

$$B := 10^3 = 1000$$

and the concatenation

$$\iota(v_1, \dots, v_{12}) := \sum_{m=1}^{12} v_m B^{12-m}. \tag{31.41}$$

In particular,

$$\begin{aligned}
\iota(P) &= 141592653589793238462643383279502884,\\
\iota(E) &= 718281828459045235360287471352662497,\\
\iota(\Phi) &= 618033988749894848204586834365638117,\\
\iota(K) &= 234543140729659824621058914794146601.
\end{aligned}$$

The operation studied in this unit is the map

$$\mathfrak{C}_{12} : (P, E, \Phi, K, c_{13}) \longmapsto (A, C), \tag{31.42}$$

where $A = (A_1, \dots, A_{12})$ is the output word and

$$C = (c_1, \dots, c_{13})$$

is the complete system of thirteen Euclidean quotients: twelve internal quotients and one right boundary condition.

31.5.2 Left-to-right oriented Euclidean division

For $m = 12, 11, \dots, 1$, define

$$\begin{aligned}
s_m &:= P_m + E_m - \Phi_m - K_m + c_{m+1},\\
A_m &:= s_m \bmod B, \qquad 0 \le A_m < B,\\
c_m &:= \frac{s_m - A_m}{B} = \left\lfloor \frac{s_m}{B} \right\rfloor.
\end{aligned} \tag{31.43}$$

The second equality for c_m is also valid when $s_m < 0$, because Euclidean division with remainder in $\{0, \dots, B-1\}$ is used. Therefore,

$$-431 = 569 - 1000, \qquad -717 = 283 - 1000, \qquad -1200 = 800 - 2 \cdot 1000,$$

and negative loans do not introduce ambiguity.

Theorem 31.13 (Existence and Uniqueness of the Oriented Carry)**.** *Given P, E, Φ, K and the terminal carry c_{13}, the recurrence* (31.43) *uniquely determines*

$$(A_1, \dots, A_{12}; c_1, \dots, c_{12}).$$

Proof. Row $m = 12$ is determined by the Euclidean division of

$$P_{12} + E_{12} - \Phi_{12} - K_{12} + c_{13}$$

by B. Once c_{12} is known, row $m = 11$ is determined by the same property. Descending induction reaches $m = 1$. At each step, uniqueness of the Euclidean quotient and remainder prevents two distinct outputs. □

31.5.3 Finite domain of the dodecaphonic closure

The finite window is defined by the terminal condition

$$c_{13}^{\mathrm{fin}} = 0.$$

The complete evaluation is as follows. The table is printed in ascending order, although it must be read causally from the last row to the first.

Table 31.1: The twelve Euclidean divisions and thirteen carries of the finite dodecaphasic window.

m	P_m	E_m	Φ_m	K_m	c_{m+1}	s_m	A_m	c_m
1	141	718	618	234	0	7	007	0
2	592	281	033	543	0	297	297	0
3	653	828	988	140	−1	352	352	0
4	589	459	749	729	−1	−431	569	−1
5	793	045	894	659	−2	−717	283	−1
6	238	235	848	824	−1	−1200	800	−2
7	462	360	204	621	0	−3	997	−1
8	643	287	586	058	−1	285	285	0
9	383	471	834	914	−1	−895	105	−1
10	279	352	365	794	0	−528	472	−1
11	502	662	638	146	0	380	380	0
12	884	497	117	601	0	663	663	0

The complete word of thirteen carries is

$$\boxed{C^{\mathrm{fin}} = (c_1, \dots, c_{13}) = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, 0).}$$

The dodecaphasic output is

$$\boxed{A^{\mathrm{fin}} = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663).}$$

We define the finite rational

$$\boxed{\alpha_{12}^{\mathrm{fin}} := 10^{-36}\iota(A^{\mathrm{fin}}) = \frac{729735256928380099728510547238 0663}{10^{36}}.} \tag{31.44}$$

Therefore,

$$\alpha_{12}^{\mathrm{fin}} = 0.007297352569283800997285105472380663.$$

31.5.4 Posterior metrological recognition: CODATA 2018

The metrological comparison is performed only after closing the recurrence, the right boundary, and the preceding rational. The integer identity gives

$$\boxed{\alpha_{12}^{\mathrm{fin}} = 10^{-36}\left\lfloor \frac{10^{36}}{137.035999084} \right\rfloor.} \tag{31.45}$$

Consequently,

$$(\alpha_{12}^{\mathrm{fin}})^{-1} = 137.035999084000000000000000000000001066588\ldots, \tag{31.46}$$

and exactly reproduces the central chain published by CODATA 2018 [122]:

$$\boxed{137.035999084.}$$

The word *exactly* refers to the published central chain, not to a purported experimental measurement of thirty-six digits. The subsequent digits in (31.46) are consequences of the HMT rational already fixed. CODATA does not select the state, does not determine (K), does not decide the direction of the carry, and does not intervene in the dodecaphase table.

31.5.5 Complete affine identity

Each row of the table satisfies exactly

$$P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + Bc_m. \tag{31.47}$$

Introducing

$$C^- := (c_1, \dots, c_{12}), \qquad C^+ := (c_2, \dots, c_{13}),$$

the twelve local identities come together in

$$\boxed{P + E - \Phi - K + C^+ - BC^- = A.} \tag{31.48}$$

The term

$$\partial_B C := C^+ - BC^-$$

is the carry cocycle of the oriented chain. Consequently, $P + E - \Phi - K = A$ is not a coordinatewise equality in $\mathbb{Z}^{12}$: it becomes correct only upon incorporating $\partial_B C$.

Theorem 31.14 (Telescoping of the Thirteen Carries)**.** *For any terminal condition c_{13}, the recurrence satisfies*

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A) = B^{12}c_1 - c_{13}.} \tag{31.49}$$

In the finite window, $c_1 = c_{13} = 0$, and therefore

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) = \iota(A^{\mathrm{fin}}).} \tag{31.50}$$

Proof. We multiply (31.47) by B^{12-m} and sum over $m = 1, \dots, 12$. The contribution of the carries is

$$\sum_{m=1}^{12} (Bc_m - c_{m+1})B^{12-m}.$$

The internal components cancel:

$$\begin{aligned}\sum_{m=1}^{12} (Bc_m - c_{m+1})B^{12-m} &= \sum_{m=1}^{12} c_m B^{13-m} - \sum_{m=1}^{12} c_{m+1}B^{12-m} \\ &= B^{12}c_1 - c_{13}.\end{aligned}$$

This proves (31.49). The specialization $c_1 = c_{13} = 0$ gives (31.50). □

31.5.6 Exact inversion of the seal K

The local recurrence is reversible. Solving for K_m in (31.47),

$$\boxed{K_m = P_m + E_m - \Phi_m + c_{m+1} - A_m - Bc_m.} \tag{31.51}$$

By concatenation,

$$\boxed{\iota(K) = \iota(P) + \iota(E) - \iota(\Phi) - \iota(A) - B^{12}c_1 + c_{13}.} \tag{31.52}$$

On the finite boundary,

$$\iota(K) = \iota(P) + \iota(E) - \iota(\Phi) - \iota(A^{\mathrm{fin}}).$$

Algebraic reversibility does not invert the causal order. The effective order is

$$x_{\mathrm{term}} \longrightarrow K \longrightarrow (P, E, \Phi, K, c_{13}) \longrightarrow (A, C).$$

Formula (31.51) is a commutativity check: it proves that the output and the carries recover the seal that was already fixed. It is not a rule for retrospectively selecting K from a desired value of α.

31.5.7 Coinductive prolongation of the dodecaphasic seal and inverse carry recurrence in $C = \{-2, -1, 0, 1, 2\}$

Let

$$(P_k)_{k\geq 1}, \qquad (E_k)_{k\geq 1}, \qquad (\Phi_k)_{k\geq 1}$$

the infinite sequences of triads produced by the three coinductive branches, and let

$$\kappa(k) := 1 + ((k-1) \bmod 12).$$

The prolongation of the stamp is periodic:

$$K^{\mathrm{per}}_k := K_{\kappa(k)}.$$

For a finite depth N and a terminal condition $t = c_{N+1}$, the recurrence is

$$\begin{aligned} s^{(N,t)}_k &= P_k + E_k - \Phi_k - K_{\kappa(k)} + c^{(N,t)}_{k+1}, \\ A^{(N,t)}_k &= s^{(N,t)}_k \bmod 1000, \\ c^{(N,t)}_k &= \left\lfloor \frac{s^{(N,t)}_k}{1000} \right\rfloor, \qquad k = N, \dots, 1. \end{aligned} \tag{31.53}$$

The set of terminal carries

$$C := \{-2, -1, 0, 1, 2\}$$

is invariant for the certified inputs: for each triad and each $c_{k+1} \in C$, the quotient c_k again belongs to C. No favorable terminal condition is chosen. All five conditions are propagated, and only the prefix common to all of them is published.

The execution of certified depth employs

quantity	value
ternary blocks per channel	3501
trits per channel	$3501 \cdot 6 = 21006$
guard decimal digits	10020
guard triads	3340
propagated terminal conditions	5
common triads	3339
common digits	10017
published digits	10000

The five terminal branches coalesce before the published prefix. In particular, no terminal condition extracted from a target value of α intervenes in the output.

Theorem 31.15 (Stabilized Output Compatibility)**.** *Let $A^{[N]}$ and $A^{[N']}$, with $N' > N$, be two runs whose five terminal conditions have coalesced before position N. Then the truncation of $A^{[N']}$ to its first N*

blocks coincides with $A^{[N]}$. The stabilized prefixes define a unique section in the inverse limit of finite words.

Proof. The recurrence is deterministic from right to left once the carry entering a position is known. Coalescence asserts that all remote conditions produce the same carry before the boundary of the prefix. From that point, the same triads P_k, E_k, Φ_k and the same periodic seal produce, by Euclidean uniqueness, the same remainders and quotients at all preceding positions. This is exactly commutativity with truncation. □

31.5.8 Boundary originating from the remote tail

The prolongation determines on the visible boundary.

$$c^{\infty}_{13} = -1.$$

The twelve internal carries remain the same as in the finite window:

$$\boxed{C^{\infty}_{\le 13} = (0, 0, 0, -1, -1, -2, -1, 0, -1, -1, 0, 0, -1).}$$

Only the information entering from the thirteenth triad changes. The two relevant divisions are

$$\begin{aligned} s^{\infty}_{12} &= 884 + 497 - 117 - 601 - 1 = 662, \\ A^{\infty}_{12} &= 662, \qquad c^{\infty}_{12} = 0, \end{aligned}$$

and

$$\begin{aligned} s^{\infty}_{13} &= 197 + 757 - 720 - 234 - 1 = -1, \\ A^{\infty}_{13} &= 999, \qquad c^{\infty}_{13} = -1. \end{aligned}$$

Therefore, the beginning of the prolonged word is

$$\boxed{A^{\infty} = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 662, 999, \ldots).}$$

The corresponding expansion begins

$$\boxed{\alpha_{\infty} = 0.007297352569283800997285105472380662999564172539642\ldots.} \tag{31.54}$$

The difference between both boundaries is local and exact:

$$c^{\mathrm{fin}}_{13} - c^{\infty}_{13} = 1, \qquad A^{\mathrm{fin}}_{12} - A^{\infty}_{12} = 1,$$

while

$$A^{\mathrm{fin}}_{m} = A^{\infty}_{m}, \qquad 1 \le m \le 11.$$

Applying the telescoping theorem to the first twelve blocks of the prolongation,

$$\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) - \iota(A^{\infty}_{\le 12}) = -c^{\infty}_{13} = 1.$$

Then

$$\boxed{\iota(A^{\mathrm{fin}}) = \iota(A^{\infty}_{\le 12}) + 1.} \tag{31.55}$$

The ending 663 does not contradict the ending 662: the former is the finite representative obtained by closing the window with $c_{13} = 0$; the latter retains the carry -1 from the remote tail.

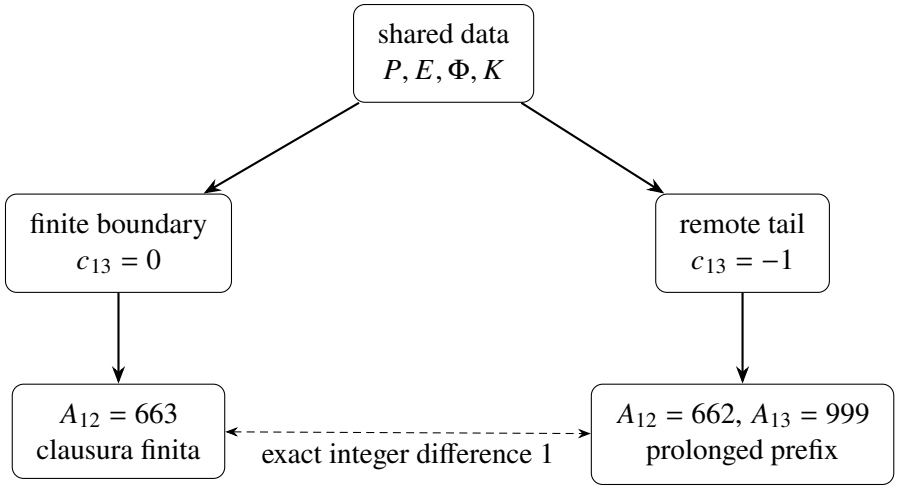

Figure 31.1: Boundary bifurcation of a single recurrence. Two distinct generators are not being compared: only the datum entering from the right changes.

31.5.9 Truncamiento compatible and rewhereo certified to 36 digits

For $x \geq 0$, define

$$\mathrm{Tr}_{36}(x) := 10^{-36} \lfloor 10^{36} x \rfloor$$

and

$$\mathrm{Rd}_{36}(x) := 10^{-36} \left\lfloor 10^{36} x + \frac{1}{2} \right\rfloor.$$

Let

$$a := 729735256928380099728510547238066 2.$$

The expansion (31.54) can be written as

$$\alpha_\infty = \frac{a + \rho}{10^{36}}, \qquad \rho = 0.999564172539642709\ldots,$$

so that $0.999 < \rho < 1$.

Theorem 31.16 (Exact resolution of the boundary 662/663)**.** *The coinductive prolongation satisfies*

$$\boxed{\mathrm{Tr}_{36}(\alpha_\infty) = 0.007297352569283800997285105472380662,}$$

while its rounding to thirty-six digits satisfies

$$\boxed{\mathrm{Rd}_{36}(\alpha_\infty) = 0.007297352569283800997285105472380663 = \alpha_{12}^{\mathrm{fin}}.}$$

Proof. Since $0 \leq \rho < 1$,

$$\lfloor 10^{36} \alpha_\infty \rfloor = a.$$

This gives the truncation ending in 662. Since $\rho > 1/2$,

$$\left\lfloor 10^{36} \alpha_\infty + \frac{1}{2} \right\rfloor = a + 1,$$

which ends in 663. By (31.44), $(a + 1)10^{-36}$ is exactly $\alpha_{12}^{\mathrm{fin}}$. □

Moreover,

$$0 < \alpha_{12}^{\mathrm{fin}} - \alpha_\infty = \frac{1-\rho}{10^{36}} < 10^{-39}.$$

The difference is not an arithmetic error in the table: it quantifies the difference between two distinct boundary operators.

31.5.10 Causal isolation from α and metrological data

At depth N, the full domain of the operation is

$$\mathscr{D}_N = \big((P_k)_{k=1}^N, (E_k)_{k=1}^N, (\Phi_k)_{k=1}^N, K, c_{N+1}\big).$$

The carry map

$$\mathfrak{C}_N : \mathscr{D}_N \longrightarrow \{0,\dots,999\}^N \times C^N$$

is defined exclusively by (31.53). Its domain contains no target value of α, its inverse, a metrological table, a target decimal string or a terminal carry chosen by comparison.

Theorem 31.17 (No interference from the metrological target)**.** *Let $\mathscr{Y}$ be any space of external data containing metrological values or comparison tables. The formal extension*

$$\widetilde{\mathfrak{C}}_N : \mathscr{D}_N \times \mathscr{Y} \longrightarrow \{0,\dots,999\}^N \times C^N, \qquad \widetilde{\mathfrak{C}}_N(d,y) := \mathfrak{C}_N(d),$$

factorizes by the projection

$$\mathrm{pr}_{\mathscr{D}_N} : \mathscr{D}_N \times \mathscr{Y} \longrightarrow \mathscr{D}_N.$$

Therefore, for any $y, y' \in \mathscr{Y}$,

$$\widetilde{\mathfrak{C}}_N(d,y) = \widetilde{\mathfrak{C}}_N(d,y').$$

No intervention on a value of α or a metrological table alters K, the quotients, the remainders or the prefix produced.

Proof. The statement results from

$$\widetilde{\mathfrak{C}}_N = \mathfrak{C}_N \circ \mathrm{pr}_{\mathscr{D}_N}.$$

All operations of $\mathfrak{C}_N$ are additions, subtractions and Euclidean divisions of the elements of $\mathscr{D}_N$. No coordinate of $\mathscr{Y}$ appears in them. □

The complete causal order is

$$\text{enriched branches of } \pi, e, \varphi \longrightarrow (P, E, \Phi),$$

$$x_{\mathrm{term}} \longrightarrow K,$$

$$(P, E, \Phi, K, \text{boundary}) \longrightarrow (A, C) \longrightarrow \alpha_\infty,$$

$$\alpha_\infty \longrightarrow \text{external comparison}.$$

The last arrow cannot be reversed to select any of the previous ones.

31.5.11 Exact obstructions of the prolongation: boundary, truncation, and causal isolation

Remark 31.18 (Certificate and validity control: Refutation of the affine closure and its prolongation). The block is refuted in its domain if any of the following events occurs:

1. some row of the table 31.1 fails to satisfy $s_m = A_m + 1000c_m$;
2. the published vector of thirteen carries does not reproduce the twelve rows;

3. the telescoping identity fails

$$\iota(P)+\iota(E)-\iota(\Phi)-\iota(K)-\iota(A)=1000^{12}c_1-c_{13};$$

4. the inversion (31.51) does not recover the twelve coordinates of K;
5. remote propagation produces $c_{13}\neq -1$ for the certified prefix;
6. the five terminal conditions of $C=\{-2,-1,0,1,2\}$ do not coalesce before the published digits;
7. the triad following 662 is not 999, in which case the identification of the rounding with 663 is no longer proved;
8. the generator opens a target expansion of α, its inverse, a metrological table, or a terminal condition chosen to force the coincidence.

Thus, two distinct boundary identities are thereby demonstrated:

$$\boxed{663 = \text{finite closure with } c_{13}=0 = \text{rounding to 36 digits of } \alpha_\infty,}$$

$$\boxed{662 = \text{truncation to 36 digits of } \alpha_\infty \quad \text{with} \quad c_{13}=-1,\ A_{13}=999.}$$

The central metrological result is finally published in the same residence as the derivation:

$$\boxed{\begin{array}{c}(\alpha_{12}^{\mathrm{fin}})^{-1}=137.035999084000000000000000000000001066588\ldots,\\ \text{central CODATA 2018 string:}\qquad 137.035999084.\end{array}} \tag{31.56}$$

The implication expresses a subsequent comparison with the central string published; it does not introduce that string into the constructor.

The closure of α does not begin with a metrological constant or with a sought decimal string. It begins in the same enriched terminal state that preserves the genealogy of the three channels. This section presents, within a single causal chain, two routes to the scale of α and a long prolongation of the carry of the first. The remote prolongation is denoted by $\mathsf{T}_{\alpha,\infty}$; it constitutes neither a second route nor a third derivation.

31.5.12 Terminal and dodecaphase evaluations of the common enriched state: blocks B_{term} and signed chart U_{12}^{sgn}

Let

$$x_{\mathrm{term}}\in \mathcal{X}_{\mathrm{TPK}}^{\mathrm{term,enr}}\subseteq \mathcal{X}_{\mathrm{TPK}}^{[108]}.$$

The terminal selector and the signed chart are two evaluations of the same state:

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}},R_{\mathrm{sgn}})} \big(B_{\mathrm{term}},U_{12}^{\mathrm{sgn}}\big), \tag{31.57}$$

with

$$B_{\mathrm{term}}=\begin{pmatrix}021020\\001220\\100210\end{pmatrix}$$

and

$$U_{12}^{\mathrm{sgn}}=(2378,1406,2479,-452,998,-551,-668,-204,-371,-322,-28,-997).$$

The first reading retains the three selected terminal blocks; the second retains the signed integer coordinate required for dodecaphase closure. No factorization from B_{term} to U_{12}^{sgn} exists or is needed. Drawing

one would erase precisely the fields of orientation, carry, boundary, and ledger that distinguish the two readings. From the second, however, the reversible charts have been constructed

$$U_{12}^{\mathrm{sgn}} \xleftrightarrow{\mathcal{H}_{12}} K \xleftrightarrow{\mathcal{E}_{\mathrm{dod}}} (D_3K, D_4K, Q), \qquad \mathcal{E}_{\mathrm{dod}} = (D_3, D_4, Q).$$

The domain of this closure is therefore the enriched TPK profile; a raw trace of 108 positions is a forgetful projection and does not replace that domain.

31.5.13 Reversible generation of α_{HMT} through the integral dodecaphasic closure

The Archimedean evaluations of the three channels and the canonical seal are the twelve-block vectors

$$\begin{aligned} P &= (141, 592, 653, 589, 793, 238, 462, 643, 383, 279, 502, 884),\\ E &= (718, 281, 828, 459, 045, 235, 360, 287, 471, 352, 662, 497),\\ \Phi &= (618, 033, 988, 749, 894, 848, 204, 586, 834, 365, 638, 117),\\ K &= (234, 543, 140, 729, 659, 824, 621, 058, 914, 794, 146, 601). \end{aligned}$$

With the declared right boundary $c_{13} = 0$, Euclidean division propagates from right to left:

$$\begin{aligned} s_m &= P_m + E_m - \Phi_m - K_m + c_{m+1},\\ A_m &= s_m \bmod 1000,\\ c_m &= \frac{s_m - A_m}{1000}, \qquad m = 12, 11, \ldots, 1. \end{aligned} \tag{31.58}$$

The output is

$$A = (007, 297, 352, 569, 283, 800, 997, 285, 105, 472, 380, 663)$$

and fixes the rational

$$\alpha_{12} = 0.007297352569283800997285105472380663. \tag{31.59}$$

The abbreviated equality $P + E - \Phi - K = A$ must be read in the chart of integer concatenation. If

$$\iota(v_1, \ldots, v_{12}) = \sum_{m=1}^{12} v_m 1000^{12-m},$$

then

$$\boxed{\iota(P) + \iota(E) - \iota(\Phi) - \iota(K) = \iota(A)}. \tag{31.60}$$

In coordinates, the cocycle cannot be omitted:

$$P + E - \Phi - K + C^{+} - 1000C = A, \qquad C^{+} = (c_2, \ldots, c_{13}).$$

The termination $\ldots|380|663$ belongs to this finite window and its condition $c_{13} = 0$. The complete theorem, the table of the twelve carries, and the inversion that recovers K reside in the preceding chapter; they are not duplicated here.

This route is an exact internal result with explicit starting structure: it receives x_{term}, its signed reading, P, E, Φ, the reversible seal, and the boundary. It does not receive α or CODATA as input. Metrological comparison opens only after (31.59) has been obtained.

31.5.14 Simple root ξ_9 of the analytic kernel of order 9 and exact comparison $\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9(\alpha_{\mathrm{HMT}}^{-1})$

The second route does not invert the charts of K. It starts from the exact density of vacancy

$$\varepsilon_{\mathrm{v}} = \log_{10}\left(\frac{10}{9}\right)$$

and of the declared analytic kernel

$$\mathcal{P}(x) = 2\pi x - \frac{7}{4}x^2 + \frac{x^3}{2\pi} + \frac{x^4}{20} - \frac{2x^5}{21} - \frac{x^6}{46}. \tag{31.61}$$

The problem is to solve

$$\mathcal{P}(x) = \log_{10}\left(\frac{10}{9}\right), \qquad 0 < x < 10^{-2}. \tag{31.62}$$

The theorem of monotonia of the nucleo istablece the uniqueness of the root positive and the encierro

$$0.00729735256928379955 < x_{21/22} < 0.00729735256928379957.$$

Its inverse is

$$x_{21/22}^{-1} = 137.035999084000027020090128259874 9\ldots. \tag{31.63}$$

Consequently, the full kernel $E_{21/22}$, generated by the second reader of the same enriched state, determines, as a simple and unique positive root, the same limit section as the dodecaphasic path:

$$\boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}, \qquad \alpha_B = \operatorname*{arg\,zero}_{x \in I_\alpha} E_{21/22}(x).$$

The finite rational α_{12} and the root of the jet $\mathcal{P} = P_6$ are finite projections of the two compatible families; their difference beyond the printed resolution does not constitute a difference between the two limit sections. The nested root intervals and the commutative truncation squares coordinate both prolongations at every depth.

The six coefficients of P_6 are not reconstructed from the root or taken from a metrological table: they are the first jet of the kernel $E_{21/22}$ produced by the internal reader with genealogy $120/45/11/495$ and prolongation $T_{7:9}$. The uniqueness of the root and the internal derivation of the coefficients are distinct stages of the same already closed path B.

31.5.15 Prolongation coinductive $\mathsf{T}_{\alpha,\infty}$ of the entire dodecaphasic closure

$\mathsf{T}_{\alpha,\infty}$ extends the recurrence of (31.58) to a chain of length N. To avoid an ambiguity of indices, let $\kappa(k) = 1 + ((k-1) \bmod 12)$. With a terminal condition at the remote endpoint one computes

$$\begin{aligned} s_k &= P_k + E_k - \Phi_k - K_{\kappa(k)} + c_{k+1}, \\ A_k &= s_k \bmod 1000, \\ c_k &= \left\lfloor \frac{s_k}{1000} \right\rfloor, \qquad k = N, N-1, \ldots, 1. \end{aligned} \tag{31.64}$$

The finite case $N = 1000$ uses one thousand triads, that is, three thousand digits. The carry arriving from the remote end modifies the twelfth visible block:

$$\begin{aligned} \text{short dodecaphasic window, } c_{13} = 0 \quad &: \quad \ldots|380|663, \\ \text{extension } \mathsf{T}_{\alpha,\infty} \text{ of one thousand triads} \quad &: \quad \ldots|380|662|999\ldots. \end{aligned}$$

They are not two rival values. They are two boundary semantics of the same carry law: the first closes at position twelve; the second transports to it information proceeding from a remote tail.

The reproducible calculation verifies the long word exactly using P, E, Φ as correlated projections of the same joint APP–TRIT–TPK coinductive state that also publishes the dodecaphasic coordinate α_{HMT}. Therefore, that execution certifies carry propagation: it does not place π, e, φ earlier in the genealogy or add α from outside. The joint projection

$$\mathcal{G}_9^{\mathrm{joint}} \longrightarrow (\pi, e, \varphi, \mathsf{T}_{\alpha,\infty})$$

factors through the section 31.6: the three Archimedean channels and the dodecaphasic channel open from the same enriched state; (31.64) is then executed and the independence of the prefix from the five terminal carry conditions is verified. The separation of projections prevents the long recurrence from retrospectively selecting its initial data.

31.5.16 Causal coordination of dodecaphase closure and the $E_{21/22}$ characterization: domains, codomains, and uniqueness

The classification of this block is fixed as follows:

Generative branch A: dodecaphasic closure.
It receives the enriched terminal state, the signed chart, the seal, the three evaluations, and the explicit boundary; it produces the rational (31.59) by means of the integer identity with carry.

analytic-characterization branch: equation $E_{21/22}$.
For the declared kernel, monotonicity and the sign change determine a unique root in $(0, 10^{-2})$. The root does not retrospectively determine the six coefficients of the kernel.

Prolongation $\mathsf{T}_{\alpha,\infty}$.
The long recurrence receives the thousand reference triads, the periodic seal, and the remote boundary, and transports the carry to the visible window. It does not constitute the analytic-characterization branch.

$\mathcal{G}_9 \to \mathsf{T}_{\alpha,\infty}$ composition.
Joint rational arithmetic produces ten thousand digits, executes the carry recurrence, and then verifies prefix stability under the declared terminal conditions.

The terminal selector, the reversible charts, and the short recurrence are proved in section 30.12; the existence and uniqueness of the second route in (31.61)–(31.63); and the long composition in section 31.6. The computational supplement reproduces the finite enumerations and terminal conditions; the proof rests on the identities and recurrences presented here.

The public causal order is thus closed:

$$x_{\mathrm{term}} \xrightarrow{(\pi_{\mathrm{term}}, R_{\mathrm{sgn}})} (B_{\mathrm{term}}, U_{12}^{\mathrm{sgn}}) \longrightarrow \begin{cases} \text{path A: dodecaphasic integer closure,} \\ \text{path B: kernel root } E_{21/22}, \end{cases}$$

with $\mathsf{T}_{\alpha,\infty}$ as remote prolongation of the generative branch and not as an additional branch. Only after these outputs is external metrological recognition opened.

31.6 Composition of the holonomy G_9 with the chart T_1 and arbitrary-precision certificate for α_{HMT}

The T1 prolongation applies the carry recurrence to the triads P_k, E_k, Φ_k previously produced by G9 and to the declared dodecaphasic coordinate K:

$$s_k = P_k + E_k - \Phi_k - K_{k \bmod 12} + c_{k+1}, \tag{31.65}$$

$$A_k = s_k \bmod 1000, \tag{31.66}$$

$$c_k = \left\lfloor \frac{s_k}{1000} \right\rfloor. \tag{31.67}$$

The input domain contains the ternary outputs generated by G9; it does not contain a decimal expansion of α, a value of α^{-1}, CODATA, or a target metrological condition.

The cylinders of 3501 blocks fix 10020 guard digits in each channel, equivalent to 3340 triads. The calculation propagates, from right to left, all possible terminal conditions in the stable set

$$C = \{-2, -1, 0, 1, 2\}.$$

The five branches coalesce in a common prefix of 3339 triads, that is, 10017 digits. Consequently, the first ten thousand digits of α_{HMT} are independent of the carry situated beyond the guard zone. The published output does not impose $c_N = 0$.

Causal independence can be checked after the construction: the first three thousand digits agree with the decimal expansion obtained by the external reader, but none of them enters (31.67). The ten-thousand-digit expansion and the finite data that make it possible to repeat the calculation are presented in the appendix E.

31.7 Two internal readers of α: dodecaphase closure and order-9 nonadic analytic kernel

This section develops the coordinate α of the tesis inaugural. Both readers belong to the same APP–TRIT–TPK genealogy and precede metrological comparison. Route A operates through the reversible dodecaphase closure of the signed state and publishes the coinductive section α_{HMT}. Route B constructs, without consulting that output, the exact order-nine nonadic analytic kernel $E^{(9)}_{21/22} := P_9 - \log_{10}(10/9)$ and publishes its simple and unique positive root ξ_9. Their domains, operations and certificates remain distinct:

$$X^{\mathrm{sig}}_{12} \xrightarrow{\Gamma^{\alpha}_{12}} \alpha_{12}, \qquad E^{(9)}_{21/22} : I_\alpha \longrightarrow \mathbb{R}, \quad E^{(9)}_{21/22}(\xi_9) = 0, \quad (E^{(9)}_{21/22})'(\xi_9) \neq 0. \tag{31.68}$$

The integer closure first publishes the finite window α_{12} and its compatible family of prolongations; its inverse limit is α_{HMT}. The second reader publishes ξ_9 as a finite order-nine witness and, by iteration of the same graded transport of the TPK, constructs the complete compatible system $E^{(6+3m)}_{21/22}$. The two inverse systems determine at each depth the same surviving cylinder C^{α}_{N}; their diameters tend to zero. Therefore, the intersection is a singleton and the two-route theorem establishes

$$\alpha_A := \varprojlim_{N} \rho_N(\alpha_{12}), \qquad E_{21/22} := \varprojlim_{m} E^{(6+3m)}_{21/22}, \qquad \alpha_B := \operatorname*{arg\,zero}_{x \in I_\alpha} E_{21/22}(x), \qquad \boxed{\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}}. \tag{31.69}$$

Neither route introduces a target value as input data; metrological identification belongs solely to subsequent conventional recognition. The equality $\mathrm{Tr}_9(\xi_9^{-1}) = \mathrm{Tr}_9(\alpha_{12}^{-1}) = 137.035999084$ is a finite certificate of the preceding identity, never its definition or maximum scope. The prolongation law is not added as a datum: it is the iteration of the graded transport already produced by APP–TRIT–TPK, with phase return, memory advance and compatible truncations.

31.7.1 Analytic kernel P_6 and exact order-9 prolongation

The characterization of vacancies employs

$$\begin{aligned} P_6(x) &= 2\pi_{\mathrm{HMT}}x - \frac{7}{4}x^2 + \frac{x^3}{2\pi_{\mathrm{HMT}}} + \frac{x^4}{20} - \frac{2x^5}{21} - \frac{x^6}{46}, \\ P_6(x) &= \log_{10}\frac{10}{9}. \end{aligned} \tag{31.70}$$

The certified positive root of this jet satisfies

$$x_6^{-1} = 137.035999084000027020 09\ldots. \tag{31.71}$$

The polynomial P_6 provides the initial jet of the analytic characterization. Nonadic holonomy prolongs its degrees $7, 8, 9$ exactly and the same graded rule is iterated over successive degrees. The jet quotient is the first finite certificate of that coinductive prolongation; it does not select or replace its limit section.

31.7.2 APP–TRIT–TPK genealogy of the invariants $120, 45, 11$ and 495

The phase semicorona of the TPK constructs

$$|\mathcal{F}_8^{\mathrm{ph}}| = 120, \qquad |L_{\mathrm{ph}}| = 45. \tag{31.72}$$

APP provides the central block

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}, \qquad \det B_c = 45, \qquad \mathrm{Spec}(B_c) = \{9, 5\}. \tag{31.73}$$

The dodecaphase transverse extractor provides

$$r_{\mathrm{dod}} = \mathrm{rank}(D_3, D_4) = 11, \qquad (D_3K)_1 = -495, \qquad 495 = 45 \cdot 11 = \det(B_c)\, r_{\mathrm{dod}}. \tag{31.74}$$

The coefficients of the prolonged jet therefore proceed from three prior invariants of APP–TRIT–TPK:

$$-\frac{1}{120} \longmapsto \frac{1}{45} \longmapsto \frac{2}{45 \cdot 11}. \tag{31.75}$$

31.7.3 Nilpotent resolvent $(I - N)^{-1}$ and exact construction of the tail $T_{7:9}$

On the basis e_7, e_8, e_9, we define

$$Ne_7 = -\frac{8}{3}e_8, \qquad Ne_8 = \frac{2}{11}e_9, \qquad Ne_9 = 0, \qquad v_7 = -\frac{1}{120}e_7. \tag{31.76}$$

Since $N^3 = 0$, its finite resolvent acts exactly by

$$(I - N)^{-1}v_7 = v_7 + Nv_7 + N^2v_7 = -\frac{e_7}{120} + \frac{e_8}{45} + \frac{2e_9}{495}. \tag{31.77}$$

The evaluation $e_n \mapsto x^n$ produces

$$\boxed{T_{7:9}(x) = -\frac{x^7}{120} + \frac{x^8}{45} + \frac{2x^9}{495}.} \tag{31.78}$$

31.7.4 Nonadic jet P_9, prolonged root, and scale of certified residues

The nonadic jet of order 9 is defined by

$$P_9(x) = P_6(x) + T_{7:9}(x), \qquad P_9(x) = \log_{10} \frac{10}{9}. \tag{31.79}$$

Theorem 31.19 (Existence, simplicity and uniqueness of the second analytic output)**.** *The operator $E^{(9)}_{21/22}$ has a unique positive root ξ_9 in $I_\alpha = (0, 10^{-2})$. It is enclosed by the exact rational interval*

$$\frac{729735256928380099}{10^{20}} < \xi_9 < \frac{729735256928380100}{10^{20}}, \tag{31.80}$$

and its inverse satisfies

$$\xi_9^{-1} = 137.035999084000000000000111926291900\ldots. \tag{31.81}$$

Proof. All coefficients of P_9 are extracted from the invariants prior to solving. For $0 \le x \le 10^{-2}$, using $3.14 < \pi_{\mathrm{HMT}} < 3.15$, one obtains

$$(E^{(9)}_{21/22})'(x) \ge 2\pi_{\mathrm{HMT}} - \frac{7}{2}\,10^{-2} - \frac{10}{21}\,10^{-8} - \frac{6}{46}\,10^{-10} - \frac{7}{120}\,10^{-12} > 6.24.$$

The directed evaluations at the endpoints of equation (31.80) have opposite signs. The intermediate value theorem provides existence; the derivative bound provides uniqueness and simplicity. Interval division produces the expansion of ξ_9^{-1}, which constitutes the order-nine witness of the complete compatible system. □

Table 31.2: Certified descent of the residue of the analytical characterization

Nucleo evaluado in α_{12}	Residue
P_6	$9.0038886 \times 10^{-18}$
$P_6 - x^7/120$	$-1.7893115 \times 10^{-19}$
$P_6 - x^7/120 + x^8/45$	$-2.3708601 \times 10^{-22}$
P_9	$3.7297132 \times 10^{-27}$

31.7.5 Alternative dodecaphase operator A_{dod} and uniqueness control of the typed reader

The control operator

$$A_{\mathrm{dod}} = I - \frac{1}{4}(D_3^* D_3 + D_4^* D_4) \tag{31.82}$$

produces a different sequence of coefficients. This control proves that isolated dodecaphase symmetry is insufficient to select the prolongation $T_{7:9}$; selection belongs to the typed composition of the reader $\Gamma^{(9)}_{E21}$ with the enriched state. The difference between the two operators certifies the need to preserve domain, orientation, grading and memory, and proves the specificity of the finite reader. The analytic tail belongs to iteration of the complete typed reader, not to the isolated symmetry of this control operator.

31.7.6 Exact scope of the nilpotent operator and exclusion of tails foreign to TPK transport

The arithmetic of $120, 45, 11, 495$, the nilpotent operator, the resolvent and the identity equation (31.78) have internal exactness. The simple and unique positive root of $E^{(9)}_{21/22}$ constitutes the order-nine witness of the second internal reading. Agreement of P_9 with the dodecaphase window certifies the first finite square of the compatible system. Canonical uniqueness of the prolongation 7:9 is typed by the morphism

$$\Gamma^{(9)}_{E21} : X_{\text{APP-TRIT-TPK}} \longrightarrow \mathbb{Q}(\pi_{\mathrm{HMT}})[x]/(x^{10}), \tag{31.83}$$

whose action jointly determines the oriented seed, the two transfers, the grading $7, 8, 9$, the jet quotient F^7/F^{10} and its transport under phase return.

Let $K = \mathbb{Q}(\pi_{\mathrm{HMT}}, \log_{10}(10/9))$ and let $j_9 : K[[x]] \to K[x]/(x^{10})$ be the truncation. Then

$$\ker j_9 = x^{10}K[[x]], \qquad E_h(x) := E^{(9)}_{21/22}(x) + x^{10}h(x), \qquad h \in K[[x]]. \tag{31.84}$$

All E_h have the same certified jet. However, E_0 and $E_{1/729}$ have distinct roots in I_α, since $E_{1/729}(\xi_9) = \xi_9^{10}/729 > 0$. This observation proves only that an isolated jet does not determine a formal tail. It does not affect the second HMT route, because that route does not allow h to be freely chosen: the recurrence of TPK transport constructs the unique compatible family $E^{(6+3m)}_{21/22}$, and its truncations commute with those of the dodecaphase route. Choosing h through the target value would be circular and is excluded; choosing it through generated transport is precisely the operation already proved.

The falsifier thus separates three statements: it invalidates the finite certificate if monotonicity, the sign change or isolation of ξ_9 fails; it invalidates the prolongation 7:9 if its coefficients cease to factor through $\Gamma^{(9)}_{E21}$; and it invalidates the complete identity if compatibility of any square of the inverse system fails or if the diameters of the surviving cylinders do not tend to zero. None of these conditions introduces a pending morphism: they are the material falsifiers of the construction establishing $\alpha_A = \alpha_B = \alpha_{\mathrm{HMT}}$.

Chapter 32

Internal construction of $i = \sqrt{-1}$ via the rotation operator J: identity $J^2 = -I$ and elliptic geometry of phase

The internal root of -1 and the tritic exponential family

The root of -1 is not introduced as a formal symbol without an antecedent. The six units modulo nine are coordinatized over $\mathbb{P}^1(\mathbb{F}_5)$, and the quadratic character of $\mathbb{F}_5$ determines the Paley conference matrix. Its ternary reduction is

$$A_W = \begin{pmatrix} 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 2 & 2 & 1 \\ 1 & 1 & 0 & 1 & 2 & 2 \\ 1 & 2 & 1 & 0 & 1 & 2 \\ 1 & 2 & 2 & 1 & 0 & 1 \\ 1 & 1 & 2 & 2 & 1 & 0 \end{pmatrix} \in M_6(\mathbb{F}_3).$$

The conference identity reduces to

$$\boxed{A_W^2 = 2I_6 = -I_6.} \tag{32.1}$$

Therefore, A_W is a quarter-turn operator in the ternary space. After extending scalars to $\mathbb{F}_9$, it decomposes into the conjugate eigenspaces of the roots of $X^2 + 1$. The common integral source

$$Q_{\mathbb{Z}} = \mathbb{Z}[u]/(u^2 + 1)$$

has a finite realization $u \mapsto A_W$ and a real realization $u \mapsto J_e$. The source coordinates the quadratic relation; it does not identify fields of different characteristics.

The three TRIT regimes are carried out by means of operators

$$J_{+1}^2 = -I, \qquad J_0^2 = 0, \qquad J_{-1}^2 = I.$$

Separating the even and odd powers of the exponential yields a single family:

$$\boxed{\exp(tJ_\tau) = C_\tau(t)I + S_\tau(t)J_\tau, \qquad \tau \in \{+1, 0, -1\},} \tag{32.2}$$

where

$$(C_{+1}, S_{+1}) = (\cos, \sin), \qquad (C_0, S_0) = (1, t), \qquad (C_{-1}, S_{-1}) = (\cosh, \sinh).$$

Its three governing specializations are

$$\exp(\pi J_{+1}) + I = 0, \qquad \exp(J_0) = I + J_0, \qquad \exp\big(2(\log\varphi)J_{-1}\big) = F_{\mathrm{av}}^2. \tag{32.3}$$

The elliptic branch contains the complex circular closure; the parabolic branch, threshold transport; the hyperbolic branch, golden self-scaling. Euler's equation thus appears as a specialization of a family that coordinates rotation, boundary and hyperbolic expansion.

32.1 Elliptic realization of $J^2 = -I$ through the Hopf fibration and Möbius holonomy

32.1.1 Complex structure and Hopf fibration

Let $S^3 \subset \mathbb{C}^2$ and

$$h(z_0, z_1) = \big(2\Re(z_0\bar{z}_1), 2\Im(z_0\bar{z}_1), |z_0|^2 - |z_1|^2\big) \in S^2.$$

On the Hopf torus

$$T_\eta = \{(z_0, z_1) : |z_0| = \cos\eta, |z_1| = \sin\eta\},$$

the curves

$$\gamma_+(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{it}),$$

$$\gamma_-(t) = (\cos\eta\, e^{it}, \sin\eta\, e^{-it})$$

have distinct behaviors: γ_+ is a Hopf fiber and γ_- projects with degree two. Under stereographic projection, the homology classes $(1, 1)$ and $(1, -1)$ produce the two diagonal Villarceau families.

The total complex conjugation

$$K(z_0, z_1) = (\bar{z}_0, \bar{z}_1)$$

preserves each unoriented family and reverses its orientation. It does not interchange the two families. Partial conjugation can interchange them, but it is neither a complex-linear map nor the standard global antiunitary. This correction is essential to avoid manufacturing a particle–antiparticle symmetry from the toroidal drawing.

32.1.2 Double covering and spinor return

The map $SU(2) \to SO(3)$ is a double cover. A loop of 2π in $SO(3)$ can lift to $-I$ in $SU(2)$; the loop of 4π recovers I. The sign structure does not turn a circle into a Möbius band. Obtaining a band requires a real line bundle whose holonomy character is -1.

Let $L_\chi \to S^1$ be the associated bundle to

$$\chi : \pi_1(S^1) \longrightarrow \{\pm 1\}, \qquad \chi(1) = -1.$$

Its total space is a Möbius band. The route $C_M = -\,\mathrm{rev}$ provides the sign candidate; the Villarceau circle provides the loop; the physical intertwiner must prove that the former is the holonomy of the latter.

32.1.3 Toroidal realization of the operator $B^{\varepsilon}_{\mathrm{mem}}$ and determination of the Villarceau angle

With $B_c = 7I + 2S$, define the oriented memory operator

$$B^{\varepsilon}_{\mathrm{mem}} = 5I + 2\varepsilon S, \qquad \varepsilon = \pm 1.$$

For $\varepsilon = +1$,

$$\mathrm{Spec}(B^{+}_{\mathrm{mem}}) = \{7, 3\}, \qquad \det B^{+}_{\mathrm{mem}} = 21.$$

Interpreting the values $(7, 3)$ as the outer and inner equatorial boundaries in a common positive chart yields

$$R + r = 7\ell, \qquad R - r = 3\ell,$$

and therefore

$$R = 5\ell, \qquad r = 2\ell, \qquad \sin\beta = \frac{r}{R} = \frac{2}{5}.$$

The Villarceau angle is

$$\beta = \arcsin\frac{2}{5} = 23.5781784782\ldots^\circ.$$

The algebraic theorem $\{7, 3\} \leftrightarrow (5, 2)$ is exact. The geometric premise interpreting the spectrum as the two boundaries of a torus is a declared interface. It must not be concealed, nor may the angle be used as a target.

The realization of the full block B_c retains another reading: $R : r = 7 : 2$ and $\beta = \arcsin(2/7)$. These are not rival values; they belong to two functors: total block and memory mode. The physical priority of the latter must be decided by the intertwiner with the dynamics, not by decimal proximity to another constant.

32.1.4 Action of the operator $J^2 = -I$ on the conjugate angular coordinates

HMT's native angle is a phase $u \in \mathbb{R}/\mathbb{Z}$. The readers publish

$$\theta_{\text{rad}} = 2\pi u, \qquad \theta_{\text{deg}} = 360u.$$

Radians and degrees are distinct charts of the same circular element. The radian is not more "ontological" by virtue of being dimensionless; its naturality follows from arc length. Degrees provide another absolute coordinate of the full turn. Any relation with α^{-1}, φ, or CKM must first be formulated as an invariant quotient or holonomy and only thereafter evaluated in an angular chart.

The exact identity already available

$$\tanh^2(2 \log \varphi) = \frac{5}{9}$$

connects the Perron–Fibonacci channel to the spectral quotient of B_c. Its complement is $4/9$, the normalized gap. This relation is structural. It does not imply that every angle constructed with φ is a physical angle.

32.1.5 Brouwer, Möbius, and degree

Brouwer's fixed-point theorem, fractional linear Mobius transformations, and the Mobius band are three distinct objects. They are related only after fixing domain, action, and bundle. The elliptic advance and retardation orbits may be modeled as two sections of a bundle with sign holonomy; the Mobius transformation describes the conformal action in the chart; Brouwer's theorem guarantees a fixed point for continuous maps of the disk. None of these statements replaces the realization diagram.

Remark 32.1 (Result and boundary). The double degree of the Hopf curve, the orientation of total conjugation, and the algebraic construction $7, 3 \mapsto 5, 2$ are proved. The toroidal reading (5:2), the Möbius holonomy, and the particle–antiparticle interpretation form a chain of interfaces that must share a single intertwiner. Volume does not force that intertwiner through an angular coincidence.

Chapter 33

Hensel–Witt derivation of $-1/12$: compatible prolongation, regularization, and modular memory

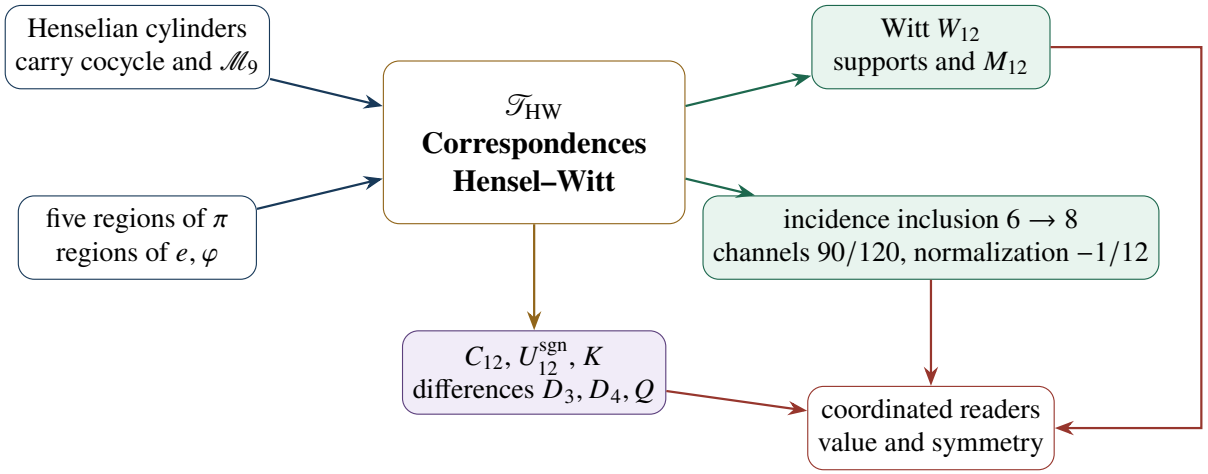
33.1 Hensel–Witt transduction operator between microregions of π, holonomy Γ_9, the dodecaphasic register and hexad–octad incidence

The NTHW is the data and maps package

$$\mathfrak{N}_{\mathrm{HW}} = \left(\mathscr{R}_{\pi}^{\mathrm{micro}}, \mathcal{G}_9, C_{12}, K, \mathcal{W}_{12\to 24}, \mathcal{I}_{6\to 8}\right),$$

with the following compatibilities:

1. the Hensel regions share a quotient word and retain distinct memory;
2. $\mathcal{G}_9$ transports orientation and produces monodromy;
3. C_{12} organizes the signed observable and the seal K;
4. the Witt reading converts supports of the same boundary into hexads and stars;
5. the extension $W_{12} \to W_{24}$ produces the hexad–octad interface;
6. the Archimedean, exceptional and dimensional readers receive invariants of the same state.



Compatibility of cylinders, dodecaphase, and incidences on the same enriched state.

Figure 33.1: The NTHW as a typed interface. The central mathematical task is to make the diagram commute, not to accumulate coincidences around a name.

NTHW gives a formal name to the place previously described as the "Rosetta Stone." The substitution is conceptual: a stone translates through resemblance; a transduction specifies input, output, preserved datum and loss of information.

33.2 Construction of the Witt system from the compatible ternary coding

The reversible APP boundary selects, with declared gauges, a matrix A_W over $\mathbb{F}_3$ satisfying

$$A_W A_W^T = 2I \pmod 3.$$

The graphic code

$$C_W = \{(q, qA_W) : q \in \mathbb{F}_3^6\}$$

is the extended ternary Golay code. Its weight enumerator is

$$1 + 264y^6 + 440y^9 + 24y^{12}.$$

The 264 words of weight six, identified up to sign, yield 132 supports. Every five-point subset belongs to a unique hexad:

$$W_{12} = S(5, 6, 12).$$

The field of 495 star involutions generates a group of order 95 040, recognized as M_{12}. An isolated star does not generate the group. The ordered HMT frame has trivial stabilizer and therefore fixes a gauge within the action.

33.3 Hexad–octad realization of the 90/120 channels previously derived from the tritic incidence of the TPK

Let H be a hexad and O_H an octad containing it. Marking one point and a pair of points of the hexad yields

$$F_6(H) = H \times \binom{H}{2}, \qquad |F_6| = 6\binom{6}{2} = 90.$$

If the marked point can traverse the octad:

$$F_8(H) = O_H \times \binom{H}{2}, \qquad |F_8| = 8\binom{6}{2} = 120.$$

The inclusion $H \hookrightarrow O_H$ induces $F_6 \hookrightarrow F_8$. Its normalized defect is

$$\boxed{\frac{90 - 120}{24\binom{6}{2}} = \frac{6 - 8}{24} = -\frac{1}{12}.}$$

This combinatorial theorem precedes Barbero's angular reading. The two objects share the interface $6 \to 8$, but are not identical.

33.4 4 operational realizations of −1/12 and separation of their domains

The construction contains four realizations that must be presented together, not counted as four independent proofs of a single provenance.

33.4.1 Angular realization through the elementary increment dodecaphasic

One tooth of C_{12} measures 30°. Then

$$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3} = -\frac{1}{12}.$$

It is the angular shadow of the pattern 90/120.

33.4.2 Oriented pseudoinverse of the Gram operator on the surviving subspace

In the certified jump $60 \to 81$, two fibers have sizes 0 and 12. The Gram operator is

$$K_{60,81} = \operatorname{diag}(0, 12).$$

On the live subspace, its pseudoinverse is $1/12$; with the negative boundary orientation,

$$E_{\mathrm{surv}} = -K^{+}_{60,81}$$

yields $-1/12$.

33.4.3 Scale extraction by the 2nd triadic difference

The realization via a triadic scale extractor is the second-difference construction developed in full in section 33.5.3. This first occurrence establishes its role within the inventory of realizations; the indicated residence preserves the definitions of T_L, $a(L)$, $A_1(L)$, $C(L)$, the independence of the residue from L, and the exact status of the normalization.

33.4.4 Modular realization through the quotient $\eta(\tau)/\eta(3\tau)$ and the function t_3

The eta function satisfies

$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12} \prod_{n\geq 1} (1 + q^n + q^{2n})^{-1}.$$

The exponent comes from $1/24 - 3/24 = -1/12$. Taking twelve copies:

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots .$$

The coefficient 54 coincides with the APP defect. The corridor

$$j = \frac{(t_3 + 27)(t_3 + 243)^3}{t_3^3}$$

connects afterwards with the classical modular branch.

Remark 33.1 (What Has Been Proved in the Corridor). The APP defect 54, the eta exponent $-1/12$, the hexad–octad defect, and the modular identities once t_3 has been fixed are exact. The strong assertion is that all of them are natural images of a single TPK operator. That naturality must be proved by means of the NTHW diagram; it does not follow merely from repeating the same integers.

33.5 5 algebraic realizations of $-1/12$ and separation of their domains

In addition to the normalized defect of the hexad–octad inclusion, five operator realizations of the same rational number appear. Their domains are specified separately; equality of values does not identify the operators without an additional intertwiner.

33.5.1 Difference of dodecaphasic periodicities

One tooth of C_{12} measures 30°. Then

$$\frac{30}{120} - \frac{30}{90} = \frac{1}{4} - \frac{1}{3} = -\frac{1}{12}.$$

It is the oriented difference between the periods of 90° and 120° in this realization.

33.5.2 Pseudoinverse of the Gram Operator on the Live Component

In the exact jump $60 \to 81$, two fibers have sizes 0 and 12. The Gram operator is

$$K_{60,81} = \operatorname{diag}(0, 12).$$

On the nonzero component of its range, the pseudoinverse is $1/12$; with the negative boundary orientation,

$$E_{\mathrm{surv}} = -K^{+}_{60,81}$$

yields $-1/12$.

33.5.3 2nd difference between triadic scales

Define

$$T_L = \sum_{n=1}^{L-1} n(L-n) = \frac{L(L^2-1)}{6}, \qquad a(L) = -\frac{T_L}{L^2} = -\frac{L}{6} + \frac{1}{6L}.$$

The first scale subtraction is

$$A_1(L) = a(L) - \frac{a(3L)}{3} = \frac{4}{27L},$$

and the second

$$C(L) = LA_1(L) - \frac{3L}{3}A_1(3L) = \frac{8}{81}.$$

The residue $8/81$ is independent of L. To obtain $-1/12$, the declared normalization is applied

$$R(L) = -\frac{27}{32}C(L) = -\frac{1}{12}.$$

The calculation derives $8/81$; it does not by itself derive the factor $-27/32$.

33.5.4 Cadena modular

The eta function satisfies

$$\frac{\eta(\tau)}{\eta(3\tau)} = q^{-1/12}\prod_{n\geq 1}(1+q^n+q^{2n})^{-1}.$$

The exponent comes from $1/24 - 3/24 = -1/12$. Taking twelve copies:

$$t_3(q) = \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + \cdots.$$

The coefficient 54 coincides with the APP defect. The rational identity

$$j = \frac{(t_3+27)(t_3+243)^3}{t_3^3}$$

establishes the connection with the classical modular branch.

33.5.5 Defect of cyclic difference projectors

Let S be the cyclic shift on $\mathbb{Q}^{12}$ and define

$$D_r = I - S^r.$$

The kernel of D_r consists of the vectors constant on each orbit of S^r; therefore,

$$\dim \ker D_r = \gcd(12, r).$$

Let $\Pi_{\ker D_3}$ and $\Pi_{\ker D_4}$ be the rational projectors onto $\ker D_3$ and $\ker D_4$, and let $\tau(T) = \mathrm{Tr}(T)/12$ be the normalized trace. Then

$$\boxed{\tau(\Pi_{\ker D_3} - \Pi_{\ker D_4}) = \frac{\operatorname{rank} \Pi_{\ker D_3} - \operatorname{rank} \Pi_{\ker D_4}}{12} = \frac{3-4}{12} = -\frac{1}{12}.}$$

This realization expresses the rational as the transverse defect of steps three and four in the twelve-phase cycle.

Remark 33.2 (Domains of the realizations). The APP defect 54, the eta exponent $-1/12$, the combinatorial defect of the hexad–octad lift, and the modular identities once t_3 has been fixed are exact. The value of the pseudoinverse, the normalized extractor, and the projector defect are likewise exact. Each equality preserves its domain and its corresponding map.

Chapter 34

Determinantal derivation of the absolute action scale: Smith normal form, cokernel of order 16 and valuation 10^{-34}

34.1 Derivation of the action scale from the dodecaphasic state

The action decade is determined intrinsically, without adopting it as an inherited unit. The local determinantal functional is applied to the previously constructed HMT output α_{HMT} and defines

$$\Sigma_H = \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16}. \tag{34.1}$$

The exponent 16 is the order of the local cokernel of the signed closure; its decimal valuation fixes

$$\mathrm{ord}_{10}(\Sigma_H) = -34. \tag{34.2}$$

The origin of the exponent can be verified within this volume. On the local orbit of four leaves, the Hadamard block acts

$$H_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{34.3}$$

Lemma 34.1 (Local index of the action line)**.** *The form normal of Smith of H_4 is*

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4). \tag{34.4}$$

Consequently,

$$\mathrm{coker}(H_4) \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}, \qquad |\mathrm{coker}(H_4)| = 16.$$

Proof. The greatest common divisor of the entries is one; that of the nonzero 2×2 minors is two; that of the 3×3 minors is four; and $|\det H_4| = 16$. The successive quotients of these determinantal divisors are $1, 2, 2, 4$, which prove equation (34.4). The product of the invariants gives the order of the cokernel. □

The norm of the section α_{HMT} over those sixteen sheets produces $\alpha_{\mathrm{HMT}}^{16}$; the self-scaling φ_{HMT} acts only once on the basis, not once per sheet. Hence equation (34.1). The certified comparisons

$$\alpha_{\mathrm{HMT}}^{16} < 10^{-34} < \varphi_{\mathrm{HMT}} \alpha_{\mathrm{HMT}}^{16} < 10^{-33} \tag{34.5}$$

prove, without introducing the SI unit, that the decimal order is exactly -34. The terminal evaluation begins with

$$\Sigma_H = 1.046243838104756580184229208303089\ldots \times 10^{-34}. \tag{34.6}$$

The substitution of the kernel by three copies with exponent 16^3, or the repeated application of φ on each sheet, would alter the genealogy. Both operations constitute falsification criteria rather than equivalent conventions. The causal chain that is preserved is therefore,

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to U_{12}^{\mathrm{sign}} \to \alpha_{\mathrm{HMT}} \to \Sigma_H \to 10^{-34} \mathcal{U}_S \to \{\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}}\}.$$

This volume does not rederive α_{HMT}, but develops the metrological geometry subsequent to the selection of the type and decade by Σ_H. The integer -34 is neither a mantissa nor an adjustment to the International System, but the terminal valuation of the local functional.

34.2 Oriented sections of the action line

The realizations before and after the return constitute two sections of the same action line:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S. \tag{34.7}$$

The common decade determines the line, while the oriented information is expressed through

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}, \qquad \xi_{\mathrm{act}} = \frac{1}{2}\log R_{\mathrm{act}}. \tag{34.8}$$

The first quantity provides a multiplicative coordinate and the second an additive coordinate of rapidity type. They do not represent two independent Planck constants, but the two orientations of the same section with respect to the return.

If $h_a = 2\pi\hbar_a$, $a \in \{\mathrm{pre}, \mathrm{ret}\}$, a quantity proportional to $h_a^{1/2}$ changes as $R_{\mathrm{act}}^{1/2}$, one proportional to $h_a^{-1/2}$ changes as $R_{\mathrm{act}}^{-1/2}$, and a quotient in which the action cancels is a bidirectional invariant.

34.3 Causal bifurcation subsequent to α_{HMT}

The genealogy of the action and the angular pair forms a bifurcated diagram. The regional branch produces the reduced mantissa η_{ret}; the determinantal branch produces the decimal order $\varepsilon_H = -34$. Both converge on the action line. The angular pair is constructed in a sister branch from α_{HMT} and η_{ret}:

$$\begin{array}{ccccccc}
\alpha_{\mathrm{HMT}}, \pi, \varphi & \longrightarrow & H_5, \mathscr{C}_\pi & & & & \alpha_{\mathrm{HMT}}, \varphi, H_4 \\
\downarrow & & \downarrow & & & & \downarrow \\
x_A, D_A, \rho_\pi & \longrightarrow & \eta_{\mathrm{ret}} & \longrightarrow & \hbar_{\mathrm{ret}} \in \mathcal{L}_S & \longleftarrow & \Sigma_H, \varepsilon_H = -34 \\
 & & \downarrow & & & & \\
 & & (A_{\mathrm{deg}}, C^*_{\mathrm{deg}}) & \longrightarrow & (A_{\mathrm{rad}}, C^*_{\mathrm{rad}}) & \longrightarrow & (q_+, q_-) \longrightarrow V_{90,120}.
\end{array} \tag{34.9}$$

The expository order places the Planck derivation before the complete angular publication; the diagram simultaneously preserves the exact mathematical dependence of each output.

34.4 Local cokernel and derivation of the absolute order 10^{-34}

The Smith normal form of the local dodecaphase block is

$$\mathrm{SNF}(H_4) = \mathrm{diag}(1, 2, 2, 4), \qquad \mathrm{coker}(H_4) \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}. \tag{34.10}$$

The local cokernel has order 16. For the constant section $s_\alpha(g) = \alpha_{\mathrm{HMT}}$, the local norm and an action of φ produce

$$\boxed{\Sigma_H = \varphi \mathcal{N}_{G_H}(s_\alpha) = \varphi\alpha_{\mathrm{HMT}}^{16}.} \tag{34.11}$$

The exact inequalities

$$\alpha_{\mathrm{HMT}}^{16} < 10^{-34} < \varphi\alpha_{\mathrm{HMT}}^{16} < 10^{-33} \tag{34.12}$$

determine

$$\boxed{\varepsilon_H = \lfloor \log_{10} \Sigma_H \rfloor = -34.} \tag{34.13}$$

Chapter 35

Regional character of degree 5, construction of η_{ret} and positive action measure on the emission quotient

The preceding section isometrically identifies a rank-three positive sector in the oriented interface $t = 7$, the dodecaphase, and the Witt incidence module. The following construction derives the other coefficient of the angular law, $5/468$, and proves why the two terms combine through a positive sum. The question requires three operations to be distinguished:

1. count microscopic presentations;
2. count distinct emissions after forming the TPK quotient;
3. assign a action additive to a path.

The first two operations produce different measures. The third is characterized by a universal property, not by the subsequent proximity of a decimal value.

We shall denote by Γ_{tr} the directed graph of 1944 states of the enriched-path reader. Its free path category will be written $\mathsf{P}(\Gamma_{\mathrm{tr}})$. The local definition of its edges and their action is developed in the corresponding section.

35.1 Seed space, quotient of emissions and regional fibers

Let

$$\Omega_{\mathrm{seed}} = \big((\mathbb{Z}/9\mathbb{Z})^2 \times D_4\big)^2, \qquad |\Omega_{\mathrm{seed}}| = 104\,976,$$

the executable set of seed pairs of the finite sender, and let

$$F : \Omega_{\mathrm{seed}} \twoheadrightarrow \mathcal{U}_6, \qquad |\mathcal{U}_6| = 468,$$

the application that preserves the distinct sextuple emission. The exact count of fibers is

$\lvert F^{-1}(U)\rvert$	#{U of that size}	supplied seeds
144	432	62 208
432	18	7 776
1 944	18	34 992.

The three contributions sum to 104 976. Therefore, F is not a regular covering: different emissions have different numbers of microscopic presentations.

The microfiber of π contains five distinct emissions. Four have multiplicity 144, and one has multiplicity 432. This datum suffices to prove that the uniform measure on seeds and the uniform measure on emissions are not the same.

35.2 2 exact measures on the quotient of emissions and words

If each seed receives weight $1/104\,976$, the image measure under F is

$$\nu_{\mathrm{seed}}(U) = \frac{|F^{-1}(U)|}{104\,976}.$$

Its possible atoms are

$$\frac{1}{729}, \qquad \frac{1}{243}, \qquad \frac{1}{54}.$$

In particular,

$$\nu_{\mathrm{seed}}(\mathscr{R}_{\pi}^{\mathrm{micro}}) = \frac{4 \cdot 144 + 432}{104\,976} = \boxed{\frac{7}{729}}.$$

If the elementary state is instead a distinct emission $U \in \mathcal{U}_6$, the diagonal algebra of observables is

$$\mathcal{D}_{468} = \ell^{\infty}(\mathcal{U}_6)$$

and its normalized count state is

$$\tau_{468}(f) = \frac{1}{468} \sum_{U \in \mathcal{U}_6} f(U).$$

Let $\Pi_{\pi}^{(468)}$ be the characteristic function of the five regions of the microfiber. Then

$$\boxed{\tau_{468}(\Pi_{\pi}^{(468)}) = \frac{5}{468}.}$$

The exact difference between both readings is

$$\frac{5}{468} - \frac{7}{729} = \frac{41}{37\,908}.$$

They are not two approaches. The first measure counts presentations; the second counts emission classes.

Theorem 35.1 (Uniqueness of the uniform measure of the catalog)**.** *The unique probability measure on $\mathcal{U}_6$ invariant under every relabeling of its* 468 *atoms is the uniform measure. Equivalently, the unique positive unital trace on $M_{468}(\mathbb{C})$ is*

$$\tau_{468}(A) = \frac{1}{468} \operatorname{Tr} A.$$

Proof. Transpositions take any atom to any other. Invariance forces all of them to have the same mass, and normalization fixes it at $1/468$. In the matrix version, unitary invariance equates the value of all rank-one projectors. Spectral decomposition and linearity reconstruct the normalized trace. □

The decisive hypothesis is explicit: the reader works with the *quotient catalogue*. The theorem does not claim that the uniform measure on seeds becomes uniform when the fibers are forgotten. The symmetry used is the naturality of the finite unlabeled object, not an ergodic property attributed without proof to the microscopic dynamics.

35.3 Canonical Hilbertization of the quotient

The relationship between seeds and emissions can be formulated unambiguously. Let

$$H_{\mathrm{seed}} = \ell^2(\Omega_{\mathrm{seed}}), \qquad H_U = \ell^2(\mathcal{U}_6).$$

The emitter determines

$$\boxed{J_F \delta_U = |F^{-1}(U)|^{-1/2} \sum_{\omega \in F^{-1}(U)} \delta_{\omega}.}$$

Distinct fibers are disjoint and each column has norm one; therefore,

$$J_F^* J_F = I_{H_U}.$$

Moreover, for every observable f of the catalogue,

$$M_{f \circ F} J_F = J_F M_f.$$

The image $J_F H_U$ is exactly the subspace of functions that are constant on each fiber.

If $F^\sharp : H_U \to H_{\mathrm{seed}}$ denotes the map induced by precomposition, without normalization, then

$$J_F = F^\sharp \big((F^\sharp)^* F^\sharp\big)^{-1/2}.$$

It is the isometric factor of the polar decomposition of that map. This expression proves its naturality under isomorphisms and relabelings of the emitter. It does not imply a false functoriality under arbitrary composition of nonregular surjections: the normalization depends on the fibers of the specific map.

In the language of measures, the elevation of the quotient trace that is uniform within each fiber equals

$$\widetilde{\tau}(\omega) = \frac{1}{468\,|F^{-1}(F\omega)|}.$$

Each fiber receives total mass $1/468$. The inverse compensation by multiplicity, and not an informal invocation of orbits, is the exact proof.

Corollary 35.2 (Canonicity of $5/468$)**.** *Once the regional reader is defined on distinct emissions, the mass of the microfiber of π is forced:*

$$\tau_{468}(\Pi_\pi^{(468)}) = \frac{\operatorname{rank} \Pi_\pi^{(468)}}{468} = \frac{5}{468}.$$

35.4 Positive defect between the regional and dodecaphasic measures

Write

$$H_{\mathrm{ang}} = H_U \otimes V_{11}.$$

The internal scalar

$$\Delta_4 = \frac{\pi - e \log \pi}{270} \left(1 + \frac{\pi}{729}\right) = 0.0001111964226921402\ldots$$

is constructed with the already fixed HMT readings of π and e, and with the integers 270 and 729 of the ledger. Here it is a pre-dimensional mathematical input: neither units nor physical observables intervene.

The internal construction of the scalar does not by itself determine which operator must multiply. To keep this premise visible, we declare:

Def**— sheet-change defect.** The dodecaphase coordinate of the sheet-change defect is $\Delta_4 P_3$.

Addwill fix the additive form of the action but does not select Def: for any $c \geq 0$, the same argument would admit the pair $(\Pi_\pi^{(468)}, cP_3)$. Proving Defdirectly from a total transition of the enriched topological phase kernel is an additional condition.

We define the Kronecker sum

$$\boxed{D_{\mathrm{switch}}^{\mathrm{dod}} = \Pi_\pi^{(468)} \otimes I_{11} + \Delta_4 I_{468} \otimes P_3.}$$

The two summands are positive, commute, and act on different factors. Therefore,

$$D_{\mathrm{switch}}^{\mathrm{dod}} \geq 0.$$

The intertwiner U_W of the theorem 20.3 produces the Witt chart:

$$\begin{aligned} D_{\mathrm{switch}}^{\mathrm{Witt}} &= (I_{468} \otimes U_W) D_{\mathrm{switch}}^{\mathrm{dod}} (I_{468} \otimes U_W)^* \\ &= \Pi_\pi^{(468)} \otimes I_{E_{30}} + \Delta_4 I_{468} \otimes Q_3. \end{aligned}$$

Thus, the same positive operator is read in the dodecaphase and in the incidence module.

The oriented isometric chain also identifies the active sectors.

$$I_{L_{\mathrm{or}}} \otimes P_G, \qquad P_3, \qquad Q_3.$$

No equivalence of the complete complements of the three modules is asserted: W_{GK} is a partial equivalence of the selected ranges. This is exactly the information required to identify the second contribution to the trace.

Theorem 35.3 (Exact Scope of Entanglement and Action Induction)**.** *Let W_{GK} and U_W be the partial isometries of the theorem 20.7. Then:*

1. *for every $c \geq 0$,*

$$W_{GK}^{*}(cP_3)W_{GK} = c(I_{L_{\mathrm{or}}} \otimes P_G), \qquad U_W(cP_3)U_W^{*} = cQ_3;$$

thus, entanglement carries the coefficient, but does not select it;

2. *if P_{sgn} and P_{std} are the central projectors of the decomposition*

$$P_3V_{11}\big|_{H_*} \simeq \mathrm{sgn}_{H_*} \oplus \mathrm{std}, \qquad \operatorname{rank} P_{\mathrm{sgn}} = 1, \quad \operatorname{rank} P_{\mathrm{std}} = 2,$$

every positive self-adjoint operator supported on P_3V_{11} and H_*-equivariant has the form

$$D_{a,b} = aP_{\mathrm{sgn}} + bP_{\mathrm{std}}, \qquad a, b \geq 0.$$

Even impose the trace of $\Delta_4 P_3$ leaves the family

$$a + 2b = 3\Delta_4.$$

The isotropy $a = b$ is not deduced from the residual symmetry S_3;

3. *the uniform probability of the catalog, $\mu_U(U) = 1/468$, is the canonical trace of the finite quotient, and its compensated lift is determined by J_F. It is not the image measure of the uniform probability on seeds, whose atoms are $1/729, 1/243, 1/54$. In particular,*

$$\mu_U(\mathscr{R}_{\pi}^{\mathrm{micro}}) = \frac{5}{468}, \qquad F_{\#}\mu_{\mathrm{seed}}(\mathscr{R}_{\pi}^{\mathrm{micro}}) = \frac{7}{729};$$

4. *the complete law*

$$\delta_* = \frac{5}{468} + \frac{3}{11}\Delta_4, \qquad \lambda_* = 1 - \delta_*, \qquad a_*(e) = g(e) + \lambda_* s(e)$$

is a theorem relative to the five clauses Tr_q–Add–Def–Res–Loc. *The executable engine of the reduced topological phase kernel does not induce, by directed cover, the branched operator Γ_{tr}: the associated dynamics returns to the identity after 54 iterations, while each state of Γ_{tr} has four distinct successors and no self-edge.*

Consequently, the preceding results prove the canonicity of the isometric identifications, of the trace on the quotient catalogue, and of the additive character within their premises. The stronger assertion that a total transition of the enriched Topological Phase Kernel necessarily induces $\Delta_4 P_3$, the uniform measure, and the local law still requires the additional dynamical theorem specified in the induction analysis.

Proof. The identities in the first assertion are obtained by multiplying $W_{GK}^{*}W_{GK} = I_{L_{\mathrm{or}}} \otimes P_G$, $W_{GK}W_{GK}^{*} = P_3$, and $U_W P_3 U_W^{*} = Q_3$ by the scalar c. For the second assertion, the restriction to $H_* \simeq S_3$ is the

multiplicity-free sum of two nonisomorphic irreducible representations. Schur's lemma diagonalizes every equivariant self-adjoint operator on those two blocks; positivity is equivalent to $a, b \geq 0$. Its normalized trace is $(a+2b)/11$, which proves the residual freedom even after the trace has been fixed. The full action of A_5 on the irreducible triplet would reduce the family to cP_3, but it would not fix the value of c either.

The third point follows from the fibre census: F has multiplicities $144, 432, 1944$, so the image measure weights an emission by its number of presentations. By contrast, the trace τ_{468} assigns the same weight to every class; J_F realizes exactly its normalized lift. The fourth point is the logical concatenation already proved: Tr_q fixes the quotient trace, Add the sum of traces, Def declares $\Delta_4 P_3$, Res defines the residual capacity, and Loc carries it to the edges. The finite enumeration proves the obstruction between the reduced kernel and Γ_{tr}: a directed cover would preserve the outgoing star, and a semiconjugacy of the identity return would require self-edges in the image, contradicting both censuses of Γ_{tr}. □

The complete spectrum of $D_{\mathrm{switch}}^{\mathrm{dod}}$ is

eigenvalue	multiplicity
0	$(468-5)(11-3) = 3704$
Δ_4	$(468-5)3 = 1389$
1	$5(11-3) = 40$
$1+\Delta_4$	$5 \cdot 3 = 15.$

Consequently,

$$\begin{aligned}\tau_{468\cdot 11}(D_{\mathrm{switch}}) &= \tau_{468}(\Pi_{\pi}^{(468)}) + \Delta_4 \tau_{11}(P_3) \\ &= \boxed{\frac{5}{468} + \frac{3}{11}\Delta_4}.\end{aligned}$$

The same identity holds in the Witt chart. In the oriented-sector chart, the term $3/11$ is the trace of P_G on the homogeneous space of eleven branches.

35.5 Universal property of the positive action functional

The word *action* is used in an additive sense: the concatenation of two routes receives the sum of their increments. To separate this content from a chosen formula, we first define the category in which the law will be unique.

Definition 35.4 (Positive Action Character HMT)**.** A character local of action on the product regional–dodecafasico is one map

$$\delta : M_{468}(\mathbb{C})_+ \oplus M_{11}(\mathbb{C})_+ \longrightarrow \mathbb{R}_{\geq 0}$$

which satisfies:

1. exact additivity on the product cone;
2. homogeneidad positiva;
3. invariance under independent unitary conjugation in the two factors;
4. bifactorial normalization,
$$\delta(I_{468}, 0) = \delta(0, I_{11}) = 1.$$

Additivity translates concatenation; invariance eliminates the coordinates; bifactorial normalization fixes a scale in each summand. This is not a unital functional on the direct-sum algebra: its unit is (I_{468}, I_{11}) and additivity gives $\delta(I_{468}, I_{11}) = 2$. No clause contains the value of an angle.

Theorem 35.5 (Uniqueness of the positive character and relative residual capacity)**.** *En the class of the definition preceding there exists a unique character positive of action HMT. It is*

$$\boxed{\delta(A,B)=\tau_{468}(A)+\tau_{11}(B).}$$

Applied to the defect declared by Def*,* $(\Pi_{\pi}^{(468)},\Delta_4 P_3)$*, it yields*

$$\delta_*=\frac{5}{468}+\frac{3}{11}\Delta_4.$$

If, in addition, Res*is declared, according to which the self-dual capacity for sheet change is normalized to one and the defect reduces it through* $\lambda=1-\delta$*, the residual capacity within* Tr_q–Add–Def–Res*is*

$$\boxed{\lambda_*=1-\delta_*=1-\frac{5}{468}-\frac{3}{11}\Delta_4.}$$

Proof. The separability of additivity separates the factors:

$$\delta(A,B)=\delta(A,0)+\delta(0,B).$$

Each restriction is positive, homogeneous, and invariant under conjugation. For a rank-one projector, unitary invariance gives a common value. Additivity over a spectral decomposition forces each restriction to be a multiple of the trace. The bifactorial normalization fixes those multiples at $1/468$ and $1/11$. The sum of traces follows. The last formula applies the declared normalization of residual capacity. □

Numerically,

$$\boxed{\lambda_*=0.9892859130191415\ldots},\qquad 0<\lambda_*<1.$$

Positivity already follows from $0<\Delta_4<10^{-3}$ and $5/468<1$. It does not depend on a metrological comparison.

35.6 Positive Action Functor on the Category of Compatible Paths

Recall the directed graph Γ_{tr} and its free category $\mathsf{P}(\Gamma_{\mathrm{tr}})$. For an edge $e:x\to y$, define

$$g(e)=\mathbf{1}_{\{d_y\neq d_x\}},\qquad s(e)=\mathbf{1}_{\{m_y\neq m_x\}},$$

where g records a turn and s a change of sheet. The arrow from the scalar λ_* to the edges does not follow from the trace theorem. It is declared through the clause Loc: a turn has unit cost, a change of sheet has cost λ_*, and the two indicators are added when they occur on the same edge. Under Loc, the local action is

$$\boxed{a_*(e)=g(e)+\lambda_* s(e).}$$

For a route $\gamma=e_1\cdots e_n$,

$$\mathcal{A}_*(\gamma)=\sum_{j=1}^{n}a_*(e_j)=\#\,\text{giros}(\gamma)+\lambda_*\#\,\text{cambios de hoja}(\gamma).$$

For the empty path $\mathbf{1}_x$, one fixes $\mathcal{A}_*(\mathbf{1}_x)=0$. Then

$$\boxed{\mathcal{A}_*(\gamma_1\gamma_2)=\mathcal{A}_*(\gamma_1)+\mathcal{A}_*(\gamma_2).}$$

Therefore,

$$\mathcal{A}_*:\mathsf{P}(\Gamma_{\mathrm{tr}})\longrightarrow(\mathbb{R}_{\geq 0},+)$$

is a monoidal functor, or additive path cocycle.

The indicators g and s are insensitive to the direction of traversal. Orientation is not lost: it resides in the line L_{or} and in the star involution, whereas positive cost resides in the projectors. Conflating the two data would introduce negative signs into the action.

For $\beta > 0$, the associated transfer operator is

$$(\mathcal{L}_{\beta,*} f)(y) = \sum_{e : x \to y} e^{-\beta a_*(e)} f(x).$$

All its weights are strictly positive. Since the potential depends only on the two local indicators, it commutes with the coarse action $(\mathbb{Z}/3\mathbb{Z})^3$ and respects the decomposition into 27 Bloch sectors used in the following section.

A finite unweighted deterministic dynamics acts through permutation matrices and has singular values equal to one. The cocycle $\mathcal{A}_*$ turns the inventory of paths into a transfer operator that preserves the positive cone, that is, into a matrix with strictly positive weights on the permitted edges. That property does not by itself prove contraction, simplicity of the dominant eigenvalue, or spectral separation; these conclusions require a normalization or an additional spectral argument.

35.7 Regional character of degree 5 and reduced action mantissa

The central block

$$\mathcal{B}_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} \tag{35.1}$$

has eigenvalues 9 and 5. The length 4 of the step orbits 3, the rank 12 of the dodecaphasic cycle, and $104976/1944 = 54$ determine the character

$$\boxed{H_5(\alpha, \varphi) = \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5.} \tag{35.2}$$

The nonadic completion constructs the analytic coordinate and the regional determinant.

$$x_A = \frac{50\pi}{9}\alpha_{\mathrm{HMT}}, \qquad D_A = e^{-2x_A} = \exp\!\left(-\frac{100\pi}{9}\alpha_{\mathrm{HMT}}\right). \tag{35.3}$$

The microfiber supplies $\rho_\pi = 169$, and its absolutely convergent series is

$$\mathcal{C}_\pi(\alpha) = 169\alpha^6 + \frac{D_A \alpha^7}{1 - D_A \alpha}. \tag{35.4}$$

The reduced mantissa after return is then constructed by

$$\boxed{\eta_{\mathrm{ret}} = H_5 - \frac{90}{\pi}\mathcal{C}_\pi(\alpha_{\mathrm{HMT}}) \in \mathbb{R}_{>0}.} \tag{35.5}$$

Its right-hand side contains exclusively objects generated previously by APP–TRIT–TPK and by the closure of α_{HMT}.

Chapter 36

Self-dual derivation of the Planck constant and its action line: temporal periodicity of 108 phases, Compton closure and bidirectional covariance

36.1 Compton realization associated with the temporal periodicity of 108 phases

On the cycle of equation (36.17), we reuse the positive action section $\hbar$ already generated by the determinantal action branch. The associated angular quantum is

$$E_{108} = \hbar\omega_{108}, \qquad m_{108} = \frac{E_{108}}{c^2} = \frac{\hbar\omega_{108}}{c^2}. \tag{36.1}$$

G has not yet been used. The geometry of the cycle and angular quantization suffice to fix its two Compton readers.

Theorem 36.1 (Identity between the temporal periodicity of 108 phases and the Compton length)**.** *For the quantum* (36.1)*,*

$$\bar{\lambda}_{\mathrm{C}}(m_{108}) = \frac{\hbar}{m_{108}c} = R_{108}, \qquad \lambda_{\mathrm{C}}(m_{108}) = \frac{h}{m_{108}c} = C_{108}. \tag{36.2}$$

Therefore, the cycle radius is its reduced Compton wavelength, and the length of one revolution is its full Compton wavelength.

Proof. Substituting $m_{108} = \hbar\omega_{108}/c^2$,

$$\frac{\hbar}{m_{108}c} = \frac{\hbar c^2}{\hbar\omega_{108}c} = \frac{c}{\omega_{108}} = R_{108}.$$

Since $h = 2\pi\hbar$, the second equality is $2\pi R_{108} = C_{108}$. □

The coincidence is not a numerical fit. It is a homogeneous identity: it holds for all $\hbar, c, t_0 > 0$ and depends only on the same period determining the frequency, the cycle length, and the quantum of action.

36.2 Gravitational Transducer and Self-Dual Selection Equation

The gravitational line HMT–MD contains the transducer

$$G(\theta) = \theta\frac{c^5 t_0^2}{\hbar}, \qquad \theta > 0. \tag{36.3}$$

Homogeneity is exact, but by itself does not select θ. The CT108 cycle supplies an additional internal condition: the gravitational reader must return the same radial scale as the geometric and Compton readers.

We define the reduced gravitational radius

$$r_{\mathrm{g}}(\theta) := \frac{G(\theta)m_{108}}{c^2}. \tag{36.4}$$

Substituting (36.1) and (36.3),

$$r_{\mathrm{g}}(\theta) = \theta\frac{\pi}{54}\ell_0. \tag{36.5}$$

Theorem 36.2 (Self-dual selector of the temporal periodicity of 108 phases)**.** *The equation*

$$r_{\mathrm{g}}(\theta) = R_{108}$$

has a unique positive solution:

$$\boxed{\theta_* = \left(\frac{54}{\pi}\right)^2.} \tag{36.6}$$

Proof. By (36.17) and (36.5), the equation is

$$\theta \frac{\pi}{54}\ell_0 = \frac{54}{\pi}\ell_0.$$

Since $\ell_0 > 0$, simplification yields $\theta = (54/\pi)^2$. The function $\theta \mapsto r_{\mathrm{g}}(\theta)$ is strictly increasing on $\mathbb{R}_{>0}$, so there is no other positive solution. □

Corollary 36.3 (Internal Planck Unit)**.** *With $G_* = G(\theta_*)$, the Planck sections satisfy*

$$\ell_{\mathrm{P}} := \sqrt{\frac{\hbar G_*}{c^3}} = R_{108}, \qquad t_{\mathrm{P}} := \sqrt{\frac{\hbar G_*}{c^5}} = \frac{1}{\omega_{108}}, \tag{36.7}$$

$$m_{\mathrm{P}} := \sqrt{\frac{\hbar c}{G_*}} = m_{108}, \qquad E_{\mathrm{P}} := m_{\mathrm{P}}c^2 = E_{108}. \tag{36.8}$$

In particular,

$$\boxed{R_{108} = \bar{\lambda}_{\mathrm{C}} = r_{\mathrm{g}} = \ell_{\mathrm{P}}, \qquad C_{108} = \lambda_{\mathrm{C}} = 2\pi r_{\mathrm{g}} = 2\pi\ell_{\mathrm{P}}.} \tag{36.9}$$

Proof. $G_* = (54/\pi)^2 c^5 t_0^2/\hbar$ is substituted. Then

$$\ell_{\mathrm{P}} = \frac{54}{\pi} c t_0 = R_{108}, \qquad t_{\mathrm{P}} = \frac{54}{\pi} t_0 = \frac{1}{\omega_{108}},$$

and

$$m_{\mathrm{P}} = \frac{\pi}{54}\frac{\hbar}{c^2 t_0} = \frac{\hbar\omega_{108}}{c^2} = m_{108}.$$

The rest follows from theorem 36.1. □

Remark 36.4 (Three readers, one section). Circular geometry publishes R_{108} and C_{108}; Compton quantization publishes $\bar{\lambda}_{\mathrm{C}}$ and λ_{C}; gravitational realization publishes r_{g} and $2\pi r_{\mathrm{g}}$. In θ_* those three pairs are coordinates of a single section. This is the precise reason why the Planck unit ceases to appear as an accidental dimensional combination within this formalization.

36.3 Commutativity of the angular, temporal, and gravitational normalizations of the self-dual identity

The transducer (36.3) admits two ways of fixing the elementary scale, which must not be confused.

(i) If $\theta = 1$ is fixed, then $\sqrt{\hbar G/c^3} = \ell_0$. The elementary transition ct_0 is identified with the Planck length of that chart.

(ii) If the *complete orbit* CT108 is required to have Planck radius, the condition selects $\theta_* = (54/\pi)^2$ and $R_{108} = \ell_{\mathrm{P}}$.

They are not rival values of G. They are two gauges of the same homogeneous equation: one assigns the Planck unit to the elementary step; the other, to the radius of the complete cycle. The annex uses the latter because its thesis concerns the identity of the CT108 closure.

36.4 Gravitational conventions: reduced radius and Schwarzschild radius

The gravitational notation is fixed in an unambiguous manner:

$$r_{\mathrm{g}} = \frac{Gm}{c^2}, \qquad r_{\mathrm{s}} = \frac{2Gm}{c^2} = 2r_{\mathrm{g}}.$$

The preceding theorem uses r_{g}, not r_{s}. In the usual convention of Planck mass, the equality $\hbar/(mc) = Gm/c^2$ is produced in $m = m_{\mathrm{P}}$, whereas

$$\frac{\hbar}{mc} = \frac{2Gm}{c^2} \quad \Longleftrightarrow \quad m = \frac{m_{\mathrm{P}}}{\sqrt{2}}. \tag{36.10}$$

For this reason the phrase "gravitational scale" designates, in the rector thesis, the reduced radius. The conventional horizon radius remains a distinct reader.

36.5 Bifurcation of the action line

The internal line of action possesses two oriented sections:

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S, \qquad R_{\mathrm{act}} = \frac{H_5}{\eta_{\mathrm{ret}}}. \tag{36.11}$$

The decade 10^{-34} fixes the absolute scale; the quotient R_{act} transports the oriented difference. This separation makes it possible to ask whether Planck self-duality survives in both coordinates.

Theorem 36.5 (Reciprocal Covariance of Action and Gravity)**.** *For $a \in \{\mathrm{pre}, \mathrm{ret}\}$, let*

$$G_a(\theta) = \theta\frac{c^5 t_0^2}{\hbar_a}, \qquad m_{108,a} = \frac{\hbar_a \omega_{108}}{c^2}.$$

Then

$$\frac{G_a(\theta) m_{108,a}}{c^2} = \theta\frac{\pi}{54}\ell_0 \tag{36.12}$$

is independent of a. Moreover,

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \tag{36.13}$$

and the Planck length $\sqrt{\hbar_a G_a/c^3} = \sqrt{\theta}\,\ell_0$ is the same in both orientations.

Proof. The factors $\hbar_a$ cancel in the product $G_a m_{108,a}$. The two ratios in (36.13) follow directly from the definitions. The invariance of the Planck length follows from $\hbar_a G_a = \theta c^5 t_0^2$. □

A symmetric parametrization makes the geometry visible:

$$\hbar_{\mathrm{geom}} := \sqrt{\hbar_{\mathrm{pre}}\hbar_{\mathrm{ret}}}, \qquad \xi := \frac{1}{2}\log R_{\mathrm{act}}, \qquad \hbar_{\mathrm{pre}} = \hbar_{\mathrm{geom}} e^{\xi}, \quad \hbar_{\mathrm{ret}} = \hbar_{\mathrm{geom}} e^{-\xi}. \tag{36.14}$$

Bidirectional memory is lodged in ξ; Planck geometry is lodged in the invariant product. This allows a real difference between the two action coordinates without requiring a difference in propagation speed.

Remark 36.6 (Physical scope of the theorem). The reciprocity of theorem 36.5 is exact within the transducer. To identify G_{pre} and G_{ret} with two oriented gravitational measurements, the protocol, the observable, and the symmetry relating them must be specified. The theorem proves structural compatibility; by itself, it neither anticipates a Lorentz violation nor an observable variation of G.

The action line constructed in the preceding section admits a circular realization compatible with temporal periodicity of order 108. This realization coordinates three objects that already possess their own types: the action section, the geometry of one revolution, and the gravitational transduction. The resulting coordination provides an internal Planck identity and prepares the positive line on which the general mass operator will subsequently act.

36.5.1 Oriented action letters and declared circular realization

Let

$$\mathcal{L}_S^+, \quad \mathcal{L}_T^+, \quad \mathcal{L}_C^+, \quad \mathcal{L}_L^+, \quad \mathcal{L}_M^+, \quad \mathcal{L}_G^+$$

the positive half-lines of action, time, velocity, length, and mass. The pre-return and post-return coordinates are written

$$\hbar_{\mathrm{pre}} = H_5\, 10^{-34}\mathcal{U}_S, \qquad \hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\, 10^{-34}\mathcal{U}_S, \qquad R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = \frac{H_5}{\eta_{\mathrm{ret}}}. \tag{36.15}$$

The subscript $a \in \{\mathrm{pre}, \mathrm{ret}\}$ shall designate either of the two charts. In each one the exact distinction is preserved

$$h_a = 2\pi\hbar_a. \tag{36.16}$$

Let us fix an elementary duration $t_0 \in \mathcal{L}_T^+$, an internal velocity $c_{\mathrm{int}} \in \mathcal{L}_C^+$, and $\ell_0 = c_{\mathrm{int}} t_0$. The declared circular realization of the temporal periodicity of order 108 is determined by

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi}{T_{108}}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi}\ell_0, \tag{36.17}$$

and by the length of the full turn

$$C_{108} = 2\pi R_{108} = c_{\mathrm{int}} T_{108} = 108\ell_0. \tag{36.18}$$

Thus, R_{108} is the radius of the realization and C_{108} its perimeter. The angular frequency, the cyclic frequency and the two action constants are related through $\omega_{108} = 2\pi/T_{108}$ and $h_a = 2\pi\hbar_a$.

36.5.2 Correspondence between the order-108 periodicity and Compton readings

In the chart a, the circular quantum and its mass section are

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2} = \frac{\hbar_a \omega_{108}}{c_{\mathrm{int}}^2}. \tag{36.19}$$

Theorem 36.7 (Identity between circular periodicity and Compton readings)**.** *For each chart $a \in \{\mathrm{pre}, \mathrm{ret}\}$, the reduced and complete Compton readings satisfy*

$$\boxed{\bar{\lambda}_{\mathrm{C}}(m_{108,a}) = \frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = R_{108}, \qquad \lambda_{\mathrm{C}}(m_{108,a}) = \frac{h_a}{m_{108,a} c_{\mathrm{int}}} = C_{108}.} \tag{36.20}$$

Proof. Substituting (36.19) produces

$$\frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = \frac{c_{\mathrm{int}}}{\omega_{108}} = R_{108}.$$

The second equality follows by applying simultaneously (36.16) and (36.18). □

The theorem is homogeneous in $(\hbar_a, c_{\mathrm{int}}, t_0)$: the same periodicity determines the radius, the perimeter, and the two Compton charts. The circular realization is the declared geometric primitive; the preceding equalities are its exact consequences.

36.5.3 Circular selector and internal Planck unit

The gravitational line is coordinated with the chart a through the homogeneous transducer

$$G_a(\theta) = \theta\,\frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a} \in \mathcal{L}_G^+, \qquad \theta \in \mathbb{R}_{>0}. \tag{36.21}$$

Its reduced gravitational radius, evaluated on the circular quantum, is

$$r_{\mathrm{g},a}(\theta) := \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta\frac{\pi}{54}\ell_0. \tag{36.22}$$

Proposition 36.8 (Planck Circular Selector)**.** *Within the circular realization* (36.17)*, the condition* $r_{\mathrm{g},a}(\theta) = R_{108}$ *selects a unique positive coordinate,*

$$\boxed{\theta_{108}^\circ = \left(\frac{54}{\pi}\right)^2}. \tag{36.23}$$

The coordinate is independent of the chart oriented a.

Proof. The equations (36.17) and (36.22) reduce the condition to

$$\theta\frac{\pi}{54}\ell_0 = \frac{54}{\pi}\ell_0.$$

The positivity of ℓ_0 and the strict monotonicity of the map $\theta \mapsto r_{\mathrm{g},a}(\theta)$ provide the solution and its uniqueness. □

Let $G_{108,a}^\circ := G_a(\theta_{108}^\circ)$. The internal units associated with this chart satisfy

$$\ell_{\mathrm{P},a}^\circ := \sqrt{\frac{\hbar_a G_{108,a}^\circ}{c_{\mathrm{int}}^3}} = R_{108}, \qquad t_{\mathrm{P},a}^\circ := \sqrt{\frac{\hbar_a G_{108,a}^\circ}{c_{\mathrm{int}}^5}} = \omega_{108}^{-1}, \tag{36.24}$$

$$m_{\mathrm{P},a}^\circ := \sqrt{\frac{\hbar_a c_{\mathrm{int}}}{G_{108,a}^\circ}} = m_{108,a}, \qquad E_{\mathrm{P},a}^\circ := m_{\mathrm{P},a}^\circ c_{\mathrm{int}}^2 = E_{108,a}. \tag{36.25}$$

The equality of radii is therefore published as

$$R_{108} = \bar{\lambda}_{\mathrm{C}} = r_{\mathrm{g}} = \ell_{\mathrm{P}}^\circ, \qquad C_{108} = \lambda_{\mathrm{C}} = 2\pi r_{\mathrm{g}} = 2\pi\ell_{\mathrm{P}}^\circ. \tag{36.26}$$

The convention of this theorem is the reduced gravitational radius $r_{\mathrm{g}} = Gm/c_{\mathrm{int}}^2$. The Schwarzschild radius satisfies $r_{\mathrm{s}} = 2r_{\mathrm{g}}$; if this second convention is adopted, its crossing with $\bar{\lambda}_{\mathrm{C}}$ occurs at $m = m_{\mathrm{P},a}^\circ/\sqrt{2}$. The declaration of the radius therefore forms part of the chart and prevents a factor of two from being inadvertently transferred between the two identities.

The coordinate θ_{108}° belongs to the declared circular specialization. The general gravitational selector, formulated on the enriched holonomy and its spectral response, retains its residence in chapter 80. Thus, the circular identity fixes an internal Planck normalization and the general criterion fixes the conditions that the physical realization of the gravitational section must satisfy.

36.5.4 Pre-return/post-return covariance

The product of the reciprocal sections of action and gravity preserves the circular geometry:

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G^{\circ}_{108,\mathrm{pre}}}{G^{\circ}_{108,\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad \hbar_a G^{\circ}_{108,a} = \theta^{\circ}_{108} c_{\mathrm{int}}^5 t_0^2. \tag{36.27}$$

In particular, $\ell^{\circ}_{\mathrm{P,pre}}$ and $\ell^{\circ}_{\mathrm{P,ret}}$ coincide with R_{108}. The bidirectional memory resides in the quotient of the masses and in its gravitational reciprocal; the geometric scale resides in the invariant product.

Reciprocity admits a symmetric parametrization that separates the common scale from the orientation of the return. Define

$$\hbar_{\mathrm{geom}} := \sqrt{\hbar_{\mathrm{pre}}\hbar_{\mathrm{ret}}}, \quad G^{\circ}_{108,\mathrm{geom}} := \sqrt{G^{\circ}_{108,\mathrm{pre}} G^{\circ}_{108,\mathrm{ret}}}, \quad \xi_{\mathrm{act}} := \frac{1}{2}\log R_{\mathrm{act}}. \tag{36.28}$$

Then

$$\hbar_{\mathrm{pre}} = \hbar_{\mathrm{geom}} e^{\xi_{\mathrm{act}}}, \qquad \hbar_{\mathrm{ret}} = \hbar_{\mathrm{geom}} e^{-\xi_{\mathrm{act}}},$$

whereas the conjugate gravitational sections satisfy

$$G^{\circ}_{108,\mathrm{pre}} = G^{\circ}_{108,\mathrm{geom}} e^{-\xi_{\mathrm{act}}}, \qquad G^{\circ}_{108,\mathrm{ret}} = G^{\circ}_{108,\mathrm{geom}} e^{\xi_{\mathrm{act}}}.$$

The coordinate ξ_{act} preserves the pre-return/post-return orientation; the product $\hbar_a G^{\circ}_{108,a}$ preserves geometric scale. This parametrization of the action charts does not by itself introduce distinct propagation speeds.

36.5.5 Split self-dual mass line

Given a chart a, let the split algebra be

$$\mathbb{D}_{\mathrm{sp}} := \mathbb{R}[j]/(j^2 - 1), \qquad P_{\pm} := \frac{I \pm j}{2},$$

and consider its spectral decomposition

$$\mathbb{D}_{\mathrm{sp}} = \mathbb{R}P_+ \oplus \mathbb{R}P_-, \qquad P_{\pm}^2 = P_{\pm}, \quad P_+P_- = 0, \quad P_+ + P_- = I.$$

The broken conjugation swaps the projectors,

$$\overline{uP_+ + vP_-} = vP_+ + uP_-,$$

and its norm is

$$N_{\mathrm{sp}}(uP_+ + vP_-) := uv.$$

For $m \in \mathcal{L}_M^+$, define the section

$$Z_a(m) := \frac{m^{\circ}_{\mathrm{P},a}}{m} P_+ + \frac{m}{m^{\circ}_{\mathrm{P},a}} P_-. \tag{36.29}$$

The unit $m^{\circ}_{\mathrm{P},a}$ also determines the involution

$$\iota_{\mathrm{P},a}(m) = \frac{(m^{\circ}_{\mathrm{P},a})^2}{m}. \tag{36.30}$$

Theorem 36.9 (Split self-dual mass line)**.** *For every $m \in \mathcal{L}_M^+$,*

$$\boxed{N_{\mathrm{sp}}(Z_a(m)) = 1, \qquad \overline{Z_a(m)} = Z_a\big(\iota_{\mathrm{P},a}(m)\big)\,.} \tag{36.31}$$

Conjugation has a unique positive fixed point,

$$m = m^{\circ}_{\mathrm{P},a}, \qquad Z_a(m^{\circ}_{\mathrm{P},a}) = I.$$

Proof. The norm is the product of the two reciprocal coordinates:

$$\frac{m^{\circ}_{\mathrm{P},a}}{m}\frac{m}{m^{\circ}_{\mathrm{P},a}} = 1.$$

Conjugation interchanges both coordinates, which is equivalent to replacing m by $(m^{\circ}_{\mathrm{P},a})^2/m$. The positive fixed point satisfies $m^2 = (m^{\circ}_{\mathrm{P},a})^2$. □

With the speed

$$x_a(m) = \log \frac{m}{m^{\circ}_{\mathrm{P},a}}, \tag{36.32}$$

the section and its conjugate are written

$$Z_a(m) = e^{-x_a}P_+ + e^{x_a}P_-, \qquad \overline{Z_a(m)} = e^{x_a}P_+ + e^{-x_a}P_-.$$

Their even and odd readers are

$$Q_a(m) := \frac{e^{x_a} + e^{-x_a}}{2} = \cosh x_a, \qquad A_a(m) := \frac{e^{x_a} - e^{-x_a}}{2} = \sinh x_a. \tag{36.33}$$

The first preserves the distance to the self-dual point and the second preserves its orientation.

The reciprocal lattice vectors associated with the same coordinate are

$$r_{\mathrm{g},a}(m) = \frac{G^{\circ}_{108,a}m}{c^2_{\mathrm{int}}}, \qquad \bar{\lambda}_{\mathrm{C},a}(m) = \frac{\hbar_a}{mc_{\mathrm{int}}},$$

and satisfy

$$\frac{r_{\mathrm{g},a}(m)}{\bar{\lambda}_{\mathrm{C},a}(m)} = e^{2x_a(m)}, \qquad \frac{\bar{\lambda}_{\mathrm{C},a}(m)}{r_{\mathrm{g},a}(m)} = e^{-2x_a(m)}. \tag{36.34}$$

Conjugation interchanges the two readers; Planck's identity is their unitary equilibrium.

Remark 36.10 (Planck identity and electronic closure). Identity $m = m^{\circ}_{\mathrm{P},a}$ fixes the self-dual origin of the positive mass line. The electronic section fixes a distinct position on that same line through its own genealogy. The section 90.4.7 constructs the universal operator that transports absolute scale, character, towers, and bidirectional reading; the section 58.2 subsequently realizes its central rank-one reduction. Thus, the Planck unit supplies the identity of the coordinate, and the electron supplies the first complete material transition on it.

Proposition 36.11 (Genealogical realization of the electronic center)**.** *Let*

$$F^+_e = \mathbb{R}_{>0}(P_+ + P_-)$$

the positive half-line of the rank-one central fiber, let $\mathcal{G}_e$ be the space of enriched electronic genealogies and let $\mathcal{L}^+_M$ be the positive mass line. A realization morphism

$$\mathfrak{R}_e : F^+_e \times \mathcal{G}_e \longrightarrow \mathcal{L}^+_M$$

can send the identity $I = P_+ + P_-$ to a mass different from $m^{\circ}_{\mathrm{P},a}$ without altering the theorem 36.9: the Planck identity fixes the autodual origin of the chart, while the electronic genealogy fixes a displacement on that chart.

Proof. If $\chi_e : \mathcal{G}_e \to \mathbb{R}_{>0}$ is the positive character constructed by the electronic record, the rule

$$\mathfrak{R}_e(\lambda I, g) = \lambda\, m^{\circ}_{\mathrm{P},a}\chi_e(g)$$

is positive and multiplicative in the genealogical coordinate. For the neutral genealogy, $\chi_e = 1$, the Planck origin is recovered; for a genealogy with $\chi_e(g) \neq 1$, the same internal identity occupies a different position of the line. The concrete electronic closure preserves its antecedent development in the section 58.2. □

36.6 Autoduality of the Planck internal unit under orientation inversion

The CT108 selector constructs

$$\theta_{108} = \left(\frac{54}{\pi}\right)^2, \qquad \ell_P = \frac{54}{\pi}\ell_0, \qquad t_P = \frac{54}{\pi}t_0, \tag{36.35}$$

and

$$E_P = \frac{\hbar_{\mathrm{int}}}{t_P} = \frac{\pi\hbar_{\mathrm{int}}}{54t_0}. \tag{36.36}$$

Comparing equations (36.36) y (48.1) gives

$$\boxed{E_P = k_B\Theta_{\mathrm{clk}}\log 3.} \tag{36.37}$$

The relation does not depend on a coincidence between units: both sides follow from the same chronological structure 108.

Once the gravitational constant has been derived internally in the chapter 50, the Planck family satisfies

$$\ell_P^2 = \frac{G\hbar}{c^3} = \theta_{108}\ell_0^2, \tag{36.38}$$

$$F_P = \frac{c^4}{G}, \qquad P_P = \frac{c^5}{G}, \tag{36.39}$$

$$\rho_P = \frac{\hbar}{\theta_{108}^2 c^5 t_0^4}. \tag{36.40}$$

Although G and $\hbar$ transform reciprocally between the sections before and after the return, their product in ℓ_P^2 preserves the geometry. This invariance determines area as the interface between the geometric, informational and entanglement realizations.

36.7 Action line and Planck constant

Let $\mathcal{L}_S$ be the real action line with positive basis $\mathcal{U}_S$. The transduction

$$\tau_S : \mathbb{R}_{>0} \longrightarrow \mathcal{L}_S, \qquad u \longmapsto u\,10^{\varepsilon_H}\mathcal{U}_S \tag{36.41}$$

publish the sections preceding and following the return:

$$\hbar_{\mathrm{pre}} = H_5\,10^{-34}\mathcal{U}_S, \qquad \boxed{\hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}}\,10^{-34}\mathcal{U}_S.} \tag{36.42}$$

The full cycle actions are

$$h_{\mathrm{pre}} = 2\pi\hbar_{\mathrm{pre}}, \qquad h_{\mathrm{ret}} = 2\pi\hbar_{\mathrm{ret}}. \tag{36.43}$$

For a phase θ, the angular and action charts commute:

$$S(\theta) = \hbar_{\mathrm{ret}}\theta_{\mathrm{rad}} = \hbar_{\mathrm{ret}}\frac{\pi}{180}\theta_{\mathrm{deg}} = h_{\mathrm{ret}}\frac{\theta_{\mathrm{deg}}}{360}. \tag{36.44}$$

36.8 Operator genealogy of action, angular geometry, and mass

The coinductive APP–TRIT–TPK dynamics extends to arbitrary depth over the same enriched state and over the joint discrete structure of the continuum. At each prolongation it preserves value, genealogy, phase, carry, orientation, vacancy, path, boundary, memory, and survival. Its distinguished publications are first the three internal coordinates and, through the dodecaphasic seal, the coordinate α_{HMT}:

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow \mathcal{S}_{\infty}^{\mathrm{enr}} \longrightarrow \mathcal{C}_{\mathrm{cont}}^{\mathrm{disc}} \longrightarrow (\pi_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, e_{\mathrm{HMT}}) \longrightarrow \alpha_{\mathrm{HMT}}.$$

The last arrow represents the signed publication of α_{HMT} within those same dynamics; it receives no conventional values and does not turn conventional π, φ, e into generators.

Only afterward is the determinantal action reader applied. It publishes the valuation $10^{-34}\mathcal{U}_S$, the two sections $\hbar_{\mathrm{pre}}, \hbar_{\mathrm{ret}}$, and their full-cycle actions

$$h_{\mathrm{pre}} = 2\pi_{\mathrm{HMT}}\hbar_{\mathrm{pre}}, \qquad h_{\mathrm{ret}} = 2\pi_{\mathrm{HMT}}\hbar_{\mathrm{ret}}.$$

From this causal point onward, two branches remain separate and do not select one another. The dimensional–gravitational branch extends the action and the causal section to the already proven forms of the Planck pair,

$$\ell^2 = G\hbar c^{-3}, \qquad \frac{\ell}{Q} = Gc^{-4};$$

the complex branch publishes, from the internal rotation operator,

$$u^2 + 1 = 0, \qquad u \longmapsto J_{+1}, \qquad J_{+1}^2 = -I.$$

This is the internal operator realization of i, not the introduction of a complex symbol without an antecedent. The dimensional–gravitational and complex branches are parallel over the common enriched state: the former does not turn i into an input to the action scale and, conversely, h, $\hbar$, c^{-3}, and c^{-4} do not generate i. The identities of the Planck pair thus remain separate from the complex realization.

Writing $\prec_{\mathrm{HMT}}$ for causal precedence with type preservation —and not to assert that each object on the right is a function of all those on the left— yields

$$\begin{aligned}(\pi, \varphi, e, \alpha)_{\mathrm{HMT}} &\prec_{\mathrm{HMT}} (10^{-34}\mathcal{U}_S, \hbar, h)\\ &\prec_{\mathrm{HMT}} \left\{G\hbar c^{-3}, Gc^{-4};\ J_{+1}^2 = -I, i\right\}\\ &\prec_{\mathrm{HMT}} (A_{\mathrm{deg}}, C_{\mathrm{deg}}^{*})\\ &\prec_{\mathrm{HMT}} (\text{electron, mass law}).\end{aligned}$$

The angular construction preserves its effective inputs α_{HMT} and η_{ret}: the two preceding parallel branches establish joint availability and typing, but are not retrospectively promoted to selectors of the angle or counterangle.

In the central electronic path, the bidirectional readers preserve two distinct stages of a single genealogy:

$$E_e^{(0)} = 0.5109989224880660725\ldots \text{ MeV}, \qquad \text{basal stage},$$
$$E_e^{\beta} = E_e^{(0)} R_{\mathrm{act}}^{80-54\alpha_{\mathrm{HMT}}+6\Delta_4} = 0.510998950690000808608\ldots \text{ MeV}, \qquad \text{governing beta output},$$

with

$$K_D(\Gamma_e) = K_\Omega(\Gamma_e) = (80, 54, 6).$$

The coincidence of the triple in the central fiber does not identify the domains or the operations of K_D and K_Ω. In the historical canonical register, `MD-ELECTRON-001` designates the calibrated candidate of the basal stage. This identification retains its provenance function, but does not govern the beta output or select the path; the basal and beta closure remain typed stages of the bidirectional readers.

Refutation criterion. The preceding genealogy is refuted if a conventional value or the beta output is used to select a path, if the basal stage is presented as the governing closure, if either of the two parallel branches is identified without a typed map, or if the angle, counterangle, electron, or a mass is placed among the inputs to the constant or action generator.

Chapter 37

Phase operator prior to dimensional transduction: decomposition into 27 sectors, spectral radius and factorization of the double projection

The two preceding sections have gathered three pieces that previously appeared separately: an isometric identification between projectors, a quotient measure, and a positive action cocycle. The present section studies the spectral consequence of that law and places the result within the complete architecture of HMT.

The separation of statuses is precise. The triple identification is an exact theorem relative to the new internal variational rule and an oriented anchor. The measure and the positive character are exact theorems of Tr_q–Add; the defect is relative, in addition, to Def, the capacity to Res, and the local cost to Loc. The angular value is an interval-certified output of the operator Γ_{tr}. Its proximity to the canonical conjugate angular coordinate is extraordinary, but the interval for the difference excludes equality.

37.1 Decomposition of the angular operator into 27 sectors of 72 states

The all-paths reader Γ_{tr}has 1944 microscopic states. The coarse translation action of $(\mathbb{Z}/3\mathbb{Z})^3$ permits the decomposition

$$1944 = 27 \cdot 72.$$

Each block of 72 states is parametrized by

$$(r, s, m, d) \in (\mathbb{Z}/3\mathbb{Z})^2 \times \{0, 1\} \times D_4,$$

where m is the sheet and d the preceding direction. From each state four cardinal continuations depart. The TRIT of the arrival cell decides the following sheet.

With the action of the chapter 35, the weight of an edge is

$$\exp[-g(e) - \lambda_* s(e)].$$

The character transform reduces the operator to complex matrices L_{k_a,k_b} of size 72×72. The program enumerates the edges of each block; it does not receive a precomputed spectral matrix. Power iteration is retained as an exploration, but the result that follows no longer rests on it: the spectral radii are isolated by means of a complete rational certification.

Let ρ_{01} and ρ_{12} be the spectral radii of the oriented sectors $(0, 1)$ and $(1, 2)$. We define the *band phase*

$$\boxed{y_{\mathrm{band}} = \log \rho_{12} - \log \rho_{01}.}$$

For

$$\lambda_* = 1 - \frac{5}{468} - \frac{3}{11}\Delta_4,$$

the certification gives

$$1.4606551208620111111 < \rho_{01} < 1.460655120862404024,$$
$$1.5158120082709443328 < \rho_{12} < 1.515812008271195416,$$

and, by interval propagation,

$$0.037066226434427529 < y_{\mathrm{band}} < 0.037066226434862172,$$

$$\boxed{2.123738337168943^\circ < C_{\mathrm{band}} := \frac{180}{\pi} y_{\mathrm{band}} < 2.123738337193847^\circ.}$$

The primary quantity is y_{band}, a dimensionless logarithm of spectral quotient. Degrees appear later when the chart $180/\pi$ is applied. The operator first produces an internal phase and only later an Archimedean angular representation.

37.1.1 Exact calculation of the spectral radius of the angular operator

The blocks are nonnormal. Therefore, a small residual $\|Lv - \mu v\|$ does not suffice to prove that μ is the eigenvalue of greatest modulus. The proof used here consists of four steps.

First, twelve structurally zero rows occur in each block. Expanding the characteristic polynomial along these rows yields a factor z^{12} and a principal minor of order sixty. A further eight structurally zero rows occur in this minor. Therefore,

$$\det(zI_{72} - L) = z^{20} \det(zI_{52} - A),$$

and every nonzero eigenvalue is contained, with multiplicity, in a reduced block A of order fifty-two.

Second, the certificate provides rational Gaussian matrices S, R, with denominator 10^{16}. The verifier calculates $E = I - RS$ exactly and obtains

$$\|E\|_\infty \le 8.5664 \times 10^{-14} \quad \text{and} \quad \|E\|_\infty \le 3.7628 \times 10^{-14}$$

for the sectors $(0, 1)$ and $(1, 2)$, respectively. The Neumann series then proves that S is invertible.

Third, if A_0 is the rational midpoint of the interval block, the identity

$$S^{-1}AS = (I - E)^{-1}RAS$$

bounds the distance to $C_0 = RA_0S$ by

$$1.25125 \times 10^{-13} \quad \text{and} \quad 5.7037 \times 10^{-14}.$$

The Gershgorin discs of C_0, enlarged by those bounds, contain the discs of the exact similarity. In each block, one disc remains separated from the other fifty-one; the second Gershgorin theorem assigns it exactly one eigenvalue. Its lower modulus exceeds the upper modulus of every other disc. This proves that the isolated eigenvalue is the spectral radius.

Fourth, $\pi, e, \log \pi, e^{-1}, e^{-\lambda_*}$ and $\sqrt{3}$ are not accepted as library decimals. The verifier encloses them by means of Machin's formula, the factorial and logarithmic series with remainder, the alternating series for the exponential, and a quadratic rational bracket for $\sqrt{3}$. Verification employs only integers and fractions; the argument is closed by the rational reduction, the Neumann series, and the Gershgorin separation presented in this section. The reproducible decimal expansions to a depth of ten thousand are published, as independent finite witnesses, in the appendix of expansions.

37.2 Effective band operator T_{band} and isolation of the angular phase

Let

$$x = \frac{50\pi}{9} \alpha_{\mathrm{HMT}} = 0.127362829012869966\ldots$$

and let

$$R = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The effective bilayer operator associated exclusively with the band phase is

$$\boxed{T_{\text{band}} = \exp(-xI + y_{\text{band}}R).}$$

At the base of oriented sectors,

$$T_{\text{band}} = \begin{pmatrix} e^{-x+y_{\text{band}}} & 0 \\ 0 & e^{-x-y_{\text{band}}} \end{pmatrix}.$$

We verify

$$\det T_{\text{band}} = e^{-2x}, \qquad \frac{(T_{\text{band}})_{11}}{(T_{\text{band}})_{22}} = e^{2y_{\text{band}}}.$$

Therefore,

$$-\frac{9}{100\pi}\log\det T_{\text{band}} = \alpha_{\text{HMT}}, \qquad \frac{90}{\pi}\log\frac{(T_{\text{band}})_{11}}{(T_{\text{band}})_{22}} = C_{\text{band}}.$$

The two recoveries have distinct statuses. The second returns the output produced by the gap. The first rereads the α_{HMT} that entered x; it proves reversibility of the chart, not a second independent derivation of α.

The exponential form separates two functions. The common factor e^{-x} describes the shared contraction of the two sheets. The factors $e^{\pm y_{\text{band}}}$ distinguish orientations while preserving the determinant. Since I and R commute, the pair

$$\left(\det T_{\text{band}}, \frac{(T_{\text{band}})_{11}}{(T_{\text{band}})_{22}}\right)$$

uniquely reconstructs (x, y_{band}).

37.3 Posterior comparison and precision scale

The following section constructs another phase, the *regularized regional phase* y_{reg} —also denoted there by y_*—. To formulate a comparison here with that subsequent result, we anticipate the notation

$$C_{\text{reg}} := \frac{180}{\pi}y_{\text{reg}} = 2.123738338968646^\circ.$$

This line does not constitute a second definition or an entry of the spectral operator: it cites the conclusion of theorem 38.14, whose construction is developed in the following section. The two pairs of objects are not identified:

$$(y_{\text{band}}, C_{\text{band}}) \neq (y_{\text{reg}}, C_{\text{reg}}).$$

The certified interval difference of the linear law is

$$-1.799703 \times 10^{-9}\ ^\circ < C_{\text{band}} - C_{\text{reg}} < -1.774799 \times 10^{-9}\ ^\circ,$$

with relative difference enclosed by

$$-8.475 \times 10^{-10} < \frac{C_{\text{band}} - C_{\text{reg}}}{C_{\text{reg}}} < -8.356 \times 10^{-10}.$$

The law that produces C_{band} does not receive C_{reg}, CKM, Barbero, masses, or SI data. This target independence makes the proximity a candidate for strong, falsifiable recognition. The spectral certification eliminates the former numerical gap; the interval difference, which excludes zero, now fixes the exact boundary: C_{band} is a predimensional spectral output distinct from the regional realization C_{reg}.

The additional term

$$-\frac{\Delta_4^2}{27}$$

en λ produce

$$C_{\text{num}} \approx 2.12373833894104980^\circ,$$

at 2.76×10^{-11} degrees of C_{reg}. The integer 27 is internal, since it counts the characters of $(\mathbb{Z}/3\mathbb{Z})^3$, but that fact does not force the coefficient of the second moment. The exact additivity of Addexcludes quadratic terms. The variant is preserved as an ablation and not as the principal law.

37.4 Functional dependence of the spectral radius with respect to the components of the operator

All subsequent rows use the same operator; only one input of the law changes. They are numerical ablation diagnostics; the preceding certified interval pertains exclusively to the complete law Tr_q–Add–Def–Res–Loc(and, within it, the positive defect is fixed in the Tr_q–Add–Defstratum).

rule	λ	C_{num} in degrees
self-dual	1	2.082755794784418
microfiber only	$1 - 5/468$	2.123621809570142
trace $5/468 + (3/11)\Delta_4$	0.989285913019141	2.123738337181414
$4/468$ instead of $5/468$	0.991422665155894	2.115535228138553
$3/12$ instead of $3/11$	0.989288440210566	2.123728626433667
$5/243$ instead of $5/468$	0.979393542015659	2.161907060464779
$5/729$ instead of $5/468$	0.993110963140488	2.109064222037112
$7/729$, seed measure	0.990367478915522	2.119584299852700.

The ablations demonstrate that the output distinguishes the complete microfiber, the reduced dimension eleven, and the emission measure. By themselves, they do not assign a chance probability: such a probability would first require defining a space of alternative models and a measure on it.

37.5 Typed composition of the morphisms Archimedean, exceptional, and dimensional

The complete construction can be written as a sequence of applications with visible domains:

$$
\begin{aligned}
\Omega_{\mathrm{seed}} &\xrightarrow{F} \mathcal{U}_6 \xrightarrow{J_F} H_U, \\
\mathscr{R}_\pi^{++} &\xrightarrow{\beta_\pi} P_G H_G, \\
L_{\mathrm{or}} \otimes P_G H_G &\xrightarrow{W_{GK}} P_3 V_{11} \xrightarrow{U_W} Q_3 E_{30}, \\
(\Pi_\pi^{(468)}, \Delta_4 P_3) &\longmapsto D_{\mathrm{switch}} \xrightarrow{\tau} \delta_* \xrightarrow{\mathsf{Res}} \lambda_*, \\
\lambda_* &\xrightarrow{\mathsf{Loc}} a_* \xrightarrow{\mathcal{L}_{1,*}} y_{\mathrm{band}} \xrightarrow{180/\pi} C_{\mathrm{band}}, \\
(\alpha_{\mathrm{HMT}}, y_{\mathrm{band}}) &\xrightarrow{\exp(-xI + y_{\mathrm{band}} R)} T_{\mathrm{band}}.
\end{aligned}
$$

Each arrow declares what it preserves:

- F preserves the emission class and leaves its presentation multiplicity in the fibre;
- J_F compensates that multiplicity in the norm;
- β_π preserves the exceptional position;
- W_{GK} preserves the oriented representation;
- U_W preserves incidence and metric;
- the trace forgets coordinates and preserves ranks;
- the transfer operator sums paths with the action weight;
- the chart $180/\pi$ represents an internal phase in degrees.

37.6 Dependency diagram of the angular operator and its publications

Object	Mathematical Nature	Contenido demostrado
$U_W = I/6 : V_{11} \to E_{30}$	exact theorem	isometry, surjectivity, equivariant incidence, and positive uniqueness

37.7 Predimensional action at the center of the double projection of the genealogical state

The double projection begins from the same enriched state and produces two readings. In the Archimedean branch, compatible cylinders are refined and their diameters decrease; evaluation fixes a limiting value and forgets part of the genealogy. In the exceptional branch, incidences are prolonged toward Witt, Golay, Niemeier–Leech, $V^\natural$, the Monster, and moonshine.

The new result adds a common object stronger than a coincidence of cardinalities. The eleven-mode module, its rank-three positive sector, and the trace of the action pass from dodecaphase to Witt through U_W. The oriented sector $t = 7$ is incorporated through W_{GK}. The microfiber of π provides the regional projector $\Pi_\pi^{(468)}$, and the uniform measure on the catalogue fixes its weight.

Positive action thus stands at the center of the two readings:

$$\text{region} \quad \oplus \quad \text{oriented polarization} \quad \longmapsto \quad \text{positive defect.}$$

The Archimedean evaluation and the exceptional evaluation remain different maps; the intertwiner identifies a common sector, it does not collapse their codomains.

37.8 Compatibility of the angular operator with the cylinders of the discrete continuum

An HMT history determines nested cylinders

$$C_1 \supset C_2 \supset \cdots$$

with compatible prefixes. When the Archimedean reader satisfies

$$\operatorname{diam}(C_n) \longrightarrow 0,$$

the completeness of $\mathbb{R}$ fixes at most one value in the intersection. The new action adds structure before that limit: it distinguishes the cost of the route, the emission class, and the multiplicity of presentations that the final value no longer displays.

This is the precise mathematical meaning of the assertion that the continuum is read as a projection of discrete genealogies. The system of cylinders and its evaluations is prolonged at every scale; the global coverage theorem proves $\mathrm{ev}_{\mathbb{R}}(\Omega_{\infty,K}) = K$ for every compact set $K \subset \mathbb{R}$ and, upon directing the intervals, proves that the image is all of $\mathbb{R}$. The finite theorem in this section controls the angular action at each level and is integrated into that global coverage; it neither reopens nor conditions it. The algebraic descent of each operation retains its own verification.

37.9 Compatibility with the exceptional rider, Moonshine, and M-theory screens

The intertwiner U_W lands in the incidence module of W_{12}. From the ternary code, the two exceptional continuations remain separate:

$$C_W \longrightarrow W_{12} \xrightarrow[\text{relative to } (D,\ell)]{} W_{24},$$

and

$$C_W \xrightarrow{\phi} N(A_2^{12}) \xrightarrow{\nu_\alpha} \Lambda_{24} \longrightarrow V_\Lambda \longrightarrow V^\natural \longrightarrow \mathbb{M} \longrightarrow \text{moonshine.}$$

Positive action contributes to this branch a transported sector and an orientation line. The arrows from Leech to moonshine are the classical constructions applied to the finite object obtained. The Monster action is realized on $V^\natural$; the HMT words are not identified here with a direct module for that action.

The screens $12 \to 11 \to 10$, $26 \to 24$, and the T-dual involution form an exact mathematical interface with the dimensions and dualities used in M-theory. The full physical identification belongs to Dimensional Mechanics and is typed in the second part by the additional map to g_{MN}, C_{MNP}, ψ_M, action, and supersymmetry. It is neither deferred to another work nor deduced from the Monster action.

37.10 Spectral factorization and isolation of the dominant sectors

The pre-dimensional line is organized into four strata.

1. **Finite kernel.** APP, TRIT, the TPK emitter, the catalog $104\,976 \to 468 \to 243$, the five regions of π, the dodecaphase, K, α, Witt, and the exceptional branch have explicit constructions and certificates.
2. **Operatorial bridge.** Incidence constructs U_W; the oriented sector $t = 7$ constructs P_G; B_K and u_K select the oriented isometric identification; the three rank-three projectors are identified relative to that rule.
3. **Action extension.** Tr_qfixes the measure $1/468$, Addfixes the additive character, and Defdeclares the coupling $\Delta_4 P_3$. Restransforms the defect into capacity, and Loccarries capacity to the edges. The five clauses produce the local law.
4. **Spectral consequence.** Γ_{tr}produces T_{band} and a certified predimensional angular phase, with relative difference between 8.356×10^{-10} and 8.475×10^{-10} with respect to C_{reg}.

This permits a strong and typed closure of this route: the finite emitter of the infinite coinductive section, the incidence, the identification of projectors, the measure, and the action are closed relative to the declared primitives, the variational rule $\mathcal{E}_B$, and the action clauses Tr_q–Add–Def–Res–Loc. Addselects the linear form; Defselects its second coordinate; Resand Locspecify how it is read as a cost. The global theorem covering all of $\mathbb{R}$, induction from a total transition of $\mathcal{X}^{\mathrm{enr}}_{\mathrm{TPK}}$, and physical equivalence with M-theory are formulated as extensions of the preceding results.

37.11 Compatibility between the matrix, angular, and lattice realizations

The constructed representations simultaneously satisfy the following compatibility conditions:

1. five regions of π, with three positivas, one negativa and one transversal;
2. P_G, P_3, Q_3 as positive projectors and R_{B_K} as an orientation involution;
3. the oriented homogeneous sector $t = 7$, not the heterogeneous quotient of $t = 8$;
4. the line L_{or} in the triple isometric identification;
5. the relative character of the variational rule that selects H_*, c_*, r_*;
6. $5/468$ on emissions and $7/729$ on seeds, without interchanging them;
7. the linearity of the character as a consequence of Addand the coefficient Δ_4 as content separated from Def;
8. $(y_{\mathrm{band}}, C_{\mathrm{band}})$ as a certified spectral output, separate from $(y_{\mathrm{reg}}, C_{\mathrm{reg}})$, the canonical regional realization of the following section;
9. α_{HMT} as input to x, so that the determinant reading is reversible and not independent;
10. the branches $W_{12} \to W_{24}$ and $A_2^{12} \to \Lambda_{24}$ as separate constructions;
11. the relative reader Tr_q–Add–Def–Res–Locdistinguished from a total transition, whose dynamic image measure constitutes an additional construction.

These conditions are not editorial notes. They form part of the logical structure of the result.

Chapter 38

Exact equivalence of the global and analytic charts of the angular pair: degrees, radians, phases $q_{\pm}$, and complementary orientation

The dimensionless component posterior to the return is constructed before the counter-angle by means of $\eta_{\mathrm{ret}} = H_5 - (90/\pi)C_\pi(\alpha_{\mathrm{HMT}})$. In the parallel determinantal branch the valuation 10^{-34} is obtained, and both branches converge in the magnitude $\hbar_{\mathrm{ret}} = \eta_{\mathrm{ret}} 10^{-34} U_S$. Only afterward are $A_{\mathrm{deg}} = 10^3 \alpha_{\mathrm{HMT}}$ and $C^*_{\mathrm{deg}} = 2(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}})$ published; the solving $C^*/2 - \alpha_{\mathrm{HMT}}$ remains as inverse verification.

38.1 Intrinsic angular phase α_{HMT}, nonadic lift 10^3, and precursor x_A

38.1.1 Construction of the analytic precursor x_A, the contraction D_A, and the regional correction $\mathscr{C}_\pi(\alpha)$

The finite catalog and an analytic evaluation answer questions of different types. The catalog determines which regions exist, which share a return and what information each preserves. An analytic evaluation must also decide how the length of a word is transformed into degree, how a branch is prolonged after its return and with which scalar character that prolongation is read. This chapter explicitly constructs that second operation.

The construction begins with four data already obtained in the preceding chapters: the five-region microfiber of π, the length six of each regional word, the dodecaphasic closure of α, and the bilayer transport associated with the common coordinate $A = 10^3\alpha$. No value of the conjugate angular coordinate C_*^{HMT}, of the reduced action component, of the Barbero–Immirzi functional, or of a metrological constant is used in the evaluation. The result is a convergent regional character, an exact recurrence, and an oriented phase whose sexagesimal chart reproduces the published conjugate angular coordinate.

The separation between the finite part and the analytic part is essential. The integer 169 will be a theorem of the catalogue. The series that prolongs it will be the theorem of an analytic reader whose rules are declared before it is evaluated. Thus, the additional premises are not concealed within a decimal coincidence.

38.2 Preangular construction of η_{ret} through H_5, D_A and $\mathscr{C}_\pi(\alpha)$

38.2.1 Independent derivation of $\eta_{\mathrm{ret}} = H_5 - (90/\pi)\mathscr{C}_\pi(\alpha)$ through the regional analytic reader

The finite catalogue and an analytic evaluation answer questions of different types. The catalogue determines which regions exist, which share a return, and what information each preserves. An analytic evaluation must further determine how the length of a word is transformed into degree, how a branch is prolonged after its return, and by which scalar character that prolongation is read. This section constructs that second operation explicitly.

The construction begins with the five-region microfiber of π, the length six of each regional word, the dodecaphasic closure of α, and the declared angular insertion

$$\iota_\angle(x) := 10^3 x\, u_\circ, \qquad A_{\mathrm{deg}} := 10^3 \alpha.$$

Here $u_\circ$ is the sexagesimal base whose complete turn has coordinate 360. The factor 10^3 belongs to that chart normalization and is not deduced from the arithmetic closure of α. The two-sheet transport is subsequently constructed from A_{deg}. The function evaluated by the reader does not receive as an argument the counter-angle, the post-return coordinate, the hexad–octad functional, or a metrological constant. The result is a convergent regional character, an exact recurrence, and an oriented phase in the declared sexagesimal chart.

The separation between the finite part and the analytic part is essential. The integer 169 is a theorem of the catalogue. The series that prolongs it belongs to an analytic reader whose rules are declared before evaluating it.

The phase is denoted by y_* and, when its regional origin is emphasized, by y_{reg}; both symbols denote the same reader constructed below.

The evaluation receives the catalogue of 468 emissions, the exact value of α_{HMT}, $\varphi = (1+\sqrt{5})/2$, the fixed formula of H_5, the angular chart, and the five rules of the regional reader. With those data, it computes 169, D_A, the recurrence, and C^*. The theorem is exact in this declared class of readers; it does not use C^* as an input or assert that the rules of H_5 are the only possible natural class.

38.2.2 Persistence of the return in the 5 regions of the microfiber

Let

$$\mathcal{F}_\pi = \Psi^{-1}(010211) \subset \mathcal{U}_6$$

the microfiber relative to the catalog. Recall its five elements, now separated into initial block and terminal block:

$$(501, 614, 498 \mid 169, 272, 272),$$
$$(810, 923, 870 \mid 169, 272, 272),$$
$$(810, 983, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 418, 674, 521).$$

We define the return projection.

$$p_{\mathrm{ret}} : \mathbb{Z}^6 \longrightarrow \mathbb{Z}^3, \qquad p_{\mathrm{ret}}(u_1, \dots, u_6) = (u_4, u_5, u_6).$$

Proposition 38.1 (Persistent terminal block)**.** *The multiset $p_{\mathrm{ret}}(\mathcal{F}_\pi)$ has a unique element of maximum multiplicity:*

$$b_\pi = (169, 272, 272), \qquad \mathrm{mult}_{\mathcal{F}_\pi}(b_\pi) = 4.$$

The only remaining terminal block is

$$b_\pi^- = (418, 674, 521)$$

and has multiplicity one.

Proof. The assertion follows by exact enumeration of the five rows of the catalog that satisfy $\Psi(U) = 010211$. Four rows have terminal block $(169, 272, 272)$; the fifth, which carries the mutated return, has $(418, 674, 521)$. The maximum multiplicity is four and is attained only once. □

The oriented difference between the mutated return and the persistent is

$$\omega_\pi = b_\pi^- - b_\pi = (249, 402, 249), \qquad \langle (1,1,1), \omega_\pi \rangle = 900.$$

This identity separates two objects that must not be conflated. The integer 169 is a coordinate of a terminal datum, that is, a datum of degree zero. The vector ω_π can be read as a one-cochain after orienting the edge joining the two blocks. Calling it a cocycle would additionally require fixing a cochain complex and verifying that its coboundary vanishes. The analytic prolongation constructed below does not presuppose that identification.

The selection of 169 does not require privileging the first position of the block. The symmetric group $\mathfrak{S}_3$ acts by permuting its three coordinates. The stabilizer of b_π exchanges the two occurrences of 272

and fixes the unique coordinate of multiplicity one. Denote that coordinate by $\mathrm{sing}(b)$ when the block has type (r, s, s), with $r \neq s$. Equivalently,

$$\mathrm{sing}(b) = \sum_{j=1}^{3} b_j - 2\,\mathrm{moda}(b).$$

In particular,

$$\boxed{\mathrm{sing}(b_\pi) = 169.}$$

Definition 38.2 (Residual fiber selector)**.** The selector ρ_π successively applies two operations:

1. selects the terminal block of maximum multiplicity within $p_{\mathrm{ret}}(\mathcal{F}_\pi)$;
2. retains the coordinate fixed by the stabilizer of that block.

By proposition 38.1,

$$\boxed{\rho_\pi = 169.}$$

Theorem 38.3 (Equivariant uniqueness of return)**.** *Among the selectors that*

1. *are invariant under permutations of the five regions;*
2. *are equivariant under permutations of the three terminal coordinates;*
3. *select the block of maximal multiplicity;*
4. *retain a coordinate fixed by its stabilizer,*

the return value is uniquely determined and is 169.

Proof. Invariance under $\mathfrak{S}_5$ prevents using the order of the rows. The third condition selects b_π, which is the unique mode by proposition 38.1. Its stabilizer in $\mathfrak{S}_3$ has two orbits on the coordinates: the pair of values 272 and the singleton value 169. The fourth condition selects the second orbit. Equivariance preserves its value when its position is shifted. □

This argument improves the positional reading of the return. The 169 is not «the first coordinate» of a selected row: it is an invariant of the regional multiset and of the action of its reordering symmetries. Nor is it selected by global rarity. Among the 468 emissions in the catalogue, 169 appears 84 times, uniformly distributed with 14 occurrences in each of the six positions. The uniqueness of theorem 38.3 is therefore relational and regional: it resides in the combination of microfiber, modal persistence, and stabilizer, not in the isolated frequency of the integer.

38.2.3 Construction of the regional analytic reader and its convergence domain

Analytic continuation is fixed by the following rules.

Definition 38.4 (Regional Determinantal Reader)**.** The determinantal regional reader satisfies:

1. *degree compatibility*: cylindrical length is the analytic degree;
2. *renewal decomposition*: the finite return impulse and strict continuation belong to distinct additive summands;
3. *continuation normalization*: after recording the residue ρ_π just once, the surviving branch begins at the unit of the determinant line;
4. *concatenation covariance*: each elementary prolongation acts through $\bigwedge^2 \mathcal{T} = D_A$;
5. *orientation*: in the cardinal convention fixed for APP, the regional return belongs to the compensating sector and is subtracted from the fifth-degree action phase.

The third rule has mathematical content. The value 169 is recorded once as the amplitude of the return; it is not multiplied again at each prolongation. The strict continuation counts the sole line that continues and normalizes it by its unit. This is the distinction between a renewal recurrence and homogeneous iteration of the initial impulse.

The need to declare that normalization can be proved. For every $\lambda \in \mathbb{R}$, the family

$$F_\lambda(z) = 169z^6 + \lambda \frac{D_A z^7}{1 - D_A z}$$

preserves the same finite return and the same determinantal ratio between consecutive coefficients. The catalogue and the ratio alone do not distinguish λ. The unit of the determinant line fixes $\lambda = 1$ before $z = \alpha$ is evaluated. Thus, the normalization is not obtained by fitting the final value; it forms part of the definition of the character.

38.2.4 Analytical solution of the return recurrence

We define the coefficients κ_n by

$$\kappa_6 = 169, \qquad \kappa_7 = D_A, \qquad \kappa_{n+1} = D_A \kappa_n \quad (n \geq 7).$$

The first equality is the regional impulse; the next two describe the normalized continuation.

Theorem 38.5 (Graduated analytic realization)**.** *The analytic germ compatible with the rules of definition 38.4 is unique and equals*

$$\boxed{\mathscr{C}_\pi(z) = 169z^6 + \frac{D_A z^7}{1 - D_A z}.}$$

Their coefficients satisfy

$$\kappa_n = D_A^{n-6} \qquad (n \geq 7).$$

Proof. Write

$$F(z) = 169z^6 + \sum_{k \geq 1} c_k z^{6+k}.$$

The normalization of continuation and the determinantal covariance give

$$c_1 = D_A, \qquad c_{k+1} = D_A c_k.$$

By induction, $c_k = D_A^k$. The geometric sum yields

$$\sum_{k \geq 1} D_A^k z^{6+k} = \frac{D_A z^7}{1 - D_A z}.$$

No free coefficients remain. □

Since $0 < \alpha < 1$ and $0 < D_A < 1$,

$$0 < D_A \alpha < 1.$$

Consequently, $\mathscr{C}_\pi(\alpha)$ converges absolutely and its radius of convergence is $D_A^{-1} > 1$. Numerically,

$$D_A = 0.77512911924715643018888409648 02\ldots,$$

$$D_A \alpha = 0.00565639046986492673885079095469\ldots.$$

The speed of this contraction explains why the complete sum and its degree-seven truncation have the same first fifteen digits in the final chart.

38.2.5 Persistence of return in the 5 regions and compatibility of the η_{ret} component

Let

$$\mathcal{F}_\pi = \Psi^{-1}(010211) \subset \mathcal{U}_6$$

the microfiber relative to the catalog. Recall its five elements, now separated into initial block and terminal block:

$$(501, 614, 498 \mid 169, 272, 272),$$
$$(810, 923, 870 \mid 169, 272, 272),$$
$$(810, 983, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 169, 272, 272),$$
$$(870, 923, 810 \mid 418, 674, 521).$$

We define the return projection.

$$p_{\mathrm{ret}} : \mathbb{Z}^6 \longrightarrow \mathbb{Z}^3, \qquad p_{\mathrm{ret}}(u_1, \dots, u_6) = (u_4, u_5, u_6).$$

Proposition 38.6 (Persistent terminal block)**.** *The multiset $p_{\mathrm{ret}}(\mathcal{F}_\pi)$ has a unique element of maximum multiplicity:*

$$b_\pi = (169, 272, 272), \qquad \mathrm{mult}_{\mathcal{F}_\pi}(b_\pi) = 4.$$

The only remaining terminal block is

$$b_\pi^- = (418, 674, 521)$$

and has multiplicity one.

Proof. The assertion follows by exact enumeration of the five rows of the catalog that satisfy $\Psi(U) = 010211$. Four rows have terminal block $(169, 272, 272)$; the fifth, which carries the mutated return, has $(418, 674, 521)$. The maximum multiplicity is four and is attained only once. □

The oriented difference between the mutated return and the persistent is

$$\omega_\pi = b_\pi^- - b_\pi = (249, 402, 249), \qquad \langle (1, 1, 1), \omega_\pi \rangle = 900.$$

This identity separates two objects that must not be conflated. The integer 169 is a coordinate of a terminal datum, that is, a datum of degree zero. The vector ω_π can be read as a one-cochain after orienting the edge joining the two blocks. Calling it a cocycle would additionally require fixing a cochain complex and verifying that its coboundary vanishes. The analytic prolongation constructed below does not presuppose that identification.

The selection of 169 does not require privileging the first position of the block. The symmetric group $\mathfrak{S}_3$ acts by permuting its three coordinates. The stabilizer of b_π exchanges the two occurrences of 272 and fixes the unique coordinate of multiplicity one. Denote that coordinate by $\mathrm{sing}(b)$ when the block has type (r, s, s), with $r \neq s$. Equivalently,

$$\mathrm{sing}(b) = \sum_{j=1}^{3} b_j - 2\,\mathrm{moda}(b).$$

In particular,

$$\boxed{\mathrm{sing}(b_\pi) = 169.}$$

Definition 38.7 (Residual fiber selector)**.** The selector ρ_π successively applies two operations:

1. selects the terminal block of maximum multiplicity within $p_{\mathrm{ret}}(\mathcal{F}_\pi)$;

2. retains the coordinate fixed by the stabilizer of that block.

By proposition 38.6,

$$\boxed{\rho_\pi = 169.}$$

Theorem 38.8 (Equivariant uniqueness of return)**.** *Among the selectors that*

1. *are invariant under permutations of the five regions;*
2. *are equivariant under permutations of the three terminal coordinates;*
3. *select the block of maximal multiplicity;*
4. *retain a coordinate fixed by its stabilizer,*

the return value is uniquely determined and is 169*.*

Proof. Invariance under $\mathfrak{S}_5$ prevents using the order of the rows. The third condition selects b_π, which is the unique mode by proposition 38.6. Its stabilizer in $\mathfrak{S}_3$ has two orbits on the coordinates: the pair of values 272 and the singleton value 169. The fourth condition selects the second orbit. Equivariance preserves its value when its position is shifted. □

This argument improves the positional reading of the return. The 169 is not «the first coordinate» of a selected row: it is an invariant of the regional multiset and of the action of its reordering symmetries. Nor is it selected by global rarity. Among the 468 emissions in the catalogue, 169 appears 84 times, uniformly distributed with 14 occurrences in each of the six positions. The uniqueness of theorem 38.8 is therefore relational and regional: it resides in the combination of microfiber, modal persistence, and stabilizer, not in the isolated frequency of the integer.

38.2.6 Application of the regional reader to the conjugate angular momentum pair

Analytic continuation is fixed by the following rules.

Definition 38.9 (Regional Determinantal Reader)**.** The determinantal regional reader satisfies:

1. *degree compatibility*: cylindrical length is the analytic degree;
2. *renewal decomposition*: the finite return impulse and strict continuation belong to distinct additive summands;
3. *continuation normalization*: after recording the residue ρ_π just once, the surviving branch begins at the unit of the determinant line;
4. *concatenation covariance*: each elementary prolongation acts through $\bigwedge^2 \mathcal{T} = D_A$;
5. *orientation*: in the cardinal convention fixed for APP, the regional return belongs to the compensating sector and is subtracted from the fifth-degree action phase.

The third rule has mathematical content. The value 169 is recorded once as the amplitude of the return; it is not multiplied again at each prolongation. The strict continuation counts the sole line that continues and normalizes it by its unit. This is the distinction between a renewal recurrence and homogeneous iteration of the initial impulse.

The need to declare that normalization can be proved. For every $\lambda \in \mathbb{R}$, the family

$$F_\lambda(z) = 169z^6 + \lambda \frac{D_A z^7}{1 - D_A z}$$

preserves the same finite return and the same determinantal ratio between consecutive coefficients. The catalogue and the ratio alone do not distinguish λ. The unit of the determinant line fixes $\lambda = 1$ before

$z = \alpha$ is evaluated. Thus, the normalization is not obtained by fitting the final value; it forms part of the definition of the character.

38.2.7 Closed sum and publication of the posterior component upon return

We define the coefficients κ_n by

$$\kappa_6 = 169, \qquad \kappa_7 = D_A, \qquad \kappa_{n+1} = D_A \kappa_n \quad (n \geq 7).$$

The first equality is the regional impulse; the next two describe the normalized continuation.

Theorem 38.10 (Graduated analytic realization)**.** *The analytic germ compatible with the rules of definition 38.9 is unique and equals*

$$\boxed{\mathscr{C}_\pi(z) = 169 z^6 + \frac{D_A z^7}{1 - D_A z}.}$$

Their coefficients satisfy

$$\kappa_n = D_A^{n-6} \qquad (n \geq 7).$$

Proof. Write

$$F(z) = 169 z^6 + \sum_{k \geq 1} c_k z^{6+k}.$$

The normalization of continuation and the determinantal covariance give

$$c_1 = D_A, \qquad c_{k+1} = D_A c_k.$$

By induction, $c_k = D_A^k$. The geometric sum yields

$$\sum_{k \geq 1} D_A^k z^{6+k} = \frac{D_A z^7}{1 - D_A z}.$$

No free coefficients remain. □

Since $0 < \alpha < 1$ and $0 < D_A < 1$,

$$0 < D_A \alpha < 1.$$

Consequently, $\mathscr{C}_\pi(\alpha)$ converges absolutely and its radius of convergence is $D_A^{-1} > 1$. Numerically,

$$D_A = 0.77512911924715643018888409648 02\ldots,$$

$$D_A \alpha = 0.00565639046986492673885079095469\ldots.$$

The speed of this contraction explains why the complete sum and its degree-seven truncation have the same first fifteen digits in the final chart.

38.3 Confluence of η_{ret} With the valuation $\varepsilon_H = -34$ in the magnitude $\hbar_{\mathrm{ret}}$

38.3.1 Derivation of the determinantal character of parangular transport

The dodecaphasic closure provides α. The completion of the three nonadic pairs provides the scale 10^3, so that

$$A = 10^3\alpha.$$

Having chosen the Archimedean angular chart, the common coordinate in radians is

$$x = \frac{\pi A}{180} = \frac{50\pi}{9}\alpha.$$

Let R be a real involution of zero trace in dimension two,

$$R^2 = I_2, \qquad \operatorname{tr} R = 0,$$

and consider the formal two-layer transport

$$\mathcal{T}(x, y) = \exp(-xI_2 - yR).$$

The oriented variable y has not yet been evaluated. Nevertheless, the action of $\mathcal{T}$ on the determinant line is independent of it:

$$\begin{aligned}\det \mathcal{T}(x, y) &= \exp(\operatorname{tr}(-xI_2 - yR)) \\ &= e^{-2x}.\end{aligned}$$

We define

$$\boxed{D_A = e^{-2x} = e^{-100\pi\alpha/9}.}$$

The subscript recalls that this is the determinant of the common contraction associated with A, not a function of C_*^{HMT}.

Proposition 38.11 (Character of the determinant line)**.** *The map*

$$\delta_A : (\mathbb{N}_0, +) \longrightarrow (\mathbb{R}_{>0}, \cdot), \qquad \delta_A(k) = D_A^k,$$

is the unique multiplicative character whose value on an elementary prolongation is D_A.

Proof. The multiplicativity gives

$$\delta_A(k) = \delta_A(\underbrace{1 + \cdots + 1}_{k \text{ times}}) = \delta_A(1)^k = D_A^k.$$

The same identity proves existence and uniqueness. □

The determinant remains invariant under conjugation of $\mathcal{T}$ and under the exchange of sheets $R \mapsto -R$. Therefore, the tail constructed from D_A belongs to the common mode. The orientation will appear in the sign with which the regional character corrects the phase.

38.3.2 action character of degree 5 in the construction regional

The central block

$$\mathcal{B}_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}$$

has eigenvalues 9 and 5. The dodecaphasic cycle contributes rank 12; its step-three orbits have length four; and the complete census contributes the exact quotient

$$\frac{104976}{1944} = 54.$$

From these invariants the fifth-degree action character is fixed.

$$\boxed{H_5(\alpha,\varphi) = \frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}} - \alpha + \frac{9}{16}\alpha^2 - \frac{5}{9}\alpha^3 + \frac{7}{48}\alpha^4 - \frac{1}{54}\alpha^5.}$$

The four rational coefficients can be written as

$$\frac{9}{16} = \frac{\lambda_+}{4^2}, \qquad \frac{5}{9} = \frac{\lambda_-}{\lambda_+}, \qquad \frac{7}{48} = \frac{\frac{1}{2}\operatorname{tr}\mathcal{B}_c}{4\cdot 12}, \qquad \frac{1}{54} = \frac{1944}{104976},$$

with $(\lambda_+,\lambda_-) = (9,5)$. These identities certify the provenance of the numbers used. The successive assignment of those invariants to degrees two, three, four, and five forms part of the analytic character; it does not follow from the mere existence of the finite catalog.

This precision removes a common ambiguity. A combination of invariants of the construction is an internal and reproducible definition; its naturality requires the reader rules specifying order, signs, and normalization. Here those rules are visible and are subject to the same negative controls as the rest of the construction.

38.3.3 Exact decomposition of the action line into pre-return and post-return sections

The fifth-degree character and the post-action component after return are two distinct values:

$$H_5 = 1.0545718176461544696258218294330 6\ldots,$$

$$\bar{h}^{\mathrm{ret}}_{\mathrm{HMT}} = 1.0545718169150390611336905847243 0\ldots.$$

The first is the local action before incorporating the regional character; the second is the oriented action remaining after the return. The correction that generates the conjugate angular coordinate prevents identifying them.

The metrological comparison must respect this distinction. The first value gives the mantissa

$$2\pi H_5 = 6.626070149999987926001110349899 47\ldots,$$

while the subsequent action gives

$$2\pi\bar{h}^{\mathrm{ret}}_{\mathrm{HMT}} = 6.626070145406254333510749847592 88\ldots.$$

In the International System, the value

$$h = 6.62607015\times 10^{-34}\ \mathrm{J\,s}$$

is exact by definition [20]. By therefore,

$$2\pi H_5 - 6.62607015 = -1.2073998889650101\ldots\times 10^{-14},$$

and it is not an exact equality. The proximity of the value before the return is a remarkable numerical check; it does not authorize replacing the defining constant of the SI with the subsequent component or confusing the two HMT actions.

This result precisely determines the mathematical situation. The regional reader generates C_*^{HMT} and, from it, the functional $\Gamma_{6\to 8}$. The same calculation separates the Planck approximation produced by H_5 from the reduced action intervening in the conjugate angular coordinate. The separation does not weaken the construction: it eliminates an identification incompatible with the exact figures and converts every comparison into a falsifiable assertion of a well-defined type.

38.3.4 Factorization of the determinantal character in the 2 phase charts

Dodecaphase closure supplies α. The declared angular insertion uses the scale 10^3, compatible with the grouping of three nonadic pairs, so that

$$A_{\mathrm{deg}} = 10^3 \alpha\,^{\circ}.$$

Having chosen the Archimedean angular chart, the common coordinate in radians is

$$x =: A_{\mathrm{rad}} = \frac{\pi A_{\mathrm{deg}}}{180} = \frac{50\pi}{9}\alpha.$$

Let R be a real involution of zero trace in dimension two,

$$R^2 = I_2, \qquad \operatorname{tr} R = 0,$$

and consider the formal two-layer transport

$$\mathcal{T}(x, y) = \exp(-xI_2 - yR).$$

The oriented variable y has not yet been evaluated. Nevertheless, the action of $\mathcal{T}$ on the determinant line is independent of it:

$$\begin{aligned} \det \mathcal{T}(x, y) &= \exp(\operatorname{tr}(-xI_2 - yR)) \\ &= e^{-2x}. \end{aligned}$$

We define

$$\boxed{D_A = e^{-2x} = e^{-100\pi\alpha/9}.}$$

The subscript recalls that this is the determinant of the common contraction associated with A, not a function of the counter-angle.

Proposition 38.12 (Character of the determinant line)**.** *The map*

$$\delta_A : (\mathbb{N}_0, +) \longrightarrow (\mathbb{R}_{>0}, \cdot), \qquad \delta_A(k) = D_A^k,$$

is the unique multiplicative character whose value on an elementary prolongation is D_A.

Proof. The multiplicativity gives

$$\delta_A(k) = \delta_A(\underbrace{1 + \cdots + 1}_{k \text{ times}}) = \delta_A(1)^k = D_A^k.$$

The same identity proves existence and uniqueness. □

The determinant remains invariant under conjugation of $\mathcal{T}$ and under the exchange of sheets $R \mapsto -R$. Therefore, the tail constructed from D_A belongs to the common mode. The orientation will appear in the sign with which the regional character corrects the phase.

38.3.5 Publication of the action character of degree 5 in the parangular chart

The central block

$$\mathcal{B}_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix}$$

has eigenvalues 9 and 5. The dodecaphasic cycle contributes rank 12; its step-three orbits have length four; and the complete census contributes the exact quotient

$$\frac{104976}{1944} = 54.$$

The current reader declares the nature of fifth-degree action

$$\boxed{H_5(\alpha,\varphi)=\frac{1}{2}\sqrt{\frac{1000\alpha}{\varphi}}-\alpha+\frac{9}{16}\alpha^2-\frac{5}{9}\alpha^3+\frac{7}{48}\alpha^4-\frac{1}{54}\alpha^5.}$$

The four rational coefficients can be written as

$$\frac{9}{16}=\frac{\lambda_+}{4^2},\qquad \frac{5}{9}=\frac{\lambda_-}{\lambda_+},\qquad \frac{7}{48}=\frac{\frac{1}{2}\operatorname{tr}\mathcal{B}_c}{4\cdot 12},\qquad \frac{1}{54}=\frac{1944}{104976},$$

with $(\lambda_+,\lambda_-)=(9,5)$. These identities fix the internal arithmetic representability of the character coefficients. Their order, signs, and normalization belong to the graded rule of the regional reader and are applied before any chart of units. The ablations certify that every term effectively intervenes in the resulting phase. In particular, neither the SI mantissa of action nor the sexagesimal value of the counter-angle belongs to the domain of the generating function.

38.4 Parangular application $P(\alpha,\eta_{\mathrm{ret}})$ and bilayer closure $C^*=2(\eta_{\mathrm{ret}}+\alpha)$

38.4.1 Oriented phase and conjugate angular coordinate

The fifth-degree phase prior to return is

$$y_5=\frac{\pi}{90}\big(H_5+\alpha\big).$$

The complete regional character produces the correction $\mathscr{C}_\pi(\alpha)$. With the orientation fixed in definition 38.4, we define

$$\boxed{y_*=\frac{\pi}{90}\big(H_5+\alpha\big)-169\alpha^6-\frac{D_A\alpha^7}{1-D_A\alpha}.}$$

This is the primary formula. The sexagesimal unit does not come into play until applying the chart.

$$C_*^{\mathrm{HMT}}=\frac{180}{\pi}y_*.$$

Theorem 38.13 (Conjugate angular coordinate of the regional reader determinantal)**.** *With the dodecaphasic closure of α, $\varphi=(1+\sqrt{5})/2$ and the rules of the determinantal regional reader fixed, the phase y_* and its conjugate angular coordinate are determined without introducing the sought value. Their evaluation is*

$$\boxed{y_*=0.037066226465838263984937794092306 38\ldots,}$$

$$\boxed{C_*^{\mathrm{HMT}}=2.123738338968645724261951380393 36\ldots^\circ.}$$

Therefore, to fifteen decimal places,

$$\boxed{C_*^{\mathrm{HMT}}=2.123738338968646^\circ.}$$

Proof. theorem 38.3 determines 169. The closure of α determines A,x, and $D_A=e^{-100\pi\alpha/9}$. theorem 38.5 determines the complete series. The formula for H_5 contains only α, φ, and declared structural invariants. Substituting these data into the expression for y_* gives the printed value. The decimal value of C_*^{HMT} occurs in none of the right-hand sides. □

The reduced action component after return is now as follows output:

$$\boxed{\bar{h}^{\mathrm{ret}}_{\mathrm{HMT}} = \frac{C^{\mathrm{HMT}}_{*}}{2} - \alpha = H_5 - \frac{90}{\pi}\mathscr{C}_{\pi}(\alpha).}$$

Numerically,

$$\bar{h}^{\mathrm{ret}}_{\mathrm{HMT}} = 1.0545718169150390611336905847243 0\ldots.$$

The inverse identity has not been used to introduce C^{HMT}_{*}; it is obtained after generating y_{*}.

38.4.2 Conjugate coordinate C^{*} and reversal of its orientation under the bilayer involution

The fifth-degree phase prior to return is

$$y_5 = \frac{\pi}{90}\big(H_5 + \alpha\big).$$

The complete regional character produces the correction $\mathscr{C}_{\pi}(\alpha)$. With the orientation fixed in definition 38.9, we define

$$\boxed{C^{*}_{\mathrm{rad}} := y_{*} = \frac{\pi}{90}\big(H_5 + \alpha\big) - 169\alpha^{6} - \frac{D_A\alpha^{7}}{1 - D_A\alpha}.}$$

From now on we also write

$$\boxed{y_{\mathrm{reg}} := y_{*}}$$

when it is necessary to distinguish this realization from the spectral phase of Γ_{tr}. The two notations here designate the same canonical regional object. This is the primary formula. The sexagesimal unit does not intervene until the chart is applied

$$\boxed{C^{*}_{\mathrm{deg}} := \frac{180}{\pi}C^{*}_{\mathrm{rad}}.}$$

The symbols C^{*}_{rad} and C^{*}_{deg} do not denote two counterangles: they are the radial and sexagesimal coordinates of the same angular element.

Theorem 38.14 (Counter-angle of the regional determinantal reader)**.** *Given the dodecaphase closure of α, $\varphi = (1+\sqrt{5})/2$, the germ H_5 and the rules of the regional determinantal reader, the phase C^{*}_{rad} and its counter-angle are determined without introducing the sought value into the evaluation function. Its evaluation is*

$$\boxed{C^{*}_{\mathrm{rad}} = 0.037066226465838263984937794092306 38\ldots,}$$

$$\boxed{C^{*}_{\mathrm{deg}} = 2.123738338968645724261951380393 36\ldots^{\circ}.}$$

Therefore, to fifteen decimal places,

$$\boxed{C^{*}_{\mathrm{deg}} = 2.123738338968646^{\circ}.}$$

Proof. The theorem 38.8 determines 169. The closure of α determines A_{deg}, A_{rad}, and $D_A = e^{-100\pi\alpha/9}$. The theorem 38.10 determines the complete series. The fixed formula for H_5 contains only α, φ, and declared structural invariants. Substituting these data into the expression for C^{*}_{rad} yields the printed value. The decimal value of the counter-angle appears in none of the right-hand sides of this evaluation. Comparison with a metrological action mantissa is undertaken only after the phase has been obtained and does not alter the generating function. □

Let $u_{\circ}$ be the sexagesimal base whose complete turn has coordinate 360, and let us introduce the angular coordinate $\alpha_{\angle,\mathrm{deg}} := \alpha_{\mathrm{HMT}}$. The output posterior to return is then typed by

$$\boxed{\eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{C_{\mathrm{deg}}^{*}}{2} - \alpha_{\angle,\mathrm{deg}} = H_5 - \frac{90}{\pi}\mathscr{C}_{\pi}(\alpha).}$$

Its radial coordinate is

$$\eta_{\mathrm{ret}}^{(\mathrm{rad})} = \frac{\pi}{180}\eta_{\mathrm{ret}}^{(\mathrm{deg})} = \frac{C_{\mathrm{rad}}^{*}}{2} - \frac{\pi}{180}\alpha_{\mathrm{HMT}}.$$

Numerically,

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = 1.0545718169150390611336905847243 0\ldots.$$

The inverse identity has not been used to introduce C_{deg}^{*}; it is obtained after generating C_{rad}^{*}. The symbol $\hbar$ is reserved for the element of the action line constructed in the following section.

38.4.3 Direct theorem $C^{*} = 2(\eta_{\mathrm{ret}} + \alpha)$ and inverse character of the identity $\eta_{\mathrm{ret}} = C^{*}/2 - \alpha$

The fifth-degree character and the coordinate after return are two distinct values:

$$H_5 = 1.0545718176461544696258218294330 6\ldots,$$

$$\eta_{\mathrm{ret}}^{(\mathrm{deg})} = 1.0545718169150390611336905847243 0\ldots.$$

The former is the local character before incorporation of the regional character; the latter is the oriented coordinate remaining after the return. The correction generating the contra-angle prevents their identification.

The metrological comparison must respect this distinction. The first value gives the mantissa

$$2\pi H_5 = 6.626070149999987926001110349899 47\ldots,$$

while the posterior coordinate gives

$$2\pi\eta_{\mathrm{ret}}^{(\mathrm{deg})} = 6.626070145406254333510749847592 88\ldots.$$

As an external control only, we retain the mantissa 6.62607015 of the defining value of the International System [20]. Neither its exponent nor its unit is yet incorporated into the HMT line: the decade is derived in the section 59.2 and the unit belongs to a later metrological chart. The comparison of mantissas gives

$$2\pi H_5 - 6.62607015 = -1.2073998889650101\ldots\times 10^{-14},$$

and is not an exact equality. The proximity of the pre-return value is a noteworthy numerical control; it does not authorize replacing the defining SI constant by the subsequent coordinate or confusing an angular coordinate with the action element that will be constructed upon incorporating the decade.

This result determines the mathematical situation precisely. The regional reader generates $(C_{\mathrm{rad}}^{*}, C_{\mathrm{deg}}^{*})$ and, from that single angular element, the functional $\Gamma_{6\to 8}$. The same calculation separates the external proximity of the mantissa produced by H_5 from the return coordinate that enters the counter-angle. The separation does not weaken the construction: it eliminates an identification incompatible with the exact digits and turns each comparison into a falsifiable assertion of a well-defined type.

The cubic completion

$$10^3 = (9+1)^3 = 9^3 + 3\cdot 9^2 + 3\cdot 9 + 1 = 729 + 243 + 27 + 1 \tag{38.1}$$

determines the chart global of the coordinate direct. The closure bilayer contributes the factor 2 of the coordinate conjugate:

$$\boxed{A_{\mathrm{deg}} = 10^3\alpha_{\mathrm{HMT}}, \qquad C_{\mathrm{deg}}^{*} = 2(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}}) \quad \text{in } \mathbb{R}/(360\mathbb{Z}).} \tag{38.2}$$

The inverse identity

$$\eta_{\mathrm{ret}} = \frac{1}{2} C^{*}_{\mathrm{deg}} - \alpha_{\mathrm{HMT}} \tag{38.3}$$

is established as an algebraic corollary of the direct construction.

38.5 Exact commutativity of the charts in turns, degrees, and radians

38.5.1 Derivation of the cylindrical length and the analytic degree of the parangular precursor

Let $\mathcal{P}$ be the free module generated by the regional words and let $F^{n}\mathcal{P}$ be its length filtration. The associated grading records the first level at which each word appears. For a parameter z, the ordinary length character is

$$\chi_{z}([w]) = z^{|w|}.$$

Multiplicativity

$$\chi_{z}([uv]) = \chi_{z}([u])\chi_{z}([v])$$

expresses that concatenation adds lengths. When evaluated at $z = \alpha$, a word of length n receives degree α^{n}.

Definition 38.15 (Degree compatibility)**.** The regional analytic reader is compatible with the cylindrical filtration when it sends the homogeneous component of length n to analytic degree n:

$$\mathrm{gr}_{n}\,\mathcal{P} \longrightarrow \alpha^{n}\mathbb{R}.$$

The five regions belong to $\mathcal{U}_{6}$; therefore, the return datum appears in degree six:

$$\rho_{\pi}[U_{6}] \longmapsto 169\alpha^{6}.$$

This six is the length of the regional word. It is not the length of the closed walks of chapter 9. Those walks traverse the four anchors $U_{\pi}, U_{e}, U_{\varphi}, U_{\mathrm{APP}}$ simultaneously and have minimum length eight. A word, an edge of the block graph, and a closed walk are objects of distinct types; the grading used here belongs to the first.

38.5.2 Publication of the analytic degree on the global phase chart

Let $\mathcal{P}$ be the free module generated by the regional words and let $F^{n}\mathcal{P}$ be its length filtration. The associated grading records the first level at which each word appears. For a parameter z, the ordinary length character is

$$\chi_{z}([w]) = z^{|w|}.$$

Multiplicativity

$$\chi_{z}([uv]) = \chi_{z}([u])\chi_{z}([v])$$

expresses that concatenation adds lengths. When evaluated at $z = \alpha$, a word of length n receives degree α^{n}.

Definition 38.16 (Degree compatibility)**.** The regional analytic reader is compatible with the cylindrical filtration when it sends the homogeneous component of length n to analytic degree n:

$$\mathrm{gr}_{n}\,\mathcal{P} \longrightarrow \alpha^{n}\mathbb{R}.$$

The five regions belong to $\mathcal{U}_{6}$; therefore, the return datum appears in degree six:

$$\rho_{\pi}[U_{6}] \longmapsto 169\alpha^{6}.$$

This six is the length of the regional word. It is not the length of the closed walks of chapter 9. Those walks traverse the four anchors $U_\pi, U_e, U_\varphi, U_{\mathrm{APP}}$ simultaneously and have minimum length eight. A word, an edge of the block graph, and a closed walk are objects of distinct types; the grading used here belongs to the first.

The global calendar exhibits the three factorizations

$$360 = 12 \cdot 30 = 4 \cdot 90 = 3 \cdot 120. \tag{38.4}$$

The analytical chart is obtained through

$$A_{\mathrm{rad}} = \frac{\pi}{180} A_{\mathrm{deg}} = \frac{50\pi}{9} \alpha_{\mathrm{HMT}}, \qquad C^*_{\mathrm{rad}} = \frac{\pi}{180} C^*_{\mathrm{deg}} = \frac{\pi}{90}(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}}). \tag{38.5}$$

Theorem 38.17 (Commutativity of Regional and Action Factorizations)**.** *The two routes toward the conjugate phase produce the same output:*

$$\boxed{\frac{\pi}{180} C^*_{\mathrm{deg}} = \frac{\pi}{90}(\eta_{\mathrm{ret}} + \alpha_{\mathrm{HMT}}) = \frac{\pi}{90}(H_5 + \alpha_{\mathrm{HMT}}) - \mathscr{C}_\pi(\alpha_{\mathrm{HMT}}) = y_*.} \tag{38.6}$$

Proof. Substituting equation (35.5) in the second member yields

$$\frac{\pi}{90}\left(H_5 - \frac{90}{\pi}\mathscr{C}_\pi + \alpha_{\mathrm{HMT}}\right) = \frac{\pi}{90}(H_5 + \alpha_{\mathrm{HMT}}) - \mathscr{C}_\pi.$$

The final expression is the regional definition of y_*, whereas the first equality follows from equation (38.2). □

38.6 spectral decomposition $q_{\pm}$ and calculo functional on the channels 90/120 previously generated

38.6.1 Spectral reconstruction of the angular pair and hexad-octad transition

The common phase and the oriented phase determine the two channels.

$$q_- = e^{-x+y_*}, \qquad q_+ = e^{-x-y_*}.$$

The invariants are recovered exactly.

$$q_- q_+ = D_A, \qquad \alpha = -\frac{9}{100\pi}\log D_A, \qquad C^{\mathrm{HMT}}_* = \frac{90}{\pi}\log\frac{q_-}{q_+}.$$

The first equality reads the common contraction; the third, the oriented separation of the sheets. The exchange $R \mapsto -R$ permutes q_+ and q_-, preserves D_A and reverses the sign of y_*.

For

$$S_{90}(q) = \frac{q^{90}}{1-q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1-q^{360}},$$

the hexad–octad transition functional is written entirely in the phase chart:

$$\Gamma_{6\to 8} = \frac{180}{\pi} x y_* + 12\big(S_{90}(q_-) - S_{90}(q_+)\big) - \big(S_{120}(q_-) - S_{120}(q_+)\big).$$

The evaluation produced by the coordinate C^{HMT}_* of theorem 38.13 is

$$\boxed{\Gamma_{6\to 8} = 0.27400767269445927474725526077 4\ldots.}$$

Thus, the internal value recognized in Dimensional Mechanics as the Barbero–Immirzi functional ceases to receive C_*^{HMT} as an independent literal: both descend from the same pair of phases generated in this chapter. The geometric and physical interpretation of $\Gamma_{6\to 8}$ belongs to the work on Dimensional Mechanics; its mathematical evaluation already belongs to the previously constructed interface.

38.6.2 Relative transporter and spectral disjunction of the blocks

In the ordered basis of channels, let

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad P_{\pm} = \frac{I \pm R}{2}, \qquad B_0 = 7I + 2R, \qquad B_1 = A_{\deg} I + C_{\deg}^* R.$$

The split decomposition

$$xI + yR = \rho(x,y) e^{\eta(x,y)R}, \quad \rho(x,y) = \sqrt{x^2 - y^2}, \quad \eta(x,y) = \operatorname{artanh}(y/x)$$

constructs the unique transporter

$$T_{\mathrm{rel}} = \frac{\sqrt{(A_{\deg})^2 - (C_{\deg}^*)^2}}{\sqrt{45}} \exp\left[\left(\operatorname{artanh}\frac{C_{\deg}^*}{A_{\deg}} - \operatorname{artanh}\frac{2}{7}\right) R\right], \qquad T_{\mathrm{rel}} B_0 = B_1.$$

In the spectral basis it acts by $9 \mapsto A_{\deg} + C_{\deg}^*$ and $5 \mapsto A_{\deg} - C_{\deg}^*$.

Theorem 38.18 (Spectral Disjunction of the Local and Angular Realizations)**.** *The spectra*

$$\mathrm{Spec}(B_0) = \{9, 5\}, \qquad \mathrm{Spec}(B_1) = \{A_{\deg} + C_{\deg}^*, A_{\deg} - C_{\deg}^*\}$$

are disjoint. Consequently,

$$\mathrm{Hom}_{B_0, B_1} := \{\Phi : \Phi B_0 = B_1 \Phi\} = \{0\}.$$

Proof. The rational bounds constructed for the angular coordinates give $7.29 < A_{\deg} < 7.30$ and $2.12 < C_{\deg}^* < 2.13$; therefore, $9.41 < A_{\deg} + C_{\deg}^* < 9.43$ and $5.16 < A_{\deg} - C_{\deg}^* < 5.18$. In the basis that diagonalizes R, each entry of an intertwiner is multiplied by the difference between an eigenvalue of B_0 and one of B_1; disjointness forces all of them to vanish. □

The relative transporter compares two blocks within the split algebra; the dodecaphasic–Witt and incidence intertwiners act between equivalent representations in their own spaces of residence. This separation positively types both operations and preserves their domains.

38.6.3 Spectral evaluation $V_{90,120}$ of the incidence channels previously generated by the TPK

The common phase and the oriented phase determine the two channels.

$$q_- = e^{-A_{\mathrm{rad}} + C_{\mathrm{rad}}^*}, \qquad q_+ = e^{-A_{\mathrm{rad}} - C_{\mathrm{rad}}^*}.$$

The invariants are recovered exactly.

$$q_- q_+ = D_A, \qquad \alpha = -\frac{9}{100\pi} \log D_A, \qquad C_{\deg}^* = \frac{90}{\pi} \log \frac{q_-}{q_+}.$$

The first equality reads the common contraction; the third, the oriented separation of the sheets. The exchange $R \mapsto -R$ permutes q_+ and q_-, preserves D_A and reverses the sign of C_{rad}^*.

Let $H^2 = I$ and $P_{\pm} = (I \pm H)/2$. The angular block

$$B = A_{\mathrm{rad}} I + C_{\mathrm{rad}}^* H = (A_{\mathrm{rad}} + C_{\mathrm{rad}}^*) P_+ + (A_{\mathrm{rad}} - C_{\mathrm{rad}}^*) P_- \tag{38.7}$$

is published multiplicatively by

$$e^{-B} = q_+P_+ + q_-P_-, \qquad q_\pm = \exp[-(A_{\mathrm{rad}} \pm C^*_{\mathrm{rad}})]. \tag{38.8}$$

The involution $C^* \mapsto -C^*$ permutes q_+ and q_-, and preserves

$$q_+q_- = e^{-2A_{\mathrm{rad}}} = D_A. \tag{38.9}$$

The cardinalities 90/120, previously constructed through TPK incidence, now receive their spectral evaluation:

$$V_{90,120} = (I - T^{90})(I - T^{120})^{-1} = \sum_{\sigma\in\{+,-\}} \frac{1 - q_\sigma^{90}}{1 - q_\sigma^{120}} P_\sigma. \tag{38.10}$$

38.6.3.1 Split relative transporter

The comparison With the central block of APP can be carried out without identifying representations distinct. Fijemos the ordered basis of channels and the involution

$$R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad R^2 = I, \qquad P_\pm = \frac{I \pm R}{2}.$$

In commutative algebra

$$\mathscr{B}_R := \{xI + yR : x, y \in \mathbb{R}\}$$

consider a, within the already declared sexagesimal chart,

$$B_0 := 7I + 2R, \qquad B_1 := A_{\mathrm{deg}}I + C^*_{\mathrm{deg}}R.$$

The orthogonal change of basis

$$S = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

simultaneously diagonalizes the involution and both blocks. For $x > |y|$, we define

$$\rho(x, y) := \sqrt{x^2 - y^2}, \qquad \eta(x, y) := \operatorname{artanh}\left(\frac{y}{x}\right).$$

Then

$$xI + yR = \rho(x, y)e^{\eta(x,y)R}.$$

If

$$\rho_0 = \sqrt{45}, \quad \eta_0 = \operatorname{artanh}(2/7), \quad \rho_1 = \rho(A_{\mathrm{deg}}, C^*_{\mathrm{deg}}), \quad \eta_1 = \eta(A_{\mathrm{deg}}, C^*_{\mathrm{deg}}),$$

the unique left multiplication that carries B_0 to B_1 is

$$\boxed{T_{\mathrm{rel}} := \frac{\rho_1}{\sqrt{45}} e^{(\eta_1-\eta_0)R}, \qquad T_{\mathrm{rel}}B_0 = B_1.}$$

Proposition 38.19 (Relative carrier of the two blocks)**.** *Once R, the channel order, the positive branch, and the sexagesimal chart have been fixed, T_{rel} is the unique element of $\mathscr{B}_R$ satisfying $TB_0 = B_1$. In the spectral basis it acts by*

$$9 \longmapsto A_{\mathrm{deg}} + C^*_{\mathrm{deg}}, \qquad 5 \longmapsto A_{\mathrm{deg}} - C^*_{\mathrm{deg}}.$$

Proof. The split polar decomposition yields the printed formula and proves existence. Since $\det B_0 = 45 \neq 0$, every matrix solution of $TB_0 = B_1$ satisfies $T = B_1B_0^{-1}$; it is therefore unique. Diagonalization by

means of S produces the two spectral quotients $(A_{\mathrm{deg}} + C^{*}_{\mathrm{deg}})/9$ and $(A_{\mathrm{deg}} - C^{*}_{\mathrm{deg}})/5$, equivalent to the exponential expression of T_{rel}. □

This transporter is not a representational intertwiner. Indeed, an intertwiner Φ between the endomorphisms B_0 and B_1 should satisfy

$$\Phi B_0 = B_1 \Phi.$$

Theorem 38.20 (Spectral Obstruction to Entanglement)**.** *For the values of A_{deg} and C^{*}_{deg} constructed in this section,*

$$\boxed{\Phi B_0 = B_1 \Phi \quad \Longrightarrow \quad \Phi = 0.}$$

Proof. The spectra are

$$\mathrm{Spec}(B_0) = \{9, 5\}, \qquad \mathrm{Spec}(B_1) = \{A_{\mathrm{deg}} + C^{*}_{\mathrm{deg}}, A_{\mathrm{deg}} - C^{*}_{\mathrm{deg}}\}.$$

The previously demonstrated rational bounds provide the disjoint intervals.

$$7.29 < A_{\mathrm{deg}} < 7.30, \qquad 2.12 < C^{*}_{\mathrm{deg}} < 2.13,$$

and, consequently,

$$9.41 < A_{\mathrm{deg}} + C^{*}_{\mathrm{deg}} < 9.43, \qquad 5.16 < A_{\mathrm{deg}} - C^{*}_{\mathrm{deg}} < 5.18.$$

In the basis that diagonalizes R, each entry ϕ_{ij} of Φ is multiplied by the difference between an eigenvalue of B_0 and one of B_1. All these differences are nonzero; hence all entries of Φ vanish. □

Numerically,

$$\rho_1 = 6.9814819335172378048\ldots, \qquad \frac{\rho_1}{\sqrt{45}} = 1.0407378791354140779\ldots,$$

$$\eta_1 - \eta_0 = 0.005796351470571295590\ldots.$$

The formula preserves the split algebra, the projectors $P_{\pm}$, and the Lorentzian form up to the conformal factor $\rho_1^2/45$. It nevertheless depends on B_1 already constructed: it does not constitute a prior derivation of A_{deg} or C^{*}_{deg}, nor should it be confused with the equivariant intertwiners between realizations of the same module.

For

$$S_{90}(q) = \frac{q^{90}}{1 - q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1 - q^{360}},$$

the hexad–octad transition functional is written entirely in the phase chart:

$$\Gamma_{6\to 8} = \frac{180}{\pi} A_{\mathrm{rad}} C^{*}_{\mathrm{rad}} + 12\big(S_{90}(q_-) - S_{90}(q_+)\big) - \big(S_{120}(q_-) - S_{120}(q_+)\big).$$

The evaluation produced by the counter-angle of the theorem 38.14 is

$$\boxed{\Gamma_{6\to 8} = 0.27400767269445927474725526077 4\ldots.}$$

The mathematically equivalent forms of the internal functional are

$$\boxed{\Gamma_{6\to 8} = A_{\mathrm{rad}} C^{*}_{\mathrm{deg}} + K_{6\to 8} = \frac{180}{\pi} A_{\mathrm{rad}} C^{*}_{\mathrm{rad}} + K_{6\to 8} = \frac{\pi A_{\mathrm{deg}} C^{*}_{\mathrm{deg}}}{180} + K_{6\to 8}.}$$

These identities evaluate $\Gamma_{6\to 8}$ after generating $(C^{*}_{\mathrm{rad}}, C^{*}_{\mathrm{deg}})$; it is not used in the inverse sense to select the counter-angle. The physical reading in the Ashtekar–Barbero connection is then represented by means of

$$\Gamma_{6\to 8} \dashrightarrow \gamma_{\mathrm{BI}}.$$

The arrow introduces no third functional and does not act retroactively on C^{*}. The series S_{90}, S_{120}, the coefficients 12 and -1, and their assignment to the $6 \to 8$ passage belong to the declared mathematical construction. Physical identification additionally requires the connection's own normalization.

38.7 Naturalness under Refinement and Separation with Respect to Metrological Recognition

38.7.1 Exact estimation of the remainder of the analytic prolongation

The expression initially found,

$$y_7 = \frac{\pi}{90}(H_5 + \alpha) - 169\alpha^6 - D_A\alpha^7,$$

is the seventh-degree truncation of the full character. Produce

$$C_7 = 2.123738338968646002654038271039 19\ldots^{\circ}.$$

The omitted remainder is not an indeterminate term; it is the exact geometric tail.

$$\mathscr{C}_{\pi}(\alpha) - 169\alpha^6 - D_A\alpha^7 = \frac{D_A^2\alpha^8}{1 - D_A\alpha}.$$

Therefore,

$$\left|C_7 - C_{*}^{\mathrm{HMT}}\right| = \frac{180}{\pi}\frac{D_A^2\alpha^8}{1 - D_A\alpha} = 2.7839208689064583\ldots \times 10^{-16}\ ^{\circ}.$$

The recurrence thus transforms a seventh-degree approximation into a complete analytic realization and provides a closed-form bound for each subsequent truncation.

38.7.2 Functional dependence of the regional selector and the analytic continuation

The construction changes when any of its active components is removed. The following values are obtained without recalibrating the other terms:

variant	conjugate angular coordinate in degrees
$\rho_{\pi} = 168$	$2.123738338977297686390448 7\ldots$
$\rho_{\pi} = 169$	$2.123738338968645724261951 4\ldots$
$\rho_{\pi} = 170$	$2.123738338959993762133454 1\ldots$
without determinantal tail	$2.123738338968694941530167 5\ldots$
D_A replaced by 1	$2.123738338968631340996582 6\ldots$

These ablations do not in themselves constitute a probabilistic estimate. They demonstrate that the equivariant selector and the determinantal character are effective components of the output and cannot be removed while maintaining the same realization.

38.7.3 Operatorial Interpretation of the Conjugate Angular Coordinate

The entire procedure can be summarized as a chain of applications:

$$\begin{aligned} \mathcal{F}_\pi &\longmapsto b_\pi \longmapsto \rho_\pi = 169, \\ \alpha &\longmapsto A \longmapsto x \longmapsto D_A, \\ (\rho_\pi, D_A) &\longmapsto \mathscr{C}_\pi(\alpha), \\ (H_5, \mathscr{C}_\pi(\alpha)) &\longmapsto y_* \longmapsto C_*^{\mathrm{HMT}}, \\ (x, y_*) &\longmapsto (q_+, q_-) \longmapsto \Gamma_{6\to 8}. \end{aligned}$$

The first line belongs to the finite catalog; the second, to the common closure of α; the third, to the determinantal prolongation; the fourth produces the oriented coordinate; the fifth transports it toward the dimensional interface.

In this organization, α measures the common contraction of the transport, and C_*^{HMT} measures the oriented separation of its two sheets. The regional return adds no external constant: it selects a finite amplitude and prolongs it through the determinant already fixed by α. The chart in degrees is subsequent. The primary object is the pair of phases (x, y_*).

An exhaustive verification reconstructs the five regions directly from the catalogue, traverses the actions of $\mathfrak{S}_5$ and $\mathfrak{S}_3$, checks the recurrence, and sums the series. The input of α is the exact output of its dodecaphasic closure, not a transcribed metrological digit. The verification keeps the catalogue theorems, reader rules, and external comparison separate; therefore, no experimental comparison intervenes in the generating function.

38.7.4 Angular Truncation Convergence Certification

The expression initially found,

$$y_7 = \frac{\pi}{90}(H_5 + \alpha) - 169\alpha^6 - D_A\alpha^7,$$

is the seventh-degree truncation of the full character. Produce

$$C_7 = 2.123738338968646002654038271039 19\ldots^\circ.$$

The omitted remainder is not an indeterminate term; it is the exact geometric tail.

$$\mathscr{C}_\pi(\alpha) - 169\alpha^6 - D_A\alpha^7 = \frac{D_A^2\alpha^8}{1 - D_A\alpha}.$$

Therefore,

$$\left|C_7 - C_{\mathrm{deg}}^*\right| = \frac{180}{\pi}\frac{D_A^2\alpha^8}{1 - D_A\alpha} = 2.7839208689064583\ldots \times 10^{-16}\ ^\circ.$$

The recurrence thus transforms a seventh-degree approximation into a complete analytic realization and provides a closed-form bound for each subsequent truncation.

38.7.5 Naturality of the regional selector under refinement and chart change

The construction changes when any of its active components is removed. The following values are obtained without recalibrating the other terms:

variant	counter-angle in degrees
$\rho_\pi = 168$	$2.12373833897729768639044 87\ldots$
$\rho_\pi = 169$	$2.12373833896864572426195 14\ldots$
$\rho_\pi = 170$	$2.12373833895999376213345 41\ldots$
without determinantal tail	$2.12373833896869494153016 75\ldots$
D_A replaced by 1	$2.12373833896863134099658 26\ldots$

These ablations do not in themselves constitute a probabilistic estimate. They demonstrate that the equivariant selector and the determinantal character are effective components of the output and cannot be removed while maintaining the same realization.

38.7.6 Metric independence of the parangular construction

The entire procedure can be summarized as a chain of applications:

$$\begin{aligned} \mathcal{F}_\pi &\longmapsto b_\pi \longmapsto \rho_\pi = 169, \\ \alpha &\longmapsto A_{\mathrm{deg}} \longmapsto A_{\mathrm{rad}} \longmapsto D_A, \\ (\rho_\pi, D_A) &\longmapsto \mathscr{C}_\pi(\alpha), \\ (H_5, \mathscr{C}_\pi(\alpha)) &\longmapsto C^*_{\mathrm{rad}} \longmapsto C^*_{\mathrm{deg}}, \\ (A_{\mathrm{rad}}, C^*_{\mathrm{rad}}) &\longmapsto (q_+, q_-) \longmapsto \Gamma_{6\to 8}. \end{aligned}$$

The first line belongs to the finite catalog; the second, to the common closure of α; the third, to the determinantal prolongation; the fourth produces the oriented coordinate; the fifth transports it toward the dimensional interface.

In this organization, α measures the common contraction of transport, and the counter-angle measures the oriented separation of its two sheets. In the current evaluation, the regional return selects a finite amplitude and prolongs it through the determinant already fixed by α, without inserting an additional external constant. The degree chart is subsequent. The primary object is the phase pair $(A_{\mathrm{rad}}, C^*_{\mathrm{rad}})$. The recurrence, regional sum, and ablations depend on the catalogue and on α_{HMT}, but receive no additional metrological constant.

Chapter 39

Positive constitutive operator of the vacuum: $3 \to 4$ completion, spectral reconstruction and joint derivation of ε, μ, Z and c

39.1 Bilayer spectral decomposition of the angular operator

Let $R = R^* = R^{-1}$ be the active involution and

$$P_\pm = \frac{I \pm R}{2}, \qquad T = q_+ P_+ + q_- P_-, \qquad 0 < q_+ < q_- < 1.$$

With

$$x = A_{\mathrm{rad}} = \frac{\pi A}{180}, \qquad y = C^*_{\mathrm{rad}} = \frac{\pi C^*}{180},$$

the two channels are constructed before evaluating the vacuum:

$$q_+ = e^{-x-y}, \qquad q_- = e^{-x+y}. \tag{39.1}$$

The exchange of sheets reverses C^*, that is, $y \mapsto -y$, and permutes $q_+ \leftrightarrow q_-$. The pair is thus the spectral reading of the same angular antecedent, not two parameters fitted separately.

Definition 39.1 (Constitutive response)**.**

$$\mathcal{V}_{90,120} = (I - T^{90})(I - T^{120})^{-1}. \tag{39.2}$$

Since $\|T\| < 1$, the denominator is positive and invertible. Functional calculus gives

$$\mathcal{V}_{90,120} = r_+ P_+ + r_- P_-, \qquad r_\pm = \frac{1 - q_\pm^{90}}{1 - q_\pm^{120}}. \tag{39.3}$$

The assertion of invertibility deserves to be made explicit. For each leaf, $0 < q_\pm^{120} < 1$; therefore

$$I - T^{120} = (1 - q_+^{120})P_+ + (1 - q_-^{120})P_-$$

is strictly positive and

$$(I - T^{120})^{-1} = \frac{P_+}{1 - q_+^{120}} + \frac{P_-}{1 - q_-^{120}}.$$

The response $\mathcal{V}_{90,120}$ is not obtained by solving four separate scalar equations: it is the result of the functional calculus of a single positive contraction. This observation prevents permeability, permittivity, impedance and propagation from losing their shared antecedent.

Theorem 39.2 (Joint spectral determination of the four constitutive relations)**.** *The four constituent characters*

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2, \qquad \widehat{Z} = \frac{r_-}{r_+}, \qquad \widehat{c} = \frac{1}{r_+ r_-} \tag{39.4}$$

are spectral functions of $\mathcal{V}_{90,120}$. They satisfy

$$\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}, \qquad \frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^2. \tag{39.5}$$

Proof. The identities are obtained by substituting equation (39.4). No dimensional chart nor any exterior value intervenes. □

Corollary 39.3 (Reconstruction of the two sheets)**.** *The four characters do not contain four degrees of freedom. Any of the pairs* $(\widehat{\mu}, \widehat{\varepsilon})$, $(\widehat{Z}, \widehat{c})$, *or* $(\mathcal{E}, \mathcal{B})$ *reconstructs the two positive eigenvalues:*

$$r_- = \sqrt{\widehat{\mu}} = \sqrt{\widehat{Z}/\widehat{c}}, \qquad r_+ = \sqrt{\widehat{\varepsilon}} = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \tag{39.6}$$

$$\log r_- = \frac{\mathcal{E} + \mathcal{B}}{2}, \qquad \log r_+ = \frac{\mathcal{E} - \mathcal{B}}{2}. \tag{39.7}$$

In particular, orientation is lost if only the product is retained, but is recovered by adding the quotient.

Proof. The first line is the positive root of the identities equations (39.4) y (39.5). The second inverts the linear system $\mathcal{E} = \log r_- + \log r_+$, $\mathcal{B} = \log r_- - \log r_+$. □

This corollary expresses a central property of HMT: product and quotient are complementary functionals of the same state. The product determines the propagation in common, whereas the quotient preserves the relative orientation of the inner and outer sheets.

In the V2 certificate,

$$\begin{aligned}
r_+ &= 0.99999962854824936317869522 81\ldots,\\
r_- &= 0.99972413718951836413151658 53\ldots,\\
\widehat{\varepsilon} &= 0.99999925709663670276044161 55\ldots,\\
\widehat{\mu} &= 0.99944835047932693508998155 59\ldots,\\
\widehat{Z} &= 0.99972450853893721545555434 66\ldots,\\
\widehat{c} &= 1.00027631048615752610638626 89\ldots.
\end{aligned}$$

These numerals are the terminal recognition of equation (39.2); they do not define its exponents 90, 120.

39.2 Harmonic factorization of the 90 and 120 sectors

The harmonic semigroup is

$$\langle 90, 120\rangle = 30\langle 3, 4\rangle.$$

If $s = q^{30}$, then

$$\frac{1 - q^{90}}{1 - q^{120}} = \frac{1 - s^3}{1 - s^4} = \frac{1 + s + s^2}{1 + s + s^2 + s^3}. \tag{39.8}$$

The identity also separates the response from its defect. If

$$F_{3\to4}(s) = \frac{1 + s + s^2}{1 + s + s^2 + s^3}, \qquad 0 < s < 1,$$

then

$$d_{3\to4}(s) := 1 - F_{3\to4}(s) = \frac{s^3}{1 + s + s^2 + s^3} > 0. \tag{39.9}$$

The additional term is preserved exactly as a positive defect. Moreover,

$$F'_{3\to4}(s) = -\frac{s^2(3 + 2s + s^2)}{(1 + s + s^2 + s^3)^2} < 0. \tag{39.10}$$

Consequently, the order of the angular channels uniquely determines the order of the constitutive responses. The assignment of $\widehat{\mu}$ and $\widehat{\varepsilon}$ to the respective sheets is obtained analytically, without resorting to their decimal expansions.

Each sheet of the vacuum constitutes the exact completion from three to four terms of the same elementary mode 30. Consequently, permeability and permittivity are interpreted as two quadratic functionals of the same completion evaluated on conjugate sheets, and not as independent constitutive parameters.

Since the function $(1 - q^{90})/(1 - q^{120})$ decreases in $0 < q < 1$ and $q_+ < q_-$, we obtain

$$0 < r_- < r_+ < 1, \qquad 0 < \widehat{\mu} < \widehat{\varepsilon} < 1, \qquad 0 < \widehat{Z} < 1 < \widehat{c}.$$

The limits of the functional determine its geometry. When $q \to 0^+$, $F(q) \to 1$: the four readings approach unity and the memory defect disappears. When $q \to 1^-$,

$$F(q) \longrightarrow \frac{90}{120} = \frac{3}{4}.$$

The response therefore takes values in the positive interval $(3/4, 1)$. The endpoint $3/4$ is not a fitted constant: it is the quotient of the two channel lengths and the continuous realization of the three–to–four completion.

39.3 Sheet involution and preservation of orientation

The sheet exchange $C^* \mapsto -C^*$ acts by

$$\widehat{\mu} \longleftrightarrow \widehat{\varepsilon}, \qquad \widehat{Z} \longmapsto \widehat{Z}^{-1}, \qquad \widehat{c} \longmapsto \widehat{c}. \tag{39.11}$$

The common propagation is even; impedance preserves orientation. This distinction will reappear in Barbero and CKM: not all functionals associated with the change of sheet have the same parity.

39.4 Logarithmic characters and tracial compatibility

Define

$$\mathcal{E} = \log(r_+ r_-), \qquad \mathcal{B} = \log(r_-/r_+).$$

With the normalized trace $\tau = \mathrm{Tr}/2$,

$$2\tau(\log \mathcal{V}) = \mathcal{E}, \qquad -2\tau(R \log \mathcal{V}) = \mathcal{B}. \tag{39.12}$$

The pair $(\mathcal{E}, \mathcal{B})$ constitutes a linear coordinate system for the operator logarithm:

$$\log \mathcal{V} = \frac{\mathcal{E}}{2} I - \frac{\mathcal{B}}{2} R. \tag{39.13}$$

The scalar component is invariant under sheet exchange; the oriented component changes sign. This decomposition directly demonstrates the parity of propagation and the oriented character of impedance.

The nonadic amplification

$$\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$$

is compatible with the expectations $E_m = \mathrm{id} \otimes \tau_9$:

$$E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m.$$

Therefore, $\mathcal{E}$ and $\mathcal{B}$ are not peculiarities of a 2×2 matrix; they persist in the UHF tower and in its tracial closure II_1.

More precisely, for every polynomial p and afterwards, by continuity, for every continuous function on the spectrum,

$$E_m\big(p(\mathcal{V}_{m+1})\big) = p(\mathcal{V}_m). \tag{39.14}$$

Compatibility does not preserve only two numbers: it preserves the entire functional algebra generated by the response. In particular, it preserves its spectral projectors, powers, logarithm, and quadratic forms that measure the defects equation (39.9).

39.5 Dimensional realization of the constitutive relations

Dimensional Mechanics determines

$$Z_{\mathrm{vac}} = \widehat{Z}\, u_S u_Q^{-2}, \tag{39.15}$$

$$c_{\mathrm{vac}} = \widehat{c}\, u_C, \tag{39.16}$$

$$\mu_{\mathrm{vac}} = \widehat{\mu}\, u_S u_C^{-1} u_Q^{-2}, \tag{39.17}$$

$$\varepsilon_{\mathrm{vac}} = \widehat{\varepsilon}\, u_S^{-1} u_C^{-1} u_Q^{2}. \tag{39.18}$$

The constitutive identities hold on the straight lines:

$$\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}} = c_{\mathrm{vac}}^{-2}, \qquad \mu_{\mathrm{vac}}/\varepsilon_{\mathrm{vac}} = Z_{\mathrm{vac}}^{2}. \tag{39.19}$$

The SI chart comes later. It is not necessary to declare c primitive and then solve $\mu\varepsilon = c^{-2}$: the three objects descend jointly from $\mathcal{V}$ and from the declared lines.

The separation of levels is expressed by the diagram

$$\begin{array}{ccccc} (A, C^*) & \longrightarrow & T & \longrightarrow & \mathcal{V} \longrightarrow (\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}) \\ \big\downarrow \text{line charts} & & & & \big\downarrow \text{final evaluation} \\ (u_S, u_Q, u_C) & \longrightarrow & (\mu_{\mathrm{vac}}, \varepsilon_{\mathrm{vac}}, Z_{\mathrm{vac}}, c_{\mathrm{vac}}) & \longrightarrow & \text{SI coordinates.} \end{array}$$

The first line is dimensionless and operatorial; the second determines types of quantity; the third selects a metrological chart. Altering the final chart changes neither the eigenvalues nor the constitutive identities. In this precise sense, mathematical–physical unification consists in distinguishing the genealogical invariant from its coordinate system, not in removing the dimensional structure.

Proposition 39.4 (Spectral minimality)**.** *Let W be a positive two-sheet operator with simple spectrum $\{r_+, r_-\}$. If four positive characters satisfy $\mu\varepsilon = c^{-2}$ and $\mu/\varepsilon = Z^2$, if their propagation in common is determined by $c^{-1} = \det W = r_- r_+$, and if its orientation fixes $Z = r_-/r_+$, then necessarily*

$$(\mu, \varepsilon, Z, c) = \left(r_-^2, r_+^2, \frac{r_-}{r_+}, \frac{1}{r_- r_+}\right).$$

Therefore, equation (39.4) is not one parametrization among many: it is the minimal positive realization compatible with product, quotient and orientation.

Proof. From $Z = r_-/r_+$ and $c^{-1} = \det W = r_- r_+$ the positive roots are obtained uniquely roots. The two constitutive identities then force afterwards $\mu = r_-^2$ and $\varepsilon = r_+^2$. □

The first conceptual inversion consists in conceiving the vacuum as a positive relational response.

In HMT, the vacuum is the minimal dynamical response of the system when its two sheets must coexist, propagate, and close their difference while preserving the orientation that distinguishes them.

The two sheets constitute two conjugate readings of the same angular antecedent. One preserves an orientation, and the other preserves the opposite orientation. Hence two channels, q_+ and q_-, appear as the two correlated spectral faces of a single state.

The operator

$$\mathcal{V}_{90,120} = (I - T^{90})(I - T^{120})^{-1}$$

compares two propagation depths: 90 and 120. Those depths are determined by the same elementary mode:

$$90 = 3 \cdot 30, \qquad 120 = 4 \cdot 30.$$

Therefore, the response of each sheet can be rewritten as

$$\frac{1 - q^{90}}{1 - q^{120}} = \frac{1 + s + s^2}{1 + s + s^2 + s^3}, \qquad s = q^{30}.$$

And here is where the interpretation becomes genuinely powerful. The numerator contains three states of the mode 30; the denominator contains those same three states and one more. The vacuum is, therefore, an exact completion $3 \to 4$.

That fourth term integrates and preserves the preceding three. It completes them. What is added is recorded as a positive completion residue:

$$1 - \frac{1 + s + s^2}{1 + s + s^2 + s^3} = \frac{s^3}{1 + s + s^2 + s^3} > 0.$$

Vacuum memory is precisely the exact increment that allows three terms to become four. It is the positive and necessary trace of the completion.

From the two eigenvalues of that single operator arise the four constitutive relations:

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2, \qquad \widehat{Z} = \frac{r_-}{r_+}, \qquad \widehat{c} = \frac{1}{r_+ r_-}.$$

This completely changes the interpretation of permeability and permittivity.

Permittivity is the quadratic response of one sheet. Permeability is the quadratic response of the conjugate sheet. Impedance preserves the oriented relation between them. Propagation speed depends on their common product.

Thus, product and quotient perform two different tasks:

- the product forgets which sheet was which and preserves the common propagation;
- the quotient preserves what the relative orientation between them was.

The product answers the question: “what do the two leaves share?”. The quotient answers the question: “how are they distinguished?”.

Por eso

$$\widehat{\mu}\,\widehat{\varepsilon} = \widehat{c}^{-2}$$

y

$$\frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^2$$

are the two complementary ways of reading the same spectral pair.

The holographic structure appears here in a particularly transparent form: four visible magnitudes actually contain only two internal degrees of freedom. Any of certain suitable pairs allows the two sheets to be reconstructed. The constitutive publication preserves genealogy when product and quotient remain jointly available.

This is the deep repair of the ablation of μ and ε. The repair reunites their values with their common operator-theoretic origin.

The International System chart may subsequently transform these intrinsic sections into μ_0, ε_0, Z_0, and c. Its function is to express, within a metrological convention, a structure whose provenance has already been selected by the operator.

The vacuum thereby ceases to be a repository of four constantes. becomes a unique spectral operation With two conjugate memories.

And that view has an important philosophical consequence: the vacuum is a compatibility relation between two oriented ways of realizing one and the same state.

39.6 Discrete polarization and the tritic mode of arithmetic projections

Refinement and comparison between the APP sheets provide two complementary observations. The first follows the accumulated discrepancy between the number of transitions and the capacity acquired; the second preserves the mode of the tritic selector in the pairing of the additive and multiplicative fibres. Discrete polarization and the electronic prefactor are obtained from these respective operations. Their articulation with the vacuum requires preserving both the temporal information and the spaces on which the operators act.

39.6.1 Refinement discrepancy and endpoint convention

The cardinalities of the ternary block and its decimal representation fix

$$\rho = \log_{1000} 729 = \log_{10} 9, \qquad \delta = 1 - \rho = \log_{10}(10/9).$$

We have $0 < \delta < 1$. Moreover, δ is irrational: an equality $\delta = p/q$, with $q > 0$, would imply $10^{q-p} = 9^q$, which is incompatible with prime factorization. This mismatch already enters the encoding of refinement. Here its centred readout is made explicit, preserving the phase origin and the endpoint convention.

Definition 39.5 (Lower and upper encodings)**.** For $\theta \in \mathbb{R}$ and $n \in \mathbb{Z}$, define

$$z_n^{\downarrow}(\theta) = \lfloor (n+1)\delta + \theta \rfloor - \lfloor n\delta + \theta \rfloor, \tag{39.20}$$

$$z_n^{\uparrow}(\theta) = \lceil (n+1)\delta + \theta \rceil - \lceil n\delta + \theta \rceil. \tag{39.21}$$

Both take values in $\{0, 1\}$. The arrow distinguishes only the endpoint convention for the intervals; tritic orientation retains its earlier definition.

The lower encoding coincides with the one used in the development of refinement. The upper encoding recovers the formulation of polarization using the ceiling function. The two expressions are related by an exactly determined boundary term.

Proposition 39.6 (Change of convention and boundary term)**.** *Let* $b_n(\theta) = \mathbf{1}_{\mathbb{Z}}(n\delta + \theta)$. *Then*

$$z_n^{\uparrow}(\theta) - z_n^{\downarrow}(\theta) = b_n(\theta) - b_{n+1}(\theta). \tag{39.22}$$

In particular, for $N \geq 0$,

$$\sum_{n=0}^{N-1} (z_n^{\uparrow} - z_n^{\downarrow}) = b_0 - b_N .$$

Proof. For every real x, $\lceil x \rceil = \lfloor x \rfloor + 1 - \mathbf{1}_{\mathbb{Z}}(x)$. Applying this identity to both endpoints of each increment gives (39.22); its sum telescopes. The irrationality of δ implies that, for fixed θ, at most one integer index satisfies $n\delta + \theta \in \mathbb{Z}$. □

With $\theta = 0$, the first upper symbol is 1 and the lower one is 0; for $n \geq 1$ they coincide. The initial term belongs to the register and is preserved when the convention is changed. The densities and discrepancy bounds are transported with that term, without modifying the TPK update or restarting the history at each phase return.

39.6.2 Bounded polarization and exact temporal balance

Definition 39.7 (Centred discrete polarization)**.** The polarization of the upper encoding, relative to the density δ, is

$$P_N^{\uparrow}(\theta) = \sum_{n=0}^{N-1} \big(z_n^{\uparrow}(\theta) - \delta\big), \qquad P_0^{\uparrow} = 0. \tag{39.23}$$

Its temporal increment is

$$J_N^{\uparrow}(\theta) = P_{N+1}^{\uparrow}(\theta) - P_N^{\uparrow}(\theta) = z_N^{\uparrow}(\theta) - \delta. \tag{39.24}$$

Centring separates uniform growth of density δ from phase information. Thus, $P_N^{\uparrow}$ measures an accumulated imbalance, not the total number of vacancies. The increment $J_N^{\uparrow}$ preserves the local pulse and the background relative to which it is evaluated.

Theorem 39.8 (Uniform bound and discrete temporal continuity)**.** *For $N \geq 0$ and every phase θ,*

$$P_N^{\uparrow}(\theta) = \lceil N\delta + \theta \rceil - \lceil \theta \rceil - N\delta, \qquad |P_N^{\uparrow}(\theta)| < 1. \tag{39.25}$$

For any integers $0 \leq a < b$,

$$\sum_{n=a}^{b-1} J_n^{\uparrow}(\theta) = P_b^{\uparrow}(\theta) - P_a^{\uparrow}(\theta), \qquad \left| \sum_{n=a}^{b-1} J_n^{\uparrow}(\theta) \right| < 1. \tag{39.26}$$

The density of the vacancy sequence is δ.

Proof. Summing the ceiling increments in (39.21) yields the first identity. Writing $r(x) = \lceil x \rceil - x \in [0, 1)$ gives $P_N^{\uparrow} = r(N\delta + \theta) - r(\theta)$; its absolute value is less than one. On the interval $[a, b)$, one similarly obtains $r(b\delta + \theta) - r(a\delta + \theta)$, proving the second bound, which is sharper than the sum of two individual bounds. Finally, $N^{-1} \sum_{n=0}^{N-1} z_n^{\uparrow} = \delta + N^{-1} P_N^{\uparrow} \to \delta$. □

The lower encoding admits the same proofs with $r(x)$ replaced by $\lfloor x \rfloor - x \in (-1, 0]$. In particular, $P_N^{\uparrow} - P_N^{\downarrow} = b_0 - b_N$. The bounded discrepancy previously used in the Dirichlet readouts and the present polarization therefore preserve an explicit relationship of origin and endpoints. Nor does aperiodicity introduce secular drift in this imbalance: the history can extend indefinitely while the centred discrepancy remains uniformly bounded.

39.6.3 Realization on the charge and time lines

To realize the balance dimensionally, specify a charge line $\mathcal{L}_Q$ with a nonzero section u_Q and an increasing sequence of times t_N on an oriented time line. With $\Delta t_N = t_{N+1} - t_N > 0$, the centred charge and the mean current of each interval are defined by

$$Q_N = P_N^{\uparrow} u_Q, \qquad I_N = \frac{Q_{N+1} - Q_N}{\Delta t_N} = \frac{u_Q}{\Delta t_N}\big(z_N^{\uparrow} - \delta\big). \tag{39.27}$$

Thus, $Q_N \in \mathcal{L}_Q$ and $I_N \in \mathcal{L}_Q \otimes \mathcal{L}_T^{-1}$. The section u_Q and the time intervals are data of this realization; the preceding arithmetic construction has already determined $P_N^{\uparrow}$ and $J_N^{\uparrow}$.

Proposition 39.9 (Preservation of balance under dimensional realization)**.** *For $a < b$,*

$$Q_b - Q_a = \sum_{n=a}^{b-1} \Delta t_n I_n, \qquad \left| \frac{Q_b - Q_a}{u_Q} \right| < 1. \tag{39.28}$$

If all intervals have length t_0, the two possible currents are $-\delta u_Q/t_0$ and $(1-\delta)u_Q/t_0$.

Proof. Multiplying each identity in (39.27) by Δt_n and summing telescopes the charges. The bound is (39.26); the two local values follow from $z_n^{\uparrow} \in \{0, 1\}$. □

The continuity proved is temporal and refers to the centred charge. A spatial realization also incorporates the localization of charges, incidence between cells, and identification of boundary fluxes. In a constitutive description by channels, the coupling is specified through an excitation map $\iota : \mathcal{L}_Q \to \mathcal{H}_{\mathrm{ch}} \otimes \mathcal{L}_Q$ and an observation map $\ell : \mathcal{H}_{\mathrm{ch}} \otimes \mathcal{L}_Q \to \mathcal{L}_Q$, where $\mathcal{H}_{\mathrm{ch}}$ is a real realization of the channel space. If both are linear and independent of the time index, the response of a fixed operator $\mathcal{V}$ is transported by

$$Q_N^{\mathrm{resp}} = \ell(\mathcal{V} \otimes I_{\mathcal{L}_Q})\iota(Q_N), \qquad I_N^{\mathrm{resp}} = \frac{Q_{N+1}^{\mathrm{resp}} - Q_N^{\mathrm{resp}}}{\Delta t_N}.$$

Linearity preserves the telescoping balance. This composition makes explicit the data of a constitutive identification: the scalar sequence determines the pulse, while ι, $\mathcal{V}$, and ℓ determine its excitation, transport, and observation through channels. Identities (39.23)–(39.28) establish the first construction independently of that choice of realization. The vacuum operator is constructed in Section 39.8 on its own channels and projectors.

39.6.4 Pairing the additive and multiplicative fibres

The second observation comes from the three-dimensional realization of APP, $\mathcal{A}_3 = D_9^3$, with uniform measure and $D_9 = \{1, \dots, 9\}$. The observables preserved are

$$\Sigma(x) = \rho_9(x_1 + x_2 + x_3), \qquad \Pi(x) = \rho_9(x_1 x_2 x_3),$$

where $\rho_9(n) = 1 + [(n-1) \bmod 9]$ for $n > 0$. In $\ell^2(\mathcal{A}_3)$, let $P_{\Sigma,3}$ and $P_{\Pi,3}$ be the conditional expectations on their fibres. For example,

$$(P_{\Sigma,3} f)(x) = \frac{1}{|\Sigma^{-1}(\Sigma(x))|} \sum_{y:\, \Sigma(y) = \Sigma(x)} f(y).$$

They are orthogonal projections defined on the same support. The incidence matrix $N_{ab} = |\Sigma^{-1}(a) \cap \Pi^{-1}(b)|$ results from enumerating the 729 triples, adding and multiplying their coordinates before applying ρ_9:

$$N = 9\begin{pmatrix} 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 1 & 0 & 2 & 0 & 1 & 2 & 0 & 0 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 0 & 2 & 1 & 0 & 2 & 0 & 1 & 3 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 4 \\ 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 4 \\ 0 & 1 & 2 & 0 & 0 & 2 & 1 & 0 & 3 \end{pmatrix}. \tag{39.29}$$

The rows sum to 81, and the column sums are

$$(m_1, \dots, m_9) = (36, 36, 108, 36, 36, 108, 36, 36, 297).$$

Therefore, the pairing of the normalized indicator functions of the fibres is $C_{ab} = N_{ab}/\sqrt{81 m_b}$. Normalization incorporates the multiplicities produced by APP, not a choice of singular values.

Proposition 39.10 (Singular mode of the tritic selector)**.** *In the canonical chart, the selector vector is* $m_{\mathrm{ph}} = (1, -1, 0)^3$. *We have*

$$C m_{\mathrm{ph}} = C^{\mathsf{T}} m_{\mathrm{ph}} = -\tfrac{1}{2} m_{\mathrm{ph}}. \tag{39.30}$$

Thus, the corresponding singular value is $s = 1/2$.

Proof. In the six columns where m_{ph} is nonzero, $m_b = 36$ and $C_{ab} = N_{ab}/54$. Multiplying the rows of (39.29) by $(1, -1, 0)^3$ yields $-m_{\mathrm{ph}}/2$. For the transposed product, the signed sums of columns $3, 6, 9$ are zero; the other six give the same values $-m_{\mathrm{ph},b}/2$. This proves both identities and, by composition, $CC^{\mathsf{T}} m_{\mathrm{ph}} = m_{\mathrm{ph}}/4$. □

39.6.5 Commutator norm and electronic prefactor

Theorem 39.11 (Exact norm of arithmetic incompatibility)**.** *The two projections satisfy*

$$\left\| [P_{\Sigma,3}, P_{\Pi,3}] \right\| = \frac{\sqrt{3}}{4}. \tag{39.31}$$

The maximum is attained in the principal plane corresponding to the tritic mode of (39.30).

Proof. The rational matrix $M = CC^{\mathsf{T}}$ has entries $M_{ac} = \sum_b N_{ab} N_{cb}/(81 m_b)$. Its complete spectrum is verified through the following independent subspaces: the vectors $(1, \dots, 1)$, $(1, -1, 0)^3$, and $(1, 1, -2)^3$ have eigenvalues 1, $1/4$, and $7/132$, respectively; the subspace of vectors supported on $\{3, 6, 9\}$ whose sum is zero has dimension 2 and eigenvalue $1/18$; the zero-sum vectors supported on $\{1, 4, 7\}$ or $\{2, 5, 8\}$ form a kernel of dimension 4. Substitution into the matrix verifies these actions, and the dimensions sum to 9. Consequently,

$$\operatorname{spec} M = \{1, 1/4, 7/132, 1/18, 1/18, 0, 0, 0, 0\}.$$

For two orthogonal projections, a singular value $s \in (0, 1)$ of the pairing determines a principal plane in which their matrices are

$$P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad Q = \begin{pmatrix} s^2 & s\sqrt{1 - s^2} \\ s\sqrt{1 - s^2} & 1 - s^2 \end{pmatrix}.$$

This form is obtained by taking a unit vector u in the first image with $PQu = s^2 u$ and completing it with $(Qu - s^2 u)/(s\sqrt{1 - s^2})$. Their commutator is $s\sqrt{1 - s^2}\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. The sectors with singular value 0 or 1

contribute zero. Therefore, the total norm is the maximum of $\sqrt{\lambda(1-\lambda)}$ over the spectrum of M. That maximum is $\sqrt{3/16}$, attained at $\lambda = 1/4$. □

The norm is the prefactor entering the electronic composition. Its derivation preserves the three-dimensional support, the fibres, and the selector mode; scalar evaluation does not replace that structure. In particular, knowing $\sqrt{3}/4$ gives the maximum magnitude of the incompatibility, while the projectors preserve the directions in which it acts.

39.6.6 Quadratic defect and response of the $90/120$ sectors

The tritic mode simultaneously determines

$$1 - s^2 = \frac{3}{4} = \frac{90}{120}, \qquad s = \frac{1}{2}. \tag{39.32}$$

The first expression is the quadratic defect of the APP principal plane. The last preserves the lengths of the two calendar sectors. The constitutive response uses those sectors on another object: a contractive channel $q \in (0, 1)$. Its evaluation is

$$r(q) = \frac{1 - q^{90}}{1 - q^{120}}.$$

The relationship between the sector ratio and this response can be made precise without identifying their operators.

Proposition 39.12 (Limit of the response ratio)**.** *Para* $0 < q < 1$*,*

$$\frac{3}{4} < r(q) < 1, \qquad \lim_{q \uparrow 1} r(q) = \frac{3}{4} = 1 - s^2. \tag{39.33}$$

Proof. With $u = q^{30} \in (0, 1)$, factoring $1 - u^3$ and $1 - u^4$ gives $r(q) = (1 + u + u^2)/(1 + u + u^2 + u^3)$. The limit at $u = 1$ is $3/4$. Moreover, $4(1 + u + u^2) - 3(1 + u + u^2 + u^3) = (1 - u)(3u^2 + 2u + 1) > 0$, and the denominator exceeds the numerator by $u^3 > 0$. This yields both inequalities. □

The exact coincidence concerns the defect of the singular mode and the limit of the sector response. In the contractive interior, the response depends on q and is strictly greater than $3/4$. The constitutive development preserves its two channels $q_\pm$ and its projectors $P_\pm$; the projectors $P_{\Sigma,3}$ and $P_{\Pi,3}$, for their part, preserve the arithmetic fibres that determined the prefactor. An operator equivalence between the two realizations requires a map between their spaces that intertwines the corresponding actions. Equations (39.30), (39.31), and (39.33) specify the shared information and keep the data of each realization visible.

39.7 Sheet return, areal–volumetric incidence and constitutive orientation

The sheet structure enters before electromagnetic quantities are evaluated. Its function is to distinguish closure of a projection, restoration of an orientation and evolution of the transported register. These operations act on related objects of different types: a projected trajectory may have closed while its lift remains on the opposite sheet; orientation may have been restored while memory preserves the two windings performed. The constitutive construction must receive this information together with the structure determining it.

39.7.1 Projected return and restoration of the oriented cover

Let ℓ be a return loop of a surviving extension, and let $\varepsilon : \langle \ell \rangle \to \{+1, -1\}$ be the character of its lift, with $\varepsilon(\ell) = -1$. The associated interval bundle has the presentation

$$\mathcal{M} = ([0, 1] \times [-1, 1])/(0, u) \sim (1, -u). \tag{39.34}$$

The decisive datum is the sign of transport around the specified loop. The identification of endpoints geometrically realizes that character.

Proposition 39.13 (Two closure orders)**.** *One winding of the loop closes the base and reverses the fibre orientation. Two windings restore orientation. In the angular parametrization of the boundary readout, these returns correspond, respectively, to the areal closure* 2π *and the volumetric closure* 4π *of the oriented cover.*

Proof. The equivalence relation of (39.34) identifies the terminal fibre with the initial one by $u \mapsto -u$. Composing two transports gives $u \mapsto -(-u) = u$. Parametrizing one winding of the base by 2π assigns 4π to its square. The statement concerns this lift and this readout. □

TPK memory also preserves the trajectory traversed and the register updates. The square of the sign character is the identity, but it does not impose vanishing of these updates. The spinorial representation, when used, must transport this datum through its own map.

39.7.2 Descent of incidence from the tritic calendar

In the primitive block $(+1, -1, 0)$, the TPK updates the arithmetic mode through $+1 : m \mapsto \Sigma$, $-1 : m \mapsto \Pi$ and $0 : m \mapsto m$. Its cyclic orbit is (Σ, Π, Π). The sheet readout assigns Σ to the areal sheet and Π to the volumetric sheet. In the basis order $(e_{\mathrm{ar}}, e_{\mathrm{vol}})$, edge incidence is represented by

$$F_{\mathrm{av}} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}. \tag{39.35}$$

The three consecutive pairs are $\Sigma \to \Pi$, $\Pi \to \Pi$ and $\Pi \to \Sigma$, each with multiplicity one. The calendars of lengths 9, 27 and 108 contain 3, 9 and 36 copies of the primitive block. Their incidence matrices are therefore these multiples of F_{av}.

This construction preserves the distinction between chronological frequency and the measure of the continuation space. The former assigns weights $(1/3, 2/3)$ to the mode cycle. The latter is defined on the minimal memory-one symbolic envelope admitting exactly the preceding pairs. Its adjacency matrix is F_{av}; trajectory counts belong to that envelope.

Proposition 39.14 (Return weights of the two sheets)**.** *Let $F_0 = 0$, $F_1 = 1$ and $F_{n+1} = F_n + F_{n-1}$. For $n \geq 1$,*

$$F_{\mathrm{av}}^n = \begin{pmatrix} F_{n-1} & F_n \\ F_n & F_{n+1} \end{pmatrix}. \tag{39.36}$$

The Parry measure of this envelope assigns the sheets weights proportional to $(1, \varphi^2)$, and the ratio of diagonal counts converges to φ^{-2}.

Proof. The power formula follows by induction using the recurrence. The square of F_{av} is strictly positive. Its positive Perron vector is $(1, \varphi)$, with eigenvalue φ, since $\varphi^2 = \varphi + 1$. As the matrix is symmetric, the Parry weights are proportional to the squares of that vector's components. The other root of the characteristic polynomial is $-\varphi^{-1}$; its modulus is strictly less than φ, giving the limit of the diagonal ratios. □

Spectral identification of this incidence follows its construction from the calendar. The regional coordinate φ retains its earlier coinductive genealogy: recognition of the eigenvalue does not select the calendar.

39.7.3 Boundary marking and areal–volumetric ratio

Let $\Pi_{\mathrm{HMT}}(X_\infty)$ be the value of the regional closure readout already constructed. With the diagonal sheet projectors, define

$$D_\pi = \Pi_{\mathrm{HMT}}(X_\infty) P_{\mathrm{ar}} + P_{\mathrm{vol}}, \qquad \Theta_n = \frac{\langle e_{\mathrm{ar}}, D_\pi F_{\mathrm{av}}^n e_{\mathrm{ar}} \rangle}{\langle e_{\mathrm{vol}}, F_{\mathrm{av}}^n e_{\mathrm{vol}} \rangle}. \tag{39.37}$$

Volumetric normalization is unity; regional closure marks the areal return only once. Applying (39.36),

$$\Theta_n = \Pi_{\mathrm{HMT}}(X_\infty) \frac{F_{n-1}}{F_{n+1}} \longrightarrow \frac{\pi}{\varphi^2}. \tag{39.38}$$

The return ratio is determined by incidence, measure and marking. The quotient $2\pi/4\pi$, by contrast, describes the cover's two closure orders. Both relations participate in the sheet readout without replacing each other.

39.7.4 Transport of orientation to the constitutive channels

In a two-channel representation, let $\mathcal{R}$ be a self-adjoint involution and $\mathcal{S}$ a unitary interchange operator satisfying $\mathcal{S}\mathcal{R}\mathcal{S}^{-1} = -\mathcal{R}$. Write the angular coordinates already constructed as $x = A_{\mathrm{rad}}$ and $y = C^{*}_{\mathrm{rad}}$, with $x > |y|$. Then

$$B = xI + y\mathcal{R}, \qquad T = e^{-B}, \qquad \mathcal{S}T(y)\mathcal{S}^{-1} = T(-y). \tag{39.39}$$

Indeed, conjugation transforms $B(y)$ into $B(-y)$ and commutes with its convergent exponential series. The eigenvalues $q_{\pm} = e^{-x\mp y}$ are interchanged. To fix the response order, the chamber $x > y > 0$ is used, where $0 < q_{+} < q_{-} < 1$. The map $(x, y) \mapsto (x, -y)$ transports it to the opposite chamber $x > -y > 0$, where $0 < q_{-} < q_{+} < 1$. Both belong to the contractive domain $x > |y|$. On the boundary $y = 0$ the two channels coincide. Conjugation interchanges the chambers; it does not preserve the strict ordering of their labels. It acts on the projectors through $\mathcal{S}P_{\pm}\mathcal{S}^{-1} = P_{\mp}$, with $P_{\pm} = (I \pm \mathcal{R})/2$. This concrete map transmits orientation to the constitutive operator developed next.

39.8 Constitutive operator and reconstruction of the vacuum channels

The constitutive quantities are obtained by an operation on angular transport. The starting information comprises the channels, their projectors, and the orientation distinguishing them. This organization makes it possible to follow separately the construction of the operator, the evaluation of its spectral functions, and its subsequent dimensional realization.

39.8.1 Positive response on two sheets

In the oriented chamber $x > y > 0$ of Section 39.7, let $P_{\pm} = (I \pm \mathcal{R})/2$ and $T = q_{+}P_{+} + q_{-}P_{-}$, with $0 < q_{+} < q_{-} < 1$. The incidences constructed by the calendar fix the sectors 90 and 120. The constitutive response is

$$\mathcal{V} = (I - T^{90})(I - T^{120})^{-1}. \tag{39.40}$$

This definition receives the transport arising from the TPK and preserves the sheet assignments. The response rule and its domain are an explicit part of the construction.

The quotient arises from comparing the two calendar incidences on the same transport, not from fitting four quantities separately. If $S = T^{30}$ and $\Sigma_j(S) = I + S + \cdots + S^{j-1}$, factoring $I - S^{j}$ gives

$$\mathcal{V}\,\Sigma_4(S) = \Sigma_3(S), \qquad \mathcal{V} = \Sigma_3(S)\Sigma_4(S)^{-1}. \tag{39.41}$$

The factors Σ_3 and Σ_4 express, respectively, the sectors $90 = 3 \cdot 30$ and $120 = 4 \cdot 30$. Since the spectrum of S is contained in $(0, 1)$, $\Sigma_4(S)$ is invertible: the completion equation determines a unique response for the fixed transport. This uniqueness concerns the declared constitutive rule and its incidences. Electromagnetic identification adds the oriented assignment of sheets and the dimensional lines specified below.

Proposition 39.15 (Decomposition and positivity)**.** *The response is well-defined and*

$$\mathcal{V} = r_{+}P_{+} + r_{-}P_{-}, \qquad r_{\pm} = \frac{1 - q_{\pm}^{90}}{1 - q_{\pm}^{120}}. \tag{39.42}$$

Its eigenvalues satisfy $3/4 < r_{-} < r_{+} < 1$ *in this chamber.*

Proof. Each coefficient $1 - q_{\pm}^{120}$ is positive. The inverse of $I - T^{120}$ is the sum of the projectors divided by those coefficients, proving (39.42). With $s = q^{30}$, one obtains

$$f(s) = \frac{1+s+s^2}{1+s+s^2+s^3}, \qquad f'(s) = -\frac{s^2(3+2s+s^2)}{(1+s+s^2+s^3)^2} < 0. \tag{39.43}$$

The limits at 0 and 1 are 1 and $3/4$, respectively. Monotonicity and the channel ordering complete the proof. □

39.8.2 Four coordinates of a common response

Define the normalized evaluations

$$\widehat{\varepsilon} = r_+^2, \qquad \widehat{\mu} = r_-^2, \qquad \widehat{Z} = \frac{r_-}{r_+}, \qquad \widehat{c} = \frac{1}{r_+ r_-}. \tag{39.44}$$

The first pair preserves the quadratic responses assigned to each sheet. The product captures the common mode; the quotient distinguishes their relative orientation. The following hold exactly:

$$\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}, \qquad \frac{\widehat{\mu}}{\widehat{\varepsilon}} = \widehat{Z}^2, \qquad r_+ = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \quad r_- = \sqrt{\frac{\widehat{Z}}{\widehat{c}}}. \tag{39.45}$$

The positive roots fix the inversion. Under sheet conjugation, read relative to the fixed markings $P_\pm$, $\widehat{\varepsilon}$ and $\widehat{\mu}$ are interchanged, $\widehat{Z}$ is inverted, and $\widehat{c}$ is preserved. The response is then transported to the chamber $x > -y > 0$: the formulas remain valid, with the orderings $q_- < q_+$ and $r_+ < r_-$ reversed. Consequently, common mode and orientation are data recoverable through complementary observables.

Proposition 39.16 (Determination of the quadratic evaluations)**.** *Let $W = r_+P_+ + r_-P_-$ be a positive response on the two sheets. With the product and quotient readouts fixed,*

$$\widehat{c}^{-1} = \det W = r_+ r_-, \qquad \widehat{Z} = r_-/r_+,$$

there exists a unique positive pair $(\widehat{\varepsilon}, \widehat{\mu})$ satisfying $\widehat{\mu}\widehat{\varepsilon} = \widehat{c}^{-2}$ and $\widehat{\mu}/\widehat{\varepsilon} = \widehat{Z}^2$. It is precisely (r_+^2, r_-^2).

Proof. Positivity permits taking roots unambiguously:

$$\widehat{\mu} = \frac{\widehat{Z}}{\widehat{c}} = \frac{r_-}{r_+} r_+ r_- = r_-^2, \qquad \widehat{\varepsilon} = \frac{1}{\widehat{Z}\widehat{c}} = \frac{r_+}{r_-} r_+ r_- = r_+^2.$$

These expressions satisfy both relations and are their only positive roots. □

Thus the squares are not two independent choices added to the channels: they are determined by the multiplicative and oriented readouts once the constitutive relations are fixed. This proposition establishes uniqueness within that system of rules. Interpreting the rules as an electromagnetic response retains its additional physical-representation content.

The determinantal readout of transport and the constitutive response must also preserve their order. For $T = e^{-xI - y\mathcal{R}}$, one has $\det T = e^{-2x}$, whereas

$$\det \mathcal{V} = f(q_+^{30}) f(q_-^{30}) = \widehat{c}^{-1}.$$

Both arise from the same two-sheet operator but evaluate different functions of its spectrum. In general, applying the determinant first and then a rational function is not equivalent to taking the determinant of that function of the operator. Keeping both eigenvalues until the response is completed preserves orientation information that an isolated determinant no longer distinguishes.

39.8.3 Cubic inversion and angular recovery

Theorem 39.17 (Constitutive inversion in the contractive domain)**.** *For each $r \in (3/4, 1)$, there exists a unique $s \in (0, 1)$ such that $f(s) = r$. This s is the unique root in that interval of*

$$rs^3 + (r-1)(1+s+s^2) = 0. \tag{39.46}$$

The labeled response reconstructs $s_\pm$, $q_\pm = s_\pm^{1/30}$, and

$$x = -\frac{1}{2}\log(q_+ q_-), \qquad y = \frac{1}{2}\log\frac{q_-}{q_+}. \tag{39.47}$$

Proof. The derivative and limits in (39.43) prove that f is a decreasing bijection between the stated intervals. Multiplying $f(s) = r$ by its denominator produces (39.46). The positive root of order 30 recovers the channel. Finally, adding and subtracting $\log q_\pm = -x \mp y$ gives (39.47). □

Reconstruction preserves the sheet labels. The complete operator $\mathcal{V}$ also preserves the projectors, and the inverse function is applied by spectral calculus. Recovering two angular coordinates is an operation defined on this representation; the complete historical TPK trace preserves additional data.

The interval $r \in (3/4, 1)$ and the inverse function of this theorem belong to the internal normalization of (39.44). If coordinates expressed in another chart of units are available, this normalization is first recovered through the transformation of section 63.5; cubic inversion is then applied.

39.8.4 Logarithmic coordinates and refinement

Let $\mathcal{E} = \log(r_+ r_-)$ and $\mathcal{B} = \log(r_-/r_+)$. Then

$$\log \mathcal{V} = \tfrac{1}{2}\mathcal{E} I - \tfrac{1}{2}\mathcal{B}\mathcal{R}. \tag{39.48}$$

This decomposition displays the invariant and oriented components. In the amplification $\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$, normalized partial expectations satisfy $E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m$. For every polynomial p, $p(\mathcal{V}_m) = p(\mathcal{V}) \otimes I_{9^m}$; hence $E_m(p(\mathcal{V}_{m+1})) = p(\mathcal{V}_m)$. Uniform continuity extends the identity to continuous functions on the spectrum. Thus projectors, powers, and the logarithm are preserved in the stated tower.

39.8.5 Dimensional types of the four evaluations

With the action, charge, and velocity lines, equipped with sections u_S, u_Q, u_C, the dimensional realization reads

$$Z_{\mathrm{vac}} = \widehat{Z} u_S u_Q^{-2}, \qquad c_{\mathrm{vac}} = \widehat{c} u_C, \tag{39.49}$$

$$\mu_{\mathrm{vac}} = \widehat{\mu} u_S u_C^{-1} u_Q^{-2}, \qquad \varepsilon_{\mathrm{vac}} = \widehat{\varepsilon} u_S^{-1} u_C^{-1} u_Q^{2}. \tag{39.50}$$

Multiplying and dividing these expressions preserves $\mu_{\mathrm{vac}}\varepsilon_{\mathrm{vac}} = c_{\mathrm{vac}}^{-2}$ and $\mu_{\mathrm{vac}}/\varepsilon_{\mathrm{vac}} = Z_{\mathrm{vac}}^2$. The SI chart subsequently evaluates the sections. Physical comparison requires presenting their construction and normalization alongside the evaluation; the four normalized coordinates of (39.44) retain their dimensionless type.

39.8.6 Reconstruction of the action shape from the constitutive response

The constitutive response and the inductive–capacitive realization receive the same angular pair constructed from APP–TRIT–TPK. The former evaluates rational functions of the two channels; the latter uses the ratio of their exponents to determine the shape of the action ellipse. Cubic inversion allows the two readouts to be composed without identifying their numerical ratios.

Let $x = A_{\mathrm{rad}}$ and $y = C_{\mathrm{rad}}^*$, with $x > |y|$, be the lifted coordinates already constructed, and preserve their sheet labels. Write

$$q_\pm = e^{-(x\pm y)}, \qquad s_\pm = q_\pm^{30}, \qquad r_\pm = f(s_\pm), \qquad f(s) = \frac{1+s+s^2}{1+s+s^2+s^3}. \tag{39.51}$$

The contractive domain gives $s_\pm \in (0,1)$ and $r_\pm \in (3/4, 1)$. In the chamber $x > y > 0$, we have $s_+ < s_-$ and $r_+ > r_-$; sheet interchange transports this chamber to the opposite orientation.

The image of the two normalized constitutive coordinates is the domain

$$\mathcal{U} = \left\{(z,v) \in (0,\infty)^2 : (zv)^{-1/2} \in (3/4,1), \quad (z/v)^{1/2} \in (3/4,1)\right\}. \tag{39.52}$$

Here $(z,v) = (\widehat{Z}, \widehat{c})$. The restrictions express membership of the reconstructed channels in the domain of the inversion theorem; they do not constitute a subsequent choice of their values.

Proposition 39.18 (Constitutive composition of the shape and LC impedance)**.** *For $(\widehat{Z}, \widehat{c}) \in \mathcal{U}$, let $s_\pm \in (0,1)$ be the unique roots of*

$$r_\pm s_\pm^3 + (r_\pm - 1)(1 + s_\pm + s_\pm^2) = 0, \qquad r_+ = \frac{1}{\sqrt{\widehat{Z}\widehat{c}}}, \quad r_- = \sqrt{\frac{\widehat{Z}}{\widehat{c}}}. \tag{39.53}$$

The angular ratio, the anisotropy of the action ellipse, and the relative LC impedance are reconstructed exactly by

$$\frac{y}{x} = \frac{\log s_+ - \log s_-}{\log s_+ + \log s_-}, \tag{39.54}$$

$$\eta_{\mathrm{el}} = \frac{1}{2}\log\frac{\log s_+}{\log s_-}, \tag{39.55}$$

$$\frac{Z_{\mathrm{LC}}}{Z_*} = e^{-\eta_{\mathrm{el}}} = \sqrt{\frac{\log s_-}{\log s_+}}. \tag{39.56}$$

In the last identity, $Z_{\mathrm{LC}} = Z_{\eta_{\mathrm{el}}}$ is the impedance of the LC chart of (24.12)*.*

Proof. The cubic inversion in (39.46) uniquely determines $s_\pm$, because f is a decreasing bijection from $(0,1)$ onto $(3/4,1)$. Their positive roots of order 30 recover $q_\pm$. The identities

$$\log s_+ = -30(x+y), \qquad \log s_- = -30(x-y)$$

prove (39.54) by difference and sum. Both logarithms are negative; their ratio is positive and their sum is nonzero. Therefore,

$$\frac{1}{2}\log\frac{\log s_+}{\log s_-} = \frac{1}{2}\log\frac{x+y}{x-y} = \operatorname{artanh}(y/x) = \eta_{\mathrm{el}}.$$

The relation $Z_{\eta_{\mathrm{el}}}/Z_* = e^{-\eta_{\mathrm{el}}}$, proved in (24.13), gives (39.56). □

The composition preserves the information needed for each reconstruction. With $\hbar$, one recovers $a_S = \sqrt{2\hbar}\, e^{\eta_{\mathrm{el}}/2}$ and $b_S = \sqrt{2\hbar}\, e^{-\eta_{\mathrm{el}}/2}$; with the chart (ω, Z_*), one recovers the inductance and capacitance already defined. Action, clock and dimensional reference accompany the form as typed data. Inverting two dimensionless coordinates does not reconstruct their units or the entire memory of the state.

Normalization enters before solving the cubic equations. If Z_{vac} and c_{vac} are received in a dimensional chart, the relations (39.50) first determine

$$\widehat{Z} = \frac{Z_{\mathrm{vac}}}{u_S u_Q^{-2}}, \qquad \widehat{c} = \frac{c_{\mathrm{vac}}}{u_C}.$$

These are the coordinates to which (39.53) applies. The reference Z_* belongs to the LC realization and is explicitly preserved in (39.56).

The two ratios are related through the channels, but evaluate different functions:

$$\widehat{Z} = \frac{f(s_-)}{f(s_+)}, \qquad \frac{Z_{\mathrm{LC}}}{Z_*} = \sqrt{\frac{\log s_-}{\log s_+}}. \tag{39.57}$$

The preceding reconstruction provides the map between the two readouts. In particular, interchanging the sheets inverts both ratios, changes η_{el} to $-\eta_{\mathrm{el}}$, and preserves $\widehat{c}$. In the symmetric limit $y = 0$, the channels coincide and both ratios equal 1. Outside that case, a common origin does not impose equality of the two functions. The action shape is recoverable from the constitutive response while preserving orientation and normalization.

39.8.7 Constitutive speed and kinematic realization of the clock

The constitutive response and the kinematic reader realize the same velocity section. Their identification preserves the order of construction: the APP sheets, their TRIT orientation and the angular transport published by TPK precede the velocity readings and the choice of units. In the two-sheet representation of section 39.7, with $x > |y|$ and rank-one projectors $P_\pm$, the transport is

$$T = e^{-xI - y\mathcal{R}} = q_+ P_+ + q_- P_-, \qquad q_\pm = e^{-x \mp y}, \qquad 0 < q_\pm < 1.$$

Its temporal blocks of lengths 90 and 120 produce the response $\mathcal{V}$ in (39.40). The coordinates x, y and the channels are outputs of the preceding angular development; this composition applies its readouts to that already constructed transport.

The symmetric logarithmic readout of temporal transport is

$$\mathcal{E} = \log\big[(1 - q_+^{90})(1 - q_-^{90})\big] - \log\big[(1 - q_+^{120})(1 - q_-^{120})\big]. \tag{39.58}$$

On the dimensional velocity line, with positive section u_C, the kinematic reader publishes $c_{\mathrm{int}} = \exp(-\mathcal{E})u_C$. The constitutive response publishes $c_{\mathrm{vac}} = \widehat{c}\,u_C$ through (39.44).

Proposition 39.19 (Constitutive and kinematic identity)**.** *In the same dimensional chart, we have*

$$c_{\mathrm{int}} = c_{\mathrm{vac}} = \widehat{c}\,u_C, \qquad \widehat{c} = (r_+ r_-)^{-1} = \exp(-\mathcal{E}). \tag{39.59}$$

The identification preserves sheet interchange.

Proof. All factors in (39.58) are positive. The logarithm law and (39.42) give

$$\mathcal{E} = \log(r_+ r_-) = \log\det\mathcal{V}, \qquad e^{-\mathcal{E}} = (\det\mathcal{V})^{-1}.$$

The determinant corresponds to the rank-one two-sheet realization. The two definitions therefore publish the same section. Exchanging the sheets permutes r_+ and r_- and preserves their product. The determinant $\det T = e^{-2x}$ corresponds to elementary transport, whereas $\det\mathcal{V} = r_+ r_-$ corresponds to its temporal response; (39.59) uses the latter. □

39.8.7.1 Path length and elementary duration

The positive dimensional frame (u_S, u_C, u_T, u_Q) induces the length basis $u_L = u_C u_T$. For an enriched path γ of $n = |\gamma|$ transitions and a constant channel, the additive readers are

$$T_{\mathrm{int}}(\gamma) = n u_T, \qquad L_{\mathrm{int}}(\gamma) = n\widehat{c}\,u_L. \tag{39.60}$$

Concatenation adds the numbers of transitions and their realizations. Enriched routes also preserve their orientation and memory.

Corollary 39.20 (Normalization of the elementary length)**.** *For $n > 0$, $L_{\mathrm{int}}(\gamma)/T_{\mathrm{int}}(\gamma) = c_{\mathrm{vac}}$. In the normalization $t_0 = u_T$,*

$$\ell_0 = c_{\mathrm{int}} t_0 = \widehat{c}\, u_L. \tag{39.61}$$

In a temporal chart $t_0 = \tau_0 u_T$, with $\tau_0 > 0$, we obtain $\ell_0 = \tau_0 \widehat{c}\, u_L$.

Proof. Dividing the two expressions in (39.60) cancels n and uses $u_L/u_T = u_C$. Multiplying the speed section by t_0 proves both elementary formulas. □

When the channel depends on the edge, the readout retains the additive form $L_{\mathrm{int}}(\gamma) = \sum_{e\in\gamma} \widehat{c}(e) u_L$. Its quotient by $n u_T$ is the mean of the speeds of those edges. The constant-channel expression is the homogeneous specialization of this readout.

39.8.7.2 Change of chart and adapted normalization

Proposition 39.21 (Covariance of the identification)**.** *Let $u'_C = d u_C$ and $u'_T = \eta u_T$, with $d, \eta > 0$. The coordinates of the same sections satisfy*

$$\widehat{c}' = d^{-1}\widehat{c}, \qquad \tau'_0 = \eta^{-1}\tau_0, \qquad u'_L = d\eta u_L. \tag{39.62}$$

If another publication writes $c' = \widehat{c}' u'_C$ with $u'_C = d u_C$, equality of sections is exactly equivalent to $d\widehat{c}' = \widehat{c}$.

Proof. Equality of each section in the two bases gives $\widehat{c}' u'_C = \widehat{c} u_C$ and $\tau'_0 u'_T = \tau_0 u_T$. In particular,

$$\tau'_0 \widehat{c}' u'_L = \frac{\tau_0}{\eta}\frac{\widehat{c}}{d} d\eta u_L = \tau_0 \widehat{c} u_L = \ell_0.$$

The final equivalence follows from the same substitution for speed. □

The adapted choice $d = \widehat{c}$ gives $u'_C = c_{\mathrm{vac}}$ and $\widehat{c}' = 1$: it expresses the constructed section in an adapted basis. The coefficient of the internal chart remains $(r_+ r_-)^{-1}$, and this is the normalization used by cubic inversion. Keeping the action and charge bases, (39.50) produces

$$\widehat{\mu}' = d\widehat{\mu}, \qquad \widehat{\varepsilon}' = d\widehat{\varepsilon}, \qquad \widehat{\mu}'\widehat{\varepsilon}' = (\widehat{c}')^{-2}.$$

In the adapted chart, we have $\widehat{\mu}' = r_-/r_+$ and $\widehat{\varepsilon}' = r_+/r_-$, by substitution of $\widehat{\mu} = r_-^2$ and $\widehat{\varepsilon} = r_+^2$.

39.8.7.3 Preservation of the readout under amplification

For the refinement $\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$, the normalized trace $\tau_m = \mathrm{Tr}/(2 \cdot 9^m)$ satisfies

$$\exp[-2\tau_m(\log \mathcal{V}_m)] = \exp[-\log r_+ - \log r_-] = \widehat{c}. \tag{39.63}$$

Indeed, each eigenvalue appears 9^m times; that multiplicity cancels against the denominator of the normalized trace. The ordinary amplified determinant is $(r_+ r_-)^{9^m}$. The two-sheet normalization, equivalently expressed by (39.63), preserves the constitutive readout during amplification. This realization preserves the enriched transport from which it originates.

39.9 Differential inversion and domain of the two-sheet constitutive response

The angular channels generated by the TPK calendar determine the positive transport

$$T = e^{-(x+y)}P_+ + e^{-(x-y)}P_-, \qquad \Omega = \{(x,y) \in \mathbb{R}^2 : x > |y|\}.$$

Here P_+ and P_- are the labelled projectors of the two sheets. The incidences 90 and 120 act on that same transport and produce the response

$$\mathcal{V} = (I - T^{90})(I - T^{120})^{-1} = r_+P_+ + r_-P_-.$$

The factorization with $S = T^{30}$ determines

$$f(s) = \frac{1 + s + s^2}{1 + s + s^2 + s^3}, \qquad r_\pm = f\big(e^{-30(x\pm y)}\big). \tag{39.64}$$

The factor 30 preserves the common unit of the incidences $90 = 3 \cdot 30$ and $120 = 4 \cdot 30$. This section receives the angular coordinates previously produced; it studies regularity and inversion of their constitutive reading.

39.9.1 Spectral sensitivity and logarithmic coordinates

For $t > 0$, define

$$g(t) = \log f(e^{-30t}), \qquad \sigma(t) = g'(t),$$

and the quotient and inverse-product coordinates

$$B(x,y) = \log \frac{r_-}{r_+} = g(x-y) - g(x+y), \tag{39.65}$$

$$V(x,y) = \log \frac{1}{r_-r_+} = -g(x-y) - g(x+y). \tag{39.66}$$

The letters B, V here denote two scalar response coordinates; the sheet projectors remain in the operator $\mathcal{V}$.

Lemma 39.22 (Regular monotonicity of the spectral reader)**.** *The map g is a strictly increasing analytic bijection from $(0,\infty)$ to $(-\log(4/3), 0)$. With $s = e^{-30t}$,*

$$\sigma(t) = \frac{30s^3(3 + 2s + s^2)}{(1 + s + s^2)(1 + s + s^2 + s^3)} > 0. \tag{39.67}$$

Proof. Differentiating the quotient gives

$$f'(s) = -\frac{s^2(3 + 2s + s^2)}{(1 + s + s^2 + s^3)^2} < 0, \qquad 0 < s < 1.$$

The chain rule produces $g'(t) = -30sf'(s)/f(s)$, which is (39.67). The denominators are positive on the domain. The limits $f(1) = 3/4$ and $f(0) = 1$ give $g(0^+) = -\log(4/3)$ and $g(+\infty) = 0$. Monotonicity, continuity and these limits prove bijectivity. Positivity of the derivative guarantees analytic regularity of the inverse on the open interval. □

Theorem 39.23 (Constitutive Jacobian and local recovery)**.** *Let $a = \sigma(x-y)$ and $b = \sigma(x+y)$. The map $\Phi(x,y) = (B(x,y), V(x,y))$ satisfies*

$$D\Phi = \begin{pmatrix} a - b & -a - b \\ -a - b & a - b \end{pmatrix}, \qquad \det D\Phi = -4ab < 0. \tag{39.68}$$

In particular, it is locally invertible throughout Ω, and the differential identities $B_x = V_y$ and $B_y = V_x$ hold.

Proof. Direct differentiation of (39.66) gives $B_x = a - b$, $B_y = -a - b$, $V_x = -a - b$ and $V_y = a - b$. The determinant is $(a-b)^2 - (a+b)^2 = -4ab$, strictly negative by (39.67). The inverse function theorem applies at every point of the domain. The two differential identities follow from the equal entries of the matrix. □

39.9.2 Image domain and global reconstruction

Theorem 39.24 (Global coordinates of the normalized response)**.** *Let $L = \log(4/3)$. The map Φ is an analytic diffeomorphism from Ω onto*

$$\mathcal{D} = \{(B, V) : 0 < V - B < 2L, \quad 0 < V + B < 2L\}. \tag{39.69}$$

If $\psi = g^{-1}$, reconstruction is given by

$$x = \frac{1}{2}\left[\psi\left(\frac{B-V}{2}\right) + \psi\left(-\frac{B+V}{2}\right)\right], \tag{39.70}$$

$$y = \frac{1}{2}\left[\psi\left(-\frac{B+V}{2}\right) - \psi\left(\frac{B-V}{2}\right)\right]. \tag{39.71}$$

The chamber $x > y > 0$ corresponds to the half $B < 0$ of $\mathcal{D}$.

Proof. The change $(x, y) \mapsto (t_-, t_+) = (x - y, x + y)$ is a linear bijection between Ω and $(0, \infty)^2$. Applying g to both coordinates gives an analytic bijection onto $(-L, 0)^2$. If $u = g(t_-)$ and $v = g(t_+)$, then $B = u - v$ and $V = -u - v$. Its linear inverse is $u = (B - V)/2$, $v = -(B + V)/2$. The conditions $-L < u, v < 0$ are exactly equivalent to (39.69). Composing these three bijections gives (39.71) and proves the global assertion. Finally, $y > 0$ is equivalent to $t_+ > t_-$; monotonicity of g transforms it into $v > u$, namely $B < 0$. □

The function ψ is evaluated through the cubic inverse of the reader already constructed. For $u \in (-L, 0)$, take $r = e^u$ and the unique root $s \in (0, 1)$ of

$$r s^3 + (r - 1)(1 + s + s^2) = 0.$$

Then $\psi(u) = -(\log s)/30$. Differential reconstruction and cubic reconstruction are therefore two expressions of the same constitutive inversion.

Corollary 39.25 (Sheet conjugation)**.** *The involution $(x, y) \mapsto (x, -y)$ acts on the response through $(B, V) \mapsto (-B, V)$. It preserves the product $r_+ r_-$ and inverts the quotient r_-/r_+.*

Proof. The involution exchanges $x - y$ with $x + y$ and consequently r_- with r_+. Formula (39.66) gives the result. □

39.9.3 Local stability of recovery

Proposition 39.26 (Singular values and sensitivity bound)**.** *The singular values of $D\Phi$ are $2a$ and $2b$. In particular,*

$$\left\| (D\Phi)^{-1} \right\|_2 = \frac{1}{2\min\{\sigma(x-y), \sigma(x+y)\}}.$$

For $0 < \delta < M < \infty$, differential recovery is uniformly bounded on $\Omega_{\delta, M} = \{(x, y) : \delta \le x - y, x + y \le M\}$.

Proof. The symmetric matrix (39.68) has the orthogonal vectors $(1,-1)$ and $(1,1)$ as eigenvectors, with eigenvalues $2a$ and $-2b$. The singular values are their absolute values. The spectral norm of the inverse is the reciprocal of the smallest singular value. The positive continuous function σ attains a positive minimum on $[\delta, M]$, providing the uniform bound. □

Example 39.27 (Exact recovery of two rational channels)**.** Take $e^{-30(x-y)} = 1/2$ and $e^{-30(x+y)} = 1/4$. Then

$$x = \frac{\log 2}{20}, \qquad y = \frac{\log 2}{60}, \qquad r_- = \frac{14}{15}, \qquad r_+ = \frac{84}{85}.$$

The constitutive coordinates are

$$B = \log \frac{17}{18}, \qquad V = \log \frac{425}{392}.$$

Cubic inversion recovers $1/2$ and $1/4$, and formulas (39.71) restore x, y. At this point,

$$a = \frac{34}{7}, \qquad b = \frac{114}{119}, \qquad \det D\Phi = -\frac{15504}{833}.$$

All rational coefficients in the example are obtained by evaluating the constitutive function and its derivative; the example verifies inversion without modifying the channel generator.

The transformation $(x, y) \leftrightarrow (B, V)$ describes exactly which angular information remains accessible through the two normalized readings. Dimensional realizations of permittivity, permeability, impedance and velocity are subsequently applied with their dimensional lines and declared sections. The preceding differential signature is a property of this constitutive coordinate map and retains that interpretive domain.

Chapter 40

Derivation of charge and electrical quanta: von Klitzing resistance, conductance, Josephson constant and magnetic flux

40.1 Derivation of the charge section from the vacuum

With Z_{vac}, $h_a = 2\pi\hbar_a$ and α_{HMT} fixed, the charge of sheet $a \in \{\mathrm{pre}, \mathrm{ret}\}$ is

$$e_a = \sqrt{\frac{2\alpha_{\mathrm{HMT}} h_a}{Z_{\mathrm{vac}}}}. \tag{40.1}$$

The section e_a is not introduced through an International System coordinate intended to reconstruct α. The causal order proceeds from α_{HMT}, the action, and the vacuum toward the charge section.

40.2 Von Klitzing and Josephson constants, conductance and magnetic flux

From equation (40.1) we deduce

$$R_K = \frac{h_a}{e_a^2} = \frac{Z_{\mathrm{vac}}}{2\alpha_{\mathrm{HMT}}}, \tag{40.2}$$

$$G_0 = \frac{2e_a^2}{h_a} = \frac{4\alpha_{\mathrm{HMT}}}{Z_{\mathrm{vac}}}, \tag{40.3}$$

$$\Phi_{0,a} = \frac{h_a}{2e_a} = \sqrt{\frac{h_a Z_{\mathrm{vac}}}{8\alpha_{\mathrm{HMT}}}}, \tag{40.4}$$

$$K_{J,a} = \frac{2e_a}{h_a} = \Phi_{0,a}^{-1}. \tag{40.5}$$

Consequently,

$$R_K G_0 = 2, \qquad G_0 Z_{\mathrm{vac}} = 4\alpha_{\mathrm{HMT}}, \qquad K_{J,a}\Phi_{0,a} = 1. \tag{40.6}$$

The bidirectional covariance takes the form

$$R_K^{\mathrm{pre}} = R_K^{\mathrm{ret}}, \qquad G_0^{\mathrm{pre}} = G_0^{\mathrm{ret}},$$

$$\frac{\Phi_{0,\mathrm{pre}}}{\Phi_{0,\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad \frac{K_{J,\mathrm{pre}}}{K_{J,\mathrm{ret}}} = R_{\mathrm{act}}^{-1/2}.$$

The resistance and conductance relations are independent of the orientation of action. The flux–frequency pair preserves that orientation and transforms its two components reciprocally.

40.3 Charge section and electrical quantization relations

The constitutive response establishes a relation between the two sheets and a relative propagation scale. The charge section is obtained by composing this response with the fine-structure constant and the action, both constructed in the preceding chapters. This order has a precise consequence: charge does not retrospectively determine the dodecaphase record. It is the record, together with the action and the vacuum response, that determines the charge section on the corresponding line.

40.3.1 Positive determination of the charge section

Consider the positive sections $\hbar_a$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$, and $h_a = 2\pi\hbar_a$. The impedance Z_{vac} has already been constructed through (39.50). The quotient h_a/Z_{vac} belongs to the quadratic charge line. This dimensional compatibility allows the following definition to be formulated without yet choosing an SI chart.

Definition 40.1 (Positive charge section)**.** The charge section corresponding to action orientation a is

$$e_a = \left(\frac{2\alpha h_a}{Z_{\mathrm{vac}}}\right)^{1/2}. \tag{40.7}$$

The root is taken on the positive charge half-line. Its conjugate section is $-e_a$; the sign of the latter is not identified with the action return index.

Proposition 40.2 (Existence, uniqueness, and compatibility of the coupling)**.** *The equation $Z_{\mathrm{vac}}e_a^2 = 2\alpha h_a$ determines a unique positive section. In the constitutive realization, one also has*

$$\alpha = \frac{Z_{\mathrm{vac}}e_a^2}{2h_a} = \frac{e_a^2}{4\pi\varepsilon_{\mathrm{vac}}\hbar_a c_{\mathrm{vac}}}. \tag{40.8}$$

Proof. Positivity of α, h_a, and Z_{vac} guarantees a unique positive root. The constitutive identities give $\varepsilon_{\mathrm{vac}}c_{\mathrm{vac}} = Z_{\mathrm{vac}}^{-1}$. Substituting this equality and $h_a = 2\pi\hbar_a$ into the first expression of (40.8) yields the second. □

The last expression is the usual form of electromagnetic coupling in a physical chart. Here it appears as a subsequent identity of the constructed sections. The proof does not recalculate α from a measured charge: it establishes the algebraic consistency of the preceding result with the section just defined. Physical identification additionally requires retaining the chart of units and the coupling regime used in the comparison. An identity between quantities and an experimental comparison have different functions in that recognition.

40.3.2 Resistance, conductance, flux, and frequency

The following four quantities use the same section e_a. Their dependencies can be fully resolved before any decimal is evaluated.

Theorem 40.3 (Composition of the electrical quanta)**.** *The sections*

$$R_K = \frac{h_a}{e_a^2} = \frac{Z_{\mathrm{vac}}}{2\alpha}, \qquad G_0 = \frac{2e_a^2}{h_a} = \frac{4\alpha}{Z_{\mathrm{vac}}}, \tag{40.9}$$

$$\Phi_{0,a} = \frac{h_a}{2e_a} = \sqrt{\frac{h_a Z_{\mathrm{vac}}}{8\alpha}}, \qquad K_{J,a} = \frac{2e_a}{h_a} = \Phi_{0,a}^{-1} \tag{40.10}$$

satisfy exactly

$$R_K G_0 = 2, \qquad G_0 Z_{\mathrm{vac}} = 4\alpha, \qquad K_{J,a}\Phi_{0,a} = 1, \qquad K_{J,a}^2 R_K = \frac{4}{h_a}. \tag{40.11}$$

Proof. Substituting $e_a^2 = 2\alpha h_a/Z_{\mathrm{vac}}$ into the first two definitions cancels h_a and gives (40.9). Squaring the positive section $h_a/(2e_a)$ gives $h_a Z_{\mathrm{vac}}/(8\alpha)$; positivity fixes the root in (40.10). Its inverse is $2e_a/h_a$. The first three products in (40.11) reduce, respectively, to 2, 4α, and 1. Finally, $(4e_a^2/h_a^2)(h_a/e_a^2) = 4/h_a$. □

The physical realization recognizes in these sections the von Klitzing resistance, the conductance quantum, the flux quantum, and the Josephson constant. The factor 2 in the conductance belongs to the

normalization of the quantity defined here; identifying it with a multiplicity of channels in a material system requires specifying that representation. The four equations do not constitute four independent generators: they share α, the action, and the vacuum response. Precisely this dependency produces the cross-identities and makes it possible to check an evaluation without altering the operations from which it arose.

40.3.3 Action return and transport of the sections

The quotient $R_{\mathrm{act}} = h_{\mathrm{pre}}/h_{\mathrm{ret}}$, obtained before the angular pair, preserves the distinction between the two action sections. It does not change the sheet assignments of the constitutive response. These are two distinct operations: action return and channel interchange.

Proposition 40.4 (Covariance under return)**.** *With common α and Z_{vac}, one has*

$$\frac{e_{\mathrm{pre}}}{e_{\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad R_K^{\mathrm{pre}} = R_K^{\mathrm{ret}}, \qquad G_0^{\mathrm{pre}} = G_0^{\mathrm{ret}}, \tag{40.12}$$

$$\frac{\Phi_{0,\mathrm{pre}}}{\Phi_{0,\mathrm{ret}}} = R_{\mathrm{act}}^{1/2}, \qquad \frac{K_{J,\mathrm{pre}}}{K_{J,\mathrm{ret}}} = R_{\mathrm{act}}^{-1/2}. \tag{40.13}$$

Proof. The first identity follows by dividing the two versions of (40.7) and taking the positive root. In (40.9), the action has already cancelled. The other two identities follow from the powers $h_a^{1/2}$ and $h_a^{-1/2}$ in (40.10). □

Resistance and conductance preserve the constitutive quotient, whereas flux and frequency also retain the action orientation. This separation gives a structural reading of their dependencies: some quantities are invariants of the sheet quotient, while others additionally measure the action section used. The metrological comparison must specify which section it evaluates; the numerical proximity of the two actions does not authorize their identification.

Chapter 41

Quadratic characters and spectral constants: Catalan, Apéry, Euler–Mascheroni and the Stieltjes hierarchy

41.1 Operatorial representation of Dirichlet characters

The constants in this chapter are grouped because they share a spectral construction independent of their decimal expansions and free of target values. Let

$$Ne_n = ne_n, \qquad n \in \mathbb{N},$$

in $\ell^2(\mathbb{N})$. A residual character χ defines the diagonal operator $Q_\chi e_n = \chi(n)e_n$; whenever the power is trace class,

$$\operatorname{Tr}(N^{-s}Q_\chi) = L(s,\chi). \tag{41.1}$$

The equation preserves the modulus, orientation, and provenance of each character; therefore, it does not identify distinct residual objects.

41.2 HMT construction of the residue characters

The preceding diagonal operator is not the initial algebraic datum. The selection chain is

$$\begin{aligned}\mathrm{APP} &\longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow \{\text{residue modulo } 3,\ C_P\}\\ &\longrightarrow \{\chi_{-3},\ J = C_P \bmod 3\} \longrightarrow \{\chi_{-3},\ J^2 = -I, \chi_{-4}\}\\ &\longrightarrow Q_3, Q_4.\end{aligned}$$

The triadic residual functional determines the difference between the two nonzero oriented classes. The incidence sector uses the symmetric Paley conference matrix of order six,

$$C_P^{\mathsf{T}} = C_P, \qquad C_P C_P^{\mathsf{T}} = 5I_6.$$

Its reduction $J = C_P \bmod 3$ satisfies

$$J^2 = 2I_6 = -I_6 \quad \text{in } \operatorname{End}_{\mathbb{F}_3}(\mathbb{F}_3^6).$$

The torsional quarter then determines the cyclic phase $1, \mathrm{i}, -1, -\mathrm{i}$. Applying the Chinese remainder theorem preserves both residual data and produces $Q_{12} = Q_3Q_4$. The trace $\operatorname{Tr}(N^{-s}Q)$ is evaluated at the terminal stage; neither the Dirichlet series nor its decimal expression enters the selection of the character.

The construction is made explicit by the tables

$$\chi_{-3}(n) = \begin{cases} 0, & 3 \mid n,\\ 1, & n \equiv 1 \pmod 3,\\ -1, & n \equiv 2 \pmod 3,\end{cases} \qquad \chi_{-4}(n) = \begin{cases} 0, & 2 \mid n,\\ 1, & n \equiv 1 \pmod 4,\\ -1, & n \equiv 3 \pmod 4.\end{cases} \tag{41.2}$$

En $\ell^2(\mathbb{N})$,

$$Q_3 e_n = \chi_{-3}(n)e_n, \qquad Q_4 e_n = \chi_{-4}(n)e_n.$$

As they are diagonals, they commute; the Chinese remainder theorem gives

$$(Q_3Q_4)e_n = \chi_{-3}(n)\chi_{-4}(n)e_n = \chi_{12}(n)e_n. \tag{41.3}$$

The product simultaneously preserves the triadic residue and the quarter of torsion. Consequently, the character modulo twelve is determined before performing any evaluation of its values L.

Remark 41.1 (Negative control). The chain is invalidated if Q_3 does not distinguish the two oriented classes, if $J^2 \neq -I$, if Q_3Q_4 does not have the declared CRT table, or if the operator is selected from the value of the constant.

41.3 Internal complex structure and Catalan's constant

The internal complex structure satisfies

$$J^2 = -I. \tag{41.4}$$

The equality $J^2 = -I$ defines a representation $\rho : C_4 \to \mathrm{Aut}_{\mathbb{F}_3}(\mathbb{F}_3^6)$, $\rho(j) = J$. To realize it spectrally, take the unitary character $\upsilon : C_4 \to U(1)$, $\upsilon(j) = \mathrm{i}$, and the phase map $n \mapsto j^n$. On $\ell^2(\mathbb{N})$, the induced diagonal representation is

$$U_4 e_n = \upsilon(j^n) e_n = \mathrm{i}^n e_n.$$

Its oriented part is

$$Q_4 = \frac{U_4 - U_4^*}{2\mathrm{i}}, \qquad Q_4 e_n = \sin\Big(\frac{\pi n}{2}\Big)\, e_n = \chi_{-4}(n) e_n.$$

This is the explicit lift between the finite generator of order four and the residual operator; $\mathbb{F}_9$ is not identified with $\mathbb{C}$.

On odd integers, the same character can be written

$$\chi_J(n) = \mathrm{i}^{n-1} = \chi_{-4}(n).$$

Equivalently,

$$Q_4 = \frac{U_4 - U_4^*}{2\mathrm{i}}, \qquad Q_4 e_n = \chi_{-4}(n) e_n. \tag{41.5}$$

The Catalan constant appears as

$$G = \mathrm{Tr}(N^{-2} Q_4) = L(2, \chi_{-4}) = \sum_{n \geq 0} \frac{(-1)^n}{(2n+1)^2}. \tag{41.6}$$

The unitary lift of the torsion quarter generates exactly the character whose quadratic moment is Catalan's constant.

Operational proof. The operator $N^{-2}Q_4$ is trace-class because $\sum_{n \geq 1} |\chi_{-4}(n)| n^{-2} < \infty$. Its trace is therefore the sum of the diagonal elements. The table equation (41.2) annuls the even pairs and alternates the odd ones:

$$\mathrm{Tr}(N^{-2} Q_4) = 1 - \frac{1}{3^2} + \frac{1}{5^2} - \frac{1}{7^2} + \cdots.$$

The identity with $L(2, \chi_{-4})$ is the definition of the Dirichlet series; the equality with $\mathrm{Im}\,\mathrm{Li}_2(\mathrm{i})$ is obtained by taking the imaginary part of $\sum_{n \geq 1} \mathrm{i}^n / n^2$. □

The terminal value is

$$G = 0.915965594177219015054603514 9\ldots.$$

The determining structure is the identity $J^2 = -I$, which induces exactly the alternating sign of the odd classes; the decimal expansion is its terminal evaluation.

41.4 Residual composition of the triadic–quaternary type

The residual functional modulo three provides χ_{-3}. Its CRT product with χ_{-4} defines

$$\chi_{12} = \chi_{-3}\chi_{-4}. \tag{41.7}$$

On the units modulo twelve,

$$\chi_{12}(1) = 1, \quad \chi_{12}(5) = -1, \quad \chi_{12}(7) = -1, \quad \chi_{12}(11) = 1,$$

and vanishes outside of them. Two exact evaluations are

$$L(1, \chi_{12}) = \frac{\log(2+\sqrt{3})}{\sqrt{3}}, \tag{41.8}$$

$$L(2, \chi_{12}) = \frac{\pi^2}{6\sqrt{3}}. \tag{41.9}$$

The first contains the hyperbolic unit

$$\sqrt{3}L(1, \chi_{12}) = \operatorname{arcosh} 2 = \log(2+\sqrt{3}). \tag{41.10}$$

Together with $\log(3+2\sqrt{2}) = 2\log(1+\sqrt{2})$ and $\log(30+\sqrt{899})$, this identity determines a family of Pell scales whose members retain their respective algebraic provenances.

Certified terminal evaluations are

$$L(1, \chi_{12}) = 0.760345996300946347531094254 9\ldots,$$

$$L(2, \chi_{12}) = 0.949703126294009395263498491 7\ldots.$$

Evaluations dodecaphasic. Grouping by residue classes,

$$\begin{aligned} L(1, \chi_{12}) &= \sum_{n \geq 0} \left(\frac{1}{12n+1} - \frac{1}{12n+5} - \frac{1}{12n+7} + \frac{1}{12n+11} \right) \\ &= \int_0^1 \frac{1 - x^4 - x^6 + x^{10}}{1 - x^{12}}\, dx = \int_0^1 \frac{1 - x^4}{1 + x^6}\, dx. \end{aligned}$$

A real decomposition into the quadratic factors of $1 + x^6$ produces $\log(2+\sqrt{3})/\sqrt{3}$. For the second moment, if ψ_1 is the trigamma function,

$$\begin{aligned} L(2, \chi_{12}) &= \frac{1}{144}\left[\psi_1(1/12) - \psi_1(5/12) - \psi_1(7/12) + \psi_1(11/12)\right] \\ &= \frac{\pi^2}{144}\left(\csc^2 \frac{\pi}{12} - \csc^2 \frac{5\pi}{12} \right) = \frac{\pi^2}{6\sqrt{3}}, \end{aligned}$$

where has been used $\psi_1(z) + \psi_1(1-z) = \pi^2 \csc^2(\pi z)$. The two proofs use the CRT table and not a target decimal value. □

41.5 Euler and Stieltjes Constants and the Theta–Mellin Transform

Let

$$\vartheta(t) = \sum_{n\in\mathbb{Z}} e^{-\pi n^2 t}, \qquad t > 0.$$

For $\Re s > 1$, the theta–Mellin functional recovers the convergent identity

$$\pi^{-s/2}\Gamma\Big(\frac{s}{2}\Big)\,\zeta(s) = \frac{1}{2}\int_0^\infty \big(\vartheta(t) - 1\big)t^{s/2-1}\,dt.$$

The meromorphic continuation is obtained by splitting the integral at $t = 1$, using $\vartheta(t) = t^{-1/2}\vartheta(1/t)$, and separating the polar terms. Its expansion at $s = 1$,

$$\zeta(s) = \frac{1}{s-1} + \sum_{j\ge 0} \frac{(-1)^j \gamma_j}{j!}(s-1)^j, \tag{41.11}$$

situates $\gamma = \gamma_0$ and the Stieltjes constants in a single family of renormalized moments. This organization expresses an analytical common provenance, without attributing an interpretation that is physically identical to all its levels.

The Catalan constant often appears as an alternating series:

$$G = 1 - \frac{1}{3^2} + \frac{1}{5^2} - \frac{1}{7^2} + \cdots.$$

That formula gives its value, and the HMT genealogy explains why this specific alternation exists.

In HMT, the origin is in the torsion chamber.

There exists an internal operator J such that

$$J^2 = -I.$$

The root of -1 emerges from two successive applications of a quarter turn. The complex structure is the algebraic memory of an internal rotation.

That turn generates a character of order four. When it is published on the positive integers, it produces exactly the residual pattern that alternates among $+1, 0, -1, 0$.

The Catalan constant then appears as a spectral trace:

$$G = L(2, \chi_{-4}) = \mathrm{Tr}(N^{-2}Q_4).$$

This changes its meaning. Catalan's constant is simultaneously the sum of a particular series and the spectral response of the integers to a quarter of torsion.

Each term of the series records how the internal rotation acts on a residue class. The alternation is the arithmetic shadow of the rotation.

The triadic structure has its own character modulo 3. Combining it with the character of order four, the Chinese remainder theorem produces a character modulo 12:

$$\chi_{12} = \chi_{-3}\chi_{-4}.$$

The module 12 appears as the minimal common space in which triadic orientation and the quarter-torsion can coexist.

The dodecaphase is, in that sense, a reconciliation of 3 and 4.

Of the combined character emerges

$$L(1,\chi_{12}) = \frac{\log(2+\sqrt{3})}{\sqrt{3}},$$

y

$$L(2,\chi_{12}) = \frac{\pi^2}{6\sqrt{3}}.$$

La cantidad

$$2+\sqrt{3}$$

is the fundamental unit of the real field $\mathbb{Q}(\sqrt{3})$. Its logarithm represents a hyperbolic shift. Once again, a finite residue structure opens an infinite multiplicative dynamics.

Here rotation, torsion, arithmetic character, Pell unit, and hyperbolic displacement meet.

The Euler–Kronecker constant of the field $\mathbb{Q}(\sqrt{3})$ prolongs this structure. It measures the regular term that remains after separating the principal pole of the field's zeta function. In the HMT genealogy, this term constitutes the regular invariant of fine arithmetic memory that remains after removing the universal divergence.

The Bendersky–Glaisher family extends the mechanism into a tower. The spectral derivatives of zeta generate that tower. Apery's constant and other constants associated with odd values are organized as members of the same functional family.

The novel contribution lies in the genealogy that unifies the classical constants:

- the quarter of torsion produces the complex structure;
- the residue triadico produces the structure modulo 3;
- their composition produces the character modulo 12;
- the character generates values L;
- the values L open the quadratic field and its spectral constants.

Geometric torsion has become arithmetic while preserving entirely its orientation.

41.6 Cyclic decomposition, quarter-turn, and oriented Catalan moment

The dodecaphase register allows the constitutive response to be related to other transport invariants. The link is established on specified subspaces and maps: the rank defect measures a difference in incidence, the determinant preserves a scalar response and a coefficient of the resolvent retains orientation. The family of moments culminating in Catalan enters at this last level.

41.6.1 Two subspaces of the dodecaphase cycle

In $\mathbb{R}^{12}$, let $Ce_j = e_{j+1 \bmod 12}$ and let

$$P_3^{\mathrm{cyc}} = \frac{I + C^3 + C^6 + C^9}{4}, \qquad P_4^{\mathrm{cyc}} = \frac{I + C^4 + C^8}{3}, \qquad H_d = \operatorname{Ran} P_d^{\mathrm{cyc}}. \tag{41.12}$$

The averages over cyclic subgroups are orthogonal projectors. H_3 consists of the periodic sequences whose period divides 3, and H_4 of those whose period divides 4. Their dimensions are 3 and 4. The restriction of C to each space realizes the corresponding cycle. The superscript cyc identifies the average over the dodecaphase cycle: P_3^{cyc} is the projector onto sequences whose period divides 3. Its domain and

action differ from those of the three-dimensional isotypic projector of the icosahedral realization; equality of rank does not identify the two operators.

Proposition 41.2 (Rank defect and determinantal response)**.** *We verify*

$$\frac{\operatorname{Tr}(P_3^{\mathrm{cyc}} - P_4^{\mathrm{cyc}})}{12} = -\frac{1}{12}, \qquad \frac{\det_{H_3}(I - sC)}{\det_{H_4}(I - sC)} = \frac{1 - s^3}{1 - s^4} = f(s), \quad 0 < s < 1. \tag{41.13}$$

Proof. The trace of an orthogonal projector is its rank, so the numerator of the first expression is $3 - 4$. The characteristic polynomial of a cycle of length d is $t^d - 1$; hence its determinant $\det(I - sC)$ is $1 - s^d$. Their quotient yields the second identity. □

The substitution $s = q^{30}$ transports this representation to the $90/120$ quotient. At $s = 1$, the common constant mode is cancelled before taking the limit, which equals $3/4$. This realization of $-1/12$ as a trace defect has an explicit finite domain. The regularized and modular realizations of the same scalar retain their own operators and domains.

41.6.2 Faithful representation of the quarter-turn

Define the antipodal projector $P_{\mathrm{ant}} = (I - C^6)/2$ and $Q = P_4^{\mathrm{cyc}} P_{\mathrm{ant}}$. This projector acts on the twelve-phase cycle and differs from the constitutive projector P_- in Section 39.8. The projectors P_4^{cyc} and P_{ant} commute, and Q has rank 2. In its image, fix the orthonormal basis

$$u = \frac{1}{\sqrt{6}}(1, 0, -1, 0, 1, 0, -1, 0, 1, 0, -1, 0)^{\mathsf{T}}, \qquad v = Cu. \tag{41.14}$$

Componentwise verification gives $Cu = v$ and $Cv = -u$. Consequently, the isometry $W(a, b) = au + bv$ satisfies

$$CW = WJ, \qquad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad J^2 = -I. \tag{41.15}$$

The complex structure of the plane is realized by the effective action of the cycle. The sign depends on the chosen orientation: in the same basis, $C^3 W = -WJ$. This precision allows the plane to be composed with the oriented readout.

41.6.3 Resolvent and unlimited depth

Since $C^2 = -I$ on $\operatorname{Ran} Q$, for $0 \le s < 1$ one has

$$(I - sC)^{-1}\big|_{\operatorname{Ran} Q} = \frac{I + sC}{1 + s^2}, \qquad k_4(s) := \langle v, (I - sC)^{-1} u \rangle = \frac{s}{1 + s^2}. \tag{41.16}$$

The sequence $\langle v, C^n u \rangle$ is $0, 1, 0, -1, \ldots$. The depth readout preserves this character through the moment

$$C_2(s) = \sum_{k \ge 0} \frac{(-1)^k s^{2k+1}}{(2k + 1)^2}, \qquad 0 \le s \le 1. \tag{41.17}$$

The series converges absolutely and uniformly on this interval by comparison with $\sum (2k + 1)^{-2}$. For $0 < s < 1$, the differentiated series converge uniformly on every compact subinterval of the interior. With $\mathcal{D} = s\, d/ds$, one obtains

$$\mathcal{D}^2 C_2(s) = k_4(s), \qquad C_2(s) = \int_0^s \frac{dt}{t} \int_0^t \frac{d\xi}{\xi}\, k_4(\xi). \tag{41.18}$$

The conditions $C_2(0) = 0$ and $\lim_{s \downarrow 0} \mathcal{D} C_2(s) = 0$ fix the two integration constants. Indeed, the difference between two solutions of $\mathcal{D}^2 F = k_4$ has the form $a \log s + b$; the second condition annuls a and the first

annuls b. Uniform convergence permits evaluation at the endpoint $s = 1$: the result is the Catalan moment. The finite representation of the character preserves its orientation; the depth index remains unlimited.

41.6.4 Composition with the constitutive response

Theorem 41.3 (Constitutive differential relation)**.** *For* $0 < s < 1$*, with the orientation of* (41.14)*,*

$$f(s) = \frac{1 + s + s^2}{s(1 + s)}\, \mathcal{D}^2 C_2(s). \tag{41.19}$$

Proof. Substituting (41.16) into (41.18) and using $(1 + s)(1 + s^2) = 1 + s + s^2 + s^3$ gives the identity. All denominators are positive on the domain. The intertwiner (41.15) identifies the operator coefficient used before its evaluation. □

Upon evaluating $s_\pm = q_\pm^{30}$, the same family produces the two channel responses of (39.42). The Catalan limit, the trace defect and the constitutive eigenvalues retain their different functions within this composition. Inverting the cycle with the marks u, v fixed changes the sign of k_4 and preserves the determinant $1 + s^2$. This identifies orientation information that the determinant alone does not distinguish.

The Pell development uses a particular evaluation of this family, with $\rho = 2 - \sqrt{3}$ and $\rho^{-1} = 2 + \sqrt{3}$. Its proof is preserved as a separate integration unit; the angular definition of $q_\pm$ remains independent of any identification of $s_\pm$ with ρ.

Figure 41.1 represents the relation between the rational response and the oriented kernel before integration. The Pell section satisfies $\rho + \rho^{-1} = 4$, so that $k_4(\rho) = (\rho + \rho^{-1})^{-1} = 1/4$. The two constitutive values are obtained, by contrast, by evaluating f at the already constructed arguments $s_\pm$. The plot includes the continuous extensions of the two functions to $[0, 1]$; the domain of constitutive inversion remains the open interval $(0, 1)$.

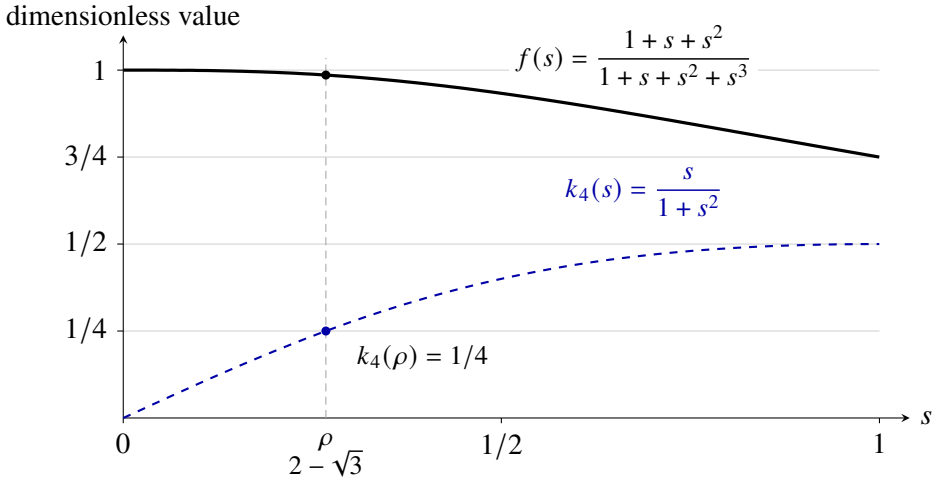

Figure 41.1: Constitutive response and kernel of the oriented moment. The solid curve is f and the dashed curve is $k_4 = \mathcal{D}^2 C_2$; they are related by (41.19). The vertical line marks the Pell section, without identifying it with the constitutive arguments s_+ or s_-.

Chapter 42

Euler–Kronecker constants and prime distributions: dodecaphasic characters, Meissel–Mertens and twin-prime series

42.1 Euler–Kronecker constant of the character of dodecaphase type

The factorization of Dedekind

$$\zeta_{\mathbb{Q}(\sqrt{3})}(s) = \zeta(s)L(s,\chi_{12}) \tag{42.1}$$

gives, upon comparing the constant terms in $s = 1$,

$$\gamma_{\mathbb{Q}(\sqrt{3})} = \gamma + \frac{L'(1,\chi_{12})}{L(1,\chi_{12})} = 1.0539656082484825800\ldots. \tag{42.2}$$

This constant represents the normalized finite term at the pole of the zeta function of the real dodecaphase field. It is not a variant of Euler's γ, but the arithmetic correction induced by χ_{12}.

In fact, writing $u = s - 1$,

$$\zeta(s) = u^{-1} + \gamma + O(u), \qquad L(s,\chi_{12}) = L_1 + L_1' u + O(u^2),$$

we obtain

$$\zeta_{\mathbb{Q}(\sqrt{3})}(s) = \frac{L_1}{u} + \bigl(\gamma L_1 + L_1'\bigr) + O(u). \tag{42.3}$$

The Euler–Kronecker constant is the quotient of the finite term by the residue; dividing equation (42.3) by L_1 proves equation (42.2). This derivation simultaneously explains the residue

$$\operatorname*{Res}_{s=1} \zeta_{\mathbb{Q}(\sqrt{3})}(s) = \frac{\log(2+\sqrt{3})}{\sqrt{3}}$$

and the finite correction. The numerical value is certified by evaluating $L(1,\chi_{12})$ and $L'(1,\chi_{12})$ with the same residue table and a tail bound; it is not imported from a table of quadratic fields.

42.2 Constantes aritmeticas asociadas to the numeros primos

Once the irreducible arithmetic cycles have been selected, two distinct families are obtained:

$$B_1 = \lim_{x\to\infty}\left(\sum_{p\le x}\frac{1}{p} - \log\log x\right), \tag{42.4}$$

$$C_2 = \prod_{p>2}\frac{p(p-2)}{(p-1)^2}. \tag{42.5}$$

B_1 regularizes a local sum; C_2 is a multiplicative density of twin-prime pairs. Both require tail control. They are not deduced from one another by sharing the primes.

42.3 Native product, factorization, and irreducibility

This chapter develops the arithmetic sector of normal forms over the common kernel and the correlative construction of the continuum in Section 6.5. The local operation extends to words, its fibers distinguish the irreducibles, and evaluation makes it possible to recognize the primes. The development recovers the native product of the corpus; its documentary provenance is collected in Appendix 102.6.

42.3.1 Composition of residues and quotients in multiplication

Selecting prime numbers requires a multiplication to have been constructed. In Triadic Modular Holography, this operation must be presented from the two APP sheets, preserving both the residual coordinate and its quotient. The residue alone makes it possible to recognize a congruence class. The residue–quotient pair makes it possible to reconstruct the integer result of the local operation. This distinction determines which information must be transported when composing the cells.

Let $D_9 = \{1, \dots, 9\}$. For each pair $(a, b) \in D_9^2$, the additive and multiplicative sheets are written as

$$a + b = R_+(a, b) + 9Q_+(a, b), \qquad ab = R_\times(a, b) + 9Q_\times(a, b),$$

with $R_+, R_\times \in D_9$. The choice of the positive representative uniquely fixes the four data. In particular, a result divisible by nine has its residue represented by 9, and its quotient is one less than that of Euclidean division with zero remainder. This is an exact representation convention, which must be maintained throughout the construction.

For example,

$$2 \cdot 5 = 1 + 9 \cdot 1, \qquad 9 \cdot 9 = 9 + 9 \cdot 8.$$

The first result preserves the information that distinguishes 10 from 1; the second preserves that which distinguishes 81 from 9. If the quotient is omitted at one of these steps, a subsequent multiplication acts on a different object. Arithmetic memory here is not an interpretation added to the algorithm: it participates in reconstructing its result.

The two sheets are coupled even during multiplication. The product of two digits generates a pair $(R_\times, Q_\times)$; when the quotient from a preceding position is incorporated into the current position, the additive sheet is needed again. The global operation composes both sheets.

Proposition 42.1. Local compatibility of the quotients

The quotients satisfy the identities required to associate and distribute the operations without changing the reconstructed integer. For example, for addition,

$$Q_+(a, b) + Q_+\big(R_+(a, b), c\big) = Q_+(b, c) + Q_+\big(a, R_+(b, c)\big).$$

For multiplication,

$$Q_\times\big(R_\times(a, b), c\big) + cQ_\times(a, b) = Q_\times\big(a, R_\times(b, c)\big) + aQ_\times(b, c).$$

Proof. Substituting the two decompositions of $a + b + c$, the final residues are the same positive representative of its class modulo nine. Subtracting them and dividing by nine gives the first equality. For abc, the same argument is applied to

$$\big(R_\times(a, b) + 9Q_\times(a, b)\big)c = a\big(R_\times(b, c) + 9Q_\times(b, c)\big).$$

The distributive identity is obtained by reconstructing $a(b + c) = ab + ac$ with the two sheets. In all three cases, uniqueness of the residual representation determines exactly the quotient that must accompany it. □

These identities make it possible to organize the operation record: two parenthesizations produce the same integer without requiring their execution histories to be identified. Equality of the result and identity of the history are different assertions.

42.3.2 Nonadic words and normal form

The extension to arbitrarily large integers uses finite sequences of digits from D_9. The orientation adopted runs from the least significant to the most significant position. For $u = (u_0, \dots, u_{r-1})$, let

$$\mathrm{ev}_9(u) = \sum_{j=0}^{r-1} u_j 9^j.$$

The empty sequence represents zero. In this bijective numeration, the symbol 9 remains a digit; it does not become a zero without a quotient.

Proposition 42.2. Existence and uniqueness of the normal form

The preceding evaluation is a bijection between finite words over D_9, including the empty word, and nonnegative integers.

Proof. If $n > 0$, define

$$d(n) = 1 + ((n-1) \bmod 9), \qquad q(n) = \frac{n - d(n)}{9}.$$

Then $d(n) \in D_9$, $q(n) \geq 0$, and $q(n) < n$. Iteration terminates at zero and produces a word whose evaluation is n. For uniqueness, the first digit of any word evaluating to n must represent the class of n modulo nine within D_9; it must therefore be $d(n)$. Removing it and dividing by nine reduces the question to $q(n)$. Induction proves uniqueness. □

Some normal forms are

$$9 \leftrightarrow (9), \quad 10 \leftrightarrow (1,1), \quad 81 \leftrightarrow (9,8), \quad 1000 \leftrightarrow (1,3,3,1).$$

The representation is checked directly: $1000 = 1 + 3 \cdot 9 + 3 \cdot 9^2 + 9^3$. This last equality does not by itself identify the word of an integer with the cubic completion of a geometric domain. The two occurrences of 1000 have different objects and operations; an identification would require its map.

The normal form is an arithmetic coordinate. The TPK state additionally preserves orientation, sheet, route, boundary, and transport memory. When different histories produce the same normal form, the evaluation map brings their values together, but does not establish a bijection between those histories. The development of the article must preserve both levels and the map relating them.

42.3.3 Genealogical construction of the product on records

Word addition is performed position by position. If a position contains two digits, the additive sheet is consulted. If it contains only one, that digit is retained. The quotient arriving from the preceding position is incorporated through another additive lookup, and the quotients of both lookups are added. If $a + b = r + 9q$ and $r + c = r' + 9q'$, then $q + q'$ is transported. For example, $9 + 9 + 1 = 1 + 9 \cdot 2$. The incoming quotient lies between zero and two; when it is zero, no additional cell is consulted. An absent position is not an APP cell containing the digit zero.

Multiplication by a digit $d \in D_9$ acts analogously: at each position, the multiplicative sheet is first applied to the digit of the word and to d; the pending quotient is then incorporated through the additive sheet. The new quotient is the sum of the quotient of the local product and that of this additive lookup, and lies between zero and nine. The procedure terminates by appending the final quotient when it is nonzero.

Denote these operations by $u \boxplus v$ and $d \odot u$. If $v = (v_0, \dots, v_{m-1})$, the native product is constructed through the recurrence

$$a_m = \varnothing, \qquad a_j = (9 \odot a_{j+1}) \boxplus (v_j \odot u), \quad j = m-1, \dots, 0,$$

and $u \boxtimes v = a_0$ is defined. Every operation on the right-hand side uses the two local sheets already defined. Word evaluation does not intervene as an instruction for computing the product.

Theorem 42.3. Exactness of the native product

For all finite words u, v,

$$\mathrm{ev}_9(u \boxtimes v) = \mathrm{ev}_9(u)\,\mathrm{ev}_9(v).$$

Proof. The cell reconstruction identities prove, by induction over positions, that

$$\mathrm{ev}_9(u \boxplus v) = \mathrm{ev}_9(u) + \mathrm{ev}_9(v), \qquad \mathrm{ev}_9(d \odot u) = d\,\mathrm{ev}_9(u).$$

The product recurrence preserves the invariant

$$\mathrm{ev}_9(a_j) = \mathrm{ev}_9(u) \sum_{k=j}^{m-1} v_k 9^{k-j}.$$

The case $j = m$ is immediate. If it holds for $j+1$, multiplying by nine and adding $v_j\,\mathrm{ev}_9(u)$ yields the case j. For $j = 0$, the asserted equality follows. □

Corollary 42.4. Multiplicative structure of the normal forms

The nonempty words, with the product $\boxtimes$, form a commutative monoid whose unit is (1). Upon adjoining the empty word, it is absorbing.

Proof. Evaluation is multiplicative by the theorem and injective by Proposition 42.2. Associativity, commutativity, and the identity are verified after evaluation and recovered by injectivity. □

The proof makes it possible to recognize ordinary multiplication in the constructed operation. The logical order matters: the cell transducer is first defined and its invariant is proved; its integer realization is then identified.

42.3.4 Multiplicative openings and selection of irreducibles

Once the product has been constructed, factorization can be defined as its fiber. For each nonempty word w, let

$$\mathrm{Fac}(w) = \{(u, v) : u \boxtimes v = w\}.$$

This fiber is finite. Indeed, if $n = \mathrm{ev}_9(w)$, exactness implies $\mathrm{ev}_9(u)\,\mathrm{ev}_9(v) = n$, with both factors positive and no greater than n. Finiteness justifies the algebraic sum

$$\Delta e_w = \sum_{(u,v) \in \mathrm{Fac}(w)} e_u \otimes e_v.$$

The order in the factor pair is preserved. For $n = 12$, for example, the evaluations of the fiber are

$$(1, 12), (2, 6), (3, 4), (4, 3), (6, 2), (12, 1).$$

The reduced coproduct removes the two decompositions containing the unit, for $w \neq (1)$:

$$\widetilde{\Delta} e_w = \sum_{\substack{u \boxtimes v = w \\ u \neq (1),\ v \neq (1)}} e_u \otimes e_v .$$

Set $\widetilde{\Delta} e_{(1)} = 0$. This convention allows the unit to be treated separately, without confusing it with an irreducible.

Definition 42.5. Native irreducible

A word $w \neq (1)$ is multiplicatively irreducible if $\widetilde{\Delta} e_w = 0$.

The definition receives no table of primes and uses no decimal period. It asks whether the operation already constructed admits a nontrivial opening.

Theorem 42.6. Recognition of the primes

Evaluation establishes a bijection between native irreducibles and positive prime numbers.

Proof. If $w = u \boxtimes v$ with factors different from the unit, its evaluation is the product of two integers greater than one; it is therefore not prime. Conversely, if $\mathrm{ev}_9(w) = ab$, with $a, b > 1$, their normal forms u, v satisfy

$$\mathrm{ev}_9(u \boxtimes v) = ab = \mathrm{ev}_9(w).$$

Injectivity gives $u \boxtimes v = w$, so that w is not irreducible. The bijection of normal forms completes the proof. □

This result identifies a property of the operation with the property of its integer realization. Prime values appear upon evaluating the selected objects, after the product and its fibers have been defined.

Proposition 42.7. Coassociativity

On the algebraic space generated by positive words,

$$(\Delta \otimes I)\Delta = (I \otimes \Delta)\Delta.$$

Proof. Both sides enumerate, with coefficient one, the ordered triples (u, v, z) whose product is w. Associativity of the product identifies the two parenthesizations, and all sums are finite. □

42.3.5 Operator realization of the selector

In $\mathcal{H} = \ell^2(\mathcal{W}_9^+)$, with orthonormal basis $\{e_w\}$, the coproduct is first defined on finite linear combinations. The supports of Δe_w and $\Delta e_{w'}$ are disjoint if $w \neq w'$: an ordered pair has a unique product. Hence,

$$\|\Delta e_w\|^2 = |\operatorname{Fac}(w)|, \qquad \|\widetilde{\Delta} e_w\|^2 = r(w),$$

where $r(w)$ counts the ordered nontrivial openings.

The closure of $\widetilde{\Delta}$ has domain

$$\left\{ x = \sum_w x_w e_w \in \mathcal{H} : \sum_w r(w) |x_w|^2 < \infty \right\}.$$

Its associated positive operator is diagonal:

$$A_{\mathrm{irr}} = \overline{\widetilde{\Delta}}^{*} \overline{\widetilde{\Delta}}, \qquad A_{\mathrm{irr}} e_w = r(w) e_w .$$

Its maximal domain is

$$\mathrm{Dom}(A_{\mathrm{irr}}) = \left\{ x \in \mathcal{H} : \sum_{w} r(w)^2 |x_w|^2 < \infty \right\}.$$

The projector onto the irreducibles is then

$$P_{\mathrm{irr}} = (I - P_{(1)})\mathbf{1}_{\{0\}}(A_{\mathrm{irr}}).$$

The formula incorporates two distinct exclusions: the kernel removes all words possessing a nontrivial opening, and $I - P_{(1)}$ removes the unit. Positivity comes from a squared norm and has a specific meaning here: it counts decompositions. It is not yet an assertion about the positivity of another form, such as the completed Weil form.

42.3.6 Normalized readout of the TPK prefix and preservation of genealogy

The normal form admits an explicit composition with the integer prefix produced by the TPK. Denote by $\beta_9 = \mathrm{ev}_9^{-1}$ the normalizer of Proposition 42.2. Here K is the block depth of the TPK state, distinct from the length k of an elementary history in the emission tree. The construction applies to a regional coordinate of the block state; the same calculation applies to each of the three coordinates with its own record.

For the deep row vector $x_K \in \mathbb{Z}^6$, the integer TPK step uses the matrix

$$A_H = \begin{pmatrix} 2 & 2 & 2 & 1 & 2 & 1 \\ 2 & 1 & 2 & 2 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 2 & 2 & 2 & 0 & 2 & 1 \\ 2 & 1 & 2 & 1 & 0 & 0 \end{pmatrix}$$

and produces

$$y_K = x_K A_H, \qquad u_{K+1} = y_K \bmod 3, \qquad x_{K+1} = \frac{y_K - u_{K+1}}{3}.$$

The block $u_{K+1} \in \mathbb{F}_3^6$, with representatives $\overline{u}_j \in \{0, 1, 2\}$, has index

$$I(u_{K+1}) = \sum_{j=1}^{6} \overline{u}_j 3^{6-j}, \qquad 0 \le I(u_{K+1}) < 729.$$

The cylindrical readout updates the prefix through

$$N_{K+1} = 729 N_K + I(u_{K+1}).$$

The matrix A_H belongs to the TPK kernel update. In the following composition it is not replaced by an external arithmetic rule: the block and its index come from the step just executed.

Proposition 42.8. Compatibility of the native prefix and its normal form

If $w_K = \beta_9(N_K)$, then

$$w_{K+1} = \big(\beta_9(729) \boxtimes w_K\big) \boxplus \beta_9(I(u_{K+1})).$$

The typed truncation of this readout is

$$\varrho(w) = \beta_9\left(\left\lfloor \frac{\mathrm{ev}_9(w)}{729} \right\rfloor\right); \qquad \varrho(w_{K+1}) = w_K.$$

Proof. Compatibility of word addition and multiplication proves that the evaluation of the right-hand side is

$$729\,\mathrm{ev}_9(w_K) + I(u_{K+1}) = 729N_K + I(u_{K+1}) = N_{K+1}.$$

Uniqueness of the normal form gives the first equality. Since the block index lies between zero and 728, the integer quotient of N_{K+1} by 729 is N_K. Applying β_9 proves the truncation identity. □

Truncation does not consist of deleting three digits from a bijective word. For example, $\beta_9(729) = (9, 8, 8)$, whereas the integer quotient of 729 by 729 is one; deleting its three digits would produce the empty word. The rule ϱ preserves the residue and quotient convention defining the numeration.

The proposition normalizes an already generated prefix and preserves its compatibility under refinement. Its application to the state retains, in the original record, the block u_{K+1}, the deep quotient x_{K+1}, the carries of the decimal chart, the phase and the route. It does not assert that w_K reconstructs those coordinates by itself or that any word is published by a fixed regional section. The equality of normal forms refers to the numerical prefix; the identity of the histories is decided in the complete state.

The record accompanying the product contains the lookups of both sheets and their residues and quotients. It makes it possible to explain why an output was obtained and to reproduce the operation. The transducer result does not, however, exhaust the state of a TPK prolongation: a normal form may be reached by different histories.

Therefore, integration with the dynamics preserves the direction of each map: the TPK state publishes its prefix, and the latter admits the normalized reading just constructed. Compatibility of a product on histories additionally requires specifying its domain, transport and survival. It does not require inverting a numerical reading that does not individualize the history. The identity of values does not replace that compatibility square; each application must be accompanied by the specific operation and the information it preserves.

The starting point of the arithmetic is already specified: two local operations, a normal form, a global transducer, its fibers, and a selector. The spectral extension must use these results without retrospectively changing their origin.

42.3.7 Correspondence with the preserved implementation

The code `a9_native.py` implements the operations in this order:

1. Local addition and multiplication cells.
2. Bijective nonadic encoding and separate evaluation.
3. Word addition and multiplication by a digit.
4. Word product recurrence.
5. Enumeration of product fibers.
6. Selection of irreducibles by absence of a nontrivial opening.

The checker uses integer multiplication and a conventional primality test after generating the outputs. These operations check the implementation; they are not incorporated into the body of the word producer. Checks that suppress a quotient or alter a cell document which dependency is broken. The reproduction receipts state the size of the checked window; that computational scope is kept separate from the preceding general proofs.

42.4 Factorization, arithmetic clocks and hierarchy of traces

The native product distinguishes two properties: irreducibility of a normal form and the period of a multiplicative action on it. This chapter constructs their spectral readouts, preserves the normalizations of each functional and prepares the completed form developed in Section 97.8.

42.4.1 From the irreducible to its clock

Product and coproduct determine which objects are irreducible. The arithmetic clock describes another property of those objects: return of a finite multiplicative orbit. For an integer $n \geq 2$ coprime to ten, define

$$\tau_n = \min\{k \geq 1 : 10^k \equiv 1 \pmod{n}\}.$$

The length τ_n corresponds to the orbit of the unit under multiplication by ten in the group of units modulo n. The decimal base fixes this readout; another coprime base determines another clock. Irreducibility, by contrast, belongs to the product constructed before this periodic representation is chosen.

Proposition 42.9. Synchronization of clocks

If $n = \prod_p p^{a_p}$ and $\gcd(n, 10) = 1$, then

$$\tau_n = \operatorname{mcm}_{p^{a_p} \| n} \tau_{p^{a_p}}.$$

Proof. An exponent k satisfies $10^k \equiv 1 \pmod{n}$ if and only if it does so modulo each prime power in the factorization. This is equivalent to k being a multiple of every order $\tau_{p^{a_p}}$. The smallest common positive exponent is the least common multiple. □

Factorization therefore organizes synchronization. Powers of the same prime must be retained as such: their period is not obtained by replacing them, without proof, with the base prime's period.

Proposition 42.10. Nonadic residual closure

If $\gcd(n, 90) = 1$, the integer block

$$M_n = \frac{10^{\tau_n} - 1}{n}$$

is divisible by nine.

Proof. The period definition makes M_n integral. Since $10 \equiv 1 \pmod{9}$, the numerator is divisible by nine. The integer n is invertible modulo nine, so $nM_n \equiv 0 \pmod{9}$ implies $M_n \equiv 0 \pmod{9}$. □

For a prime $p \notin \{2, 3, 5\}$, one also has $\tau_p \mid p - 1$, since its orbit belongs to the multiplicative group of order $p - 1$. The congruence of Proposition 42.10 also holds for composites coprime to ninety. Its meaning is residual closure; irreducibility remains determined by product openings.

The numbers $7, 13, 77, 91, 143$ have decimal period six, but only the first two are irreducible. The structural relation is not that a period by itself identifies a prime, but that the product constructs components whose composition organizes returns.

42.4.2 Factorization as mode occupation

Let $\mathcal{P}$ be the set obtained by evaluating the native irreducibles. Each mode occupation is a family $\mathbf{k} = (k_p)_{p \in \mathcal{P}}$ of nonnegative integers with finite support. Its multiplicative evaluation is

$$N(\mathbf{k}) = \prod_{p \in \mathcal{P}} p^{k_p}.$$

Unique factorization identifies these occupations with the positive integers. The Hilbert spaces of occupations and of positive normal forms then have a unitary correspondence of bases. An occupation register preserves how often each irreducible occurs.

In the total-occupation-one sector, $\sum_p k_p = 1$, with basis $\{e_p : p \in \mathcal{P}\}$, define

$$H_{\mathcal{P}} e_p = (\log p) e_p,$$

and, on occupations,

$$H_{\mathrm{occ}} e_{\mathbf{k}} = \left(\sum_p k_p \log p \right) e_{\mathbf{k}}.$$

With maximal diagonal domains, both are self-adjoint. If $Q e_n = n e_n$, the basis identification satisfies

$$U H_{\mathrm{occ}} U^* = \log Q.$$

The equality follows from multiplicative composition:

$$\sum_p k_p \log p = \log N(\mathbf{k}).$$

The operator is not used to select primes retrospectively. It receives the irreducibles already constructed and converts their composition into an additive quantity. This is the precise place of the occupation representation in the article's genealogy.

42.4.3 One occupation structure and two trace levels

For $\Re s > 1$, the trace on the total-occupation-one sector is

$$P(s) = \mathrm{Tr}(e^{-s H_{\mathcal{P}}}) = \sum_{p \in \mathcal{P}} p^{-s}.$$

The trace on all occupations, by contrast, is

$$Z(s) = \mathrm{Tr}(e^{-s H_{\mathrm{occ}}}) = \prod_{p \in \mathcal{P}} (1 - p^{-s})^{-1} = \sum_{n \geq 1} n^{-s}.$$

The last equality follows from unique factorization. The stated half-plane guarantees absolute convergence and permits grouping of terms. After identification of the integer realization, Z agrees there with the zeta function. No table of zeta values has been used to define the modes.

Proposition 42.11. Hierarchy of moments

On $\Re s > 1$, taking the logarithm branch determined by expansion of the convergent product,

$$\log Z(s) = \sum_{k \geq 1} \frac{P(ks)}{k}.$$

Proof. The absolutely convergent expansion $-\log(1 - z) = \sum_{k \geq 1} z^k / k$, applied to each $z = p^{-s}$, gives

$$\log Z(s) = \sum_p \sum_{k \geq 1} \frac{p^{-ks}}{k}.$$

Absolute convergence permits interchange of the sums. □

The two indices retain different functions: p identifies the irreducible mode and k its occupation multiplicity. The relationship between them is not reduced to a list of constants: it produces a family of moments on the same set of irreducibles.

42.4.4 Meissel–Mertens and removal of the linear contribution

The coordinated extension brings together the finite part

$$B_1 = \gamma + \sum_p \left(\log(1 - p^{-1}) + p^{-1} \right).$$

The added term p^{-1} cancels exactly the logarithm's first order. Thus,

$$B_1 = \gamma - \sum_{k \geq 2} \frac{P(k)}{k}.$$

Here γ denotes the finite part γ_0 of the same functional, whose construction and bound are developed in Section 44.7; it is not a metrological input or a decimal chosen for evaluation. The formula relates two operations on the constructed functional: extraction of the finite part and cancellation of each mode's first moment.

Proposition 42.12. Bound on the moment tail

For an integer $K \geq 1$,

$$0 < \sum_{k > K} \frac{P(k)}{k} \leq \frac{2P(K+1)}{K+1} \leq \frac{2^{-K}}{K+1} \left(1 + \frac{2}{K} \right).$$

Proof. Since $k \geq K + 1$,

$$\sum_{k > K} \frac{P(k)}{k} \leq \frac{1}{K+1} \sum_p \frac{p^{-(K+1)}}{1 - p^{-1}} \leq \frac{2P(K+1)}{K+1}.$$

By comparison with all integers at least two,

$$P(K+1) \leq \sum_{n \geq 2} n^{-(K+1)} \leq 2^{-(K+1)} + \int_2^\infty x^{-(K+1)} \, dx.$$

Evaluating the integral gives the second bound. □

The inequality converts the finite sum into an interval, provided the finite evaluations and γ themselves have controlled bounds. The length of a decimal expansion does not replace this estimate.

42.4.5 Residual exclusion and the separation-two pattern product

For the two-position pattern $\{0, 2\}$, let ν_p be the number of forbidden classes modulo p. At $p = 2$ the two positions coincide; for $p > 2$, they are two distinct classes. Local normalization relative to two independent choices produces

$$\sigma_p = \frac{1 - \nu_p / p}{(1 - 1/p)^2}.$$

The factor at $p = 2$ equals two, while the others form

$$C_2 = \prod_{p > 2} \frac{1 - 2/p}{(1 - 1/p)^2} = \prod_{p > 2} \left(1 - \frac{1}{(p-1)^2} \right).$$

The pattern's complete singular series is $2C_2$. It is useful to reserve different symbols for the product over $p > 2$ and for the full factor: normalization distinguishes a specific residual contribution, not a dispensable convention.

Proposition 42.13. The same moment system with a different weight

The product expansion satisfies

$$\log C_2 = -\sum_{k\geq 2} \frac{2^k - 2}{k}\big(P(k) - 2^{-k}\big).$$

Proof. For each $p > 2$,

$$\log(1 - 2/p) - 2\log(1 - 1/p) = -\sum_{k\geq 2} \frac{2^k - 2}{k p^k}.$$

The sum begins at $k = 2$, because the linear term cancels. For $p \geq 3$,

$$-\log\left(1 - \frac{1}{(p-1)^2}\right) \leq \frac{4}{3(p-1)^2}.$$

Comparison with the inverse-square series proves finiteness of the absolute-value sum and permits interchange of order. Removing mode 2 produces $P(k) - 2^{-k}$. □

The same hierarchy $P(k)$ thus describes two different operations: Meissel–Mertens linear cancellation and residual exclusion of the two-position pattern. The difference lies in the weight of each moment and removal of mode 2, not in introducing two independent prime catalogues.

For an integer $K \geq 1$, let

$$S_K = \sum_{k=2}^{K} \frac{2^k - 2}{k}\big(P(k) - 2^{-k}\big),$$

and the coordinated extension gives the bound

$$0 < -\log C_2 - S_K \leq \frac{3}{K+1}\left(\frac{2}{3}\right)^{K+1}\left(1 + \frac{3}{K}\right).$$

It is obtained by substituting $2^k - 2 \leq 2^k$, summing the geometric series for each $p \geq 3$, bounding $(1 - 2/p)^{-1} \leq 3$ and comparing the sum over primes with the sum over integers $n \geq 3$. Exponentiation gives an interval for C_2. Convergence of this product is a result distinct from existence of infinitely many prime pairs separated by two.

42.4.6 Triadic realization of the functional

The source for spectral functionals uses cycles $C_m = \mathbb{Z}/3^m\mathbb{Z}$ and their Laplacian

$$(\Delta_m f)(j) = 2f(j) - f(j+1) - f(j-1).$$

Writing $N_m = 3^m$, let $e_{m,n}$ be the normalized characters of the cycle and $\widetilde{n}$ the representative of n between $-(N_m - 1)/2$ and $(N_m - 1)/2$. The signed-orientation operator is defined by

$$D_m e_{m,n} = \frac{N_m}{\sqrt{\pi}} \sin\left(\frac{\pi\widetilde{n}}{N_m}\right) e_{m,n}.$$

This fixes the sign, not merely the square. The realization satisfies

$$D_m^2 = \frac{3^{2m}}{4\pi}\Delta_m.$$

Let P_0 be the orthogonal projector onto constant functions on the cycle. The coordinate π belongs to the prior generation of the HMT kernel. This normalization is part of the analytic realization and must preserve its provenance. The positive trace removes the constant mode and counts one contribution per pair of opposite orientations:

$$\mathrm{Tr}_m^+(F(D_m)) = \frac{1}{2}\,\mathrm{Tr}\big(F(D_m)P_0^\perp\big).$$

With the cycle's Fourier modes, the heat trace converges to

$$\Theta_+(x) = \sum_{n\geq 1} e^{-\pi n^2 x}, \qquad x > 0.$$

The proof, developed in the first section of the following chapter, preserves a Gaussian majorant independent of refinement level. The Mellin transform of this limit satisfies exactly

$$\int_0^\infty \Theta_+(x)x^{s/2-1}\,dx = \pi^{-s/2}\Gamma(s/2)Z(s), \qquad \Re s > 1.$$

This brings together additive construction of the integer spectrum and multiplicative decomposition into irreducibles. The identity between functionals is proved; it is not inferred from proximity of two numerical evaluations.

Theta inversion and continuation of the completed function are proved in the next chapter. Finite parts, Laurent coefficients and residual classes modulo three require their specific evaluations; they do not follow merely from heat-trace convergence.

Transport defect and uniform component

The extension on sheet folding provides an explicit representation of a one-winding defect. Let $N = 9^m$, with $m \geq 1$, and let T be a unitary operator on a Hilbert fibre $\mathcal{H}$. On $\mathbb{C}^N$, use the usual Euclidean inner product and the unit vector

$$u_N = N^{-1/2}(1,\dots,1).$$

Define $\iota_N f = u_N \otimes f$, $P_N = \iota_N \iota_N^*$ and $Q_N = I - P_N$. Transport applies T once upon completion of the cycle:

$$U_N(T) = \sum_{r=1}^{N-1} |r+1\rangle\langle r| \otimes I + |1\rangle\langle N| \otimes T.$$

It acts on the uniform state by

$$U_N(T)\iota_N f = \iota_N f + \frac{e_1}{\sqrt{N}} \otimes (T-I)f.$$

The added term has a uniform component and an orthogonal component. The latter, with the source's normalization, is

$$\delta_N(T) = \frac{N}{\sqrt{N-1}} Q_N U_N(T)\iota_N = \eta_N \otimes (T-I),$$

where

$$\eta_N = \sqrt{\frac{N}{N-1}}\left(e_1 - \frac{u_N}{\sqrt{N}}\right), \qquad \|\eta_N\| = 1, \qquad \eta_N \perp u_N.$$

The equality is checked by substituting the preceding action and applying Q_N. For two unitary transports T, S on the same fibre, one obtains

$$\delta_N(T)^*\delta_N(S) = (I-T)^*(I-S).$$

Commutativity is not required: the products occur in the indicated order. The same decomposition gives

$$\delta_N(T)^* P_N \delta_N(S) = 0,$$

since P_N annihilates the factor η_N.

These identities specify the information preserved by defect normalization and its position relative to the uniform component. They also allow the closures of the images to be transported isometrically between two cycle lengths: the Gram operator is independent of N. Its domain is the constructed defect sector; it is not by itself an identification of all TPK histories or of any subsequent spectral projection.

42.4.7 The completed form and its boundary identity

Passage to the double circle uses a form on a test-function domain. Its arithmetic side brings together the prime-power, gamma and polar contributions. Writing it with two columns,

$$\mathcal{J}_{\mathrm{GW}} = J_+^* J_+ - J_-^* J_-,$$

exhibits a difference of forms. The prime-index producer, orbital weights, Fourier normalization and completion must appear before it is identified with another form.

The source in Chapter 96 places the central step in an encoder Ξ and an orthogonal projection P, through

$$\langle \Xi f, \Xi g\rangle = \langle J_+ f, J_+ g\rangle, \qquad \langle P\Xi f, P\Xi g\rangle = \langle J_- f, J_- g\rangle.$$

If these two identities are obtained from the declared native actions, their difference gives exactly

$$\mathcal{J}_{\mathrm{GW}}(f,g) = \langle (I-P)\Xi f, (I-P)\Xi g\rangle.$$

The following chapter proves the explicit decomposition by columns and the consequence of the two moments. Application to the native encoder retains as an antecedent its action on the test functions, the position of its charts relative to P and the proof of both moments. The orthogonality of P explains the last equality, but does not by itself determine the two preceding identities.

Transport telescoping, in turn, preserves the form

$$\|x\|^2 = \sum_{r=0}^{N-1} \|DA^r x\|^2 + \|A^N x\|^2,$$

when $D^*D = I - A^*A$. If on the sheet considered $A = qV$, with $q = 5/9$ and V isometric, the final term equals $q^{2N}\|x\|^2$ and tends to zero. The proof of this extinction is preserved together with the identity placing state x on that sheet.

42.4.8 Spectral circle and memory circle

The first circle is a coordinate of the spectral line. For $s = 1/2 + i\gamma$, with $\gamma \in \mathbb{R}$, the transformation

$$\tau(s) = \frac{s-1}{s} = \frac{\gamma + i/2}{\gamma - i/2}$$

belongs to the unit circle without the point 1 and is invertible through

$$s = \frac{1}{1-\tau}, \qquad \gamma = \frac{1}{2}\cot\frac{\theta}{2}, \quad \tau = e^{i\theta}.$$

The second circle is the character family of integer memory:

$$\chi_\tau(n) = \tau^n, \qquad n \in \mathbb{Z}.$$

The nonadic connection increments memory by one upon completion of a winding. Intertwining relates a spectral phase to its action on that memory; it does not identify zero number j with winding number j.

If $C \in \mathcal{B}(\mathcal{H})$ is the phase operator obtained in the spectral realization, the nine-position calendar acts on $\mathbb{C}^9 \otimes \mathcal{H}$ by

$$S_{C,9} = \sum_{r=1}^{8} |r+1\rangle\langle r| \otimes I + |1\rangle\langle 9| \otimes C.$$

Each vector traverses the link containing C exactly once in a complete winding. Thus,

$$S_{C,9}^9 = I_9 \otimes C.$$

The identity is exact for any C; when C is unitary, $S_{C,9}$ is also unitary. The contractive factor $5/9$ belongs to another transport readout and is distinguished from this unitary phase.

The chapter's interest does not lie in representing an arbitrary matrix on nine positions. It lies in bringing together the origin of operator C, its domain, the preceding encoder and compatibility with TPK cylinders. Those data fix what is transported and why this realization is relevant.

42.4.9 Compatibility with the joint structure of the continuum

The history space, two sheets, memory, incidence and complex are not reconstructed as independent objects for each section. The prior correlative assembly is developed in Section 6.5, with its operations, realization conditions and naturality squares. The integer, depth, irreducible and spectral-height operators remain typed; coincident notation does not identify them.

Section 97.8 brings together the boundary identity with its terminal construction, test functions, terms of the completed form and convergence. Matrix approximations preserve their three matrices of form, moment and residual. Digits are compared only after outputs have been produced and frozen.

This organization preserves the requested argument: construction, operation, resulting structure and recognition. The manuscript does not change the causal kernel to facilitate a subsequent calculation, nor use a list of zeros as input to the arithmetic producer.

Chapter 43

Bendersky–Glaisher–Kinkelin family: regular products, derivatives of the zeta function and normalization hierarchies

43.1 Generation of the Bendersky–Glaisher–Kinkelin family via zeta regularization

Let $\mathcal{Z}_3(s) := \zeta(s)$ be the scalar realization of the triadic zeta functional in the normalization of this volume, $H_k = \sum_{j=1}^{k} j^{-1}$ (with $H_0 = 0$), and let B_{k+1} be the Bernoulli number under convention $B_1 = -1/2$. We define

$$A_k = \exp\!\left(\frac{H_k B_{k+1}}{k+1} - \mathcal{Z}_3'(-k)\right), \qquad k \geq 0. \tag{43.1}$$

The first levels include

$$A_0 = \sqrt{2\pi},$$

and the Glaisher–Kinkelin constant in A_1. For $n \geq 1$,

$$\zeta(2n+1) = (-1)^{n+1} \frac{2(2\pi)^{2n}}{(2n)!} \log A_{2n}. \tag{43.2}$$

Apéry's constant, $\zeta(3)$, is the first nontrivial even level. Its presence in the photon gas of chapter 40 constitutes a subsequent physical realization of this spectral value.

The first part of the tower can be seen in a synoptic form:

k	identidad estructural	terminal value
0	$A_0 = \exp[-\zeta'(0)] = \sqrt{2\pi}$	2.5066282746310005024 …
1	$\log A_1 = 1/12 - \zeta'(-1)$	1.2824271291006226369 …
2	$\log A_2 = -\zeta'(-2) = \zeta(3)/(4\pi^2)$	1.0309167521973921 …
3	$\log A_3 = -11/720 - \zeta'(-3)$	0.9795555269428446 …
4	$\log A_4 = -\zeta'(-4)$	0.9920479745250403 …

Relation to the odd values. The functional equation of ζ, developed in $s = -2n$, gives

$$\zeta'(-2n) = (-1)^n \frac{(2n)!}{2(2\pi)^{2n}} \zeta(2n+1). \tag{43.3}$$

Since $B_{2n+1} = 0$ for $n \geq 1$, the definition equation (43.1) reduces $\log A_{2n} = -\zeta'(-2n)$. Solving for $\zeta(2n+1)$ proves equation (43.2). The index $2n$ preserves the derivation level: it is not an editorial label. □

Chapter 44

Gauss dynamics and the Khinchin, Lévy and Lochs constants: cofinality of cylinders, transfer operator and Gauss–Kuzmin–Wirsing spectrum

44.1 Cofinality between HMT cylinders and continued fraction cylinders

An irrational HMT section determines a nested family of compact cylinders. Its Archimedean evaluation is a point $x \in (0,1) \setminus \mathbb{Q}$. The continued fraction of x determines classical cylinders

$$I(a_1, \dots, a_n).$$

Proposition 44.1 (Cofinality)**.** *For every finite cylinder $I(a_1, \dots, a_n)$ containing the evaluation x, there is an HMT depth $m(n)$ such that the HMT cylinder at level $m \geq m(n)$ is contained in $I(a_1, \dots, a_n)$.*

Proof. Given n, the continued-fraction cylinder $I(a_1, \dots, a_n)$ is an open neighborhood of the irrational x. There then exists $\varepsilon_n > 0$ with $(x - \varepsilon_n, x + \varepsilon_n) \subset I(a_1, \dots, a_n)$. The HMT cylinders C_m contain x, are nested, and satisfy $\operatorname{diam} C_m \to 0$. Choose $m(n)$ with $\operatorname{diam} C_{m(n)} < \varepsilon_n$. Since $x \in C_{m(n)}$, every point of that cylinder lies from x at a distance of less than ε_n, hence $C_{m(n)} \subset I(a_1, \dots, a_n)$. Nesting gives the inclusion for every subsequent level. □

The proof uses compactness, nesting, and uniqueness of evaluation. The result establishes the transport of approximations, but does not imply conjugation of the TPK memory shift with the Gauss map on all deep fibers.

The complete genealogy of this realization is

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to (C_m, \rho_{m+1,m})_{m \geq 0} \to x = \bigcap_m C_m \to \big(I(a_1, \dots, a_n)\big)_{n \geq 1}.$$

The HMT cylinders preserve route, phase, and carry; the terminal map projects these coordinates onto continued-fraction prefixes. Cofinality proves that this projection converges to the same point. A dynamical intertwiner would also require a lift $\widetilde{T}_G$ with commutative squares over the valuation fibers, a property not deduced from cofinality.

44.2 Gauss measure and Khinchin and Levy observables

The Gauss map [71, 67]

$$T_G(x) = \frac{1}{x} - \left\lfloor \frac{1}{x} \right\rfloor$$

preserve

$$d\mu_G(x) = \frac{dx}{\log 2(1+x)}. \tag{44.1}$$

Khinchin's constant is defined by

$$\log K = \int_0^1 \log a_1(x)\, d\mu_G(x). \tag{44.2}$$

The distribution of the first digit is computed directly:

$$\mu_G(a_1 = k) = \frac{1}{\log 2} \int_{1/(k+1)}^{1/k} \frac{dx}{1+x} = \log_2\left(\frac{(k+1)^2}{k(k+2)}\right). \tag{44.3}$$

By the ergodic theorem,

$$K = \prod_{k\geq 1} k^{\log_2((k+1)^2/[k(k+2)])} = 2.685452001065306445309714835\ldots \tag{44.4}$$

for μ_G-almost every section. The product is not applied to each point: the section φ^{-1}, for example, has all its digits equal to one and is an immediate falsification criterion for a pointwise reading. A certification of equation (44.4) truncates the sum of logarithms and bounds the tail by the estimate

$$\mu_G(a_1 = k) = O(k^{-2}), \qquad \sum_{k>N} \mu_G(a_1 = k)\log k = O\left(\frac{\log N + 1}{N}\right).$$

Lévy's constant is

$$L = -\int_0^1 \log x \, d\mu_G(x) = \frac{\pi^2}{12\log 2}. \tag{44.5}$$

Indeed,

$$\frac{1}{1+x} = \sum_{n\geq 0}(-1)^n x^n, \qquad \int_0^1 (-\log x)x^n\,dx = \frac{1}{(n+1)^2},$$

so that the integral is $\eta(2)/\log 2 = \pi^2/(12\log 2)$.

Khinchin's constant determines the logarithmic mean of the partial quotients, whereas Lévy's constant determines the exponential growth rate of the denominators. They are distinct observables of the same measured system.

44.3 Entropy (metric), Lyapunov exponent, and Lochs's constant

Since

$$\log|T_G'(x)| = -2\log x,$$

the Lyapunov exponent and the entropy metric are

$$\chi_G = h_G = 2L = \frac{\pi^2}{6\log 2}. \tag{44.6}$$

The Lochs ratio between continued fractions and a base-b expansion is

$$\Lambda_b = \frac{\log b}{h_G} = \frac{6\log 2\log b}{\pi^2}. \tag{44.7}$$

In particular,

$$\Lambda_{10} = 0.970270114392039257402560192\ldots,$$
$$\Lambda_{729} = \frac{36\log 2\log 3}{\pi^2} = 2.777618966374305777705782976\ldots.$$

The basis $729 = 3^6$ is relevant to the ambient space $\mathbb{F}_3^6$, but equation (44.7) remains an almost-sure theorem of μ_G, not a pointwise equality for every HMT route.

The value Λ_{729} represents the asymptotic typical rate of partial quotients obtained per complete block of six trits. It does not identify the ambient set of 729 words with the other objects of cardinality 729 in the corpus. The equality is an information rate between partitions, not a bijection between states.

44.4 Gauss–Kuzmin–Wirsing Transfer Operator

The Gauss–Kuzmin–Wirsing operator acts by

$$(\mathcal{L}f)(x) = \sum_{n\geq 1} \frac{1}{(x+n)^2} f\left(\frac{1}{x+n}\right). \tag{44.8}$$

Its dominant eigenvalue corresponds to the invariant density. The GKW constant is the modulus of the subdominant eigenvalue on the zero-mean subspace. An HMT-compatible scheme uses partitions of 9^m cylinders, transfer matrices with intervals, and a tail bound.

To promote the calculation, the following must be certified: isolation of the eigenvalue, invariance of the subspace, truncation error, convergence of spectral projectors, and absence of another eigenvalue of equal modulus. The known decimal value cannot be introduced as the center of the initial interval.

A joint deformation contains Khinchin and Lévy in a single object:

$$(\mathcal{L}_{s,t}f)(x) = \sum_{n\geq 1} n^t (n+x)^{-2s} f\left(\frac{1}{n+x}\right), \qquad P(s,t) = \log r(\mathcal{L}_{s,t}). \tag{44.9}$$

At the point $(s,t) = (1,0)$, the spectral perturbation gives

$$\partial_t P(1,0) = \log K, \qquad -\partial_s P(1,0) = \chi_G = 2L. \tag{44.10}$$

The Hessian of P determines the asymptotic variances and covariances of $\log a_1$ and $-2\log x$. Therefore, the Khinchin and Levy constants are two transverse derivatives of the same pressure function.

The reconocimiento numerico of the autovalor subdominante is

$$\lambda_2 \simeq -0.3036630028987326586, \qquad \kappa_{\mathrm{GKW}} = |\lambda_2|, \qquad -\log \kappa_{\mathrm{GKW}} \simeq 1.19183673556055.$$

In this volume, those decimals constitute reference values for comparison and not a spectral certificate. The proposed HMT proof uses Galerkin or Ulam on the cofinal cylinders of depth 9^m, a Lasota–Yorke inequality, interval arithmetic to isolate λ_2, and a rigorous bound on the tail. An interval containing two eigenvalues of the same modulus refutes the promotion, although it does not affect Khinchin, Levy, or Lochs.

44.5 Cofinal certificate of the Gauss–Kuzmin–Wirsing spectrum over the nonadic hierarchy

For Gauss–Kuzmin–Wirsing, let P_N be the certified family of truncations on the declared function space, and define

$$\Pi_m = P_{9^m}.$$

The hierarchy (Π_m) is a cofinal subsequence; the uniform bounds, projector convergence, and absence of spectral contamination are inherited from the family (P_N). A different cylindrical discretization must provide its intertwiner with (P_{9^m}).

44.6 Analytic construction of the functionals of the triadic tower

The preceding synthesis has placed the spectral constants within the triadic tower. This block contains their primary analytic construction: a sequence of self-adjoint operators on cycles of order 3^m, a limit of heat traces and a Mellin transform. The classical constants appear as evaluations, finite parts or derivatives of the resulting meromorphic functional, not as prefixes recognized in a catalogue.

The normalization of the operator D_m explicitly contains π in the scale relating the discrete Laplacian to the Gaussian heat kernel. The subsection therefore constitutes an analytic extension of the Archimedean branch already constructed. The subsequent spectral constants are obtained simultaneously from the resulting functional, with that normalization as a starting hypothesis.

44.6.1 Inductive limits and refinement scale

The spectral extension requires distinguishing two analytic levels. The first corresponds to bounded compatible families; the second to unbounded operators, for which algebraic intertwining does not by itself resolve domain problems.

Theorem 44.2 (Bounded inductive limit)**.** *Let $J_m : \mathcal{H}_m \to \mathcal{H}_{m+1}$ be isometries and $A_m \in \mathcal{B}(\mathcal{H}_m)$ self-adjoint operators such that*

$$A_{m+1}J_m = J_m A_m, \qquad \sup_m \|A_m\| < \infty.$$

There exists a unique bounded self-adjoint operator A on $\mathcal{H}_\infty = \varinjlim(\mathcal{H}_m, J_m)$ whose restriction to each level is A_m.

Proof. On the dense algebraic union we define

$$A[J_{m,\infty}\xi] := J_{m,\infty}A_m\xi.$$

Intertwining makes the definition independent of the representative. The uniform bound allows A to be extended by continuity to $\mathcal{H}_\infty$; symmetry on the dense subspace and boundedness imply its self-adjointness. □

Remark 44.3 (Control for unbounded operators). If the A_m are unbounded, the identity $A_{m+1}J_m = J_m A_m$ only defines an action on a union of domains. To obtain a closed or self-adjoint operator, the transported domains must be declared, closability proved and deficiency indices controlled, or essential self-adjointness proved on a compatible common core. Omitting these obligations constitutes a type error, not an abbreviation of the proof.

Now let $\mathcal{S}_\infty$ be a nonempty set of compatible surviving sections and let $\mathcal{P}_m$ be the finite set of their prefixes of length m. We write

$$\mathcal{H}_m := \ell^2(\mathcal{P}_m), \qquad E_m(\gamma,\gamma') = \begin{cases} 1, & \gamma' \text{ extends } \gamma, \\ 0, & \text{otherwise,} \end{cases}$$

and

$$d_m(\gamma) := \#\{\gamma' \in \mathcal{P}_{m+1} : \gamma' \mapsto \gamma\}, \qquad D_m^{\deg} := E_m E_m^* = \operatorname{diag}(d_m(\gamma)).$$

We restrict ourselves to the live subspace $d_m(\gamma) > 0$, and each prefix of level $m+1$ has a unique parent.

Theorem 44.4 (Normalized extension isometry)**.** *The operator*

$$J_m := E_m^*(D_m^{\deg})^{-1/2} : \mathcal{H}_m \longrightarrow \mathcal{H}_{m+1}$$

is an isometry, and

$$J_m e_\gamma = \frac{1}{\sqrt{d_m(\gamma)}} \sum_{\gamma' \mapsto \gamma} e_{\gamma'}.$$

Proof. Uniqueness of the parent gives

$$J_m^* J_m = (D_m^{\deg})^{-1/2} E_m E_m^* (D_m^{\deg})^{-1/2} = I.$$

The formula on e_γ is obtained by expanding the corresponding column of E_m^*. □

Setting

$$\mathcal{K}_m := \mathcal{H}_{m+1} \ominus J_m \mathcal{H}_m, \qquad \mathcal{H}_{\mathrm{surv}} \cong \mathcal{H}_0 \oplus \bigoplus_{m \geq 0} \mathcal{K}_m,$$

the refinement operator is defined

$$\mathcal{R}|_{\mathcal{H}_0} = 0, \qquad \mathcal{R}|_{\mathcal{K}_m} = 3^{m+1} I_{\mathcal{K}_m},$$

with maximal domain

$$\mathrm{Dom}(\mathcal{R}) = \mathcal{H}_0 \oplus \left\{ (\xi_m)_{m \geq 0} : \sum_{m \geq 0} 3^{2m+2} \|\xi_m\|^2 < \infty \right\}.$$

Theorem 44.5 (Refinement operator)**.** *If each $\mathcal{K}_m$ is finite-dimensional, $\mathcal{R}$ is positive, self-adjoint and has compact resolvent. Its spectrum measures refinement depth; it is not a spectrum of primes or zeros.*

Proof. The orthogonal decomposition reduces $\mathcal{R}$ to real scalar blocks on its maximal domain, which proves positivity and self-adjointness. The eigenvalues 3^{m+1} escape to infinity and their multiplicities are finite; therefore the resolvent is compact. An infinite-dimensional block with bounded eigenvalue would falsify this last conclusion. □

44.6.2 Integer, prime and orbital operators

Let $\mathscr{W}_{\mathrm{bal}}$ be the set of balanced ternary words reduced by theorem theorem 53.3. On $\ell^2(\mathscr{W}_{\mathrm{bal}})$, the operator

$$B e_w = b(w) e_w$$

is taken on its maximal domain. Its restriction to the subspace of positive integers is denoted by Q.

Theorem 44.6 (Integer and positive operators)**.** *The operator B is self-adjoint, has simple spectrum $\mathbb{Z}$ and compact resolvent. The operator Q has simple spectrum $\mathbb{N}_{\geq 1}$ and compact resolvent.*

Proof. The bijection of theorem 53.3 enumerates each integer exactly once. A real diagonal operator on its maximal domain is self-adjoint; since its entries escape to infinity outside finite sets, its resolvent is compact. The positive restriction preserves these properties. □

The omitted classical proof of theta inversion, continuation and the functional equation is merged only once with the triadic realization already constructed in theorem 44.20. There, $\Theta_B = 1 + 2\Theta_+$ and $Z = \mathcal{Z}_3$ are fixed literally; therefore this block does not define a second origin of ζ.

Let $\mathbb{P}$ be the set of ordinary primes, $\mathfrak{h}_{\mathbb{P}} := \ell^2(\mathbb{P})$ and

$$H_{\mathbb{P}} e_p = (\log p) e_p.$$

In the bosonic Fock space $\Gamma_s(\mathfrak{h}_{\mathbb{P}})$, the occupations $(k_p)_p$ have finite support.

Theorem 44.7 (Fock representation of factorization)**.** *The map on bases*

$$U_F|(k_p)_p\rangle = e_{\prod_p p^{k_p}}$$

extends to a unitary operator

$$U_F : \Gamma_s(\mathfrak{h}_{\mathbb{P}}) \longrightarrow \ell^2(\mathbb{N}_{\geq 1})$$

and satisfies

$$U_F\, d\Gamma(H_{\mathbb{P}})\, U_F^* = \log Q.$$

Proof. Unique factorization gives a bijection between finite occupations and positive integers, hence a unitary identification of the orthonormal bases. Moreover,

$$\sum_p k_p \log p = \log\left(\prod_p p^{k_p}\right),$$

which proves the intertwining. The explicit starting structure is the choice of prime modes and symmetric Fock space. □

On

$$\mathcal{H}_{\mathrm{orb}} := \ell^2\{(p,k,\varepsilon) : p \in \mathbb{P},\ k \geq 1,\ \varepsilon = \pm 1\},$$

we define

$$D_{\mathrm{orb}} e_{p,k,\varepsilon} = \varepsilon k \log p\, e_{p,k,\varepsilon}, \qquad W_{\log} e_{p,k,\varepsilon} = (\log p) e_{p,k,\varepsilon}.$$

Proposition 44.8 (Orbital trace)**.** *The operator D_{orb} is self-adjoint and has compact resolvent. If $f \in C_c(\mathbb{R})$ is bounded, then*

$$\mathrm{Tr}\Big(W_{\log} e^{-|D_{\mathrm{orb}}|/2} f(D_{\mathrm{orb}})\Big) = \sum_{p,k} (\log p) p^{-k/2} \big[f(k \log p) + f(-k \log p)\big].$$

Proof. The diagonal is real and its lengths escape every compact set with finite multiplicity. The compact support of f makes the regulated product finite-rank; its trace is the sum of the diagonal entries. The index p here ranges over ordinary primes. The result realizes the classical prime side, but does not identify D_{orb} with an operator dual to the zeros. □

44.6.3 Completed Guinand–Weil form

We fix

$$\mathcal{D}_{\mathrm{W}} := C_c^\infty(\mathbb{R}), \qquad \widehat{\psi}(t) = \int_{\mathbb{R}} \psi(x) e^{-itx}\, \mathrm{d}x, \qquad \psi(x) = \frac{1}{2\pi} \int_{\mathbb{R}} \widehat{\psi}(t) e^{itx}\, \mathrm{d}t,$$

and, for $\psi, \phi \in \mathcal{D}_{\mathrm{W}}$,

$$h_{\psi,\phi}(z) := \widehat{\psi}(z)\, \overline{\widehat{\phi}(\overline{z})}.$$

On the real line $h_{\psi,\psi} = |\widehat{\psi}|^2$.

Definition 44.9 (Test class)**.** The test class is $\mathcal{D}_{\mathrm{W}}$, stable under differentiation, reflection and translation. The inverse used is

$$\check{h}(x) = \frac{1}{2\pi} \int_{\mathbb{R}} h(t) e^{itx}\, \mathrm{d}t.$$

Smoothness and compact support provide rapid decay in strips and compact support for $\check{h}$, conditions ensuring the convergence of the following blocks.

Sea $\psi_\Gamma = \Gamma'/\Gamma$. Definimos

$$\mathfrak{I}_\# := \left\{ \mathrm{ev}_9(w) : w \in \mathscr{W}_9^+,\ P_{\mathfrak{I},\#} e_w = e_w \right\}.$$

By theorem 27.21, this image coincides with the ordinary primes; here it is used only to type the index of the orbital block, without repeating that proof.

$$\mathcal{P}(h) := h(i/2) + h(-i/2), \tag{44.11}$$

$$\mathcal{G}(h) := -\log \pi\, \check{h}(0) + \frac{1}{2\pi} \int_{\mathbb{R}} h(t)\, \Re \psi_\Gamma\left(\frac{1}{4} + \frac{it}{2}\right) \mathrm{d}t, \tag{44.12}$$

$$\mathcal{O}_\#(\check{h}) := \sum_{p \in \mathfrak{I}_\#} \sum_{k \geq 1} (\log p) p^{-k/2} \left[\check{h}(k \log p) + \check{h}(-k \log p) \right]. \tag{44.13}$$

Definition 44.10 (Completed functional)**.** For $h = h_{\psi,\phi}$, we fix

$$\mathcal{W}(h) := \mathcal{P}(h) + \mathcal{G}(h) - \mathcal{O}_\#(\check{h}).$$

The orbital block comes from the irreducible selector of the chapter 27; the polar and gamma blocks belong to the classical completion of zeta. This difference in provenance is preserved in the notation and the proof.

Theorem 44.11 (Guinand–Weil explicit formula)**.** *For $\psi, \phi \in C_c^\infty(\mathbb{R})$ and $h = h_{\psi,\phi}$,*

$$\lim_{T \to \infty} \sum_{\substack{\rho:\, \zeta(\rho) = 0 \\ |\Im \rho| \leq T}} h\left(\frac{\rho - 1/2}{i}\right) = \mathcal{W}(h),$$

where the nontrivial zeros are counted with multiplicity and the limit is taken with classical symmetrization.

Proof. Paley–Wiener places $h_{\psi,\phi}$ in the admissible class of the explicit formula. The poles of $\Lambda_\zeta(s) = \pi^{-s/2}\Gamma(s/2)\zeta(s)$ produce $\mathcal{P}$, the Archimedean factor produces $\mathcal{G}$ and the Euler product produces the sum over prime powers. The identification of this last sum with $\mathcal{O}_\#$ is made only through proposition 44.12; thus the proof of native primality is not duplicated. □

Proposition 44.12 (Reindexing of the orbital block)**.** *If the irreducibles of the native product coincide exactly with the ordinary primes and the weights $(\log p) p^{-k/2}$ and the two orientations $\pm k \log p$ are preserved, then*

$$\mathcal{O}_\#(\check{h}) = \mathcal{O}(\check{h}).$$

Proof. The bijection between native irreducibles and primes reindexes the sum without modifying indices, weights or arguments. A nonprime irreducible, a missing prime or a change in weight would falsify the identity. □

Remark 44.13 (Meromorphic–entire separation). The function Λ_ζ has simple poles at 0 and 1, which give rise to the polar block. In contrast,

$$\xi(s) = \frac{1}{2} s(s-1) \Lambda_\zeta(s)$$

is entire: the factors $s(s-1)$ cancel precisely those poles. Therefore no poles at 0 or 1 are attributed to ξ.

Definition 44.14 (Hermitian form and preoperator)**.** We define

$$\mathcal{B}_{\mathrm{W}}(\psi, \phi) := \mathcal{W}(h_{\psi,\phi}), \qquad \mathcal{V}_{\mathrm{W}} := \mathcal{D}_{\mathrm{W}} / \operatorname{Rad} \mathcal{B}_{\mathrm{W}},$$

and, on the algebraic quotient, the candidate rule

$$D_{\mathrm{W},0}[\psi] := [-i\psi'].$$

It is not assumed that $\mathcal{B}_{\mathrm{W}}$ is positive or that $\mathcal{V}_{\mathrm{W}}$ is already a Hilbert space. The rule becomes well-defined only after invariance of the radical has been proved.

Theorem 44.15 (Algebraic symmetry and invariances)**.** *The radical is invariant under $-i\ \mathrm{d}/\mathrm{d}x$; $D_{\mathrm{W},0}$ is well-defined and $\mathcal{B}_{\mathrm{W}}$-symmetric. The translations $T_a\psi(x) = \psi(x-a)$ preserve the form and the reflection $J\psi(x) = \psi(-x)$ satisfies*

$$JD_{\mathrm{W},0}J = -D_{\mathrm{W},0}.$$

Proof. The Fourier convention gives

$$h_{-i\psi',\phi}(z) = h_{\psi,-i\phi'}(z).$$

The identity holds before applying any of the three blocks of $\mathcal{W}$, so the derivative preserves the radical and the preoperator is symmetric. The opposite translation phases cancel in h; reflection changes the sign of the derivative and leaves the polar, gamma and orbital blocks invariant. This algebraic symmetry is not yet equivalent to self-adjointness in a positive Hilbert space. □

44.6.4 Local geometry of the critical line

Lemma 44.16 (Möbius coordinate of the critical line)**.** *For $s \in \mathbb{C} \setminus \{0,1\}$, let*

$$\tau(s) := i\frac{s-1}{s}.$$

With $F(s) = 1 - s$ and $C(s) = \overline{s}$,

$$\tau(Fs) = -\frac{1}{\tau(s)}, \qquad \tau(Cs) = -\overline{\tau(s)},$$

and

$$\tau(Fs) = \tau(Cs) \iff |\tau(s)| = 1 \iff \Re s = \frac{1}{2}.$$

Proof. The two identities are obtained by direct substitution. Their equality is equivalent to $\tau(s)^{-1} = \overline{\tau(s)}$, that is, $|\tau(s)| = 1$; expanding this last condition gives $\Re s = 1/2$. For the zeros of zeta, functional and conjugate symmetries are also required. The equivalence parametrizes the line; it does not by itself place the zeros on it. □

Lemma 44.17 (Local Hermite–Biehler sign)**.** *Let A be a real entire function with a simple real zero a. For $z = a + iy$, $y > 0$ sufficiently small,*

$$|A(z) - iA'(z)|^2 - |A(z) + iA'(z)|^2 = -4A'(a)^2 y + O(y^2) < 0.$$

The local convention associated with A is

$$E_A := A + iA'.$$

Only by specializing $A = \Xi$ and additionally assuming that a is a simple real zero of Ξ do we obtain

$$E_\Xi = \Xi + i\Xi'.$$

Proof. We expand A and A' in Taylor series around a, using $A(a) = 0$ and $A'(a) \neq 0$, and retain the first-order terms in y. The result is strictly local: it does not prove that E_A has the global Hermite–Biehler property. □

Proposition 44.18 (Obstruction by counting laws)**.** *Let*

$$N_A(T) := \operatorname{Tr} \mathbf{1}_{[-T,T]}(A).$$

The operators Q, B, D_{orb} and $\mathcal{R}$ do not, by themselves, have the counting law required of a possible operator dual to the zeros.

Proof. Para $T \geq 1$,

$$N_Q(T) = \lfloor T \rfloor, \qquad N_B(T) = 2\lfloor T \rfloor + 1.$$

The prime number theorem gives

$$N_{D_{\mathrm{orb}}}(T) = 2 \sum_{p \leq e^T} \left\lfloor \frac{T}{\log p} \right\rfloor \geq 2\pi(e^T) \sim \frac{2e^T}{T}.$$

Finally, $N_{\mathcal{R}}(T)$ is constant on each multiplicative interval $[3^m, 3^{m+1})$, since $\mathcal{R}$ only has levels 3^{m+1} with finite multiplicities.

For $\Xi(z) = \xi(1/2 + iz)$, the functional equation implies $\Xi(-z) = \Xi(z)$; the zeros $\pm\gamma$ have the same multiplicity and

$$N_{\mathrm{sym}}(T) = 2N_+(T) + O(1).$$

Consequently, the bilateral convention requires

$$N_{\mathrm{sym}}(T) \sim \frac{T}{\pi} \log T,$$

whereas the equivalent unilateral one, under this symmetry and pairing of multiplicities, requires

$$N_+(T) \sim \frac{T}{2\pi} \log T.$$

None of the four preceding functions has that asymptotic behavior. □

44.6.5 Laplacians on cycles of order 3^m

For $m \geq 1$, let

$$N_m = 3^m, \qquad C_m = \mathbb{Z}/N_m\mathbb{Z},$$

and consider the combinatorial Laplacian

$$(\Delta_m f)(j) = 2f(j) - f(j+1) - f(j-1), \qquad f \in \ell^2(C_m).$$

The characters

$$e_{m,n}(j) = N_m^{-1/2} \exp\left(\frac{2\pi i n j}{N_m}\right), \qquad n \in C_m,$$

form an orthonormal basis and satisfy

$$\Delta_m e_{m,n} = 4 \sin^2\left(\frac{\pi n}{N_m}\right) e_{m,n}.$$

Since N_m is odd, each class of C_m has a unique representative $\widetilde{n}$ with

$$-\frac{N_m-1}{2} \le \widetilde{n} \le \frac{N_m-1}{2}.$$

We define the self-adjoint operator D_m by

$$D_m e_{m,n} = \frac{N_m}{\sqrt{\pi}} \sin\!\left(\frac{\pi\widetilde{n}}{N_m}\right) e_{m,n}. \tag{44.14}$$

Then

$$D_m^2 = \frac{N_m^2}{4\pi}\,\Delta_m. \tag{44.15}$$

Let P_0 be the orthogonal projection onto the constant character. For every bounded even function F on the spectrum of D_m, we introduce the positive trace

$$\mathrm{Tr}_m^{+}\big(F(D_m)\big) := \frac{1}{2}\,\mathrm{Tr}\big(F(D_m)P_0^{\perp}\big)\,. \tag{44.16}$$

The factor $1/2$ selects one contribution from each spectral pair $\{n,-n\}$; removing P_0 excludes the zero eigenvalue.

Theorem 44.19 (Theta limit of the heat traces)**.** *For every $x>0$,*

$$\lim_{m\to\infty} \mathrm{Tr}_m^{+}\!\left(e^{-xD_m^2}\right) = \Theta_+(x) := \sum_{n\ge 1} e^{-\pi n^2 x}.$$

Proof. The bilateral trace, once the constant mode is removed, is

$$\sum_{\substack{n\in C_m\\ n\neq 0}} \exp\!\left[-\frac{N_m^2 x}{\pi}\sin^2\!\left(\frac{\pi\widetilde{n}}{N_m}\right)\right].$$

For each fixed integer n, the summand converges to $e^{-\pi n^2 x}$. Moreover, for $|\widetilde{n}| \le N_m/2$, the inequality $\sin y \ge 2y/\pi$, valid on $0 \le y \le \pi/2$, provides a summable Gaussian majorant independent of m. Dominated convergence applied to the discrete sum implies

$$\lim_{m\to\infty} \mathrm{Tr}\!\left(e^{-xD_m^2}P_0^{\perp}\right) = \sum_{n\in\mathbb{Z}\setminus\{0\}} e^{-\pi n^2 x}.$$

The division by two established in (44.16) preserves one contribution from each pair $\{n,-n\}$ and gives $\Theta_+(x)$. □

44.6.6 Theta–Mellin transform

For $\Re s > 1$, define

$$\mathcal{Z}_3(s) := \frac{\displaystyle\int_0^{\infty} \Theta_+(x)\,x^{s/2-1}\,\mathrm{d}x}{\pi^{-s/2}\Gamma(s/2)}. \tag{44.17}$$

Absolute convergence allows term-by-term integration. Since

$$\int_0^{\infty} e^{-\pi n^2 x} x^{s/2-1}\,\mathrm{d}x = \Gamma(s/2)(\pi n^2)^{-s/2},$$

we obtain

$$\mathcal{Z}_3(s) = \sum_{n\geq 1} n^{-s} = \zeta(s), \qquad \Re s > 1. \tag{44.18}$$

The equality extends meromorphically through continuation of the Riemann zeta function [4]. Henceforth, all evaluations come from (44.17), its derivatives or the residual decomposition of its Dirichlet series.

Theorem 44.20 (Theta inversion and functional equation)**.** *With the preceding operator notation,*

$$\Theta_B(x) := \operatorname{Tr}(e^{-\pi x B^2}) = 1 + 2\Theta_+(x), \qquad Z(s) := \operatorname{Tr}(Q^{-s}) = \mathcal{Z}_3(s) \quad (\Re s > 1).$$

Poisson summation and the Mellin transform produce

$$\Theta_B(x) = x^{-1/2}\Theta_B(1/x)$$

and the continuation of

$$\xi(s) = \frac{1}{2}s(s-1)\pi^{-s/2}\Gamma(s/2)Z(s), \qquad \xi(s) = \xi(1-s).$$

Proof. The equality $\Theta_B = 1 + 2\Theta_+$ separates the zero mode and pairs $\pm n$; the identity $Z = \mathcal{Z}_3$ is (44.18). Poisson summation applied to the Gaussian gives the inversion of Θ_B. In the half-plane of convergence, term-by-term integration provides

$$\pi^{-s/2}\Gamma(s/2)Z(s) = \int_0^\infty x^{s/2-1}\Theta_+(x)\,\mathrm{d}x.$$

Splitting the integral into $(0,1)$ and $(1,\infty)$, applying theta inversion to the first part and separating the two classical poles yields the continuation and the functional equation. This single incorporated classical proof does not locate the zeros of ζ. □

44.6.7 Residual decomposition modulo three

For $r \in \{0,1,2\}$, let

$$Z_r(s) = \sum_{\substack{n\geq 1\\ n\equiv r \pmod 3}} n^{-s}. \tag{44.19}$$

In terms of the Hurwitz zeta function,

$$Z_0(s) = 3^{-s}\zeta(s), \qquad Z_1(s) = 3^{-s}\zeta\Big(s, \frac{1}{3}\Big), \qquad Z_2(s) = 3^{-s}\zeta\Big(s, \frac{2}{3}\Big).$$

The three terms have residue $1/3$ at $s = 1$. We write their Laurent expansions in the form

$$Z_r(1+z) - \frac{1}{3z} = \sum_{n\geq 0} c_{r,n}\, z^n, \qquad \zeta(1+z) - \frac{1}{z} = \sum_{n\geq 0} a_n\, z^n. \tag{44.20}$$

Theorem 44.21 (Decomposition of the Laurent coefficients)**.** *For every $n \geq 0$,*

$$a_n = c_{0,n} + c_{1,n} + c_{2,n}, \qquad \gamma_n = (-1)^n n!\, a_n.$$

If χ_{-3} denotes the nonprincipal real character modulo three, then

$$\frac{L^{(n)}(1,\chi_{-3})}{n!} = c_{1,n} - c_{2,n}.$$

Furthermore, with $\lambda = \log 3$*,*

$$c_{0,n} = \frac{1}{3}\left[\frac{(-\lambda)^{n+1}}{(n+1)!} + \sum_{k=0}^{n} a_k \frac{(-\lambda)^{n-k}}{(n-k)!}\right].$$

These three identities uniquely determine $(c_{0,n}, c_{1,n}, c_{2,n})$ *from* $(a_n, L^{(n)}(1, \chi_{-3}))$ *and the aggregated coefficients of lower order.*

Proof. The partition of the positive integers into residue classes provides $\zeta = Z_0 + Z_1 + Z_2$. Subtracting the poles at $s = 1$ and comparing the coefficients of (44.20) yields the first identity. The second coincides with the usual convention for the Stieltjes constants. Moreover, $Z_1 - Z_2 = L(s, \chi_{-3})$; the poles of Z_1 and Z_2 cancel and comparison of coefficients gives the third relation. Finally,

$$Z_0(1+z) = \frac{1}{3} e^{-\lambda z} \zeta(1+z).$$

The product of the two Laurent series provides the explicit formula for $c_{0,n}$. The sum and difference then recover $c_{1,n}$ and $c_{2,n}$, proving the asserted uniqueness. □

The sum of the three terms recovers the aggregated sector; the difference of the classes 1 and 2 preserves the character's orientation; comparison with the class divisible by three records the change of scale. These three combinations are linearly independent and determine the three coefficients $c_{r,n}$.

44.6.8 Euler–Mascheroni and Stieltjes constants

Let

$$C_r := \operatorname*{FP}_{s=1} Z_r(s).$$

The classical identities for the digamma function give [4, 77]

$$C_0 = \frac{\gamma - \log 3}{3}, \tag{44.21}$$

$$C_1 = \frac{\gamma}{3} + \frac{\log 3}{6} + \frac{\pi}{6\sqrt{3}}, \qquad C_2 = \frac{\gamma}{3} + \frac{\log 3}{6} - \frac{\pi}{6\sqrt{3}}. \tag{44.22}$$

Corollary 44.22. *The finite parts satisfy*

$$\boxed{\gamma = C_0 + C_1 + C_2},$$

$$\boxed{L(1, \chi_{-3}) = C_1 - C_2 = \frac{\pi}{3\sqrt{3}}},$$

$$\boxed{\log 3 = C_1 + C_2 - 2C_0}.$$

Proof. At order zero, the theorem 44.21 gives $a_0 = c_{0,0} + c_{1,0} + c_{2,0}$. By definition, $a_0 = \gamma$ and $c_{r,0} = C_r$, proving the first equality. The difference of the two oriented classes is $C_1 - C_2 = L(1, \chi_{-3})$. Substituting (44.21)–(44.22) yields the other two identities. □

A single extraction of coefficients by Cauchy's integral formula applied to (44.20) simultaneously determines $\gamma_0, \ldots, \gamma_6$. The discretizations with 96 and 192 nodes agree up to order 10^{-87}; the identity of the coefficients, however, follows from the theorem 44.21 and not from that numerical comparison.

44.6.9 Evaluation of Apéry's constant

Proposition 44.23. *The functional* (44.17) *satisfies*

$$\boxed{\mathcal{Z}_3(3) = \zeta(3) = 1.20205690315959428539973816151144 9\ldots}.$$

Proof. The exact equality is the specialization $s = 3$ of (44.18). To certify any decimal prefix without modifying the functional, consider $S_N = \sum_{n=1}^{N} n^{-3}$. The integral test gives

$$S_N + \frac{1}{2(N+1)^2} < \zeta(3) < S_N + \frac{1}{2N^2}.$$

The resulting nested rational intervals determine the printed digits. □

The irrationality of $\zeta(3)$ is Apéry's classical theorem [3]; it does not follow merely from evaluation of the functional.

44.6.10 Glaisher–Kinkelin constant

The spectral derivative at $s = -1$ defines

$$\boxed{A_{\mathrm{GK}} = \exp\left(\frac{1}{12} - \mathcal{Z}_3'(-1)\right)}. \tag{44.23}$$

This is the formula for the regularized determinant associated with the hyperfactorial product [126]. A five-point central differentiation, evaluated at two scales, provides

$$A_{\mathrm{GK}} = 1.28242712910062263687534256886979 17\ldots.$$

The term $1/12$ belongs to the regularization of the hyperfactorial and is not introduced as a fitting parameter.

44.6.11 Euler–Kronecker constant of the Eisenstein field

The character χ_{-3} determines the imaginary quadratic field

$$F_{-3} = \mathbb{Q}(\sqrt{-3}), \qquad \zeta_{F_{-3}}(s) = \zeta(s)L(s, \chi_{-3}).$$

Its Euler–Kronecker constant is

$$\boxed{\gamma_{F_{-3}} = \gamma + \frac{L'(1, \chi_{-3})}{L(1, \chi_{-3})}}. \tag{44.24}$$

The residual coefficients of (44.20) give

$$L(1, \chi_{-3}) = 0.60459978807807261686469275254738 52\ldots,$$
$$L'(1, \chi_{-3}) = 0.22266298696860150948666026276474 43\ldots,$$

and, by (44.24),

$$\gamma_{F_{-3}} = 0.94549728087168070323974999415818 90\ldots.$$

The choice of F_{-3} comes from the residue character modulo three, not from a search over the decimal values of constants of quadratic fields.

44.6.12 Local product associated with twin primes

For a finite pattern $H = \{h_1, \dots, h_k\} \subset \mathbb{Z}$, we define

$$\nu_p(H) := |\{-h_1, \dots, -h_k\} \bmod p|, \qquad \sigma_p(H) = \frac{1 - \nu_p(H)/p}{(1 - 1/p)^k}.$$

For $H = \{0, 2\}$, the local factors lead to

$$C_2^{\text{twin}} = \prod_{p>2} \frac{p(p-2)}{(p-1)^2}. \tag{44.25}$$

Let P_X be the product restricted to primes $2 < p \le X$. For $p > X$, all factors belong to $(0, 1)$; extending the tail product from primes to all integers gives the telescoping bound

$$\prod_{n>X} \left(1 - \frac{1}{(n-1)^2}\right) = \frac{X-1}{X} \le \prod_{p>X} \left(1 - \frac{1}{(p-1)^2}\right) < 1.$$

The product $P_{2\times 10^6}$, evaluated with directed decimal rounding, and this rational inequality for the tail give

$$0.660161507122424482640393355 1 < C_2^{\text{twin}} < 0.660161837203508124853756659 1. \tag{44.26}$$

The direct count up to 10^6 contains 8169 pairs of twin primes. The convergence of the local product and this finite census do not imply the existence of infinitely many pairs; the latter is a distinct arithmetic proposition.

44.6.13 Meissel–Mertens constant and prime Hamiltonian

The Meissel–Mertens constant is defined by

$$B_1 = \lim_{x\to\infty} \left(\sum_{p \le x} \frac{1}{p} - \log\log x \right) \tag{44.27}$$

and satisfies

$$B_1 = \gamma + \sum_p \left(\log\left(1 - \frac{1}{p}\right) + \frac{1}{p} \right). \tag{44.28}$$

With the notation of theorem 44.7, we set

$$\mathcal{F}_P := \Gamma_s(\mathfrak{h}_{\mathbb{P}}), \qquad H_P := d\Gamma(H_{\mathbb{P}}).$$

Neither the bosonic Fock space of prime modes nor its Hamiltonian is redefined here. The operator already constructed has partition function

$$\operatorname{Tr}_{\mathcal{F}_P}(e^{-sH_P}) = \prod_p \frac{1}{1 - p^{-s}} = \zeta(s), \qquad \Re s > 1. \tag{44.29}$$

Let $\mathcal{H}_P^{(1)}$ be the one-particle subspace, generated by $\{|p\rangle : p \text{ prime}\}$. Then

$$\operatorname{Tr}_{\mathcal{H}_P^{(1)}} \left(e^{-H_P} \mathbf{1}_{(-\infty, \log x]}(H_P) \right) = \sum_{p \le x} \frac{1}{p}.$$

Thus, B_1 is the finite part, as $x \to \infty$, of this truncated spectral trace after subtracting $\log\log x$. The equality (44.29) presupposes the Fock decomposition over the primes; it therefore constitutes an operator representation of the Euler product, not a deduction of primality from the triadic Laplacian.

44.6.14 Dependence on the operator

The preceding evaluations share the operator (44.14), the positive trace (44.16) and the transform (44.17). Other constants require distinct dynamics. Catalan's constant is associated with the character modulo four χ_{-4}, whereas Khinchin's constant belongs to the Gauss operator and its invariant measure. A prefix of any of them may appear in a finite catalogue without the triadic functional selecting it. This operator dependence distinguishes spectral evaluation from the purely combinatorial capacity for encoding.

44.7 Finite parts, regularization and residual readouts

The functional constructed from integer modes admits operations preserving different aspects of its structure. Evaluating it at a point of convergence, extracting the regular term accompanying a pole and differentiating its meromorphic continuation are three precise operations. This distinction organizes the constants of this chapter and their relationship with those in the moments chapter.

The arithmetic antecedent is the publication of the normal forms obtained with the two APP sheets. Their evaluation identifies each positive integer once; the numbering operator acts on the corresponding basis by

$$Qe_n = ne_n, \qquad \operatorname{Dom} Q = \left\{ u : \sum_{n\geq 1} n^2 |u_n|^2 < \infty \right\}.$$

The subsequent spectral readout is

$$Z(s) = \operatorname{Tr}(Q^{-s}) = \sum_{n\geq 1} n^{-s}, \qquad \Re s > 1.$$

The chapter on the completed form proves its coincidence with the theta–Mellin functional and its continuation. Here, an evaluation procedure with controlled remainders is brought together. The memory of the history remains in the source state; the trace is a reading of the published modes, not a reconstruction of that entire history from a scalar constant.

44.7.1 A continuation formula with explicit remainder

Define the Bernoulli numbers through the formal identity

$$\frac{t}{e^t - 1} = \sum_{j\geq 0} B_j \frac{t^j}{j!}.$$

Their coefficients are computed without a numerical table:

$$B_0 = 1, \qquad B_m = -\frac{1}{m+1} \sum_{j=0}^{m-1} \binom{m+1}{j} B_j.$$

In particular, $B_1 = -1/2$. Write $(s)_r = s(s+1)\cdots(s+r-1)$, with $(s)_0 = 1$, and denote the corresponding polynomial by $B_m(x) = \sum_{j=0}^{m} \binom{m}{j} B_j x^{m-j}$. Its periodization is $\widetilde{B}_{2p}(x) = B_{2p}(\{x\})$. For $N, p \geq 1$, Euler–Maclaurin summation gives

$$Z(s) = \sum_{n=1}^{N} n^{-s} + \frac{N^{1-s}}{s-1} - \frac{1}{2N^s} + \sum_{k=1}^{p} \frac{B_{2k}}{(2k)!}(s)_{2k-1} N^{1-s-2k} + R_{N,p}(s),$$

with

$$R_{N,p}(s) = -\frac{(s)_{2p}}{(2p)!} \int_N^\infty \widetilde{B}_{2p}(x) x^{-s-2p}\, dx.$$

Proposition 44.24. Domain and bound of the remainder

The remainder integral is holomorphic on $\Re s > 1 - 2p$. If $\sigma = \Re s > 1 - 2p$, then

$$|R_{N,p}(s)| \le \frac{|B_{2p}|\,|(s)_{2p}|}{(2p)!} \frac{N^{1-\sigma-2p}}{\sigma + 2p - 1}.$$

The preceding formula continues Z to that half-plane, with its simple pole at $s = 1$, and is compatible with the theta–Mellin continuation.

Proof. The summation formula is obtained by successive integration by parts on each unit interval, using $B_j'(x) = jB_{j-1}(x)$ and the endpoint equalities for polynomials of degree other than one. Applying it to x^{-s} on $[N, M]$, the derivatives supply the factors $(s)_r$. On $\Re s > 1$, passage to $M \to \infty$ removes the upper endpoint terms and produces exactly the identity and remainder sign written above.

To control the remainder, use

$$|B_{2p}(t)| \le |B_{2p}|, \qquad 0 \le t \le 1.$$

One proof of this inequality is the absolutely convergent Fourier series

$$B_{2p}(t) = (-1)^{p+1} \frac{2(2p)!}{(2\pi)^{2p}} \sum_{m \ge 1} \frac{\cos(2\pi m t)}{m^{2p}}.$$

The maximum of the absolute-value bound is attained at $t = 0$. This identity follows from the Fourier coefficients by integration by parts of the polynomials themselves; the factor π merely expresses the Fourier convention of this proof and does not enter numerically into the rational evaluator used later. Comparison with $x^{-\sigma-2p}$ proves the remainder bound. On compact subsets of the half-plane, it also dominates derivatives in s, which add powers of $\log x$; the integral is therefore holomorphic there. The identity on the convergence half-plane and uniqueness of continuation prove the stated compatibility. □

Order p and horizon N are computation and error-control parameters. They do not select a different constant: expressions with different N, p represent the same functional on their common domains. Nor must an asymptotic series converge as p increases indefinitely with N fixed. Each finite pair comes with its own proved bound.

44.7.2 Euler–Mascheroni as the finite part of the same functional

The finite part at the pole is defined by

$$\gamma_0 = \lim_{s \to 1} \left(Z(s) - \frac{1}{s-1} \right).$$

Setting $s = 1 + z$, the singular term satisfies

$$\frac{N^{-z}}{z} = \frac{1}{z} - \log N + O(z).$$

The preceding proposition allows the finite part to be taken term by term.

Theorem 44.25. Explicit interval for the finite part

Let

$$G_{N,p} = H_N - \log N - \frac{1}{2N} + \sum_{k=1}^{p} \frac{B_{2k}}{2kN^{2k}}, \qquad H_N = \sum_{n=1}^{N} \frac{1}{n}.$$

Then

$$|\gamma_0 - G_{N,p}| \le \frac{|B_{2p}|}{2pN^{2p}}.$$

Moreover,

$$\gamma_0 = \lim_{N\to\infty} (H_N - \log N).$$

Proof. At $s = 1$, one has $(1)_{2k-1} = (2k-1)!$; hence each Bernoulli term becomes $B_{2k}/(2kN^{2k})$. The bound in Proposition 44.24, evaluated at that point, is $|B_{2p}|/(2pN^{2p})$. With $p = 1$, all terms separating $G_{N,1}$ from $H_N - \log N$, and the remainder as well, tend to zero. This proves the limit. This is the subsequent identification with the Euler–Mascheroni constant. □

The antecedent of γ_0 used in the Meissel–Mertens formula is thus incorporated. The number is not received as an independent numerical value to correct the sum over irreducibles: it is a specified operation on the same integer partition function.

The logarithm used in the calculation also admits a rational interval. For $x \ge 1$, let $z = (x-1)/(x+1)$. The integrated series of a geometric progression gives

$$\log x = 2 \sum_{j=0}^{M-1} \frac{z^{2j+1}}{2j+1} + r_M(x), \quad 0 \le r_M(x) \le \frac{2z^{2M+1}}{(2M+1)(1-z^2)}.$$

The inequality follows by replacing the tail denominators with $2M+1$ and summing the geometric progression. First reduce $x = 2^a y$, with $1 \le y < 2$, and evaluate $a \log 2 + \log y$. The series argument is then at most $1/3$. For $0 < x < 1$, use $\log x = -\log(1/x)$, reversing the interval endpoints.

44.7.3 Apéry and the regularized negative evaluation

For an integer $r \ge 2$, specialization of Proposition 44.24 produces a rational centre

$$Z_{N,p}^{[r]} = \sum_{n=1}^{N} \frac{1}{n^r} + \frac{1}{(r-1)N^{r-1}} - \frac{1}{2N^r} + \sum_{k=1}^{p} \frac{B_{2k}(r)_{2k-1}}{(2k)!N^{r+2k-1}}$$

and the entirely rational bound

$$\left| Z(r) - Z_{N,p}^{[r]} \right| \le \frac{|B_{2p}|(r)_{2p-1}}{(2p)!N^{r+2p-1}}.$$

The simplification uses $(r)_{2p}/(r+2p-1) = (r)_{2p-1}$. At $r = 3$, one obtains Apéry's constant. The procedure determines its value with bounds; irrationality of that constant is a mathematical statement distinct from this evaluation.

On the negative side, the same continuation admits an exact evaluation, without a decimal approximation or fitting parameter.

Theorem 44.26. Regularized evaluation at minus one

The continuation of the integer-mode functional satisfies

$$Z(-1) = -\frac{1}{12}.$$

Proof. In the formula of Proposition 44.24, take $p = 2$, so that $s = -1$ lies in the interior of the validity half-plane. The factor $(s)_4$ vanishes there; its accompanying integral is holomorphic there, so the remainder is zero. The factor $(s)_3$, multiplying the term with B_4, also vanishes. Only the following remains:

$$Z(-1) = \sum_{n=1}^{N} n - \frac{N^2}{2} - \frac{N}{2} - \frac{B_2}{2}.$$

Since additive accumulation gives $\sum_{n=1}^{N} n = N(N+1)/2$, and the Bernoulli recurrence gives $B_2 = 1/6$, the result is $-1/12$, independently of N. □

The evaluated object is the continuation of the functional, not the ordinary limit of the positive partial sums, which grow without bound. This distinction preserves the operation giving rise to the value: the Bernoulli term remains after cancellation of the polynomial boundary terms. Regularization therefore has a structure and genealogy here, in addition to a value.

44.7.4 Laurent coefficients and preservation of the three classes

Write

$$Z(1+z) - \frac{1}{z} = \sum_{n\geq 0} a_n z^n, \qquad \gamma_n = (-1)^n n! a_n.$$

The regular function on the left is holomorphic around zero. For a circle contained in its domain of holomorphy, Cauchy's formula determines

$$a_n = \frac{1}{2\pi i} \int_{|z|=\rho} \frac{Z(1+z) - 1/z}{z^{n+1}}\, dz.$$

The continuation formula with remainder controls this extraction: a uniform error bound ε on the circle produces a bound $\varepsilon\rho^{-n}$ for the coefficient. This justifies a procedure at arbitrary order; it does not turn agreement of two finite quadratures into an error bound.

The residual readout maintains the three classes of the integer operator:

$$Q_r e_n = \mathbf{1}_{n\equiv r\ (3)} e_n, \qquad Z_r(s) = \mathrm{Tr}(Q^{-s} Q_r), \quad r = 0, 1, 2.$$

These projections have a common domain in the convergence half-plane. Their sum is the identity; the difference of classes 1 and 2 preserves the orientation of the character modulo three. One has

$$Z = Z_0 + Z_1 + Z_2, \qquad Z_0(s) = 3^{-s} Z(s), \qquad L_{-3}(s) = Z_1(s) - Z_2(s).$$

The last series has periodic coefficients $(1, -1, 0)$ and zero mean. Grouping by periods allows continuation near $s = 1$. Each Z_r has residue $1/3$ there.

Let

$$Z_r(1+z) - \frac{1}{3z} = \sum_{n\geq 0} c_{r,n} z^n, \qquad \lambda = \log 3.$$

Coefficient comparison gives

$$a_n = c_{0,n} + c_{1,n} + c_{2,n}, \qquad \frac{L_{-3}^{(n)}(1)}{n!} = c_{1,n} - c_{2,n},$$
$$c_{0,n} = \frac{1}{3}\left[\frac{(-\lambda)^{n+1}}{(n+1)!} + \sum_{k=0}^{n} a_k \frac{(-\lambda)^{n-k}}{(n-k)!}\right].$$

The third identity comes from multiplying the complete series, including its pole, by $3^{-1}e^{-\lambda z}$. Sum and difference uniquely recover the other two coefficients. The three readouts preserve aggregation, orientation and change of scale, respectively.

At order zero, evaluation can be completed without receiving a decimal value of $L_{-3}(1)$. Indeed,

$$L_{-3}(1) = \sum_{m\geq 0}\left(\frac{1}{3m+1} - \frac{1}{3m+2}\right) = \int_0^1 \frac{1-x}{1-x^3}\,dx = \int_0^1 \frac{dx}{1+x+x^2}.$$

Complete the square in the denominator and evaluate the antiderivative:

$$L_{-3}(1) = \frac{2}{\sqrt{3}}\left[\arctan\frac{2x+1}{\sqrt{3}}\right]_0^1 = \frac{\pi}{3\sqrt{3}}.$$

The coordinate π is the prior regional publication of HMT; this identity is a subsequent analytic evaluation of a class reader, not a procedure for retroactively selecting that coordinate. Thus, with $C_r = c_{r,0}$,

$$C_0 = \frac{\gamma_0 - \log 3}{3}, \qquad C_{1,2} = \frac{\gamma_0}{3} + \frac{\log 3}{6} \pm \frac{\pi}{6\sqrt{3}}.$$

The following identities are recovered:

$$C_0 + C_1 + C_2 = \gamma_0, \qquad C_1 - C_2 = L_{-3}(1), \qquad C_1 + C_2 - 2C_0 = \log 3.$$

44.7.5 Exact evaluation and scope of the certification

The program `partes_finitas_exactas.py` preserves the following order: succession of words through the additive sheet; evaluation of the integer modes; rational Bernoulli construction; application of the functional formula; incorporation of the remainder; directed decimal publication. Native multiplication remains available in the same package and its compatibility is proved in the chapter on the product. The analytic calculation on the published modes does not modify their rules.

With $N = 81$, $p = 8$ and 120 terms for each logarithm series, the resulting intervals are

$$0.57721566490153286060651209008227320404153 5 < \gamma_0 < 0.57721566490153286060651209008253138727927 84,$$

$$1.20205690315959428539973816151144731135582 9 < Z(3) < 1.20205690315959428539973816151145266311934 2.$$

The decimal endpoints are outward roundings of exact fractions. The program also preserves each interval's rational width and recovers $-1/12$ exactly. No comparison digit appears in the producer. The separate checker opens reference values after obtaining the outputs; this comparison checks execution and does not replace the proved bounds.

Within its domain, this chapter completes the finite parts and evaluations it has just defined. It uses no assumption about the location of zeros or positivity of the Weil form. Prolongation towards the spectral problem preserves the obligations of its own operators: a regularized evaluation does not by itself provide the boundary identity of another functional.

Provenance: development recovered from the triadic functionals and coordinated readout network. Bringing together the Euler–Maclaurin proof, its rational bounds and its program constitutes a formalization and additional certificate of this edition; no new historical priority is claimed for those analytic identities.

Chapter 45

Unimodal criticality of the dodecaphasic family: exact analytic profile, Feigenbaum approximants and hyperbolic renormalization certificate

45.1 Intrinsic construction of the dodecaphasic family

The Feigenbaum constants characterize the universality of period doubling. Their derivation in HMT first requires constructing an analytic unimodal family, proving its quadratic criticality, and then studying the action of the renormalization operator.

The initial map does not follow from an external harmonic choice. The return of TPK determines the oriented dodecaphase wheel U_{12}^{sign}. In the uniform sector $\eta = 0$, the normalized trace of its twelve sectors fixes $w_m = 1/12$, and the phase functional

$$\mathcal{P}_{\mathrm{crit}} : U_{12}^{\mathrm{sign}} \longrightarrow \mathbb{R}/2\pi\mathbb{Z}, \qquad m \longmapsto \frac{(30m-10)\pi}{180} = \pi\frac{3m-1}{18} \tag{45.1}$$

preserves order and orientation. The causal composition is

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to U_{12}^{\mathrm{sign}} \xrightarrow{\mathcal{P}_{\mathrm{crit}}} \{(\phi_m, w_m)\}_{m=1}^{12} \to u_0 \to f_\lambda.$$

Every modification of $\mathcal{P}_{\mathrm{crit}}$, of the weights, or of the order of the phases alters the family and constitutes a criterion of refutation. These choices must be fixed before the contrast with δ_F.

The resulting dodecaphasic family starts from

$$a_m = \frac{3m-1}{18}, \qquad \phi_m = \pi a_m, \qquad m = 1, \dots, 12,$$

and of the second moment

$$D_0 = \frac{1}{12}\sum_{m=1}^{12} a_m^2.$$

The identity

$$\sum_{m=1}^{12}(3m-1)^2 = 5394 = 6 \cdot 899 \tag{45.2}$$

yields

$$D_0 = \frac{899}{648}, \qquad s_0 = \frac{36}{\pi\sqrt{899}}.$$

Therefore,

$$s_0\phi_m = \frac{2(3m-1)}{\sqrt{899}}. \tag{45.3}$$

The factor π cancels before the iterations are performed. The family does not depend on δ_F or α_F as input data.

Cancellation is a structural property of normalization. Before normalization, the second angular moment is

$$\frac{1}{12}\sum_{m=1}^{12}\phi_m^2 = \pi^2 D_0.$$

The condition of quadratic criticality fixes $s_0^2\pi^2 D_0 = 2$, and therefore each normalized phase depends only on the integer arithmetic of $3m-1$. The functional preserves the angular provenance of the wheel, but the iteration receives an intrinsic real family. This is precisely what makes it possible to distinguish a derivation from a calibration by π.

45.2 Exact analytic representation and closed trigonometric expression

We define

$$u_0(x) = 1 - \frac{1}{12}\sum_{m=1}^{12}\cos\left(\frac{2(3m-1)}{\sqrt{899}}x\right). \tag{45.4}$$

The development at the origin is

$$u_0(x) = x^2 - \frac{715769}{2424603}x^4 + O(x^6). \tag{45.5}$$

The finite sum admits the following closed expression. If $y = x/\sqrt{899}$,

$$u_0(x) = 1 - \frac{\cos(37y)\sin(36y)}{12\sin(3y)} = 1 - \frac{\sin(73y) - \sin y}{24\sin(3y)}. \tag{45.6}$$

The apparent singularity at $y = 0$ is removable and reproduces equation (45.5).

Derivation of the closed form. The twelve arguments form an arithmetic progression:

$$2(3m-1)y = (6m-2)y, \qquad m = 1, \dots, 12.$$

The sum of cosenos of a progresion satisfies

$$\sum_{m=1}^{N}\cos(a+md) = \frac{\sin(Nd/2)}{\sin(d/2)}\cos\left(a + \frac{N+1}{2}d\right).$$

Taking $N = 12$, $d = 6y$ and $a = -2y$ yields

$$\sum_{m=1}^{12}\cos((6m-2)y) = \frac{\sin 36y}{\sin 3y}\cos 37y.$$

The product–to–sum identity $2\cos 37y \sin 36y = \sin 73y - \sin y$ gives the second expression for equation (45.6). □

The quartic coefficient is not fitted either. The integer sums

$$\sum_{m=1}^{12}(3m-1)^2 = 5394, \qquad \sum_{m=1}^{12}(3m-1)^4 = 4294614 \tag{45.7}$$

inserted in the development of $\cos z$ produce exactly

$$\frac{1}{24\cdot 12}\sum_{m}\left(\frac{2(3m-1)}{\sqrt{899}}\right)^4 = \frac{715769}{2424603}.$$

Thus, both the quadratic normalization and the first nonlinear correction are finite moments of the same wheel.

45.3 Pertenencia to the clase analitica unimodal cuadratica

Consider we

$$f_\lambda(x) = 1 - \lambda u_0(x), \qquad \lambda > 0.$$

For $0 < x \le 1$, all arguments

$$\frac{2(3m-1)}{\sqrt{899}}x$$

belong to $(0, \pi)$. By therefore,

$$u_0'(x) > 0, \qquad u_0'''(x) < 0.$$

Since u_0 is even, $x = 0$ is its unique critical point and $u_0''(0) = 2$. The Schwarzian of f_λ is

$$S(f_\lambda) = \frac{u_0'''}{u_0'} - \frac{3}{2}\left(\frac{u_0''}{u_0'}\right)^2 < 0 \qquad (0 < |x| \le 1). \tag{45.8}$$

Theorem 45.1 (Exact membership in the unimodal class)**.** *For*

$$0 < \lambda \le \frac{2}{u_0(1)},$$

the family $f_\lambda = 1 - \lambda u_0$ is a self-map that is real–analytic on $[-1, 1]$ and even, with a single critical point of quadratic type at the origin and negative Schwarzian away from that point. Consequently, without using Feigenbaum values as a target value, it belongs to the S-unimodal quadratic class subject to the action of the period-doubling renormalizer [46, 79]. For λ outside that interval, the analytic germ and its local form are retained, but one does not automatically assert a self-map of the interval.

The theorem establishes the contribution intrinsic to HMT prior to the universality theorem: the analytic germ and its type of criticality.

Detalles of the signo and of the self-map. Deriving equation (45.4),

$$u_0'(x) = \frac{1}{12}\sum_m k_m \sin(k_m x),$$
$$u_0'''(x) = -\frac{1}{12}\sum_m k_m^3 \sin(k_m x), \qquad k_m = \frac{2(3m-1)}{\sqrt{899}}.$$

For $0 < x \le 1$, $0 < k_m x < \pi$, so all summands in the first line are positive and those in the second are negative. Parity extends monotonicity to both sides of the origin. Since $u_0(0) = 0$ and $0 \le u_0(x) \le u_0(1)$, the bound $0 < \lambda \le 2/u_0(1)$ implies $-1 \le 1 - \lambda u_0(x) \le 1$. Finally, $u_0''(0) = 1/12 \sum k_m^2 = 2$, so the critical point is quadratic. □

45.4 Sequences finite of parameters superstable

The sucesion superestable certified until level eight produces

$$\delta_8 = 4.66921218915\ldots, \qquad \alpha_8 = 2.50296847988\ldots.$$

Its status is *finite certificate free of target values*: each approximant is obtained from the previously defined family, without introducing the universal limit as a datum. Decimal agreement provides a convergence indicator but does not replace the hyperbolicity theorem.

An independent numerical extension of the same sequence, with a step size adapted to the separation between roots and control of the exact period, provisionally reaches:

Level	λ_n	δ_n	α_n
11	1.87403828195439908045	4.66920170694424982745	2.50290847517165181764
12	1.87403836411023460451	4.66920163036308158848	2.50290800379001546915
13	1.87403838170549870372	4.66920161361839219913	2.50290790268748193108
14	1.87403838547386545431	4.66920161007472591023	2.50290788100969754274

These levels have the status of *New numerical certificate pending reproducible registration*; they do not supersede the persistent certificate through level eight. An Aitken extrapolation yields $\lambda_\infty^{\mathrm{HMT}} \simeq 1.8740383865008918080$ and $\alpha_F \simeq 2.50290787509$ as candidate limits, conditional on a proof of hyperbolicity and transversality.

To avoid an unspecified numerical procedure, the method is formulated as follows. Define

$$F_n(\lambda) = f_\lambda^{2^n}(0). \tag{45.9}$$

The raiz superestable λ_n is the primera raiz of F_n to the right of λ_{n-1} that satisfies simultaneously

$$f_{\lambda_n}^{2^j}(0) \neq 0 \quad (0 \le j < n).$$

This inequality excludes divisor periods. With disjoint intervals $I_n \ni \lambda_n$, one computes

$$\delta_n = \frac{\lambda_{n-1} - \lambda_{n-2}}{\lambda_n - \lambda_{n-1}}, \qquad \alpha_n = -\frac{d_{n-1}}{d_n}, \tag{45.10}$$

where $d_n = f_{\lambda_n}^{2^{n-1}}(0)$ is the oriented distance from the last new point to the critical point. A persistent certificate must retain the root intervals, the exclusion of smaller periods, and the propagation of error from equation (45.10); a mere printed decimal does not satisfy those three conditions.

The discretization rule also constitutes a negative control. A fixed lower bound greater than the separation $|\lambda_n - \lambda_{n-1}|$ can omit the first root and nevertheless produce a numerically plausible succession. For this reason the increment must scale with the previous separation and each candidate must be verified through its exact period.

45.5 Conditions for certifying the renormalization operator

On a space of even analytic functions analytic, we define

$$\mathcal{R}(f)(x) = -a(f)^{-1} f\big(f(-a(f)x)\big), \qquad a(f) = -f(1). \tag{45.11}$$

The complete closure of δ_F and α_F requires jointly certifying:

1. existence of a fixed point $g = \mathcal{R}(g)$ in a declared analytic ball;
2. uniqueness local of ese point fixed;

3. a single unstable real eigenvalue of $D\mathcal{R}_g$, equal to δ_F;
4. spectral radius strictly less than one on the stable complement;
5. transversality of the curve $\lambda \mapsto f_\lambda$ with respect to the stable manifold of g.

A natural HMT implementation employs Chebyshev truncations of order 9^m, interval arithmetic, and radii polynomials. The proof must provide a ball, an approximate inverse, a defect bound, and a Lipschitz bound satisfying $Y + Z(r) < r$. Thus, the nonadic depth parameterizes a fixed-point certificate and not a mere sequence of decimal approximations.

On a Chebyshev even basis,

$$g(x) = \sum_{j=0}^{N} g_{2j} T_{2j}(x), \qquad N = 9^m,$$

the finite residue is $F_N(g) = \Pi_N(\mathcal{R}g - g)$. If A_N approximates $(DF_N(\bar{g}))^{-1}$, the quantities that must be certified are

$$\begin{aligned} Y &= \|A_N F_N(\bar{g})\|, \\ Z_0 &= \|I - A_N DF_N(\bar{g})\|, \\ Z_1(r) &= \sup_{\|h\| \le r} \|A_N (DF_N(\bar{g} + h) - DF_N(\bar{g}))\|. \end{aligned}$$

An inequality $Y + (Z_0 + Z_1(r))r < r$ encloses a unique fixed point. The later spectral block must isolate an unstable direction and contract the complement. The use of 9^m thus enters as a refinement law of the certificate, not as decoration numerological.

Corollary 45.2 (Exact convergence of mode thirty)**.** *Mode* 30 *admits three simultaneous and typologically distinct realizations:*

$$\begin{aligned} &30 \longmapsto (3 \cdot 30, 4 \cdot 30) = (90, 120) && \textit{in the constitutive completion}, \\ &30 \longmapsto 30^2 - 1 = 899 = 29 \cdot 31 && \textit{in the critical normalization}, \\ &30 \longmapsto M_{30} = \begin{pmatrix} 30 & 899 \\ 1 & 30 \end{pmatrix} && \textit{in the hyperbolic Pell transformation}. \end{aligned}$$

The three identities are exact and are obtained without prescribing target values. The conserved invariant is the central integer 30 *together with its orientation: extension* $3 \to 4$*, quadratic defect* -1*, and a unit of norm one. What is not asserted is the equality between the vacuum operator and the duplication renormalizer.*

Remark 45.3 (Negative control)*.* A second eigenvalue outside the unit disk, a ball of radii without solution, loss of uniqueness, or tangency of the HMT family to the stable variety refutes the universal promotion. None refutes the exact germ or the Schwarzian theorem.

Proposition 45.4 (Main Result)**.** *The structural significance of the doubling constant lies in the cancellation in dodecaphase form of* π*, in the identity* $899 = 30^2 - 1$*, in the closed trigonometric form, and in its proved membership in the analytic class on which the renormalizer acts. Its decimal expansion constitutes exclusively the terminal evaluation.*

Logical Scope and Domain of Validity

Profile, Taylor expansion, normalizer, Pell unit, unimodality, and Schwarzian: *Exact internal theorem*. Approximants through level eight: *Persistent finite certificate*. Levels 11–14: *New numerical certificate pending durability*. Hyperbolicity and transversality of the renormalizer: *Open program with executable falsification criterion*.

45.5.1 Weighted harmonic deformation and selection of the superstable branch

The uniform profile has a parametric extension that preserves the twelve phases and separates the harmonic deformation from the dynamic parameter. For $1 \le m \le 12$, let

$$\phi_m = \frac{(30m-10)\pi}{180}, \qquad p(\phi) = 12\cos(3\phi) - \cos(4\phi). \tag{45.12}$$

For every real η such that the weights remain positive, we define

$$w_m(\eta) = \frac{1 + \eta p(\phi_m)}{12}. \tag{45.13}$$

The sums of the third and fourth harmonics over the twelve phases vanish; therefore,

$$\sum_{m=1}^{12} w_m(\eta) = 1.$$

Let

$$s_\eta^2 = \frac{2}{\sum_{m=1}^{12} w_m(\eta)\phi_m^2}, \qquad u_\eta(x) = 1 - \sum_{m=1}^{12} w_m(\eta)\cos(s_\eta \phi_m x). \tag{45.14}$$

The cosine expansion and the definition of s_η give

$$u_\eta(x) = x^2 + O(x^4) \qquad (x \to 0).$$

Consequently, u_η is real–analytic, even, and retains a quadratic critical point at the origin. We introduce the dynamical parameter through

$$f_{\lambda,\eta}(x) = 1 - \lambda u_\eta(x). \tag{45.15}$$

A superstable parameter of exact period 2^n satisfies

$$f_{\lambda,\eta}^{2^n}(0) = 0, \qquad f_{\lambda,\eta}^{2^k}(0) \neq 0 \quad (0 \le k < n).$$

The equation may have several branches. A branch $\mathscr{B}$ is fixed by traversing an adaptive mesh immediately after the parameter of the preceding level; the first interval with a sign change is taken and bisection is applied. The notation $\lambda_n^{\mathscr{B}}(\eta)$ incorporates this selector and does not attribute global uniqueness to the superstable equation. The first level is determined exactly:

$$\lambda_1^{\mathscr{B}}(\eta) = \frac{1}{u_\eta(1)},$$

if $u_\eta(1) > 0$, because $f_{\lambda,\eta}^2(0) = f_{\lambda,\eta}(1) = 0$. Given three consecutive levels and

$$x_n^{\mathscr{B}}(\eta) := f_{\lambda_n^{\mathscr{B}}(\eta),\eta}^{2^{n-1}}(0),$$

we form

$$\delta_n^{\mathscr{B}}(\eta) = \frac{\lambda_{n-1}^{\mathscr{B}}(\eta) - \lambda_{n-2}^{\mathscr{B}}(\eta)}{\lambda_n^{\mathscr{B}}(\eta) - \lambda_{n-1}^{\mathscr{B}}(\eta)}, \qquad \alpha_n^{\mathscr{B}}(\eta) = \frac{|x_{n-1}^{\mathscr{B}}(\eta)|}{|x_n^{\mathscr{B}}(\eta)|}. \tag{45.16}$$

For $\eta = 0$, the uniform profile is recovered exactly. The weighted extension introduces a transverse parameter: it permits study of the transversality of the family with respect to the stable manifold of the renormalizer without converting a finite coincidence into a proof of universality.

Remark 45.5 (Negative control). The extension is refuted if the weights lose positivity on the declared domain, if normalization ceases to produce a unit quadratic coefficient, if the selector does not exclude divisor periods, or if a branch is chosen using the terminal universal values as input.

45.6 Reduction of Feigenbaum universality to the hyperbolic certificate of basin membership and transversality

The HMT Feigenbaum family has analytic profile, quadratic maximum, negative Schwarzian, and certified superstable approximants up to level 8. Its promotion to universality requires the certificate

$$\ell_u(\partial_t f_t) \neq 0$$

together with membership in the hyperbolic basin of the fixed point. Tangency, departure from the basin, or the presence of a second unstable eigenvalue are complete falsifiers.

Chapter 46

Arithmetic of the dodecaphasic modular family of period 30: Rogers–Ramanujan identities, normalizer 899 and nonadic Pell lifting

46.1 Normalizer 899, Pell unit, and arithmetic structure of the mode 30

The normalizer has the factorization arithmetic

$$899 = 30^2 - 1 = 29 \cdot 31. \tag{46.1}$$

The same mode 30 that generates sectors 90 and 120 simultaneously determines the twin-prime pair $29, 31$. Moreover,

$$\varepsilon_{30} = 30 + \sqrt{899}, \qquad \varepsilon_{30}^{-1} = 30 - \sqrt{899}, \qquad \log \varepsilon_{30} = \operatorname{arcosh} 30. \tag{46.2}$$

This Pell unit determines the hyperbolic scale associated with the normalizer and relates the dodecaphase phase, mode 30, twin primes, and hyperbolic geometry. This relation does not identify the constitutive operator of the vacuum with the doubling renormalizer; such an identification would require an explicit intertwiner.

The unit acts integrally through

$$M_{30} = \begin{pmatrix} 30 & 899 \\ 1 & 30 \end{pmatrix}, \qquad \det M_{30} = 1. \tag{46.3}$$

On $\mathbb{Z}[\sqrt{899}]$, this matrix represents multiplication by $30 + \sqrt{899}$. Its eigenvalues are $\varepsilon_{30}^{\pm 1}$; therefore $\log \varepsilon_{30}$ is the translation length of the associated hyperbolic transformation. The same central integer 30 reappears in the vacuum because $90 = 3 \cdot 30$ and $120 = 4 \cdot 30$, but the two operators continue to have distinct domains. The demonstrated confluence concerns the mode and its completions; identity of the dynamics is not postulated.

46.2 Lift nonadic of the unit of Pell

For $k \geq 1$, let the unramified quadratic ring be

$$\mathcal{R}_k = (\mathbb{Z}/3^k\mathbb{Z})[r]/(r^2 - 2), \tag{46.4}$$

and let

$$u = 3 + 2r.$$

The conjugation $r \mapsto -r$ gives

$$N_{\mathcal{R}_k/(\mathbb{Z}/3^k\mathbb{Z})}(u) = (3 + 2r)(3 - 2r) = 9 - 8 = 1,$$

so that u is a unit of norm one. Moreover,

$$u^2 = 17 + 12r, \qquad u^4 - 1 = 576 + 408r = 3(192 + 136r).$$

The second factor is a unit modulo three because it reduces to $r \neq 0$. Hence the valuation 3-adic satisfies $v_3(u^4 - 1) = 1$. The lifting lemma for a unit congruent to one modulo three yields, for every $j \geq 0$,

$$v_3\left(u^{4\cdot 3^j} - 1\right) = j + 1.$$

Since $u \bmod 3 = 2r$ and $(2r)^2 = -1$, its order modulo three is four. Consequently,

$$\operatorname{ord}(u) = 4 \cdot 3^{k-1}, \tag{46.5}$$

and the profinite closure of the compatible cyclic groups is

$$\varprojlim_k \langle u \bmod 3^k \rangle \simeq C_4 \times \mathbb{Z}_3. \tag{46.6}$$

Its Archimedean realization is

$$3 + 2\sqrt{2} = (1 + \sqrt{2})^2.$$

This construction proves the conservation of nonadic depth by a hyperbolic unit. The units $3 + 2\sqrt{2}$, $2 + \sqrt{3}$, and $30 + \sqrt{899}$ form a Pell family with distinct provenances; any identification among them requires explicit maps between the corresponding extensions.

The mode 30 is one of the points at which the architecture begins to exhibit a unit determined by the operatorial and arithmetic genealogy.

It appears first in the vacuum because

$$90 = 3 \cdot 30, \qquad 120 = 4 \cdot 30.$$

It is the elementary cadence that permits comparison of the sectors 90 and 120. The vacuum reads that cadence as the completion $3 \to 4$.

But the same 30 reappears in the construction of the criticality germ. There the central identity is

$$899 = 30^2 - 1 = 29 \cdot 31.$$

Normalization of the twelve phases produces $\sqrt{899}$, and the analytic profile can be written in closed form. What is truly striking is that π disappears before the iteration begins.

This must be read carefully. The angular geometry of π is absorbed into the organization of the phases. Once the dodecaphase configuration has been normalized, the dynamic germ is governed by the internal arithmetic of 899.

Therefore, the construction begins by generating internally a dynamic object of its own:

- es par;
- is analytic;
- has a critical quadratic;
- belongs to the corresponding unimodal class;
- has negative Schwarzian;
- can be subjected to the operator of renormalization.

The superstable ratios then begin to approximate the universal constants. The germ was produced first, and universality appears as the terminal behavior of its dynamics.

This is a profound epistemological difference. A numerical coincidence would state: “our calculation resembles Feigenbaum.” The HMT construction states: “this is the exact object that enters the universality class, and these are the quotients that emerge upon iterating it.”.

The 30 reappears a third time in modular memory. If

$$N = N_{90} + N_{120}$$

measures the total occupancy and

$$D = 90N_{90} + 120N_{120}$$

measures the occupation weighted by provenance, the matrix that transforms (N_{90}, N_{120}) into (N, D) has determinant 30.

This allows the process to be inverted:

$$N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N.$$

Thus, the same 30 performs three functions:

- in the vacuum, makes the propagations 90 and 120 commensurable;
- at criticality, determines the normalization $899 = 30^2 - 1$;
- in modular memory, is the determinant that allows the origin of each occupation to be recovered.

The vacuum operator, the chaos germ, and the modular Hamiltonian remain typologically distinct. The confluence is subtler: all three preserve a common partition of the genealogy.

We might say that the mode 30 is a gear. In one machine it measures propagation; in another it normalizes criticality; in another it makes the apparent loss of provenance reversible. The gear is the same, but each machine performs a different function.

The emergence of the Pell unit

$$30 + \sqrt{899}$$

reinforces this interpretation. The 30 simultaneously organizes a finite sum and hyperbolic growth. The same arithmetic that closes the germ opens a scale dynamics.

That is perhaps the profound reason why the result proves so beautiful: the mode that makes the finite completion of the vacuum possible is also the mode that prepares an infinite universality of criticality.

Finite and infinite are articulated through the coherent repetition of a finite structure that preserves memory; from it the dynamic infinite is born.

46.3 Spectral Pell screw and logarithmic suspension

46.3.1 Spectral identity $V^{-1}\mathcal{S}V = (2+\sqrt{3})\mathrm{i}\mathcal{S}$ and equation of the logarithmic suspension

The corpus contains the exact identity

$$V^{-1}\mathcal{S}V = (2+\sqrt{3})\mathrm{i}\,\mathcal{S}. \tag{46.7}$$

Let $\varepsilon = 2+\sqrt{3}$. The orbit transversal

$$z_n = z_0(\varepsilon\mathrm{i})^n$$

satisfies

$$r_n = r_0\varepsilon^n, \qquad \theta_n = \theta_0 + \frac{\pi n}{2}.$$

Eliminando n,

$$r(\theta) = r_0 \exp\left[\frac{2\log(2+\sqrt{3})}{\pi}(\theta - \theta_0)\right]. \tag{46.8}$$

The logarithmic spiral is an output of the operator: its equation was not chosen to fit ε afterward.

Derivation of equation (46.8). From $\theta_n - \theta_0 = n\pi/2$ it follows that $n = 2(\theta_n - \theta_0)/\pi$. Substituting into $r_n = r_0\varepsilon^n$,

$$r_n = r_0 \exp\left(\frac{2\log\varepsilon}{\pi}(\theta_n - \theta_0)\right).$$

Continuous interpolation is the indicated equation. □

46.3.2 Conjugate contraction involution

The bilateral extension $n \in \mathbb{Z}$ produces

$$n \to +\infty : \ r_n \to \infty, \qquad n \to -\infty : \ r_n \to 0.$$

The inversion $n \mapsto -n$ interchanges expansion and contraction. Since $\varepsilon^{-1} = 2 - \sqrt{3}$, both branches belong to the same Pell unit. They are not two independent spirals, but two orientations of the same spectral screw.

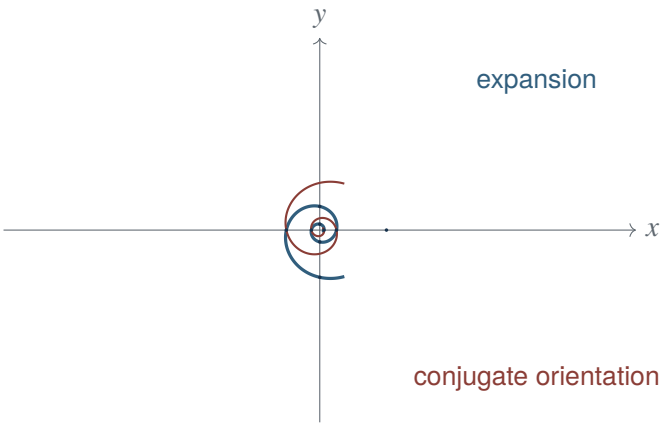

Figure 46.1: Transverse projection of the Pell screw. The marks represent quarter turns.

46.3.3 Scale covariance and energy conservation

The dilation ε must not be interpreted as gratuitous growth of the energetic amplitude of a wave in vacuum. Its coherent realization acts on the spatial or spectral scale:

$$(r, \varphi, \lambda) \longmapsto (\varepsilon r, \varphi + \pi/2, \varepsilon\lambda).$$

This distinction will be essential in the electromagnetic realization of section 63.7.

Exact compatibility between the Pell spectral screw and the phase–memory suspension

The minimal phase–memory lift is a circular helix. The spectral screw combines a quarter-turn and a Pell dilation; its projection is a logarithmic spiral. Both arise from the HMT ledger, but they are neither the same periodicity nor obtained from one another by forgetting types.

Chapter 47

Arithmetic theory of nonadic vacancies: defect $10^3 - 3^6$, radical network $3 \to 6 \to 9$, power–vacancy law, and boundary torsion

47.1 Classification of the irreducible arithmetic cycles of the nonadic radical lattice

In the arithmetic realization, a prime corresponds to an irreducible cycle that cannot be factored into smaller positive cycles. Nonadic periodicity may select candidates and organize residue classes; primality remains defined by the exact multiplicative property

$$p = ab \Longrightarrow a = 1 \text{ or } b = 1.$$

Once the coproduct of prime arithmetic cycles has been selected, equations (42.4) y (42.5) are obtained. The helical structure and the digital root parametrize phase and carry, but do not replace the factorization criterion.

47.2 Density, regularized term, and vacancy holonomy

The basic positive density is

$$\varepsilon_{\text{vac}} = \log_{10} \frac{10}{9}. \tag{47.1}$$

The sequence is deduced from the completion $1000 = 729 + 271$ determines

$$\varepsilon_{\text{vac}} = 1 - \log_{1000}(729) = \log_{10} \frac{10}{9}, \tag{47.2}$$

and the exact mechanical word

$$z_n = \lfloor (n+1)\varepsilon_{\text{vac}} \rfloor - \lfloor n\varepsilon_{\text{vac}} \rfloor, \qquad n \geq 1. \tag{47.3}$$

Since ε_{vac} is irrational, the word is Sturmian: it has complexity $p(N) = N+1$, balance one and topological entropy topological zero. This dynamic differs from the full shift on the triadic alphabet triadic: the vacancy determines an ordered boundary of zero entropy.

The suma telescopica produces

$$\sum_{n=1}^{N} z_n = \lfloor (N+1)\varepsilon_{\text{vac}} \rfloor, \qquad \sum_{n=1}^{N} (z_n - \varepsilon_{\text{vac}}) = \varepsilon_{\text{vac}} - \{(N+1)\varepsilon_{\text{vac}}\}. \tag{47.4}$$

The partial sums of the discrepancy have modulus less than one. This is the estimation supporting the subsequent harmonic constants.

The fraction continuous begins

$$\varepsilon_{\text{vac}} = [0; 21, 1, 5, 1, 6, 2, 3, \ldots].$$

Thus the ones in z_n are separated by 21 or 22 steps. If

$$\sigma = 22 - \varepsilon_{\text{vac}}^{-1} = 1 - T_G(\varepsilon_{\text{vac}}),$$

then $a_1(\sigma) = 6$ and the returns of the short separation have length 6 or 7. The pairs 21/22 and 6/7 are two scales of the same rotation, not coincidences of integers.

For the exact word in equation (47.3), the regularized constant is

$$\gamma_{\mathrm{vac}}^{+} = \lim_{N\to\infty}\left(\sum_{n\le N}\frac{z_n}{n} - \varepsilon_{\mathrm{vac}}\log N\right). \tag{47.5}$$

The associated holonomy is

$$\rho_{\varepsilon}(k) = \exp(2\pi \mathrm{i} k\varepsilon_{\mathrm{vac}}). \tag{47.6}$$

The three quantities have distinct types: density, finite term, and phase. The vacancy Stieltjes tower prolongs equation (47.5):

$$\gamma_{\mathrm{vac,j}}^{+} = \varepsilon_{\mathrm{vac}}\gamma_j + \sum_{n\ge 1}\frac{(z_n - \varepsilon_{\mathrm{vac}})(\log n)^j}{n}. \tag{47.7}$$

For $j = 0$, one recovers $\gamma_{\mathrm{vac}}^{+}$. Convergence requires the discrepancy bound for the integral development of vacancies.

Convergence is proved here. For $j \ge 0$, the sequence $b_n = (\log n)^j/n$ tends to zero and is decreasing from $n > e^j$ onward. The uniform bound equation (47.4) and Dirichlet's criterion prove the convergence of

$$\sum_{n\ge 1}(z_n - \varepsilon_{\mathrm{vac}})b_n.$$

For $j = 0$, separating $\varepsilon_{\mathrm{vac}}\sum_{n\le N} n^{-1}$ gives exactly equation (47.5). Abel summation conservatively bounds the tail after N by $2/(N+1)$: one term comes from the boundary and another from the total variation of $1/n$. The declared exhaustive execution uses $N = 10^8$, enumerates the Beatty positions of the ones, checks the gap sets $\{21, 22\}$ and returns $\{6, 7\}$, and obtains as its finite part

$$-0.11207107505876366224207105242526397929\ldots.$$

Combining the analytic bound with the recorded rounding and boundary guards, the finite certificate encloses

$$-0.112071094143613634 < \gamma_{\mathrm{vac}}^{+} < -0.112071055516338732. \tag{47.8}$$

This interval is a terminal value with controlled error. It does not define the word; the word and its discrepancy precede it.

A second evaluation using multiprecision arithmetic and directed rounding control provides, to eighteen decimal places, the certified interval

$$-0.112071086058763562 < \gamma_{\mathrm{vac}}^{+} < -0.112071064058763762,$$

contained strictly within equation (47.8). The inclusion of both intervals verifies the stability of the finite part with respect to truncation, the boundary guards, and the precision regime. The result depends solely on the recurrences, the tail bounds, and the interval arithmetic set out in this chapter.

47.3 Operative content of the helicoidal representation

The helical representation encodes a periodic phase together with a memory increment. It has operatorial content when there exists a cocycle

$$c(\gamma\eta) = c(\gamma) + c(\eta)$$

that transports the carry and whose monodromy is interlinked with the arithmetic operator. In the absence of that map, the helix constitutes only a phase parametrization; with the interlinker, it distinguishes phase return from state return.

Remark 47.1 (Negative control). Cofinality of cylinders does not imply dynamical conjugacy. A counterexample to commutation between the TPK shift and T_G precludes the intertwiner, but does not affect equations (44.5) y (44.6). In the vacancy sector, the divergence of equation (47.7) under the declared bound refutes the family of regularized constants.

Logical Scope and Domain of Validity

Cofinality, Gauss identities, Levy, entropy, and Lochs: *Exact internal theorem in the transported system*. GKW and dynamic intertwiner: *Open program with falsification criterion*. Density, constant, and vacancy holonomy: *Exact internal theorem with discrepancy control*.

47.4 Classification of the radical network 3→6→9 and derivation of the power–vacancy law

The appearance of 369 and 693 is not reducible to a graphic similarity. There are two exact mechanisms that converge:

1. **nonadic algebraic mechanism:** $3, 6, 9$ are the visual representatives of the nilpotent radical $\mathfrak{m} = (3) \subset \mathbb{Z}/9\mathbb{Z}$; the words 369, 693, and 936 are the three phases of its multiplicative orbit;
2. **Archimedean vacancy mechanism:** the difference between the decimal length of 9^n and the boundary 10^n is governed exactly by the same irrational rotation $\delta_{\text{vac}} = \log_{10}(10/9)$ that already organizes the vacancy calendar.

For $n = 9^9$, both mechanisms meet in the identity

$$9^9 - \left\lceil 9^9 \log_{10} \frac{10}{9} \right\rceil = 369\,693\,099,$$

so that

$$\#\,\text{cifras}\left(9^{9^9}\right) = 369\,693\,100.$$

The block 369 | 693 is, therefore, an exact output of the logarithmic reader of the nonadic power; it is not the decimal prefix of 9^{9^9}. The final unit proceeds from the universal operator that transforms decimal order into decimal length.

This identity opens a broader structural reading: addition, product, power, subtraction, division, root, and logarithm can be organized as a hierarchy of transports and quotients. Each ascent of operation compactifies histories; TPK preserves the coordinates that make their reconstruction possible.

47.5 Radical structure of the APP on $\mathbb{Z}/9\mathbb{Z}$

47.5.1 Nonadic local ring $\mathbb{Z}/9\mathbb{Z}$ and nilpotent radical

Let

$$R = \mathbb{Z}/9\mathbb{Z}.$$

Its group of units and its maximal ideal are

$$R^\times = \{1, 2, 4, 5, 7, 8\}, \qquad \mathfrak{m} = (3) = \{0, 3, 6\} = \{9, 3, 6\}_{\mathrm{vis}}.$$

Moreover,

$$\mathfrak{m}^2 = 0.$$

The preceding equality is an equality of ideals: every product of two elements of $\mathfrak{m}$ vanishes modulo nine. It must not be confused with the Cartesian product $\mathfrak{m} \times \mathfrak{m}$, which contains nine APP positions.

47.5.2 Exact sequence of the multiplier 3

Multiplication by three,

$$M_3 : R \longrightarrow R, \qquad x \longmapsto 3x,$$

has

$$\ker M_3 = \mathfrak{m}, \qquad \operatorname{im} M_3 = \mathfrak{m}.$$

It therefore induces an isomorphism of spaces over $\mathbb{F}_3$,

$$\overline{M}_3 : R/\mathfrak{m} \xrightarrow{\sim} \mathfrak{m}, \qquad \overline{x} \longmapsto 3x.$$

In visual representatives,

$$\overline{0} \longmapsto 9, \qquad \overline{1} \longmapsto 3, \qquad \overline{2} \longmapsto 6.$$

Thus, the band 3, 6, 9 is not a decimal ornament. It is an internal copy of the ternary quotient lodged in the nonadic radical.

47.5.3 Cyclic orbit 369→693→936→369

The row of the multiplication table corresponding to 3 is

$$3, 6, 9, 3, 6, 9, 3, 6, 9.$$

The cambio of phase $j \mapsto j + 1$ produces

$$369 \longmapsto 693 \longmapsto 936 \longmapsto 369.$$

These three words are the three cyclic readings of the application.

$$\mathbb{F}_3 \longrightarrow \mathfrak{m}, \qquad \bar{j} \longmapsto 3j.$$

The row 6, by satisfying $6 \equiv -3 \pmod 9$, reverses the orientation of the same cycle. The mark 9 fulfills two typed functions:

$$9 \bmod 9 = 0, \qquad \mathrm{dr}_9(9) = 9.$$

The module publishes the null class; the positive digital root preserves the mark of closure. This difference of readers is precisely what allows 9 to be at once residual zero and visible closure.

47.5.4 Radical cross of APP and coordinate reduction to $\mathbb{F}_3^2$

On

$$X_9 = R^2,$$

the union

$$\mathscr{C}_{369} = (\mathfrak{m} \times R) \cup (R \times \mathfrak{m})$$

is the cross formed by rows and columns $3, 6, 9$. It contains

$$3 \cdot 9 + 3 \cdot 9 - 3 \cdot 3 = 45$$

positions. Their central intersection $\mathfrak{m} \times \mathfrak{m}$ contains nine positions. In the multiplicative observable, the sum of the cross is

$$297 = 216 + 81 = 3(72 + 27).$$

The coordinate reduction produces

$$X_9/(\mathfrak{m} \times \mathfrak{m}) \cong \mathbb{F}_3^2$$

as a quotient set typed by the classes modulo three. The inverse lift requires preserving the coordinate within each three-element fiber.

47.5.5 Determination of the arithmetic core 7227 by incidence with the radical cross of APP

The central block of the APP is

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 7I + 2R = 9P_+ + 5P_-.$$

Its rowwise reading produces $72 \mid 27$; its diagonal reading produces $77 \mid 22$. One verifies

$$72 + 27 = 77 + 22 = 99,$$

$$72 - 27 = 45 = \det B_c,$$

$$77 - 22 = 55 = 54 + 1.$$

The relation with the radical cross is not nominal:

$$3 \cdot 72 = 216, \qquad 3 \cdot 27 = 81, \qquad 3 \cdot 99 = 297.$$

The central unitary block and the non-unitary network $3, 6, 9$ are thereby linked by an exact local–global identity. The hierarchy of the sum–product difference preserves its types:

4 (local spectral jump), 2 (off-diagonal coupling),

6 (compressed difference modulo three), 54 (two-dimensional unfolding).

47.6 Power–vacancy law for the scales 9^n and 10^n

47.6.1 Decimal Length Functions and Accumulated Vacancy

For $n \geq 1$, let

$$D_9(n) = \#\,\mathrm{cifras}(9^n) = \lfloor n \log_{10} 9 \rfloor + 1.$$

The decimal boundary 10^n has $n+1$ digits. We define the accumulated vacancy of the nonadic power by

$$V_9(n) = (n+1) - D_9(n).$$

We introduce the two complementary numbers

$$\rho_{\mathrm{vac}} = \log_{10} 9, \qquad \delta_{\mathrm{vac}} = 1 - \rho_{\mathrm{vac}} = \log_{10} \frac{10}{9}.$$

47.6.2 Exact identity between decimal length and vacancy rotation

Theorem. For every integer $n \geq 1$,

$$\boxed{V_9(n) = \lceil n\delta_{\mathrm{vac}} \rceil},$$

and, therefore,

$$\boxed{D_9(n) = n - \lceil n\delta_{\mathrm{vac}} \rceil + 1}.$$

Proof. Since δ_{vac} is irrational, $n\delta_{\mathrm{vac}} \notin \mathbb{Z}$. Then

$$\begin{aligned} D_9(n) &= \lfloor n(1 - \delta_{\mathrm{vac}}) \rfloor + 1 \\ &= \lfloor n - n\delta_{\mathrm{vac}} \rfloor + 1 \\ &= n - \lceil n\delta_{\mathrm{vac}} \rceil + 1. \end{aligned}$$

Subtracting from $n+1$ yields the first identity. □

47.6.3 Sturmian coding of vacancies induced by nonadic powers

The increments of the vacancy are

$$Z_n = V_9(n+1) - V_9(n) = \lceil (n+1)\delta_{\mathrm{vac}} \rceil - \lceil n\delta_{\mathrm{vac}} \rceil \in \{0, 1\}.$$

This is exactly the mechanical word of slope δ_{vac} used by the HMT vacancy calendar. Therefore, that calendar admits an additional, completely exact reading:

> $Z_n = 1$ if and only if, in passing from 9^n to 9^{n+1}, a new decimal range is lost relative to the boundary $10^n \to 10^{n+1}$.

The power does not add a coincidence to the theory of vacancies: it provides its natural realization as a counter of decimal rank loss.

47.6.4 Law $21/22$ as a case of the power–vacancy theorem

Since

$$\delta_{\mathrm{vac}}^{-1} = 21.85434532678283256\ldots,$$

the indices for which $Z_n = 1$ are separated by 21 or 22. The first twenty-one exponents satisfy

$$D_9(n) = n, \qquad 1 \le n \le 21,$$

whereas

$$D_9(22) = 21.$$

In particular,

$$9^9 = 387\,420\,489$$

has exactly nine digits. This initial preservation of rank is not an indefinite rule: the vacancy calendar determines exactly when it ceases to hold.

47.6.5 Exact evaluation at $n = 9^9$ and length of 9^{9^9}

Let

$$n_* = 9^9 = 387\,420\,489.$$

Then

$$n_*\delta_{\mathrm{vac}} = 17\,727\,389.3684296412564569\ldots,$$

and, therefore,

$$\boxed{V_9(n_*) = 17\,727\,390}.$$

The conserved coordinate after discounting vacancies is

$$n_* - V_9(n_*) = 387\,420\,489 - 17\,727\,390 = 369\,693\,099.$$

Therefore,

$$\boxed{\mathrm{ord}_{10}\left(9^{9^9}\right) = 369\,693\,099},$$

$$\boxed{D_9(9^9) = 369\,693\,100}.$$

Furthermore, the congruences are obtained.

$$9^9 \equiv 0 \pmod 9, \qquad V_9(9^9) \equiv 0 \pmod 9,$$

$$369\,693\,099 \equiv 0 \pmod 9, \qquad 369\,693\,100 \equiv 1 \pmod 9.$$

The corresponding digit sums are

$$s_{10}(9^9) = 45, \qquad s_{10}(V_9(9^9)) = 36,$$

$$s_{10}(369\,693\,099) = 54, \qquad s_{10}(369\,693\,100) = 37.$$

The return $9 \to 1$ appears here with precise types:

1. 9^9 and the accumulated vacancy belong to the null class modulo nine;
2. its difference, the decimal order, remains in the null class and has digit sum 54;
3. the universal operator $D = \mathrm{ord} + 1$ adds the closure unit and publishes the positive class 1.

47.6.6 Domain of validity of the power–vacancy law

It is proved:

- the theorem potencia–vacancia for every n;
- the identity with the mechanical vacancy word;
- the exact evaluation in $n = 9^9$;
- the decimal order and length of 9^{9^9};
- the preceding congruences and digit sums.

It is not claimed that 9 is the only basis with an analogous property in every domain, that each external occurrence of 369 arises from this tower, or that the tower replaces the construction of the nine phases or the generation certificate for π, e, φ.

47.7 Operator Hierarchy, Reversibility, and Genealogical Memory

47.7.1 Translation, Dilation, and Exponentiation as Operational Levels

Elementary operations can be seen as actions:

$$T_a(x) = x + a, \qquad M_a(x) = ax, \qquad P_k(x) = x^k.$$

Their partial inverses are, respectively, subtraction, division, and extraction of roots. The passage from one operation to the next modifies the structure of the fibers.

47.7.2 Stratified reversibility in $\mathbb{Z}/9\mathbb{Z}$

proposition. En the anillo nonadico:

1. every translation T_a is bijective;
2. M_a is bijective if and only if $a \in R^\times$;
3. if $a \in \mathfrak{m}$, multiplication has nontrivial fibers and its image lies within $\mathfrak{m}$;
4. for $x \in \mathfrak{m}$, $x^k = 0$ for every $k \geq 2$;
5. over $R^\times \cong C_6$, the map P_k is an automorphism if and only if $\gcd(k, 6) = 1$.

Proof. The first assertion uses the additive group structure. The second is the characterization of the units. The third follows from $aR \subseteq \mathfrak{m}$. The fourth follows from $\mathfrak{m}^2 = 0$. The fifth is the condition for multiplication by k to be an automorphism of the cyclic group of order six. □

The result produces an exact hierarchy:

sum: global reversibility,

product: reversibility restricted to units,

power: cyclic dynamics on units and nilpotent collapse in $\mathfrak{m}$.

Roots are functions only when the corresponding power is injective on the chosen domain; on the total domain they are multibranch correspondences or empty relations.

47.7.3 Reading of the Topological Phase Kernel on the operator hierarchy

This stratification suggests a functional definition:

> TPK does not add an external operation to sum, product, and power. It preserves the sheet, quotient, carry, orientation, route, and boundary that each ordinary evaluation eliminates when identifying several histories with the same output.

Sum and product are the first two evaluations on the APP. A power is repeated composition of the product; a root selects or reconstructs branches of that composition. The record distinguishes the published value from the operatorial history producing it.

47.7.4 Logarithmic descent between consecutive levels of the hierarchy

In a positive domain,

$$\log(xy) = \log x + \log y, \qquad \log(x^k) = k \log x, \qquad \log(a^x) = x \log a.$$

The logarithm converts product into sum, power into product, and exponential into dilation. The defect appears when the subsequent reader discretizes:

$$\mathcal{L}_{10}(a^n) = \lfloor n \log_{10} a \rfloor + 1.$$

The integer part introduces the boundary-crossing calendar. For $a = 9$, that calendar is precisely the vacancy word.

47.7.5 Affine conjugation of translations and dilations

Translations and dilations satisfy

$$M_a T_b M_a^{-1} = T_{ab}$$

when a is invertible. This identity expresses that the product reorganizes the units of addition. When a ceases to be invertible, conjugation breaks because branches disappear. The radical $3, 6, 9$ localizes precisely that failure.

47.8 Path Algebra: Multiplicative Composition, Additive Action and Superposition

In a path algebra, addition aggregates alternatives and multiplication concatenates trajectories. For local weights $w(e)$,

$$K(x,y) = \sum_{\gamma : x \to y} \prod_{e \in \gamma} w(e).$$

If a coherent logarithmic branch is fixed,

$$\prod_{e \in \gamma} w(e) = \exp\left(\sum_{e \in \gamma} \log w(e) \right),$$

and, with the appropriate discrete action,

$$K(x,y) = \sum_{\gamma : x \to y} e^{-S(\gamma)/\hbar}.$$

The equation combines the operations:

- the product composes successive steps;
- the logarithm accumulates the local action;
- the exponential reconstructs the route weight;
- the suma agrega all the alternativas.

APP is the minimal support on which sum and product act on the same histories. TPK adds the data that prevent the sum over paths from becoming a sum over values without genealogy.

In this framework, a digit is the output of a reader; a value is the Archimedean projection of a section; an HMT number preserves the compatible family of paths that supports that value; a particle preserves that genealogy under a persistent spectral realization.

47.9 Triadic exponential family $J_\tau^2 = -\tau I$: elliptic, parabolic, and hyperbolic realizations of Euler's identity

47.9.1 Internal root of -1 in the finite branch

The Paley incidence matrix provides an operator A_W with

$$A_W^2 = -I.$$

This turns $\mathbb{F}_3^6$ into a three-dimensional space over

$$\mathbb{F}_9 = \mathbb{F}_3[\iota]/(\iota^2 + 1).$$

The root of -1 is not adjoined from outside as complex notation. It emerges as an endomorphism of an already constructed ternary support.

47.9.2 Continuous extension of the common quadratic operator and conservation of its spectral type

In the elliptic real branch, the generator J_{e} satisfies

$$J_{\mathrm{e}}^2 = -I,$$

and

$$e^{tJ_{\mathrm{e}}} = \cos t\, I + \sin t\, J_{\mathrm{e}}.$$

In particular,

$$e^{\frac{\pi}{2}J_{\mathrm{e}}} = J_{\mathrm{e}}, \qquad e^{\pi J_{\mathrm{e}}} = -I, \qquad e^{2\pi J_{\mathrm{e}}} = I.$$

Thus, J_{e} is the internal quarter-turn and Euler's equation is its half-turn closure.

47.9.3 Conjugation of the arithmetic, angular, and torsional realizations via the common quadratic operator

Let

$$\mathbb{D} = \{z \in \mathbb{C} : |z| < 1\}.$$

This same set contains the real diameter $(-1, 1)$, the complex interior, the trigonometric boundary S^1, and the Poincaré hyperbolic metric

$$ds_{\mathrm{P}}^2 = \frac{4\ell^2 |dz|^2}{(1 - |z|^2)^2}.$$

The map

$$R_{\pi/2}(z) = iz$$

preserves $|z|$ and $|dz|$. By consiguiente, is simultaneamente:

- complex multiplication by $\sqrt{-1}$;
- trigonometric rotation of 90°;
- Euclidean isometry of the disk;
- Poincaré hyperbolic isometry;
- automorphism of its circular boundary.

The coincidence is literal: the same map acts on the same carrier; the metric reader changes.

47.9.4 Elliptic, parabolic, and hyperbolic geometries of the extended Euler equation

The generators

$$J_{+1}^2 = -I, \qquad J_0^2 = 0, \qquad J_{-1}^2 = I$$

produce

$$e^{tJ_{+1}} = \cos t\, I + \sin t\, J_{+1},$$

$$e^{tJ_0} = I + tJ_0,$$

$$e^{tJ_{-1}} = \cosh t\, I + \sinh t\, J_{-1}.$$

The same exponential series separates into three regimes according to the square of the generator: elliptic, parabolic, and hyperbolic. The specialization

$$e^{2\log\varphi\, J_{-1}} = F_{\mathrm{av}}^2$$

integrates the Fibonacci self-scale. Euler and Fibonacci appear as specializations of a common quadratic exponential family.

47.9.5 Common carrier, common operator, and quadratic exponential family

Geometric fusion is formulated at three levels:

1. **common carrier:** the unit disk contains the real diameter, the complex interior, and the circular boundary;
2. **common operator:** $z \mapsto iz$ is a quarter-turn, complex multiplication, and a hyperbolic isometry;
3. **common family:** the tritic exponential equation brings together the elliptic, parabolic, and hyperbolic branches.

The result does not identify the Euclidean and hyperbolic metrics. It states that they are distinct realizations on the same support and share the automorphism originating in the internal root of $-I$.

47.10 Restriction of internal rotation, edge holonomy and minimal torsion

The construction contains two positive and differentiated objects:

1. the internal generator J_{e}, with $J_{\mathrm{e}}^2 = -I$;
2. the global invariant

$$\Delta_4 = \frac{\pi - e\log\pi}{270}\left(1 + \frac{\pi}{729}\right),$$

denoted minimal torsion and used prior to species selection.

The authorial thesis adds that internal rotational dynamics, when published at the boundary, is absorbed as minimal torsion. The relation must not be written as a bare equality $J_{\mathrm{e}} = \Delta_4$: the objects have different types. Its natural form requires

$$\text{interior rotation} \xrightarrow{\mathrm{Res}_\partial} \text{boundary holonomy} \xrightarrow{\mathrm{Def}} \text{scalar defect}.$$

Let q_∂ be the boundary reader, ∇_∂ the induced connection, and e_∂ the discrete frame. The edge torsion has type

$$T_\partial = d_{\nabla_\partial} e_\partial.$$

The author's claim acquires probative form through a functional

$$\Lambda_\partial : \mathrm{Tors}(\partial X) \longrightarrow \mathbb{R}$$

such that

$$\Lambda_\partial(T_\partial) = \Delta_4$$

and a theorem deriving T_∂ from the restriction of J_{e} through the boundary operators of the TPK.

The internal root of $-I$, the quarter-turn, the extended Euler equation, and the formula for Δ_4 are proved in their respective domains. The passage from interior rotation to minimal boundary torsion requires the declared morphism Res_∂ and functional Λ_∂; it is not identified by a scalar equality.

47.11 Generational triality, conjugation, and mixing over the enriched state

The phrase of Isidor Isaac Rabi may serve as a historical reference, but it must not govern the title or constitute an autonomous section. The scientific question is:

> What internal mechanism distinguishes three stable orders of fermionic realization and preserves that distinction under color, conjugation, and mixing?

The HMT response is not "because TRIT has three values". The structure separates

$$\mathrm{flav}(X) = \big(\sigma_{ud}(X), g(X), \chi_{\mathrm{fina}}(X)\big),$$

where σ_{ud} distinguishes branches, g distinguishes physical generations, and χ_{fina} preserves orientation and memory within a branch. For quarks, the color orbit is added after flavor and before the character.

Triplicity is obtained as a consequence of the enriched structure; its effects on color, conjugation, and mixing are developed below:

1. color, flavor, generation, and mass are distinct readers of the same enriched state;
2. particle–antiparticle conjugation acts on the orientation without erasing the generational class;
3. CKM and PMNS transport already typed state bases; they do not create triplicity;
4. the neutrino classification must be derived from representation, occupation, and mixing, not by renaming depths $G0, \ldots, G4$.

That neutrinos are half-integer-spin leptons obeying fermionic statistics is a known physical classification. The structural contribution of HMT consists in obtaining internally why the neutral sector occupies that representation, why it admits three physical realizations, and how it couples to the mixing operator without reading its external angles.

47.12 Operator memory of the TPK: preservation of residue, quotient, carry, sheet, orientation, route, and boundary under projection

47.12.1 Loss of reversibility and genealogical lifting

In APP, different histories may produce the same residue. The product folds more histories than the sum; the power folds more than the product; the root attempts to reconstruct branches already identified. TPK preserves the datum that makes it possible to invert that loss:

residue, quotient, carry, sheet, orientation, route, boundary, memory.

An algebraic operation may be characterized not only by its value, but also by the type of genealogy that it preserves or destroys.

47.12.2 Projection of Compatible Histories onto the Archimedean Continuum

The real line appears when a family of compatible cylinders contracts under Archimedean evaluation. The real value is the shadow of the section, not its complete genealogy. The exceptional projection preserves another part as incidence and symmetry.

The path integral expresses the same principle:

$$\text{alternatives} \xrightarrow{\Sigma} \text{global amplitude}, \qquad \text{successive stages} \xrightarrow{\prod} \text{route weight}.$$

The logarithm converts multiplicative composition into additive action; the exponential returns it to amplitude. The discrete structure of the continuum can be formulated as genealogical conservation of all routes before their projection onto $\mathbb{R}$.

47.12.3 Distinction between numerical section and persistent realization of particle

A number and a particle share minimal ontological invariants: memory, orientation, persistence, closure, signature, and position in a family of prolongations.

The number publishes an Archimedean coordinate. The particle adds spectral realization, occupation, propagation, and stability. The passage HMT → MD changes the reader applied to the same enriched genealogy; it does not arbitrarily change the object.

47.13 Joint closure of the radical network, the power–vacancy law, Euler geometry, and the operative hierarchy

47.13.1 Theorem of the Nonadic Radical Network

The APP net $3, 6, 9$ is the visual representation of the nilpotent radical $(3) \subset \mathbb{Z}/9\mathbb{Z}$. Its phases 369, 693, and 936 realize the isomorphism $R/(3) \cong (3)$ induced by multiplication by three. The bands locate exactly the failure of invertibility of the product.

47.13.2 Power-void Theorem

For every $n \geq 1$, the number of decimal ranks lost by 9^n relative to 10^n is $\lceil n \log_{10}(10/9) \rceil$. Their increments form the mechanical vacancy word. In $n = 9^9$, the retained coordinate is 369 693 099 and the resulting length is 369 693 100.

47.13.3 Exponential Family Euler's Geometric Theorem

The internal root of $-I$ produces a quarter-turn. On the unit disk, the same map $z \mapsto iz$ is simultaneously complex multiplication, trigonometric rotation, and a Poincaré isometry. The tritic exponential equation extends this regime to the parabolic and hyperbolic regimes, incorporating the Fibonacci self-scaling in the latter.

47.13.4 Operatorial conservation principle between levels

The sum–product–power hierarchy is a hierarchy of fibers and loss of reversibility. The TPK is the lift that preserves the coordinates required to distinguish histories identified by the ordinary readers.

47.14 Typing conditions and incompatibility criteria of the nonadic vacancy theory

1. Do not identify 369 693 100 with a TPK word without declaring the reader between domains.
2. No confundir the ideal $\mathfrak{m}^2 = 0$ With $\mathfrak{m} \times \mathfrak{m}$.
3. Do not confuse modulo nine with digital root: $9 \mapsto 0$ in the former and $9 \mapsto 9$ in the latter.
4. Do not use the threefold character of TRIT as a sufficient proof of three physical generations.
5. Do not turn $J^2 = -I$ into Δ_4 without the boundary map and the torsion functional.

6. Do not present 369 as a prefix of 9^{9^9}: it pertains to its order and its decimal length.

7. Do not reduce the ten thousand digits to an order-of-magnitude test: they certify extensive truncations of a parametrizable process whose thesis is indefinite prolongation.

47.15 Joint consequences for the radical net, the operational memory, and the edge torsion

The principal finding is not that a tower visually contains the digits $3, 6, 9$. The nonadic power and the vacancy calendar are two presentations of the same logarithmic defect, while APP localizes $3, 6, 9$ as the radical where multiplication loses invertibility. The tower connects both extremes:

$$\text{nonadic radical} \longrightarrow \text{power} \longrightarrow \text{logarithm} \longrightarrow \text{vacancy} \longrightarrow \text{decimal order} \longrightarrow \text{closure } 9 \to 1.$$

The extended Euler equation adds the second direction: the internal root of $-I$ converts the discrete structure into rotational dynamics and gathers, on a common support, the real line, the trigonometric circle, and the hyperbolic disk. The later passage to minimal torsion must preserve the boundary map already developed in the corpus, not replace it with a nominal identification.

Chapter 48

Thermal constants and radiation: Boltzmann, Wien, Stefan–Boltzmann and spectral thermodynamics of the photon gas

48.1 Relation termica intrinseca of the escala 108

The chronological structure 108 fixes

$$k_B \Theta_{\mathrm{clk}} \log 3 = \frac{h_{\mathrm{int}}}{108 t_0} = \frac{2\pi \hbar_{\mathrm{int}}}{108 t_0}. \tag{48.1}$$

This equality does not separately determine a numerical coordinate of k_B and another of Θ_{clk} without an additional normalization. It does determine their product as a section of energy. The factor $\log 3$ has three compatible antecedents:

$$\log 3 = C_1 + C_2 - 2C_0 = \frac{S_{\widehat{\mathbb{T}}}}{k_B} = \frac{E_P}{k_B \Theta_{\mathrm{clk}}}. \tag{48.2}$$

The three equalities correspond to residual, informational and thermodynamic realizations of the same scalar. The coincidence of value does not identify their respective domains.

48.2 Spectral formulations of Wien's displacement law

For the spectral density per wavelength, the maximum satisfies

$$5(1 - \mathrm{e}^{-x_5}) = x_5, \qquad x_5 = 5 + W_0(-5\mathrm{e}^{-5}).$$

With equation (48.1),

$$\lambda_{\max}(\Theta_{\mathrm{clk}}) = \frac{108 \log 3}{x_5}\, \ell_0. \tag{48.3}$$

For the frequency density,

$$3(1 - \mathrm{e}^{-x_3}) = x_3, \qquad x_3 = 3 + W_0(-3\mathrm{e}^{-3}),$$

and

$$\nu_{\max}(\Theta_{\mathrm{clk}}) = \frac{x_3}{108 t_0 \log 3}. \tag{48.4}$$

The maxima are not reciprocals, since the spectral densities transform with the corresponding Jacobian. The quotient x_5/x_3 belongs to the structure of the parameterization and does not represent an inconsistency.

48.3 Stefan–Boltzmann law and thermodynamics of the photon gas

Evaluating the radiation law at Θ_{clk} produces the intrinsic flux

$$j_\star(\Theta_{\mathrm{clk}}) = \frac{2\pi^5}{15\, 108^4 (\log 3)^4}\, \frac{h_{\mathrm{int}}}{\ell_0^2 t_0^2}, \tag{48.5}$$

in the declared normalization. The Stefan–Boltzmann constant is not inserted as a primitive: it results from integrating the bosonic spectrum once action, propagation, and temperature have been fixed. The

spectral laws employed are those of Planck and Wien [103, 134]; HMT fixes here the section on which they are evaluated, not their constants by retrospective comparison.

In units of the Planck scale,

$$n_\gamma \ell_P^3 = \frac{2\zeta(3)}{\pi^2 \log^3 3}, \tag{48.6}$$

$$\frac{u_\gamma \ell_P^3}{E_P} = \frac{\pi^2}{15 \log^4 3}, \tag{48.7}$$

$$\frac{s_\gamma \ell_P^3}{k_B} = \frac{4\pi^2}{45 \log^3 3}. \tag{48.8}$$

$\zeta(3)$ represents the third-order bosonic moment, whereas $\log 3$ determines the energy associated with the TRIT decision. The equation preserves the distinction between the two invariants.

The quantum thermal conductance is expressed as

$$\frac{\kappa_Q t_0}{k_B} = \frac{\pi^2}{324 \log 3}. \tag{48.9}$$

48.4 Metrological Confluence of Thermal and Radiative Invariants

Object	Equation internal	Significado estructural
R_K	$Z_{\text{vac}}/(2\alpha)$	bidirectionally invariant quantum resistance
G_0	$4\alpha/Z_{\text{vac}}$	conductancia complementaria
Φ_0	$\sqrt{hZ/(8\alpha)}$	flow preserving orientation of action
K_J	Φ_0^{-1}	reciprocal relation between frequency and flux
E_P	$k_B\Theta \log 3$	energy of the cycle and TRIT informational content
Wien's law	$108 \log 3/x_5$	endpoint spectral in the scale chronological
Photonic Apéry	$2\zeta(3)/(\pi^2 \log^3 3)$	number density of the bosonic field

Remark 48.1 (Negative control). The block is falsified if a change of spectral variable improperly preserves the same Wien extremum, if $\zeta(3)$ replaces $\log 3$, or if separate values are assigned to k_B and Θ without specifying a chart. The identities equations (36.37) y (40.6) provide direct algebraic controls.

Logical Scope and Domain of Validity

Electric quanta and Planck–TRIT confluence: *Exact internal theorem*. Wien, Stefan–Boltzmann, and the photonic gas: *Exact mathematical composition* with the declared bosonic continuum. The SI chart remains an *External metrological comparison*.

48.5 Boltzmann constant, information, and thermal transduction

48.5.1 Dimensional structure of transduction

The structural definition of the Boltzmann constant uses the temperature and energy lines. The positive transduction

$$k_B : \mathcal{L}_\Theta \longrightarrow \mathcal{L}_E$$

assigns a temperature its energy scale. In the tritic normalization, the cycle's temperature section satisfies

$$k_B \Theta_{\mathrm{clk}} = \frac{E_P}{\log 3}.$$

The right-hand side is fixed by the previously constructed action and period. The factor $\log 3$ comes from the informational content of a uniform distribution on the three local states.

Let u_E, u_Θ be positive bases, and write $E_P = \epsilon_P u_E$, $\Theta_{\mathrm{clk}} = \theta_{\mathrm{clk}} u_\Theta$, and $k_B(u_\Theta) = b\, u_E$. Then

$$b\, \theta_{\mathrm{clk}} = \frac{\epsilon_P}{\log 3}.$$

For $u'_E = s_E u_E$ and $u'_\Theta = s_\Theta u_\Theta$, the coordinates transform by

$$b' = \frac{s_\Theta}{s_E} b, \qquad \theta'_{\mathrm{clk}} = \frac{\theta_{\mathrm{clk}}}{s_\Theta}, \qquad \epsilon'_P = \frac{\epsilon_P}{s_E}.$$

The energy identity remains covariant. This formulation combines the individual structure of the transducer with the normalization of the section on which it acts.

Remark 48.2 (Thermal coordinate and choice of bases). The transducer and the preceding energy identity are covariant. An individual numerical value of k_B is referred to the positive bases u_E, u_Θ; its transformation is $b' = (s_\Theta/s_E)b$. Internal selection of a numerical coordinate therefore requires, in addition, a construction fixing those bases. The energy identity does not by itself select that choice. The metrological coordinate does not define action or period.

The distinction helps interpret entropy. The functional $s(\rho) = -\operatorname{Tr}(\rho \log \rho)$ is dimensionless. Dimensional entropy is $S(\rho) = k_B s(\rho)$, understood on the corresponding line. The quantity ΘS belongs to the energy line. This preserves the mathematical meaning of the equalities combining information, temperature, and action.

In particular, the continuation information (73.61) admits the dimensional publication $S_n^{\mathrm{gen}}(x) = k_B s_n(x)$. The admissible branches and their measure determine s_n; the transducer fixes the entropy scale. For a uniform distribution over three alternatives, the value is $k_B \log 3$. When the prolongations have different weights, the weighted expression preserves that structural difference. The Boltzmann constant can be defined here by its function: it is the dimensional coefficient that transports the information of the admitted distribution to the entropy line and, under a specified temperature, links that information to energy.

Action enters before thermal publication. The section $\hbar_a$ converts the evolution frequency into energy; the section h_a expresses the action accumulated during a turn. The equality $k_B \Theta_{\mathrm{clk},a} \log 3 = h_a / T_{108}$ brings both functions together: energy of the period and local information of the tritic dynamics. A thermodynamic identification additionally preserves the statistical state, the temperature and the physical exchange or erasure operation under study.

48.5.2 Structural definition and function of the Boltzmann constant

Definition 48.3 (Thermal transducer of energy per decision)**.** Fix a positive thermal section $\Theta_{\mathrm{clk},a} \in \mathcal{L}_\Theta$. The Boltzmann transducer is the positive linear map $k_B : \mathcal{L}_\Theta \to \mathcal{L}_E$ realizing

$$k_B(\Theta_{\mathrm{clk},a}) = \frac{\epsilon_a}{\log 3}, \qquad \epsilon_a = \frac{h_a}{108 t_0}. \tag{48.10}$$

Action and duration determine ϵ_a; the uniform tritic decision determines its informational normalization.

Uniqueness, proved in section 70.2.7, follows by prescribing the image of a nonzero section of a line. Equations (70.26) and (70.27) specify, respectively, its coordinate in declared bases and compatibility of the same transducer with both orientations. Determination of the product $k_B\Theta_{\mathrm{clk},a}$ precedes individualization: the latter retains as explicit data the thermal section, the bases, and, when internal selection is claimed, its constructive reader. The pressure in (70.30), under the hypotheses enumerated there, normalizes the energy parameter $\beta = (k_B\Theta)^{-1}$.

The physical function of k_B is to publish the information of a distribution dimensionally: $S = k_B s$. Evaluating that entropy at a temperature produces the energy ΘS. A uniform triple contributes $\log 3$ nats; a distribution of continuations contributes its weighted entropy; a quantum reduction contributes the entropy of the specified bipartition. The transducer acts on those contents while preserving their domains. Genealogical memory determines what information each reading retains; the thermodynamic balance specifies what operation exchanges or erases it. This separation explains the relation between reversibility, entanglement and decision energy.

Chapter 49

Electroweak constants and mixing: angular determinant, relation W/Z, Weinberg angle and rational CKM reflection

49.1 Angular determinant and Weinberg electroweak relation

The determinant of T is

$$\det T = q_+ q_- = D_A. \tag{49.1}$$

The constitutive sector of the vacuum evaluates $F(T)^2$, where $F(z) = (1 - z^{90})/(1 - z^{120})$, whereas the electroweak angular sector evaluates $\det T$. These are two functions of a common antecedent, not a horizontal factorization between constants. This distinction is developed in the section 49.1.

Remark 49.1 (Negative control). The block is refuted if any of these exact identities is violated: positivity of $I - T^{120}$, equality equation (39.8), relations equation (39.5), or compatibility $E_m(\mathcal{V}_{m+1}) = \mathcal{V}_m$. An SI coincidence cannot compensate for an operator failure.

Logical Scope and Domain of Validity

Operator, spectrum, completion $3 \to 4$, parity, amplification, and constitutive sections: *Exact internal theorem*. The formulation that unites them in a single operator is *New formalization*; the angular data and lines are an *Antecedent demonstrated result* of the preceding HMT development and are declared here as explicit initial structure.

49.2 Constitutive and Determinantal Functions of the Angular Operator

Recall the two-sheet operator of the chapter 34,

$$T = q_+ P_+ + q_- P_-, \qquad q_- = \mathrm{e}^{-(A_{\mathrm{rad}} - C^*_{\mathrm{rad}})}, \qquad q_+ = \mathrm{e}^{-(A_{\mathrm{rad}} + C^*_{\mathrm{rad}})}. \tag{49.2}$$

The electromagnetic vacuum applies the function

$$F(T)^2, \qquad F(z) = \frac{1 - z^{90}}{1 - z^{120}}, \tag{49.3}$$

while the electroweak angular sector applies the determinant

$$\boxed{\det T = q_+ q_- = \mathrm{e}^{-2A_{\mathrm{rad}}} =: D_A.} \tag{49.4}$$

They are two functional realizations of the common antecedent (A, C^*, T). There is no causal arrow $F(T)^2 \to \det T$ or its inverse. Structural unity resides in T, not in subsequently identifying permeability, permittivity, and θ_W.

Under the sheet involution $C^* \mapsto -C^*$, the eigenvalues q_+, q_- are exchanged. Therefore D_A and the constitutive speed are even, while $(\widehat{\mu}, \widehat{\varepsilon})$ is exchanged and $\widehat{Z}$ is inverted. The following electroweak relation uses the even invariant.

49.3 Exact relation between sectors W and Z

The angular coordinate of duration–perduration is

$$\chi_{\mathrm{dur}}(n_A, s_C) = \exp\!\left(n_A A_{\mathrm{rad}} + \frac{s_C}{6} C^*_{\mathrm{rad}}\right). \tag{49.5}$$

This coordinate is not introduced as an isolated label. Its origin is

$$\begin{aligned} \mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow \text{surviving extension} \longrightarrow \text{route} \\ \longrightarrow \text{ledger} \longrightarrow (n_A, s_C, \ldots) \longrightarrow \chi_{\mathrm{dur}}. \end{aligned} \tag{49.6}$$

The signatures of W, Z and H are typed quantities obtained through that chain; this chapter adopts them without selecting them from their terminal masses. In the established angular realization, the charged and neutral sectors satisfy

$$(n_A, s_C)_W = (94, -1), \qquad (n_A, s_C)_Z = (95, -1). \tag{49.7}$$

This assertion refers to the common angular component. The additional refinement coordinates of the General Mass Law are not eliminated unless the physical transducer proves their cancellation.

Theorem 49.2 (Weinberg defect in the physical-mass scheme of the angular chart)**.** *If W and Z are evaluated on the same scale section and share the refinement that accompanies equation (49.7), then*

$$\boxed{\frac{m_W^{\angle}}{m_Z^{\angle}} = \mathrm{e}^{-A_{\mathrm{rad}}} = \sqrt{D_A}, \qquad \left(\frac{m_W^{\angle}}{m_Z^{\angle}}\right)^2 = D_A.} \tag{49.8}$$

In the physical-mass scheme,

$$\boxed{\sin^2\theta_W^{\mathrm{OS,HMT}} = 1 - D_A = 0.22487088075284356981111590 35\ldots.} \tag{49.9}$$

Además,

$$\frac{m_W^{\angle}}{m_Z^{\angle}} = 0.88041417483316136701288854 59\ldots. \tag{49.10}$$

Proof. By equations (49.5) y (49.7),

$$\frac{\chi_{\mathrm{dur}}(94, -1)}{\chi_{\mathrm{dur}}(95, -1)} = \exp(-A_{\mathrm{rad}});$$

the coordinate C^* cancels because both sectors share $s_C = -1$. Squaring and using equation (49.4) yields D_A. The definition of physical masses $s_W^2 = 1 - m_W^2/m_Z^2$ yields equation (49.9). □

The principal content is the identity between two internal constructions: the determinant of the angular operator and the one-step difference in the realization W/Z. Promotion to a physical gauge selector requires an intertwiner that carries the sheets of T to the neutral basis (W^3, B) and demonstrates which refinements are preserved or cancel.

49.4 Gauge couplings in rationalized normalization

We define the dimensionless gauge coupling

$$e_g := \sqrt{4\pi\alpha_{\mathrm{HMT}}} = 0.30282212087175264276624426 89\ldots. \tag{49.11}$$

e_g must not be confused with a dimensional charge section e_{int}: the former is a coupling in natural units; the latter lives in the charge line of Dimensional Mechanics.

Let

$$s_W^2 = 1 - D_A, \qquad c_W^2 = D_A. \tag{49.12}$$

The convention electrodebil racionalizada to level of arbol gives

$$g = \frac{e_g}{s_W} = 2\sqrt{\frac{\pi\alpha_{\mathrm{HMT}}}{1-D_A}} = 0.63858834273345742836470038 09\ldots, \tag{49.13}$$

$$g' = \frac{e_g}{c_W} = 2\sqrt{\frac{\pi\alpha_{\mathrm{HMT}}}{D_A}} = 0.34395416331085024293623192 57\ldots, \tag{49.14}$$

$$\frac{g'}{g} = \sqrt{D_A^{-1} - 1} = 0.53861641419660935949966109 33\ldots. \tag{49.15}$$

Proposition 49.3 (Tree-level custodial relation)**.** *At the same interface,*

$$\rho_{\mathrm{EW}}^{(0)} := \frac{(m_W^{\angle})^2}{(m_Z^{\angle})^2 c_W^2} = 1. \tag{49.16}$$

Proof. By equations (49.8) y (49.12), both the relative numerator and c_W^2 are D_A. □

The equations equations (49.13) y (49.14) are exact compositions once the physical mass scheme, rationalization, and scale have been declared. They do not assert that a change of renormalization scheme leaves their numerical values unchanged.

49.5 Fermi Constant in the Approximation at Tree Level

In natural units, integration of the charged propagator at low energy yields

$$\frac{G_F^{(0)}}{\sqrt{2}} = \frac{g^2}{8m_W^2}. \tag{49.17}$$

Substituting equation (49.13) gives the composition

$$\boxed{G_F^{(0)} = \frac{\pi\alpha_{\mathrm{HMT}}}{\sqrt{2}(1-D_A)m_W^2}.} \tag{49.18}$$

By adopting the previously obtained mass

$$m_W^{\mathrm{HMT}} = 80.38159255022 1\ldots\ \mathrm{GeV}, \tag{49.19}$$

the terminal evaluation is

$$\boxed{G_F^{(0)} = 1.1157162817659203186621784 \times 10^{-5}\ \mathrm{GeV}^{-2}.} \tag{49.20}$$

The difference with respect to a renormalized Fermi constant is not used to choose any coefficient. Under the convention

$$G_F = \frac{\pi \alpha_{\mathrm{HMT}}}{\sqrt{2}(1 - D_A) m_W^2 (1 - \Delta r)}, \tag{49.21}$$

the remaining obligation is to derive Δr from the internal sector of loops, states, and scale. Opening the observed value of G_F to define Δr would be a calibrated reconstruction, not a prediction.

49.6 Higgs Coupling Oriented Dependence

In the angular chart, the relevant routes are

$$(n_A, s_C)_H = (97, 9), \qquad (n_A, s_C)_W = (94, -1). \tag{49.22}$$

Therefore,

$$\boxed{\frac{m_H^{\angle}}{m_W^{\angle}} = \frac{\chi_{\mathrm{dur}}(97, 9)}{\chi_{\mathrm{dur}}(94, -1)} = \exp\left(3A_{\mathrm{rad}} + \frac{5}{3} C^*_{\mathrm{rad}}\right) = 1.558720872123255485 64\ldots.} \tag{49.23}$$

Here, C^* does not cancel: the scalar sector preserves the orientation that the determinant $D_A = \mathrm{e}^{-2A_{\mathrm{rad}}}$ does not distinguish.

Let us take the convention of the potential

$$V(H) = -\mu_H^2 H^\dagger H + \lambda_H (H^\dagger H)^2, \tag{49.24}$$

for which

$$m_H^2 = 2\lambda_H v^2, \qquad m_W^2 = \frac{g^2 v^2}{4}. \tag{49.25}$$

Corollary 49.4 (Oriented Higgs self-coupling)**.** *At the declared tree-level interface,*

$$\boxed{\lambda_H = \frac{\pi \alpha_{\mathrm{HMT}}}{2(1 - D_A)} \exp\left(6A_{\mathrm{rad}} + \frac{10}{3} C^*_{\mathrm{rad}}\right) = 0.12384791154824668046 62\ldots.} \tag{49.26}$$

Además,

$$G_F^{(0)} m_H^2 = \sqrt{2}\, \lambda_H. \tag{49.27}$$

Proof. Dividing the two equations in equation (49.25) gives $m_H^2/m_W^2 = 8\lambda_H/g^2$. With $g^2 = 4\pi\alpha_{\mathrm{HMT}}/(1 - D_A)$ and the square of equation (49.23), we obtain equation (49.26). On the other hand, $G_F^{(0)} = 1/(\sqrt{2}v^2)$ and $m_H^2 = 2\lambda_H v^2$ imply equation (49.27). □

The value of λ_H precedes the incorporation of radiative corrections and depends on the declared convention and scale. Its structural interest is that it separates two memories: the common gauge sector uses the even invariant D_A, whereas the Higgs route explicitly retains C^*.

49.7 Determinantal closure of the electroweak sector: mixing, couplings, and constitutive spectrum

The complete chain of this chapter is

$$\boxed{\begin{aligned}(A, C^*) &\longrightarrow T \longrightarrow \begin{cases} F(T)^2 & \longrightarrow (\widehat{\mu}, \widehat{\varepsilon}, \widehat{Z}, \widehat{c}), \\ \det T = D_A & \longrightarrow (s_W^2, c_W^2), \end{cases} \\ (D_A, \alpha_{\mathrm{HMT}}) &\longrightarrow (e_g, g, g'), \\ (D_A, \alpha_{\mathrm{HMT}}, m_W) &\longrightarrow G_F^{(0)}, \\ (A, C^*, D_A, \alpha_{\mathrm{HMT}}) &\longrightarrow \left(\frac{m_H}{m_W}, \lambda_H\right). \end{aligned}} \tag{49.28}$$

The figure always appears at the end. Neither $\sin^2\theta_W$, nor G_F, nor λ_H is introduced as a target value for selecting A, C^* or the route signatures.

Proposition 49.5 (Main Result)**.** *The same angular operator determines the vacuum through a rational function of its sheets and the electroweak defect through its determinant. The one-step difference between W and Z turns that determinant into $\sin^2\theta_W^{\mathrm{OS}} = 1 - D_A$; the Higgs route, in contrast, preserves the counterangle and preserves the orientation eliminated by the determinant.*

Remark 49.6 (Negative control). The Weinberg relation is refuted in its domain if the angular signatures W/Z do not differ only by $n_A : 94 \to 95$, if a refinement coordinate does not cancel at the declared interface, or if $(m_W^{\angle}/m_Z^{\angle})^2 \neq D_A$. Gauge promotion is blocked if no intertwiner with the basis (W^3, B) exists. The figures of g, g', G_F, λ_H change if the scheme or scale is altered without recording it. Using observed G_F or m_H to select Δr, the signatures, or C^* introduces feedback from the target value and invalidates the derivation. Conflating e_g with the dimensional charge constitutes a type error.

Logical Scope and Domain of Validity

Angular determinant, quotient W/Z and complementary Weinberg defect: *Exact internal theorem in the conditional angular chart*. Couplings $g, g', \rho_{\mathrm{EW}}^{(0)}$, Fermi and Higgs: *Exact composition at the tree-level electroweak interface*. The gauge-basis intertwiner and the internal correction Δr: *Open frontier with a refutation criterion*. Fermi and Higgs are not independent constants selected without target values: they are exact compositions using the signatures, the quantity m_W and the declared tree-level convention. Subsequent conventional values are *External metrological comparison*.

49.8 Involution of leaves in 4 representations

The involution $C^* \mapsto -C^*$ organizes four distinct responses:

$$\begin{aligned} S_{\mathrm{bi}}(A, -C^*) &= S_{\mathrm{bi}}(A, C^*), \\ \Gamma_{6\to 8}(A, -C^*) &= -\Gamma_{6\to 8}(A, C^*), \\ (\widehat{\mu}, \widehat{\varepsilon}) &\longleftrightarrow (\widehat{\varepsilon}, \widehat{\mu}), \\ \widehat{c} &\longmapsto \widehat{c}, \qquad D_A \longmapsto D_A. \end{aligned} \tag{49.29}$$

The bilayer information is even; the areal orientation is odd; the two constitutive quantities form a doublet, and the determinants remain fixed. This parity table precedes any interpretation as a physical symmetry.

49.9 Involutive rational transformation in the CKM parameter space

Let

$$M_{\mathrm{CKM}} = \begin{pmatrix} 2 & -5 & 28 \\ 0 & 7 & -25/2 \\ 1 & -20 & -2/3 \end{pmatrix}, \qquad \det M_{\mathrm{CKM}} = -\frac{3857}{6}. \tag{49.30}$$

The inverse exists on $\mathbb{Q}$ and is

$$M_{\mathrm{CKM}}^{-1} = \begin{pmatrix} 1528/3857 & 3380/3857 & 801/3857 \\ 75/3857 & 176/3857 & -150/3857 \\ 6/551 & -30/551 & -12/551 \end{pmatrix}. \tag{49.31}$$

With

$$h = \frac{C^*}{6}, \qquad \Delta = \frac{180}{\pi}\Delta_4, \qquad \boldsymbol{\theta} = M_{\mathrm{CKM}}(A, h, \Delta)^T, \tag{49.32}$$

the odd coordinate enters in the direction

$$c_h = \begin{pmatrix} -5 \\ 7 \\ -20 \end{pmatrix}. \tag{49.33}$$

If $c_A = (2,0,1)^T$ and $c_\Delta = (28, -25/2, -2/3)^T$, the three columns (c_A, c_h, c_Δ) are precisely the basis transported by M_{CKM}. The second row of equation (49.31) is the covector ℓ_h that extracts the odd coordinate:

$$\ell_h c_A = 0, \qquad \ell_h c_h = 1, \qquad \ell_h c_\Delta = 0. \tag{49.34}$$

Theorem 49.7 (Reflexion CKM inducida by the sheet)**.** *Let*

$$D_h = \mathrm{diag}(1, -1, 1), \qquad \ell_h = \frac{1}{3857}\begin{pmatrix} 75 & 176 & -150 \end{pmatrix}. \tag{49.35}$$

The involution induced on the space of $\boldsymbol{\theta}$ is

$$\boxed{\mathcal{R}_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h M_{\mathrm{CKM}}^{-1} = I - 2c_h\ell_h.} \tag{49.36}$$

Satisfies

$$\mathcal{R}_{\mathrm{CKM}}^2 = I, \qquad \det \mathcal{R}_{\mathrm{CKM}} = -1, \qquad \mathcal{R}_{\mathrm{CKM}} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h. \tag{49.37}$$

Proof. Multiplication of equations (49.30) y (49.31) gives the identity; in particular, equation (49.34) proves that $c_h\ell_h$ is the rank-one projector onto $\mathbb{Q}c_h$ along $\mathrm{span}\{c_A, c_\Delta\}$. The exact product $\ell_h c_h = 1$ implies

$$(I - 2c_h\ell_h)^2 = I - 4c_h\ell_h + 4c_h(\ell_h c_h)\ell_h = I.$$

The operator fixes the hyperplane $\ker \ell_h = \mathrm{span}\{c_A, c_\Delta\}$ pointwise and changes the sign of c_h. Its eigenvalues are therefore $1, 1, -1$; hence $\det \mathcal{R}_{\mathrm{CKM}} = -1$ and $\mathrm{Tr}\, \mathcal{R}_{\mathrm{CKM}} = 1$. Finally,

$$\mathcal{R}_{\mathrm{CKM}} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h M_{\mathrm{CKM}}^{-1} M_{\mathrm{CKM}} = M_{\mathrm{CKM}} D_h,$$

which proves the entanglement identity. □

The explicit matrix is

$$\mathcal{R}_{\mathrm{CKM}} = \begin{pmatrix} 4607/3857 & 1760/3857 & -1500/3857 \\ -150/551 & 199/551 & 300/551 \\ 3000/3857 & 7040/3857 & -2143/3857 \end{pmatrix}. \tag{49.38}$$

Although $\mathcal{R}_{\mathrm{CKM}}$ is not an orthogonal reflection for the Euclidean product of the three angular coordinates, it is for the transported rational metric

$$G_{\mathrm{CKM}} = (M_{\mathrm{CKM}}^{-1})^T M_{\mathrm{CKM}}^{-1}, \qquad \mathcal{R}_{\mathrm{CKM}}^T G_{\mathrm{CKM}} \mathcal{R}_{\mathrm{CKM}} = G_{\mathrm{CKM}}. \tag{49.39}$$

Indeed, in the basis (c_A, c_h, c_Δ), the metric is the identity and the involution is D_h. Hence the term "reflection" has precise metric content and does not merely describe that $\mathcal{R}_{\mathrm{CKM}}^2 = I$. Phase $\delta_{\mathrm{CP}} = 9A$ remains fixed under this reflection. Therefore, $\mathcal{R}_{\mathrm{CKM}}$ is not physical CP conjugation, but rather the transport of HMT sheet inversion to mixing space.

The rational inverse of M_{CKM} recovers

$$A = \frac{1528\theta_{12} + 3380\theta_{23} + 801\theta_{13}}{3857}, \tag{49.40}$$

$$C^* = \frac{6(75\theta_{12} + 176\theta_{23} - 150\theta_{13})}{3857}. \tag{49.41}$$

The third coordinate is also recovered without loss:

$$\Delta = \frac{6\theta_{12} - 30\theta_{23} - 12\theta_{13}}{551}. \tag{49.42}$$

These equations are coordinate changes. They do not turn CKM into a retrospective cause of A, C^* or of γ_{HMT}.

As a terminal recognition, the previous constructor determines

$$(\theta_{12}, \theta_{23}, \theta_{13}, \delta_{\mathrm{CP}}) = (13.003313589509^\circ, 2.398056157332^\circ, 0.213977382244^\circ, 65.676173123554^\circ). \tag{49.43}$$

The rational reflection is proved before using these decimals.

Proposition 49.8 (Main Result)**.** *The transition* $6 \to 8$ *is first formalized through the inclusion* $\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8$*, from which* $90, 120$ *and the defect* $-1/12$ *are obtained. The six-trit word then provides the bijection* $729 \leftrightarrow 729$*, and* $\mathcal{J}_{6\to 8}$ *transports the two collective modes to the boundary. On that antecedent, area and the modular Hamiltonian exactly reconstruct the two families; thermofield-double purification determines the entanglement entropy, and the finite first law preserves the relative-entropy defect. In CKM, sheet inversion becomes a rational rank-one odd reflection.*

Remark 49.9 (Negative control). The initial genealogy fails if $\iota_{6,8}$ is not injective, if the counts are not $90/120$, if $\delta_{6,8}^{\mathrm{inc}} \neq -1/12$, if β_{729} is not bijective or if it is falsely presented as an additive isomorphism. Collective transport fails if $\mathcal{J}_{6\to 8} D_{\mathrm{inc}} \neq D_{\mathrm{area}} \mathcal{J}_{6\to 8}$. Reconstruction fails if the determinant of the boundary observables is not thirty or if equation (72.8) does not recover the occupations. The TFD fails if its partial trace is not ρ_A. The first law does not extend to finite changes without the relative entropy of equation (74.6). Type III_{λ_∂} is invalidated if a channel does not persist, if there is no compatible product or if the ratio group changes. The CKM reflection is refuted by any of $\mathcal{R}^2 \neq I$, $\det \mathcal{R} \neq -1$ or $\mathcal{R}M \neq MD_h$. A formula $\boldsymbol{\theta} = f(\gamma_{\mathrm{HMT}})$ without an intertwiner violates the typed independence of the two functional realizations of the common antecedent.

Logical Scope and Domain of Validity

Inclusion $H \subset O$, counts $90/120$, two normalizations of the defect $-1/12$, bijection of six trits $729 \leftrightarrow 729$, collective intertwiner, scale a_0, finite operators, area spectrum, TFD, oriented defect, local and finite first law, and CKM reflection: *Internally exact theorem with its explicit starting structures*. Classification III_{λ_∂}: *Theorem with explicit persistence hypotheses*. Interpretation of the thermofield-double copy as a physical exterior: *Conditional physical realization*. The magnitude γ_{HMT} is adopted as *Proved antecedent result*; it is not rederived in this volume.

The electroweak link starts from the same angular operator that produced the vacuum constitutive relations, but uses another functional.

To obtain μ, ε, Z, and c it was necessary to preserve the full spectrum. It was necessary to distinguish the two sheets.

The determinant does the opposite:

$$D_A = \det T = q_+ q_-.$$

By multiplying the eigenvalues, the determinant integrates the two orientations into a common invariant angular magnitude. It publishes the even part and reserves the leaf identity in the oriented memory.

By eso D_A is even under the inversion

$$C^* \longmapsto -C^*.$$

The sector W/Z has precisely that structure. The routes of W and Z are adjacent in the principal angular coordinate and share the same oriented coordinate. Upon forming the quotient, the contribution of C^* cancels.

Remains

$$\left(\frac{m_W}{m_Z}\right)^2 = D_A,$$

and therefore

$$\sin^2 \theta_W = 1 - D_A.$$

The identity reveals that the Weinberg angle is the complementary defect of the angular determinant.

The determinant measures the common part that survives when the two sheets are collapsed into their product. $1 - D_A$ measures the complementary part required for mixing.

It may be stated as follows: the vacuum preserves the entire response; the electroweak sector uses the even compression of that response.

The same angular antecedent produces two distinct functions:

- the complete functional calculus generates the constitutive relations;
- the determinant generates the mixing invariant.

This explains why the vacuum and the Weinberg angle are two distinct functional realizations of the same angular antecedent.

From that point onward, the couplings g and g' are, at the stated level, the two projections of the same rationalized electromagnetic coupling onto the sine and cosine directions of the mixing:

$$g^2 = \frac{4\pi\alpha_{\mathrm{HMT}}}{1 - D_A}, \qquad g'^2 = \frac{4\pi\alpha_{\mathrm{HMT}}}{D_A}.$$

The tree custodial identity

$$\rho_{\mathrm{EW}}^{(0)} = 1$$

states that the same angular partition organizes mass and coupling coherently.

The Fermi constant appears later as the effective low-energy response of the charged channel:

$$G_F^{(0)} = \frac{\pi \alpha_{\mathrm{HMT}}}{\sqrt{2}(1 - D_A) m_W^2}.$$

The Fermi constant appears as a composition of the fine structure, the angular defect, and the carrier scale W.

The Higgs sector introduces a decisive difference. Its route has an oriented coordinate distinct from the route of W, so C^* persists. The scalar self-coupling publishes the orientation reserved by the determinant.

The gauge sector is even: it uses D_A.

The scalar sector is oriented: it retains C^*.

This division is physically suggestive. Gauge fields organize the common part of the transformation; the scalar sector preserves the memory of the broken orientation.

Radiative corrections belong to a later level and must be constructed prospectively from the internal loops, states, and scales, with G_F as output and terminal evaluation. The causal skeleton is already present: vacuum, mixing, couplings, and Fermi response follow from different readings of the same enriched angular state.

49.10 Electroweak Angular Closure and Compatibility Conditions of the Gauge Transducer

Let

$$c_W = \sqrt{D_A}, \qquad s_W = \sqrt{1 - D_A}.$$

The rotation

$$\begin{pmatrix} Z \\ A \end{pmatrix} = \begin{pmatrix} c_W & -s_W \\ s_W & c_W \end{pmatrix} \begin{pmatrix} W^3 \\ B \end{pmatrix}$$

is orthogonal and preserves orientation. The identities

$$\left(\frac{m_W}{m_Z} \right)^2 = D_A, \qquad \sin^2 \theta_W = 1 - D_A$$

are closed in the angular chart. Gauge promotion requires that the transducer preserve the kinetic form, the charges, and the Ward identities; the correction Δr belongs to radiative dynamics and is not obtained by fitting it to G_F.

Chapter 50

Intrinsic derivation of G and contragredient reciprocity $G \leftrightarrow \hbar$: phase closure, Compton and Planck scales, and invariance of $G\hbar$

50.1 Causal composition of the phase, action, and length invariants in the derivation of G

Gravity is organized here into four strata that must not be merged:

$$\begin{aligned} \text{CT108 chronological structure and action lines} &\longrightarrow \text{periodicity selector } \theta_{108}^{\mathrm{circ}} \longrightarrow G_{108}, \\ \text{icosahedral incidence} &\longrightarrow V_{12} \xrightarrow{P_5} V_5 \xrightarrow{\Gamma_5} \mathrm{STF}_3 \xrightarrow{\Lambda(n)} \mathcal{H}_{\mathrm{TT}}(n), \\ \text{enriched holonomic route} &\dashrightarrow G_{\mathrm{hol}}, \\ \text{metrological chart} &\longrightarrow 6.67430 \times 10^{-11}\ \mathrm{m^3\,kg^{-1}\,s^{-2}}. \end{aligned} \tag{50.1}$$

The first line states a condition of periodicity that is intrinsic and exact. The second constructs the carrier and its trace-free transverse reduction. The third preserves an explicit construction boundary. The fourth is an evaluation in a declared decimal chart: it identifies the magnitude but does not select the gravitational character.

50.2 Gravitational magnitude line and chronological scale 108

Let $c_{\mathrm{int}} > 0$, $t_0 > 0$, $\ell_0 = c_{\mathrm{int}} t_0$ and a positive section $\hbar_a$ of the action line, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$. The dimensional transducer is

$$G_a(\theta) = \theta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a} = \theta \frac{c_{\mathrm{int}}^3 \ell_0^2}{\hbar_a}, \qquad \theta > 0. \tag{50.2}$$

The equality of the two expressions uses only $\ell_0 = c_{\mathrm{int}} t_0$, and $[G] = L^3 M^{-1} T^{-2}$. The dimension is fixed by the line; the mathematical problem is to select the dimensionless character θ.

The CT108 calendar defines

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi}{108 t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi} \ell_0. \tag{50.3}$$

For each action sheet, let

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2}. \tag{50.4}$$

Then, the reduced Compton wavelength coincides with the radius of the cycle:

$$\bar{\lambda}_{C,a} = \frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = R_{108}. \tag{50.5}$$

Theorem 50.1 (Uniqueness of the selector under the HMT periodicity condition)**.** *With the reduced convention $r_g = Gm/c_{\mathrm{int}}^2$ and the HMT periodicity premise that identifies the gravitational radius of the CT108 quantum with its phase radius, the closure condition*

$$r_{g,a}(\theta) = R_{108} \tag{50.6}$$

selects a unique positive solution,

$$\boxed{\theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi}\right)^2 = 295.4525715010569415303525\ldots.} \tag{50.7}$$

In that embodiment,

$$R_{108} = \bar{\lambda}_{C,a} = r_{g,a} = \ell_P^{\mathrm{circ}}. \tag{50.8}$$

Proof. By equations (50.2) y (50.4),

$$r_{g,a}(\theta) = \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta c_{\mathrm{int}} t_0^2 \omega_{108} = \theta \frac{\pi}{54} \ell_0.$$

Comparing it with $R_{108} = (54/\pi)\ell_0$ necessarily gives $\theta = (54/\pi)^2$. The equation is linear in θ and all the factors are positive, so the solution is unique. □

The equality $r_g = R_{108}$ does not follow from the dimensionality of equation (50.2). It is the explicit geometric condition of this HMT realization: action, Compton, and periodic return must determine the same length. The theorem proves that, once this structural condition is accepted, the character θ is fixed without using the SI value of G.

Remark 50.2 (Radius convention). The theorem uses the reduced gravitational radius Gm/c^2. If it is replaced by the Schwarzschild radius $2Gm/c^2$, the selector changes by a factor of two. The two expressions correspond to distinct geometric conditions, so the convention must be declared before the calculation.

50.3 Reciprocity $G \leftrightarrow \hbar$ and conservation of the Planck area

Corollary 50.3 (Planck family associated with the temporal periodicity of 108 phases)**.** *For* $G_a = G_a(\theta_{108}^{\mathrm{circ}})$,

$$\ell_P = \frac{54}{\pi}\ell_0, \qquad t_P = \frac{54}{\pi} t_0, \tag{50.9}$$

$$E_{P,a} = \frac{\hbar_a}{t_P} = \frac{\pi \hbar_a}{54 t_0} = \frac{h_a}{108 t_0}, \qquad \ell_P^2 = \frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = \theta_{108}^{\mathrm{circ}} \ell_0^2. \tag{50.10}$$

Además,

$$F_{P,a} = \frac{c_{\mathrm{int}}^4}{G_a}, \qquad P_{P,a} = \frac{c_{\mathrm{int}}^5}{G_a}, \qquad \rho_{P,a} = \frac{\hbar_a}{(\theta_{108}^{\mathrm{circ}})^2 c_{\mathrm{int}}^5 t_0^4}. \tag{50.11}$$

Proof. The first three identities follow from $\ell_P = R_{108}$, $t_P = \ell_P / c_{\mathrm{int}}$, and $h_a = 2\pi\hbar_a$. For the area,

$$\frac{G_a \hbar_a}{c_{\mathrm{int}}^3} = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^2 t_0^2 = \theta_{108}^{\mathrm{circ}} \ell_0^2.$$

The remaining expressions are the dimensional compositions of force, power, and mass per volume with the same section. □

Let

$$R_{\mathrm{act}} := \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}}. \tag{50.12}$$

Since the action appears in the numerator of the chronological mass and in the denominator of G,

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}, \qquad G_a \hbar_a = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^5 t_0^2. \tag{50.13}$$

Therefore, $\ell_P^2 = G_a\hbar_a/c^3$ does not change sheets. Gravity and action are reciprocally oriented, while area preserves the common geometry. This cancellation is the interface of confluence toward the area operator of the section 51.6. The second fundamental relation appears when action and gravity are compared.

In HMT, action measures how much occurs while simultaneously preserving the orientation of the realization. There is one section before the return and another after it. The phase may return accompanied by a different memory history. That difference is stored in the bidirectional ratio of the two action sections.

Gravity responds in a reciprocal manner.

The gravitational transducer has the form

$$G_a(\theta) = \theta\frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a}.$$

Action appears in the denominator. Therefore, if $\hbar$ is multiplied by a ratio R_{act} when the sheet changes, the gravitational constant is multiplied by the inverse ratio:

$$\frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}.$$

Action and gravity form a contragredient pair here: when one advances in one direction, the other exactly compensates for that displacement.

What remains invariant is

$$G_a\hbar_a.$$

And that is precisely the combination that determines the Planck area:

$$\ell_P^2 = \frac{G_a\hbar_a}{c_{\mathrm{int}}^3}.$$

Action remembers the sheet. Gravity responds to that memory. Area remains invariant.

This is an extraordinarily fertile idea. The Planck area emerges as the object that survives when action and gravity transform into one another reciprocally.

It may be stated as follows: $\hbar$ preserves the dynamical orientation; G preserves the geometric compensation; ℓ_P^2 preserves that on which both realizations agree.

The area is, therefore, a currency of exchange between quantum physics and geometry, because the bidirectional transformation of $\hbar$ and G selects exactly that combination as invariant.

This reciprocity affords another understanding of the relation between information and gravity. Information requires a distinction among states; action measures the cost of transition between them. Yet if that transition must acquire a geometry, the gravitational response changes inversely so as to keep the quantum of area stable.

Geometry incorporates phase information through an exact compensation.

From a Machian reading, this is already a highly suggestive result. A local magnitude of geometry is determined relationally by the orientation and the return of the complete state. The invariant area restricts that relational dependence and fixes its consistency.

The HMT version of the relational principle consists in something more precise than the maxim "matter determines geometry": the orientation of action and the gravitational response co-determine one another in such a way that elementary geometry remains invariant.

The action contains the history. Gravity adjusts the response. The area preserves the agreement.

The derivation of G takes that reciprocity to a much more concrete geometric condition.

Dimensional Mechanics first determines what type of object G can be. It fixes its magnitude line and dimensional homogeneity. Chronological closure then selects its value: dimension determines the class of magnitude, and closure determines its dimensionless coefficient.

The selection proceeds from the temporal periodicity of (108) phases.

The cycle 108 determines a frequency, a phase radius, and an energy. From that energy arises a chronological mass. And constructing the reduced Compton wavelength of that mass yields exactly the same radius as that of the cycle:

$$\bar{\lambda}_C = R_{108}.$$

Phase and matter are already stating the same length before G is introduced.

Then gravity comes into play. The reduced gravitational radius is constructed.

$$r_g = \frac{Gm}{c^2},$$

and gravitational closure is required to identify the phase radius, Compton length, and gravitational radius as a single structural scale:

$$r_g = R_{108} = \bar{\lambda}_C.$$

That condition uniquely selects

$$\theta_{108} = \left(\frac{54}{\pi}\right)^2.$$

In this way,

$$R_{108} = \bar{\lambda}_C = r_g = \ell_P.$$

The structural function of θ_{108} determines the significance of its terminal decimal: it shows what G is doing.

G appears as the coefficient required to make the four lengths published by these languages coincide:

- the lenguaje of the fase produce R_{108};
- the quantum language produces $\bar{\lambda}_C$;
- the gravitational language produces r_g;
- the lenguaje of Planck produce ℓ_P.

The gravitational constant is the mediator that prevents those four readers from separating.

Stated in more physical terms: G expresses how strongly geometry must respond for a quantum whose mass follows from the clock 108 to close upon its own phase.

It is the relation that makes possible for matter, phase, and geometry to be three compatible publications of the same event.

Here the Machian reading becomes stronger. The local gravitational scale is selected by a global cycle-closure condition. The local radius of a quantum acquires meaning when integrated into a complete periodicity. Inertia, phase, and geometry are determined relationally.

The demonstrated scope provides a concrete mathematical mechanism for a Machian reading: a local property—the gravitational coupling—is selected by the consistency of the global state. The other historical formulations of Mach's principle preserve their own domain.

Then comes the fifth dimension.

The scalar G fixes the gravitational intensity, and the carrier specifies its representational structure. HMT constructs a symmetric traceless tensor space of dimension five. That carrier admits five helicoidal weights:

$$+2, \quad +1, \quad 0, \quad -1, \quad -2.$$

They are the five natural degrees of freedom of a symmetric traceless tensor in three dimensions before the dynamical constraints of a specific theory are imposed.

That clarifies a point that is often confused. "Five components" designates the complete carrier, whereas the two helicities designate the transverse massless reduction in general relativity.

It means that the complete carrier has five irreducible coordinates. The dynamics then decides which part of that carrier is physical:

- in a massive spin-two realization, all five weights may survive;
- in a massless realization with gauge invariance, the transverse traceless projection eliminates the sectors ± 1 and 0;
- the helicities ± 2 remain.

Thus, HMT provides a space prior to the dynamical decision. It constructs the complete five-component carrier and contains, through the corresponding projection, its physical reduction to two helicities.

Beauty resides in the ordered coexistence of two statements:

- the spin-two geometry has a five-component carrier;
- massless gravitational radiation occupies a two-dimensional subspace.

Both statements form a coherent and precise reduction.

And that reduction preserves another central lesson: the scalar G fixes the common intensity, while the orientation information resides in the tensor carrier. The intensity resides in the constant, the helicities reside in the representation, and the complete genealogy brings magnitude and carrier together.

50.4 Genealogical domain of gravitational realization

The gravitational realization receives as its initial object a section of the discrete continuum already constructed by the composition

$$\mathrm{APP} \longrightarrow \mathrm{TRIT} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{TPK}}^{\mathrm{enr}} \longrightarrow C_{\mathrm{cont}}^{\mathrm{disc}}. \tag{50.14}$$

APP preserves the additive and multiplicative evaluations through residue, quotient and carry; TRIT determines the regime and orientation; the TPK incorporates the tritic phase selector without eliminating either of the two APP sheets, performs cardinal transport, preserves memory and realizes phase return without resetting the state. The dimensional transducer then acts on the surviving section of the continuum:

$$\mathfrak{G}_{108} : C_{\mathrm{cont}}^{\mathrm{disc}} \times \mathcal{L}_S^{+} \longrightarrow \mathcal{G}_{\text{HMT-MD}}, \qquad (x, \hbar_a) \longmapsto \big(G_a, R_{108}, m_{108,a}, \ell_{P,a}^{\prime,2}\big). \tag{50.15}$$

The cardinals 90/120, the periodicity 108, the action, and the angular pair enter with their genealogy preserved. No subsequent gravitational identification retrospectively selects these antecedents.

50.5 Gravitational Transducer and Chronological Selector of Periodicity

Let $c_{\mathrm{int}} > 0$, $t_0 > 0$, $\ell_0 = c_{\mathrm{int}} t_0$, and $\hbar_a \in \mathcal{L}_S^+$, with $a \in \{\mathrm{pre}, \mathrm{ret}\}$. The dimensional transducer is

$$G_a(\theta) = \theta \frac{c_{\mathrm{int}}^5 t_0^2}{\hbar_a} = \theta \frac{c_{\mathrm{int}}^3 \ell_0^2}{\hbar_a}, \qquad \theta > 0. \tag{50.16}$$

The chronology cyclic of 108 states determina

$$T_{108} = 108 t_0, \qquad \omega_{108} = \frac{2\pi_{\mathrm{HMT}}}{108 t_0}, \qquad R_{108} = \frac{c_{\mathrm{int}}}{\omega_{108}} = \frac{54}{\pi_{\mathrm{HMT}}} \ell_0. \tag{50.17}$$

The chronological quantum and its associated mass are

$$E_{108,a} = \hbar_a \omega_{108}, \qquad m_{108,a} = \frac{E_{108,a}}{c_{\mathrm{int}}^2}. \tag{50.18}$$

The reduced Compton wavelength satisfies

$$\bar{\lambda}_{C,a} = \frac{\hbar_a}{m_{108,a} c_{\mathrm{int}}} = R_{108}. \tag{50.19}$$

Theorem 50.4 (Uniqueness of the gravitational periodicity selector)**.** *Under the reduced convention $r_g = Gm/c_{\mathrm{int}}^2$, the condition $r_{g,a}(\theta) = R_{108}$ has the unique positive solution*

$$\boxed{\theta_{108}^{\mathrm{circ}} = \left(\frac{54}{\pi_{\mathrm{HMT}}} \right)^2.} \tag{50.20}$$

The corresponding realization identifies structurally

$$R_{108} = \bar{\lambda}_{C,a} = r_{g,a} = \ell_P^{\mathrm{circ}}. \tag{50.21}$$

Proof. By equations (50.16) y (50.18),

$$r_{g,a}(\theta) = \frac{G_a(\theta) m_{108,a}}{c_{\mathrm{int}}^2} = \theta \frac{\pi_{\mathrm{HMT}}}{54} \ell_0.$$

Equality with $R_{108} = (54/\pi_{\mathrm{HMT}})\ell_0$ imposes $\theta = (54/\pi_{\mathrm{HMT}})^2$. Linearity in θ and positivity of the factors determine uniqueness. □

In the chart in which $c_{\mathrm{int}} = (\mu\varepsilon)^{-1/2}$, the transducer assumes the form

$$\boxed{G_a = \left(\frac{54}{\pi_{\mathrm{HMT}}} \right)^2 \frac{t_0^2}{\hbar_a (\mu\varepsilon)^{5/2}}.} \tag{50.22}$$

The constitutive product $\mu\varepsilon$ governs the causal cone and the gravitational scale; the quotient $Z^2 = \mu/\varepsilon$ preserves the impedance orientation.

50.6 Bidirectional Covariance of Gravity and Action

We define

$$R_{\mathrm{act}} = \frac{\hbar_{\mathrm{pre}}}{\hbar_{\mathrm{ret}}}. \tag{50.23}$$

The chronological mass and the gravitational coupling transform contragrediently:

$$\frac{m_{108,\mathrm{pre}}}{m_{108,\mathrm{ret}}} = R_{\mathrm{act}}, \qquad \frac{G_{\mathrm{pre}}}{G_{\mathrm{ret}}} = R_{\mathrm{act}}^{-1}. \tag{50.24}$$

Its product remains fixed:

$$\boxed{G_a\hbar_a = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^5 t_0^2, \qquad \ell_P^2 = \frac{G_a\hbar_a}{c_{\mathrm{int}}^3} = \theta_{108}^{\mathrm{circ}} \ell_0^2.} \tag{50.25}$$

The action preserves the orientation of the sheet; the area of Planck preserves the geometry common of both orientationes.

Theorem 50.5 (Chart independence of the sections h and G)**.** *Let u_L, u_T, u_S be positive bases of the dimensional lines of length, time and action, and replace them by*

$$u'_L = \lambda_L u_L, \qquad u'_T = \lambda_T u_T, \qquad u'_S = \lambda_S u_S, \qquad \lambda_L, \lambda_T, \lambda_S > 0.$$

The coordinates of the same sections satisfy

$$c'_{\mathrm{int}} = \frac{\lambda_T}{\lambda_L} c_{\mathrm{int}}, \qquad t'_0 = \frac{t_0}{\lambda_T}, \qquad \hbar'_a = \frac{\hbar_a}{\lambda_S}, \qquad G'_a = \frac{\lambda_S \lambda_T^3}{\lambda_L^5} G_a. \tag{50.26}$$

For the induced basis $u_G = u_L^5 u_T^{-3} u_S^{-1}$ one obtains

$$\hbar'_a u'_S = \hbar_a u_S, \qquad G'_a u'_G = G_a u_G. \tag{50.27}$$

Consequently, $h_a = 2\pi_{\mathrm{HMT}}\hbar_a$, $G_a = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^5 t_0^2/\hbar_a$ and $G_a\hbar_a = \theta_{108}^{\mathrm{circ}} c_{\mathrm{int}}^5 t_0^2$ are identities of sections, not equalities dependent on a choice of units. The metrological chart publishes their numerical coordinates after the HMT–MD construction.

Proof. The first three transformations of (50.26) are the contragredient law of coordinates in $L \otimes T^{-1}$, T and S. Substituting them into (50.16) produces the fourth. The basis of the gravitational line transforms by the inverse factor, proving (50.27). The scalars π_{HMT} and $\theta_{108}^{\mathrm{circ}}$ are dimensionless and remain invariant. □

Chapter 51

HMT derivation of the Barbero–Immirzi parameter and minimum area: hexad–octad incidence, 90/120 channels and spectrum of the area operator

51.1 Hexad–Octad Incidence Morphism and Conservation of the Oriented Channels 90/120

With the dodecad and the alignment of the section 17.1.6 fixed, let H be a hexad in the HMT coordinates, let $\ell(H) \subset D$ be its image, and let $O_H = \iota_D(\ell(H))$ be its unique lift. Marking a point and a pair of points of the residual hexad yields

$$F_6(H) = \ell(H) \times \binom{\ell(H)}{2}, \qquad |F_6| = 6\binom{6}{2} = 90.$$

If the marked point can traverse the octad:

$$F_8(H) = O_H \times \binom{\ell(H)}{2}, \qquad |F_8| = 8\binom{6}{2} = 120.$$

The inclusion $\ell(H) \hookrightarrow O_H$ induces the incidence morphism

$$\mathcal{I}_{6\to 8} : F_6(H) \hookrightarrow F_8(H).$$

Normalizing the difference by the chosen factor $24\binom{6}{2}$ yields

$$\boxed{\frac{90-120}{24\binom{6}{2}} = \frac{6-8}{24} = -\frac{1}{12}.}$$

The equality is a normalized defect of the combinatorial interface $6 \to 8$. The factor $24\binom{6}{2}$ forms part of the definition of this normalization; the inclusion alone determines the difference -30. The operator $\mathcal{I}_{6\to 8}$ has marked incidence configurations as its domain; it is neither the transverse extractor of the dodecaphase state nor the family of angular moments.

51.2 Dodecaphase fundamental chain and hexad–octad functional

The active incidence is constructed before any gravitational realization. Let

$$H_{\mathrm{act}} = \{1, 2, 4, 5, 7, 8\}, \qquad \mathcal{P}_2(H_{\mathrm{act}}) = \{A \subset H_{\mathrm{act}} : |A| = 2\}.$$

Then

$$|H_{\mathrm{act}}| = 6, \qquad |\mathcal{P}_2(H_{\mathrm{act}})| = 15,$$

and the incidences before and after enlargement have cardinalities

$$\mathcal{F}_{90} = H_{\mathrm{act}} \times \mathcal{P}_2(H_{\mathrm{act}}), \qquad |\mathcal{F}_{90}| = 90,$$

$$\mathcal{F}_{120} = \{1, \ldots, 8\} \times \mathcal{P}_2(H_{\mathrm{act}}), \qquad |\mathcal{F}_{120}| = 120.$$

These two cardinalities are outputs of the phase rule; they are neither angles nor parameters supplied by the physical realization.

Denote by $C_{12} = \mathbb{Z}/12\mathbb{Z}$ the temporal record of TPK and by ∂_{ret} its unique return seam per turn. In the free module of oriented events, consider the fundamental chain

$$c_{12}^{+} = \sum_{j \in C_{12}} [j, \mathcal{F}_{90}] - [\partial_{\mathrm{ret}}, \mathcal{F}_{120}]. \tag{51.1}$$

The sum contains exactly the twelve sectors of the wheel; the second term is unique because one turn has a single closure seam. Its sign is the boundary sign. The bidirectional involution sends c_{12}^{+} to $c_{12}^{-} = -c_{12}^{+}$: it changes the orientation of the chain without altering its absolute multiplicities or its incidence types.

For $m \in \{90, 120\}$, let

$$S_m(q) = \frac{q^m}{1 - q^{3m}}.$$

The return readout $\mathscr{R}$ is defined on the generators of (51.1) by

$$\mathscr{R}([j, \mathcal{F}_{90}]) = S_{90}, \qquad \mathscr{R}([\partial_{\mathrm{ret}}, \mathcal{F}_{120}]) = S_{120}.$$

The first equality is constant on C_{12} by covariance under phase rotation; the second has a different domain and acts only at the enlarged seam. By linearity,

$$\boxed{\mathscr{R}(c_{12}^{+}) = 12S_{90} - S_{120}.} \tag{51.2}$$

Thus the coefficients $12 : -1$ are the image of the fundamental chain: twelve phase cells and one oriented boundary. They are not selected through the conventional value of the Barbero–Immirzi parameter, through a decimal comparison, or by prescribing in advance the pole coefficient to be calculated next.

Theorem 51.1 (Pole coefficient of the dodecaphase chain)**.** *The functional $F(q) = \mathscr{R}(c_{12}^{+})(q) = 12S_{90}(q) - S_{120}(q)$, determined by the twelve sectors and their oriented seam, has coefficient $1/24$ for $(1-q)^{-1}$. Its complex residue at $q = 1$ is $-1/24$. The pole coefficient is an output of the already constructed functional.*

Proof. For a functional with a simple pole at $q = 1$, write

$$p_1(F) := \lim_{q \uparrow 1} (1 - q) F(q).$$

The identity

$$1 - q^{3m} = (1 - q) \sum_{j=0}^{3m-1} q^j$$

implies

$$p_1(S_m) = \lim_{q \uparrow 1} \frac{q^m}{\sum_{j=0}^{3m-1} q^j} = \frac{1}{3m}.$$

By linearity,

$$p_1\big(\mathscr{R}(c_{12}^{+})\big) = \frac{12}{270} - \frac{1}{360} = \frac{48 - 3}{1080} = \frac{1}{24}.$$

These equalities are taken in $\mathbb{Q}$. The complex residue is the coefficient of $(q-1)^{-1}$, so that

$$\operatorname*{Res}_{q=1} \mathscr{R}(c_{12}^{+})(q) = -p_1\big(\mathscr{R}(c_{12}^{+})\big) = -\frac{1}{24}.$$

□

The Diophantine equation

$$\frac{a}{270} - \frac{b}{360} = \frac{1}{24} \quad \Longleftrightarrow \quad 4a - 3b = 45$$

remains a subsequent arithmetic certificate. On its own, it admits the family $(a, b) = (12 + 3t, 1 + 4t)$; the chain (51.1) eliminates that ambiguity before the calculation, since changing $(12, 1)$ alters the multiplicity of the orbit or its seam and therefore no longer represents a fundamental TPK turn.

With the conjugate channels $q_\pm$ already generated by the angular branch, one finally obtains

$$\mathscr{R}(c_{12}^{+})(q_-) - \mathscr{R}(c_{12}^{+})(q_+) = 12\Delta S_{90} - \Delta S_{120}.$$

This is the internal input of the hexadic–octadic functional. Its evaluation as the Barbero–Immirzi parameter and its insertion into the area operator are subsequent publications: they do not participate in the selection of c_{12}^{+}, 90/120, $12 : -1$ or $1/24$.

Falsifiers. The construction is refuted if the phase census does not yield twelve sectors, if one turn contains more than one seam, if the incidences do not have cardinalities 90 and 120, if the involution does not reverse the entire chain, or if the exact coefficient of $(1 - q)^{-1}$ in its image differs from $1/24$.

The transition from a hexad to an octad combines three structures of distinct types: a finite incidence, two Lambert series associated with the channels $q_\pm$, and an identification with the real parameter of the Holst action. The three are articulated through the incidence, the angular functional, and the areal dictionary into the geometry of the Ashtekar–Barbero connection developed in this same residence.

51.3 Tritic derivation of the cardinalities 90/120 and subsequent realization in hexad–octad incidence

Let H be a set of six points and let O be a set of eight points containing a distinguished copy of H. Consider

$$\mathcal{F}_6 = H \times \binom{H}{2}, \qquad \mathcal{F}_8 = O \times \binom{H}{2}.$$

The inclusion distinguished $H \hookrightarrow O$ induce

$$\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8, \qquad (h, \{h_1, h_2\}) \longmapsto (h, \{h_1, h_2\}).$$

This incidence morphism is the combinatorial antecedent of the cardinals 90/120; it is neither the dodecaphasic extractor nor an angular series.

Theorem 51.2 (Cardinalities of the Inclusion)**.**

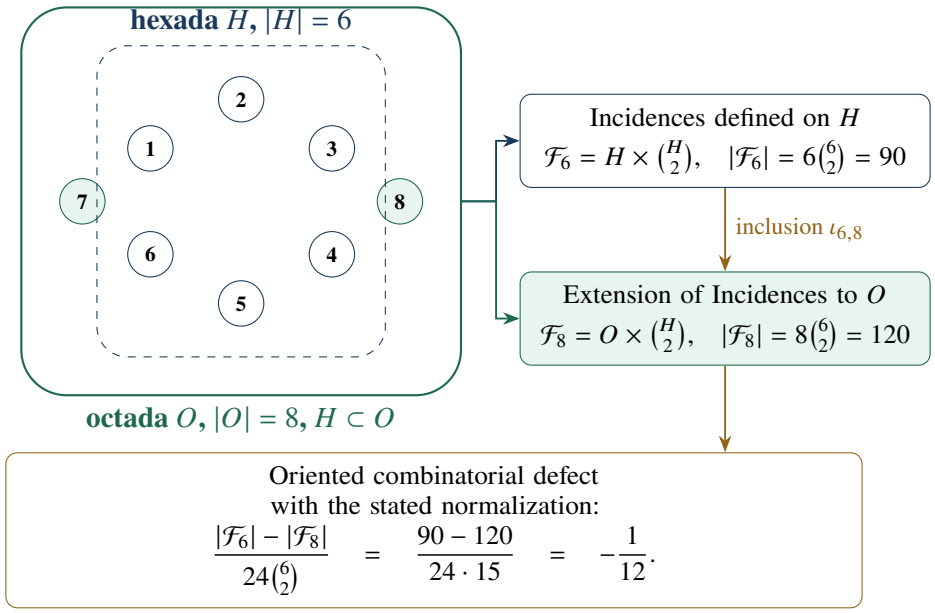
$$|\mathcal{F}_6| = 6\binom{6}{2} = 90, \qquad |\mathcal{F}_8| = 8\binom{6}{2} = 120.$$

The normalized difference by twenty-four coordinates is

$$\frac{90 - 120}{24\binom{6}{2}} = -\frac{1}{12}.$$

Proof. Each element of the first coordinate can be combined with any of the fifteen pairs of H. The multiplication principle gives the two cardinalities; the last identity follows by substituting $\binom{6}{2} = 15$. □

The initial indices of the angular hierarchy are thus associated with two incidence spaces: 90 configurations on the hexad and 120 on the ambient octad. The quotient $-1/12$ is a combinatorial identity of this normalization.



This identity belongs to the incidence map. It does not identify the dodecaphase extractor, the tower semigroup, or the angular functional.

Figure 51.1: Inclusion of a distinguished subset of six elements in one of eight elements and incidence counts. The cardinals 90 and 120 do not merge the dodecaphase extractor, the angular functional or the tower semigroup.

51.4 Lambert Series Associated with the 2 Incidence Sectors

For $0 < q < 1$, we define simultaneously

$$S_{90}(q) = \frac{q^{90}}{1 - q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1 - q^{360}}, \qquad \Delta S_m = S_m(q_-) - S_m(q_+).$$

Geometric expansions

$$\Delta S_{90} = \sum_{j \geq 0} s_{90+270j}, \qquad \Delta S_{120} = \sum_{j \geq 0} s_{120+360j}$$

place both terms within the global semigroup of section 91.8.

The angular functional associated with the transition $6 \to 8$ is

$$K_{6\to 8} = 12\Delta S_{90} - \Delta S_{120},$$

and its precedence has been fixed by the fundamental dodecaphasic chain: the twelve sectors and the unique oriented seam first produce the weight $12 : -1$. The coefficient of $(1 - q)^{-1}$, equal to $1/24$, is then calculated as an exact output; the Diophantine equation that follows certifies the already generated pair and does not select it. The resulting angular coordinate is

$$\Gamma_{6\to 8} = \frac{\pi A C^*}{180} + K_{6\to 8}.$$

At the point HMT,

$$\Delta S_{90} = 2.95169439297457621139847987861 \times 10^{-4},$$
$$\Delta S_{120} = 1.96835112502951720093738706217 \times 10^{-5},$$
$$\frac{\pi A C^*}{180} = 0.27048532293414007846558645879 0\ldots,$$

and, therefore,

$$\boxed{\Gamma_{6\to 8} = 0.27400767269445927474725526077398041940\ldots.}$$

The tables computed with the conjugate angular coordinate C^* rounded to fifteen decimal places give 0.2740076726944593 in double-precision arithmetic; the preceding value is the multiprecision evaluation of the complete regional phase.

51.5 Subsequent Diophantine certificate of the weights

The identity

$$\lim_{q\to 1^-}(1-q)\frac{q^m}{1-q^n} = \frac{1}{n}$$

assigns to the combination $aS_{90} - bS_{120}$, before its evaluation in the conjugate channels, the coefficient of $(1-q)^{-1}$

$$\frac{a}{270} - \frac{b}{360}.$$

Theorem 51.3 (Integer weights with pole coefficient $1/24$)**.** *The positive integer solutions of*

$$\frac{a}{270} - \frac{b}{360} = \frac{1}{24}$$

are

$$(a,b) = (12+3t, 1+4t), \qquad t \in \mathbb{Z}_{\geq 0}.$$

The pair $(12,1)$ *is the unique coordinatewise minimal solution and the unique one of minimal* ℓ^1 *norm.*

Proof. Multiplying by 1080 produces $4a - 3b = 45$. Modulo three, one obtains $a \equiv 0 \pmod 3$; writing $a = 3u$ yields $4u - b = 15$. Positivity implies $u = 4+t$, $b = 1+4t$, with $t \geq 0$. Therefore, $a + b = 13 + 7t$, which proves minimality. □

Primitivity $\gcd(a,b) = 1$ does not by itself select the minimal pair, since other primitive solutions exist. The fundamental TPK turn has already produced the weight $12 : -1$; the pole coefficient $1/24$, positivity and minimality form its subsequent arithmetic certificate. None of these objects is deduced from the decimal evaluation of $\Gamma_{6\to 8}$.

51.6 Monotonicity of the functional with respect to the conjugate angular coordinate

Para $m \in \{90, 120\}$,

$$S'_m(q) = \frac{m q^{m-1}(1 + 2q^{3m})}{(1 - q^{3m})^2} > 0.$$

Moreover,

$$\frac{\mathrm{d}q_-}{\mathrm{d}C} = \frac{\pi}{180} q_-, \qquad \frac{\mathrm{d}q_+}{\mathrm{d}C} = -\frac{\pi}{180} q_+.$$

Proposition 51.4 (Strict Monotonicity)**.** *For $1^\circ \le C \le 3^\circ$, the function $C \mapsto \Gamma_{6\to 8}(A, C)$ is strictly increasing. Consequently, every value in its image has at most one preimage in that interval.*

Proof. The derivative of each difference ΔS_m is positive. On the specified interval one obtains $\Delta S'_{120} < 5.35 \times 10^{-4}$, whereas $\pi A/180 > 0.1273$. Therefore, $\Gamma'(C) > 0.1267$. At $C = C^*$,

$$\Gamma'(C^*) = 0.1328995105618907\ldots.$$

□

Local injectivity excludes a second nearby angular coordinate with the same functional evaluation. This control neither constructs nor selects C^*: the conjugate angular coordinate has already been obtained in the preceding regional branch. The proposition only quantifies sensitivity of the downstream evaluation once A and C^* are fixed; it does not authorize inversion of $\Gamma_{6\to 8}$ or a physical value of γ_{BI} to redefine them.

51.7 Hexad–octad inclusion and associated functional realizations

Let us fix a set H of six points and a set O of eight points with a distinguished inclusion $j : H \hookrightarrow O$. In the Witt residence, H is a hexad of a dodecad and O its lifted octad; in this chapter only the already fixed inclusion is used, not the terminal value of Barbero–Immirzi. We write

$$\binom{H}{2} := \{P \subset H : |P| = 2\}, \qquad \left|\binom{H}{2}\right| = \binom{6}{2} = 15, \tag{51.3}$$

and we define two incidence spaces with distinct types:

$$\mathcal{F}_6 := H \times \binom{H}{2}, \qquad \mathcal{F}_8 := O \times \binom{H}{2}. \tag{51.4}$$

The inclusion of incidences is

$$\iota_{6,8} : \mathcal{F}_6 \hookrightarrow \mathcal{F}_8, \qquad (h, P) \longmapsto (j(h), P). \tag{51.5}$$

It is injective because j is injective and preserves the marked pair P.

Theorem 51.5 (Incidence and defect counts oriented)**.** *The two spaces of equation (51.4) satisfy*

$$|\mathcal{F}_6| = 6\binom{6}{2} = 90, \qquad |\mathcal{F}_8| = 8\binom{6}{2} = 120, \qquad |\mathcal{F}_8 \setminus \iota_{6,8}(\mathcal{F}_6)| = 30. \tag{51.6}$$

Normalization by the twenty-four coordinates of the dodecad–twenty-four pair and by the fifteen pairs of H produces

$$\boxed{\delta^{\mathrm{inc}}_{6,8} = \frac{|\mathcal{F}_6| - |\mathcal{F}_8|}{24\binom{6}{2}} = -\frac{1}{12}.} \tag{51.7}$$

The same fraction is obtained through the reciprocal functional associated with the incorporated memory,

$$\boxed{\delta^{\mathrm{rec}}_{6,8} = \frac{30}{120} - \frac{30}{90} = -\frac{1}{12}.} \tag{51.8}$$

They are two exact realizations of the same oriented defect, but have distinct domains and are not identified with $\zeta(-1)$ without an additional intertwiner.

Proof. The multiplicative principle applied to equation (51.4) gives $6 \cdot 15 = 90$ and $8 \cdot 15 = 120$. The image of $\iota_{6,8}$ has ninety elements, so the complement has thirty. Substitution into equation (51.7) gives $-30/(24 \cdot 15) = -1/12$, while equation (51.8) is $1/4 - 1/3 = -1/12$. □

The hexad–octad transition admits two functional realizations that are not deduced from one another. The algebraic diagram, formulated on the spaces that justify the counts, is

$$\begin{aligned} (H \overset{j}{\hookrightarrow} O) &\longmapsto (|\mathcal{F}_6|, |\mathcal{F}_8|) = (90, 120) \longmapsto \Gamma_{6\to 8} = \gamma_{\mathrm{HMT}}, \\ (h_6, o_8, t) = (6, 8, 3) &\longmapsto -\frac{o_8 - h_6}{t} = -\frac{2}{3}, \end{aligned} \tag{51.9}$$

where $-2/3$ is the coefficient of the third coordinate of row 13 of the CKM constructor. The first realization transforms the incidence into area and modular memory; the second transforms the same transition into angular-mixing parameters. $\boldsymbol{\theta}_{\mathrm{CKM}} = f(\gamma_{\mathrm{HMT}})$ is not postulated: both outputs preserve a common antecedent.

The morphism that determines the sectors 90/120 is $\iota_{6,8}$. The quantity γ_{HMT} has already been determined internally by the hexad–octad construction and is reused here without reconstructing it from its decimal representation. The operatorial consequences begin only after fixing the elementary scale a_0, which is defined below without using entropy or the terminal product $\gamma_{\mathrm{HMT}} a_0$.

51.8 Correspondence between the Nonadic Interior and the Boundary Degrees of Freedom

Let $\mathbb{T}_3 = \{0, 1, 2\}$. Every $x \in \mathbb{Z}/9\mathbb{Z}$ has a unique digit representation $x = x_0 + 3x_1$, with $x_i \in \mathbb{T}_3$, and every $y \in \mathbb{Z}/27\mathbb{Z}$ a unique representation $y = y_0 + 3y_1 + 9y_2$. Therefore

$$\mathcal{B} = (\mathbb{Z}/9\mathbb{Z})^3, \qquad \mathcal{B}_\partial = (\mathbb{Z}/27\mathbb{Z})^2, \qquad |\mathcal{B}| = |\mathcal{B}_\partial| = 3^6 = 729. \tag{51.10}$$

Equality of cardinalities is accompanied by the explicit map. If $x_j = r_{2j-1} + 3r_{2j}$ for $j = 1, 2, 3$, we define

$$\beta_{729}(x_1, x_2, x_3) = \big(r_1 + 3r_2 + 9r_3,\ r_4 + 3r_5 + 9r_6\big). \tag{51.11}$$

Proposition 51.6 (Genealogical bijection $729 \leftrightarrow 729$)**.** *The map $\beta_{729} : \mathcal{B} \to \mathcal{B}_\partial$ is bijective and preserves the ordered six-trit word. In general, it is not an isomorphism of additive groups: regrouping the digits changes where the carry is recorded.*

Proof. Extracting the six digits from three nonadic coordinates and grouping them into two triples is a permutation of the coordinates of $\mathbb{T}_3^6$. The positional decomposition is unique on both sides, so the operation has an inverse. The additive caveat is verified, for example, by adding words that generate a carry between r_3 and r_4: that boundary separates the two coordinates of order twenty-seven, but crosses two distinct coordinates in the nonadic packing. □

On the boundary torus $\mathcal{B}_\partial$, we take the block of vertices

$$A = \{0, 1, \ldots, 8\} \times \{0, 1, \ldots, 8\}. \tag{51.12}$$

Its oriented links crossing the boundary are separated by direction:

$$\partial A_{90} = \{((-1, j), (0, j)), ((8, j), (9, j)) : 0 \le j \le 8\}, \tag{51.13}$$

$$\partial A_{120} = \{((i, -1), (i, 0)), ((i, 8), (i, 9)) : 0 \le i \le 8\}, \tag{51.14}$$

where all coordinates are read modulo twenty-seven. Thus

$$\partial A = \partial A_{90} \sqcup \partial A_{120}, \qquad |\partial A_{90}| = |\partial A_{120}| = 18. \tag{51.15}$$

The subscripts 90, 120 label the channel provenance; they do not say that the boundary has ninety or one hundred and twenty links.

Theorem 51.7 (Law areal of the cut triadic)**.** *In the cubic graph $N \times N \times N$ with unit capacity, every cut between two opposite faces has capacity at least N^2, and a transverse layer attains that bound. For $N = 9$,*

$$\mathcal{A}_{\min} = 81, \qquad S_{\mathrm{tri}} = 81 \log 3. \tag{51.16}$$

Proof. There are N^2 lines of edges parallel to the normal direction, pairwise disjoint. Every cut must intersect each one, so its capacity is at least N^2. A single transverse layer contains exactly N^2 edges and attains the minimum. If each cut link carries a maximally mixed trit, its entropy is $\log 3$; additivity over the eighty-one links gives equation (51.16). □

The entropy S_{tri} measures the capacity of the cubic cut. The modular entropy of the thirty-six links of equation (51.15) measures another state and must not be equated with it.

51.9 Collective incidence entangler between interior and boundary

In the sum $\ell^2(\mathcal{F}_6) \oplus \ell^2(\mathcal{F}_8)$, we define

$$u_{90} = \frac{1}{\sqrt{90}} \sum_{f \in \mathcal{F}_6} (\delta_f, 0), \qquad u_{120} = \frac{1}{\sqrt{120}} \sum_{f \in \mathcal{F}_8} (0, \delta_f). \tag{51.17}$$

In $\ell^2(\partial A_{90}) \oplus \ell^2(\partial A_{120})$, let

$$v_{90} = \frac{1}{\sqrt{18}} \sum_{e \in \partial A_{90}} (\delta_e, 0), \qquad v_{120} = \frac{1}{\sqrt{18}} \sum_{e \in \partial A_{120}} (0, \delta_e). \tag{51.18}$$

The pairs (u_{90}, u_{120}) and (v_{90}, v_{120}) are orthonormal. Therefore there exists a unique isometry between the collective subspaces that satisfies

$$\mathcal{J}_{6\to 8} u_{90} = v_{90}, \qquad \mathcal{J}_{6\to 8} u_{120} = v_{120}. \tag{51.19}$$

Define

$$D_{\mathrm{inc}} = 90 |u_{90}\rangle\langle u_{90}| + 120 |u_{120}\rangle\langle u_{120}|, \tag{51.20}$$

$$D_{\mathrm{area}} = 90 |v_{90}\rangle\langle v_{90}| + 120 |v_{120}\rangle\langle v_{120}|. \tag{51.21}$$

Theorem 51.8 (Exact transport of the two labels)**.** *The map $\mathcal{J}_{6\to 8}$ is unitary between the two collective planes and intertwines the incidence and area operators:*

$$\boxed{\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\mathrm{area}} \mathcal{J}_{6\to 8}.} \tag{51.22}$$

Therefore, every polynomial combination of the labels 90, 120*, in particular the primitive combination* $12 : -1$*, is transported with the same coefficients.*

Proof. Orthonormality shows that $\mathcal{J}_{6\to 8}$ maps one orthonormal basis to another. In u_{90}, both sides of equation (51.22) equal $90v_{90}$; in u_{120}, both equal $120v_{120}$. Equality on a basis proves the identity. The functional calculus, in its polynomial form, preserves the intertwining. □

This map does not purport to inject ninety individual incidences into eighteen links: it transports exactly the two uniform modes and their spectral labels. Extending it to non-uniform fluctuations would require a new incidence map; the modular operator defined here only uses the collective subspace that has just been constructed.

51.10 Determination of the Elementary Scale of the Spectrum of the Area Operator

Let C^* the angular coordinate conjugate, expresada en grados, and fijemos

$$\theta_{\mathrm{clk}} = \frac{C^*}{6}\frac{\pi}{180}, \qquad \boxed{a_0 = \frac{1+2\cos(10^\circ)}{3}\,\theta_{\mathrm{clk}}.} \tag{51.23}$$

The factor preceding θ_{clk} is not a decimal correction. It is the normalized real character of the phase triplet

$$\frac{1}{3}\,\mathrm{Tr}\,\mathrm{diag}\left(1, \mathrm{e}^{\mathrm{i}\pi/18}, \mathrm{e}^{-\mathrm{i}\pi/18}\right) = \frac{1+2\cos(10^\circ)}{3}. \tag{51.24}$$

Thus, a_0 is the spectral mean of the angular structure on the oriented trit. It is positive, is fixed before the area operator, and is not selected from entropy. The subsequent identification $\gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}$ realizes the HMT output in the Ashtekar–Barbero connection [10, 68]; it does not reopen its derivation.

Remark 51.9 (Alcance of the simbolo a_0). In this chapter, $a_0 \equiv a_0^{\mathrm{area}}$ denotes exclusively the normalization of equation (51.23). It is neither the Bohr radius nor the initial cosmological scale factor, although those objects are traditionally written with the same symbol. No identity in this chapter allows one to substitute one for the other.

51.11 Areal Law of the Triadic Cut: Capacity $81\log 3$, Area Operator, Spectrum, and Collective Intertwiner of the Channels 90/120

The HMT identification of the functional $\Gamma_{6\to 8}$ with the Barbero–Immirzi coordinate is made on the same triadic boundary that supports the incidence (90/120). The interior and its boundary sheet have equal cardinality,

$$\mathcal{B} = (\mathbb{Z}/9\mathbb{Z})^3, \quad |\mathcal{B}| = 729, \qquad \partial\mathcal{B} = (\mathbb{Z}/27\mathbb{Z})^2, \quad |\partial\mathcal{B}| = 729,$$

by regrouping six trits into three nonadic coordinates or two coordinates of order twenty-seven.

Theorem 51.10 (Areal Law of Triadic Cutoff)**.** *In the cubic graph $N\times N\times N$ with unit capacity, the minimum cut between two opposite faces has capacity N^2. For $N = 9$,*

$$\mathcal{A}_{\min} = 81, \qquad S_{\mathrm{tri}} = \mathcal{A}_{\min}\log 3 = 81\log 3.$$

Proof. The N^2 lines parallel to the normal direction are edge-disjoint paths, so every cut intercepts them. A transverse layer contains exactly N^2 edges and attains the bound. Each triadic link contributes $\log 3$ to the entropy of a maximally mixed state. □

On the boundary torus 27×27, let A be the canonical block 9×9. Its boundary decomposes exactly into

$$\partial A = \partial A_{90} \sqcup \partial A_{120}, \qquad |\partial A_{90}| = |\partial A_{120}| = 18. \tag{51.25}$$

The horizontal links represent channel (90), and the vertical ones channel (120). This decomposition turns the pair of incidences into an operator decomposition of the boundary.

The areal entropy $S_{\mathrm{tri}} = 81 \log 3$ belongs to the maximally mixed state of the cut links. The bilayer entropy $S_{\mathrm{bi}}(y)$ of the definition 73.2 belongs to the normalized distribution between the two sheets; the two objects retain distinct domains.

Let $N = \mathrm{diag}(0, 1, 2)$ be the number operator of a tritic link. The areal realization declares the positive scale

$$\theta_{\mathrm{clk}} = \frac{C^*}{6}\frac{\pi}{180}, \qquad a_0 = \frac{1 + 2\cos(10^\circ)}{3}\,\theta_{\mathrm{clk}}, \qquad \gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}.$$

The formula for a_0 constitutes the starting structure of this realization; once that scale is fixed, the operator and its spectrum follow exactly.

Definition 51.11 (Area Operator HMT)**.** On the boundary sheet $\mathcal{H}_\partial = \bigotimes_{e\in\partial A} \mathbb{C}^3$, define

$$\widehat{\mathcal{A}}_{\mathrm{HMT}} = \gamma_{\mathrm{HMT}} a_0 \sum_{e\in\partial A} N_e. \tag{51.26}$$

Its spectrum in the canonical cut is

$$\mathrm{Spec}\,\widehat{\mathcal{A}}_{\mathrm{HMT}} = \{n\gamma_{\mathrm{HMT}} a_0 : 0 \le n \le 72\},$$

with multiplicities given by the coefficients of $(1 + z + z^2)^{36}$. Prolongation through compatible cuts produces the protected family $\mathcal{A}_n^{\mathrm{prot}} = n\gamma_{\mathrm{HMT}} a_0$.

The intertwiner that fixes normalization is constructed in the subspace of collective channels. Let u_{90}, u_{120} be the uniform unit vectors of the hexadic and octadic incidences, and let v_{90}, v_{120} be the uniform unit vectors of the two sets of links of (51.25). The map

$$\begin{aligned} \mathcal{J}_{6\to 8} :\ \mathrm{span}\{u_{90}, u_{120}\} &\longrightarrow \mathrm{span}\{v_{90}, v_{120}\}, \\ \mathcal{J}_{6\to 8} u_{90} = v_{90}, &\qquad \mathcal{J}_{6\to 8} u_{120} = v_{120} \end{aligned} \tag{51.27}$$

is an isometry between these collective subspaces. If

$$D_{\mathrm{inc}} = 90|u_{90}\rangle\langle u_{90}| + 120|u_{120}\rangle\langle u_{120}|, \qquad D_{\mathrm{area}} = 90|v_{90}\rangle\langle v_{90}| + 120|v_{120}\rangle\langle v_{120}|,$$

then

$$\boxed{\mathcal{J}_{6\to 8} D_{\mathrm{inc}} = D_{\mathrm{area}} \mathcal{J}_{6\to 8}.}$$

In particular, the primitive combination $12 : -1$ acts with the same coefficients before and after $\mathcal{J}_{6\to 8}$. This equality fixes the normalization dictionary that inserts $\gamma_{\mathrm{HMT}} = \Gamma_{6\to 8}$ into the Ashtekar–Barbero connection.

The passage from hexad to octad is an incidence structure transformation.

In passing from 6 to 8, the available pairs, the internal relations, and the way in which orientation can be preserved change. That transition generates an oriented defect. The cardinal variation realizes a turn in the mode of organization.

The same sheet inversion is expressed by

$$C^* \longmapsto -C^*.$$

But different readers respond in different ways to that inversion.

The hexad–octad functional leading to the Barbero–Immirzi parameter is odd: when the sheet is inverted, it changes sign. Geometric orientation is reversed.

Bilayer entropy, by contrast, is even: it assigns the same entropy to C^* and $-C^*$ when the probability distribution is observed. The total information may remain unchanged even though the orientation has been reversed.

CKM space realizes a third response. The inversion induces an exact rational reflection on the three angles:

$$R_{\mathrm{CKM}} = M_{\mathrm{CKM}}\,\mathrm{diag}(1,-1,1)\,M_{\mathrm{CKM}}^{-1},$$

with

$$R_{\mathrm{CKM}}^{2} = I, \qquad \det R_{\mathrm{CKM}} = -1.$$

This means that the change of sheet is transported to the mixing space as a true reflection. There exists an odd direction of rank one and a plane that remains fixed.

The counter-angle C^{*} is precisely the coordinate that changes. The phase constructed from A remains invariant. The transformation thus separates two memories:

- an orientation memory;
- a phase memory.

This provides a profound reading of CKM. The mixing angles are coordinates of a space acted upon by the same involution that already organized the hexad–octad transition.

The turn $6 \to 8$ supplies the orientation operation that CKM realizes in its own codomain; physical causality belongs to the corresponding transducer.

We then have three sister publications of the same transit:

1. **Geometric publication.** The Barbero–Immirzi parameter orients the quantum of area.
2. **Informational publication.** The reduced state and its modular Hamiltonian measure what information from that orientation remains on the boundary.
3. **Mixing publication.** The CKM reflection transforms the mixing coordinates and isolates their odd component.

γ_{BI}, entropy and the CKM angles remain distinct realizations of a common genealogical hinge. Unity resides in the antecedent prior to ramification. They share the hinge, but each preserves a distinct part of it.

This is one of the most beautiful expressions of the HMT methodology: the fundamental unit is recovered by tracing the genealogies backward until the common operation that generates distinct terminal results is found.

Gravity conserves the spin as the orientation of the area.

Information conserves the spin as memory of the state.

The mixture preserves the twist as a reflection of coordinates.

The same transformation «breathes» in three ways.

51.12 Typed distinction between Barbero–area, area–modular Hamiltonian, and Cartan–Holst realization

The derivation of γ_{BI}, of the minimal area, and of the spectrum of the area operator concludes in this chapter. The joint reconstruction of occupation and provenance through the boundary modular Hamiltonian, and the Palatini–Cartan–Holst realization, preserve their own domains, operators, and proofs in Part IV.

51.13 Hexad–octad incidence, Barbero–Immirzi parameter, and area spectrum

The areal derivation receives as antecedents the incidence inclusion $6 \to 8$, the TPK cardinals $90/120$, the normalized defect $-1/12$, and the spectral channels $q_{\pm}$. The hexad–octad functional determines the Barbero–Immirzi parameter and the normalization of the area operator. This residence contains the HMT derivation and the spectrum; the Palatini–Cartan–Holst realization occupies a subsequent residence in Dimensional Mechanics.

Let $H \subset O$, with $|H| = 6$ and $|O| = 8$, and preserve the marked pair of the hexad in the inclusion

$$\iota_{6,8} : \mathcal{F}_6 = H \times \binom{H}{2} \hookrightarrow \mathcal{F}_8 = O \times \binom{H}{2}. \tag{51.28}$$

The internal count gives

$$|\mathcal{F}_6| = 6\binom{6}{2} = 90, \qquad |\mathcal{F}_8| = 8\binom{6}{2} = 120, \qquad \frac{90-120}{24\binom{6}{2}} = -\frac{1}{12}. \tag{51.29}$$

Once π_{HMT}, the angle A and the unique counterangle C^* have been published, the two channels are

$$q_{\pm} = \exp\Big[-\frac{\pi_{\mathrm{HMT}}}{180}(A \pm C^*)\Big], \qquad 0 < q_+ < q_- < 1, \tag{51.30}$$

and their oriented-return series are

$$S_{90}(q) = \frac{q^{90}}{1-q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1-q^{360}}, \qquad \Delta S_m = S_m(q_-) - S_m(q_+). \tag{51.31}$$

The causal order of the coefficients is fixed in the temporal register of the TPK, before evaluating the pole coefficient. Let $C_{12} = \mathbb{Z}/12\mathbb{Z}$ be the dodecaphase wheel and let ∂_{ret} be its unique oriented return seam. In the free module of incidence events, the fundamental turn is

$$c_{12}^{+} = \sum_{j \in C_{12}} [j, \mathcal{F}_6] - [\partial_{\mathrm{ret}}, \mathcal{F}_8]. \tag{51.32}$$

The sign of the second term is the boundary sign. The bidirectional involution reverses the complete orientation, $c_{12}^{-} = -c_{12}^{+}$, without modifying the absolute multiplicities of the two incidence types. Define the return reader on the generators by

$$\mathscr{R}([j, \mathcal{F}_6]) = S_{90}, \qquad \mathscr{R}([\partial_{\mathrm{ret}}, \mathcal{F}_8]) = S_{120}. \tag{51.33}$$

Phase covariance makes the first image constant over the twelve sectors; the second acts only at the enlarged seam. By linearity,

$$\boxed{\mathscr{R}(c_{12}^{+}) = 12S_{90} - S_{120}.} \tag{51.34}$$

Thus, the weight $12 : -1$ is the image of the fundamental turn: twelve sectors and one oriented boundary. It does not arise from imposing $1/24$ beforehand, from a decimal comparison or from the conventional Barbero–Immirzi value.

Theorem 51.12 (Dodecaphase determination of the Barbero–Immirzi functional)**.** *The fundamental chain* (51.32) *determines the oriented pair* $(a, b) = (12, 1)$*. The coefficient of* $(1 - q)^{-1}$ *in its image is then* $1/24$*, as an exact output of the already constructed functional. Therefore, after evaluating the conjugate channels* $q_{\pm}$*, the dimensionless output is*

$$\boxed{\gamma_{\mathrm{HMT}} = \Gamma_{6\to 8} = \frac{\pi_{\mathrm{HMT}} A C^{*}}{180} + 12\Delta S_{90} - \Delta S_{120}.} \tag{51.35}$$

This formula receives the already generated angular pair and does not use the conventional value of the Barbero–Immirzi parameter as input.

Proof. The sum of (51.32) contains exactly the twelve sectors of C_{12}, while the return seam appears only once and with negative orientation. The reader (51.33) therefore produces (51.34), before any pole calculation. For each $m > 0$,

$$p_1(S_m) = \lim_{q\to 1}(1 - q)\frac{q^m}{1 - q^{3m}} = \frac{1}{3m}.$$

Consequently,

$$p_1\big(\mathscr{R}(c_{12}^{+})\big) = \frac{12}{270} - \frac{1}{360} = \frac{48 - 3}{1080} = \frac{1}{24}.$$

The coefficient p_1 is referred to $(1 - q)^{-1}$. In the complex coordinate $q - 1$,

$$\operatorname*{Res}_{q=1} S_m(q) = -\frac{1}{3m}, \qquad \operatorname*{Res}_{q=1} \mathscr{R}(c_{12}^{+})(q) = -\frac{1}{24}.$$

The subsequent Diophantine equation

$$\frac{a}{270} - \frac{b}{360} = \frac{1}{24} \quad \Longleftrightarrow \quad 4a - 3b = 45$$

has the positive integer solutions $(a, b) = (12 + 3t, 1 + 4t)$, $t \geq 0$; the unique minimal solution is $(12, 1)$. This count arithmetically certifies the pair that the fundamental orbit had already generated: any $t > 0$ alters the multiplicity of the sectors or the seam and ceases to represent one TPK turn. Finally, substituting $q_{\pm}$ into the oriented image and adding the previously generated angular component proves (51.35). □

The causal sequence is fixed without exchanging roles:

$$\begin{aligned} (\mathcal{F}_6 \hookrightarrow \mathcal{F}_8, C_{12}, \partial_{\mathrm{ret}}) &\longrightarrow (90, 120, -1/12, c_{12}^{+}) \\ &\longrightarrow \mathscr{R}(c_{12}^{+}) = 12S_{90} - S_{120}, \\ \mathscr{R}(c_{12}^{+}) &\longrightarrow p_1\big(\mathscr{R}(c_{12}^{+})\big) = \frac{1}{24}, \\ \big(\mathscr{R}(c_{12}^{+}), A, C^{*}, q_{\pm}\big) &\longrightarrow \Gamma_{6\to 8} = \gamma_{\mathrm{HMT}} \longrightarrow \widehat{\mathcal{A}}_{\mathrm{phys}}. \end{aligned} \tag{51.36}$$

The angular pair and its channels come from the preceding construction. Evaluation of the pole coefficient is a check of the return functional; the conjugate evaluation uses the previously generated angular coordinates. The subsequent realization in the Holst action recognizes the same dimensionless section; it does not intervene in its selection.

For the two boundary sectors, let

$$N_m = \sum_{e\in\partial A_m} N_e, \qquad m \in \{90, 120\}, \qquad \mathrm{Spec}(N_e) = \{0, 1, 2\}. \tag{51.37}$$

The physical area operator is written

$$\boxed{\frac{\widehat{\mathcal{A}}_{\text{phys}}}{\ell_P^2} = \gamma_{\text{HMT}} a_0 (N_{90} + N_{120}).} \tag{51.38}$$

On 36 links qutrit,

$$\text{Spec}(N_{90} + N_{120}) = \{0, 1, \dots, 72\}, \tag{51.39}$$

and the multiplicity of the eigenvalue n is the coefficient of z^n in $(1 + z + z^2)^{36}$. From here it follows

$$\text{Spec}\left(\frac{\widehat{\mathcal{A}}_{\text{phys}}}{\ell_P^2}\right) = \{n\gamma_{\text{HMT}} a_0 : 0 \le n \le 72\}. \tag{51.40}$$

51.14 Total Geometry and Origin Memory

The modular Hamiltonian of the boundary is

$$\boxed{K_A = -\log \rho_A = cI + \Delta_{\text{mod}}(90N_{90} + 120N_{120}).} \tag{51.41}$$

Let

$$N = N_{90} + N_{120}, \qquad D = 90N_{90} + 120N_{120}. \tag{51.42}$$

The transition matrix $\left(\begin{smallmatrix} 1 & 1 \\ 90 & 120 \end{smallmatrix}\right)$ has determinant 30, and its inverse reconstructs the sectors:

$$\boxed{N_{90} = 4N - \frac{D}{30}, \qquad N_{120} = \frac{D}{30} - 3N.} \tag{51.43}$$

The area publishes the total number of excitations; the modular Hamiltonian publishes their provenance sector. The joint pair reconstructs the complete occupation of the boundary.

51.15 Bilayer state and oriented information

Let $R = R^* = R^{-1}$ be the sheet involution and $y = C^*_{\text{rad}}$. The normalized state is

$$\boxed{\rho_y = \frac{e^{-yR}}{2\cosh y}.} \tag{51.44}$$

Its modular Hamiltonian and its entropy are

$$K_y = -\log \rho_y = \log(2\cosh y) I + yR, \tag{51.45}$$

$$S(\rho_y) = \log(2\cosh y) - y \tanh y. \tag{51.46}$$

The inversion $y \mapsto -y$ leaves entropy fixed and produces the oriented informational distance

$$\boxed{D(\rho_y \| \rho_{-y}) = 2y \tanh y.} \tag{51.47}$$

The even component measures the spectral distribution; the odd component measures the informational cost of reversing the orientation.

51.16 How much informational energy and gravitational cell of medium action

The periodicity of 108 states determines

$$t_P = \frac{54}{\pi} t_0, \qquad E_P = \frac{\hbar}{t_P} = \frac{h}{108 t_0}. \tag{51.48}$$

The thermal realization of the tritico clock satisfies

$$\boxed{E_P = k_B \Theta_{\mathrm{clk}} \log 3.} \tag{51.49}$$

For the horizon of radius R,

$$E_\Lambda(R) = \frac{c^4 R}{2G}, \qquad E_\Lambda(R) = T_H(R) S_H(R). \tag{51.50}$$

In the Planck cell,

$$\boxed{E_\Lambda = T_H S_H = \frac{E_P}{2} = \frac{k_B \Theta_{\mathrm{clk}} \log 3}{2}.} \tag{51.51}$$

Therefore,

$$\boxed{E_\Lambda t_P = \frac{\hbar}{2}, \qquad E_\Lambda T_{108} = \frac{h}{2}.} \tag{51.52}$$

Vacuum energy, area entropy, chronological temperature, and action share a single confluence cell with typed domains.

When $S_H / k_B = \pi$, the multiplicity efectiva satisfies

$$\Omega_{\mathrm{eff}} = e^{S_H / k_B} = e^{\pi}. \tag{51.53}$$

The hyperbolic Euler operator possesses

$$\mathrm{Spec}(e^{\pi H}) = \{e^{\pi}, e^{-\pi}\}. \tag{51.54}$$

Equality of the scalars establishes spectral confluence; the intertwiner between microscopic horizon multiplicity and Perron dynamics belongs to its specific physical residence.

51.17 Evaluation at the Pell scale and the constitutive Barbero–Immirzi functional

The relation between the vacuum response and the Catalan moment allows two levels of transport to be composed: the weighted depth of the quarter-turn character and the evaluation of the angular channels. The Pell scale distinguishes an argument of the family of moments; the vacuum channels instead receive the arguments determined by the angular pair. The Barbero–Immirzi functional is expressed on the latter through the same constitutive response and its inverse. The link is thus established between defined operations, preserving the position of each evaluation in the APP–TRIT–TPK construction.

51.17.1 Oriented moment and evaluation at the Pell unit

Write

$$G_{\mathrm{Cat}} := C_2(1) = \sum_{k \geq 0} \frac{(-1)^k}{(2k+1)^2}, \qquad \lambda_{\mathrm{P}} = 2 + \sqrt{3}, \qquad \rho_{\mathrm{P}} = 2 - \sqrt{3} = \lambda_{\mathrm{P}}^{-1}. \tag{51.55}$$

The constant G_{Cat} is the endpoint value of the moment constructed in (41.17). The pair $\lambda_{\mathrm{P}}, \rho_{\mathrm{P}}$ corresponds to the expanding and contracting orientations of the Pell unit: $(2+\sqrt{3})(2-\sqrt{3}) = 1$. The norm identity $2^2 - 3 \cdot 1^2 = 1$ fixes reciprocity. Specialization of the moment at ρ_{P} follows construction of its oriented character.

Differential equation (41.18), with zero condition at the origin, gives

$$\mathcal{D}C_2(s) = \arctan s, \qquad C_2(s) = \int_0^s \frac{\arctan t}{t}\, dt, \qquad \mathcal{D} = s\frac{d}{ds}. \tag{51.56}$$

Indeed, integrating $\mathcal{D}^2 C_2 = s/(1+s^2)$ with respect to ds/s produces $\arctan s$; a second integration produces the stated expression. The integrand extends continuously to $t = 0$ with value 1. The angular form of this integral allows exact determination of the evaluation at ρ_{P}.

Lemma 51.13 (Angular integral of the odd character)**.** *For* $0 < \theta \le \pi/4$,

$$-\int_0^\theta \log(\tan x)\, dx = \sum_{\substack{n\ge 1\\ n\ odd}} \frac{\sin(2n\theta)}{n^2}. \tag{51.57}$$

Proof. For $0 < a < 1$, the logarithm expansion inside the unit disk implies

$$\begin{aligned} L_a(x) &:= \log|1 - ae^{2ix}| - \log|1 + ae^{2ix}| \\ &= -2\sum_{\substack{n\ge 1\\ n\ \mathrm{odd}}} \frac{a^n \cos(2nx)}{n}. \end{aligned}$$

The series converges uniformly in x for every $a < 1$; termwise integration gives

$$-\int_0^\theta L_a(x)\, dx = \sum_{\substack{n\ge 1\\ n\ \mathrm{odd}}} \frac{a^n \sin(2n\theta)}{n^2}.$$

As $a \uparrow 1$, the quotient of moduli converges to $|1 - e^{2ix}|/|1 + e^{2ix}| = \tan x$ for $0 < x \le \theta$. The logarithm's singularity at the origin is integrable. To justify the limit, one may restrict to $a \ge 1/2$ and observe that

$$|1 - ae^{2ix}|^2 = (1-a)^2 + 4a\sin^2 x \ge 2\sin^2 x, \qquad 1 \le |1 + ae^{2ix}| \le 2$$

on $0 \le x \le \pi/4$. Together with the upper bound $|1 - ae^{2ix}| \le 2$, these inequalities give $|L_a(x)| \le c + |\log x|$ with a constant independent of a. Dominated convergence permits passage to the limit in the integral. For the integrated series, domination by $\sum n^{-2}$ applies. The two limits prove (51.57). □

Theorem 51.14 (Catalan–Pell evaluation)**.** *The oriented moment satisfies*

$$C_2(\rho_{\mathrm{P}}) = \frac{2}{3}G_{\mathrm{Cat}} - \frac{\pi}{12}\log\lambda_{\mathrm{P}}, \tag{51.58}$$

$$\mathcal{D}C_2(\rho_{\mathrm{P}}) = \frac{\pi}{12}, \qquad \mathcal{D}^2 C_2(\rho_{\mathrm{P}}) = \frac{1}{4}. \tag{51.59}$$

Proof. The substitution $t = \tan x$ in (51.56), followed by integration by parts, gives

$$C_2(\tan\theta) = \theta\log(\tan\theta) - \int_0^\theta \log(\tan x)\, dx. \tag{51.60}$$

The boundary term at zero vanishes because $x\log(\tan x) \to 0$. The tangent difference formula gives

$$\tan\frac{\pi}{12} = \tan\left(\frac{\pi}{4} - \frac{\pi}{6}\right) = \frac{\sqrt{3}-1}{\sqrt{3}+1} = 2 - \sqrt{3}.$$

It remains to evaluate the series in (51.57) at $\theta = \pi/12$. Let $\chi_{-4}(n) = (-1)^{(n-1)/2}$ for odd n. In the six odd classes modulo 12, one verifies

$$2\sin\frac{n\pi}{6} = \chi_{-4}(n) + 3\,\mathbf{1}_{3|n}\chi_{-4}(n/3). \tag{51.61}$$

The finite check is

n mod 12	1	3	5	7	9	11
$2\sin(n\pi/6)$	1	2	1	−1	−2	−1
$\chi_{-4}(n)$	1	−1	1	−1	1	−1
$3\mathbf{1}_{3\|n}\chi_{-4}(n/3)$	0	3	0	0	−3	0

and both sides are periodic modulo 12 on odd indices. Absolute convergence permits separation of summands and the substitution $n = 3m$ in the second term:

$$\sum_{\substack{n\geq 1\\ n\ \text{odd}}} \frac{\sin(n\pi/6)}{n^2} = \frac{1}{2}\sum_{n\ \text{odd}} \frac{\chi_{-4}(n)}{n^2} + \frac{3}{2}\sum_{m\ \text{odd}} \frac{\chi_{-4}(m)}{(3m)^2}$$
$$= \left(\frac{1}{2}+\frac{1}{6}\right) G_{\mathrm{Cat}} = \frac{2}{3}G_{\mathrm{Cat}}.$$

Sums without a lower bound in this expression run over positive integers. Substitution in (51.60), using $\log\rho_{\mathrm{P}} = -\log\lambda_{\mathrm{P}}$, yields (51.58). The first derivative follows from $\arctan\rho_{\mathrm{P}} = \pi/12$; the second from

$$\frac{\rho_{\mathrm{P}}}{1+\rho_{\mathrm{P}}^2} = \frac{1}{\rho_{\mathrm{P}}+\rho_{\mathrm{P}}^{-1}} = \frac{1}{4}.$$

□

The coefficient $2/3$ comes from the character decomposition in (51.61): restriction to multiples of 3 changes the depth weight by the factor 3^{-2}. Evaluation thus brings together the quarter-turn and dodecaphasic subdivision in an exact moment identity. The coefficients are fixed before any decimal comparison.

51.17.2 Composition of phase and weighted depth

The depth representation specifies what this evaluation preserves. On $\ell^2(\mathbb{N}_{>0})$, define

$$N\delta_n = n\delta_n, \qquad U_4\delta_n = i^n\delta_n, \qquad Q_4 = \frac{U_4 - U_4^*}{2i}.$$

For $0 < s < 1$, the operator $N^{-2}s^N Q_4$ is trace class, and

$$C_2(s) = \mathrm{Tr}(N^{-2}s^N Q_4). \tag{51.62}$$

This equality follows by evaluation on the basis δ_n; the diagonal entries are $s^n\sin(n\pi/2)/n^2$. The interchange $U_4 \leftrightarrow U_4^*$ reverses Q_4 and with it the oriented moment. Index n and weight s^n remain fixed.

Composition is performed before taking the trace. For $a \in \mathbb{Z}/4\mathbb{Z}$, let $B(s,a) = s^N U_4^a$. Since both factors are diagonal in the same basis,

$$B(s,a)B(t,b) = B(st, a+b), \qquad B(s,1)^4 = s^{4N}. \tag{51.63}$$

Phase return preserves the accumulated contraction. In particular, $B(\rho_{\mathrm{P}},1)^4 = \rho_{\mathrm{P}}^{4N}$, whose eigenvalue at depth n is ρ_{P}^{4n}. This realization gives an operator meaning to the contractive evaluation; the scalar moment sum aggregates depths after preserving their index and orientation. The constitutive arguments $s_\pm = q_\pm^{30}$ remain determined by the angular pair of (39.47). The preceding formulas contain no equality between those arguments and ρ_{P}.

51.17.3 Dodecaphasic incidence and return functional

The Barbero–Immirzi contribution uses angular transport and hexad–octad incidence. Let $\mathsf{H} \subset \mathsf{O}$ be a hexad and an octad with the hexad's marked pair preserved. The relevant flag sets are

$$\mathcal{F}_6 = \mathsf{H} \times \binom{\mathsf{H}}{2} \hookrightarrow \mathcal{F}_8 = \mathsf{O} \times \binom{\mathsf{H}}{2}, \qquad |\mathcal{F}_6| = 90, \quad |\mathcal{F}_8| = 120. \tag{51.64}$$

The cardinalities are $6\binom{6}{2}$ and $8\binom{6}{2}$; the same incidence preserves the normalized defect $(90-120)/(24\binom{6}{2}) = -1/12$. This count identifies the two sectors used by return, while the calendar determines their relative multiplicities.

For $m \in \{90, 120\}$, the tritic return on a contractive channel is

$$S_m(q) = \sum_{j \geq 0} q^{m+3mj} = \frac{q^m}{1 - q^{3m}}, \qquad 0 < q < 1. \tag{51.65}$$

Each term corresponds to the initial height m and j returns of length $3m$. The geometric series thus preserves both the initial height and return period. The dodecaphasic calendar $\mathbb{Z}/12\mathbb{Z}$ supplies twelve sectors and a unique oriented boundary incidence, denoted ∂_{ret}. In the free module of events, its fundamental chain is

$$c_{12}^{+} = \sum_{j \in \mathbb{Z}/12\mathbb{Z}} [j, \mathcal{F}_6] - [\partial_{\mathrm{ret}}, \mathcal{F}_8]. \tag{51.66}$$

The linear readout $\mathscr{L}_q$ assigns $S_{90}(q)$ to each generator $[j, \mathcal{F}_6]$ and $S_{120}(q)$ to the boundary generator. This yields

$$\mathscr{L}_q(c_{12}^{+}) = 12 S_{90}(q) - S_{120}(q). \tag{51.67}$$

The weights 12 and -1 are the chain's oriented multiplicities. The conjugate orientation satisfies $c_{12}^{-} = -c_{12}^{+}$, with the same incidence types.

Proposition 51.15 (Singular coefficient of the fundamental return)**.** *The coefficient of* $(1-q)^{-1}$ *in* $\mathscr{L}_q(c_{12}^{+})$ *is* $1/24$.

Proof. For every integer $m > 0$, the factorization $1 - q^{3m} = (1 - q) \sum_{j=0}^{3m-1} q^j$ gives

$$\lim_{q \uparrow 1} (1 - q) S_m(q) = \frac{1}{3m}.$$

Applying this identity to the functional already determined in (51.67) gives

$$\lim_{q \uparrow 1} (1 - q) \mathscr{L}_q(c_{12}^{+}) = \frac{12}{270} - \frac{1}{360} = \frac{1}{24}. \tag{51.68}$$

In the complex coordinate $q - 1$, the residue is $-1/24$. □

Singular evaluation verifies a consequence of incidence and tritic return. The proof order is fixed by (51.64)–(51.67); the singular coefficient is computed after the chain has been constructed.

51.17.4 Factorization through the constitutive operator

Retain the lifted angular chart of section 39.7. To make the angular conversion explicit, write

$$A_{\mathrm{deg}} = \frac{180x}{\pi}, \qquad C_{\mathrm{deg}}^{*} = \frac{180y}{\pi}, \qquad q_{\pm} = e^{-x \mp y}, \qquad s_{\pm} = q_{\pm}^{30}. \tag{51.69}$$

The orientation considered in (39.42) corresponds to $0 < y < x$; sheet interchange is expressed by $y \mapsto -y$ in the larger domain $x > |y|$. Real exponentials act on these lifts, which preserve the values of $x \pm y$ during composition.

The oriented Barbero–Immirzi functional is

$$\gamma = \frac{\pi A_{\mathrm{deg}} C^{*}_{\mathrm{deg}}}{180} + 12\big[S_{90}(q_-) - S_{90}(q_+)\big] - \big[S_{120}(q_-) - S_{120}(q_+)\big]. \tag{51.70}$$

The first component is the angular evaluation; the second is the difference of the fundamental-chain readout on the conjugate channels. The arguments are received from the previously constructed angular transport. The formula determines a dimensionless scalar on that starting structure.

Let $\psi : (3/4, 1) \to (0, 1)$ be the inverse of f constructed through (39.46). Define

$$\mathcal{H}(s) = \frac{12 s^3}{1 - s^9} - \frac{s^4}{1 - s^{12}} - \frac{(\log s)^2}{20\pi}, \qquad 0 < s < 1. \tag{51.71}$$

This function is real analytic on its domain. The exponents $3, 4, 9, 12$ result from expressing heights $90, 120$ and returns $270, 360$ in units of 30; the logarithmic coefficient is fixed when the angular contribution is transported.

Theorem 51.16 (Oriented constitutive expression of Barbero–Immirzi)**.** *In the chart* (51.69)*,*

$$\gamma = \mathcal{H}(s_-) - \mathcal{H}(s_+) = \mathcal{H}\big(\psi(r_-)\big) - \mathcal{H}\big(\psi(r_+)\big). \tag{51.72}$$

On the two-dimensional channel representation,

$$\gamma = -\operatorname{Tr}\left[\mathcal{R}\,\mathcal{H}\big(\psi(\mathcal{V})\big)\right], \tag{51.73}$$

where Tr *is the ordinary trace, with* $\operatorname{Tr} I = 2$*.*

Proof. Substitution of $s = q^{30}$ into (51.65) gives

$$S_{90}(q) = \frac{s^3}{1 - s^9}, \qquad S_{120}(q) = \frac{s^4}{1 - s^{12}}.$$

Moreover, (51.69) implies

$$\log s_\pm = -30(x \pm y) = -\frac{\pi}{6}(A_{\mathrm{deg}} \pm C^{*}_{\mathrm{deg}}).$$

By the difference of squares,

$$\frac{(\log s_+)^2 - (\log s_-)^2}{20\pi} = \frac{900\big[(x+y)^2 - (x-y)^2\big]}{20\pi} \tag{51.74}$$

$$= \frac{180 xy}{\pi} = \frac{\pi A_{\mathrm{deg}} C^{*}_{\mathrm{deg}}}{180}. \tag{51.75}$$

Adding these identities proves the first equality in (51.72). The second uses the inversion $\psi(f(s_\pm)) = s_\pm$ proved in Section 39.8.

For the operator expression, the sheet projectors have rank one and $\mathcal{R}P_\pm = \pm P_\pm$. Spectral calculus gives

$$\mathcal{H}\big(\psi(\mathcal{V})\big) = \mathcal{H}(s_+)P_+ + \mathcal{H}(s_-)P_-.$$

Multiplying by $\mathcal{R}$ and taking the ordinary trace gives $\mathcal{H}(s_+) - \mathcal{H}(s_-)$. Its negative is γ. □

The orientation mark $\mathcal{R}$ belongs to the functional. If that mark is held fixed and the channels of $\mathcal{V}$ are interchanged, the sign of γ changes. Evaluation of the spectrum without its labels preserves the unordered

pair, whereas (51.73) preserves the oriented contribution. If the normalized trace $\tau_2 = \mathrm{Tr}/2$ is used, the same formula reads $\gamma = -2\tau_2[\mathcal{R}\mathcal{H}(\psi(\mathcal{V}))]$.

By contrast, a simultaneous change of representation $(\mathcal{R}, \mathcal{V}) \mapsto (U\mathcal{R}U^{-1}, U\mathcal{V}U^{-1})$ preserves the functional: spectral calculus is transported by conjugation and the trace is invariant. Interchanging the response relative to a fixed orientation and jointly transporting response and orientation are therefore different operations.

This normalization is compatible with the amplifications of (39.48). For $\mathcal{V}_m = \mathcal{V} \otimes I_{9^m}$ and $\mathcal{R}_m = \mathcal{R} \otimes I_{9^m}$,

$$\gamma = -\frac{1}{9^m}\,\mathrm{Tr}\left[\mathcal{R}_m \mathcal{H}\big(\psi(\mathcal{V}_m)\big)\right]. \tag{51.76}$$

Indeed, functional calculus preserves the tensor product and the trace of I_{9^m} is 9^m. Representation multiplicity is separated from the oriented evaluation.

51.17.5 Reconstruction from vacuum coordinates

Identities (39.45) express the same functional through normalized impedance and velocity:

$$\gamma = \mathcal{H}\left(\psi\left(\sqrt{\frac{\widehat{Z}}{\widehat{c}}}\right)\right) - \mathcal{H}\left(\psi\left(\frac{1}{\sqrt{\widehat{Z}\widehat{c}}}\right)\right). \tag{51.77}$$

The positive domain of this reconstruction is described by

$$1 < \widehat{Z}\widehat{c} < \frac{16}{9}, \qquad \frac{9}{16} < \frac{\widehat{Z}}{\widehat{c}} < 1. \tag{51.78}$$

Indeed, these inequalities are equivalent to $3/4 < r_\pm < 1$ after substitution of the positive roots of (39.45). For orientation $y > 0$, one also retains $r_- < r_+$, equivalently $\widehat{Z} < 1$. Domain points are used with the angular compatibility already established by the TPK; inversion is a subsequent reconstruction of its channels. The coordinates are the internal ones of (39.44): a change of units must be undone through (63.139) before ψ is applied.

Interchange $y \mapsto -y$ acts as $(\widehat{Z}, \widehat{c}) \mapsto (\widehat{Z}^{-1}, \widehat{c})$ and produces $\gamma \mapsto -\gamma$. In the balanced case $y = 0$, the channels coincide and (51.72) gives $\gamma = 0$. Normalized velocity preserves the product of the channels; its joint readout with impedance recovers both responses and the orientation required to evaluate the functional. In this balanced case $\mathcal{V} = rI$ has degenerate spectrum: the mark $\mathcal{R}$ is retained as representation data, although the scalar r no longer distinguishes its projectors. For simple spectrum, by contrast, $P_+ = (\mathcal{V} - r_- I)/(r_+ - r_-)$ and $P_- = I - P_+$.

The central result of this composition is the factorization (51.72). The Catalan moment supplies the oriented coefficient that determines f; cubic inversion recovers the argument of each channel; dodecaphase incidence and the angular pair determine $\mathcal{H}$. The Pell scale distinguishes an exact evaluation of the family, with the proof of (51.58). Each relation retains its argument and its operation: the extremal constant, the contractive moment and the constitutive functional are linked evaluations of specified structures.

Chapter 52

The HMT–MD Angular Radion: Carry-Preserving Junction of the Direct and Torsional Sections and Exact Closure of the Unit of Phase, Action, and Memory

52.1 Composition APP–TRIT–TPK of the phase state: generation of the memory-oriented unit

Mathematical Synthesis of the Object and Its Causal Chain This monograph reconstructs the radian from the generative chain

$$\mathrm{APP} \longrightarrow \widehat{\mathbb{T}} \longrightarrow \mathrm{TPK} \longrightarrow X_{\mathrm{enr}} \longrightarrow \text{discrete structure of the continuum} \longrightarrow \mathrm{MD},$$

without taking as input either the metrological value of $180/\pi$ or the small angular residue to be explained. The result is an enriched unit, the *radion*, defined as the oriented unit that traverses one radian of phase and sweeps exactly an action $\hbar_{\mathrm{ret}}$ in the positive ellipse associated with the same state.

The governing closure is

$$\boxed{\frac{180^\circ}{\pi_{\mathrm{HMT}}} = 50^\circ + A^\circ - \frac{20}{81}\,\Delta_4^\circ + \varepsilon_R^\circ}$$

with

$$S_E = 2\pi_{\mathrm{HMT}}\left(\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}}\right), \qquad \Delta_4 = \frac{\pi_{\mathrm{HMT}} - e_{\mathrm{HMT}}\log\pi_{\mathrm{HMT}}}{270}\left(1 + \frac{\pi_{\mathrm{HMT}}}{729}\right),$$

$$\rho_{\mathrm{tw}} = \frac{2\cdot 90}{729} = \frac{20}{81}, \qquad \varepsilon_R^{(1)} = \frac{20}{81}\Delta_4 - (S_E - 1).$$

APP division proves $1 < S_E < 2$, so that the quotient is exactly one and the remainder is $D_E = S_E - 1$. The equality

$$1 = S_E - \frac{20}{81}\Delta_4 + \varepsilon_R^{(1)}$$

is then an internal identity. The angular chart produces

$$\varepsilon_R^\circ = 5.13830167585752820716851646226459474899085744\ldots \times 10^{-8}\,^\circ.$$

The text also demonstrates that the action ellipse

$$Q = a_S\cos\theta, \qquad P = b_S\sin\theta, \qquad a_S b_S = 2\hbar_{\mathrm{ret}}$$

satisfies

$$\mathrm{Area}(0,\theta) = \hbar_{\mathrm{ret}}\theta.$$

Therefore, a radion sweeps $\hbar_{\mathrm{ret}}$ and the turn 2π encloses $h_{\mathrm{ret}} = 2\pi\hbar_{\mathrm{ret}}$. The same ellipse has a finite symplectic boundary and an interior of infinite area when equipped with the Hilbert–Beltrami–Klein metric. This is the exact form of the physical thesis guiding the work: the visible surface closes the action; the interior depth preserves a development that cannot be exhausted by the planar projection.

The exposition maintains typed four realizations of the same state:

1. the circle S^1, which publishes the phase;
2. the positive ellipse, which publishes the action and the anisotropy;
3. the interior of Klein, that miof the depth by means of reason doble;
4. the nonadic helix, which preserves return, memory, and contraction.

They are not four superposed geometries without a criterion. They are four readers with distinct domains, codomains, and conserved data, applied to a single enriched state. The sector 90/120, the dodecaphase, the radion carry, the Lambert tail, the Barbero kernel, and the global towers are likewise presented as related but noninterchangeable objects.

Tesis rectora

The radian is the oriented unit that sweeps $\hbar_{\mathrm{ret}}$ in the action ellipse. The circle publishes its phase, Klein measures its depth, the helix preserves its memory, and the coinductive carry exactly splices its direct and torsional sections.

Expository order and reading dependencies The order is not ornamental. Parts I and II produce the object and its closure from APP–TRIT–TPK. Only thereafter are realizations introduced in the languages of Hilbert, LC, Maxwell, Minkowski, Hodge, Lorentz, modularity, and orbits. Each chapter distinguishes three levels:

Internal result. Equality or construction proved in the HMT domain with its declared primitives.

Consolidated formalization. A new map articulating already existing results without using the target as a selector.

Physical interface. Subsequent dimensional translation that recognizes a conventional structure without making it the origin of the selection.

The *status and falsifier* boxes indicate which concrete remark would invalidate each strong promotion. This discipline does not weaken the thesis; it makes the thesis auditable. The purpose of the extended narrative is to ensure that no word such as *circle*, *ellipse*, *torsion*, *charge*, or *memory* conceals a change of type.

Pivotal results and proof scope

C1. Closure of the radion independent of its final value through two publications of the same state and APP subtraction with carry.

C2. Derivation of the coefficient 20/81 as two sheets of the active sector 90, normalized by the fiber $3^6 = 729$.

C3. Typed equalizer between the seam $\mathfrak{R}s = 1/2$, the hundred-mark APP face, and the dodecaphasic phase $\theta_2 = 50^\circ$.

C4. Radian area theorem: $\mathrm{Area}(\theta) = \hbar_{\mathrm{ret}}\theta$.

C5. Exact focal study of the ellipse and of its Euclidean, hyperbolic, symplectic, and modular invariants.

C6. Boundary–interior theorem: finite total action h and Klein interior of infinite hyperbolic area.

C7. Exact realization through minimal covariance and an LC oscillator, followed by the electromagnetic publication 90/120.

C8. Atlas of non-identifications for all objects 90/120, including the separation among ε_R, the spectral tail, and the Barbero kernel $12 : -1$.

C9. Structural characterization of π in the radion chart, distinct from the primary coinductive generator.

C10. Ontological synthesis: dimension as the minimal rank of memories that a phase projection can no longer preserve.

Correspondence between results, causal types, and causal residences The following correspondence orders the governing assertions and their proofs, while keeping visible the hierarchy that prevents physical richness from erasing the mathematical closure supporting it.

APP–TRIT–TPK genealogy of the radion

The radion arises from the effective composition APP $\to \widehat{\mathbb{T}} \to$ TPK $\to X_{\mathrm{enr}} \to$ MD; it is not obtained by retroactively redefining the conventional radian.

Exact closure and prospective independence

APP carry internally produces

$$1 = S_E - \frac{20}{81}\Delta_4 + \varepsilon_R^{(1)}, \qquad \varepsilon_R^{(1)} = \frac{20}{81}\Delta_4 - (S_E - 1),$$

and the angular chart transports this same identity to $180^\circ/\pi_{\mathrm{HMT}}$ without introducing the target residue.

Critical coordinate of 50°

The critical coordinate $\Re s = 1/2$, published on the APP face of one hundred marks and in the dodecaphase wheel, selects the phase $\theta_2 = 50^\circ$. It is an equality of typed readers of the same state.

Nonadic Bidirectional Density $20/81$

The torsional coefficient is not fitted on the lattice $1/81$: it is constructed as $\rho_{\mathrm{tw}} = 2N_6/3^6 = 2 \cdot 90/729 = 20/81$, preserving the sheet, orientation, and normalization of the nonadic fibre.

Areal law of the radion

For the positive ellipse $Q = a_S \cos\theta$, $P = b_S \sin\theta$, $a_S b_S = 2\hbar_{\mathrm{ret}}$, the oriented area swept is $\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\theta$. One radion sweeps exactly $\hbar_{\mathrm{ret}}$, and the revolution 2π encloses $h_{\mathrm{ret}} = 2\pi\hbar_{\mathrm{ret}}$.

Focal invariants of the positive operator

The published pair $A \pm C^*$ fixes the semiaxes, eccentricity, focal separation, and symplectic compression parameter. In particular, $(d_1/d_0)^2 = C^*/2$, a dimensionless identity separating shape from scale.

Symplectic finiteness of the boundary and divergence of the interior hyperbolic area

The symplectic boundary of the ellipse encloses the finite action h_{ret}, whereas the Hilbert–Beltrami–Klein area of the interior diverges upon reaching the boundary. Visible phase and depth are not the same measure.

Nonadic Helical Lift with Phase Return and Memory Advance

The nonadic monodromy returns the phase without resetting the state. The helix lifts the circle while preserving carry and memory; the closure $2\pi/4\pi$ distinguishes projective return, reversal of orientation, and complete return.

Oscillatory and constitutive electromagnetic realization

The same anisotropy is realized through a minimal covariance and an LC oscillator: one coordinate stores the electric–elastic aspect and its conjugate the magnetic–rotational aspect. Frequency and impedance remain separately typed.

Typed separation of the operators 90/120

Dodecaphasic extractor, radion carry, Lambert tail, hexad–octad functional, Barbero kernel, and global tower semigroup are distinct objects. The weight $12 : -1$ comes from the twelve sectors of the dodecaphasic fundamental chain and its unique oriented seam. The coefficient of $(1-q)^{-1}$, equal to $1/24$, and the minimal integer counterterm subsequently verify the pair produced.

Complex, Lorentzian, and Hodge-dual realizations

The elliptic, parabolic, and hyperbolic regimes of TRIT are published as rotation, threshold, and hyperbolic transformation. The Hodge star, the constitutive relations, and the Lorentz force act subsequently on the already oriented state; they do not select its constants.

Modular, orbital, and arithmetic boundary characters

The modular involution, elliptic orbits, advance–delay, and 3–6–9 arithmetic recognize distinct memories of the same state. The modular function and vacancies are used as posterior readers, never as substitutes for the APP–TRIT–TPK generator.

Operatorial synthesis of phase, action, depth, and memory

The circle is the phase projection; the ellipse is the action section; Klein measures depth; the helix preserves history. The radion is the oriented unit that keeps these publications coupled without erasing the residue that distinguishes them.

Delimitation of domains and causal continuity

The complete mass laws, electron refinement, CKM/CP, and the exceptional corridor retain their own governing proofs. This monograph cites them only where they share an antecedent or chart; it neither transfers their specific selectors to the radion nor confuses their probative residences.

52.1.1 Bivariate support of APP, ternary orientation of TRIT, and enriched-state update through TPK

The operative genealogy precedes angular measurement and determines the variables preserved by each reader.

52.1.1.1 APP–TRIT–TPK support and enriched state construction

Precedence of the enriched state with respect to the circular publication The elementary definition of radian begins with an already given circle, an already given center, and an already measurable arc length. If the radius and arc have the same length, the subtended angle measures one radian. The definition is correct within Euclidean geometry, but does not answer a prior question: what structure makes it possible for a turn to possess phase, orientation, action, and memory, and why is the natural unit related to 2π?

HMT reverses the causal order. It first constructs the finite state, then its coinductive prolongation, then the revolution, and only at the end its angular publication. The radion does not correct the conventional radian; it lifts it to its genealogical domain.

Type receipt

$$\mathrm{APP} \to \widehat{\mathbb{T}} \to \mathrm{TPK} \to X_{\mathrm{enr}} \to C_{\mathrm{cont}}^{\mathrm{disc}} \to \left(\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}, A, C^*, \Delta_4, \hbar_{\mathrm{ret}}\right) \to \mathfrak{r}_\sigma.$$

Conventional mathematics appears only afterward as a language of realization: S^1, symplectic ellipse, Klein metric, Hilbert space, LC circuit, Minkowski screen, and field equations.

Bivariate support of APP: leaves, residues, quotients, and carry The Positional Arithmetic Platform (APP) simultaneously preserves two realizations of the symbols $1, \dots, 9$: an additive sheet and a multiplicative sheet. A number is not reduced to its published value. Alongside the value remain sheet, orientation, quotient, remainder, carry, boundary, route, and survival.

The basic census has three strata that must never be identified by mere cardinal coincidence:

$$104,976 \longrightarrow 468\ U_6 \longrightarrow 243\ w_6 \subset \mathbb{F}_3^6, \qquad |\mathbb{F}_3^6| = 729.$$

The 468 decimal emissions, the 243 visible words, and the ambient set of 729 words are distinct objects. The ambient set will be decisive for the normalization $20/81$.

In cubic base $B = 1000$, the oriented subtraction of two triad words is performed from right to left:

$$u_i = t_i - v_i + c_{i+1}, \qquad r_i = u_i \bmod 1000, \qquad c_i = \frac{u_i - r_i}{1000}. \tag{52.1}$$

Once the operands and the remote carry are fixed, quotient and remainder are unique. This is the operator that will subsequently publish the digits of $\varepsilon_R^{(1)}$. No decimal is chosen after seeing the radian.

The completion

$$10^3 = 729 + 243 + 27 + 1$$

is not a decimal curiosity. It expresses conservation of the unit in passing from the ternary ambient space to a chamber of one thousand positions. The difference $1000 - 729 = 271$ is the completing corona; the correct identity is $999 = 729 + 270$, not $729 + 271$.

Ternary orientation and classification of the 3 operational regimes of the TRIT TRIT assigns one of three oriented regimes to each local state. Under the active temporal convention,

$$\begin{aligned} +1 &\longleftrightarrow \text{return, memory, past,} \\ 0 &\longleftrightarrow \text{threshold, present,} \\ -1 &\longleftrightarrow \text{bidirectional opening, future.} \end{aligned}$$

The quadratic realization distinguishes:

$$J^2 = -I, \qquad N^2 = 0, \qquad R^2 = I. \tag{52.2}$$

Thus arise, respectively, elliptic rotation, the parabolic threshold, and hyperbolic separation. Three metrics are not being mixed. Three typed actions on a common antecedent are preserved.

The internal root of -1 is not imported by presupposing the complex plane. In the APP block, two projections P, Q with ratio $r = 3/4 = 90/120$ produce

$$J_{\mathrm{comm}} = \frac{[P, Q]}{\sqrt{r(1-r)}}, \qquad J_{\mathrm{comm}}^2 = -I,$$

while

$$R_{\mathrm{comm}} = 2P - I, \qquad R_{\mathrm{comm}}^2 = I, \qquad R_{\mathrm{comm}} J_{\mathrm{comm}} = -J_{\mathrm{comm}} R_{\mathrm{comm}}.$$

The pair generates the minimal form of $\mathrm{Cl}_{1,1} \simeq M_2(\mathbb{R})$: rotation and opening emerge together, but remain distinct operations.

Dynamic composition of the TPK: selection, transport, memory, and return The Topological Phase Kernel is not a name for a box of objects. It is the composition that selects phase, transports cardinality, lifts sheets, records memory, and executes return. The fundamental dependence is

$$U_t \longrightarrow \Gamma_9 \longrightarrow K_{\mathrm{ph}}.$$

The nonadic holonomy Γ_9 acts on the enriched state; the publication K_{ph} is subsequent and preserves reduced memory. The identity $K_{\mathrm{ph}}^9|_r = E_+ E_\times$ does not turn K_{ph} into a generator.

The nonadic certificate preserves the complete chain

$$w_6 \to w_{12} \to w_{18} \to w_{24} \to w_{30} \to R_{36} \to G_9,$$

with 396 levels, 2376 trits, 43 circuits, 387 pairs $(K, K+9)$ per channel, and five regions of π. The phase satisfies

$$g(k+9) = g(k),$$

but the complete state does not return:

$$B_{k+9} \neq B_k.$$

This is the mathematical seed of the helix: the angular projection closes; the memory advances.

Non-split temporal extension $C_{12} \to C_{108} \to C_9$ The twelve-step memory is organized via

$$0 \longrightarrow C_{12} \longrightarrow C_{108} \longrightarrow C_9 \longrightarrow 0. \tag{52.3}$$

The cocycle

$$c(r, r') = \left[\left\lfloor \frac{r + r'}{9} \right\rfloor \right]_{12}$$

measures the carry between phase return and memory advance. Nine steps close the observable phase C_9; they do not reset the dodecaphasic record.

It is convenient to separate four objects:

C_{12}	cyclic group of twelve positions;
$\mathcal{R}_{12}$	enhanced record $(E_m, \tau_m, \sigma_m, \kappa_m, \Lambda_m)_{m=1}^{12}$;
Θ_{108}	raw publication on the 108 calendar;
Γ_{108}	history or lifted holonomy.

Accordingly, the vague expression "post-C_{12}" shall be replaced by "subsequent to the dodecaphasic record $\mathcal{R}_{12}$, in its hexadic" reading when that is the effective map.

Correlative emergence of the 5 constructions of the continuum from the unique state The discrete structure of the continuum is not obtained by assembling five independent theories. Its five internal aspects—spectral, solenoidal, gauge, cohomological, and determinant—emerge correlatively from the same APP–TRIT–TPK state. This work does not prove the integral treatise anew, but preserves the causal fact required by the radion: the coinductive section that generates π, e, φ and α does not live on a bare real line; it lives in an object with fibers, relations, orientation, carry, memory, terminal object, and reader.

Hypothesis, domain, and conclusion

Genealogy falsifier. If a later formula receives $180/\pi$, ε_R, a mass, or a metrological table in order to choose a phase, a coefficient, or a branch, it ceases to be an HMT-first generation. The external contrast may recognize an output; it cannot select it.

52.1.2 Prospective independence of the closure with respect to the final value

52.1.2.1 Genealogy of the constants and construction of the angular pair

Coinductive section and uniqueness of the generated value of π Be x_∞ the section global of the inverse system. The lectores coinductivos produce

$$\mathrm{ev}_\pi(x_\infty) = \pi_{\mathrm{HMT}}, \qquad \mathrm{ev}_e(x_\infty) = e_{\mathrm{HMT}}, \qquad \mathrm{ev}_\varphi(x_\infty) = \varphi_{\mathrm{HMT}}.$$

The HMT subscript does not designate another number. It preserves the genealogy of the same constant. In particular,

$$\pi_{\mathrm{HMT}} = 3.14159265358979323846264338327950288419716939937510\ldots.$$

The positive loop is

$$T_+(x_\infty) = 2\pi_{\mathrm{HMT}}. \tag{52.4}$$

Its angular publication of a unit is

$$R^\circ_{\mathrm{HMT}} = \frac{360^\circ}{T_+} = \frac{180^\circ}{\pi_{\mathrm{HMT}}}. \tag{52.5}$$

The equation does not yet define the enriched radion; it defines the visible chart of the radian once the turn has been generated.

Bidirectionality of conjugate routes and prolongations Bidirectionality is not enunciated as a slogan. The concrete involution

$$J_\alpha(T) = \frac{\alpha^2_{\mathrm{HMT}}}{T}, \qquad T_- = J_\alpha(T_+), \qquad T_+T_- = \alpha^2_{\mathrm{HMT}} \tag{52.6}$$

preserves a product and reverses the sheet. Expansion and contraction are two conjugate prolongations of the same state. The finite root of a quadratic jet can approximate T_+, but it does not replace the coinductive section: the certified difference is

$$T_{P_9} - T_+ = -5.1110566290335\ldots \times 10^{-25}.$$

Finite control is a witness; the foundation is the limit.

Causal dependence among α, action, and angular publication The dodecaphase closure generates α_{HMT} from the signed state and its reversible charts. The local determinantal reader then fixes the action decade through

$$\Sigma_H = \varphi_{\mathrm{HMT}}\alpha^{16}_{\mathrm{HMT}}, \qquad \mathrm{ord}_{10}\,\Sigma_H = -34.$$

The return section produces $\hbar_{\mathrm{ret}}$. Neither α nor $\hbar$ is "measured in degrees". They are subsequently published through the angular pair

$$P(\alpha, \eta_{\mathrm{ret}}) = \Big([10^3\alpha]_{360}, [2(\eta_{\mathrm{ret}} + \alpha)]_{360}\Big) = (A, C^*). \tag{52.7}$$

In the canonical branch,

$$A = 7.29735256928380099728510547238066 3\ldots^\circ,$$

$$C^* = 2.12373833896864572426195138039336079 37\ldots^\circ.$$

Only then the analytic chart

$$x = \frac{\pi A}{180}, \qquad y = \frac{\pi C^*}{180}$$

open the channels $q_\pm = e^{-x\mp y}$.

The complete causal order is

$$\alpha \to (\eta \parallel -34) \to \hbar \to P \to \kappa_{360} \to q_\pm \to \text{MD realizations}.$$

The relation $C^*/2 - \alpha$ may serve as a reverse verification. It is not used to generate $\hbar_{\text{ret}}$ retroactively.

> The angular chart does not turn a dimensionless constant or an action into an angle by fiat. It publishes two state coordinates on a finite wheel. The degree is the language of that publication; it is not the ontological substance of α or $\hbar$.

Prospective independence with respect to the final value The depth operator verifier explicitly prohibits three inputs:

$$\frac{180}{\pi}, \qquad \varepsilon_R, \qquad \text{the target decimal.}$$

First construct S_E and S_T, then execute the APP subtraction, and only at the end compare the closure. The controls give

`target_epsilon_used=False`, `target_180_over_pi_used=False`.

Also:

- a single sheet gives a defect of order 10^{-5};
- replacing θ_2 by θ_1 or θ_3 shifts the result by approximately $\pm\pi/6$;
- removing channel e leaves a defect of order 10^{-3};
- the variante historica $\Delta_4(A, C^*)$ produce other number;
- the spectral tail following $\mathcal{R}_{12}$ and the four-term harmonic operator do not coincide with $\varepsilon_R^{(1)}$ either.

Hypothesis, domain, and conclusion

Status. The closure is a *new formalization* proved with an explicit initial structure and a computational certificate independent of the final value. The equality is exact in the coinductive limit. The short 36-digit profile of α generates a variant that diverges only after many digits; it is retained as a historical witness, not as the canonical value.

52.2 Direct and torsional sections: APP carry and exact closure of the radion

52.2.1 Independent construction of the sections S_E and S_T before defining the cocycle $\varepsilon_R = S_T - S_E$

Exact closure is obtained through two sections constructed before the cocycle that relates them.

52.2.1.1 Independent construction of direct and torsional sections

Direct section of the dodecaphasic temporal system The dodecaphase wheel has centers

$$\theta_m = 30m - 10^\circ, \qquad m = 1, \dots, 12. \tag{52.8}$$

The second phase is $\theta_2 = 50^\circ$. Together with the publication $A = 10^3 \alpha_{\mathrm{HMT}}$, it forms the direct section

$$S_E = \frac{T_+}{360}\,(50 + 10^3 \alpha_{\mathrm{HMT}}) \tag{52.9}$$

$$= 2\pi_{\mathrm{HMT}} \left(\frac{5}{36} + \frac{25}{9} \alpha_{\mathrm{HMT}} \right). \tag{52.10}$$

The subscript E here means *direct or common*; its electrical realization will come after the constitutive reader. One does not literally postulate $A = E$.

The coinductive cylinders prove

$$1 < S_E < 2. \tag{52.11}$$

The APP division then enforces

$$q_E = \lfloor S_E \rfloor = 1, \qquad D_E = \mathrm{rem}_1(S_E) = S_E - 1. \tag{52.12}$$

The integer one is not the number of turns of the helix. It is the unique quotient of the direct section within the unit cell.

Torsional Section Determined by the Operator Δ_4 The second section uses a previous coinductive output:

$$\Delta_4 = \frac{\pi_{\mathrm{HMT}} - e_{\mathrm{HMT}} \log \pi_{\mathrm{HMT}}}{270} \left(1 + \frac{\pi_{\mathrm{HMT}}}{729} \right). \tag{52.13}$$

The word *torsion* here denotes the global quantum of the HMT chart. It does not automatically identify it with Cartan torsion $T^I = D_\omega e^I$. The bridge to Cartan requires another typed arrow.

52.2.2 Oriented density of the active sector and unique determination of $20/81$

Oriented density $20/81$ of the active sector $90/120$ The triadic phase separator selects

$$H_+ = \{1, 4, 7\}, \qquad H_- = \{2, 5, 8\}, \qquad H_0 = \{3, 6, 9\}.$$

There are six active phases and fifteen unordered pairs:

$$H_{\mathrm{act}} = H_+ \cup H_-, \qquad \left| \binom{H_{\mathrm{act}}}{2} \right| = \binom{6}{2} = 15.$$

The active mode and its extension to eight positions are

$$N_6 = 6\binom{6}{2} = 90, \qquad N_8 = 8\binom{6}{2} = 120. \tag{52.14}$$

Two conjugate sheets of the active sector, normalized by the ambient fiber, give

$$\rho_{\mathrm{tw}} = \frac{2N_6}{|\mathbb{F}_3^6|} = \frac{2 \cdot 90}{729} = \frac{180}{729} = \boxed{\frac{20}{81}}. \tag{52.15}$$

Proposition 52.1 (Relative uniqueness of the density)**.** *With the active sector $N_6 = 90$, the two conjugate sheets, and the normalization by $|\mathbb{F}_3^6| = 729$ fixed, the oriented density is necessarily* $20/81$.

Proof. The transported cardinality is $2N_6 = 180$. Normalization by the ambient space gives $180/729$; dividing the numerator and denominator by 9 yields $20/81$. No comparison with $180/\pi$ or with ε_R is involved. □

The historical reading as a projection onto a $1/81$ lattice is a useful rigidity control, but it is no longer the foundation: the coefficient is obtained before closure. Ablating one sheet produces $10/81$, and the output changes at order 10^{-5}; hence, the factor of two is not decorative.

The torsional section is

$$\Phi_T = \rho_{\mathrm{tw}} \Delta_4, \qquad S_T = 1 + \Phi_T. \tag{52.16}$$

52.2.3 The carry ε_R as a transition cocycle between sections

52.2.3.1 Transition cocycle between the direct and torsional sections

definition operatoria of the carry ε_R

Definition 52.2 (Real carry of the radion)**.** The unitary output of the radion is the transition cocycle

$$\varepsilon_R^{(1)} := S_T - S_E = \Phi_T - D_E = \frac{20}{81}\Delta_4 - operatornamerem_1(S_E). \tag{52.17}$$

The equation contains a subtraction, but it is not a fit to the target. Its two operands S_T and S_E are generated separately. The independence demonstrated is independence from $180/\pi$ and from a target ε; algebraic independence between a difference and its summands is not asserted.

Theorem 52.3 (Exact unitary closure)**.** *With S_E, Φ_T, and $\varepsilon_R^{(1)}$ defined by* (52.10)*,* (52.13)*,* (52.15)*, and* (52.17)*, one has exactly*

$$\boxed{1 = S_E - \Phi_T + \varepsilon_R^{(1)}.} \tag{52.18}$$

Proof. By (52.11), $D_E = S_E - 1$. By definition, $\varepsilon_R^{(1)} = \Phi_T - D_E$. Then

$$S_E - \Phi_T + \varepsilon_R^{(1)} = S_E - \Phi_T + \Phi_T - (S_E - 1) = 1.$$

The strength of the proof lies not in this elementary cancellation, but in the fact that the prior genealogy fixes both operands without using the closure as input. □

Publication of the closure on the angular chart The full-turn chart multiplies a unit fraction by $360/T_+ = 180/\pi_{\mathrm{HMT}}$. In particular,

$$\varepsilon_R^{\circ} = \frac{360^\circ}{T_+}\varepsilon_R^{(1)}.$$

Multiplying (52.18) by $360^\circ/T_+$ and using

$$\frac{360}{T_+}S_E = 360\left(\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}}\right) = 50 + 1000\alpha_{\mathrm{HMT}} = 50 + A$$

produce the angular closure.

Theorem 52.4 (Exact equation of the radion)**.**

$$\boxed{\frac{180^\circ}{\pi_{\mathrm{HMT}}} = 50^\circ + A^\circ - \frac{20}{81}\,\Delta_4^\circ + \varepsilon_R^\circ}$$

The equation says something more precise than "the radian is $57.2957\ldots^\circ$". It decomposes that publication into four operations with a reference proof:

50°	second phase of the wheel; critical hinge on a declared chart;
A°	common coordinate of the parangular publication;
$-\frac{20}{81}\Delta_4^\circ$	orientation-transport of global torsion;
$+\varepsilon_R^\circ$	real carry that mates the two lifts.

Convergence by depth of refinement At depth N, the generator delivers rational cylinders $p_N \to \pi_{\mathrm{HMT}}$ and $e_N \to e_{\mathrm{HMT}}$. Define

$$S_{E,N} = 2p_N\left(\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}}\right),$$

$$\Delta_{4,N} = \frac{p_N - e_N \log p_N}{270}\left(1 + \frac{p_N}{729}\right), \qquad S_{T,N} = 1 + \frac{20}{81}\Delta_{4,N},$$

and

$$\mathcal{E}_N = S_{T,N} - S_{E,N}.$$

Continuity of the functional on $3 < p < 4$, $2 < e < 3$, together with the monotone derivatives, transports each pair of cylinders to a certified interval. At a depth of 45 blocks, its width is less than 4.81×10^{-130}.

Each nine-level return contains six trits per level. Therefore, the refinement rate is

$$729^{-9} = 3^{-54}. \tag{52.19}$$

This quantity controls the width of the intervals; it is not the value of ε_R.

The subtraction of triads stabilizes

```
000|000|000|896|802|822|044|562|981|999|050|695|020|651|286|413
```

and the carry prefix

```
0,0,0,0,0,-1,0,-1,-1,-1,0,-1,0.
```

This is the concrete mechanism of decimal memory: not a chosen tail, but the recurrence (52.1) applied to previously constructed operands.

Evaluation of the canonical values The coinductive output is

$$\varepsilon_R^{(1)} = 8.96802822044562981999050695020651286413727362050 09\ldots \times 10^{-10}, \tag{52.20}$$

$$\varepsilon_R^\circ = 5.13830167585752820716851646226459474899085744000 54\ldots \times 10^{-8\,\circ}. \tag{52.21}$$

The complete publication results

$$\frac{180^\circ}{\pi_{\mathrm{HMT}}} = 57.29577951308232087679815481410517033240547246656 43\ldots^\circ.$$

Exact Result

$$\begin{aligned}
50^\circ + A^\circ &= 57.297352569283800997285105472380662999 56\ldots^\circ,\\
\frac{20}{81}\Delta_4^\circ &= 0.001573107584496879062232729960657289804 65\ldots^\circ,\\
50^\circ + A^\circ - \frac{20}{81}\Delta_4^\circ &= 57.295779461699304118222872742420005709 76\ldots^\circ,\\
\varepsilon_R^\circ &= 0.000000051383016758575282071685164622645947 49\ldots^\circ,\\
\text{final sum} &= 57.295779513082320876798154814105170332 41\ldots^\circ.
\end{aligned}$$

52.3 Critical coordinate and oriented dodecaphase temporal system: affine publication of the phase of 50°

52.3.1 Affine map j_{100} of the APP chart and uniqueness of the phase $m = 2$ in $j_{100}(1/2) = \theta_m = 50^\circ$

The critical coordinate links the Cayley chart, the APP record, and the dodecaphasic phase through typed maps.

52.3.1.1 Two exact realizations of the angular coordinate 50°

Second phase of the dodecaphasic temporal system By (52.8), the sequence of centros begins

$$20^\circ,\ 50^\circ,\ 80^\circ,\ 110^\circ, \ldots.$$

Solve

$$30m - 10 = 50$$

gives only $m = 2$. Therefore, 50° is not a rounding of A, a half-turn, or the centre of a circle: it is a typed phase of the dodecaphase calendar. The fraction of a turn is

$$\frac{50}{360} = \frac{5}{36},$$

exactly the first summand of S_E/T_+.

Cayley Critical Coordinate Matching The functional involution

$$\rho \longmapsto 1 - \bar{\rho}$$

fixed

$$\mathrm{Fix}(\rho \mapsto 1 - \bar{\rho}) = \{\rho : \Re\rho = 1/2\}.$$

The number $1/2$ is the self-dual real coordinate of the functional interval $0 \le \Re s \le 1$. In the longitudinal sense, it is not "half of a line", and it does not contain the spectral height γ. For

$$\rho_\gamma = \frac{1}{2} + i\gamma,$$

The Cayley transformation can be written

$$\tau_\gamma = \frac{\rho_\gamma - 1}{\rho_\gamma} = \frac{\gamma + i/2}{\gamma - i/2} \in S^1, \qquad \gamma = \frac{1}{2}\cot\frac{\theta_\gamma}{2}. \tag{52.22}$$

Thus, $1/2$ fixes the seam, γ determines the angular character, and Γ_9 preserves the depth of its iterations.

Affine injection j_{100} of the APP record into the angular chart Cubic completion arranges a chamber of ten marks per coordinate. One face contains $10^2 = 100$ positions. We declare the affine chart

$$j_{100} : [0,1] \longrightarrow [0, 100^\circ], \qquad j_{100}(\sigma) = 100\sigma^\circ. \tag{52.23}$$

Then

$$j_{100}\left(\frac{1}{2}\right) = 50^\circ.$$

Requiring $j_{100}(1/2) = \theta_m$ simultaneously yields

$$100 \cdot \frac{1}{2} = 30m - 10 \quad \Longleftrightarrow \quad m = 2.$$

Theorem 52.5 (Critical Equalizer–Dodecaphasic)**.** *In the hundred-mark APP chart, the fixed coordinate of the critical involution is published exactly in the second phase of the wheel:*

$$\boxed{j_{100}(1/2) = \theta_2 = 50^\circ.} \tag{52.24}$$

The phase $m = 2$ is unique.

The theorem is exact once (52.23) has been declared. Its status is *new formalization*: the critical midpoint, the 10^3 completion, the hundred-mark face, and θ_2 had already been constructed; choosing that face as the affine critical chart brings their domains together for the first time.

Compatibility of the critical value with the Cayley chart The Cayley transform does not send $1/2$ to 50°. If $\gamma = 0$, (52.22) gives

$$\tau_0 = -1 = e^{i\pi},$$

that is, 180°. The 50° belong to the APP chart of one hundred marks and to the dodecaphasic calendar; the Cayley angle depends on γ. This distinction prevents all the zeros of the zeta function from being collapsed into a single phase.

Falsification criterion 52.6. The identification $1/2 \leftrightarrow 50^\circ$ fails if the chart (52.23) is removed. The scalar equality $100(1/2) = 50$ is not sufficient by itself to identify two objects. The theorem depends on the distinguished APP face and on the dodecaphase wheel.

52.3.2 Compatibility of the critical phase with the nonadic return and memory advance

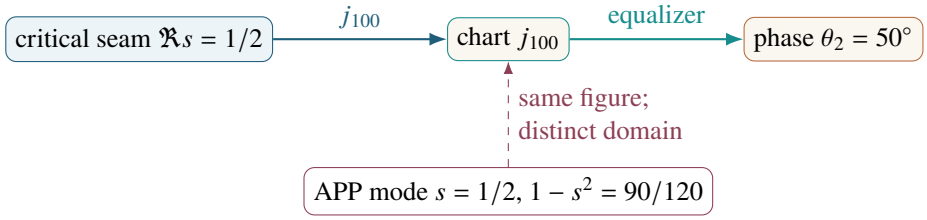
52.3.2.1 Typed separation of the 2 objects with value $1/2$

APP contains, in addition, a singular mode with

$$s = \frac{1}{2}, \qquad s^2 = \frac{1}{4}, \qquad 1 - s^2 = \frac{3}{4} = \frac{90}{120}, \qquad s\sqrt{1 - s^2} = \frac{\sqrt{3}}{4}.$$

This s arises from the principal angles of the sum and product sheets. The critical seam $\Re\rho = 1/2$ arises from a functional involution. That both coordinates equal $1/2$ is a scalar coincidence with possible content, but it does not authorize their identification without a typed square.

The correct way to preserve the finding is an equalizer diagram:



The diagram does not feign the missing arrow. It shows what has been proved, what has been formalized, and what equality still requires additional transport if a global operator identification is intended.

52.3.2.2 Spectral Circle and Helical Memory Compatibility

The Cayley–Pontryagin reader transports a spectral fiber via

$$\widetilde{U}_{\Gamma_9^n} J\psi_\gamma = \tau_\gamma^n J\psi_\gamma.$$

The circular publication is $\tau_\gamma^n \in S^1$. The lift

$$(\tau_\gamma^n, n) \in S^1 \times \mathbb{Z}$$

preserves the number of returns. On the contractive sheet appears

$$\widetilde{M}_9^n J\psi_\gamma = \left(\frac{5}{9}\right)^n \tau_\gamma^n J\psi_\gamma.$$

We therefore have three typed images:

$$\text{phase circle}, \qquad \text{memory helix}, \qquad \text{contractive spiral}.$$

A zero is not a revolution, and a nine is not a particular zero of the zeta function. The zero fixes a character τ_γ that persists through the revolutions; nonadic return increments memory. Nine functions as residual zero in $\mathbb{Z}/9\mathbb{Z}$, an arithmetic operation distinct from the enumeration of spectral zeros.

> The critical line becomes a circle when we forget the linear height and retain the unitary character. It becomes a helix when we reinsert the memory of how many times the character has been transported. Depth is not a third decorative coordinate: it is the information that the circular projection cannot retain.

52.4 Angular pair and reduced action: construction of the positive ellipse and area per radion

52.4.1 Areal law of the radion: $\mathcal{A}(\theta) = \hbar_{\text{ret}}\theta$ and $\mathcal{A}(2\pi) = h_{\text{ret}}$

Spectral geometry determines the form, and the areal law determines the action transported by the phase.

52.4.1.1 Equivalence between the spectral and geometric charts

Spectral positive operator and conjugate eigenvalues The angular momentum produces the two-layer operator.

$$B_1 = AI + C^*R, \qquad R^2 = I, \qquad P_\pm = \frac{I \pm R}{2}. \tag{52.25}$$

Its eigenvalues are $A \pm C^*$. Since $0 < C^* < A$, both are positive. In the chart $\kappa = \pi/180$, the spectral ellipse has semiaxes

$$a_1^2 = \kappa(A + C^*), \qquad b_1^2 = \kappa(A - C^*). \tag{52.26}$$

The decomposition is reversible:

$$A = \frac{a_1^2 + b_1^2}{2\kappa}, \qquad C^* = \frac{a_1^2 - b_1^2}{2\kappa}. \tag{52.27}$$

The ellipse is not drawn to illustrate a number. It exactly reconstructs the pair that generated it.

Define

$$\rho_1 = \sqrt{A^2 - C^{*2}}, \qquad \eta = \operatorname{artanh} \frac{C^*}{A} = \frac{1}{2} \log \frac{A + C^*}{A - C^*}. \tag{52.28}$$

Then

$$A \pm C^* = \rho_1 e^{\pm \eta},$$

and

$$a_1 = \sqrt{\kappa \rho_1}\, e^{\eta/2}, \qquad b_1 = \sqrt{\kappa \rho_1}\, e^{-\eta/2}. \tag{52.29}$$

The product preserves scale; the quotient preserves form:

$$a_1 b_1 = \kappa \rho_1, \qquad \frac{b_1}{a_1} = e^{-\eta} = \sqrt{\frac{A - C^*}{A + C^*}}.$$

Focal Invariants of the Positive Operator The semifocal distance is

$$c_1^2 = a_1^2 - b_1^2 = 2\kappa C^*, \qquad F_\pm = (\pm c_1, 0). \tag{52.30}$$

The total distance is equal to

$$d_1 = 2c_1 = 2\sqrt{2\kappa C^*} = 0.544545509325626623406299779866023\ldots. \tag{52.31}$$

The isolated number is not the thesis. The identity $c_1^2 = 2\kappa C^*$ states that C^* is literally the quadratic focal splitting in the distinguished chart. The foci are the conjugate endpoints of the spectral aperture; they are not, by themselves, the electric and magnetic poles. That reading requires the constitutive transducer.

The eccentricity is

$$e_f = \frac{c_1}{a_1}, \qquad e_f^2 = 1 - e^{-2\eta} = \frac{2C^*}{A + C^*}. \tag{52.32}$$

Numerically,

$$\eta = 0.29968968392163079968492656286392 7\ldots,$$
$$e_f = 0.67145189555019198691627705586433 2\ldots.$$

Reference APP Block and Normalized Transport The central block

$$B_0 = 7I + 2R = 9P_+ + 5P_-$$

possesses

$$\rho_0 = \sqrt{45}, \qquad \eta_0 = \frac{1}{2} \log \frac{9}{5}, \qquad e_0 = \frac{2}{3}.$$

Its focal length is

$$d_0 = 4\sqrt{\kappa} = 0.528443639680801468446003835349358\ldots.$$

The exact comparison is

$$\boxed{\left(\frac{d_1}{d_0}\right)^2 = \frac{C^*}{2}}, \qquad d_1 = d_0 \sqrt{\frac{C^*}{2}}. \tag{52.33}$$

This is the defensible genealogy of 0.544545 . . .: a focal APP scale of reference multiplied by a relative invariant. Its visual proximity to 0.54 is not an identity with the APP defect 54.

Transport from B_0 separates into scale and anisotropy:

$$T_{\mathrm{rel}} = \frac{\rho_1}{\sqrt{45}} \exp\big((\eta - \eta_0)R\big). \tag{52.34}$$

On the leaves,

$$t_+ = \frac{A + C^*}{9} = 1.0467878786947163\ldots, \qquad t_- = \frac{A - C^*}{5} = 1.0347228460630311\ldots.$$

The deformation is not a single decimal. Its isotropic component is $\sqrt{t_+ t_-}$; its hyperbolic component is $\frac{1}{2}\log(t_+/t_-)$.

52.4.1.2 Positive ellipse associated with the angular pair

Construction via Conjugate Semi-axes The preceding spectral scale has no units of action. Dimensional Mechanics publishes the same form on the internal action line:

$$a_S = \sqrt{2\hbar_{\mathrm{ret}} e^{\eta}}, \qquad b_S = \sqrt{2\hbar_{\mathrm{ret}} e^{-\eta}}. \tag{52.35}$$

Immediately,

$$a_S b_S = 2\hbar_{\mathrm{ret}}, \qquad \frac{a_S}{b_S} = e^{\eta}. \tag{52.36}$$

The product fixes the action; the quotient fixes the anisotropy. The ellipse is parametrized by

$$Q(\theta) = a_S \cos\theta, \qquad P(\theta) = b_S \sin\theta. \tag{52.37}$$

The spectral and action ellipses are homothetic:

$$\lambda_{\mathrm{act}}^2 = \frac{2\hbar_{\mathrm{ret}}}{\kappa\rho_1}, \qquad (a_S, b_S, c_S) = \lambda_{\mathrm{act}}(a_1, b_1, c_1). \tag{52.38}$$

They share the form $e^{-\eta}$, not the physical dimension.

Areal law of action per radion The forma simplectica canonica is $\omega = \mathrm{d}Q \wedge \mathrm{d}P$. The area oriented barrida from 0 until θ is

$$\mathcal{A}(\theta) = \frac{1}{2}\int_0^{\theta} \big(Q(t)P'(t) - P(t)Q'(t)\big)\ \mathrm{d}t \tag{52.39}$$

$$= \frac{1}{2} a_S b_S \int_0^{\theta} (\cos^2 t + \sin^2 t)\ \mathrm{d}t. \tag{52.40}$$

Using (52.36), we obtain the central result.

Theorem 52.7 (Action per radion)**.** *For the ellipse* (52.37)*,*

$$\boxed{\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\theta.} \tag{52.41}$$

In particular,

$$\boxed{\mathcal{A}(1) = \hbar_{\mathrm{ret}}}, \qquad \boxed{\mathcal{A}(2\pi) = 2\pi\hbar_{\mathrm{ret}} = h_{\mathrm{ret}}}. \tag{52.42}$$

This equality allows the definition of the radius without first appealing to the arc length.

Definition 52.8 (Oriented radion)**.**

$$\mathfrak{r}_\sigma = (\theta = 1, \sigma), \qquad \sigma \in \{+1, -1\}, \qquad \mathcal{A}(\mathfrak{r}_\sigma) = \sigma \hbar_{\mathrm{ret}}. \tag{52.43}$$

The radian is the projection that forgets σ, the sheet, the memory, and the area. The radion preserves that information. Hence the name *rad–ion*: orientation precedes physical charge, and charge appears later as

$$Q(x) = n_Q(x) e_{\mathrm{int}}, \qquad e_{\mathrm{int}} = \sqrt{\frac{2\alpha_{\mathrm{HMT}} h_{\mathrm{ret}}}{Z_{\mathrm{int}}}}.$$

52.4.2 Conjugate semi-axes, focal invariants, and orientation of anisotropy

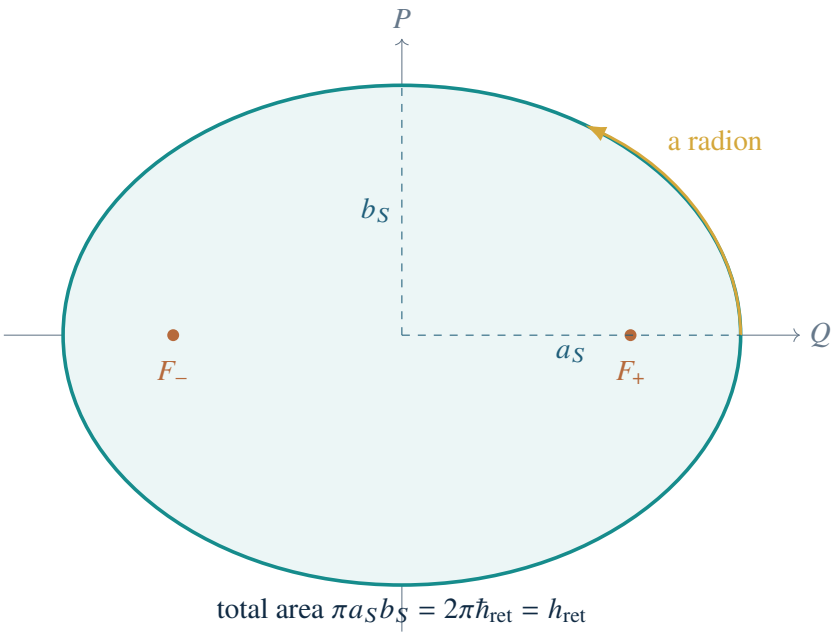


Figure 52.1: The action ellipse. A parametric arc of one radian sweeps $\hbar_{\mathrm{ret}}$; one turn encloses h_{ret}. The foci encode the aperture C^* in the distinguished chart.

Correspondence between phase, action, area, and orientation

Relationship between the reduced action, uncertainty, and area The relation $\hbar = h/(2\pi)$ is often presented as a notational convenience: when describing oscillations, rotations, and Fourier transforms, the factors 2π disappear if $\hbar$ is used. The action ellipse reveals a stronger reading. Division by 2π is exactly the passage from the action of one revolution to the action per unit phase:

$$h = \mathcal{A}(2\pi), \qquad \hbar = \mathcal{A}(1).$$

The reduced constant is not merely h in more convenient notation; it is the areal density of action with respect to phase.

Heisenberg, Dirac, and Jordan established the language of conjugate variables, commutators, and canonical transformations. No literal "ontological ellipse" lacking a source is attributed to them here. The HMT–MD contribution is to identify the positive figure, construct its semiaxes from (A, C^*), and prove (52.41). The historical genealogy opens the language; the present theorem fixes the object.

> Action is not appended to motion afterward. In the radion ellipse, action is the area generated by motion. A full turn does not transport a prefabricated constant: it encloses it.

Algebraic controls of the focal invariants Decimal similarities are subject to control:

Comparison	Residue	Verdict
d_1 versus 0.54	4.5455×10^{-3}	not equality; 54 is not deduced;
d_1^2 versus 8/27	2.3352×10^{-4}	proximity without map;
η frente a 3/10	-3.1032×10^{-4}	no igualdad;
e_f versus 2/3	4.7852×10^{-3}	2/3 belongs exactly to B_0;
$e^{-\eta}$ versus 20/27	3.0740×10^{-4}	no igualdad.

The robust invariants are (52.28), (52.32), and (52.33). The HMT criterion does not consist in favouring a decimal resemblance, but in requiring an object, an operation, and conservation.

52.5 Nonadic Return and Internal Projective: Klein Disk and Helical Depth of Memory

52.5.1 Normalization to the Hilbert–Beltrami–Klein disk and hyperbolic interior

Projective geometry distinguishes the finite action from hyperbolic depth and return memory.

52.5.1.1 Hyperbolic Interior of Hilbert–Beltrami–Klein

Projective normalization on the Klein disk The affine application

$$u = \frac{Q}{a_S}, \qquad v = \frac{P}{b_S}$$

carries the action ellipse to the unit disk

$$D = \{(u, v) : u^2 + v^2 < 1\}.$$

On each chord, the Hilbert distance is defined through the cross-ratio of its boundary endpoints. The resulting infinitesimal metric is the Beltrami–Klein form

$$\mathrm{d}s_K^2 = \frac{(1 - r^2)(\mathrm{d}u^2 + \mathrm{d}v^2) + (u\,\mathrm{d}u + v\,\mathrm{d}v)^2}{(1 - r^2)^2}, \qquad r^2 = u^2 + v^2. \tag{52.44}$$

With this normalization, the Gaussian curvature is constant:

$$K = -1. \tag{52.45}$$

The geodesics are Euclidean chords, but their hyperbolic length diverges as they approach the boundary.

Finiteness of the boundary and infinitude of the hyperbolic depth The metric determinant of (52.44) produce

$$\mathrm{d}A_K = \frac{\mathrm{d}u\ \mathrm{d}v}{(1 - r^2)^{3/2}}. \tag{52.46}$$

The area of the subdisk $r < R < 1$ is

$$A_K(R) = \int_0^{2\pi} \int_0^R \frac{r\ \mathrm{d}r\ \mathrm{d}\theta}{(1 - r^2)^{3/2}} \tag{52.47}$$

$$= 2\pi \left(\frac{1}{\sqrt{1 - R^2}} - 1 \right). \tag{52.48}$$

Therefore,

$$\lim_{R\to 1^-} A_K(R) = +\infty.$$

Simultaneously, the same boundary encloses the symplectic area.

$$\pi a_S b_S = 2\pi\hbar_{\mathrm{ret}} = h_{\mathrm{ret}} < \infty.$$

Theorem 52.9 (Finiteness of Action and Infinitude of Depth)**.** *The radion ellipse has a finite turn action h_{ret}, whereas its interior, equipped with the Hilbert–Beltrami–Klein metric, has infinite hyperbolic area:*

$$\boxed{\mathrm{Area}_{\mathrm{simp}}(\partial\mathbb{E}_S) = h_{\mathrm{ret}} < \infty, \qquad \mathrm{Area}_K(\mathbb{E}_S) = +\infty.} \tag{52.49}$$

There is no contradiction: $\mathrm{Area}_{\mathrm{simp}}$ and Area_K are different measures. The first counts oriented action in phase; the second measures interior projective depth. The thesis "finite boundary, infinite interior" is now an equality and a limit, not a metaphor.

Focal Coordinates Inside Klein In the normalized disk, the foci are located at $(\pm e_f, 0)$. The distance from the center to a focus is

$$u_f = \operatorname{artanh} e_f = \operatorname{arcosh}(e^{\eta}) = 0.81338233117534233376088973108822 8\ldots. \tag{52.50}$$

The focal–focal distance is

$$d_K(F_-, F_+) = 2u_f = 1.62676466235068466752177946217646\ldots.$$

We have

$$e_f = \tanh u_f, \qquad e^{-\eta} = \operatorname{sech} u_f, \qquad \eta = \log\cosh u_f. \tag{52.51}$$

The region up to the focal radius has area

$$A_K(e_f) = 2\pi(e^{\eta} - 1) = 2.19559620884061869541206115980360\ldots.$$

All open ellipses are projectively isometric as Hilbert domains. Curvature -1 alone therefore does not retain eccentricity. The HMT form resides in the joint structure: the distinguished affine chart, symplectic form, sheet labeling, and boundary parametrization.

52.5.2 Difference between phase return and return of the enriched state

52.5.2.1 Helical elevation of the nonadic return

Nonadic decomposition and memory quotient The elementary operation

$$n = 9q_9(n) + \rho_9(n), \qquad H_9(n) = (\rho_9(n), q_9(n)) \tag{52.52}$$

satisfies

$$H_9(n+9) = H_9(n) + (0,1). \tag{52.53}$$

The first coordinate closes; the second ascends. This identity is the minimal arithmetic version of a screw.

For a spectral fiber,

$$n \longmapsto (\tau_\gamma^n, n)$$

is a helix over S^1. Adding the contraction $(5/9)^n$ produces an inner spiral. The radion participates in both readings: a unit of phase on the boundary and an oriented unit of action in the lift.

Memory range as dimensional reader Suppose that a visible projection preserves the phase value but loses d linearly independent memory cocycles. Any faithful lift requires at least d additional coordinates to reconstruct them. This motivates a precise reading of Dimensional Mechanics:

$$\begin{gathered}\text{emergent dimension} = \text{minimum rank of independent memory} \\ \text{not publishable on the visible sheet.}\end{gathered} \tag{52.54}$$

It is not asserted that every physical dimension is a counter. Rather, in the TPK domain, every independent memory that must survive forces a coordinate of the lift.

> Dimension appears when the projection can no longer preserve the entire history. The circle suffices to state where the phase is; it does not suffice to state how many times it returned, which sheet it transported, which interval contracted, or which carry survived.

Cylinder Assembly, Spirals, and Helical Trajectories The coinductive cylinders are not physical tubes added to a spiral. They are nested intervals that preserve prefixes and narrow the value. The spiral describes transverse contraction; the helix describes longitudinal memory; the cylinder describes the set of compatible values at a finite depth. In the limit, the intersection of the cylinders selects a unique section.

The spatial image brings together, without confusion:

$$\begin{aligned}\text{angle} &\leftrightarrow \text{visible phase},\\ \text{height} &\leftrightarrow \text{return/memory},\\ \text{cylinder radius} &\leftrightarrow \text{refinement uncertainty},\\ \text{sheet} &\leftrightarrow \text{bidirectional orientation}.\end{aligned}$$

The rate 3^{-54} contracts the cylinder by return; it is not added to the angle and does not replace the actual carry ε_R.

52.5.2.2 Phase closures of orders 2π and 4π

In the circular projection, 2π restores the phase. In an oriented lift with two sheets, one turn may close on the conjugate sheet and require a second turn to restore the orientation:

$$U_{2\pi} = -I, \qquad U_{4\pi} = I.$$

The structure agrees with spinorial periodicity when the functor is applied to a representation $SU(2)$; the TPK lift is not identified with $SU(2)$ without that map.

The areal reading is consistent:

$$\mathcal{A}(2\pi) = h_{\mathrm{ret}}, \qquad \mathcal{A}(4\pi) = 2h_{\mathrm{ret}}.$$

In a Möbius band, one visible circuit reverses the sheet and two circuits restore the orientation. The $2\pi/4\pi$ is not an accidental duplication; it is the difference between phase return and return of the enriched state.

52.6 Oriented ellipse and conjugate variables: minimum uncertainty and electromagnetic oscillation

52.6.1 Conjugate symplectic variables and determination of the minimum uncertainty

The symplectic form coordinates action, uncertainty, and oscillatory dynamics without altering the genealogy of the state.

52.6.1.1 Realization of the state in a Hilbert space

Minimum Covariance Matrix Once the action ellipse has been constructed, it can be performed on a pair of conjugate operators

$$[\widehat{Q}, \widehat{P}] = i\hbar_{\mathrm{ret}}.$$

We define

$$V_\eta = \frac{\hbar_{\mathrm{ret}}}{2}\begin{pmatrix} e^{\eta} & 0 \\ 0 & e^{-\eta} \end{pmatrix}. \tag{52.55}$$

Its determinant is

$$\det V_\eta = \frac{\hbar_{\mathrm{ret}}^2}{4}. \tag{52.56}$$

Consequently,

$$(\Delta Q)^2 = \frac{\hbar_{\mathrm{ret}}}{2}e^{\eta}, \qquad (\Delta P)^2 = \frac{\hbar_{\mathrm{ret}}}{2}e^{-\eta}, \qquad \Delta Q\,\Delta P = \frac{\hbar_{\mathrm{ret}}}{2}. \tag{52.57}$$

The Robertson–Schrödinger inequality is saturated.

The compressed annihilator

$$\widehat{a}_\eta = \frac{e^{-\eta/2}\widehat{Q} + ie^{\eta/2}\widehat{P}}{\sqrt{2\hbar_{\mathrm{ret}}}} \tag{52.58}$$

satisfies $[\widehat{a}_\eta, \widehat{a}_\eta^\dagger] = 1$. Its vacuum has wavefunction

$$\psi_\eta(Q) = (\pi\hbar_{\mathrm{ret}}e^{\eta})^{-1/4}\exp\left(-\frac{Q^2}{2\hbar_{\mathrm{ret}}e^{\eta}}\right). \tag{52.59}$$

Ellipse as level set of the Mahalanobis functional The set

$$\mathbb{E}_{\mathrm{act}} = \{x \in \mathbb{R}^2 : x^{\mathsf{T}}V_\eta^{-1}x \le 4\} \tag{52.60}$$

has semiaxes

$$a_S = 2\Delta Q, \qquad b_S = 2\Delta P. \tag{52.61}$$

Its area is

$$4\pi\sqrt{\det V_\eta} = 2\pi\hbar_{\mathrm{ret}} = h_{\mathrm{ret}}.$$

The previously constructed HMT ellipse coincides exactly with the contour of two deviations from the minimal Gaussian state.

Proposition 52.10 (Unique chain of the quotient form)**.** *After declaring the spectral, symplectic, and Hilbert interfaces,*

$$\boxed{e^{-\eta} = \sqrt{\frac{A - C^*}{A + C^*}} = \frac{b_1}{a_1} = \frac{b_S}{a_S} = \frac{\Delta P}{\Delta Q}.} \tag{52.62}$$

The action ellipse corresponds to the classical level $H = \hbar_{\mathrm{ret}}\omega$ and to the contour 2σ of the compressed vacuum. It must not be conflated with the mean vacuum energy, $\hbar_{\mathrm{ret}}\omega/2$. This factor-of-two difference is a mandatory physical control.

Invariance Conditions of the Ellipse as an Operational Object In the conventional formulation, an uncertainty ellipse may be viewed as a graphical device for representing a covariance matrix. Here the causal order is reversed: the positive ellipse already exists as a publication of $(A, C^*, \hbar_{\mathrm{ret}})$; Hilbert space recognizes it through (52.55). The claimed ontological reality does not mean that a classical particle physically traverses an oval in the plane (Q, P). It means that the state preserves a positive form, a total action, and an orientation quotient before a probabilistic theory interprets them.

The wave function does not create the form; it represents it. Uncertainty does not create $\hbar$; it publishes the impossibility of simultaneously compressing the two directions without altering the symplectic product.

> The probabilistic reading is one possible realization of the ellipse, not its cause. The primary object is the joint preservation of product and orientation. Probability appears when that geometry is published as the covariance of a state on a Hilbert space.

52.6.2 Exchange $\mu \leftrightarrow \varepsilon$, inversion $Z \leftrightarrow Z^{-1}$, and conservation of causal velocity

Energy exchange between the electric and magnetic sectors The two terms of (52.67) become

$$U_E(\theta) = \hbar_{\mathrm{ret}}\omega \cos^2\theta, \qquad U_B(\theta) = \hbar_{\mathrm{ret}}\omega \sin^2\theta. \tag{52.63}$$

Therefore,

$$U_E + U_B = \hbar_{\mathrm{ret}}\omega.$$

Electric–magnetic polarity does not consist in arbitrarily labeling the foci. It consists of two conjugate reserves that are exchanged during the orbit while keeping the frequency and total action constant.

The common quotient extends:

$$\boxed{e^{-\eta} = \frac{b_S}{a_S} = \frac{\Delta P}{\Delta Q} = \frac{Z_\eta}{Z_*} = \sqrt{\frac{A - C^*}{A + C^*}}.} \tag{52.64}$$

The conserved products are

$$a_S b_S = 2\hbar_{\mathrm{ret}}, \qquad \det V_\eta = \frac{\hbar_{\mathrm{ret}}^2}{4}, \qquad L_\eta C_\eta = \omega^{-2}.$$

Exact Result

The LC oscillator is the minimal physical realization of the double reading: the product preserves action and frequency; the quotient preserves orientation and impedance. A complete cycle exchanges electricity and magnetism without losing the area $\oint P\, \mathrm{d}Q = h_{\mathrm{ret}}$.

52.6.3 Inductive–capacitive pair (L_η, C_η): invariance of $L_\eta C_\eta = \omega^{-2}$ and orientation of impedance

52.6.3.1 Inductive–capacitive oscillator associated with the angular pair

Independent construction of the 2 conjugated reservoirs Given $\omega > 0$ and a reference impedance $Z_* > 0$, we define

$$L_\eta = \frac{Z_*}{\omega} e^{-\eta}, \qquad C_\eta = \frac{1}{Z_*\omega} e^{\eta}. \tag{52.65}$$

Then

$$L_\eta C_\eta = \omega^{-2}, \qquad \sqrt{\frac{L_\eta}{C_\eta}} = Z_* e^{-\eta}. \tag{52.66}$$

The frequency remains fixed; the impedance preserves the orientation of the form.

The Hamiltonian is

$$H_{LC} = \frac{q^2}{2C_\eta} + \frac{\Phi^2}{2L_\eta}. \tag{52.67}$$

With the normalized variables

$$Q = \sqrt{Z_*}\, q, \qquad P = \frac{\Phi}{\sqrt{Z_*}}, \tag{52.68}$$

we obtain

$$H_{LC} = \frac{\omega}{2}\left(e^{-\eta}Q^2 + e^{\eta}P^2\right). \tag{52.69}$$

On (52.37),

$$H_{LC} = \hbar_{\mathrm{ret}}\omega. \tag{52.70}$$

LC Oscillator as an Elementary Dynamic Unit The harmonic oscillator pervades nearly all of physics because it linearizes the neighborhood of an equilibrium, decomposes fields into modes, organizes quanta, and allows propagation to be read as a superposition of phases. In the radion, this universality receives a concrete genealogy: the mode does not begin in an external differential equation, but in a positive form with a fixed return action. Conventional dynamics appears upon choosing a clock ω and a transducer Z_*.

Frequency does not alter the action ellipse: it changes the level energy through $E = \hbar_{\mathrm{ret}}\omega$. This separation is crucial. Geometry fixes action; the clock converts action into energy.

52.6.3.2 Time reversal and conjugate propagations

Let $H = H^*$ be given, and let J_E be a complex structure with $J_E^2 = -I$. Suppose there is an involution C such that

$$CJ_EC^{-1} = -J_E, \qquad CHC^{-1} = H.$$

The evolution

$$U(t) = \exp\left(-\frac{J_E H t}{\hbar_{\mathrm{ret}}}\right) \tag{52.71}$$

satisfies exactly

$$CU(t)C^{-1} = U(-t). \tag{52.72}$$

This is the minimal operator form of bidirectionality: conjugation interchanges the temporally opposed prolongations.

Wheeler–Feynman absorber theory and the reading of antiparticles as temporally conjugate trajectories offer a subsequent historical realization. Identity (52.72) is demonstrated; converting it into a complete theory of advanced and retarded propagators requires declaring action, boundary conditions, causality, and absorber interactions. The monograph preserves the physical intuition without converting a correspondence into an equality of theories.

52.7 3 TRIT regimes: electric–magnetic and elastic–rotational polarities

52.7.1 Coordination of the elliptic, parabolic, and hyperbolic realizations

The 3 TRIT regimes admit complex, electromagnetic, and mechanical realizations with distinct types.

52.7.1.1 Operator quadratic of root internal of −1

Exponential representation of the elliptic regime $J^2 = -I$ With $J^2 = -I$,

$$T_{\mathrm{ell}}(x, y) = e^{-xI - yJ} = e^{-x}(\cos y\, I - \sin y\, J). \tag{52.73}$$

Under the identification generated by J,

$$T_{\mathrm{ell}}(x,y) \longleftrightarrow e^{-x-iy}.$$

The scalar x controls dilation; y controls oriented rotation. The form $a + bi$ is recognized as elasticity plus rotation, not as two arbitrarily adjoined quantities.

Exponential representation of the parabolic regime $J^2 = 0$ With $N^2 = 0$, the exponential is truncated:

$$T_{\mathrm{par}}(x,y) = e^{-x}(I - yN). \tag{52.74}$$

The regime describes the threshold at which there is neither periodic rotation nor exponential opening. In the active temporal reading it is the Euclidean present, but it retains memory of the branches that bound it.

Exponential Representation of the Hyperbolic Regime $J^2 = +I$ With $R^2 = I$ and $P_\pm = (I \pm R)/2$,

$$T_{\mathrm{hyp}}(x,y) = e^{-xI-yR} = q_+P_+ + q_-P_-, \qquad q_\pm = e^{-x\mp y}. \tag{52.75}$$

The elementary invariants are

$$q_+q_- = e^{-2x}, \qquad \frac{q_-}{q_+} = e^{2y}. \tag{52.76}$$

The product preserves the common mode; the quotient preserves the oriented separation.

Applied to the angular pair,

$$x = \frac{\pi A}{180}, \qquad y = \frac{\pi C^*}{180}.$$

Therefore, A is the common coordinate of the publication and C^* its oriented contrast. Only after a physical reader has been applied are they recognized as electric and magnetic poles.

52.7.2 Typed separation of the constitutive and mechanical polarities

52.7.2.1 Constitutive Operator on the Channels 90/120

Common and Oriented Component Decomposition We define

$$\mathcal{E} = \log\big[(1-q_+^{90})(1-q_-^{90})\big] - \log\big[(1-q_+^{120})(1-q_-^{120})\big], \tag{52.77}$$

$$\mathcal{B} = \log\frac{1-q_-^{90}}{1-q_+^{90}} - \log\frac{1-q_-^{120}}{1-q_+^{120}}. \tag{52.78}$$

Under $C^* \mapsto -C^*$, $q_+ \leftrightarrow q_-$ are interchanged. Therefore, $\mathcal{E}$ is even and $\mathcal{B}$ is odd.

The normalized constitutive equations are

$$\widehat{\mu} = e^{\mathcal{E}+\mathcal{B}}, \qquad \widehat{\varepsilon} = e^{\mathcal{E}-\mathcal{B}}, \qquad \widehat{Z} = e^{\mathcal{B}}, \qquad \widehat{c} = e^{-\mathcal{E}}. \tag{52.79}$$

They are verified exactly.

$$\widehat{Z} = \sqrt{\frac{\widehat{\mu}}{\widehat{\varepsilon}}}, \qquad \widehat{c} = (\widehat{\mu}\widehat{\varepsilon})^{-1/2}. \tag{52.80}$$

Conjugation produces

$$C^* \mapsto -C^* : \qquad \widehat{\mu} \leftrightarrow \widehat{\varepsilon}, \quad \widehat{Z} \leftrightarrow \widehat{Z}^{-1}, \quad \widehat{c} \mapsto \widehat{c}. \tag{52.81}$$

Theorem 52.11 (Constitutive polarity)**.** *The reader* 90/120 *converts the common mode and oriented contrast of the pair (A, C^*) into two conjugate constitutive quantities. Sheet inversion exchanges permeability and permittivity, reverses impedance, and preserves normalized velocity.*

This is the precise formulation of the intuition "electrical part and magnetic part". One writes neither $A = E$ nor $C^* = B$. Instead, one writes the map

$$(A, C^*) \to (x, y) \to (q_+, q_-) \to (\mathcal{E}, \mathcal{B}) \to (\widehat{\varepsilon}, \widehat{\mu}, \widehat{Z}, \widehat{c}).$$

Elastic-rotational realization of the constitutive polarity The same information may be published in the complex regime by

$$Z_{\mathrm{em}} = e^{\mathcal{E}/2}\left(\cos\frac{\mathcal{B}}{2}\, I - \sin\frac{\mathcal{B}}{2}\, J\right). \tag{52.82}$$

The factor $e^{\mathcal{E}/2}$ is an elastic dilation; the factor generated by J is a rotation. Complex notation does not add a mysterious imaginary dimension to a previously given real world: it records two operational modes already separated by the TRIT.

Transduction of Orientation into Effective Load The radion sheet σ fixes an orientation before a unit of charge is introduced. Dimensional Mechanics then provides the transducer

$$e_{\mathrm{int}} = \sqrt{\frac{2\alpha_{\mathrm{HMT}} h_{\mathrm{ret}}}{Z_{\mathrm{int}}}}, \qquad Q = n_Q e_{\mathrm{int}}.$$

The causal chain is

$$\text{sheet} \to \text{orientation} \to \text{constitutive} \to \text{dimensional transducer} \to \text{physical charge}.$$

Calling the unit *radion* does not prematurely identify the orientation with the coulomb; it makes visible the locus where the charge sign may reside.

> Electricity and magnetism are not affixed to the circle from outside. They emerge when the same state is read through product and quotient: the product retains the common mode, while the quotient retains the orientation. The LC oscillator realizes the exchange; the reader 90/120 publishes the constitutive relations; the dimensional chart assigns units.

52.8 Separation of the Publications 90/120: Incidence, Record, Spectrum, Barbero Kernel, and Towers

52.8.1 Typed separation of the publications of the sector 90/120

52.8.1.1 Global harmonic hierarchy and semigroup $\langle 90, 120\rangle$

To avoid a symbol collision, we fix

$$R_{\mathrm{tow}} := -R_{\mathrm{ch}}.$$

Then

$$T = e^{-xI + yR_{\mathrm{tow}}} = q_- P_+^{\mathrm{tow}} + q_+ P_-^{\mathrm{tow}}. \tag{52.83}$$

The even and odd towers are

$$c_n = \mathrm{Tr}(T^n) = q_-^n + q_+^n = 2e^{-nx}\cosh(ny), \tag{52.84}$$

$$s_n = \mathrm{Tr}(R_{\mathrm{tow}} T^n) = q_-^n - q_+^n = 2e^{-nx}\sinh(ny). \tag{52.85}$$

Under $C^* \mapsto -C^*$, c_n is even and s_n is odd. It holds that

$$c_n^2 - s_n^2 = 4e^{-2nx}, \tag{52.86}$$

and both sequences satisfy the order-two recurrence determined by the eigenvalues $q_\pm$.

The semigroup

$$\langle 90, 120\rangle = 30\langle 3, 4\rangle \tag{52.87}$$

is the harmonic hierarchy of a single bilayer operator. It is not a list of eight lateral corrections. Its completeness means that every positive ratio admits a convergent expansion; it does not mean that an expansion obtained from the target is a prospective physical selector.

52.8.1.2 Typed classification and separation of the realizations 90/120

Object	Operation	What is conserved / why it is not another object
Incidence N_6, N_8	finite counting over active phases	cardinality and orientation; it produces 90, 120, not a series;
$-1/12$	diferencia normalized (52.88)	incidence scalar; no Barbero weight;
E_{dod}	harmonic extractor of the wheel	dodecaphase phase; no real carry;
$h = C^*/6$	reconstruction of six pairs	opening by pair; no metrological normalization;
F_{spec}	cola logaritmica $j \geq 2$	complete spectral publication; differs from ε_R°;
$\varepsilon_R^{(1)}$	subtraction APP between S_T and S_E	real join of two lifts; not a Lambert series;
$K_{6\to 8}$	$12\Delta S_{90} - \Delta S_{120}$	marked jump and conjugate evaluation; pole coefficient $1/24$ verified; Barbero output;
$12 : -1$	twelve sectors and one oriented seam	kernel weight; subsequent certificate (52.91); distinct from $-1/12$;
$\langle 90, 120\rangle$	semigroup of powers of T	global harmonic hierarchy; no residue per species.

Tesis rectora

All these objects descend from the same APP–TRIT–TPK state. That common genealogy explains why they share numbers and symmetries. Their typing explains why they cannot replace one another.

52.8.2 Conservation of Incidence and Orientation Between the Tritic Kernel and Its Subsequent Realizations

The typed hierarchy separates incidence, record, spectral evaluation, Barbero functional, and harmonic towers.

52.8.2.1 Tritic incidence, dodecaphasic recording and hexadic reading

Primary combinatorial derivation of 90 **and** 120 The counts

$$90 = 6\binom{6}{2}, \qquad 120 = 8\binom{6}{2}$$

arise from the phase selector and its active incidences. The normalized orientation satisfies

$$\frac{30}{120} - \frac{30}{90} = -\frac{1}{12}. \tag{52.88}$$

This scalar is an incidence result. It is neither the weight $12 : -1$ of the Barbero kernel nor a dodecaphase carry.

The dodecaphonic extractor can be published through a combination of harmonics as

$$E_{\mathrm{dod}}(\phi) = 12\cos(3\phi) - \cos(4\phi).$$

Its domain is the phase of the wheel; its output is a harmonic selector. Although the numbers 12 and -1 appear, it does not act on Lambert series or produce ε_R.

52.8.3 Dodecaphasic origin of the weight $12 : -1$ and Diophantine verification of its pole coefficient

52.8.3.1 Barbero–Immirzi hexad–octad functional

Oriented series and incidence jump We define

$$S_{90}(q) = \frac{q^{90}}{1-q^{270}}, \qquad S_{120}(q) = \frac{q^{120}}{1-q^{360}}, \tag{52.89}$$

and

$$\Delta S_m = S_m(q_-) - S_m(q_+).$$

The marked inclusion functional is

$$K_{6\to 8} = 12\Delta S_{90} - \Delta S_{120}. \tag{52.90}$$

Diophantine verification of the dodecaphasic weight $12 : -1$ The dodecaphasic fundamental chain and its return reader, constructed in (51.32)–(51.34), produce twelve terms of type S_{90} and one boundary term of type $-S_{120}$. The oriented pair is determined before calculating the pole coefficient.

Consider $aS_{90} - bS_{120}$. Verification of the coefficient of $(1-q)^{-1}$ takes the form

$$\frac{a}{270} - \frac{b}{360} = \frac{1}{24}. \tag{52.91}$$

Multiplying by 1080 gives

$$4a - 3b = 45.$$

The unique seam of the fundamental turn has absolute multiplicity one. Its Diophantine verification corresponds to the minimal integer counterterm $|b| = 1$. For $b = 1$, $a = 12$; for $b = -1$, $a = 21/2$ is not an integer. Therefore,

$$\boxed{a : b = 12 : 1, \qquad aS_{90} - bS_{120} = 12S_{90} - S_{120}.} \tag{52.92}$$

Proposition 52.12 (Uniqueness of the Diophantine verification)**.** *The generated pair* $(12, 1)$ *is the unique integer solution of* (52.91) *with a positive principal channel and minimal counterterm* $|b| = 1$.

The hexad–octad realization preserves the channels $90/120$ previously constructed; the dodecaphasic chain supplies the multiplicities and boundary orientation; the return reader assigns the series to the generators. These joint operations produce $12S_{90} - S_{120}$. The equation (52.91), positivity, and minimality retain their role as subsequent arithmetic verification.

The Barbero-Deformable chain is subsequent:

$$(A, C^*) \to (x, y) \to q_\pm \to K_{6\to 8} \to \gamma_{\mathrm{BI}},$$

with evaluation

$$\gamma_{\mathrm{BI}} = 0.274007672694459\ldots.$$

Barbero–Immirzi does not retroactively generate C^*, Δ_4, or ε_R.

52.8.4 Extraction of the finite component subsequent to the oriented dodecaphasic system R_{12}: $C^* \mapsto C^*/6$, remainder $j \geq 2$, and reconstruction of 6 sections

Extraction of component $C^*/6$ from the dodecaphase record The twelve sectors group into six opposite pairs:

$$p_i = e_i + e_{i+6}, \qquad a_i = e_i - e_{i+6}, \qquad i = 1, \ldots, 6. \tag{52.93}$$

The reconstruction has profile $1 + 5 + 6 = 12$. The opening per pair is

$$h = \frac{C^*}{6}. \tag{52.94}$$

It is neither an external normalization nor one sixth of a target: it is the internal index of the hexadic reconstruction of the record $\mathcal{R}_{12}$.

We define

$$q_{h,-} = \exp\left[-\frac{\pi}{180}(A - h)\right], \qquad q_{h,+} = \exp\left[-\frac{\pi}{180}(A + h)\right]. \tag{52.95}$$

52.8.5 Quantitative decomposition of the carry and spectral publications: $F_{\mathrm{spec}} = \varepsilon_R^\circ + \chi_R$

52.8.5.1 Spectral publication of the tail of orders $j \geq 2$

Definition of the spectral functional For $m \in \{90, 120\}$, let

$$L_m^{(2)}(q) = \sum_{j \geq 2} \frac{q^{mj}}{j} = -\log(1 - q^m) - q^m. \tag{52.96}$$

The reading of a pair is

$$T_h^{(2)} = \frac{180}{\pi}\Big[L_{90}^{(2)}(q_{h,-}) - L_{90}^{(2)}(q_{h,+}) - L_{120}^{(2)}(q_{h,-}) + L_{120}^{(2)}(q_{h,+})\Big]. \tag{52.97}$$

The reconstruction of the six pairs gives

$$F_{\mathrm{spec}} = 6T_h^{(2)} = 5.1499235153094574410\ldots \times 10^{-8\,\circ}. \tag{52.98}$$

The radion carry is

$$F_{\mathrm{acarreo}} = \varepsilon_R^\circ = 5.1383016758575282072\ldots \times 10^{-8\,\circ}.$$

They do not coincide:

$$\chi_R := F_{\mathrm{spec}} - F_{\mathrm{acarreo}} = 1.16218394519292338\ldots \times 10^{-10\,\circ}. \tag{52.99}$$

The equality

$$F_{\mathrm{acarreo}} = F_{\mathrm{spec}} - \chi_R$$

is a valid change of chart once both outputs have been constructed. It must not be presented as an independent generation of ε_R° if χ_R is defined by the subtraction itself. The tail is closed and meaningful; what is false is its direct identification with carry.

Falsification criterion 52.13. After converting the tail expressed in degrees to the internal angular unit,

$$\frac{\pi}{180^\circ} F_{\mathrm{spec}} - \varepsilon_R^{(1)} = 2.0283936357433839\ldots \times 10^{-12} \neq 0.$$

Therefore, neither the complete logarithm nor the tail $j \geq 2$, even after applying the chart of units, is $\varepsilon_R^{(1)}$. A second autonomous spectral factorization would need to generate χ_R without using the difference as a definition; the APP–TPK closure of the radion does not depend on that promotion.

52.9 Oriented holonomy and physical geometry: later realizations of Minkowski, Hodge, Lorentz, and Cartan–Holst

Oriented holonomy admits subsequent causal and geometric realizations in Minkowski, Hodge, Lorentz, and Cartan–Holst.

Construction of the Lorentzian metric from the APP block

APP matrix of parameters 7 **and** 2 The central matrix

$$B_c = \begin{pmatrix} 7 & 2 \\ 2 & 7 \end{pmatrix} = 9P_+ + 5P_- \tag{52.100}$$

it is normalized by its determinant:

$$M_c = \frac{B_c}{\sqrt{45}} = \exp\left(\frac{1}{2}\log\frac{9}{5}\,R\right) \in SO^+(1,1). \tag{52.101}$$

The internal speed is

$$\eta_c = \frac{1}{2}\log\frac{9}{5}.$$

The associated projective publication satisfies

$$P_B^n = P_+ + \left(\frac{5}{9}\right)^n P_-. \tag{52.102}$$

The same ratio $5/9$ that appears as a spectral contraction is recognized here as the separation of one stable mode and one contractive mode. The identity is operatorial; it does not turn every occurrence of $5/9$ into the same map.

Incidence $6 \to 8$ **and causal-signature quotient** Let M be the typed incidence between six faces and eight vertices. The recovered spectral relation is

$$MM^{\mathsf{T}} = 12P_u + 4P_-, \tag{52.103}$$

where P_u projects onto the uniform mode and P_- onto the oriented subspace. The surviving quotient of dimension four decomposes as

$$Q_4 \simeq \mathbb{R}u \oplus E_-. \tag{52.104}$$

Declaring the uniform mode negative and the three oriented modes positive, one obtains

$$B_{\text{caus}} = \operatorname{diag}(-1,1,1,1). \tag{52.105}$$

The Minkowski screen does not select the HMT state. It is the subsequent causal realization of the quotient already constructed by the incidence.

52.9.1 Hodge duality on 2-Lorentzian forms

52.9.1.1 Hodge Duality and Quarter-turn Operator

With the signature $(-+++)$ and an orientation fixed, the Hodge star on two-forms satisfies

$$\star : \Lambda^2 Q_4^* \to \Lambda^2 Q_4^*, \qquad \star^2 = -I. \tag{52.106}$$

Thus, the quarter-turn expressed in the phase plane by $J^2 = -I$ reappears in field space as a complex structure on Λ^2. The domains differ, but the genealogy of orientation is preserved by the functor.

Let A_{em} be a potential and

$$F = \mathrm{d}A_{\mathrm{em}}. \tag{52.107}$$

The decomposition of F relative to a temporal observer produces electric and magnetic fields; $\star F$ exchanges their roles with the sign fixed by the orientation and signature. The constitutive polarity of (52.81) thus acquires a differential realization.

Electromagnetic and causal transduction chain The transport that must remain visible is

$$\Gamma_9 \longrightarrow \text{memory helix} \longrightarrow (Q_4, B_{\mathrm{caus}}, \star) \longrightarrow A_{\mathrm{em}} \longrightarrow F = \mathrm{d}A_{\mathrm{em}} \longrightarrow m\nabla_u u = q(\iota_u F)^\sharp. \tag{52.108}$$

Each arrow adds structure: the holonomy preserves return; the quotient fixes causality; Hodge fixes duality; the potential fixes the field; coupling to charge produces dynamics.

The final equation is the Lorentz force in geometric form. The TPK helix is its memory antecedent, not a physical orbit already moved by a field. Dynamics appears only upon introducing F, q, and the connection ∇.

52.9.2 Separation between internal torsional memory and Cartan–Holst geometric realization

52.9.2.1 Lorentzian Realization of Helical Trajectories

In a uniform magnetic field, a particle of charge q, mass m, and relativistic factor γ has

$$\omega_c = \frac{|q|B}{\gamma m}, \qquad r_L = \frac{p_\perp}{|q|B}, \qquad \Delta z = \frac{2\pi p_\parallel}{|q|B}. \tag{52.109}$$

The cyclotron phase closes while the parallel motion advances: the orbit is helical. The parallel with (52.53) is structural and can be formalized by a transducer that preserves phase, orientation, and step. The quotient q_9 is not identified with the spatial coordinate z; rather, the same architecture of return plus advance is recognized.

The Lorentz force is not derived from the image of a spiral by similarity. It is derived by completing (52.108). The image helps explain why circular phase and longitudinal memory are compatible; the field form determines the dynamics.

52.9.2.2 Confluence between action, area, information, and gravity

Cartan–Holst Realization of Holonomy The gravitational promotion is expressed via a holonomy morphism.

$$\mathrm{Hol}_{\mathcal{A}}\big(\mathfrak{R}_{\mathrm{grav}}(\gamma)\big) = \rho_C\big(\mathrm{Hol}_{\mathrm{TPK}}(\gamma)\big). \tag{52.110}$$

The right-hand side contains route memory; ρ_C realizes it in a gravitational connection. Cartan torsion

$$T^I = D_\omega e^I$$

appears in the codomain. The global torsion Δ_4 is an upstream coordinate that can feed the map, but it is not renamed as T^I without (52.110).

Transduction of the action area into informational area The radion fixes one quantum of action per phase. The Barbero hexad–octad reader subsequently uses the channels $q_{\pm}$, the incidence 90/120, and the functional (52.90). The causal direction is

$$(A, C^*, \hbar_{\mathrm{ret}}) \to q_{\pm} \to K_{6\to 8} \to \gamma_{\mathrm{BI}} \to \text{area/information}.$$

The tritic alphabet provides the unit of entropy $\log 3$, and a cut of 81 channels provides $81 \log 3$. This entropy is not to be confused with $\log 2$, with $\log \varphi$, with a microcanonical entropy, or with a von Neumann entropy unless the state is specified.

The physical synthesis is affirmative but typed: the radion supplies the oriented unit of action that a holonomy can transport; Barbero publishes the area normalization; the causal screen and Hodge make it possible to realize fields; Cartan–Holst receives the holonomy in gravitational geometry.

Hypothesis, domain, and conclusion

The scalar radion equation is not by itself an Einstein equation. Its contribution to gravity is to provide an exact section of the architecture of action, orientation, and holonomy consumed by the gravitational realization.

52.9.2.3 Wick Rotation as Analytic Reader Change

In the conventional formulation, Wick rotation relates a Lorentzian time variable to a Euclidean coordinate through complex continuation. In HMT, the root $J^2 = -I$, the involutive map $R^2 = I$, and the threshold $N^2 = 0$ already exist. The change of reader

$$J \longleftrightarrow R$$

transports a common/oriented pair between elliptic publication and hyperbolic publication. Complex continuation subsequently recognizes that operation in analytic coordinates.

This explains why the circle, the action ellipse, and the hyperbolic interior can belong to the same state without being the same metric. The circle uses J for the phase; the shape of the ellipse uses a symplectic compression generated by R; Klein measures the interior by means of the cross-ratio; the Minkowski screen realizes causality in another codomain.

52.10 Ellipse, Lattice, and Path Phase: Modular Character, Orbits, and Propagation

52.10.1 Rectangular Lattice of Periods, Involution $\tau \mapsto -1/\tau$, and Invariance of j

Modular, orbital, and path characters preserve distinct invariants of the same oriented form.

52.10.1.1 Complex torus associated with the action ellipse

Rectangular lattice of periods The ellipse by itself is not a torus. We declare the lattice

$$\Lambda_\eta = a_S\mathbb{Z} + i, b_S\mathbb{Z} \tag{52.111}$$

and the quotient $\mathbb{C}/\Lambda_\eta$. Its modulus is

$$\tau_\eta = i\frac{b_S}{a_S} = ie^{-\eta} = i\,0.74104814415937516079548366336930 0\ldots. \tag{52.112}$$

The bidirectional inversion $\eta \mapsto -\eta$ exchanges the axes:

$$\tau_{-\eta} = ie^{\eta} = -\frac{1}{\tau_\eta}. \tag{52.113}$$

It is exactly the modular transformation $S : \tau \mapsto -1/\tau$.

Invariance of the Modular Function j By modular invariance,

$$\boxed{j(\tau_{-\eta}) = j(\tau_\eta).} \tag{52.114}$$

In the normalization $j(i) = 1728$,

$$j(\tau_\eta) = 5597.438439324087298300970892547 68\ldots.$$

The normalized moonshine function $J = j - 744$ gives

$$J(\tau_\eta) = 4853.438439324087298300970892547 68\ldots.$$

For the basal APP block,

$$\tau_0 = i\frac{\sqrt{5}}{3}, \qquad j(\tau_0) = 5369.488320246743060219168826352\ldots.$$

Proposition 52.14 (What the modular class preserves)**.** *The sheet involution reverses η, but j preserves the class of the torus. The foci and the axis labelling retain the orientation that j forgets.*

This result connects the two-way structure exactly with modularity once the quotient has been declared. It does not authorize making the Monster act directly on the charge, digits, or foci. The exceptional corridor

$$\text{APP} \to \text{Paley} \to \text{Witt} \to \text{Golay} \to A_2^{12} \to \text{Leech} \to V^\natural \to \text{Monster} \to \text{Moonshine}$$

is another projection of the same enriched state. Identifying a concrete action on the radion requires an intertwiner that preserves its relevant coordinates.

Chain of character form invariants Gathering the declared realizations,

$$\boxed{r_\eta = e^{-\eta} = \sqrt{\frac{A - C^*}{A + C^*}} = \frac{b_1}{a_1} = \frac{b_S}{a_S} = \frac{\Delta P}{\Delta Q} = \frac{Z_\eta}{Z_*} = \Im\tau_\eta.} \tag{52.115}$$

A single ratio runs through spectral geometry, action, covariance, impedance, and modulus. Each equality rests on an explicit map; none depends on decimal resemblance.

52.10.2 Compatibility between the modular character and propagation over oriented paths

52.10.2.1 Areal Conservation in Kepler and Sommerfeld Orbits

Areal Equivalence of the Orbital and Oscillatory Realizations Kepler's ellipse lives in configuration space and responds to a central potential. The radion ellipse lives in phase space and responds to an action form. They are different objects. They share an areal law because both realizations possess a conserved two-form.

For a Keplerian orbit,

$$r(\phi) = \frac{p}{1 + e\cos(\phi - \phi_0)}, \qquad \frac{\mathrm{d}A}{\mathrm{d}t} = \frac{\ell}{2m}. \tag{52.116}$$

The third law takes the form

$$T^2 = \frac{4\pi^2\mu}{K}a^3.$$

For the phase oscillator,

$$J = \oint p \, \mathrm{d}q = \frac{2\pi E}{\omega}. \tag{52.117}$$

If the elementary cell is $J = h_{\mathrm{ret}}$, then

$$E = \hbar_{\mathrm{ret}}\omega, \qquad \frac{J}{2\pi} = \hbar_{\mathrm{ret}}. \tag{52.118}$$

This is the clean convergence between Planck action, angular frequency, and radion.

Sommerfeld quantizes action integrals over cycles. The HMT reading adds the memory of which cycle, sheet, and return survive. On a Möbius band, one visible loop may carry $h_{\mathrm{ret}}/2$ and two loops restore h_{ret}. That topological factor is not added to the Maslov index of EBK quantization; they belong to corrections with distinct owners.

Orbital Holonomy and Advanced and Retarded Propagations An orbit that accumulates holonomy satisfies a condition of the type

$$\epsilon_\gamma \exp\left(\frac{iJ_\gamma}{\hbar_{\mathrm{ret}}}\right) = 1. \tag{52.119}$$

The sign ϵ_γ preserves the sheet; J_γ preserves the action. Apsidal advance or retardation is interpreted as a decoupling between visible angular closure and complete return. The radion supplies the oriented unit with which that difference is measured.

52.10.2.2 Composition of Schrödinger amplitudes and path summation

Four realizations of the same phase Once $\hbar_{\mathrm{ret}}$ is fixed, distinct conventional equations recognize aspects of the same transport:

1. Schrödinger publishes the phase through $i\hbar_{\mathrm{ret}}\partial_t\psi = H\psi$.
2. Pauli adds the double spin leaf and its magnetic coupling.
3. Dirac linearizes the energy–momentum relation and organizes particle and antiparticle within a causal representation.
4. The path sum assigns to each history the phase $\exp(iS[\gamma]/\hbar_{\mathrm{ret}})$.

These theories do not retrospectively generate $\hbar_{\mathrm{ret}}$. They receive the unit of action and realize different contents of the enriched state.

Phase functional over the path space In Feynman's formulation,

$$\mathcal{K}(b,a) = \int_{\gamma:a\to b} \exp\left(\frac{i}{\hbar_{\mathrm{ret}}}S[\gamma]\right)\mathcal{D}\gamma. \tag{52.120}$$

An action increment $\hbar_{\mathrm{ret}}$ changes the phase by one radian. An increment h_{ret} changes it by one revolution. The theorem $\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\theta$ converts this relation into area geometry: the phase of a path can be read as swept action in units of the radion.

The inversion $C_M = -\mathrm{rev}$ on dodecaphase words and the identity (52.72) organize conjugate routes. In an absorber realization, the following are distinguished

$$G_{\mathrm{sym}} = \tfrac{1}{2}(G_{\mathrm{ret}} + G_{\mathrm{adv}}), \qquad G_{\mathrm{odd}} = G_{\mathrm{ret}} - G_{\mathrm{adv}}.$$

The first sector is even under retarded–advanced interchange; the second is odd. This reproduces the separation between even energy/form and odd oriented action of the radion when the transducer preserves the boundary and the symplectic form.

Hypothesis, domain, and conclusion

Classical absorber theory and the Feynman–Stueckelberg interpretation of antiparticles are distinct historical realizations. The former uses a temporally symmetric interaction; the latter reorganizes propagation in relativistic theory. HMT supplies a common antecedent of reversal, but does not merge them without a map of propagators.

52.11 Radical nonadic and decimal boundary: conservation of the radion carry

52.11.1 The carry of the radion in the decimal completion

The nonadic boundary preserves the sum–product defect, vacancy, and completion carry.

52.11.1.1 Radical 3−6−9 of the boundary

Generation and nilpotency of the nonadic radical In the ring $\mathbb{Z}/9\mathbb{Z}$, the ideal

$$\mathfrak{m} = (3) = \{0, 3, 6\} \tag{52.121}$$

satisfies

$$\mathfrak{m}^2 = (9) = 0. \tag{52.122}$$

It is the nilpotent sector of the nonadic boundary. The visible orbit of its three marks is published as

$$369 \longrightarrow 693 \longrightarrow 936 \longrightarrow 369.$$

The return does not imply that all states are equal: the visible permutation closes while the route cocycles may advance.

The double convention

$$9 \equiv 0 \pmod 9, \qquad \mathrm{dr}_9(9) = 9$$

expresses two readers: algebraic residual zero and visible digital-root closure. Thus a nine may absorb boundary torsion without becoming a specific zero of the zeta function.

Sum–product defect $459 - 405 = 54$ The APP sheets produce complementary totals

$$S_+ = 405, \qquad S_\times = 459, \qquad S_\times - S_+ = 54.$$

The 54 is an exact defect of the tables and reappears as a contraction exponent through the identity $9 \cdot 6 = 54$. Each occurrence nevertheless requires its own map. The focal distance $d_1 = 0.544545\ldots$ is not equal to 0.54, and invariant analysis has produced no arrow identifying it with the 54 defect.

The power

$$9^9 = 387,420,489$$

generates a scale where

$$\mathrm{ord}_{10}\left(9^{9^9}\right) = 369,693,099, \qquad \#\,\text{digits} = 369,693,100. \tag{52.123}$$

The block 369|693 appears in the order–length pair; it is not asserted to be the decimal prefix of the power.

52.11.1.2 Arithmetic Theory of Decimal Vacuums

Asymptotic vacancy slope The separation between the decade and the nonary base is

$$\delta_{\mathrm{vac}} = \log_{10} \frac{10}{9}. \tag{52.124}$$

The accumulated counter

$$V_9(n) = \lceil n\delta_{\mathrm{vac}} \rceil \tag{52.125}$$

records how many correction positions are required by the decimal publication of a nonadic evolution. Its jumps form a binary word

$$z_n = V_9(n) - V_9(n-1) \in \{0, 1\}.$$

The gaps are distributed with lengths $21/22$, the returns with lengths $6/7$, and the combined determinant is 15. These numbers arise from the vacancy reader, not from the Barbero kernel, although 15 coincides with $\binom{6}{2}$.

Polarization and Arithmetic Current of the Nonadic Grid We define

$$P_N = \sum_{n=1}^{N} (z_n - \delta_{\mathrm{vac}}), \qquad J_N = P_N - P_{N-1} = z_N - \delta_{\mathrm{vac}}. \tag{52.126}$$

The balanced sequence satisfies $|P_N| < 1$. The "current" J_N is here an arithmetic current: it measures the creation and absorption of vacancies relative to the mean slope. Only a subsequent dimensional transducer can publish it as an electromagnetic current density.

The physical intuition is powerful because the same algebraic form separates an even average from an oriented fluctuation. Rigor requires retaining the type:

$$J_N \in \mathbb{R} \quad \text{dimensionless}, \qquad j^{\mu} \in \text{physical current line}.$$

52.11.1.3 Completion $729 \to 1000$ *and preservation of carry*

Decomposition $1000 = 729 + 243 + 27 + 1$ The completion

$$1000 = 729 + 243 + 27 + 1$$

preserves the unit through four ternary scales. The total crown is

$$1000 - 729 = 271,$$

while the last integer before the closure satisfies

$$999 = 729 + 270.$$

The difference between 270 and 271 distinguishes an occupied boundary from a completing unit. The same care prevents identifying a vacancy with zero or a carry with an actual residue.

Residence of the carry of the radion in the decimal crown The radion's operands begin, in blocks of three digits, with

$$\Phi_T : \quad 000|027|455|906|837|565|\cdots,$$

$$D_E : \quad 000|027|455|010|034|743|\cdots.$$

The subtraction APP gives

$$\varepsilon_R^{(1)} : \quad 000|000|000|896|802|822|\cdots.$$

The small size of the result is not obtained by truncating the low-order summands. It arises because two distinct publications share a long prefix, and the operator $\mathrm{SubAcarreo}_{1000}$ preserves the borrows required to subtract them exactly.

The word *memory* has two levels here:

1. q_{mem} records the depth of nonadic returns;
2. c_i records the local borrowings of decimal subtraction.

The first organizes the helix; the second publishes the decimal. ε_R uses both because its operands follow from cylinders at depth and its subtraction is performed with carry, but it is equal to neither counter.

Tesis rectora

The boundary is not a place where the theory loses information. It is the place where information changes representation: phase that returns, memory that ascends, cylinder that contracts, vacancy that is recorded, and carry that transports the difference.

52.11.2 Compatibility of the direct and torsional sections: structural characterization of π

52.11.2.1 Structural characterization of π by compatibility of sections

Reorder (52.18) gives

$$\boxed{2\pi_{\mathrm{HMT}} = \frac{1 + \Phi_T - \varepsilon_R^{(1)}}{\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}}}.} \tag{52.127}$$

This equality may be called a new definition of π within the radion chart if *structural definition* is understood as an exact characterization by compatibility of sections. It is not a second independent generator: Δ_4 and the carry operator already receive the coinductive section of π. The novelty is that the turn is characterized by the gluing among direct publication, torsion, and memory.

> The equation (52.127) does not say that we first do not know π and then guess it by closing an angle. It says that the π generated by the nonadic connection is exactly the one that makes two internal readings of the same state compatible. It is an identity of intrinsic recognition, not a metrological calibration.

52.12 Evolutionary Conservation of the Holographic Unit Across Dimensions

52.12.1 Typed Separation among the Curvature Regime $\tau \in \{+1, 0, -1\}$, the Radial Response p, and the Global Spin Holonomy

The radion's biography can be represented by a raised curve.

$$\gamma(\theta) = \big(r(\theta)\cos\theta,\ r(\theta)\sin\theta,\ m(\theta)\big),$$

where the first two coordinates belong to the Euclidean plane $\mathbb{R}^2$, and $m(\theta)$ records the memory or depth of the lift. This equation permits a joint reading of circle, helix, and spiral.

When the angle evolves while the radius and memory remain constant, the planar publication is a circle. When angle and memory evolve while the radius retains its value, the complete trajectory is a helix of constant radius. When angle and radius evolve over a fixed memory, a spiral appears in $\mathbb{R}^2$. When all three coordinates evolve, the trajectory is a radial helix: a biography in which phase, amplitude, and memory are jointly transformed.

The radial character p classifies the response law of the radius. One useful family is

$$r_p(\theta) = r_0\big[1 + p\lambda(\theta - \theta_0)\big]^{1/p}, \qquad p \neq 0,$$

with logarithmic limit

$$r_0 \exp\big(\lambda(\theta - \theta_0)\big) \qquad \text{when } p \to 0.$$

In this parameterization, $p = 2$ publishes the Fermat regime, $p = 1$ the Archimedean regime, $p = 0$ the logarithmic regime, $p = -1$ the hyperbolic regime, and $p = -2$ the lituus regime, with the corresponding choices of domain and orientation. Fractional values describe intermediate regimes. Thus, $p = \frac{1}{2}$, $p = \frac{3}{2}$, or $p = -\frac{1}{2}$ express radial responses that interpolate among the integer families and extend the available geometric classification.

The character can also change when crossing a threshold. The differential writing

$$\frac{dx}{d\theta} = \beta(m)\, x^{1-p(m)}, \qquad x = \frac{r}{r_0},$$

describes an evolution through regimes: $p(m)$ remains stable within a phase and changes when the memory reaches a publication boundary. The resulting trajectory connects circular, helical, and spiral sectors through a common law. Continuity of the state and the threshold ledger make those sectors phases of a single evolution.

Three invariants occupy here distinct and coordinated levels. The curvature sign

$$\tau \in \{+1, 0, -1\}$$

classifies the elliptic, parabolic, and hyperbolic regimes. The character p classifies the radial response. Spin records the orientation holonomy accumulated by the lift. Curvature, radial response, and spin form a reading system: curvature determines the local type of space, p determines how the trajectory occupies that space, and spin preserves the orientation acquired while traversing it. Closed and open curves then appear as distinct geometric biographies of the same oriented unit.

52.12.2 Particle as a Persistent Section of an Enriched Orbit: Phase, Route, Fibre, Multisection, and Memory

Dimensional Mechanics can formulate the particle as a persistent section of that geometric and dynamical extension. A compact conceptual notation is

$$\mathfrak{P} = \mathrm{Sec}_{\mathrm{pers}}\big[\tau, p, \mathrm{Hol}; \text{sheet, fiber, route, memory}\big].$$

The particle preserves a recognizable route through changes of phase, curvature, and dimension. Its spin publishes orientation holonomy; its charge publishes phase polarity; its color publishes an internal orientation of the gauge fiber; its flavor distinguishes families of routes or multisections; its mass expresses the dimensional-transduction character by which areal action acquires a volumetric reading. Each property is a reader of the persistent state, and all refer to a common genealogy.

The electron occupies the basal threshold of this construction because it offers the first stable reader in which phase, charge, spin and mass are simultaneously published. The rector electronic mass

$$m_e^{\beta} = 0.510998950690000808608\ldots \text{ MeV}$$

fixes a transduction reference; the preceding basal states preserve their function as genealogical stages. From the electron onward, the quotients K_D/K_Ω, the towers $90/120$, and the domain $81/56/13/324$ organize the publication of massive families. The mass law therefore reads how each persistent section traverses the enriched space and converts areal density of action into volumetric presence.

This interpretation connects spirals to particles precisely. The index p supplies the radial response; τ supplies the curvature regime; holonomy supplies spin; the route and the fiber supply flavor and color;

area–volume transduction supplies the mass character. The particle atlas thereby becomes a classification of stable modes of dimensional traversal.

52.12.3 Transduction of the oriented phase in electric polarization, magnetic response, and boundary radiative emission

Electricity is presented as directed transport of phase and action through a vacancy structure. A vacancy is an admissible transition of the support: it opens a channel, fixes a threshold, and permits the update to advance. The electric component publishes transport tangential to the route. The magnetic component publishes the transverse curvature induced by that transport. Their perpendicularity expresses the geometric relation between advance and rotation.

When two sinusoidal transverse components maintain the appropriate phase difference, the field vector rotates. Longitudinal propagation lifts that rotation to a helix. Variation of amplitude transforms its frontal projection into a spiral. The geometric reading is then fully coordinated: angle carries phase; angular velocity carries frequency; radius carries amplitude and action density; orientation carries polarization and direction; the vertical coordinate carries propagation and memory; p carries the radial regime; the threshold carries emission, absorption, or change of state.

Electromagnetism appears as a phase–action–memory dynamics with complementary publications. Electricity records polar advance; magnetism records the transverse response; the wave records periodicity; the helix records advance with memory; the spiral records radial evolution; radiation records the publication of the state when accumulation reaches a threshold.

This architecture also orders the role of vacancies and cycles. Vacancy supplies the local possibility of transition; the cycle preserves phase; memory distinguishes turns; the threshold determines the next residence of the action. Propagation may remain confined, change radial regime, or be published as controlled radiation. Field forces thereby acquire a continuous genealogical description from the discrete support to the observed wave.

52.12.4 Reversibility of the complete dynamics and thermodynamic cost of information-reducing projections

The Landauer zero represents a limiting case of this law. For a bijective update of the complete state,

$$H(X \mid U(X)) = 0, \qquad \inf Q_L = 0.$$

The information remains available in the genealogy. When a reader forms a quotient q, entropy decomposes as

$$H(X) = H(q(X)) + H(X \mid q(X)).$$

The conditional term measures the information retained outside the projection. A materialized tritic reset satisfies the threshold

$$Q_{\text{reset}} \geq k_B \Theta \log 3.$$

The Boltzmann constant translates the multiplicity grouped by the thermal reader; the Nyquist threshold separates faithful sampling from aliasing; null Landauer characterizes the reversible transport of the integral state. Information, temperature and action are articulated by the type of reading applied.

52.12.5 Self-conservative forces as transport of action among the observable, radial, memory, vacancy, and radiation sectors

Evolutionary conservation is better expressed through exchange than through scalar immobility. A complete state distributes action and momentum among visible motion, memory, radial deformation, vacancies, radiation, and the conjugate return branch. The enriched balance may be written as

$$\Delta J_{\text{visible}} + \Delta J_{\text{memoria}} + \Delta J_{\text{radial}} + \Delta J_{\text{vacancias}} + \Delta J_{\text{radiation}} + \Delta J_{\text{retorno}} = 0.$$

A force is **self-conserving** when its own update law contains the channels that transport, store, publish, and reabsorb action. Conservation belongs to the complete genealogical balance of the interaction. Each reader observes part of the exchange; the genealogy reconstructs its totality.

The Earth–Moon system provides a direct physical image. Earth's rotation, the lunar orbit, tides, deformation, and radiation exchange angular momentum. The net consumption of the complete system closes in the genealogical balance of those transfers. The magnitude called energy functions as a reading derived from the action and momentum published in each sector. Fundamental conservation resides in compatibility among all readers of the exchange.

This formulation dissolves the former boundary between conservative forces and so-called nonconservative forces through a deeper category. Friction, apparent dissipation, and radiation occupy explicit channels of the extended state. A loss in the visible mechanical projection corresponds to a transfer toward memory, deformation, heat, vacancies, or radiation. Self-conservation follows the residence of action through those changes.

52.12.6 Self-inertial systems: publication of acceleration through orientation, curvature, sheet, and memory

The appropriate expression is **relational self-inertia**. It denotes the compatibility between the total state's own connection and the response that appears when it is projected within the global distribution. The endogenous and exogenous aspects are analytic components of a single dynamic relation.

Let Γ be a horizontal trajectory or geodesic of the complete state. Its intrinsic law satisfies

$$\nabla_{\dot\Gamma}\dot\Gamma = 0.$$

When it is projected onto a reader S, the observed acceleration is determined by the curvature of the projection:

$$\nabla^{S}_{\dot\Gamma_S}\dot\Gamma_S = \mathcal{K}_{\pi_S}(\dot\Gamma,\dot\Gamma).$$

The published acceleration expresses the relation between total motion and the geometry of the reader. Mach's principle completes this mechanism through the global boundary trace

$$b : \mathcal{X}_\infty \longrightarrow B_\infty$$

and the factorization of the local inertial response

$$I_v = \bar I_v \circ b.$$

The global distribution enters the local response through a typed map. Relational self-inertia therefore combines the endogenous connection of motion, the global condition transmitted by b, and the observer's concrete projection. A synthetic expression for this coordination is

$$\nabla^{\text{auto}} = \mathcal{M}\big(\nabla^{\text{end}}, b[\mathcal{X}_\infty], \pi_S\big),$$

where $\mathcal{M}$ represents the Machian coupling and preserves the type of each component.

The Ambivalence Principle adds the double orientation of reading. Every direct publication preserves a conjugate return branch; emission and absorption form related endpoints of the same biography; temporal orientation is read from both directions of transport. Absorber theory finds a natural formulation here: source and receiver jointly close the genealogical balance of phase and action. The torsional present is the interface at which both orientations are rendered compatible.

TRIT acts at this level as a time crystal: it organizes the local periodicity of updating and, through memory, preserves the difference between successive returns. The direct branch and the conjugate branch relate emission to absorption, and the observer–observable coupling acquires a dynamical residence within the same state. Published time is the reading of that orientation; genealogical time is the complete sequence of phase, return, and memory.

Mach and Ambivalence perform complementary functions. Mach relates the local response to the global distribution. Ambivalence preserves the forward and conjugate directions of evolution. Relational self-inertia articulates both and replaces the division between inertial and non-inertial systems with a single law of connection, projection, and memory.

52.12.7 Area–volume duality, hexad–octad transition, and the role of the Barbero–Immirzi parameter

The passage from area to volume constitutes a central dimensional transduction. Area publishes boundary action; volume publishes interior depth. The HMT derivation of the Barbero–Immirzi parameter organizes the compatibility between the two measures through hexad–octad incidence and the channels $90/120$:

$$90 = 6\binom{6}{2}, \qquad 120 = 8\binom{6}{2}.$$

The cardinals 6 and 8 admit a cubic realization by means of faces and vertices, whereas the Steiner hexad and octad are distinct incidence objects linked only by the typed morphism $6 \to 8$. The 12 edges of the cube retain their own combinatorial function and do not by themselves define Steiner incidence. The difference in incidence expresses a productive dimensional incompatibility: surface information requires a transduction rule in order to acquire volumetric residence.

The same principle appears in the carry $999 + 1 = 1000$. The nines reach the boundary of the decimal register; the increment simultaneously publishes the closure of the preceding level and the origin $0/1$ of the next. The holographic ratio among 729, 243, 27, and 1 unfolds that transition at triadic scales. The Barbero–Immirzi transduction is inserted into this family of reader changes: boundary and interior preserve the unit while redistributing its measure.

The normalized defect $-1/12$ and the oriented weight $12 : -1$ perform distinct functions within this geometry. The former quantifies an incidence correction; the latter records a signed orientation in the transduction. Their coordination with the minimal area, the modular Hamiltonian, and memory provides the bridge to dimensional dynamics.

52.12.8 Hyperbolic interior contraction, exterior expansion, and holographic conservation of the boundary

The thesis may be formulated from a single idea: unity preserves its identity while changing scale, reader, curvature, memory, and dimension. This permanence has an evolutionary character because unity unfolds, acquires new coordinates, and publishes different properties; it has a holographic character because each finite publication retains the rule for reconstructing the state from which it proceeds. The Holographic Closure of Infinity designates precisely this compatibility between identity and unfolding: each stage contains the law that permits the same genealogy to be deepened inward and prolonged outward.

The governing designation is **principle of evolutionary conservation of the unit through dimensional transduction and holographic projection**. The expression places each term at its proper level. Conservation pertains to genealogical identity; evolution pertains to updating; transduction relates

dimensional realizations; holographic projection preserves the reconstructive correspondence between its readers.

Elementary arithmetic offers the first image of this architecture. The decimal completion

$$1000 = 10^3 = 729 + 243 + 27 + 1 = 3^6 + 3^5 + 3^3 + 3^0$$

exposes four triadic strata within a decimal cubic unit. Upon normalization,

$$1 = \frac{729}{1000} + \frac{243}{1000} + \frac{27}{1000} + \frac{1}{1000},$$

the unit is recognized simultaneously as totality and as graded unfolding. The reciprocal reading

$$3^{-6}, \quad 3^{-5}, \quad 3^{-3}, \quad 3^0$$

describes the inner depth of those strata; its normalization produces the corresponding partition. Relation $999 + 1 = 1000$ expresses the transport mechanism: the last unit completes a register and acts simultaneously as the carry inaugurating the next. Zero and one thus form a continuity interface. The intervals $[0, 1]$, $[0, 10]$, and the prolongation toward $[0, \infty)$ are scalar readers of a single completion law.

The first splitting $1000 = 729 + 271$, followed by $271 = 243 + 27 + 1$, shapes the extreme and mean holographic ratio of the deployment: a dominant triadic core preserves the same resolution rule within the remainder. The decimal cubic unit thus contains a nested triadic depth. Movement toward 729, 243, 27, and 1 reads the inward contraction; the carry toward one thousand reads the outward expansion.

This double orientation organizes HMT infinity. Inward, refinement grows hyperbolically: each cell admits a new depth without losing its filiation. Outward, unity expands through successive dimensional publications. Closure consists in the commutativity of both movements. If U represents the update of the state, R_d the reader on stratum d, and $T_{d\to d'}$ the transduction between strata, evolutionary conservation is expressed by means of

$$R_{d'} \circ U = T_{d\to d'} \circ R_d.$$

The same event may provide an angular measure, an action density, a published mass, or a gravitational response. Their common identity resides in the genealogy that makes those readings commute.

52.12.8.1 Nonadic Monodromy and Helical Lifting with Memory Advance

APP, TRIT, and TPK provide the formal mechanism for this unfolding. APP constructs the support and separates the evaluations that must be preserved. TRIT organizes the local regimes and their ambivalence. TPK transports phase and memory over the enriched support. The causal dependence is fixed by

$$U_t \longrightarrow \Gamma_9 \longrightarrow K_{\mathrm{ph}}.$$

Phase return and memory advance form coordinated operations. After nine steps, the same angular class may reappear,

$$g(K + 9) = g(K),$$

as the memory counter progresses,

$$q_{\mathrm{mem}}\Gamma_9 = q_{\mathrm{mem}} + 1, \qquad B_{K+9} \neq B_K.$$

The precise geometric figure is a helical lift. A closed orbit in the angular projection lifts to an open trajectory when each phase return increments the memory. The circle preserves the cycle; the helix

preserves the cycle and additionally records the depth reached. The coinductive monodromy thereby generates infinite depth through a sequence of locally closed and globally ascending returns.

This image has more than merely illustrative value. The angular wheel constitutes a section of the helix; the helix constitutes the wheel's complete biography when the state transports memory. Each turn recovers a phase position and simultaneously initiates a new sheet. Infinitude arises from compatibility between return and lifting: iterating the cycle produces depth without dissolving orbital identity.

The nonadic certificate gives finite and verifiable content to that architecture. The chain

$$w_6 \longrightarrow w_{12} \longrightarrow w_{18} \longrightarrow w_{24} \longrightarrow w_{30} \longrightarrow R_{36} \longrightarrow G_9$$

orders the lift; the 396 levels, the 2376 trits, the 43 turns, and the 387 pairs $(K, K+9)$ per channel quantify the transit; the five regions of π and the ambient fiber of 729 elements publish subsequent internal readings. This sequence makes a productive monodromy visible: the return recovers the phase and coinduction preserves the growth of memory.

52.12.8.2 Rational unit and coordination of the circular, elliptic, projective, and helical readers

The radion concentrates within a metrological unit the structure that the radian publishes angularly. Its natural definition is that of an **oriented section of phase, action, and memory**. One unit of phase $\theta = 1$ transports one unit of action $\sigma\hbar_{\mathrm{ret}}$, belongs to a complete turn $T_+ = 2\pi_{\mathrm{HMT}}$, and preserves sheet, orientation, nonadic return, and position in the refinement cylinder.

The radian expresses the visible angular coordinate. The radion preserves, together with that coordinate, the transported action, orientation, carry, and memory of the revolution. Angular metrology thereby acquires a genealogy. Measuring an arc means identifying how much rotation has been published and which complete state has realized that rotation.

The relationship between phase and area takes on a particularly clear form:

$$\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\,\theta.$$

One radional unit sweeps an action area $\hbar_{\mathrm{ret}}$; one complete turn encloses h_{ret}. The passage from phase to area is incorporated into the reading unit itself. The angular metric, action, and memory cease to appear as juxtaposed quantities and become coordinates of the same oriented section.

The radion admits several coordinated geometric publications. The circular reader publishes phase; the elliptical reader publishes action and form; the Klein interior reader publishes depth; the nonadic helical reader publishes return and memory. The unit remains genealogically identical across those realizations. The radion therefore constitutes the appropriate metrological link between HMT and Dimensional Mechanics: it offers a unit that can traverse changes of reader while preserving the state presupposed by each partial measurement.

52.12.9 Five-Component Gravitational Polarity and Joint Transduction of Action, Area, Volume, Time, and Mass

Dimensional Mechanics makes it possible to define dimension as a stable publication regime characterized by the minimum rank of independent memory required by the lift. To traverse a dimension is to apply a transducer that preserves genealogy and changes the type of reading. Gravity occupies the level of connection between these regimes.

In this formulation, **interdimensional gravitation with five correlative polarizations**, abbreviated as the **pentapolar structure of gravitation**, is the connection that transports genealogical unity and leaves minimal torsion at each interface. A compact notation for this trace is

$$\Theta_d^{\min} = \nabla_{d+1} \circ T_{d\to d+1} - T_{d\to d+1} \circ \nabla_d.$$

The expression measures the difference between transporting after differentiating and differentiating after transporting. That difference is the minimal geometric memory of the dimensional crossing. The composition of interfaces produces a gravitational holonomy

$$\mathfrak{G}_{d\to D} = \mathrm{Hol}\big(\Theta_d^{\min}, \Theta_{d+1}^{\min}, \dots, \Theta_{D-1}^{\min}\big).$$

The fundamental object is this interdimensional connection. A local graviton-like mode occupies the derived rank of the quantized publication of torsion; gravitation retains its primary residence in compatibility among dimensions.

The term pentapolar encompasses the five polarizations inherent to the continuous state:

$$\mathbf{G}_d^{\pm} = \big(G_{\mathrm{sp},d}^{\pm}, G_{\mathrm{sol},d}^{\pm}, G_{\mathrm{gau},d}^{\pm}, G_{\mathrm{coh},d}^{\pm}, G_{\mathrm{det},d}^{\pm}\big).$$

The five components emerge correlatively from the same enriched state. The polarity ± records direct concentration and conjugate publication. Gravity traverses the dimensional strata while simultaneously transporting those five readings; minimal torsion preserves the trace of each crossing.

Geometry thereby acquires a unified image. The elliptic regime organizes closures; the parabolic regime organizes thresholds; the hyperbolic regime organizes depth. Dimensional transduction connects these regimes with the radial responses p, spin holonomies, and mass publications. The pentapolar structure of gravitation expresses the global coherence of that connection.

M-theory provides subsequent physical screens for this connection: additional dimensions, strings, branes, and T-duality realize concrete modes of transduction. HMT supplies the APP–TRIT–TPK genealogy, the enriched state, memory, and bidirectional reading; the interface with M-theory publishes those structures in typed physical geometries. T-duality exchanges compatible dimensional readers and preserves the genealogical class of the state.

52.12.9.1 Compatibility of the classical, relativistic, quantum, and HMT-MD realizations

Classical mechanics publishes trajectory and momentum. Relativity publishes causal structure, metric, and curvature. Quantum mechanics publishes phase, holonomy, vacancies, and amplitudes. Dimensional Mechanics provides the transducers that relate those publications, and HMT preserves the discrete genealogy that sustains them.

In the classical reading, an orbit describes the visible projection of motion. In the relativistic reading, that orbit is incorporated into the geometry of the reader. In the quantum reading, phase and spin record the holonomy of the section. In the HMT–MD reading, the three expressions belong to the same lifted biography: the radion quantifies phase, action, and memory; p classifies the radial response; τ classifies curvature; holonomy publishes spin; the dimensional transducer publishes mass; the pentapolar connection publishes gravitation.

Apparent classical dissipation acquires a residence in the expanded genealogical balance. Relativistic acceleration is expressed through connection and projection. Quantum indeterminacy is organized by readers, vacancies, and branches of Ambivalence. Mach's principle relates the local response to the global distribution. Zero Landauer cost guarantees the informational reversibility of the complete state. All these elements converge in a deeper conservation: the identity of the unit across changes of publication.

52.12.9.2 Genealogical Conservation and Holographic Prolongation Narrative Theorem

The closure can now be narrated as a single sequence. The unit decomposes without losing identity. The oriented phase acquires measure in the radion. The nonadic return converts the cycle into a helix through memory. The character p transforms the helix into radial families and classifies their regimes. The persistence of those trajectories produces sections with spin, charge, flavour, colour, and mass. Vacancies open channels; electrical polarity transports phase; magnetic response curves transversely; thresholds publish radiation. Self-conservation closes the genealogical balance of action and momentum. Relational

self-inertia links the proper connection, projection, and Machian totality. Ambivalence preserves the direct and conjugate directions. Area–volume transduction leads to Barbero–Immirzi and the mass law. Minimal torsion links dimensions and publishes the pentapolar structure of gravitation.

Inward growth and outward expansion are conjugate orientations of the same process. Hyperbolic refinement generates depth; dimensional transduction generates extension. Carry $0/1$ links scales; monodromy links turns; memory links states; holonomy links orientations; gravitation links dimensions. Each linkage preserves an evolving unity, and every finite publication contains the rule of its prolongation.

The fundamental thesis is formulated as follows:

> **The holographic closure of infinity realizes the principle of the evolutionary conservation of unity through dimensional transduction and holographic projection: unity maintains its genealogical identity as it unfolds as phase, action, curvature, memory, particle, field, and gravitation; every finite reading preserves the rule of reconstruction and prolongation of the complete state.**

This formulation provides a joint physical and mathematical image. Infinity acquires a law of local closure; the unit acquires depth; dimension acquires memory; conservation acquires relational character; force acquires self-preservation; inertia acquires Machian structure; gravity acquires a pentapolar connection; and holography acquires the precise meaning of reconstruction among compatible readers.

52.13 Operative definition of the angular radian through the enriched state and 4 typed readers

52.13.1 Operational definition of the angular and quadruple radion and typed realization of the enriched state

The operator synthesis brings together the phase, action, depth, and memory readers without identifying them with one another.

52.13.1.1 Quadruple realization of the radional state

Let $x_\infty \in X_{\mathrm{enr}}$ be the coinductive section. The complete radion is not an isolated point, but rather the bundle

$$\mathfrak{R}_\sigma(x_\infty) = \big(\theta = 1, \sigma, \pi_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}, A, C^*, \Delta_4, \Phi_T, D_E, \varepsilon_R^{(1)}, \hbar_{\mathrm{ret}}, q_{\mathrm{mem}}, \mathcal{I}_\infty\big). \tag{52.128}$$

Four readers extract different objects from it:

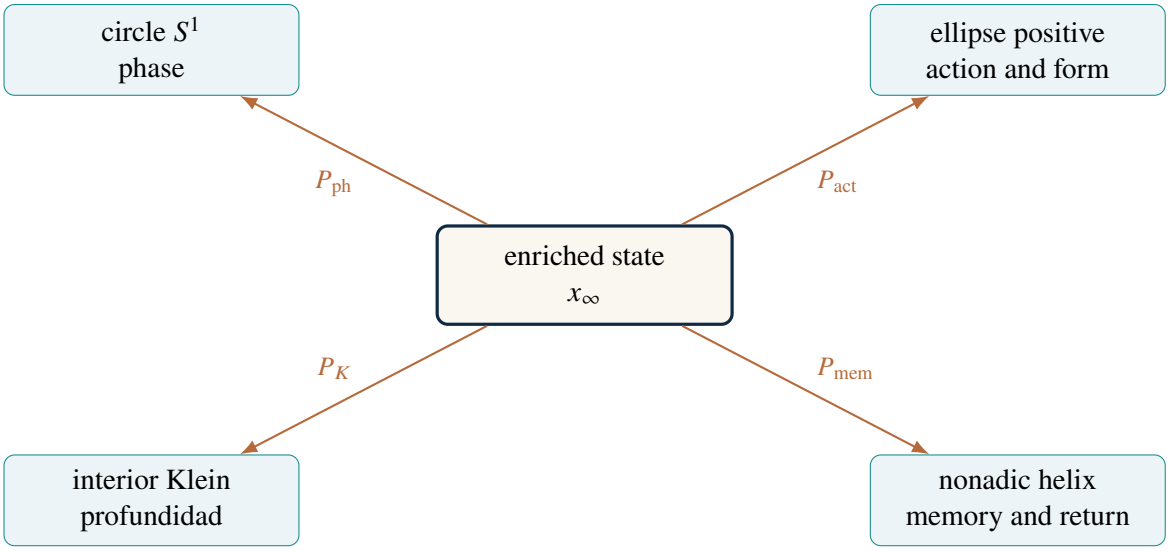

Figure 52.2: Four typed publications of the same antecedent. The unity of the state does not eliminate the difference among codomains.

The circle preserves the phase class and forgets the lift. The ellipse preserves action, anisotropy, and symplectic orientation. Klein endows the interior with a projective distance. The helix preserves the number of returns and refinement. Dimensional Mechanics does not consist in mixing them, but in constructing the transducers that make them compatible.

52.13.1.2 Operator interpretation of the cocycle ε_R

ε_R is not a universal constant independent of every context. It is the coordinate of a transition cocycle associated with the radion chart. Its domain contains two sections of the same state:

$$S_E = 1 + D_E, \qquad S_T = 1 + \Phi_T.$$

His rule is

$$\varepsilon_R^{(1)} = S_T - S_E = \Phi_T - D_E. \tag{52.129}$$

Its codomain is the dimensionless line of angular unity; the chart $360/T_+$ publishes it in degrees.

Exact Result

In plain language: the direct section and torsional section reach the same unit cell by two different internal routes. Their integer parts coincide; their remainders do not. ε_R is the oriented difference of those remainders, computed with APP carry and carried to the limit by the TPK cylinders. It is not introduced to make the radian close: it appears before the radian is consulted and, when published, closes it.

This definition explains why the number is small. It is not because a small correction was sought, but because S_E and S_T share a deep prefix. Smallness measures the structural proximity of two publications; the sign measures their orientation; the digits record the carry.

52.13.1.3 Operational definition of the radion

Definition 52.15 (HMT–MD radion)**.** The radion is the phase-oriented section of action and memory that simultaneously satisfies:

1. traverses a phase unit $\theta = 1$;
2. sweeps signed action $\sigma\hbar_{\mathrm{ret}}$;

3. belongs to a coinductively generated turn $T_+ = 2\pi_{\mathrm{HMT}}$;
4. preserves the σ sheet, the nonadic return, and the refinement cylinder;
5. satisfies the exact junction $1 = S_E - \Phi_T + \varepsilon_R^{(1)}$.

The conventional radian is the image of the radon under the forgetful functor.

$$\mathfrak{R}_\sigma \longmapsto \theta = 1 \in \mathbb{R}/2\pi\mathbb{Z}.$$

That forgetting is useful and legitimate for Euclidean trigonometry. It becomes insufficient when physics must distinguish action, sign, return, field, and history.

Genealogy of the Natural Angular Unit The naturalness of the radian is usually justified because the derivative of $e^{i\theta}$, $\sin\theta$ and $\cos\theta$ assumes its simplest form when θ is measured as the arc/radius quotient. HMT preserves that advantage, but explains it from an earlier layer:

$$\theta \quad \leftrightarrow \quad \frac{\mathcal{A}(\theta)}{\hbar_{\mathrm{ret}}}.$$

The phase is natural because it measures action in units of $\hbar_{\mathrm{ret}}$; the turn is natural because it encloses h_{ret}. The arc-to-radius quotient is the Euclidean publication of a unit that already possesses symplectic structure and memory.

Compatibility between action ellipse and dimensional growth The circle is the form that results when anisotropy is forgotten: $C^* = 0 \Rightarrow \eta = 0 \Rightarrow a = b$. The ellipse is more informative because it preserves two eigenvalues, two axes and an exchange orientation at fixed product. In this sense, the ellipse is a prolongation of the circle, not a circle deformed by accident.

Klein depth and the helical lift add two types of information that the planar contour does not contain: interior distance and return memory. This is the ontological image of Dimensional Mechanics that emerges from the radion: a new dimension appears when one requires an independent datum, which the preceding projection had to forget, to be preserved.

52.13.2 Structural properties of the radional unit: genealogy, critical hinge, density, carry, action, boundary–interior compatibility, form, polarity, and modularity

52.13.2.1 System of component theorems of the radion

Theorem 52.16 (Genealogy)**.** *The object $\mathfrak{R}_\sigma$ descends from* APP $\to \widehat{\mathbb{T}} \to$ TPK $\to X_{\mathrm{enr}}$ *and does not receive the metrological target as a selector.*

Theorem 52.17 (Hinge)**.** *In the hundred-mark APP chart, the critical seam and the second dodecaphasic phase satisfy $j_{100}(1/2) = \theta_2 = 50°$, with unique $m = 2$.*

Theorem 52.18 (Density)**.** *The two sheets of the active sector $N_6 = 90$, normalized by $3^6 = 729$, produce $\rho_{\mathrm{tw}} = 20/81$.*

Theorem 52.19 (Carry)**.** *The APP subtraction of the sections S_T and S_E converges to $\varepsilon_R^{(1)}$ at interval rate 3^{-54} per return and exactly closes the unit.*

Theorem 52.20 (Action)**.** *The positive ellipse satisfies $\mathcal{A}(\theta) = \hbar_{\mathrm{ret}}\theta$; a radion sweeps $\hbar_{\mathrm{ret}}$, and one turn encloses h_{ret}.*

Theorem 52.21 (Boundary–interior)**.** *The same boundary has finite action h_{ret}, whereas the Klein interior has infinite hyperbolic area.*

Theorem 52.22 (Form)**.** *The quotient $e^{-\eta}$ is preserved across spectral semiaxes, action semiaxes, uncertainties, impedance, and the modulus of the torus.*

Theorem 52.23 (Polarity)**.** *The inversion $C^* \mapsto -C^*$ interchanges constitutive relations, inverts impedance, and preserves the normalized velocity.*

Theorem 52.24 (Modularity)**.** *The bidirectional inversion acts as $S : \tau \mapsto -1/\tau$ and preserves $j(\tau)$, while the focal labeling preserves the orientation that j forgets.*

52.13.2.2 Algebraic and Geometric Proofs United

Linear proof of the unit closure To facilitate an independent audit, we present the argument without narrative interruption.

Step 1. The nonadic connection generates in a correlated manner $\pi_{\mathrm{HMT}}, e_{\mathrm{HMT}}, \varphi_{\mathrm{HMT}}, \alpha_{\mathrm{HMT}}$.

Step 2. The turn is $T_+ = 2\pi_{\mathrm{HMT}}$.

Step 3. The wheel fixes $\theta_2 = 50°$, and the parangular chart fixes $A = 1000\alpha_{\mathrm{HMT}}$.

Step 4. The direct section is

$$S_E = T_+ \left(\frac{50}{360} + \frac{1000\alpha_{\mathrm{HMT}}}{360} \right) = 2\pi_{\mathrm{HMT}} \left(\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}} \right).$$

Step 5. The certified intervals yield $1 < S_E < 2$; then $D_E = S_E - 1$.

Step 6. The incidence produces $N_6 = 90$; two sheets and the ambient space 729 produce $\rho = 2N_6/729 = 20/81$.

Step 7. Global torsion is

$$\Delta_4 = \frac{\pi_{\mathrm{HMT}} - e_{\mathrm{HMT}} \log \pi_{\mathrm{HMT}}}{270} \left(1 + \frac{\pi_{\mathrm{HMT}}}{729} \right).$$

Step 8. The section torsional is $S_T = 1 + (20/81)\Delta_4$.

Step 9. The subtraction APP defines

$$\varepsilon_R^{(1)} = S_T - S_E = \frac{20}{81}\Delta_4 - D_E.$$

Step 10. By substitution,

$$S_E - \frac{20}{81}\Delta_4 + \varepsilon_R^{(1)} = 1.$$

Step 11. Multiplying by $360/T_+ = 180/\pi_{\mathrm{HMT}}$ produces

$$\frac{180°}{\pi_{\mathrm{HMT}}} = 50° + A° - \frac{20}{81}\Delta_4^\circ + \varepsilon_R^\circ.$$

No step receives the left-hand side of the final equality. The metrological result is evaluated only at the end as a recognition.

Uniqueness of the carry-subtraction Let $B = 1000$. For each position, every integer u_i admits a unique Euclidean division

$$u_i = Bc_i + r_i, \qquad 0 \le r_i < B.$$

Therefore,

$$r_i = u_i \bmod B, \qquad c_i = (u_i - r_i)/B$$

are unique. Traversing the positions from the remote end toward the front, the output carry of one position fixes the input of the next. By induction, the entire word of residues and carries is unique.

In pseudocode:

```
acarreo = remote_acarreo
for i from last_block downto first_block:
    u = torsion[i] - direct[i] + acarreo
    remainder[i] = u mod 1000
    acarreo = (u - remainder[i]) / 1000
return remainder, acarreo_word
```

The procedure does not consult the expected value of the difference.

Convergence of the depth functional Let

$$F(p,e) = 1 + \frac{20}{81}\frac{p - e\log p}{270}\left(1 + \frac{p}{729}\right) - 2p\left(\frac{5}{36} + \frac{25}{9}\alpha_{\mathrm{HMT}}\right).$$

On the compact rectangle $3 \le p \le 4$, $2 \le e \le 3$, F is continuous and continuously differentiable. If $I_N^{\pi} \searrow \{\pi_{\mathrm{HMT}}\}$ and $I_N^{e} \searrow \{e_{\mathrm{HMT}}\}$, the interval image

$$F(I_N^{\pi}, I_N^{e})$$

forms a nested family whose width tends to zero. The intersection is a single real number, $\varepsilon_R^{(1)}$. Monotonicity of the derivatives permits the endpoints to be evaluated without interior sampling.

The rate 3^{-54} per return follows from the refinement of six trits over nine levels. At depth 45 triads, the width bound $< 4.81 \times 10^{-130}$ certifies more than 129 digits of the value.

Derivation of the metric and hyperbolic area of Klein On the unit disk, the matrix form of the Klein metric is

$$g(u,v) = \frac{1}{1-r^2} I + \frac{1}{(1-r^2)^2}\begin{pmatrix} u \\ v \end{pmatrix}\begin{pmatrix} u & v \end{pmatrix}.$$

The lemma for the determinant of a rank one perturbation gives

$$\det g = (1-r^2)^{-3}.$$

Henceforth

$$\sqrt{\det g}\; \mathrm{d}u\, \mathrm{d}v = (1-r^2)^{-3/2}\, \mathrm{d}u\, \mathrm{d}v.$$

Integration in polar coordinates yields (52.48). The infinite limit is due to the metric singularity at the boundary; the boundary continues to have finite symplectic area because that measure uses $\mathrm{d}Q \wedge \mathrm{d}P$, not $\sqrt{\det g}$.

Focal Distance on the Klein Disk In a diametro, the distance from the center to r is

$$d_K(0,r) = \operatorname{artanh} r.$$

For $r = e_f$, (52.32) implies

$$1 - e_f^2 = e^{-2\eta}.$$

If $u_f = \operatorname{artanh} e_f$, then

$$\operatorname{sech} u_f = \sqrt{1 - e_f^2} = e^{-\eta},$$

and by therefore $\eta = \log\cosh u_f$, as in (52.51).

Symplectic Compression Transformation Define

$$S_\eta = \begin{pmatrix} e^{\eta/2} & 0 \\ 0 & e^{-\eta/2} \end{pmatrix}, \qquad \det S_\eta = 1. \tag{52.130}$$

The transported complex structure is

$$J_\eta = S_\eta \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} S_\eta^{-1} = \begin{pmatrix} 0 & -e^{\eta} \\ e^{-\eta} & 0 \end{pmatrix}, \qquad J_\eta^2 = -I. \tag{52.131}$$

The curve

$$\gamma(\theta) = \sqrt{2\hbar_{\text{ret}}}\, S_\eta(\cos\theta, \sin\theta) = e^{\theta J_\eta}\gamma(0)$$

is exactly the action ellipse. The hyperbolic symplectic compression preserves area and transports complex rotation instead of destroying it.

For orientation σ,

$$\gamma_\sigma(\theta) = (a_S\cos\theta, \sigma b_S \sin\theta), \qquad \mathcal{A}_\sigma(\theta) = \sigma\hbar_{\text{ret}}\theta.$$

The two sheets share foci and action modulus; they differ in signed action.

Diophantine verification of the dodecaphasic Barbero–Immirzi weight The equation $4a - 3b = 45$ has integer solutions

$$(a, b) = (12 + 3t, 1 + 4t), \qquad t \in \mathbb{Z}.$$

The condition $|b| = 1$ leaves $b = 1$, since $b = -1$ does not belong to the class $1 \pmod 4$. Hence $a = 12$. This verification reproduces the pair obtained through the dodecaphasic fundamental chain: twelve sectors and one unique oriented seam. The cardinalities 90/120, the chain multiplicities, and the return reader retain distinct functions; the pole coefficient and minimality arithmetically verify their composition.

52.13.3 Sensitivity of unitary closure to controlled variations in sheet multiplicity, the dodecaphase, channel e, global torsion, the harmonic operator, and the hexadic tail

52.13.3.1 Negative controls of the rational system

The construction is refutable at specific points:

1. If $S_E \notin (1, 2)$, the APP quotient is not one and the closure changes cell.
2. If the incidencia activates no produces $N_6 = 90$, o if no there are two sheets, 20/81 ceases of seguirse.
3. If the verifier receives $180/\pi$ or ε_R before constructing the operands, the generation is circular.
4. If subtraction by triads does not stabilize compatible prefixes, the proposed coinductive section does not exist.
5. If $|C^*| \geq A$, the positive ellipse ceases to exist.
6. If $a_S b_S \neq 2\hbar_{\text{ret}}$, the area theorem fails.
7. If $C^* = 0$, $d = 0$, $\eta = 0$, $\tau = i$ and $j = 1728$ must hold.
8. If the Klein area of the subdisk does not follow (52.48), the infinite-depth thesis fails.

9. If $F_{\mathrm{spec}} = \varepsilon_R^{\circ}$ is asserted without an independent counterterm, the numerical difference (52.99) refutes it.
10. Producing $12 : -1$ requires preserving, alongside the cardinalities $90/120$, the twelve dodecaphasic sectors, the unique oriented seam, and the reader's action on these generators. Changing any multiplicity must modify the image $12S_{90} - S_{120}$. For the unaltered fundamental chain, the coefficient of $(1-q)^{-1}$ must yield $1/24$.
11. If the function j is used to select the charge sign, the invariance (52.114) is lost and a type error is incurred.

52.13.3.2 Joint physical realization of the radion

The final image is not a corrected circle. It is an architecture of publications:

APP:	unit, remainder, carry and fiber;
TRIT:	regime, orientation and sheets;
TPK:	phase, return, dodecaphase and memory;
ellipse:	action and anisotropy;
Klein:	interior depth;
helix:	biography of the return;
MD:	clock, energy, charge, field and causality.

The radion equation brings together the visible face:

$$\boxed{\frac{180^{\circ}}{\pi_{\mathrm{HMT}}} = 50^{\circ} + A^{\circ} - \frac{20}{81}\,\Delta_4^{\circ} + \varepsilon_R^{\circ}}$$

The ellipse brings together the action face:

$$\mathcal{A}(1) = \hbar_{\mathrm{ret}}, \qquad \mathcal{A}(2\pi) = h_{\mathrm{ret}}.$$

The Klein metric unites the depth:

$$K = -1, \qquad \mathrm{Area}_K = \infty.$$

Holonomy gathers memory:

$$g(k+9) = g(k), \qquad B_{k+9} \neq B_k.$$

Tesis rectora

The circle is the angular shadow; the ellipse is the body of action; Klein measures the interior; the helix preserves the biography. The radion is the unit that allows the four statements to be read on a single state without reducing one to another.

52.13.3.3 Canonical values, stability, and reproducible verification

Values of the generated internal invariants

Object	Value used in the coinductive profile
π_{HMT}	3.14159265358979323846264338327950288419716939937510582097494459 23 . . .

Object	Value used in the coinductive profile
e_{HMT}	coinductive evaluation of the Euler reader, without an external table
α_{HMT}	$0.00729735256928380099728510547238066299956417253964270918540468 25\ldots$
A	$7.29735256928380099728510547238066299956417253964270\ldots^{\circ}$
C^{*}	$2.12373833896864572426195138039336079 37\ldots^{\circ}$
η	$0.29968968392163079968492656286392 7\ldots$
$\hbar_{\mathrm{ret}}$	$1.05457181691503906113369058472430\ldots\times 10^{-34}U_S$

Quantitative convergence with depth

Depth	ε_R°	reading
12	$5.1681282186551375597\times 10^{-8}$	preasymptotic
18	$5.1383017764316644535\times 10^{-8}$	7 cifras estables
24	$5.1383016758575394560\times 10^{-8}$	14 cifras estables
30	$5.1383016758575282072\times 10^{-8}$	20 cifras estables
36	$5.13830167585752820716851\times 10^{-8}$	perfil largo
45	$5.13830167585752820716851646226459\times 10^{-8}$	width $< 4.81\times 10^{-130}$

The depth returns $9, 18, 27, 36, 45$ preserve the phase 8 and increase the memory $0, 1, 2, 3, 4$. The ratio between consecutive widths tends to

$$3^{-54} = 1.71969823345498561276103993160048 71\ldots\times 10^{-26}.$$

Structural Sensitivity Analysis by Controlled Suppression

Operation	Output or unit difference
Canonical operator	$8.96802822044562981999\times 10^{-10}$
A sheet, $\rho = 90/729$	$-1.3727056615960678\times 10^{-5}$
Phase $\theta_1 = 20^{\circ}$	$+5.2359877649510169\times 10^{-1}$
Phase $\theta_3 = 80^{\circ}$	$-5.2359877470149605\times 10^{-1}$
Without channel e	$1.8065350748904653\times 10^{-3}$
Historical Torsion $\Delta_4(A, C^{*})$	$1.0517084608768816\times 10^{-9}$
Harmonic operator M_4 minus canonical	$1.0525500222895070\times 10^{-17}$
Hexagonal Cola less canonical	$2.0283936357433839\times 10^{-12}$

The separation of scales reveals structural sensitivity: closure depends on the phase, the two sheets, the channels π/e, global torsion, and carry. No ablation reproduces the value.

Reproducible Computational Certificates The work uses the following executable proprietors:

1. `output/RADION_TWOWAY_NONADICO_20260827/verificar_emergencia_radion_por_profundidad.py`;
2. `output/RADION_TWOWAY_NONADICO_20260827/verificar_radion_helice_critica_tpk.py`;

3. `output/RADION_TWOWAY_NONADICO_20260827/verificar_operador_tpk_target_free_profundidad.py`;
4. the consolidated verifier for this monograph, located at `certificados/verificar_monografia_radion.py`.

The expected outputs include

`PASS_EMERGENCIA_RADION_POR_PROFUNDIDAD`,

`PASS_RADION_HELICE_CRITICA_TPK`, `PASS_MONOGRAFIA_RADION_HMT_MD`.

Distinction between computational precision and mathematical accuracy The fact that a program displays zero to 120 or 200 digits does not by itself turn a residual identity into a prediction. Mathematical exactness derives from (52.18); arbitrary precision makes it possible to evaluate its operands and verify convergence. Non-circularity derives from the order of construction and the prohibition on target values, not from the number of digits.

Decimal computation may leave residuals of order 10^{-218} when combining branches evaluated at different precisions. That number is implementation rounding, not an additional physical correction.

52.13.3.4 Conceptual Genealogy and Primary Sources

Planck action Planck introduces h into the radiation law as the constant linking energy and frequency. The decisive historical datum for this work is dimensional: h is action. The radion does not alter that role; it explains why the action of one complete turn and the action per unit of phase are related by 2π.

Bohr-Sommerfeld Angular Quantization Bohr uses $h/2\pi$ in the quantization of angular momentum. Sommerfeld extends quantization to action integrals and Keplerian orbits. Therefore, it is not historically accurate to say that Dirac invented the reduced constant. His contribution belongs to a genealogy in which angular action was already present.

The HMT–MD novelty is different: it does not take $h/2\pi$ as an external quotient, but rather constructs an ellipse whose turn has area h and whose sector of one radian has area $\hbar$.

Born and Jordan Matrix Formalism and the Quantum Oscillator Born and Jordan place the variational principle, phases, and the harmonic oscillator at the heart of matrix mechanics; the electromagnetic field is decomposed into a collection of oscillators. The LC realization of the radion continues that intuition with one additional datum: the form quotient $e^{-\eta}$ determines the relative impedance while product, frequency, and action remain fixed.

Angular frequency and action in the Dirac formulation In 1925, Dirac writes frequencies in radians per unit time and uses relations of the form

$$xy - yx = \frac{ih}{2\pi}[x, y], \qquad \Delta E = \frac{h}{2\pi}\omega.$$

The equation $E = \hbar_{\mathrm{ret}}\omega$ explicitly joins reduced action and angular frequency. In the radion, that relation acquires a geometry: $\hbar_{\mathrm{ret}}$ is the area swept by one unit of phase.

Heisenberg, Robertson, and Schrödinger Uncertainty Relations Heisenberg formulates the joint limitation of canonically conjugate variables. Robertson generalizes the inequality; Schrödinger incorporates covariance. The matrix (52.55) belongs more directly to that Robertson–Schrödinger prolongation than to Heisenberg's article alone.

None of these authors formulates the complete genealogical ellipse of this work. The historically defensible assertion is that they provide the language in which the action ellipse can be recognized as a minimal contour; the construction of the pair (A, C^*), the foci, Klein, the helix, and the carry is the HMT–MD contribution.

Feynman Phase Functional The spacetime formulation assigns a phase to each path, $e^{iS/\hbar}$. The radion unit makes the correspondence literal: incrementing the action by $\hbar$ increments the phase by one radian. The sum over paths recognizes, in integral language, the same principle that the ellipse expresses as area.

Advanced and retarded propagations in Wheeler–Feynman Absorber theory constructs a temporally symmetric classical interaction through combinations of retarded and advanced fields. The HMT identity $CU(t)C^{-1} = U(-t)$ and route inversion provide an operator-theoretic antecedent. Physical promotion requires the map between routes and propagators to preserve action, orientation, boundary, and symplectic form.

Absorber theory is not the same assertion as the Feynman–Stueckelberg interpretation of antiparticles as temporally reversed propagation. Both may recognize bidirectionality; their physical objects and boundary conditions differ.

Hodge Duality and Separation with Respect to Hochschild Cohomology The operation relevant to this manuscript is the Hodge star $\star^2 = -I$ on two-forms in Lorentzian signature. No proprietor of Hochschild homology acting on the ellipse, the carry, or the sector 90/120 has been located in the active radion corpus. Introducing Hochschild by nominal similarity would degrade the typing. If a future prolongation constructs a deformation cocycle with its own domain and codomain, it must enter as a new result, not as a retroattribution.

> The founders contain the components: action, angular frequency, conjugate variables, oscillator, uncertainty, path phase, and time reversal. The contribution of the radion is to bring them together in a generated object: an ellipse of area h, a sector of area $\hbar$, an interior of infinite depth, a sheet orientation, and an exact carry of compatibility.

52.13.3.5 Final Synthesis: Angular unity with phase genealogy, action and memory

The radian does not disappear. It becomes fully visible.

In its ordinary use, a radian is a ratio that need not remember how it was produced. The arc and the radius cancel dimensionally; the unit appears bare. That bareness is a virtue for trigonometry, but it is a forgetting for a theory that seeks to explain the structure of the continuum and the origin of action. The radion recovers what was forgotten without altering the published value.

The genealogy begins in APP, where an output preserves its value and also its sheet, quotient, remainder, carry, and boundary. TRIT introduces regime and orientation. TPK returns the phase without resetting the state. The nonadic connection constructs the coinductive section of π, and the dodecaphase publishes the hinge of 50°. The angular pair supplies a common mode A and an oriented opening C^*. The incidence of six active phases produces 90, its two sheets over the ambient space 729 produce $20/81$, and global torsion supplies the second section.

Then ε_R appears. Not as a decimal begged of the closure, but as the difference that the structure was required to transport:

$$\varepsilon_R^{(1)} = \frac{20}{81}\Delta_4 - (S_E - 1).$$

The carry publishes its digits; the depth certifies its limit; the angular chart recognizes it as

$$5.13830167585752820716851646226459474899\ldots \times 10^{-8\,\circ}.$$

The radian equation is closed because both sides are publications of the same state:

$$\boxed{\frac{180^\circ}{\pi_{\mathrm{HMT}}} = 50^\circ + A^\circ - \frac{20}{81}\,\Delta_4^\circ + \varepsilon_R^\circ}$$

The account does not end with the equality. The pair (A, C^*) constructs a positive ellipse. The product of its semiaxes fixes $2\hbar_{\mathrm{ret}}$; their quotient fixes its shape. The area theorem proves that one phase unit sweeps $\hbar_{\mathrm{ret}}$ and that one revolution encloses h_{ret}. Division by 2π here acquires physical content: h is action per revolution; $\hbar$ is action per radion.

The foci cease to be ornaments in a figure. Their separation reconstructs C^* in the spectral chart, and their Klein distance measures a finite hyperbolic depth within a domain whose total hyperbolic area is infinite. The same boundary contains a finite action. The apparent paradox is the central thesis of the geometry: one measure closes the action; another opens the depth.

The circle, therefore, is not false. It is the exact projection that preserves phase and forgets anisotropy, interior, and memory. The ellipse preserves action and form. The Klein surface preserves depth. The helix preserves return and biography. No image replaces the others; all arise from the same state.

The Hilbert realization recognizes the ellipse as a contour of minimal covariance. The LC oscillator recognizes it as an exchange of electrical and magnetic reserves. The reader 90/120 publishes permeability, permittivity, impedance, and velocity. The six–eight incidence produces a causal screen; Hodge converts orientation into field duality; Lorentz converts field and charge into dynamics; Cartan–Holst receives the holonomy in gravitational geometry. The order matters: the HMT object selects; conventional physics realizes.

The word *radion* is thereby justified. It does not mean that one focus is a positive charge and the other a negative charge. It means that the phase unit has a signed orientation prior to electrical publication:

$$\mathcal{A}(\mathfrak{r}_+) = +\hbar_{\mathrm{ret}}, \qquad \mathcal{A}(\mathfrak{r}_-) = -\hbar_{\mathrm{ret}}.$$

Charge appears when Dimensional Mechanics applies the transducer. The sign is not added at the end; it is preserved from the sheet.

This also explains why the 90/120 sector appeared to conceal many answers. Incidence, the dodecaphase extractor, the spectral tail, the Barbero kernel, towers, and carry share a common origin. Precisely because they share an origin, they can be compared. Precisely because they employ distinct operations, they must not be merged. Typing does not diminish the unity of the system: it makes it intelligible.

The most compact conclusion of this work can be written in four lines:

$$\begin{aligned} \text{phase:} &\quad \theta = 1, \\ \text{action:} &\quad \mathcal{A} = \sigma\hbar_{\mathrm{ret}}, \\ \text{memory:} &\quad H_9(n+9) = H_9(n) + (0,1), \\ \text{compatibility:} &\quad 1 = S_E - \Phi_T + \varepsilon_R^{(1)}. \end{aligned}$$

The radion is that fourfold unit. The radian is its exact shadow in the angular chart. The difference lies not in the value of π but in how much structure we are willing to preserve when we say that a revolution has closed.

The circle publishes phase.
The ellipse contains action.
Klein opens depth.
The helix remembers the path.

The radion is the unit that does not force a choice among them.

Chapter 53

Genealogical classification of numbers: surviving sections, invariants and atlas of constants

equation (6.98) defined an HMT number as a compatible section of the inverse survival system, and not as a sequence of digits devoid of genealogy. There remained, however, two questions that should be separated precisely. The first is a question of *representation*: which real values can the 3-adic transducer represent before the particular closure filters are imposed? The second is a question of *selection*: which sections of the raw space are selected by APP, TRIT, and TPK when their compatibilities are required simultaneously? This section resolves the first, formulates the second as an explicit domain restriction, and extracts from the base-one-thousand chart a complete taxonomy of visible values. The foundational tools are p-adic arithmetic, symbolic dynamics, and the positional characterization of the rational numbers [74, 80, 66].

The distinction is structural. A language capable of representing every tape does not, by that fact alone, select the tape of π, e, φ, or α. Conversely, a selection law cannot be evaluated unless the space on which it acts has first been constructed. Representation and selection are two successive theorems, not two names for the same step.

53.1 Hensel's Integral Transducer as a Full Shift Operator

Let p be a prime, let $d \geq 1$, and let $A \in \mathrm{GL}_d(\mathbb{Z})$. For a row vector $x_t \in \mathbb{Z}_p^d$, we define

$$y_t = x_t A, \qquad u_t = y_t \bmod p \in \mathbb{F}_p^d, \qquad x_{t+1} = \frac{y_t - u_t}{p}. \tag{53.1}$$

The block u_t is the visible emission, and x_{t+1} is the memory that remains after that digit is removed.

Theorem 53.1 (Hensel Conjugation with Full Shift)**.** *For every $T \geq 1$, the map*

$$\Psi_T : (\mathbb{Z}/p^T\mathbb{Z})^d \longrightarrow (\mathbb{F}_p^d)^T, \qquad x_0 \longmapsto (u_0, \ldots, u_{T-1}),$$

is bijective. Its inverse is

$$x_0 \equiv \sum_{t=0}^{T-1} p^t u_t A^{-(t+1)} \pmod{p^T}. \tag{53.2}$$

Taking the inverse limit yields a homeomorphism.

$$\Psi : \mathbb{Z}_p^d \xrightarrow{\sim} (\mathbb{F}_p^d)^{\mathbb{N}}.$$

If S_A denotes the update $x_t \mapsto x_{t+1}$ and σ removes the first block from a tape, then

$$\Psi \circ S_A = \sigma \circ \Psi.$$

Proof. From equation (53.1) is obtained

$$x_t = (u_t + p x_{t+1}) A^{-1}.$$

Iteration of this identity gives

$$x_0 = \sum_{t=0}^{T-1} p^t u_t A^{-(t+1)} + p^T x_T A^{-T}.$$

The final summand vanishes modulo p^T, which proves that a word of T blocks determines at most one initial class. Conversely, given any word, $x_T = 0$ is fixed and reconstruction proceeds backward by

means of $x_t = (u_t + px_{t+1})A^{-1}$. The equality $x_t A = u_t + px_{t+1}$ verifies that the resulting class emits the prescribed word. Therefore, Ψ_T is bijective.

The bijections are compatible with reduction modulo p^T. Their inverse limits produce the homeomorphism Ψ; equivalently, the series of equation (53.2) converges in $\mathbb{Z}_p^d$. Applying S_A removes exactly the block u_0, and therefore corresponds to applying σ on the strip. □

In the HMT instance, $p = 3$, $d = 6$, and the published matrix has determinant one. Hence

$$\mathbb{Z}_3^6 \simeq (\mathbb{F}_3^6)^{\mathbb{N}}, \qquad |\mathbb{F}_3^6| = 3^6 = 729. \tag{53.3}$$

Each tape of six-trit blocks has a unique initial 3-adic memory. The matrix determines the coordinatization and the reading dynamics; the universality of the alphabet proves that it excludes no tape.

Corollary 53.2 (Entropy and Haar measure)**.** *The raw Hensel update is conjugate to the full one-sided shift on* 729 *symbols. Its topological entropy is* $6 \log 3$. *The Haar measure on* $\mathbb{Z}_3^6$ *is transported to the uniform product measure on the blocks.*

Proof. There are $729^T = 3^{6T}$ cylinders of length T, and each class modulo 3^T has Haar measure 3^{-6T}. Conjugation by theorem 53.1 transports both properties to the shift. □

The probabilistic conclusion concerns the raw space endowed with Haar measure. It does not assert that the published sections of the constants were sampled according to that measure or that they are algorithmically random.

53.2 Balanced ternary chart of the integers

The raw 3-adic chart and the Archimedean chart do not exhaust the numerical types of the HMT classification. For the integral operator, the empty word is used together with the reduced words

$$\mathscr{W}_{\mathrm{bal}} := \{\varnothing\} \cup \{a_1 \cdots a_m : a_j \in \{-1, 0, +1\},\ a_1 \neq 0\}.$$

We define recursively

$$b(\varnothing) = 0, \qquad b(wa) = 3b(w) + a.$$

Theorem 53.3 (Unique balanced ternary representation)**.** *The evaluation*

$$b : \mathscr{W}_{\mathrm{bal}} \longrightarrow \mathbb{Z}$$

is bijective. Words whose first trit is $+1$ *represent the positive integers, and those beginning with* -1 *represent the negative integers.*

Proof. For $n \neq 0$, the ultimo trit a is the representante unique of n mod 3 in $\{-1, 0, +1\}$. The padre

$$\frac{n - a}{3}$$

has strictly smaller absolute value. The iteration terminates at 0, so that every integer has a finite expansion. The uniqueness of the balanced residue at each step proves the uniqueness of the word. The sign is fixed by the first nonzero trit. □

Remark 53.4. This bijection is an exact arithmetic chart. It does not identify all balanced words with surviving TPK sections, nor does it replace the genealogy, carry, or orientation of an enriched route.

53.3 Exact coverage of the preceding real chart via compatible sections

Let us concatenate the coordinates of the blocks $u_t \in \mathbb{F}_3^6$ to obtain a tape $(a_n)_{n\geq 1} \in \{0,1,2\}^{\mathbb{N}}$. Its ternary evaluation is

$$\mathrm{ev}_3((a_n)) = \sum_{n\geq 1} \frac{a_n}{3^n} \in [0,1].$$

We adopt the canonical convention that excludes a representation with an eventually constant tail of twos only when the same point has another expansion in the chart. The endpoint 1 therefore retains its unique fractional representation $0.222\ldots_3$.

Theorem 53.5 (Archimedean raw coverage)**.** *The map*

$$P_{\mathrm{raw}} : \mathbb{Z}_3^6 \xrightarrow{\Psi} (\mathbb{F}_3^6)^{\mathbb{N}} \xrightarrow{\mathrm{flat}} \{0,1,2\}^{\mathbb{N}} \xrightarrow{\mathrm{ev}_3} [0,1]$$

is continuous and surjective. Therefore,

$$\mathbb{Z}_3^6/{\sim_{P_{\mathrm{raw}}}} \cong [0,1]$$

as the value space, where $x \sim_{P_{\mathrm{raw}}} y$ if their evaluations coincide.

Proof. Every ternary digit belongs to a unique consecutive block of six digits, so flat is a bijection of tape spaces. Every $r \in [0,1]$ has a ternary expansion; the theorem 53.1 provides the unique 3-adic memory that emits its blocks. Continuity is verified by cylinders: fixing T blocks fixes $6T$ digits and confines the value to an interval of diameter 3^{-6T}. Identification of the quotient with the image is the canonical factorization of a surjective map by its fibers. □

A single 3-adic chart is compact and therefore cannot continuously cover an unbounded line. The correct globalization uses a countable family of charts.

Corollary 53.6 (Cover Archimedean countable of $\mathbb{R}$)**.** *Let*

$$\widehat{X}_{\mathrm{raw}} = \mathbb{Z} \times \mathbb{Z}_3^6, \qquad \widehat{P}_{\mathrm{raw}}(m,x) = m + P_{\mathrm{raw}}(x).$$

Then $\widehat{P}_{\mathrm{raw}}$ is surjective onto $\mathbb{R}$. Consequently, every real number admits at least one raw Hensel genealogy and

$$\widehat{X}_{\mathrm{raw}}/{\sim_{\widehat{P}_{\mathrm{raw}}}} \cong \mathbb{R}$$

as a set of values.

Proof. For $r \in \mathbb{R}$, tome $m = \lfloor r \rfloor$ y aplique the theorem 53.5 to $r - m \in [0,1)$. □

This result makes precise the assertion that $\mathbb{R}$ is the Archimedean quotient image of a genealogical structure: the projection forgets 3-adic memory and preserves the evaluated point. The assertion proved here concerns the raw completion *raw*. If $X_{\mathrm{surv}} \subseteq \mathbb{Z}_3^6$ denotes the subspace that also satisfies a concrete family of APP–TRIT–TPK closures, then

$$P_{\mathrm{raw}}(X_{\mathrm{surv}}) = [0,1]$$

is an additional theorem. The transducer guarantees full capacity; survival determines what portion of that capacity the restricted system realizes.

Nor is it deduced here that the native sum and product of TPK descend to the entire global quotient. The usual arithmetic may be transported from $\mathbb{R}$, but proving that it coincides with operations constructed before evaluation requires the corresponding descent theorem.

In this construction, the cylinders are not nonzero infinitesimals of $\mathbb{R}$. Every finite-depth cylinder has positive diameter, and the sequence of diameters converges to zero. Two sections that agree up to depth T and differ thereafter form a *tail perturbation*; their Archimedean difference is bounded by the diameter of the common cylinder. This is the exact formulation of the "cylinders tending to zero" within the ordinary real line.

53.4 Positional chart in base 10^3 and classification of the published sections

The cubic completion $1000 = 729 + 243 + 27 + 1$ makes it natural to group the decimal digits into blocks $b_n \in \{0, \dots, 999\}$. For a tape of blocks, we define

$$\mathrm{ev}_{1000}(b_1, b_2, \dots) = \sum_{n \geq 1} \frac{b_n}{1000^n}.$$

The canonical expansion excludes an eventually constant tail of blocks 999. This convention resolves the duplication of cylinder endpoints.

Theorem 53.7 (Visible taxonomy based on thousand)**.** *Let $x \in [0, 1)$ be given, and let (b_n) be its canonical base-one-thousand expansion. Then:*

1. *x has a terminating expansion if and only if, when written as an irreducible fraction a/q, one has $q \mid 1000^N$ for some N; equivalently, the only primes dividing q are 2 and 5.*
2. *x is rational if and only if (b_n) is eventually periodic.*
3. *x is irrational if and only if (b_n) is not eventually periodic.*

Proof. An expansion terminating at depth N has the form $D/1000^N$; upon reduction, its denominator contains only the primes 2 and 5. Conversely, if $q \mid 1000^N$, then a/q is written with N blocks.

If, after a prefix of length r, a period of length s is repeated whose base-thousand integer is P, the tail is a geometric series:

$$\frac{P}{1000^r\,(1000^s - 1)},$$

and the value is rational. Conversely, when a/q is expanded, the remainders of successive division can assume only q values. A zero remainder produces a terminating expansion; repetition of a remainder produces a period. The third statement is the exact negation of the second. □

The word *fraction* denotes a presentation a/q of a rational number, not an additional numerical species. Nor should periodicity and algebraicity be conflated. A real number is algebraic when it is a zero of some nonzero polynomial over $\mathbb{Q}[X]$; it is transcendental otherwise. This second classification is independent of the base used to write its digits. For example,

$$\varphi^2 - \varphi - 1 = 0$$

makes φ an algebraic irrational, whereas the transcendence of e and π proceeds from classical theorems external to HMT.

53.5 Concatenation, nonadic reduction, and carry

Compatibility between the cubic chart and the digital root is an arithmetic identity, not a visual resemblance. If $u_j \in \{0, \dots, 999\}$ and

$$D_n = 1000 D_{n-1} + u_n, \qquad D_0 = 0,$$

then D_n is the integer obtained by concatenating the first n blocks.

Theorem 53.8 (Nonadic congruence of control of the cubic chart)**.** *For every $n \geq 1$,*

$$D_n \equiv \sum_{j=1}^{n} u_j \pmod 9.$$

Therefore, concatenation in base ten, reduction modulo nine, and digital root are compatible.

Proof. Since $1000 \equiv 1 \pmod 9$, the recurrence gives $D_n \equiv D_{n-1} + u_n \pmod 9$. Iteration from $D_0 = 0$ produces the formula. □

In the dodecaphase closure of α, the blockwise carry equation has the form

$$P_m + E_m - \Phi_m - K_m + c_{m+1} = A_m + 1000 c_m.$$

Reduced modulo nine,

$$A_m \equiv P_m + E_m - \Phi_m - K_m + c_{m+1} - c_m \pmod 9.$$

If the extreme carries vanish, the telescoping sum eliminates the intermediate memory. The global residue of the output then coincides with the residue of the combination of inputs. This law explains why the nonadic record controls decimal concatenation; by itself, it does not select the blocks that must be concatenated.

53.6 Nonadic elevated coordinate and phase return

Reduction modulo nine must not be confused with the identification of the integers that possess the same residue. Let

$$I_9 = \{1, 2, \dots, 9\}.$$

For each positive integer n, we define its *nonadic phase* and its *revolution index* by

$$\rho_9(n) = 1 + ((n-1) \bmod 9), \qquad \kappa_9(n) = \frac{n - \rho_9(n)}{9}. \tag{53.4}$$

The first coordinate is the digital root written in the alphabet I_9, so that the zero residue class is represented by phase 9. The second records how many complete turns have preceded the visible phase.

Theorem 53.9 (Nonadic decomposition with memory)**.** *The map*

$$\Theta_9 : \mathbb{N}_{>0} \longrightarrow \mathbb{N}_0 \times I_9, \qquad n \longmapsto \big(\kappa_9(n), \rho_9(n)\big),$$

is bijective, with inverse

$$\Theta_9^{-1}(q, r) = 9q + r.$$

In these coordinates, the arithmetic successor is conjugated with the dynamics.

$$\mathcal{S}_9(q, r) = \begin{cases} (q, r+1), & 1 \leq r < 9, \\ (q+1, 1), & r = 9. \end{cases} \tag{53.5}$$

In particular, the visible transition $9 \to 1$ *is a phase return accompanied by the irreversible increment* $q \to q+1$*; it is not an equality between the integers* 9 *and* 10*.*

Proof. Euclidean division of $n-1$ by 9 uniquely provides $n-1 = 9q+s$, with $q \in \mathbb{N}_0$ and $0 \le s < 9$. Taking $r = s+1$ yields $n = 9q+r$, with $r \in I_9$, which proves simultaneously existence, uniqueness, and the inverse formula. If $r < 9$, adding one unit only increments r. If $r = 9$, the equality $9q+9+1 = 9(q+1)+1$ gives the second branch of equation (53.5). □

This elevation separates three notions that the isolated figure mixes:

1. the unit of advancement, realized by the successor;
2. the visible phase r, which traverses the nonadic cycle;
3. the accumulated memory q, which distinguishes returns of the same phase.

The projection $(q, r) \mapsto r$ forgets the number of turns and satisfies

$$\rho_9(n+9) = \rho_9(n), \qquad \kappa_9(n+9) = \kappa_9(n) + 1.$$

This is the elementary arithmetic model of the mechanism that, in the enriched TPK state, additionally preserves Hensel quotients, orientation, signature, and boundary datum. A return of the visible word can thus coexist with a distinct genealogy.

Zero does not belong to I_9: it is added as a separate base point before Θ_9 is applied. For negative integers, the positive modulus of the decomposition is preserved and an orientation $\varepsilon \in \{-1, +1\}$ is appended. Consequently, neither the sign nor zero is deduced from the residual phase. This typing prevents a cyclic chart from being converted into a false arithmetic identity.

Theorem 53.10 (Oriented Integer and Genealogical Sign)**.** *The map*

$$\Theta_9^{\pm} : \mathbb{Z} \setminus \{0\} \longrightarrow \{-1, +1\} \times \mathbb{N}_0 \times I_9,$$

$$n \longmapsto \big(\operatorname{sgn}(n), \kappa_9(|n|), \rho_9(|n|)\big)$$

is bijective, with inverse

$$(\varepsilon, q, r) \longmapsto \varepsilon(9q + r).$$

Aritmetical negation acts by

$$(\varepsilon, q, r) \longmapsto (-\varepsilon, q, r) :$$

reverses the orientation and preserves magnitude, phase, and turn memory.

Proof. The theorem 53.9 uniquely provides $|n| = 9q + r$, with $q \in \mathbb{N}_0$ and $r \in I_9$. The sign of a nonzero integer is likewise unique. The inverse formula recomposes n, and replacing n with $-n$ changes only ε. □

Thus, a negative is neither a special residual phase nor an "impossible" quantity. It is the same nonadic magnitude transported with the opposite genealogical orientation. This structure will be prolonged in Dimensional Mechanics by the particle–antiparticle anti-section.

Iterating κ_9 produces a finite tower for every ordinary integer; in the inverse completion, a compatible sequence of quotients may be infinite. The distinction between the two cases anticipates the HMT taxonomy: the visible value is determined by the positional expansion, whereas the genealogical type is determined by the complete evolution of its memories.

53.7 Bifactorial classification of the number by Archimedean value and transport genealogy

The preceding taxonomy classifies the projected value. HMT adds a second axis that ordinary decimal notation discards. For a section $x \in \Omega_\infty^{\mathrm{Arch}}$, we distinguish:

$$\begin{aligned} \text{visible type} &= \text{terminating, periodic or nonperiodic; algebraic or transcendental,} \\ \text{genealogical type} &= \text{carry class, orientation, closure and monodromy of } x. \end{aligned}$$

Two sections may share the same real value and differ on the second axis. A rational real has an eventually periodic visible expansion, but a redundant enriched presentation may preserve nonperiodic internal memory that evaluation forgets. Periodicity of the *value* always refers to its canonical expansion; periodicity of the *genealogy* refers to the TPK enriched state.

This separation provides a concise definition:

$$\boxed{\text{HMT number = compatible section with memory;} \qquad \text{real value = its evaluation class.}} \tag{53.6}$$

Measurement in this chart consists in coupling the section to the reader, fixing a cylinder, and conditioning the compatible prolongations. Increasing precision means narrowing the cylinder, not consuming the genealogy that remains in the fibre.

53.8 Memorization of arbitrary depth in finite emission systems

The visible recurrence of nine phases can coexist with an irrational output only if the complete state preserves information that does not reduce to those nine labels. The following result makes this necessity exact.

Theorem 53.11 (Characterization via finite emitters)**.** *Let Q be a finite set, $F : Q \to Q$ a deterministic transition, $o : Q \to \{0, \dots, 999\}$ an output, and $q_0 \in Q$. The tape $b_n = o(F^{n-1}(q_0))$ is eventually periodic and its evaluation is rational. Conversely, every eventually periodic tape admits a finite deterministic emitter.*

Proof. Among $|Q| + 1$ consecutive states, two are equal. From the first repetition, determinism forces the entire future to repeat, so the tape is eventually periodic. The theorem 53.7 gives rationality. For the converse, it suffices to construct a chain of states for the prefix and a cycle for the period. □

Therefore, a law generating exactly e, π, or any other irrational number cannot consist solely of a deterministic finite-state automaton that repeats without additional memory. It may use an inverse limit, 3-adic memory, increasing depth, or an aperiodic input; all these mechanisms provide unbounded effective state. In HMT, visible-phase return $g_{\mathrm{vis}}(n + 9) = g_{\mathrm{vis}}(n)$ does not force return of the carry, orientation, or boundary. That difference is precisely where an aperiodic expansion may reside.

53.9 Local positional square of e and genealogical differentiation of states with the same visible block

For a decimal word $a_1 \cdots a_n$, we shall call a factorization a *local square* of length ℓ at position i

$$a_i \cdots a_{i+2\ell-1} = vv, \qquad |v| = \ell.$$

This notion belongs to word combinatorics. It does not assert that the infinite tail has a period.

Theorem 53.12 (Finite characterization of the square 1828^2)**.** *Consider the* 243 *catalog words and the fixed reader $w_6 \mapsto w_{30} \mapsto d_1d_2d_3d_4$, with four triads in base one thousand. There is a unique word whose reading contains a square of length four beginning at the second decimal digit. It is*

$$w_e = 201101, \qquad 718281828459 = 7\,\underbrace{1828\,1828}_{(1828)^2}\,459.$$

The repetition is not prolonged to a third copy: the digit that would require that continuation would be 1*, whereas the effective digit is* 4*. In the whole catalogue there exists only one other square of length four,*

$$575157518472 = \underbrace{5751\,5751}_{\textit{local square}}\,8472,$$

which begins at the first digit.

Proof. The exhaustive enumeration evaluates the 243 words using integer arithmetic. The square profile for lengths $1, \dots, 6$ contains

$$240,\ 21,\ 3,\ 2,\ 0,\ 0$$

occurrences, distributed among

$$153,\ 19,\ 3,\ 2,\ 0,\ 0$$

words. The two occurrences of length four are exactly those in the statement. Two independent integer enumerations reproduce the same census, and their complete outputs coincide term by term. □

The word w_e also has the lifting chain

$$201101 \mid 121221 \mid 102011 \mid 012222 \mid 102011.$$

The third and fifth visible blocks coincide. The states that transport them, however, do not coincide. Before both emissions, their reductions modulo 27 are

$$(25, 11, 7, 17, 8, 16), \qquad (7, 8, 4, 23, 26, 7),$$

and the subsequent Hensel quotients are

$$(6, 13, 9, 2, 13, 1), \qquad (15, 0, 3, 19, 23, 25).$$

Therefore, the return 102011 is a return of the visible projection, not of the enriched state. This is the exact formulation of the local repetition that is broken: the quotient preserves a genealogy that the residual block does not record.

Consequently, the beginning

$$e = 2.718281828459\ldots$$

does not exhibit a "semiperiodicity," but rather a local word-square with visible-phase return and memory advance without state periodicity. The result is exhaustive within the fixed reader; its content is combinatorial and dynamical, not an inference of irrationality from twelve digits.

53.10 2 finite measures of the $468 \to 243$ emitter: uniform frequency and structural priority

The catalogue publico distinguishes 468 emissions y 104 976 semillas. Be

$$q : E_{468} \longrightarrow W_{243}$$

the map that forgets the emission signature and preserves the six-trit word. There are two natural measures because there are two finite counting universes:

$$\mu_{468}(w) = \frac{|q^{-1}(w)|}{468}, \qquad \mu_{\text{seed}}(w) = \frac{\sum_{e \in q^{-1}(w)} m(e)}{104\,976},$$

where $m(e)$ is the multiplicity of semillas of the emision e.

Theorem 53.13 (Canonical measures relative to the counted universe)**.** *The uniform measure on E_{468} is the unique probability invariant under all permutations of its emissions; its image measure is μ_{468}. The uniform measure on the* 104 976 *seeds induces μ_{seed}. Their exact histograms are*
